Effect of interfaces on band hybridization, orbital polarization, and helical magnetism in SrFeO$_3$/CaFeO$_3$ heterostructures* [Invited] STEVEN MAY (Presenter), Materials Science and Engineering, Drexel University — The alkaline earth ferrates exhibit an array of interesting physical phenomena such as metal-insulator transitions, strong Fe-O covalency, rapid redox reactions, and helical magnetism. In this talk, I will present how the Fe-O band hybridization and Fe 3$d$ orbital occupancy changes across interfaces in isoelectronic SrFeO$_3$/CaFeO$_3$ superlattices. A consequence of the strong hybridization in these materials is that their electronic configuration can be described as containing both d$_4$L$_0$ and d$_5$L$_1$ contributions, where L indicates a ligand hole. Using resonant soft x-ray reflectivity, we find a modulation of the Fe-O hybridization across the superlattice with SrFeO$_3$ hosting a larger ligand hole density than CaFeO$_3$.[1] We show that the Fe e$_g$ orbital polarization is correlated with the degree of d$_4$L$_0$ electronic character present in the layers. Results will also be presented on the stability of the helical magnetic order in (CaFeO$_3$)$_{20}$(SrFeO$_3$)$_n$ superlattices. Using resonant x-ray diffraction, we show that the helical magnetic order coherently propagates through superlattices with $n = 1$ but does not extend through the SrFeO$_3$ layer in a superlattice with $n = 6$.[2] We describe these results in context of recently reported multi-$q$ helimagnetism in metallic SrFeO$_3$, while our results support single-$q$ helimagnetism in insulating CaFeO$_3$.

*This work is supported by the Army Research Office (grant number W911NF-15-1-0133).
The construction of superlattices, unit-cell-scale layering of two or more materials at the nanoscale, allows one to access novel properties not possessed by the constituent materials. Here, we show that in superlattices consisting of strontium iridate and lanthanum nickelate, up to one electron can transfer from iridium to nickel at the interfaces, leading to Ni\(^{2+}\)(d\(^8\)) and the unusual oxidation state Ir\(^{5+}\)(d\(^4\)). Using density functional theory based calculations including a Hubbard U correction and spin-orbit coupling, we characterize the 1:1 superlattices with both (001) and (111) ordering, allowing us to explore the competition among Hund's coupling, the crystal field splitting and spin-orbit coupling. We find that the spin-orbit coupling present for iridium does not completely dominate the d\(^4\) configuration, which would result in a nonmagnetic state with a filled \(J_{\text{eff}} = \frac{3}{2}\) manifold, but competes with the Hund's coupling and crystal field splitting. In these superlattices, the surprising competition in the energy landscape results in Ir\(^{5+}\) with a non-zero magnetic moment.

The degree of broken orbital degeneracy, which can be represented by the term \textit{orbital polarization}, can play a crucial role in the electronic and magnetic properties of transition metal oxides. Since spin, lattice, and orbital degrees of freedom are entangled, the fundamental origin and systematic understanding of the conditions leading to strong orbital polarization is lacking. Recently, we observed the strong orbital polarization of Co\(^{2+}\) in LaCoO\(_3\)+LaTiO\(_3\) (LCO+LTO) superlattice [1]. The orbital polarization of Co is particularly interesting, since Co\(^{2+}\) ion has multiple spin states and t\(_{2g}\) or e\(_g\) character is determined by these spin states. Here we systematically study the origin of the strong orbital polarization of Co\(^{2+}\) by considering the various structural phases of (LCO\(_1\)+LTO\(_1\) superlattice and La\(_2\)CoTiO\(_6\). While the symmetry reduction by forming a superlattice is the sufficient condition to break degeneracy of the e\(_g\) bands for the low-spin state, the polarization is greatly enhanced by Coulomb \(U\). The sign of the e\(_g\) polarization depends on \(U\), local octahedral distortion, and strain. For the high-spin state, the origin of the orbital polarization of t\(_{2g}\) bands is similar to e\(_g\) case.

12:39PM B64.00006: Ferromagnetism in ultrathin double perovskite La$_2$NiMnO$_6$ thin films
GABRIELE DE LUCA (Presenter), JONATHAN SPRING, UMAR BASHIR, Univ of Zurich, ANNA ZAKHAROVA, PSI, CLARIBEL DOMINGUEZ ORDONEZ, Univ of Geneva, MARTA ROSSELL, EMPA, CINTHIA PIAMONTEZE, PSI, MARTA GIBERT, Univ of Zurich — Double perovskite oxides with chemical formula A$_2$BB'O$_6$ possess the prototypical perovskite structure integrated by two different cations (B, B') ordered in a rock-salt fashion. In the R$_2$NiMnO$_6$ (RNMO) family, R being a rare-earth cation, the positive superexchange interaction between the Ni$^{2+}$ and Mn$^{4+}$ electronic states results in the coexistence of ferromagnetic order with insulating behaviour, a combination of features that is rarely found in nature. La$_2$NiMnO$_6$ (LNMO), in particular, has a bulk ferromagnetic Curie temperature of circa 280K. Although an insulating ferromagnetic oxide with near room temperature $T_C$ would be ideal for novel spintronic devices, only a few attempts of growing ultrathin LNMO films have been reported so far.
We grew LNMO films by RF off-axis magnetron sputtering and employed AFM, XRD, STEM and EDX for structural characterization. The results indicate high crystalline quality, sharp interfaces and minimal degree of antisite disorder. The valence state of the Ni and Mn ions has been also inferred by XAS. Bulk SQUID magnetometry and element sensitive XMCD reveal that the ferromagnetic order of our films is robust against epitaxial strain and is retained down to few unit cells (less than 2 nm).

12:51PM B64.00007: Probing the electronic ground states of thin film Ruddlesden-Popper ($R_{n+1}Ni_nO_{3n+1}$) nickelates*
GRACE PAN (Presenter), QI SONG, CHARLES BROOKS, SPENCER DOYLE, JAMES EHRETS, DAN FERENC SEGEDIN, Harvard University, HANJONG PAIK, Platform for the Accelerated Realization, Analysis, and Discovery of Interface Materials (PARADIM), Cornell University, JULIA MUNDY, Harvard University — The recent discovery of superconductivity in a hole-doped infinite layer nickelate has spurred the reexamination of how nickelate physics may be amenable to stabilizing new superconducting phases [1]. The nickelate identified is isostructural to the superconducting cuprates and lies squarely in the superconducting regime of the simple phase diagram by Zhang [2] but disentangling the electronic from the structural contributions presents a key challenge. We have stabilized, for the first time, the Ruddlesden-Popper nickelates (Nd$_{n+1}$Ni$_n$O$_{3n+1}$) in thin film form up to $n = 6$. We will discuss how tuning of the Ruddlesden-Popper order alters the electronic ground states of the system including the nickel 3$d$ occupancy and effects on the canonical metal-to-insulator transition.

1:03PM B64.00008: Band Offset Induced Charge Redistribution in SrNiO$_3$/LaFeO$_3$

**Superlattices**

SCOTT CHAMBERS (Presenter), LE WANG, YANG ZHENZHONG, MARK BOWDEN, Physical and Computational Sciences Directorate, Pacific Northwest National Laboratory, JOHN WILLIAM FREELAND, Advanced Photon Source, Argonne National Laboratory, SUSHKO PETER, DU YINGGE, Physical and Computational Sciences Directorate, Pacific Northwest National Laboratory — Charge transfer at oxide interfaces can drive emergent phenomena that do not occur in the bulk, thereby significantly enriching our fundamental understanding of these material. We have synthesized a series of (SrNiO$_3$)$_1$/(LaFeO$_3$)$_n$ superlattices (SLs) by oxide molecular beam epitaxy on (LaAlO$_3$)$_{0.3}$(Sr$_2$AlTaO$_6$)$_{0.7}$ (001) substrates. Our structural characterization results indicate that cubic perovskite SrNiO$_3$ (SNO), which does not exist in the bulk, can be stabilized as a single unit cell level in SLs with LaFeO$_3$. Our *in-situ* X-ray photoemission spectroscopy and X-ray absorption spectroscopy measurements indicate that depending on the value of $n$, the Ni and Fe valences are either 3+ or 4+. The $n=1$ SL contains Ni$^{3+}$ and Fe$^{4+}$, while Ni$^{4+}$ and Fe$^{3+}$ are observed in the $n=5$ SL. These results are consistent with valence band offset measurements which indicate that a potential well for holes is present in the LFO (SNO) layers for $n=1$ (5). The insights gained from these spectroscopies shed considerable light on the associated two dimensional (2D) semiconducting transport behavior in these SLs, thereby positioning us to utilize these materials systems in new and novel electronic devices.

*.

1:15PM B64.00009: Role of interface polarity in the electronic reconstruction of infinite-layer vs. perovskite nickelate films on SrTiO$_3$(001)

** BENJAMIN GEISLER (Presenter), ROSSITZA PENTCHEVA, Department of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — Motivated by the recent observation of superconductivity in the infinite-layer nickelate NdNiO$_2$ on SrTiO$_3$(001) by Li *et al.* [1], we explore the effect of interface polarity on the electronic properties of NdNiO$_n$/SrTiO$_3$(001) and LaNiO$_n$/SrTiO$_3$(001) thin films $(n=2,3)$ by performing first-principles calculations including a Coulomb repulsion term. For infinite-layer nickelate films $(n=2)$, electronic reconstruction drives the emergence of a 2DEG at the interface due to a strong occupation of the Ti 3$d$ states. This effect is more pronounced than in the paradigmatic LaAlO$_3$/SrTiO$_3$(001) system and accompanied by a substantial reconstruction of the Fermi surface. We contrast our findings with results for the perovskite compounds $(n=3)$. Moreover, we analyze the topotactic reaction from a perovskite to an infinite-layer heterostructure and show why the reduction is confined to the nickelate film, whereas the SrTiO$_3$ substrate remains intact.

*Funding by the German Research Foundation (DFG) within CRC/TRR 80 (Projects G3, G8) is acknowledged.*
Spatial distribution of hole around LaNiO$_3$/LaMnO$_3$ interface

**MASATO ANADA** (Presenter), SATOSHI SAKAGUCHI, KAZUKI NAGAI, Osaka Univ, MIHO KITAMURA, High Energy Accelerator Research Organization, HIROSHI KUMIGASHIRA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku Univ, YUSUKE WAKABAYASHI, Department of Physics, Graduate School of Science, Tohoku Univ — The superlattice of LaMnO$_3$ and LaNiO$_3$ exhibits ferromagnetism as a result of charge transfer between Mn and Ni across the interface[1]. In case of bilayer of LaNiO$_3$ on LaMnO$_3$(NMT) and of LaMnO$_3$ on LaNiO$_3$(MNT) grown on SrTiO$_3$ (001) substrate, the former shows much larger magnetization [2]. Detailed structure and valence distribution of the interfaces were examined by non-resonant and K-edge resonant surface x-ray diffraction method. Bayesian inference was applied to derive the atomic positions [3] to derive local polarization. The spatial distribution of Mn$^{4+}$ was determined from the energy spectra of scattering. As a result, Mn$^{4+}$ was found mainly in the Ni-Mn mixture region, and the total amount of transferred electron in NMT(0.8±0.2e$^-$) is larger than MNT(0.5±0.2e$^-$), which is consistent with the larger magnetization in NMT.

Disentangled transitions in artificial rare-earth nickelates

**SRIMANTA MIDDEY** (Presenter), Indian Institute of Science, DEREK MEYERS, Oklahoma State University, MIKHAIL KAREEV, YANWEI CAO, XIAORAN LIU, Rutgers University, PADRAIC SHAFER, Lawrence Berkeley National Laboratory, JOHN WILLIAM FREELAND, J.-W. KIM, P. J. RYAN, Argonne National Laboratory, JAK CHAKHALIAN, Rutgers University — The observation of simultaneous metal-insulator transition, charge ordering transition, and structural transition in rare-earth nickelates hinders our understanding of the underlying mechanism. We have devised a series of new superlattices by combining EuNiO$_3$ and LaNiO$_3$ to form ultrashort period superlattices, which allow one to disentangle the simultaneous orderings. Tailoring an incommensurate heterostructure period relative to the bulk charge ordering pattern suppresses the charge order transition while preserving metal-insulator and antiferromagnetic transitions. Such selective decoupling of the entangled phases resolves the long-standing puzzle about the driving force behind the metal-insulator transition and points to the site-selective Mott transition as the operative mechanism.
1:51PM B64.00012: Structural Distortions and the Metal Insulator Transition in (111) LaNiO$_3$

Ultrathin Films  MARGARET KANE (Presenter), LAUREN RIDDIFORD, ARTURAS VAILIONIS, Stanford Univ, APURVA MEHTA, SLAC Natl Accel Lab, ALPHA T. N'DIAYE, ELKE ARENHOLZ, Adv Light Source LBL, YURI SUZUKI, Stanford Univ — LaNiO$_3$ (LNO) is unique among rare-earth nickelates in that it doesn't exhibit a temperature dependent metal-insulator transition (MIT) in bulk. A thickness dependent MIT can be seen in (001)-oriented LNO films at ~8 Å thick and has been ascribed to ligand-holes, oxygen vacancies and charge disproportionation. We observe a similar MIT in (111)-oriented LNO on LaAlO$_3$ in transport measurements, but at a greater critical thickness than in (001) LNO on LAO. Synchrotron x-ray diffraction data and dynamical analysis show an elongation of the out-of-plane lattice parameter to 2.4 Å near the (111) interface. As the film gets thicker, the lattice constant shrinks to 2.25 Å and the film exhibits bulk metallic behavior. This distortion in the [111] direction in the first 8 unit cells is distinct from strain accommodation in (001) films, where oxygen octahedra can more easily rotate to relieve strain. We correlate the insulating behavior to this distortion and an increase in Ni$^{2+}$, measured via x-ray absorption spectroscopy. Together these results imply that metallicity in LNO films is a balance among the charge, lattice and orbital degrees of freedom.

2:03PM B64.00013: Bayesian inference of perovskite oxide interface structure based on surface x-ray diffraction data  KAZUKI NAGAI (Presenter), MASATO ANADA, Graduate School of Engineering Science, Osaka university, YOSHINORI NAKANISHI-OHNO, Graduate School of Arts and Science, University of Tokyo, MASATO OKADA, Graduate School of Frontier Sciences, University of Tokyo, YUSUKE WAKABAYASHI, Graduate School of Science, Tohoku University — Crystal truncation rod (CTR) scattering method is one of the approaches to determine the structure of ultrathin films. To perform structure refinement from CTR scattering data, a good initial model is needed to obtain the correct structure. Any surface electron density analysis requires to extrapolate the scattering data. We developed a robust structure refinement method for experimentally obtained CTR scattering data by using Bayesian inference with an exchange Monte-Carlo method. The exchange Monte Carlo method [2] enables us to search a wider parameter area in the parameter hyperspace, resulting in a better acceptance for the initial model. Our test analysis shows the structure of LaNiO$_3$ ultrathin film on LaAlO$_3$ was successfully refined from a simple LaAlO$_3$ structure as the initial model. The merit of using Bayesian inference is providing the degree of parameter uncertainty with a background of informatics. Proper estimation of uncertainty will be discussed.

Session B66 DCMP: Light-Induced Structural Control of Electronic Phases  

11:15AM B66.00001: Transient trapping into metastable states in systems with competing orders* [Invited]  
ANDREW MILLIS (Presenter), Physics/CCQ, Columbia University and Flatiron Institute — The use of tailored radiation pulses to control materials properties by guiding order parameters across a free energy landscape is an important goal of current research. Here we analyse the dynamics of systems with multiple competing or cooperative orders, focussing on situations where the radiation pulse drives the system to locally disordered states and considering the subsequent regrowth of the order. We show via a time-dependent Ginsburg Landau analysis how the distribution of fluctuations evolves and determine the circumstances under which the system may evolve into a metastable, rather than global, minimum of the free energy landscape. In the limit of small Ginsburg parameter a controlled theory of the evolution reveals generic features of the order parameter probability distributions. The theory is applied to pump problem experiments on charge ordered superconducting cuprates and to the dynamic interplay of magnetic and charge order in rare earth nickelates.

11:51AM B66.00002: Atomic-scale dynamics of strongly correlated materials: driving and seeing coherence with light at THz to x-ray frequencies* [Invited]  
STEVEN JOHNSON (Presenter), Institute for Quantum Electronics, ETH Zurich — The broad range of strongly correlated and "quantum" materials often exhibit surprisingly strong interactions between electronic, magnetic and structural properties that can manifest as strong and complex responses to impulsive excitations. Recent advances in ultrafast technology spanning frequencies from THz to x-rays have enabled a new generation of experiments, where light can be tuned to selectively excite and probe different aspects of strongly correlated materials, giving a more complete and understandable picture of the interactions in both near-equilibrium and in a strongly driven regime. Here I give an overview of some of our recent work covering two directions of development in this area. The first direction is using low-frequency (THz) pulses to drive coherent vibrational dynamics in correlated systems with minimal electronic excitation. I will discuss recent examples of this in wide gap insulators and in low conductivity metals. The second direction, complementary to the first, is to use femtosecond hard x-ray scattering techniques to quantitatively measure coherent lattice dynamics in response to impulsive excitation. One recent example that will be discussed is the recent observation of and ultrafast manifestation of the Einstein-de Haas effect in a ferromagnetic system [1]. I will also discuss THz-driven dynamics in ferroelectric systems that represent the confluence of these two directions and shows the potential of these new methods.

*This research was supported by the NCCR MUST, funded by the Swiss National Science Foundation.
12:27PM B66.00003: Ultrafast spin-dynamics: TDDFT's killer app.* [Invited] SANGEETA SHARMA (Presenter), Max Born Inst — I will talk about all-optical switching of long-range magnetic order. The type of coupling between the constituent atoms of a magnetic solid, usually ferromagnetic (FM) or anti-ferromagnetic (AFM), is a fundamental property of any magnetic material. This coupling is governed by the exchange interaction, for which the time scale of a typical magnetic material is of the order of a few 100s of femtoseconds. In our work, using time-dependent density functional theory (TDDFT), we demonstrate that a rich control over magnetization at sub-exchange time scales (of the order of few tens of femtoseconds) is possible[1,2,3,4]. This even includes changing the magnetic order from AFM to FM[5]. By investigating a wide range of multi-sublattice magnetic materials we are able to formulate three simple rules that predict the qualitative dynamics of magnetization for ferromagnetic, anti-ferromagnetic, and ferri-magnetic materials on sub-exchange time scales.

1:03PM B66.00004: Unraveling Momentum-Dependent Electron-Phonon Coupling and its Role in the Origin of Charge Density Wave Phases* [Invited] BRADLEY SIWICK (Presenter), MARTIN OTTO, JAN-HENDRIK PÖHLS, LAURENT RENÉ DE COTRET, MARK SUTTON, Department of Physics, McGill University — The nature of the couplings within and between lattice and charge degrees of freedom is central to condensed matter and materials physics. These interactions are essential to phenomena as diverse as superconductivity, charge density waves and carrier mobility in semiconductors and metals. Despite their fundamental role, detailed momentum-dependent information on the strength of electron-phonon coupling (EPC) and phonon-phonon coupling (PPC) across the entire Brillouin zone has proved elusive. This talk will describe a new technique, ultrafast electron diffuse scattering (UEDS), which provides such information. Specific applications of UEDS to 2D materials including graphite, TiSe2 and TaSe2 will be presented. These data demonstrate that UEDS patterns can separate the influence of the electronic susceptibility from the inelastic exchange of energy between the electron and phonon systems through the technique’ profound sensitivity to photoinduced changes to the phonon system. In TiSe2, this confirms key role of excitonic correlations to the phonon softening and CDW mechanism.

*Natural Sciences and Engineering Council of Canada (NSERC), Canada Foundation for Innovation (CFI), Canada Research Chairs (CRC), Fonds de Recherche du Québec – Nature et technologies (FRQNT)
Anton Burkov (Presenter), University of Waterloo — Weyl semimetal may be thought of as a gapless topological phase protected by the chiral anomaly, where the symmetries involved in the anomaly are the U(1) charge conservation and the crystal translational symmetry. The absence of a band gap in a weakly-interacting Weyl semimetal is mandated by the electronic structure topology and is guaranteed as long as the symmetries and the anomaly are intact.

The nontrivial topology also manifests in the Fermi arc surface states and topological response, in particular taking the form of an anomalous Hall effect in magnetic Weyl semimetals, whose magnitude is only determined by the location of the Weyl nodes in the Brillouin zone.

Here we consider the situation when the interactions are not weak and ask whether it is possible to open a gap in a magnetic Weyl semimetal while preserving its nontrivial electronic structure topology along with the translational and the charge conservation symmetries. Surprisingly, the answer turns out to be yes. The resulting topologically ordered state provides a nontrivial realization of the fractional quantum Hall effect in three spatial dimensions in the absence of an external magnetic field, which cannot be viewed as a stack of two dimensional states. Our state contains loop excitations with nontrivial braiding statistics when linked with lattice dislocations.

*This work was supported by Center for Advancement of Topological Semimetals, an Energy Frontier Research Center funded by the U.S. Department of Energy Office of Science, Office of Basic Energy Sciences, through the Ames Laboratory under contract DE-AC02-07CH11358.
Nonlinear dynamic conductivity in structurally chiral Weyl semimetals [Invited] JOSEPH ORENSTEIN (Presenter), DYLAN REES, University of California, Berkeley and LBL, KAUSTUV MANNA, MPI, Dresden, BAOZHU LU, Temple University, HORST BORRMANN, CLAUDIA FELSER, MPI, Dresden, DARIUS TORCHINSKY, Temple University — WSMs are 3D versions of graphene, characterized by isolated band crossings which act as monopoles of the Berry curvature field. From the properties of the Berry curvature under time-reversal and inversion, it follows that breaking either $T$ or $I$ is necessary for a crystal to exhibit a WSM phase. $I$-breaking WSMs exhibit response functions that are forbidden in systems that possess a center of symmetry. We have investigated an important example of such responses: the second-order nonlinear conductivity, defined by $J_i = \sigma_{ijk} E_i E_j$. For monochromatic electric fields the nonlinear response generates dc currents whose direction is dependent on the polarization state of the electric field, giving rise to phenomena known as photogalvanic effects (PGEs). In this talk I will present results on PGEs in response to linear and circular polarized light (LPGE and CPGE, respectively) as probes of both the symmetry and topology of the WSM phase. RhSi is an ideal candidate for such a study, as point group symmetry predicts the simplest possible structure of $\sigma_{ijk}$, in which the only nonvanishing tensor elements are even and odd permutations of $xyz$. Furthermore, RhSi is structurally chiral (or handed), and the absence of mirror planes breaks the degeneracy of Weyl nodes of opposite Berry monopole charge. I will present results on the polarization selection rules and spectra of PGEs for light incident on 111 and 001 surfaces. On 111 we observe a CPGE current whose direction is parallel to the wavevector of the light and whose spectrum is consistent with photoexcitation across a Weyl cone. More surprising is that we observe in-plane CPGE and LPGE currents at normal incidence on the 001 surface, where the bulk point group predicts a null effect. I discuss the possibility that the current is allowed because truncation at the 001 surface breaks the nonsymmorphic (screw) symmetry and therefore may derive from helicoidal surface bands that give rise to Fermi arcs (see Chang et al. 1906.03207).

Universal plateau in the thermoelectric Hall conductivity of Dirac/Weyl semimetals [Invited] BRIAN SKINNER (Presenter), Ohio State Univ - Columbus, VLADYSLAV KOZII, Department of Physics, University of California, Berkeley, WENJIE ZHANG, Peking University, PEIPEI WANG, Southern University of Science and Technology, RAN BI, Peking University, CHANG-WOO CHO, Southern University of Science and Technology, RUIDAN ZHONG, JOHN SCHNEELOCH, Brookhaven National Laboratory, DAPENG YU, Southern University of Science and Technology, GENDA GU, Brookhaven National Laboratory, LIANG FU, MIT, XIAOSONG WU, Peking University, LIYUAN ZHANG, Southern University of Science and Technology — The three-dimensional Dirac and Weyl semimetals can exhibit thermoelectric properties that are not possible in conventional metals and semiconductors. Here I focus in particular on the thermoelectric Hall effect, which is the generation of a transverse heat current upon applying an electric field in the presence of a magnetic field. I show, in particular, that the thermoelectric Hall conductivity acquires a robust plateau in the extreme quantum limit, and that the plateau value is independent of the field strength, disorder strength, carrier concentration, or carrier sign. I then discuss recent experiments on the three-dimensional Dirac semimetal ZrTe$_5$, which clearly exhibit this plateau. Other thermoelectric coefficients in the material, such as the thermopower and Nernst coefficient, are greatly enhanced over their zero-field values even at relatively low fields.
1:03PM B67.00004: Pseudo-electromagnetic fields in topological semimetals [Invited]  RONI ILAN (Presenter), Tel Aviv University — Dirac and Weyl semimetals react to position- and time-dependent perturbations, such as strain or an inhomogeneous magnetisation, as if emergent electromagnetic fields were applied. Such pseudo-electromagnetic fields differ from external electromagnetic fields in their symmetries and phenomenology, and enable a simple and unified description of a variety of inhomogeneous systems. We review the different mechanisms for creating effective pseudo-fields and their observable consequences, which can be remarkably different from those resulting from external fields.

1:39PM B67.00005: Acoustics, Weyl, and chiral transport [Invited]  SEBASTIAN HUBER (Presenter), ETH Zurich — Weyl semimetals in an external field exhibit a number of interesting transport phenomena. Here we show how we can induce pseudo-magnetic and electric fields in acoustics, how they modify the transport of acoustic energy and what we can learn from these systems for electronic transport in Weyl semimetals. Moreover, we demonstrate on a concrete model how one can capitalize on Weyl physics to create platform 9 3/4 at King's Cross station.

Monday, March 2, 2020 11:15 AM - 2:15 PM

Session B68 DPOLY: Machine Learning and Data in Polymer Physics

11:15AM B68.00001: Autonomous X-ray Scattering* [Invited]  KEVIN YAGER (Presenter), MASAFUMI FUKUTO, RUIPENG LI, GREGORY DOERK, Brookhaven National Laboratory, PAWEL W MAJEWSKI, University of Warsaw, MARCUS NOACK, Lawrence Berkeley National Laboratory — This talk will cover ongoing work to develop autonomous experimentation at a synchrotron x-ray scattering beamline. Deep learning (convolutional neural networks) is used to classify x-ray detector images, with performance improving when domain-specific data transformations are exploited ("physics-aware machine-learning"). These methods can be combining with customized data healing algorithms. To close the autonomous loop, we deploy a general-purpose algorithm that selects high-value experiments to conduct, attempting to minimize both uncertainty and experimental cost. Examples from recent autonomous experiments will be presented, including measuring nanoparticle ordering, combinatorial libraries of block copolymer materials, and realtime photo-thermal processing.

*This research used resources of the Center for Functional Nanomaterials and the National Synchrotron Light Source II, which are U.S. DOE Office of Science Facilities, at Brookhaven National Laboratory under Contract No. DE-SC0012704.
11:51AM B68.00002: Molecular Simulations Integrated Machine Learning Study of Bottlebrush Polymers* [Invited] SOUMIL JOSHI, SAMRENDRA SINGH, SANKET DESHMUKH (Presenter), Virginia Tech — Thermosensitive bottlebrush polymers (BBPs) are a type of graft polymers in which thermosensitive polymer side-chains are grafted to a polymer backbone. Most of these thermosensitive polymers with lower critical solution temperature (LCST) can undergo a coil-to-globule conformational transition with increasing temperature. This further results in a change in the overall shape of the BBPs, which is one of the most important properties needed in many biomedical applications including drug delivery, molecular actuators, etc. In this talk, I will discuss our recent coarse-grained (CG) molecular dynamics (MD) simulations study of poly(N-isopropylacrylamide) (PNIPAM; LCST= 305 K) BBPs of three different shapes: 1. Worm-like, 2. Cone-like, and 3. Dumbbell-like. The CG MD simulations were performed at 290 K (below LCST) and 320 K (above LCST) in the presence of explicit CG water for 500 ns. The analysis of simulation trajectories performed using in-house computer codes and data-driven machine-learning methods suggested that the shape of BBPs has significant impact on the conformations of side-chains as compared to other structural features (e.g. grafting density and side-chain length) and temperature.

12:27PM B68.00003: A Transfer Learning Framework for Improving Property Prediction, Interpretability, and Chemical Discovery from Scarce Datasets [Invited] BRETT SAVOIE (Presenter), Purdue Univ — Machine learning (ML) is being applied in virtually all areas of the chemical sciences to advance or complement activities that have traditionally been performed with physics-based methodologies. To sustain this progress and fulfill mounting expectations, ML must grapple with the intrinsic data scarcity of many applications. While datasets for image classification, object recognition, and some molecular properties may contain millions of samples, more typical chemical applications have access to only a few hundred to a few thousand samples. In data scarce scenarios, ML models can be severely underdetermined, exhibit limited transferability, and ultimately poor predictive power. Transfer learning addresses these data limitations with methodologies that utilize data across different domains, or data with mixed provenance and sparsity to augment and robustly train data scarce models. In this talk, I will discuss a flexible transfer learning approach to address data scarcity by using chemical latent space enrichment, whereby disparate data sources are combined in joint prediction tasks. I’ll show how this approach achieves three improvements over typical supervised learning approaches, including (i) increased property prediction accuracy from scarce data sets, (ii) increased model interpretability, and (iii) increased generative potential for use in the optimization and discovery of new chemistries. The talk will conclude with an outlook of current limitations, ongoing areas of improvement, and new applications.
1:03PM B68.00004: Optimization of organic molecules and macromolecules using machine learning* [Invited]  YAROSLAVA YINGLING (Presenter), Materials Science and Engineering, North Carolina State University — The number of applications of data driven materials discovery is rapidly growing. The large amount of available materials characterization and computational data, combined with high level statistical algorithms, is proving to be extremely useful in developing complex predictive models. However, in the field of soft matter, which includes complex materials such as polymers, liquids, emulsions, colloids, and gels, there is a slower adoption of informatics strategies than in adjacent fields mainly due to complexity of underlying processes and plethora of processing components that dictates the properties. In this talk, I will discuss the application of machine learning (ML) technique for optimization of ligand functionalized nanoparticles (NPs) and biopolymers. In our approach we use a combination of high throughput molecular dynamics simulations and data available from the literature to train the ML model. We address the uncertainty associated with MD simulations in the development of the model. Using this approach, we were able to design novel nanoparticle ligands capable specific desired properties driven by the specific optimization function. Our methods can significantly speed up the search for a new organic monomers (complex ligands or polymers) design based on experimental, in silico and available literature data.

*NSF CMMI-1763025 and CMMI-1727603

1:39PM B68.00005: Closed-loop, sequential learning for polymer systems [Invited]  KRISTOFER REYES (Presenter), State Univ of NY - Buffalo — Closed-loop, sequential machine learning has garnered an increasing amount of interest over the past few years in experimental science due to its ability to efficiently explore combinatorially large spaces of experimental parameters. Techniques in this new field can help accelerate scientific exploration of such spaces through the strategic selection of experiments whose outcomes could potentially yield a high amount of information. In this talk, we explore a few applications of such closed-loop, sequential design of experiments in the study of polymer systems, ranging from the optimization of polymer emulsions for use in drug delivery, to recent work in efficient phase mapping of polymerization phenomena and even real-time optimal control in driving block-copolymer evolution. While each example differs in application and experimental objectives, we will present a unified framework for the modeling and decision-making employed in each case. We will also present our work in the development of general-purpose tools designed to lower the barriers for applying these algorithms and techniques to other problems.

Monday, March 2, 2020 11:15 AM - 2:15 PM

Session B70 DPOLY DSOFT: Polymer Dynamics at the Nano-to Meso-Scale Revealed by X-ray and Neutron Spectroscopy II 208 - Tad Koga, State Univ of NY - Stony Brook - Tag(s): Focus
11:15AM B70.00001: Soft Matter Dynamics with Neutron Spin Echo Spectroscopy at the Spallation Neutron Source  PIOTR ZOLNIERCUZK (Presenter), Forschungszentrum Julich, LAURA-ROXANA STINGACIU, Neutron Scattering Division, ORNL, MICHAEL MONKENBUSCH, Forschungszentrum Julich —

Neutron spin echo spectroscopy is one of the most powerful techniques to study the dynamics of soft matter [1]. The SNS-NSE instrument [2] at the Spallation Neutron Source, Oak Ridge National Laboratory is the first, and to date the only one, instrument for high resolution NSE spectroscopy installed at a pulsed neutron source. The main advantage of the pulsed source NSE is the ability to resolve the neutron wavelength and collect neutrons over a wider bandwidth. This allows one to determine S(Q,t) on a flexibly chosen quasi continuous [Q,t] grid that can be selected a posteriori, trading statistical error with grid resolution.

We will show the capabilities of the SNS-NSE instrument and examples of soft matter experiments that have been performed using the SNS-NSE instrument. We will also present a new data reduction software called DrSPINE [3] that is capable to utilize all the available information contained in a series of experiments consistently in one step to yield a comprehensive representation of the intermediate scattering function S(Q,t).

11:27AM B70.00002: Dynamics of multi-domain macro-molecules in the context of polymer physics  LAURA-ROXANA STINGACIU (Presenter), VOLKER URBAN, Oak Ridge National Lab —

Conformational ensembles of synthetic polymers and intrinsic disorder in proteins are both aspects of the varying degree of order and disorder that are crucial for the properties of macromolecules. Neutron scattering techniques, in particular small angle scattering and neutron spin echo, have an important contributions to understand conformation and dynamics of macromolecules with regards to polymer physics. The possibility for altering and defining accessible conformational spaces through localized or intermediate and long-range interactions of segments along a polypeptide chain are limited by chain stiffness and local hydrodynamic friction. Our research aims for a deeper understanding of this challenging topic. We will present the dynamics of several bio-molecular species based on results of neutron scattering and the comparison with secondary and segmental relaxations, Rouse and reptation dynamics in polymers, with emphasis on the significant difference between dynamics of random coil of synthetic polymers and the dynamics of globular proteins.

11:39AM B70.00003: WITHDRAWN ABSTRACT —
11:51AM B70.00004: Length-Scale Dependence of Block Copolymer Segmental Dynamics

DANIEL HALLINAN (Presenter), OLUWAGBENGA IYIOLA, Florida State University, KUNLUN HONG, MONOJOY GOSWAMI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, PIOTR ZOLNIERCZUK, LAURA-ROXANA STINGACIU, Jülich Centre for Neutron Science – SNS, Institute of Forschungszentrum Jülich GmbH, WILLIAM THOMAS HELLER, Neutron Scattering Division, Oak Ridge National Laboratory, KYOUNGMIN KIM, Florida State University — This work examines the effect of interface proximity and tethering on polymer segmental motion. Selectively deuterated block copolymers (BCPs) were studied with neutron spin echo (NSE) spectroscopy. A strongly segregated BCP was used as a model system in which a glassy deuterated polystyrene (dPS) block acted as the interface and the dynamics of a rubbery deuterated polyethylene oxide (dPEO) block was studied. The PEO block was selectively protonated as a label to examine the dynamics near the interface in one sample and near the chain end in another sample. A strong slowing of segmental dynamics in the sample with the protonated label tethered directly to the dPS was observed compared to the dynamics of the sample with the protonated label at the chain end, but with an unexpected length scale dependence. The slowing was only observed at length scales significantly larger than the characteristic PEO segment length (1 nm), and the disparity between interfacial and chain-end dynamics grew with increasing length. The novelty of examining polymer chain motion over a wide range of length scales is enabled by NSE of selectively deuterated BCPs and can impact BCP applications including batteries, water treatment, and gas separations.

12:03PM B70.00005: Investigating the effect of salt on polymer dynamics in block copolymer electrolytes through neutron spin-echo spectroscopy

WHITNEY LOO (Presenter), University of California, Berkeley, ANTONIO FARAONE, National Institute of Standards and Technology, NITASH BALSARA, University of California, Berkeley — Block copolymers have been studied for use in lithium metal solid-state batteries due to their ability to decouple ion transport and mechanical properties. While it is well known that the salt preferentially segregates into the conducting block, and that the motion of salt molecules is coupled to that of the polymer segments that solvate the ions, many questions about the nature of this coupling remain unanswered. Neutron spin-echo spectroscopy experiments were used to elucidate the nature of this coupling; the sample used was a mixture of a protonated and deuterated polystyrene-\textit{b}-poly(ethylene oxide) doped with a lithium salt. The isotopic labeling allowed for only the dynamics of the ion-containing block, poly(ethylene oxide), to be measured. We quantified the dynamics, corresponding to length scales of about 5 nm, by comparing the data to predictions based on the Rouse model at low times as well as the standard tube model at long times. The crossover time between these modes was determined as a function of salt concentration. The tube shrinks with added salt and the segments slow down due to this. There is a direct relationship between segmental dynamics measured on the monomer length scale and ion transport under an applied field on macroscopic length scales.
12:15PM B70.00006: Ion transport in solid polymeric lithium ion electrolytes
HANS-GEORG STEINRUECK (Presenter), CHRISTOPHER TAKACS, SLAC - Natl Accelerator Lab, DAVID MACKANIC, Department of Chemical Engineering, Stanford University, BENJAMIN HOLLADAY, Department of Physics, University of California, San Diego, HONG KEUN KIM, Argonne National Laboratory, CHUNTIAN CAO, SLAC - Natl Accelerator Lab, SURESH NARAYANAN, ERIC DUFRESNE, X-Ray Science Division, Argonne National Laboratory, YURIY CHUSHKIN, FEDERICO ZONTONE, BEATRICE RUTA, ESRF, JOHANNES WILL, Institute of Micro- and Nanostructure Research (IMN) & Center for Nanoanalysis and Electron Microscopy (CENEM), University of Erlangen-Nürnberg, OLEG BORODIN, Electrochemistry Branch, Sensor and Electron Devices Directorate, U.S. Army Research Laboratory, SUNIL K SINHA, Department of Physics, University of California, San Diego, VENKAT SRINIVASAN, Argonne National Laboratory, MICHAEL TONEY, SLAC - Natl Accelerator Lab — Understanding ion transport in solid polymeric electrolytes (SPEs) continues to be of interest concerning improving safety and energy density of lithium-ion batteries. Towards this end, we present an investigation of lithium ion transport in a baseline SPE consisting of lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) in Poly(ethylene oxide) (PEO) via a combination of x-ray photon correlation spectroscopy (XPCS), x-ray absorption microscopy (XAM), continuum modelling, and molecular dynamics (MD) simulations. Our experiments yield spatially resolved ion velocities (via XPCS) and ionic concentrations (via XAM) upon polarization of a Li/PEO-LiTFSI/Li symmetric cell, which we compare to our theoretical efforts. Particular interest lies in providing direct insight into the concentration dependent transference numbers, which can be challenging to accurately measure, but are essential to ionic transport. We realize this by variation of the input transport parameters, aided by MD simulations, within the continuum model, until a match with the experimental velocities and concentration profiles is achieved.

*This work was supported by the Joint Center for Energy Storage Research (JCESR).

12:27PM B70.00007: Diffusion of Lithium Salt in Block Copolymer
KYOUNGMIN KIM (Presenter), MICAH SILVERMAN, DANIEL HALLINAN, Florida State Univ — Salt-doped polymer electrolytes can replace the flammable liquid electrolytes enhancing safety and chemical stability. The challenges to apply the polymer electrolytes to commercial batteries are dendrite formation and the low ionic conductivity. Understanding the ionic transport is essential to design high-performance batteries. Limitations of the conventional electrochemical measurements arise as the system gets complicated. Accurate and straightforward way to measure the transport properties is required. We successfully applied the measurement technique using time-resolved Fourier Transform infrared - attenuated total reflectance (FTIR-ATR) spectroscopy to polymer electrolytes. The diffusion coefficients of lithium salt through a polystyrene-poly(ethylene oxide) block copolymer (SEO) electrolytes were investigated. Since the concentration gradient is the only driving force, the diffusion coefficient could be decoupled with the ionic conductivity and transference number. The results showed non-monotonic dependence of the diffusion coefficient on the salt concentration implying the polymer structure or ion dissociation plays a role in the diffusion in concentrated polymer electrolyte.

*This study is supported by NSF Award # 1804871.
12:39PM B70.00008: Unravelling the Interplay Between Structural Dynamics and Water Transport in Perfluorosulfonated Ionomer Nanocomposites Through the use of Neutron Scattering and Infrared Spectroscopy  
APOORVA BALWANI (Presenter), ALLISON B DOMHOFF, Clemson University, MADHUSUDAN TYAGI, ANTONIO FARAONE, NIST Center for Neutron Research, National Institute of Standards & Technology, ERIC M DAVIS, Clemson University — Ionomer nanocomposites are attractive as proton exchange membranes in redox flow batteries, as they combine the thermo-chemical resistance of perfluorosulfonated ionomers with the reduced vanadium ion transport due to the presence of silica nanoparticles (SiNPs). However, elucidating the impact of SiNPs on the structural ordering and transport properties of these nanocomposites is an ongoing challenge. In this study, neutron spin echo (NSE) spectroscopy and high flux backscattering (HFBS) spectroscopy were employed to probe changes in polymer segmental dynamics and water dynamics, respectively, while small-angle neutron scattering (SANS) was used to investigate the SiNP dispersion state. In tandem with these techniques, infrared spectroscopy was used to capture water transport and water-induced swelling of the ionomer nanocomposites. Data from this complementary set of techniques indicate that SiNPs inhibit both viscoelastic relaxations and segmental dynamics of the ionomer network. Further, ionomer swelling and water transport in these nanocomposites were found to be highly coupled, leading to a complex water transport mechanism in these membranes. Finally, SiNP surface chemistry was established as a handle for tunability for ionic transport in perfluorosulfonated ionomers.

12:51PM B70.00009: WITHDRAWN ABSTRACT

1:03PM B70.00010: Structure and dynamics of homogeneously and heterogeneously crosslinked PNIPAM microgels*  
TETYANA KYREY, JUDITH WITTE, Stranski-Laboratory, Technische Universitaet Berlin, LAURA-ROXANA STINGACIU, NScD, Oak Ridge National Laboratory, MARCUS WITT, REGINE VON KLITZING, Department of Physics, Technische Universitaet Darmstadt, STEFAN WELLERT, Stranski-Laboratory, Technische Universitaet Berlin, OLAF HOLDERER (Presenter), Forschungszentrum Juelich GmbH — Thermoresponsive poly(N-isopropylacrylamide) microgel particles have been largely studied in the past due to their interesting fundamental properties as well as their potential for application in drug delivery, sensor technology or biotechnology. In this contribution, microgel particles with homogeneous and heterogeneous crosslink distribution and different crosslinker concentrations will be studied with small angle neutron scattering (SANS) and neutron spin echo spectroscopy (NSE).

The segmental dynamics of polymer chains in solution, as described by the Zimm model, is modified in microgels due to the presence of crosslinks and the crowded environment inside the particle, both inducing heterogeneities, for example “frozen” inhomogeneities or density fluctuations. Such structural heterogeneities have an impact on the segmental chain dynamics, which makes NSE, the highest resolution neutron spectroscopy technique, the experiment of choice for accessing variations and changes induced by changes in crosslink distribution and crosslink density.

An outlook on interface effects on the internal structure and inhomogeneities of microgel particles will be given.

1:15PM B70.0001: Dynamics of polymeric additives in bicontinuous microemulsions adjacent to planar hydrophilic surfaces  HENRICH FRIELINGHAUS (Presenter), FREDERIK LIPFERT, OLAFF HOLDERER, STEFAN MATTAUCH, MICHAEL MONKENBUSCH, NIKOLAS AREND, DIETER OSWALD RICHTER, Forschungszentrum Juelich GmbH — Close to a planar surface, lamellar structures are imposed upon otherwise bulk bicontinuous microemulsions. Thermally induced membrane undulations are modified by the presence of the rigid interface. While it has been shown that pure membrane dynamics are accelerated close to the interface, we observed nearly unchanged relaxation rates for membranes spiked with large amphiphilic diblock copolymers with respect to the bulk. An increase of the polymer concentration by a factor of 2–3 for the first and second surfactant membrane layers was observed. We interpret the reduced relaxation times as the result of an interplay between the bending rigidity and the characteristic distance of the first surfactant membrane to the rigid interface, which causes the hydrodynamic and steric interface effects described in Seifert's theory. The influence of these effects on decorated membranes yields a reduction of the frequencies and an amplification of the amplitudes of long-wavelength undulations, which are in accordance to our experimental findings.

1:27PM B70.0001: High shear rate rheology in microcapillary flow with SANS* PAUL SALIPANTE, RYAN MURPHY, National Institute of Standards and Technology, VISHNU DHARMARAJ, Chemical Engineering, MIT, KATIE WEIGANDT, STEVEN HUDSON (Presenter), National Institute of Standards and Technology — The rheology of shear-banding wormlike micelle solutions, which exhibit polymeric viscoelasticity, is investigated at high shear rates using capillary rheometry, particle-streak velocimetry, and small-angle neutron scattering (SANS). The capillary entrance flow was examined so that results of fully developed flow are reported. Such results show shear-thinning power-law behavior for all channel geometries from shear rates of 1,000 /s to nearly 1,000,000 /s. Two distinct power-law behaviors with increasing shear rate indicate a structural change with corresponding broadening of neutron scattering. The transition between these two power laws shifts with changing surfactant concentration and temperature.

1:39PM B70.00013: In-Situ/Operando X-ray Photon Correlation Spectroscopy Studies of Polymer Dynamics During 3D-Printing of Dual-Cure Polymer Epoxy [Invited] STANISLAS PETRASH (Presenter), Henkel Corporation — Synchrotron-based X-ray Photon Correlation Spectroscopy (XPCS) was used to probe the dynamic properties of soft matter at relevant size (submicrons) and time-scales (milliseconds). We combined XPCS with in-operando capabilities of synchrotron beamlines to shed light onto the unexplored dynamics of dual-cure (UV/thermal) industrial polymers for advanced 3D printing applications. We studied, in operando: a) the structural evolution and corresponding dynamics of the polymer during the extrusion phase of 3D printing, b) anisotropic structure formation & interfacial behavior during subsequent settling and UV curing, and c) the process of final thermal cure. The results revealed a) anisotropic polymer dynamics in different directions (printing (horizontal) vs. extrusion (vertical)) during printing and settling of the material, b) two-stage crosslinking dynamics during UV curing, and c) the chain dynamics near the polymer-polymer interface between 3D-printed filaments as a function of the distance from the interface. The present study shows that an in-situ/operando XPCS is not only an excellent technique for comprehensive, quantitative characterization of 3D printing processes, but also provides an unprecedented opportunity to perform studies of a wide variety of nonequilibrium phenomena of polymeric materials under external stimuli.

Session C01 APS: Meet Your Future Hyatt Centennial D - Tag(s): Careers, Industry, Undergrad Friendly

11:45AM C01.00001: Meet Your Future — FIAP and APS Careers will host a special lunchtime session in which representatives from industry will briefly describe their career path and answer questions about physics careers in the private sector. Topics will include research opportunities for physicists in industry, strategies for successfully pursuing industrial jobs, and advice on how to thrive in this exciting and challenging work environment.

The panelists this year are:

Cameo Lance Rhea Space Activity Director of Physics Programs
Kate Raach HRL Laboratories Research Staff Member
Jie Ren Merck Senior Scientist
Anne Smith Siemens Healthcare Systems Engineer
Stefano Spagna Quantum Design Chief Technical Officer

Note that this session will be held in the Hyatt Hotel, not the Convention Center. Join us for a slice of pizza and gain many useful insights into this career path.

Monday, March 2, 2020 2:00 PM - 2:00 PM
C71.00001: Using GALFIT to Determine Galaxy Morphologies of Quasars* KAITLYN RAUB (Presenter), MARIANA LAZAROVA, Physics and Astronomy, University of Northern Colorado, GABRIELE CANALIZO, Physics and Astronomy, University of California Riverside, MARK LACY, National Radio Astronomy Observatory, National ALMA Science Center — Little is known about the morphologies of quasars. Quasars are the brightest of the active galaxies, in which a supermassive black hole is accreting material, creating an accretion disk that outshines the host galaxy. We model images obtained from the Hubble Space Telescope of 22 nearby quasars and the galaxies in their immediate neighborhood using the GALFIT software to determine how well they are fit by typical galaxy profiles. GALFIT is an image analysis algorithm which fits parametric functions to create light profiles from two-dimensional images. We fit the quasars using two main components - a Point Spread Function (PSF), which represents a point source object (the light of the accretion disk), and a Sérsic profile, which models galaxy structures, such as a disk or a bulge. We will present details on the models, including the types of components used in each fit as well as the residual maps after subtracting the model from the data.

*Support for this work was provided by the department of Physics and Astronomy at the University of Northern Colorado and by NASA through a grant from the Space Telescope Science Institute (Program GO-11557), which is operated by the Association of Universities for Research in Astronomy, Incorporated, under NASA contract NAS5-26555.

C71.00002: UNDERGRADUATE RESEARCH  —

C71.00003: SuperCDMS: Energy Calibration of a Cryogenic Ge HV Particle Detector* SALAMONG XIONG (Presenter), Physics & Astronomy, Macalester College — The goal of the SuperCDMS collaboration is to directly detect dark matter. Potential candidates for dark matter are Weakly Interacting Massive Particles (WIMPs). To detect WIMPs, it is important to be able to predict how a Ge/Si particle detector will respond to a dark matter signal. In particular, it is necessary to calibrate the recoil energy measured by these detectors. This paper presents the energy calibration spectrum of a SuperCDMS-HV Ge particle detector using Am-241 and a PuBe neutron source. Due to high event rate, criteria were developed to remove low-quality data arising from particle interactions that occur too soon after a previous interaction. Peaks in histograms of pulse amplitudes were identified as energy peaks from the various radioactive sources, and fits of these peaks formed the basis for generating an energy calibration function. The calibration function was used to generate the calibrated energy spectrum.

*This undergraduate summer research was funded by the TRIO McNair Scholars program at the University of Minnesota - Twin Cities.
C71.00004: Effect of polyethylene oxide on camphor sulfonic acid doped polyaniline thin film field effect transistor with ionic liquid gating*  LUIS M RIJOS (Presenter), ANAMARIS MELENDIZ, ROLANDO OYOLA, NICHOLAS PINTO, Univ of Puerto Rico - Humacao — Field effect transistors (FET) using camphor sulfonic acid (CSA) doped polyaniline (PANI) blended with several polyethylene oxide (PEO) concentrations were investigated via ionic liquid gating. The pure PANI-CSA FET could not be turned “off” and had an on/off ratio of 2. Blending with 22wt%-PEO retained a high “on” state throughput current and improved the mobility, while the on/off ratio increased by $10^3$. Superior film quality and PEO assisted electrostatic long range interactions with the PANi chains led to device parameter enhancement. For higher PEO concentrations the field effect was suppressed due to disorder. Analysis of the UV/Vis spectra polaron band peak area near 810 nm show an increase in the mobility with decrease in the peak area, consistent with the observed results. Enhanced device parameters, high throughput current and low operating voltages (±2V), make PANi-CSA/PEO blends attractive materials for use in low power consumption electronics.

*This work was supported in part by NSF under grants DMR-PREM-1523463 and DMR-RUI-1800262

C71.00005: Fabrication of femtosecond laser-induced crystals in lithium nioboSilicate 30: the effects of polarization angle on orientation and growth rate.*  RUTENDO JAKACHIRA (Presenter), Drew University, COURTNEY AU-YEUNG, Physics, Lehigh University, EVAN MUSTERMAN, HIMANSHU JAIN, Material Science, Lehigh University — Optical and Electron microscope inspections reveal a dependence of light polarization on the growth of crystals in glass using a femtosecond laser. Critical for these experiments is an algorithm based on a half-wave plate that insured constant laser intensity for varying polarization directions. Laser-induced crystallization is an effective way of fabricating crystals in glass and other transparent materials owing to the fact that the process is clean, precise and contactless. The crystals obtained are of interest because of their potential use in optical data transmission. The issue tackled in this paper was that of maintaining consistent power when the polarization angle was changed. For this work, LiNbO3 crystals were fabricated in Lithium NioboSilicate glass with 30 mol percentage of silicon dioxide in the glass. Cao et al observed that at moderate pulse energies, (0.5-0.9μJ/ pulse, 300kHz) textured nanocrystals are obtained with their polar axis perpendicular to the writing laser polarization direction[1].

C71.00006: Ultrasonic Acoustic Probing Based on Gaussian Beam Analysis  EMILY LAPRIME  
(Presenter), SANICHIRO YOSHIDA, Southeastern Louisiana Univ — By analyzing differences in phase and amplitude of a signal, information about differing acoustic contrast between materials can be quantified. Prior methods used a scanning acoustic microscope which allowed for phase shifts to be identified by reflections but could not quantify phase shifts besides 0° or 180°. The new method uses a continuous signal to identify more precisely the phase and amplitude to analyze the transmitted signal. We have utilized the knowledge that the acoustic signal used behaves as a Gaussian beam travelling through a material. As the beam comes into contact with a defect, it is theorized to split into multiple source waves on either side which interfere as they travel across the plate to the receiver. By keeping the transmitter stationary and probing the receiver, we examine how the phase and amplitude change as the distance between transducers varies (transverse profiles). This approach potentially has a biological application because the acoustic contrast between healthy cells and cancerous cells is difficult to identify using current ultrasonic methods. This testing method could potentially gather more precise data with respect to the slightly differing contrasts between the cells and help better identify the presence and location of unhealthy cells.

C71.00007: Quantum Key Distribution Using Optimum Expectation Values of Maximally Entangled GHZ States*  COLLIN KESSINGER (Presenter), YE JIN HAN, QIAOREN WANG, Greenville Coll — We propose a new quantum key distribution scheme that is based on the optimum expectation values of maximally entangled Greenberger-Horne-Zeilinger states. Our protocol makes use of the degrees of freedom in continuously variable angles, thereby increasing the security of the key distribution. Outlined are two protocols that distribute a key from Alice to Bob using the above idea, followed by an extension that allows for the same key to be shared with Charlie. We show how this scheme provides for certain detection of any eavesdropper through absolute violation rather than the probabilistic violation used in many protocols.

C71.00008: Temperature dependent charge transport in graphene with ferroelectric gating*  KELOTCHI FIGUEROA (Presenter), LUIS M RIJOS, NICHOLAS PINTO, Univ of Puerto Rico - Humacao, SRINIVAS MANDYAM, MENGQIANG ZHAO, ALAN T JOHNSON, University of Pennsylvania — CVD graphene was electrically characterized in a field effect transistor configuration with ferroelectric (FE) gating in the temperature range 300K < T < 350K. Saturated hysteresis loops of the FE co-polymer poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE(75/25) showed that the memory window width decreased as temperature increased. Device trans-conductance (I-Vg) curves exhibit hysteresis behavior with two charge neutrality points (CNP) corresponding to the up/down polarization of the ferroelectric gate. Increasing the temperature decreased the change of the gate voltage and increased the change in the channel current measured between the two CNP’s. The electron mobility showed a steeper decrease compared to the hole mobility as temperature was increased. Desorption of O₂ and H₂O was used to explain these observations. Finally, non-volatile switching was realized using the charge storage property of the gate insulator.

*This work was supported by NSF under grants: DMR-PREM-1523463 and DMR-RUI-1800262
C71.00009: Developing a Method for Measuring the Optical Scattering of Silica Nanosprings*  
JEFFREY YODER (Presenter), Indiana Univ - South Bend, DAVID N MCILROY, Physics, Oklahoma State University — Nanosprings have been shown to have a variety of applications in medicine, industry and material science due to their unique nano-scale characteristics. Recent developments have vastly improved the ability to produce large quantities of high-quality silica nanosprings, making possible new avenues of research and applications. Current research includes applications in prosthetic-bone interfaces, detection of small quantities of gases, and the development of new composite materials. As such, there is a growing interest in better understanding their properties. The motivation for this work is to develop a method for studying the optical properties of these silica nanosprings. An apparatus for measuring the optical scattering of light off of the nanosprings has been constructed and measurements are ongoing. The first objective is to confirm visual observation of diffraction effects in nanosprings. The apparatus uses a visual microscope, a spectrograph, and illumination by a variety of lamps via fiber optics. A single nanospring is held by a micromanipulator; light (typically white) is then scattered off the spring and collected to produce spectra. This data is then analyzed for diffraction effects.

*Research conducted at Oklahoma State University and funded by NSF Grant #1757883.

C71.00010: Phase-Modulated Local Oscillator Effects on RF-DNA Fingerprints in IEEE 802.11a Wi-Fi Signals*  
WILLIAM MITCHELL (Presenter), Physics, Belmont University, KAITLIN HALL, Electrical and Computer Engineering, University of Utah, AHMED IBRAHIM `, DONALD REISING, THOMAS DANIEL LOVELESS, Electrical and Computer Engineering, University of Tennessee Chattanooga — With the increasing dependence on the internet in more and more consumer products, there is an urgent need to enhance existing digital security systems. RF-DNA fingerprints are one such approach to utilize discriminating waveform characteristics to augment the detection (rejection) of approved (unapproved) Wi-Fi devices. This work investigates a time-dependent approach to manipulate the RF-DNA fingerprints of a transmitting device through local oscillator phase modulation of the clocking system in Wi-Fi transmitters. Experimental results are used to investigate the ability for an unaffected receiver to detect a corresponding clock-modulated transmitter, as well as the changes of 802.11a Wi-Fi preambles of clock phase modulated transmissions. Changes in the waveforms are further analyzed using the Discrete Gabor Transform in the time-frequency domain. Analysis shows a predictable pattern of change over time, proportional in frequency to the phase-modulation frequency, and the ability for preamble structures to remain intact up to 30 kHz of phase modulation.

*This work was supported in part by the NSF through grant #1757777
C71.00011: Investigation of the Damage to Hydrophobic Self-Assembled Monolayers by Aqueous Salt Solutions  JULIANA SEBOLT (Presenter), CAYTON HORNBERGER, GRACE ROHaley, ADELE POYNOR, Allegheny Coll — When water is forced into contact with a hydrophobic surface, a depletion layer, or a low-density region of water, is formed. To study the depletion layer in more natural applications, we look at how aqueous salt solutions interact with hydrophobic surfaces made from self-assembled monolayers (SAMs) of octadecanethiol. In order to investigate this interaction we need smooth, homogeneous SAMs. Aqueous solutions can corrode the SAM, so we experiment salt molarity and cation size to eliminate this problem. The experimental methods include contact angle measurements, scanning electron microscopy, surface plasmon resonance.

C71.00012: Optimization of Microgel Imaging Using SEM*  SAMANTHA C TIETJEN (Presenter), PETRU STEFAN FODOR, KIRIL STRELETZKY, Cleveland State University — Microgels are polymer-based nanoparticles suspended in water that exhibit. The standard, noninvasive method for characterizing microgels is dynamic light scattering (DLS), which measures collective diffusion of microgels. While DLS provides reliable estimates for particle structure/dynamics, more direct methods of imaging are useful for studying polydisperse samples. Traditionally, scanning electron microscopy (SEM) uses an electron beam under high vacuum to characterize individual dried particles of dried. The dry microgel imaging suffers from two drawbacks: dehydrated particles collapse under vacuum and their dynamics is not observable. This project explored wet particle imaging in an ionic liquid stable under high vacuum. Particles were suspended in an ionic liquid film on a copper grid. Still images/movies were recorded to analyze microgel size distribution and dynamics. The average SEM size generally agreed with DLS both in ionic liquid and in water at room temperature. Variation was observed in individual particle sizes, but the average SEM size for both samples were close to the DLS size. Initial attempts at diffusion analysis using SEM particle tracking yielded mixed results as it requires tracing of many particles and further optimization.

C71.00013: Effect of cerium substitution on the superconducting state of $\text{Ba}_{0.6}\text{K}_{0.4}\text{BiO}_3$*

MOHAMED ESSAM NAWWAR (Presenter), BENJAMIN WHITE, Central Washington University — The superconducting compound $\text{Ba}_{0.6}\text{K}_{0.4}\text{BiO}_3$ has one of the highest critical temperatures ($T_c = 30$ K) of any non-cuprate oxide. In this study, we probed its superconducting properties by studying the impact of chemical substitution with Ce on the system $\text{Ba}_{0.6-x}\text{Ce}_x\text{K}_{0.4}\text{BiO}_3$. The objective of this study was to measure the effect of introducing magnetic moments by comparing the $x$-dependence of $T_c$ in $\text{Ba}_{0.6-x}\text{Ce}_x\text{K}_{0.4}\text{BiO}_3$ with the previously established behavior of $\text{Ba}_{0.6-x}\text{La}_x\text{K}_{0.4}\text{BiO}_3$. Our polycrystalline samples, synthesized using the molten salt technique, exhibited suppressed $T_c$ values compared with that of $\text{Ba}_{0.6}\text{K}_{0.4}\text{BiO}_3$; however, we were unable to observe a clear correlation between measured lattice parameter values and $x$, suggesting that the molten salt synthesis method we used is unable to finely control the Ce content of the samples. Additional measurements will be required to determine the exact stoichiometry of the samples and x-ray photoemission spectroscopy will be required to determine the oxidation state of Ce ions. In this poster, x-ray diffraction and magnetic susceptibility measurements will be presented and compared with results from $\text{Ba}_{0.6-x}\text{La}_x\text{K}_{0.4}\text{BiO}_3$.

*This project was funded by a Summer Undergraduate Research Experience grant from Central Washington University.

C71.00014: Fragmentation and Desorption of Surface-Immobilized DNA on PMMA and PAA Substrates for Sequencing Applications*

ELLEN GUO (Presenter), QINXI LIU, KATHY XING, KERUI YANG, LUISA PAN, JOCELYN ZHU, ANTHONY DEL VALLE, Stony Brook University, JOSEPH JENNINGS, Nassau Community College, JONATHAN CARL SOKOLOV, Stony Brook University — Producing ordered fragments of DNA would greatly simplify sequencing’s assembly problem. We studied the enzymatic cutting and desorption of surface-immobilized $\lambda$-DNA molecules on PMMA and PAA coated silicon wafers. Surfaces were dipped into 0.5-5.0 μg/mL DNA solutions and retracted at 1-10 mm/s speeds to stretch and immobilize (“molecularly comb”) DNAs on the surface. For PMMA, desorption was done in heated buffer solutions (DNase buffer, NEBuffer 3.1, pH-altered NEBuffer 3.1 (pH≈10) at 50-70°C). For PAA, which switches water-solubility by immersion in CaCl$_2$ or NaCl solutions, complete desorption into saline solution by PAA dissolution was observed. Relative to previous soft lithography methods, we employed a microfluidic method to improve DNA fragmentation. Holes in 1mm thick PDMS membranes were produced by piercing the PDMS with microneedles (d =250-400 μm) or by curing PDMS around the microneedles. PDMS layers with holes were pressed onto adsorbed DNAs and a DNase I cutting enzyme solution was deposited on top. By applying a vacuum (125 Torr) above the solution, the low-volume chambers fill with solution and efficiently cut the DNA, as confirmed by fluorescence microscopy.

*We acknowledge support from the Louis Morin Charitable Trust and NYS Department of Economic Development.
C71.00015: Observation on WSe$_2$/WS$_2$ hetero-bilayer spectroscopic and transport features*
ZHUOHANG YU (Presenter), Physics, Pennsylvania State University, FELIPE CERVANTES SODI, Physics and Mathematics, Universidad Iberoamericana Ciudad de México, NESTOR PEREA LOPEZ, ANA LAURA ELIAS ARRIAGA, TIANYI ZHANG, MAURICIO TERRONES, Physics, Pennsylvania State University — Semiconducting transition metal dichalcogenide (TMD) monolayers are one of the most promising materials for future optoelectronics. When two different TMD monolayers are brought together, the interlayer electronic coupling effects generate a new band structure inherent to the bilayer. We aim to fabricate hetero-bilayers comprising WSe$_2$ monolayer and WS$_2$ monolayer and analyze their optical spectroscopic and electronic transport features.
We synthesized WSe$_2$ and WS$_2$ monolayers on Si/SiO$_2$ substrates by chemical vapor deposition. After growth, both monolayers were sequentially transferred onto a pristine Si/SiO$_2$ substrate to have high quality overlapped areas of heterobilayers. The samples were then annealed to enhance the coupling between layers. Lastly, we patterned Au/Ti contacts on the bilayers by e-beam lithography for electrical property characterization.
The Raman and photoluminescence spectra of the bilayers were compared before and after annealing, and we found a significant decrease in the photoluminescence intensity for both WSe$_2$ and WS$_2$. Future work will include the analysis of the electronic transport data to obtain the carrier mobility as a function of stacking angle and possible tunability in the exciton energy emission.
*We thank the financial support from the NSF-MRSEC.

MICAH KARAHADIAN (Presenter), AUSTIN R SMITH, EMMA VAHLE, HEIDE M DOSS, Pt Loma Nazarene Univ — CR-39, a thermoset resin, is a well characterized integrative detector that, when etched, shows tracks created by energetic charged particles produced in nuclear reactions. It has been questioned whether this detection method can be used in Pd/D electrolytic cell environments. Of concern is whether the pyrophoric nature of hydrogen's interaction with palladium and its recombination with oxygen within the cell can create similar tracks. The validity of this detection method in an electrolytic cell environment is investigated. Additionally, track comparisons from detectors used in a Pd/D co-deposition experiments utilizing K-40 or Li-6 electrolytes were done to determine if Li-6 contributes to the observed tracks.
C71.00017: Topological Effects in Knotted Arrays of One-Dimensional Quantum Rings
COLIN RIGGERT (Presenter), KIERAN MULLEN, Homer L. Dodge Department of Physics and Astronomy, Univ of Oklahoma — Quantum ring arrays (QRAs) offer insight into the impact of topology in quantum systems, displaying phenomena which often have implications in quantum technology. We study the energy spectra and wavefunction behavior of small (two and three ring) QRAs by building up a model of tunnel-coupled one-dimensional quantum rings from existing models of crossed one-dimensional quantum wires. An ambiguity arises in how we connect the ends of these crossed wires, allowing us to create QRAs with the same tunnel coupling, but topologically distinct boundary conditions. We solve these systems numerically for various strengths of the tunnel coupling and find that topological differences in hole count manifest in observable differences in the single electron QRA energy spectrum in the absence of external fields. We also consider these QRAs in the presence of a uniform external magnetic field that induces an Aharonov-Bohm phase in the electron as it tunnels. By varying the induced phase, we explore magnetic phase commensuration effects in the QRA energy spectra and find that these QRAs have additional topological qualities that manifest in further differences in the energy spectra. We propose knot theory as the tool for distinguishing these systems and explaining phase commensuration effects.

C71.00018: Effect of transverse magnetic fields on an isotopically engineered diamond NV ensemble
JON CAMPAU (Presenter), PETER BRERETON, RAJRATAN BASU, US Naval Academy, DANIELLE BRAJE, MIT Lincoln Laboratory — The nitrogen vacancy (NV) in diamond is a leading candidate for quantum sensing applications such as magnetometry. Here, we study the effect of a transverse external magnetic field on the spin coherence of an ensemble of nitrogen vacancy (NV) centers in diamond with applications to high-sensitivity magnetometry. A transverse magnetic field has been shown to suppress electronic spin decoherence [1]. By utilizing 15N ions for implantation, the nuclear hyperfine interaction between the 13C spin bath and the defects is minimized. We utilize optically detected magnetic resonance and pulsed methods to explore this effect in isotopically engineered diamond films.

*This work is supported in part by the Office of Naval Research under grant N0001419WX00566 and the Admiral Frank Bowman Scholar Program.
C71.00019: Link Testing between the Data Formatter and Second Stage Boards for the Fast Tracker Trigger in the ATLAS Experiment at CERN* CHRISTINA PINO (Presenter), California State University, Sacramento — At CERN, link testing was performed between the Data Formatter (DF) board and the Second Stage Board (SSB). This was to advance the installation of the Fast Tracker Trigger (FTK) for the ATLAS collaboration by the end of the 2nd Long Shutdown (LS2). Link testing was performed in the Underground Service ATLAS hall (USA 15) where the FTK is located. Different combinations of the Data Formatter board and Second Stage Board were tested using Xilinx's Integrated Bit Error Ratio Tester (IBERT) to vary the transceiver and receiver settings between the boards. To analyze the bit error ratio between the boards, the IBERT core would generate eye scans and bathtub plots to get a visualization of the digital signal integrity.

*I would like to thank Dr. Joshua Moss (CSUS) for funding my research at CERN through the NSF Grant No. 1506502. I would also like to thank my mentors Jonathan Long (UIUC) and Stanislava Sevova (Stanford) for guiding me through the summer.

C71.00020: Highly non-stoichiometric amorphous oxide semiconductors: the structure and electronic properties of defects in a-InOx ELIZABETH CAPUTA-HATLEY (Presenter), JULIA MEDVEDEVA, Missouri Univ of Sci & Tech — Oxygen non-stoichiometry in crystalline In2O3 leads to formation of oxygen vacancies that play key role in carrier generation and transport in this transparent conducting oxide and have been well-studied both theoretically and experimentally. In contrast to the crystalline oxide, the structure and electronic properties of oxygen defects in amorphous indium oxide (a-InOx) are not understood and render to be fundamentally different due to the lack of lattice sites and periodicity as well as an increased number of degrees of freedom in disordered materials. Strikingly, the observed carrier concentration in a-InOx is two orders of magnitude higher than that in the crystalline oxide. Moreover, given the ionic nature of indium-oxygen bonding, it is possible to grow highly non-stoichiometric amorphous oxides that helps tune the properties over an extremely wide range. Here, we employ ab-initio Molecular Dynamics simulations and density-functional calculations to study the structural and electronic properties of a-InOx. Based on a thorough analysis of the interatomic distances, coordination, distortions, charge localization, and defect state energies, we derive a microscopic model of defects in disordered oxides and discuss their effect on the electrical and optical properties.
C71.00021: In situ ellipsometry of epitaxially grown bismuth antimony telluride on sapphire*  MOLLY MCDONOUGH (Presenter), Physics, Suffolk University, TIMOTHY PILLSBURY, ANTHONY R. RICHARDELLA, NITIN SAMARTH, Physics, Pennsylvania State University — Ellipsometry uses elliptically polarized light to characterize thin film and bulk materials. The light undergoes a change in polarization as it interacts with the sample structure. The measurement is typically expressed as two values: Psi (Ψ) and Delta (Δ). Bismuth telluride and its alloys are widely used as materials for thermoelectric and spintronic devices. This project uses in situ rotating compensator spectroscopic ellipsometer to measure properties of Bismuth Antimony Telluride ((BiSb)\textsubscript{2}Te\textsubscript{3}). If properties of bismuth antimony telluride such as thickness and composition can be determined by ellipsometry, it can be used as a tool to improve growth parameters in real-time, improving throughput and precision when growing these materials.

*This work was supported by NSF through the REU (DMR-1851987) and the 2DCC-MIP (DMR-1539916) programs.

C71.00022: Study of Optical Properties of composite layers of MEH-PPV nanopillars and PEDOT:PSS films  EVANGELINE BEECHING (Presenter), Slippery Rock Univ — Fabrication of MEH-PPV nanopillars was completed using porous Anodic Aluminium Oxide (AAO) templates. The diameter and height of the nanopillars was controlled by adjusting the dimensions of the template. The morphology of the nanopillars was studied using scanning electron microscopy. The absorption of light of MEH-PPV nanopillars plus thin film was greater than that of the thin film only, both being the same thickness. The dimensions of nanopillars are essential for carrier processes such as exciton generation, exciton diffusion and carrier dissociation and transport. As PEDOT: PSS can enhance hole collection and exciton diffusion, addition of PEDOT: PSS improves the performance of solar cells. The variation in optical properties of composite material consisting of MEH-PPV nanopillars and PEDOT:PSS films will be investigated using UV-Vis spectroscopy and fluorescence spectroscopy with change in height and diameters of the MEH-PPV nanopillars.

C71.00023: Modeling directed self-assembly of nanoparticles under perpendicular electric fields  ELISE BAKER (Presenter), MATTHEW WITHERS, DAN MAZILU, IRINA MAZILU, Washington & Lee Univ — We design and model an experiment to study the effect of electric bias on particle-coverage densities produced during ionic nanoparticle self-assembly. The experiment involves the application of a uniform external electric field parallel to a glass substrate during the self-assembly of silica nanoparticles. We refer to this procedure as directed self-assembly of monolayers (DSAM). In our theoretical analysis, we modify existing cooperative sequential adsorption models to account for diffusion under an applied electric field. We use the mean field approximation to solve for particle-coverage densities. To ascertain the validity of this method, we compare our solutions to Monte Carlo simulations of the system. We also discuss particular experimental implementations of an ionic self-assembled monolayer under the influence of perpendicular external electric fields.
**C71.00024: Nonlinear Magnon Scattering Observations Via The Magneto-Optical Kerr Effect**

* PAUL BAILEY (Presenter), Brigham Young Univ - Provo, PAUL CROWELL, University of Minnesota — Nonlinear Magnon Scattering is observed in Yttrium Iron Garnet (YIG) thin films. Nonlinearity is excited in the YIG thin films by high power microwave pumping. The magnetization of the films due to the microwave pumping is then observed through the Magneto Optical Kerr Effect (MOKE). The MOKE is of interest as a measurement technique because of its potential to observe magnon scattering in real time. Well-defined thresholds of the linear and nonlinear regimes are examined by ferromagnetic resonance measurements using this setup.

*This work is funded by the National Science Foundation REU grant 1757388.*

**C71.00025: Thermal metamorphism study of carbonaceous chondritic meteorites**

ROHIL KAYASTHA (Presenter), RAKA PAUL, AARON STOKKE, ANALÍA DALL'ASÉN, Physics and Astronomy, Minnesota State University, Mankato — Carbonaceous chondritic meteorites are some of the most primitive materials in our solar system. They did not experience melting or other processes on their parent bodies (e.g. asteroids) during their initial formation, and thus, they preserve information of physical and chemical mechanisms in the solar nebula, which can unveil evidence about the origin of the planets and their components. However, most carbonaceous chondrites are exposed to secondary processes on their parent bodies, such as thermal metamorphism and aqueous alteration, modifying the primary properties of the carbonaceous chondritic constituents. Hence, in order to understand how these relics formed, it is important to analyze the modifications they have experienced induced by these secondary processes. In this work, we study the thermal metamorphism of these chondrites examining their carbon composition by Raman spectroscopy. We analyze the Raman spectra of carbon allotropes to obtain specific parameters that we use for thermal metamorphism mathematical models. In addition, we correlate the Raman results with those acquired using SEM/EDS (Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy), and we compare these findings with the results obtained from previously studied meteoritic samples.
We introduce dual-color differential dynamic microscopy (DDM) for detecting fast dynamics. DDM has been used extensively to measure the diffusive or ballistic motion of small particles, macromolecules and bacteria. Rather than localizing and tracking individual particles, DDM works by measuring the intensity fluctuations in images across a range of detectable spatial frequencies and provides data similar to that provided by dynamic light scattering. However, DDM is limited by the camera frame rate. Fast dynamics can be measured with high-speed cameras but those are typically expensive. We have developed a dual-color imaging setup which allows us to detect dynamics faster than the camera’s frame rate. We trigger blue and red light at well-defined times within a single image exposure. By analyzing each color channel separately and in combination we detect dynamics that are several times faster than the camera frame rate.

Research Corporation Cottrell Scholar award

C71.00027: Gradient-Based Algorithms for Characterizing the Structure of Fibrin Clots*
NOLAN ROTH (Presenter), High Point Univ — The human body's ability to close wounds through clotting is vital to everyday function—but irregular clotting can cause diseases like deep vein thrombosis, Von Willebrand disease, or hemophilia, which lead to hundreds of thousands of deaths each year. Understanding how various clotting mechanisms affect the mechanical and structural properties of a blood clot's fibrin fiber network is integral in working to prevent and treat these clot-related diseases. Two structural characteristics of the network, the average fiber diameter and branch point density, lend themselves to discovery by applying various computational image analysis techniques to images acquired using scanning electron microscopy or fluorescence microscopy. Algorithms using gradient-based thresholding were implemented in Python to minimize data loss from classic image analysis techniques and to quantify the network’s structural characteristics.

*Society of Physics Students for generous travel funding
C71.00028: Progress on the Development of a Magnetic Field Sensor*  KATHERINE GIFFORD
(Presenter), ZOYA SHAFIQUE, SEAN JAMES BENTLEY, Adelphi University — This project aims to
develop a magnetic field sensor by using the special properties of quantum entangled photons to
intensify the sensitivity of a Faraday effect based sensor. The Faraday effect occurs when the
polarization of light rotates as it passes through select materials in the presence of a magnetic
field. For our set up, we chose crystals with high Verdet constants: Cd0.57Mn0.43Te
andCd0.86Mn0.14Te. The introduction of a super magnet creates a measurable polarization
rotation in light passing through the selected crystals. Using a magnet in the shape of an annulus,
we experimented with a variety of geometrical configurations in an attempt to maximize the
rotation produced by the magnet and crystal. In the first set up, we mounted the magnet in close
proximity to the crystal. In later designs, we placed the crystal inside of the super magnet by 3-D
printing a structure to hold the crystal. Generating position-momentum entangled photons
through parametric down-conversion, our goal is to use the quantum nature of the photons to
create a highly sensitive magnetic field sensor.

*We would like to thank Adelphi University for funding.

C71.00029: Adsorption of CO$_2$ and N$_2$ on Graphite and Cone Grid*  EMILY KOIVU (Presenter),
Emory University, SILVINA GATICA, Howard University — Adsorption is the phenomenon that occurs
when a gas is in the presence of any material and is uniquely fit for different elements. Using
molecular dynamics simulations, the adsorption of a CO$_2$ and N$_2$ mixture on graphite is studied
at differing temperatures. Attempts to increase selectivity are made by introducing cones,
inverted and upright, on top of the graphite. Results show that at molecules are more easily
adsorbed at 300K than 400K and that the presence of the cones decreases selectivity, though
upright cones perform worse than inverted cones. Further study at different ranges of
temperature and strengths of interactions with the inverted cones should provide useful in
determining the most effective way to use adsorption to separate CO$_2$ and N$_2$.

*Financial support from the REU Site in Physics at Howard University NSF Award PHY 1659224 is
gratefully acknowledged.
C71.00030: The Effect of Si Nanoparticles and SiGe Nanoparticles on the Photovoltaic Conversion Efficiency CdS/CdTe Thin Film Solar Cells  JASMYNE EMERSON (Presenter), YUNIS YILMAZ, MEHMET ALPER SAHINER, Seton Hall Univ — The addition of embedded Si nanoparticles and SiGe nanoparticles in CdS/CdTe thin films deposited on ITO coated glass has been investigated in this study. We're testing the effects of Si nanoparticles and SiGe nanoparticles on the efficiency of CdS/ CdTe thin film solar cells and comparing the effects of different deposition times, particles sizes, and how they compare with each other. Si was originally tested in order to compare to the results of Au and Ag nanoparticles. SiGe nanoparticles are also being tested because Ge is likely to form more stable nanoparticles. SiGe alloys will have higher mobility as charge carriers than Si. In the process of creating these solar cells, CdTe and CdS are deposited onto ITO coated glass substrates using the method of Pulsed Laser Deposition. Si or SiGe nanoparticles were deposited between the CdS layer and the CdTe layer using the PLD method with various deposition parameters and durations to obtain variations in nanoparticles coverage at the interface. In order to characterize the Si nanoparticle embedded thin films, XRD, AFM, and SEM/EDX were used.

C71.00031: Engine of Life: Biophysics and Tyrosine*  JI KU (Presenter), Physics, Muhlenberg College, DEANNA LUNEAU, K. V. LAKSHMI, Chemistry, Rensselaer Polytechnic Institute — Carbon dioxide emissions have increased sharply within the last few decades, which has resulted in climate change and pollution. This has led to the search for alternative energy sources, using photosynthesis as an inspiration. Within photosynthesis, photosystem II (PSII) uses light energy to drive the energetically demanding four-electron oxidation of water to dioxygen. There are two symmetric redox-active tyrosine residues, Y_Z and Y_D, in the D1 and D2 protein subunits of PSII. While these tyrosine residues are chemically identical, they are functionally distinct. It is proposed that Y_Z is directly involved in the primary electron transfer pathway of PSII. In contrast, the Y_D residue is proposed to be involved in the assembly of the catalytic Mn_4Ca-oxo cluster. My research is focused on understanding the structure and function of the Y_Z and Y_D residues of PSII. In my presentation, I will describe the methodology of cyanobacterial cell cultures, isolation and purification of PSII and the application of pulsed electron paramagnetic resonance spectroscopy to study the Y_Z and Y_D radicals of PSII.

*This work was supported by the National Science Foundation via the Physics REU site at Rensselaer Polytechnic Institute. I would like to thank Lakshmi Lab for the research support.

C71.00032: Ideal Diode Behavior at the Graphene - WSe_2 Schottky Junction  COLLIN SANBORN (Presenter), JI UNG LEE, SUNY Polytechnic Institute — The metal-semiconductor interface is a core component of many nanoelectronic devices. The Schottky junction that can form at these interfaces is key to our understanding of device behavior. We have demonstrated that in graphene-silicon junctions, the current-voltage behavior based on bulk analysis no longer applies, and the diode is best characterized by the Landauer quantum transport formalism. We extend this analysis from silicon to transition metal dichalcogenides, a class of 2D semiconductors. We construct Van der Waals heterostructures of graphene and tungsten diselenide encapsulated in hexagonal Boron Nitride, and vary the geometry to analyze the physics of this new Schottky junction.
**C71.00033: Ferromagnetic Positron Beam Guidance for Single Shot Measurement in 2D-ACAR Spectrometers**  
MARTIN GROSSHAUSER (Presenter), University of Illinois at Urbana-Champaign  
— Angular correlation of electron-positron annihilation radiation (ACAR) is a technique to determine the electronic structure of solids. It is based on detecting the annihilation gammas' deviation from collinearity in order to measure the electron momentum before annihilation. This study deals with the experimental feasibility of single-shot ACAR measurements as a way of efficiently mapping the Fermi surface of crystals with a low electron momentum directions, corresponding to a quasi 2D electronic system.  
Single-shot measurements require the sample normal to be aligned with the detector axis, with the positron source being outside the field of view at the same time.  
A novel approach of ferromagnetically guiding positrons under high external magnetic field (1.0T) conditions is explored both in simulation and experimentally. Furthermore, new radiographic methods to quickly assay positron beams are evaluated.

**C71.00034: Symmetries of Two Atoms with Contact Interactions in a Ring Trap**  
ISABEL FERNANDEZ (Presenter), NATHAN L HARSHMAN, American University  
— We consider an idealized model of ultracold atoms in a ring-shaped optical trap with s-wave and p-wave contact interactions. The relative dynamics for two interacting particles are mapped onto a single particle traveling on a ring disrupted by zero-range delta-function barriers and delta-prime barriers. We categorize the symmetry groups of these potentials and find the exact solutions for stationary states. By classifying the energy spectrum in terms of the irreducible representations of the symmetry groups, we reveal that there are additional symmetries “hidden” in contact interactions.

**C71.00035: Measurements of the Size Variation of Optically Trapped Aerosol Water Droplets Using Cavity Enhanced Raman Spectroscopy (CERS)**  
DALTON ANDERSON (Presenter), LOWELL I MCCANN, University of Wisconsin-River Falls  
— Optical traps have numerous applications including the study of aerosol droplets. It has been observed that in a single beam optical trap, micro-meter sized aerosol droplets exhibit hysteretic axial motion in the direction of beam propagation. Two meta-stable positions have been observed and it is thought that the cause of this motion between positions may be due to morphology dependent resonances (MDRs). For this to occur, thermal expansion of the droplet from a varying laser beam power must occur. Using Cavity Enhanced Raman Spectroscopy (CERS) we can investigate the size of the droplet as the position of the droplet and the laser power varied.

*This research was supported by a UWRF URSCA Undergraduate Stipends and Expenses grant.*
C71.00036: Time-integrated Four-wave Mixing Measurements on Transition Metal Dichalcogenides in High Magnetic Fields*  ALEJANDRO VILLALOBOS (Presenter), DENIS KARAISKAJ, Physics, University of South Florida, STEPHEN A MCGILL, Physics, Florida State University, VARUN MAPARA, Physics, University of South Florida — Monolayer transition metal dichalcogenides are 2D materials with unique optical properties that make them potential candidates for use in optoelectronic devices and even quantum logic gates. We can observe changes in exciton dephasing rate in TMDs under high magnetic fields and use four wave mixing spectroscopy to better understand and manipulate exciton dynamics. Using the MONSTR apparatus, we took FWM measurements of a monolayer MoSe$_2$ sample, scanning from negative to positive delay signal to analyze the dephasing time of excitons. We applied magnetic fields up to 25T and altered the polarization scheme of the excitation pulses from cross-circular to co-circular to observe the dependence of exciton dephasing rate on these factors. The preliminary data suggests non-Markovian behavior, which can be seen in the broadening of the FWM signal. This may be a result of increased biexciton formation, which we learned may be tuned using a magnetic field. In the future, the application of a magnetic field onto heterostructure TMDs may also provide interesting insights, particularly into the dynamics of interlayer excitons.

*This work was supported by the National Science Foundation (NSF) grant DMR-1852269

C71.00037: The magnetic structure of a strongly correlated rare-earth based intermetallic system Au$_2$PrIn.*  SVETLANA DOROSHEVICH (Presenter), NAMI UCHIDA, Bergen Community College, KALANI HETTIARACHCHILAGE, Department of Physics, Seton Hall University, NEEL HALDOLAARACHCHIGE, Bergen Community College — The electronic structure of the rare-earth based intermetallic system, Au$_2$PrIn, is studied using computational methods. The material, a member of a large family of Heusler compounds, was recently discovered, and only crystallographic data was reported. The never reported Lanthanum version (Au$_2$LaIn) was also studied for the comparability of non-magnetic analogue. Both Au$_2$LaIn and Au$_2$PrIn show three-dimensional metallic nature with large band dispersion at Fermi level in electronic structure. Au $d$-electrons are dominated in the electronic band structure of La system, whereas rare-earth $f$-electrons are dominated in the electronic structure of Pr system. The study suggests that the magnetism develops as the $f$-orbital fills up from non-magnetic La-compound to magnetic Pr-compound. The electronic band structure of Pr compound shows local magnetism with $f$-electron bands near the Fermi level. Calculated magnetic moment is comparable with the expected magnetic moment of Pr. Calculated Curie temperatures are comparable with the stable magnetic structure predicted by spin polarized calculations. Detailed results of electronic and magnetic properties of Pr-system with the predicted magnetic structure will be presented.

*STEMatics Grant, Department of Education
C71.00038: MCG modelling and eccentricity calculations for Pb+Pb and Au+Au collisions at various $\sqrt{s_{NN}}$ — ANYA WOLTERMAN (Presenter), Physics and Astronomy, Macalester College — Glauber models provide insight into the initial state of nuclear collisions by treating them in terms of the interactions of the constituent nucleons, in accordance with theories about the scattering of composite particles. These phenomenological techniques are commonly used to determine various geometric quantities associated with such femtoscopic many-body systems. The Glauber Monte Carlo approach uses a random impact parameter and measured nuclear densities to investigate quantifiable properties such as the particle multiplicity and the average geometric eccentricity for heavy ion collisions. The former involves the incorporation of a particle production model to calculate the total transverse energy, a measure of centrality. The latter delves into the eccentricity of different event classes, which can be used to characterize various collision shapes for measurements of elliptic flow of heavy mesons. The results of both applications are then compared with analyses of data from the CMS and STAR experiments.

C71.00039: Utilizing Electronics to Extend the Life of Musical Instruments — REBECCA CALLAWAY (Presenter), MARY DYE, ADAM SCHOENE, Univ of Mary Washington — Musical instruments are often discarded when the cost of fixing an issue becomes an inconvenience. Millions of dollars worth of instruments are thrown away each year while communities around the country struggle with funding art and music programs. This causes music to become a privilege and for certain instruments to be only associated with certain socioeconomic classes. A new system needs to be designed where students and teachers can be exposed to musical instruments without having to worry about financial constraint. Instead of disposing of an expensive instrument and adding to landfills, mass produced electronic components can be used to extend its functionality as an educational tool. Affordable light sensors are used in place of the core sound producing material on the instrument. Software is combined with the light sensors in a manner to reproduce the sound it would make with original materials along with the ability to manually change the tone. Due to an electronic interface, performance can be easily recorded in notation software to keep track of progress and enhance the musicians understanding of music.
C71.00040: Study on the Spontaneous Elemental Lysis of an Electrolyte due to the presence of a Static Magnetic Field from contact with a so-called Permanent Magnet*  DEBOSMITA PATHAK (Presenter), Grinnell College, RAJATAVA MUKHOPADHYAY, Physics, IISER Thiruvananthapuram — This is a project to verify the results of a controversial experiment performed by Prof. Felix Ehrenhaft (1944). The absence of any constructive follow up research work for 74 years has motivated this work.

This experiment is focused on studying the effects of the static magnetic field due to standard laboratory and industrial grade AlNiCo bar magnets on a 0.1 M solution of CuCl$_2$. The deposition of copper granules begins near the south pole of the bar magnet and gradually progresses to cover the entire surface of the magnet. Gas bubbles form near the north pole of the magnet. This hints at the lysis of the CuCl$_2$ electrolyte. However, this happens without any external induced potential difference acting between the terminals, and only when a magnet is present, not otherwise. The study of the lysis of electrolytes in the presence of such a static magnetic field and the implications that this phenomenon presents are the aims of this experiment.

* We acknowledge the generous support of the Jagadis Bose National Science Talent Search (JBNSTS) Research Fund, Kolkata, India.
We also acknowledge the guidance of Dr. Joy Mitra, IISER Thiruvananthapuram, Thiruvananthapuram, India and Dr. Abhijit Kar, JBNSTS, Kolkata, India as mentors.

C71.00041: Synthesis and physical properties study of polar magnet HoFeWO$_6$*  CHRISTIAN BUCHOLZ (Presenter), DUY PHAM, Physics, Kennesaw State University, RAM C RAI, Physics, Buffalo state university, CHETAN DHITAL, Physics, Kennesaw State University — Polar oxides are important system to study due to their technologically relevant properties such as ferroelectricity, multiferroicity, piezoelectricity, magnetoelectricity. Recently, RFeWO$_6$ (R=Dy, Y, Tb, Eu) type polar oxides were synthesized and type-II multiferroic property was reported [1]. We have extended this series and successfully synthesized HoFeWO$_6$ in polar structure. We have also characterized this material using dielectric and magnetization measurements. We will present the synthesis method and the results from the dielectric, structural and magnetic measurements.

*This work is supported by mentor protege grant (432134) and SABAC through student physics society (SPS) Kennesaw State University.
**C71.00042: The Development of Four-Wave Mixing Spectroscopy to Measure Vibrational Spectra in the Low-Frequency Terahertz Range**

BENNY SCHUNDELMIER (Presenter), LASZLO JANOS UJJ, Univ of West Florida — We report the progress of developing four-wave mixing spectroscopy to measure vibrational spectra in the low-frequency terahertz range. The optical tabletop system, we have improved in the Laser Spectroscopy Lab at the University of West Florida is a multipurpose system [1], capable of executing a variety of spectroscopy methods such as e.g. Raman, Coherent Raman, and Laser-Induced Breakdown spectroscopy. For this project, our focus is on Coherent Raman Spectroscopy, through three-color two-beam broadband nonlinear frequency mixing. The three-color nature of the four-wave mixing signal allows for an effective non-resonant signal suppression relative to the polarized and depolarized Raman bands. This type of nonlinear four-wave mixing has not been fully utilized for ultrafast coherent Raman microscopy. To demonstrate the precision and merit of our modified system, we present measured and processed spectra of liquid and crystalline samples and provide a characterization of the critical components that constitute our system.

*OUR Award

**C71.00043: Thermal Analysis of Pr_{1-x}Nd_xOs_4Sb_{12} in Normal State**

MATTHEW CHAZLE BROWN (Presenter), YEH-CHIA CHANG, PEI-CHUN HO, Department of Physics, California State University, Fresno, M BRIAN MAPLE, Department of Physics, University of California, San Diego, TATSUYA YANAGISAWA, Department of Physics, Hokkaido University — At low temperatures, the filled-skutterudite compounds PrOs_4Sb_{12} and NdOs_4Sb_{12} exhibit states of unconventional heavy-fermion superconductivity (SC) and ferromagnetism (FM), respectively. Thus, we have interest in studying the doping system of Pr_{1-x}Nd_xOs_4Sb_{12} in order to identify the competing mechanisms between the two states. Because the multiband superconductivity in this system may still be influenced by the electron-phonon mechanism, the normal state properties may give us insight into the properties of conduction electrons and phonons. The molar specific heat of Pr_{1-x}Nd_xOs_4Sb_{12} is measured in the normal state 10K-300K, and the thermodynamic parameters are extracted by incorporating Debye Temperature, Einstein Temperature, and the electronic specific heat coefficient, which provide information about the lattice stiffness, rattling effect, and electron correlation, respectively. Our findings convey that the Debye and Einstein temperatures have a V shaped x dependence that decreases towards central values of x, following the trend in transition temperature of low temperature ordered state.

C71.00044: Ferromagnetic Resonance of All Oxide Core / Shell Nanoparticle Variants*  
N. SCHULZ (Presenter), Concordia College Moorhead, CORISA KONS, J. SHOUP, J. ROBLES, MANH-HUONG PHAN, HARIHARAN SRIKANTH, DARIO ARENA, Univ of South Florida — Core-shell magnetic nanoparticles (MNPs) are being considered for various applications in spintronics as well as in the bio-medical field. Ferromagnetic Resonance (FMR) is a widely-used technique for determining magnetic properties such as bulk magnetization and anisotropy, gyromagnetic ratio / g-factor, and damping. Broadband FMR using a co-planar waveguide (CPW) is well-suited for examining properties of thin film samples, but MNPs present some challenges. MNPs can have a wide distribution of sizes and crystalline orientation. Also, at room temperature MNPs are generally superparamagnetic, where the magnetic orientation is unstable against thermal fluctuations. This research sought to adapt the standard CPW-FMR methods for thin films to characterize the resonant responses of MNPs, starting with commercially available magnetite (Fe₃O₄) MNPs and progressing to more complex Fe₃O₄/CoFe₂O₄ core-shell nanoparticle variants. Protocols were developed for mounting the different MNPs onto substrates suitable for CPW-FMR. The temperature- and frequency-dependent resonant response of the MNPs was explored. The determination of specific sample properties extracted from the CPW-FMR methods will be discussed.

C71.00045: Generation Optical Beating between Hyperfine levels in the Decay of Rb atoms Excited by Different Pulse Shapes.*  
OLIVIA CHIERCHIO (Presenter), CHARANPREET SINGH, ZAFIR MOMIN, JAMES P ST. JOHN, MATTHEW WRIGHT, Adelphi University — We are investigating quantum interference in the atomic decay signal in a dilute thermal atomic gas with an intense pulsed laser beam. A short pulse of laser light (~ 3 ns) is used to drive atoms from the ground state to an excited state hyperfine manifold of levels. We are exploring how quantum beating and other excitation properties depend on the shape of the driving frequency (e.g., cw, chirped, white-noise, etc).

*NSF Award #1803837
C71.00046: Analysis of Time Evolution Algorithms to be Utilized in Modeling Classical and Quantum Mechanical Systems*

KATHERINE HUDEK (Presenter), L RAMDAS RAM-MOHAN, Physics, Worcester Polytech Inst — Time evolution in classical and quantum mechanical systems has been the focus of research because the behavior of physical systems with time are determined by their initial conditions. Calculation methods for the system values as it changes throughout time have to be very accurate in order to have predictions that we can rely on. This is the challenge of time evolution and its modeling.

In this project several time evolution algorithms were implemented and evaluated according to criteria of accuracy, stability, and consistency. Several scalar algorithms were examined as well as a technique for matrix exponentiation. Results show that the matrix exponentiation technique has significant advantages and is suitable for use in extending the time evolution models for various systems.

*This project was funded by CCNS (Center for Computational Nanoscience) at Worcester Polytechnic Institute and the Clare Boothe Luce Scholarship.

C71.00047: Verifying 2D device potentials and conduction with Kelvin Probe Force Microscopy*

JOEL TOLEDO-URENA (Presenter), JOSEPH MURPHY, REBEKAH SMITH, JOSEPH SIMPSON, JENNIFER T HEATH, Linfield Coll — In a 2D field effect transistor (FET), the electrical properties of the channel are modulated using a gate voltage. The electrostatic doping of the channel and the contact resistance of the interacting layers both contribute to the overall device conductivity, which plateaus above a certain gate voltage. Other factors, such as surface cleanliness and microscopic details of the films also influence the conductivity as can be deduced from variations between multiple devices. In this study, we explore the ability of Kelvin probe force microscopy (KPFM) to separate out the different factors influencing overall device conductivity. By applying a potential bias to a simple device, we build confidence in the linear response and reproducibility of the KPFM technique. We then directly visualize the uniformity of the surfaces, the potential barriers between layers, and the characteristics of the WSe$_2$ film as a function of the applied voltage. These data deepen our understanding of device potentials and conduction in 2D FETs.

*Financial support from the National Science Foundation and the M.J. Murdock Charitable Trust is gratefully acknowledged.
C71.00048: Detecting topological superconductivity by using a dc-SQUID*  
BENJAMIN HAWN (Presenter), JOSEPH PAKIZER, ALEX MATOS ABIAGUE, Wayne State Univ — We theoretically investigate the current and phase response of a dc-SQUID composed of two Josephson junctions (JJs) in parallel. The JJs are exposed to an in-plane magnetic field and their chemical potential and Rashba spin-orbit coupling strength are tuned by top gates acting separately on each of the junctions. By tuning the system parameters, each JJ can individually be driven from the trivial to the topological phase and vice versa. We investigate the 3 possible dc-SQUID configurations: the two junctions are topological, one junction is trivial and the other topological, and the two junctions are trivial. We perform theoretical simulations of the phase difference and critical current of the dc-SQUID for the 3 different configurations, and by comparing them we identify the signatures of the topological superconducting phase and its dependence on junction transparency, magnetic field, and spin-orbit coupling.

C71.00049: Water and Carbon Dioxide in Hydrated Hyperbranched Polyethylenimine Membrane Using Molecular Dynamics Simulation and Density Functional Theory  
KYUNG IL KIM (Presenter), ROBIN LAWLER, Chemical and Biomolecular Engineering, Georgia Institute of Technology, SEUNG SOON JANG, Materials Science and Engineering, Georgia Institute of Technology — Since excessive use of fossil fuels is releasing large amounts of CO$_2$ and exacerbating global warming, developing efficient materials to capture CO$_2$ is crucial. In this study, we investigate the hydrated hyperbranched polyethylenimine (HB-PEI) membrane in the presence/absence of water and carbon dioxide using molecular dynamics (MD) simulation to characterize their distribution and reaction mechanism in the HB-PEI membrane. For this, we prepare a model HB-PEI molecule and construct a condensed HB-PEI phase in the amorphous phase with various concentration of water and carbon dioxide molecules. Large-scale Atomic/Molecular Massively Parallel Simulator (LAMMPS) package is used in our MD simulations to establish the equilibrium state of HB-PEI membranes. Through our MD simulations, we obtain samples of the local structure of water/carbon dioxide nearby amine groups in HB-PEI membranes and scrutinize a possible molecular mechanism and corresponding energy barrier for carbon dioxide capturing, via density functional theory (DFT) approach.
C71.00050: An evaluation of methods for measuring thermomagnetic transport properties of bulk and thin film materials  
ANDREW JARYMOWYCZ, JASON PRUITT, KYLE THOMSON, AUSTIN TINKESS (Presenter), MATTHEW BEEKMAN, Department of Physics, California Polytechnic State University — In the “method of four coefficients,” experimental data for electrical conductivity, Seebeck, Hall, and Nernst coefficients are fit to models based on Boltzmann transport theory to estimate quantities such as the carrier effective mass, concentration, mobility, and scattering exponent. This powerful method provides experimental information about the electronic structure and charge carrier scattering mechanisms in solids, and has been used to understand enhanced performance in some thermoelectric materials. Nevertheless, there is relatively little literature available regarding descriptions of experimental apparatuses and methods of measurement of all four coefficients on a single sample in a single measurement cycle. We recently constructed a custom system for measurement of thermomagnetic properties from 8 K to 400 K. Here we report on a study of different approaches for experimentally measuring these four coefficients on both bulk and thin films samples. For example, we have investigated the effect of mounting the sample in a flat vs. vertical geometry, which can be important for adiabatic vs. isothermal Nernst measurements. Our results provide useful guidance for constructing such apparatuses to measure the thermomagnetic properties used in the method of four coefficients.

C71.00051: Analyzing Challenging Scientific Thoughts in a Christian Academic Setting*  
MASON POHLMAN (Presenter), Belmont Univ — Throughout a significant portion of history and within modern culture, the fields of science and religion appear to be competing for the same holds in a person’s belief system. Universities are where academics and the sciences are the prevailing held truth, while in churches, the Bible reigns as supreme authority. However, in a Christian academic setting, the predominate school of thought in belief systems might turn into a little more of a melting pot. By analyzing gathered personal data (via surveys and interviews), one can begin to piece together the predominate thoughts on the apparent conflict between religion and science at such a setting. Institutions such as this, while always diverse in thought, can present a cohesion between the two seemingly opposed parties in a way where neither side loses ground culturally. Data gathered on personal religious experience, beliefs and experiences gathered around evolution, creationism, the Big Bang, and other issues that fall from that have been collected to present an image of how science and religion might be in understanding at a Christian house of higher education.

*Belmont University Honors Program
C71.00052: Electronic and Structural Properties of Yb-based Materials  BRITNEY HOPGOOD
(Presenter), Department of Natural Sciences and Technology, Ana G Mendez University, CHINEDU EKUMA,
Department of Physics, Lehigh University — We have investigated the electronic, structural, and
optical spectroscopy of YbT$_2$Zn$_{20}$-based (T = Co, Rh, and Ir) 1-2-20 compounds using first-
principles calculations that account for the strong on-site-f-electron Coulomb interactions. We
observed the strong hybridization and screening of the f-levels by the itinerant conduction
electrons that led to massive electron behavior with an unenhanced electronic Sommerfeld
coefficient of over ~600 mJ mol$^{-1}$ K$^{-2}$. The optical spectroscopy exhibits renormalized Drude
response, a partial enhancement of the dynamical conductivity below ~1.0 eV, the emergence of
the midinfrared peak structures at ~0.46 eV, and low photon-energy dynamical effective mass
and scattering rate with nontrivial energy-dependent scattering resonances from free carriers.
Surprisingly, both the electronic and optical spectroscopy of YbT$_2$Zn$_{20}$ are distinctly different
from the rest of the studied materials, with characteristic features that support its closeness to
quantum criticality.

C71.00053: 395 GHz Sample Holder Waveguide for Dynamic Nuclear Polarization*  KIRSTY
SCOTT (Presenter), Florida State Univ, THIERRY DUBROCA, Condensed Matter Science, National High
Magnetic Field Laboratory — A major issue in nuclear magnetic resonance (NMR) is the low
sensitivity which can be achieved as a result of the small magnetic moment in nuclei. At the
MagLab, we exploit dynamic nuclear polarization (DNP), which increases NMR sensitivity through
a process in which electron spins transfer their larger polarization to the nuclei of interest, to
yield larger DNP signals at 14 T. For DNP experiments, our spectrometer uses a sample holder
which doubles as a waveguide for the microwave used to saturate the electrons in the sample
under study. The lack of axial symmetry in this sample holder limits our range of experiments.
To overcome this limitation, we are manufacturing axially symmetric sample holder-waveguides
by coating sample tubes with a conductive silver layer. The layer must have thickness and
conductivity such that it is transparent to a 600 MHz radio frequency, yet reflective to a 395 GHz
microwave. Our process consists of creating silver layer prototypes using various deposition
methods, characterizing the prototypes, replicating an optimized prototype on our sample tubes,
and implementing the final product in DNP experiments.

*Funding from the National Science Foundation (DMR-1644779) and the State of Florida is
gratefully acknowledged.
C71.00054: Effect of Post-deposition Thermal Treatment on the Structural and Electrical Properties of Oxygen Deficient Perovskite Metal Oxide Thin Films

BENJAMIN MOORE (Presenter), SKYLER KING, FRANCIS F WALZ, ANTON D WIGGINS, JOHN LEVENTIS, CHARLES J AY, GRACE YONG, DAVID SCHAEFER, GARY PENNINGTON, RAJESWARI KOLAGANI, Physics, Astronomy & Geosciences, Towson University — Thin films of perovskite metal oxides such as SrTiO3 (STO), La$_{0.67}$Ca$_{0.33}$MnO$_3$ (LCMO) and CaMnO$_3$ (CMO) exhibit many interesting electronic properties that are useful for technological applications. These properties are highly sensitive to the oxygen stoichiometry in the thin films, which can be varied by subjecting the thin films to heat treatment (annealing) after the film is deposited. We will discuss the results of our experiments to study changes in the lattice constants and electrical resistivity induced by post-deposition annealing in various gas ambients and in vacuum. We will also present the effects of annealing in the presence of a fluorine-containing polymer with the goal of incorporating fluorine in the film crystal structure. Thin films in this study are grown using pulsed laser deposition, lattice constants are determined using 4-circle x-ray diffraction and resistivity is measured using a 4-probe VanDerpauw technique.

*This work was supported by the NSF Grant DMR 1709781 & Fisher Endowment Grant from the Fisher College of Science and Mathematics at Towson University

C71.00055: Unsupervised Machine Learning for Rare Signal Detection in CMS Detector Data

LUC LE POTTIER (Presenter), Physics, University of Michigan, ANNAPAOLA DECOSA, Physics, University of Zurich — We present here a method for identifying high-$p_T$ beyond the Standard Model (BSM) signals, with no dependence on the expected physics signatures of these models. We do this by constraining our detector data to the expected signal region of a given model and training a deep neural autoencoder to 'recognize' jets belonging to the Standard Model (SM) background data. In this way, our models learn the background signature of SM jets in our signal region. We then evaluate this model on a mixture of SM and BSM jets, flagging jets with a high autoencoder reconstruction error as 'anomalous' or signal jets. This method of searching independently of any physics model is especially useful when the BSM model in question involves particles of unknown mass, branching fraction, etc. This is especially relevant in Dark Matter searches, such as the search for Semi-Visible jets in missing-$E_T$ events at the LHC. In these cases, our models are capable of flagging a range of BSM models with different parameters within our signal region, as opposed to a supervised model (such as a Boosted Decision Tree) which is only able to flag the exact signal it was trained on. We show that this technique is a promising method of identifying arbitrary BSM signals to high precision in LHC data.
HAO LI (Presenter), Harvard University, JAE-HO CHUNG, Korea University — Since the discoveries of robust two-dimensional ferromagnetism in CrI$_3$ [1] and Cr$_2$Ge$_2$Te$_6$ [2], many research interests have focused on thermal stabilities of magnetism on van der Waals monolayers. In this work, we investigated the thermal evolutions of classical spins on 2D ferromagnetic honeycomb monolayers during simulated cooling and/or annealing by using the Monte Carlo method. Using the Heisenberg Hamiltonian with parameters proposed for CrI$_3$ [3], we closely reproduce the experimentally observed temperature- and in-plane magnetic field-dependences of the magnetization including the size of the Curie temperature [1]. We also find that in zero-field cooling CrI$_3$ monolayers exhibit multiple domains with high densities of domain walls. We will present how the domains behave as the temperature or magnetic field is changed.

MATTHEW WITHERS (Presenter), ELISE BAKER, BENJAMIN WOOD ZEMAN, NOLAN ZUNK, CORY MORRIS, DAN MAZILU, IRINA MAZILU, Washington & Lee Univ — We design, model, and simulate an experiment to study the effect of electric bias on particle-coverage densities produced during ionic nanoparticle self-assembly. The experiment involves the application of a uniform external electric field parallel to a glass substrate during the self-assembly of silica nanoparticles. We refer to this procedure as directed self-assembly of monolayers (DSAM). In our theoretical analysis, we modify existing cooperative sequential adsorption models to account for diffusion under an applied electric field. We use the mean field approximation to solve for particle-coverage densities. To ascertain the validity of this method, we compare our solutions to Monte Carlo simulations of the system.
C71.00058: Correlating Multiphoton-Absorption-Induced Luminescence (MAIL) with Morphology in Noble-Metal Nanostructures*  ANNA GRAFOV (Presenter), XIAOYING LIN, University of Maryland, College Park, FARAH DAWOOD, Hamilton College, JOHN T FOURKAS, University of Maryland, College Park — The optical properties of nanostructured noble metals differ drastically from those of their bulk counterparts due to surface plasmon (SP) resonance. When incident light couples with the SPs of a noble-metal nanoparticle, it gives rise to strong, localized electromagnetic field enhancement. In particular, surfaces with high curvature experience especially strong field enhancement. Silver and gold SP absorption cross sections lie in the visible region, which make nanostructures of these metals ideal for studying optical phenomena. Multiphoton-absorption-induced luminescence (MAIL) is a nonlinear optical phenomenon that involves ultrafast pulses of light impinging on a nanostructured surface. The SP field enhancement allows for more efficient multiphoton absorption, and highly-efficient, broadband luminescence over the visible spectrum is produced as a result. We examine how the morphologies of noble-metal nanostructures correlate with their MAIL signals. Specifically, we focus on silver nanodendrites, synthesized from galvanic displacement reactions, and gold nanorings and nanotriangles, grown through colloidal synthesis. The absorption order, intensities, and spatial distribution of MAIL signals are examined for different morphologies.

*NSF Grant CMMI1449309

C71.00059: Characterizing the Mechanical Properties of 3D Printed Structures for Growth Plate Tissue Engineering  RACHEL HECHT (Presenter), A. CAMILA UZCATEQUI, VICTOR CRESPO CUEVAS, ROBERT R. MCLEOD, University of Colorado, Boulder — Stem cell differentiation is highly sensitive to the biochemical and mechanical environment. A major concern in tissue engineering is the need of a robust technique for producing structures with the precise amount of rigidity to guide stem cell differentiation. Damaged cartilage within the physis does not regenerate easily and can lead asymmetric growth arrest, making it an ideal model application. The physis has three distinct zones where cells evolve differently depending on the environmental conditions. Previous in vivo rabbit studies indicate that the mechanical properties of the 3D printed structures implanted in this area have an effect on stem cell differentiation in the area. In this work we use a solvent solution consisting of a multifunctional acrylate-based resin and ethanol to control the overall modulus of the structure. 3D printed pillar structures of varying solvent concentrations and backfills (air and a poly(ethylene glycol) diacrylate based hydrogel) were put through compression testing and we found that there was an apparent reduction in the modulus of higher concentrations of the solvent solution of over 30 percent. This work allows us to control the modulus of 3D printed structures, which can be applied to future stem cell differentiation studies.
C71.00060: The Effect of Short Range Attractions on Sequence Defined Polyelectrolyte Coacervation  
NATALIA MARKIEWICZ (Presenter), TYLER LYTLE, CHARLES SING, University of Illinois at Urbana-Champaign — Complex coacervation is the liquid-liquid phase separation of polyelectrolytes in aqueous salt solution into a polymer-dense phase, the coacervate, and a polymer-dilute phase, the supernatant. Previous work using Monte Carlo simulations demonstrated that changing the sequence of charged and neutral monomers on polyelectrolytes while keeping the charge fraction constant alters the extent of phase separation. However, previous data does not account for the hydrophobicity of different neutral monomers. To understand the coacervation of polymers with various chemical structures, van der Waals interactions at various strengths are included in Monte Carlo simulations to show hydrophobic effects in the system. Comparisons are made to existing Monte Carlo simulations and experimental data. Understanding these patterning effects will enhance the knowledge of biomacromolecule phase separation, as well as expand the understanding of sequence-dependent polymer physics.

C71.00061: All-Dielectric Nanophotonics Research Involving Undergraduates at Illinois State University*  
BRIGHTON COE, DANIEL EGGENA, Illinois State University, HIROSHI SUGIMOTO, Kobe University, MAHUA BISWAS, Millikin University, MINORU FUJII, Kobe University, UTTAM MANNA (Presenter), Illinois State University — Resonant excitation and manipulation of high-index dielectric nanostructures (such as Silicon, Germanium) provide great opportunities for engineering novel optical phenomena and applications. Here, we report selective excitation and enhancement of multipolar resonances, and non-radiating anapoles in silicon nanospheres using cylindrical vector beams (CVBs). Our approach can be used as a spectroscopy tool to enhance and identify multipolar resonances as well as a straightforward alternate route to excite electrodynamic anapoles at the optical frequencies.

*This material is based upon work supported by the National Science Foundation (NSF) under Grant No. ECCS-1809410. H.S. and M. F. acknowledge KAKENHI grant numbers 18K14092 and 18KK0141.
C71.00062: Silica Polypeptide Composite Janus Particles*  SEAN RONAYNE (Presenter), ALYSSA BLAKE, ELSA SAMANTARAY, JAMIE WOODING, MARK LASEGO, PAUL RUSSO, Georgia Institute of Technology — Janus particles are interesting materials due to their inherent dual face properties. The ability to be able to have different functionalization and properties on a single particle allows these materials to be used for drug delivery and interfacial chemistry. Silica polypeptide composite Janus particles are unique because they are stimuli-responsive particles containing an organic polypeptide shell with an inorganic colloidal silica core, half of which is coated in chromium. The responsive nature comes from the polypeptide shell consisting of the homopolypeptide, poly (ε-carbobenzyloxy-L-lysine) (PCBL), which is known to exhibit a reversible coil-helix transition when dissolved in m-cresol. The silica core particle can be removed from the particle via etching to retain a hollow polypeptide vesicle, potentially with the chromium still bound to part of the vesicle. These can be used to study the conformational transition of the polypeptides while being structured but without being tethered to a solid surface. This will help to better understand the polypeptides role as a drug delivery vesicle.

*National Science Foundation under Grant No 1505105 (DMR)

C71.00063: Arbitrary Super-Resolution Patterns Formed in Quantum Dots*  THOMAS DANZA (Presenter), RICHARD O MOURADIAN, MATEO MURILLO, SEAN JAMES BENTLEY, Adelphi University —

In this research, interference patterns were etched onto quantum nanoparticle thin-film samples using the second harmonic of a nanosecond Nd: YAG laser. By forming one interference pattern on a sample and then phase shifting the beam, we are able to produce patterns with twice the resolution due to the nonlinear nature of the quantum nanoparticles. By using the interferometric method with phase and amplitude masks arbitrary 1-D (with two beams) and 2-D (with four beams) patterns can be formed using this lithographic technique.

*Funded by Horace McDonell and Adelphi University
C71.00064: Using Depolarized Dynamic Light Scattering to Characterize Microgel Dependence on Synthesis Temperature* ANDREW SCHERER (Presenter), KIRIL STRELETZKY, Cleveland State University — Microgels formed by crosslinking polysaccharide polymer chains exhibit a thermally reversible volume phase transition due to the amphiphilic properties of the parent polymer. Specifically, the microgels deswell above a volume phase transition temperature, $T_v$. Microgel dynamics above and below $T_v$ has been studied extensively by dynamic light scattering (DLS) before. Here, the structure and dynamics of microgels synthesized at various temperatures are investigated through the use of depolarized dynamic light scattering (DDLS). The technique has previously been used in our lab to examine solely geometric anisotropies in non-spherical particles. It has also been used in the literature to study shape fluctuations in microgels that have a hard, polystyrene core and a soft, polymer shell. This research project looks into a possibility that the observed DDLS signal above $T_v$, for microgels synthesized at various temperatures, arises from microgel shape fluctuations.

*Cleveland State University 2019 USRA Program

C71.00065: Neutron Spectrum Unfolding with Deuterated Liquid Scintillator Detectors FABIO RIVERO (Presenter), JESUS F PERELLO, SERGIO J ALMARAZ-CALDERON, Florida State Univ — The detection of neutrons from nuclear reactions is becoming increasingly important in nuclear physics experiments. Neutron measurements are needed for understanding reactions that drive stellar explosions and provide insight into the behavior of exotic nuclei. Traditionally, neutron energies are obtained by the time-of-flight (ToF) method which consists in measuring the time that neutrons take to travel from the target to the detector. The quality of the measurements is limited by the distance traveled, the solid angle spanned by the detector array, and a background of gamma-rays and scattered neutrons. Pulse-shape-discrimination (PSD) allows one to distinguish, in certain detectors, neutron and gamma-ray interactions due to their decay times. A promising method in neutron research involves the use of deuterated liquid scintillators as neutron detectors where a unique correlation in the pulse-height (PH) information can also be extracted. In this work a method of unfolding neutron spectra will be presented. A response matrix is created from deuterated liquid scintillator detectors by combining PSD and PH data to obtain neutron energies alongside ToF. This method will enhance neutron studies relevant for nuclear structure and nuclear astrophysics research.
C71.00066: Gold-Aluminum Thin Films as an Alternative to Pure Metals for Plasmon Resonance Sensors*  ABDUL QADEER REHAN (Presenter), ROBERT MALCOLM KENT, MARIAMA REBELLO SOUSA DIAS, Univ of Richmond — Noble metal alloys have been widely investigated as an alternative to pure metals for improving the optical response of optoelectronic devices in the visible range of the electromagnetic spectrum. However, their use is hardly extended to the ultra-violet (UV) range. As an alternative, aluminum (Al)-based alloys could expand the functionality of photonic devices into the UV range. In this work, we fabricate and measure the dielectric constant of binary mixtures of gold (Au) and Al thin films. The films were deposited on a glass substrate via the co-sputtering method. The dielectric functions were measured using spectroscopic ellipsometry. We investigated how the optical response of the samples changed under a wide range of temperatures, from 25°C to 200°C. Also, we performed AFM, SEM, XRD, and EDS measurements. We demonstrate that, in all our cases, a bimetallic material outperforms their pure metal counterparts in the near-IR range after the temperature treatment, e.g., Al0.51Au0.49 shows an increased quality factor of its surface plasmon polariton (QSPP) than pure Au and Al. To verify our calculations, we measured the SPP of pristine and temperature treated samples.

*University of Richmond Arts and Science Summer Research Fellowship

C71.00067: Water Wheel Generator*  BRIGID LONG (Presenter), Ithaca Coll — The world continues to move toward eco-friendly renewable energy by creating new, more advanced technologies. Solar panels, wind turbines, and dams are some of our biggest contributors. This project takes a second look at the potential of bringing the vertical water wheel back into the limelight. Historically water mills have been crucial in the progress and growth of civilization by being a major source of strength and power. Combining this power with a continuously recycled water flow has the potential to create a constant source of renewable energy. Using the principles of water wheel designs that have been perfected over centuries and securing a small generator creates a viable configuration for a tabletop water powered generator. The goal is to create an enclosed system where a water wheel powers its own pump for recycling water flow and still outputs enough wattage to be used to charge batteries. This prototype has gone through rapid prototyping using 3D printed wheel designs for the optimization of electrical output. On a small scale this design can be a tabletop charger however, on a larger scale, this design could power homes and office buildings without the hazards of daming.

*This project is funded by the Ithaca College Department of Physics and Astronomy.
C71.00068: Reaction Kinetics and Mechanical Properties of Reversible Epoxies by Diels-Alder reaction
NICOLE PENNERS (Presenter), YOUNGMIN LEE, New Mexico Tech — Epoxies are an important class of thermosetting polymers for many long-term applications such as adhesives, structural materials, and coatings. Epoxies have durable and robust mechanical properties; but, they are difficult to remove, recycle and rework. Epoxies capable of reversible polymerization could solve these problems. In this experiment, reversible epoxies were synthesized by introducing the Diels-Alder reaction groups to epoxy monomers. 1,1’-(Methylenedi-4,1-phenylene) bismaleimide and furfuryl glycidyl ether were reacted to form a Diels-Alder cycloadduct. This cycloadduct was confirmed using Fourier Transform-Infrared (FTIR) Spectrometry. The forward and reverse Diels-Alder reaction was monitored by FTIR measurements at 90 °C and 110 °C as a function of exposure time. IR absorption peaks relevant to the reverse Diels-Alder reaction grew due to longer exposure time at 90 °C and 110 °C. The equilibrium shift was observed toward the reverse reaction dominant side at higher temperature by comparison of FTIR spectra at 90 °C and 110 °C. Mechanical properties of the reversible epoxies was examined to confirm two states of reversible epoxies: a durable network at lower temperature and soft segments at higher temperature.

C71.00069: Hyperentangled Bell-states analysis of two-photon 2n-degree-of-freedom system
CHUNZHEN LI (Presenter), Nankai University — It is known that it is impossible to unambiguously distinguish all the Bell states in one system using only linear optics even if you also use hyperentanglement. However, we can find out how many Bell states can be unambiguously distinguished with a given n in two-photon 2n-degree-of-freedom hyperentangled system. This work, based on the criterion of Peter van Loock and Norbert Lutkenhaus, uses the symmetric matrix to express Bell states and the number of distinguished Bell states can be obtained by the rank of a matrix made with all the Bell states. The results show that with the increase of n, the number of distinguished Bell states increases exponentially by $2^{n+1}-1$, while the efficiency of discrimination decreases exponentially by $1/2^{n-1}$. This work lays a foundation for Bell-state analysis of three-photon system.

C71.00070: Electronic Structure of Negative Trions in Semiconducting Quantum Dots
JAYDEN LEONARD (Presenter), QUE HUONG NGUYEN, Marshall Univ — A trion system is one that includes an exciton system pairing with either an electron (called a negative trion) or a hole (called a positive trion). Trions in bulks typically has infinitesimal binding energies, but recent research has shown that trions in quantum well have their binding energy increased by an order of magnitude, i.e. the confinement configuration supports the formation of trions. The measurements of the photoluminescence spectra of the trions in a single, self-assembled quantum dot also show the dependence of the photoluminescence lines on the size and geometry of the quantum dot. In this project, we will theoretically investigate the electronic structure of negative trions in a spherical quantum dot of a direct band gap semiconductor. The effect of an electric field on the trions will be considered to obtain the splitting of trion energy levels under the electric field. The respective wave functions of the resulting states have been obtained as well. The dependence of the electric field effect on the size of the dots will be investigated.
C71.00071: Floquet Engineering in 1D Non-Hermitian Model

HOUCHEN LI (Presenter), Nankai University — Topological properties of non-hermitian and periodically driven (floquet) systems have attracted great attention in recent years. Here, I find we can introduce robust topological edge state in 1D non-hermitian time-periodic system while its static counterpart is trivial. Also when we adjust the frequency of the outer driving within the regime around the bandwidth $\Delta$, topological phase transition of the system has a similar behavior with the Hermitian counterpart[1]. This will help us understand non-hermitian and floquet systems better.

C71.00072: Low-Pressure Plasma Device for Activation Bonding Polydimethylsiloxane(PDMS) to Glass

JACOB CARNEY (Presenter), KRISTA MCBRIDE, Belmont Univ — Surface activation of PDMS through plasma treatment is a common technique used in the fabrication of microfluidic chips for a strong bond between PDMS and glass. Plasma treatment can be done in an open lab or low-pressure environment, in which commonly produces more activated stronger bonds. The activation levels of plasma treatment of PDMS and glass can be measured using atomic force microscopy. A low-pressure plasma bonder is being built and tested in order to produce stronger microfluidic devices. The configuration and experimentation of the self-built low-pressure plasma generator will be presented.

*This research was supported by Belmont University, and the College of Science and Mathematics.

C71.00073: Electrocolonography: Non-Invasive detection of colonic cyclic motor activity from multielectrode body surface recordings

LAURA BRUCE (Presenter), JON ERICKSON, ANDREW TAYLOR, JACK RICHMAN, CONNOR HIGGINS, BETH REED, RIWAJ SHRESTHA, JACK ROBEY, UTKRIST THAPA, Washington & Lee Univ — Approximately 20% of Americans suffer from colonic motility disorders, including slow transit constipation (STC) and irritable bowel syndrome (IBS), with significant physical and social morbidity. Accurate clinical diagnosis is often challenging due to the non-specificity of symptoms. In addition, the only direct assessment tool available in current clinical practice is colonic manometry, which involves placing a small, flexible tube, or catheter, through the rectum and into the colon. There is a substantial need in both colon research and clinical practice for an accurate, non-invasive method to analyze colon motor activity. This work validates a novel non-invasive method to identify periods of cyclic motor activity in the colon using multichannel skin-surface electrical recordings on the lower abdominal region, termed electrocolonography (ECoLG). We also explore several spatial filtering techniques to identify wave propagation of the colon.

*We acknowledge the Lenfest Summer Research Grant, Washington and Lee University, Washington and Lee University Summer Research Scholar fund, the Levy Neuroscience Grant, Washington and Lee University, and we also thank the James Ramsay Project Grant, Royal Australasian College of Surgeons and the New Zealand Health Research Council.
C71.00074: Exploring the Memory Capacity of Embedded Synfire Chains* SARAH GREBERMAN (Presenter), YEVHEN TUPIKOV, DEZHE JIN, Department of Physics, Pennsylvania State University — Memory is a long-studied property of neural systems that is not well understood yet essential for the success of any animal. The synfire chain is a popular sequence generating model which has been hypothesized to represent a building block for neural computation and memory. Our research was conducted to explore what affects the storage capacity of memory networks composed of embedded synfire chains. Using computational modeling, we compared the memory capacity of two neuron models – Leaky Integrate-and-Fire (LIF) and Izhikevich – and systematically varied factors that showed to affect each network. In both cases, we used a simplified model of global inhibition to control run-away excitation. Our studies showed that the memory capacity for networks consisting of LIF neurons depends strongly on the inhibition, excitation, and width of the chains. The observed memory capacity was low and insufficient for practical applications. The memory capacity for networks consisting of Izhikevich neurons was considerably larger. More research needs to be done on this. Future directions would also explore more targeted models for inhibition in hope for achieving larger capacity for memory networks.

*NSF Award EF-1822476 and the Huck Institutes of Life Sciences at Pennsylvania State University

C71.00075: Enhancement of Nonlinear Optical and Piezoelectric Properties in Ferroelectrics from Symmetry-Breaking Strains* BAILEY NEBGEN (Presenter), Chemistry, University of Minnesota, RUI ZU, Materials Science and Engineering, Pennsylvania State University, WILLIAM NUNN, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota, VENKATRAMAN GOPALAN, Materials Science and Engineering, Pennsylvania State University — In the pursuit of lead-free piezoelectrics, recent studies have used temperature, pressure, applied voltage, and other methods to enhance piezoelectric properties in ferroelectrics. Here, we investigate changes in symmetry, polarization, and domain structure near phase boundaries in BaTiO3 crystals and BaTiO3-xBaSnO3 thin films in order to understand how property enhancement depends on external stimuli and replicate the property enhancements in versatile thin films. We use second harmonic generation (SHG) polarimetry to detect changes in point group symmetry and polarization direction, supplemented by scanning SHG microscopy, which reveals the domain structure and allows polarimetry of specific domains. We observe lower-symmetry monoclinic phases with SHG and piezoelectric property enhancements of up to 4 times near temperature phase boundaries and with applied voltage in BaTiO3 crystals. In addition, we observe similar symmetry lowering near a compositional phase boundary of BaTiO3-xBaSnO3 thin films, indicating the potential for similar property enhancements in the thin film system which is more easily integrable into a variety of devices.

*This work was supported by NSF grants DMR-1807768 and DMR 185-1987 as well as Penn State NSF-MRSEC Center for Nanoscale Science DMR 1420620.
C71.00076: Compaction and Creep in a Photoelastic Granular System*  EDNA OLVERA

(Presenter), Physics and Astronomy, Swarthmore College, NAKUL DESHPANDE, Earth and Environmental Science, University of Pennsylvania, CACEY STEVENS BESTER, Physics and Astronomy, Swarthmore College, DOUG JEROLMACK, Earth and Environmental Science, University of Pennsylvania — Creep is the subsurface, slow movement and deformation of constituents in a granular packing, such as sand or sediments, due to the applied stress and disordered nature of its grain-scale interactions. The phenomenon of creep in dense granular systems is relatively understudied, leaving many open questions. We explored creep through experiments in which we observed the influence of a controlled disturbance on rearrangements in a granular packing. Our granular system consists of disks that are made from a birefringent material; this allows us to use image acquisition to observe both the movement of the grains and the changing stress distribution within the system. In the experiment, we deliver disturbances via taps of a pendulum to one side of the chamber that contains the granular packing. The tapping strength is measured using an accelerometer. We tilt the chamber to varying slopes to observe changes in system response as we approach the critical slope for more rapid granular flow. Using image analysis, we examine grain rearrangements, changes in packing density, and stress redistribution as the grains creep due to these disturbances.

*We would like to thank the Swarthmore College and University of Pennsylvania Provost's Offices for their funding support towards this project.

C71.00077: Influence of Spin-coating Speed and Mixing Ratio on Polymer-Fullerene Films*  SEBASTIAN VALBUENA (Presenter), CHARITY DIAMONON, CAMERON M PROSSER, PROF WEINING WANG, Seton Hall Univ — Due to increasing environmental concerns and depletion of nonrenewable resources, different forms of renewable energy must be studied. Organic solar cells are a very popular and promising form of renewable energy; however, they are still relatively new and not as well studied in comparison to traditional silicon solar cells. Thus, it is important to gain more knowledge on how those organic solar cells could be enhanced in different areas. Among the organic solar cells (OSC), OSC based on polymer-fullerene bulk heterojunctions have attracted much attention due to their low cost and easy processing conditions. The most common polymer-fullerene bulk heterojunction is poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl-C61 butyric acid methyl ester (PCBM).

In this work, we show our studies on how the characteristics of P3HT:PCBM films depend on spin coating speed and mixing ratios. By varying the ratio of PCBM:P3HT as well as using different spin coating speeds, the impact on the absorbance spectrum of the films were studied. The results help us choose the optimum processing conditions for P3HT:PCBM films to be used in bulk heterojunction solar cells.

*New Jersey Space Grant Consortium - NASA
C71.00078: The Durability of a Chiral Auxetic Structure  ANNA REPESH (Presenter), XIN DU,  Physics, Aquinas College —  Metamaterials are bulk objects with special mechanism properties defined by their repetitive inner structures, rather than the materials they are made of. One of the special mechanisms is `auxetic behavior`: when the materials are stretched in one direction, unlike conventional materials, they will also expand in the lateral direction. In this project we studied the dependence of Poisson's Ratio on the geometric parameters of a chiral auxetic structure. This chiral auxetic structure can be potentially applied in deployable antennas. We used 3-D printer to efficiently design and produce the chiral auxetic structures. With an innovative experimental setup and image analysis techniques, we were able to study the durability of the chiral auxetic structures with various geometric parameters.

C71.00079: Thermodynamic and Magnetic Properties of the System Ca$_3$Co$_{2-x}$Zn$_x$O$_6$*  ALEXANDER MANTILLA (Presenter), JANI JESENOVEC, BENJAMIN WHITE, Central Washington University —  The crystal structure of Ca$_3$Co$_2$O$_6$ is built from chains of Co$^{3+}$ ions that are separated by Ca ions. Magnetic moments associated with low-spin Co ions are located on trigonal prismatic sites within the spin chains. Ferromagnetic intrachain interactions are an order of magnitude stronger than antiferromagnetic interchain interactions, leading to a quasi-one-dimensional magnetic structure. In an effort to study its magnetic state, we substituted Zn$^{2+}$ for Co$^{3+}$ ions. Zinc ions occupy the trigonal prismatic (magnetic) sites and charge balance causes low spin Co$^{3+}$ ions occupying octrahedral sites to become low-spin Co$^{4+}$. Thus, Zn substitution dilutes moments on trigonal prismatic sites and induces them on octahedral sites. Samples of Ca$_3$Co$_{2-x}$Zn$_x$O$_6$ were synthesized via solid state reaction and phase purity was evaluated via x-ray diffraction. X-ray diffraction elucidated a solubility limit near $x = 0.1$. Heat capacity and magnetization were measured as a function of temperature and were used to construct a $T$ vs. $x$ phase diagram for Ca$_3$Co$_{2-x}$Zn$_x$O$_6$. In this poster, this phase diagram will be compared to the previously reported phase diagrams for Ca$_3$Co$_{2-x}R_x$O$_6$ with $R = $ Cu, Cr, Fe, Mn, Sc, and Ho.  

*Research supported by the Central Washington University Science Phase II Project and start-up funds.
C71.00080: Image Analysis and Model of Cytoskeletal Filament Density of C17.2 Cells
BENJAMIN HORINE (Presenter), Susquehanna Univ, SABRINA JEDLICKA, SWETHA CHANDRASEKAR, Lehigh University, MASSOOMA PIRBHAI, Susquehanna Univ — Single-Walled Carbon Nanotubes (SWCNTs) have great potential in the biomedical field as a way to deliver materials into the body. However, the long-term effects on the body are unknown, especially in regards to the cytoskeletal filaments. Many cellular functions such as differentiation, cell shape, and motility rely on the aid of filaments, such as actin and nestin. Recent studies have demonstrated that internal and external stimuli can affect these filaments thus affecting cellular behavior. In this project, neural stem cells, specifically C17.2 cells were used and the distribution of the cytoskeletal filaments were modeled. A data set was created through Filament Sensor, a program created by Benjamin Eltzner, and ImageJ, to quantitatively process and enhance images. This poster will look into the distribution of actin and nestin throughout the cell. Future work will look at how SWCNTs affect the distribution of these filaments.

C71.00081: Photo-reduction was used to reduce the oxygen content in Graphene Oxide and correlated to Young’s modulus measurements* ALEM TEKLU (Presenter), CAMERON GREEN, GEORGE RISER, NARAYANAN KUTHIRUMMAL, College of Charleston — Finding a cost-effective way to make graphene would be beneficial to our world. Mechanical properties of graphene oxide were studied using and AFM system. Specifically, Young’s modulus, stiffness, and hardness of graphene oxide samples were measured as a function of sample thickness. Results obtained for Young’s modulus ranged from 24 GPa to 277 GPa for samples of thicknesses 1.4 µm to 93 nm. Once the Young’s modulus values were obtained, photo-reduction was used to reduce oxygen content in graphene oxide samples using a 405 nm ultraviolet laser for 36 hours. Young’s modulus was reevaluated after photo reduction and its value increased from 24GPa to 44GPa for the 1.4 µm thick sample.

*The work was supported by Department of Physics & Astronomy and the School of Sciences and Math at the College of Charleston. The project was also supported by NSF/EPSCoR: SC EPSCoR/IDeA, Award no. OIA-1655740.

C71.00082: RF Antenna for Generation of Spin-Dependent Force on Cold Lithium Atoms* JIANYI CHEN (Presenter), ARIEL T SOMMER, Physics, Lehigh University — This study aims to design a small radio-frequency (RF) antenna that can generate magnetic fields with magnitude of 1 Gauss. This RF antenna is useful because the generated fields can magnify the hyperfine state of lithium atoms which are used to study the quantum atomic gas at low temperature. However, the function of the RF antenna is restricted when the diameter of the antenna is constrained in less than 1 inch. This restriction is the result of a high energy loss caused by signal reflection in the circuits if the antenna is directly connected with the power supply. In order to reduce the loss, an impedance matching configuration should be introduced between the antenna and the power supply. At the end of the experiment, a small RF antenna with impedance matching configuration that can generate a magnetic field with desired frequency and amplitude is designed.

*We acknowledge the support from Lehigh Physics Undergraduate Research Program (REU). We acknowledge the support from College of Arts and Sciences Research Grant, Lehigh University.
C71.00083: Investigation of a LCoS-SLM and Progressively More Difficult Applications of the SLM Including Optical Trapping* KADE TATKENHORST (Presenter), Department of Chemistry and Physics, Simpson College —
At the heart of all phase modulation applications is a Spatial Light Modulator (SLM). A Liquid Crystal on Silicon Spatial Light Modulator (LCoS-SLM) uses a voltage to phase retardation relationship that allows for easily programmable phase shifts. The programmable phase shifts are often programmed using phase masks. The LCoS-SLM is investigated and various applications of the SLM, including using the SLM as a “Projector”, to generate Bessel Beams, to generate a Vortex Beam with Orbital Angular Momentum, and flat-top beams of various shapes are performed. All applications are performed using a similar optical set-up with various phase masks. Finally, a vortex beam is used to optically trap micron sized nanoparticles.

*This work was done under the REU at Rensselaer Polytechnic Institute and sponsored by the National Science Foundation (Grant #1560266).

C71.00084: Achieving Flat Gold Surfaces for the Organization of Organic Molecules* JACOB MARTIN (Presenter), JESSICA BICKEL, Cleveland State University — Organic electronics are interesting for use in electronic devices but suffer in competition with inorganics due to their lower conductivity. Crystallizing organic semiconductors can increase their conductivities and a possible crystallization method is self-assembly driven by the topography and chemistry of an atomic surface reconstruction. This work aims to develop an atomically smooth Au(111) surface, which has a herring bone reconstruction. Many methods are known for samples in UHV, however these methods do not work in atmosphere or a glove box, such as is used in our lab. This work expands upon that of Maver et al. using torch annealing, which allows the atoms to rearrange into a lower energy state. We anneal the sample at 710±10°C for two minutes, and then three minutes at 410±10°C. This yields larger and flatter terraces compared to the unannealed material. The unannealed gold had mounds with no flat areas and a max depth of 7.6 nm. The annealed Au(111) had flat terraces, 13-30 nm in size, with step heights in the order of .235 nm, which matches the interplanar spacing for Au(111). In the future, we will optimize this process to achieve large terraces by adjusting the temperatures and times used.

*This work was funded by the National Science Foundation, Award Number: 1659541
C71.00085: Immunofluorescent biomarkers for distinguishing cell phenotypes in zebrafish somitogenesis and autonomous cellular oscillators.*  YIYANG CHEN (Presenter), Nankai University, QIONG YANG, Department of Biophysics, University of Michigan, Ann Arbor — During zebrafish embryogenesis, coordinated genetic oscillations occur in a population of cells in the posterior-most tissues of the body axis, the tailbud and presomitic mesoderm (PSM), which will subdivide the embryonic body into morphological segments, called somites. It has been proved previously that single cells dispersed from tailbud will oscillate automatically. However, it remains unclear that which phenotype of the cells will present as autonomous oscillators. T-domain transcription factors Ntla and Tbx16 will both express in the period of somitogenesis but in different regions. Immunofluorescence experiments for both genes demonstrated the distribution of cells in different phenotypes in zebrafish embryo during somitogenesis. Comparison of immunofluorescence results for 5-somite stage embryos and high-somite stage embryos showed the change of PSM region. Combined with results for single-cell oscillation and statistical analysis, immunofluorescence for cell dispersals was able to tell the phenotypes of the oscillating cells.

C71.00086: Stabilization of Francium Materials Using Cluster Compounds*  DAVID NUNN (Presenter), AJIT HIRA, EDWARDINE FERNANDEZ, ARRICK GONZALES, TINO PACHECO, ALICIA FRESQUEZ, MARIO VALERIO, Northern New Mexico College — We present a Quantum Mechanical study of cluster compounds Fr\(_l\)X\(_m\)Y\(_n\) and Ra\(_l\)X\(_m\)Y\(_n\) (X, Y = other; 0 <= l, m, n <= 10). Half-life \(\lambda\) of the most stable isotope of francium (\(^{223}\text{Fr}\)) is 22 minutes, and only 20–30 g of the element exists naturally at any given time. The melting point, the boiling point, and density of Fr are uncertain. Isotopes of radium are radioactive, but the most stable isotope \(^{226}\text{Ra}\) has a half-life of 1600 yr. The stabilization of radium is known to have been experimentally achieved, using a solution in which an effluent and a metal chloride are mixed, then the previously obtained mixture reacted with a sulfate ion, to obtain effluent containing stabilized radium. The chloride can be a barium, strontium or lead chloride. We are looking to see if there are similar trends, in properties, for francium. So far, we have achieved a factor of 2.7 stabilization for some of the francium cluster compounds, compared to bare Fr in our calculations. There is the possibility of application of a stabilized Fr material as a catalyst promoter, or a remover of oxygen from vacuum tubes and light bulbs, or in atomic clocks, or in petroleum exploration, analogous to the practical uses of Cs.

*New Mexico AMP program, funded by the NSF, provided some financial support for this research.
C71.00087: Arduinos and the X-Ray Diffractometer* MIA MANZER (Presenter), KELLEY D SULLIVAN, Ithaca Coll — For Ithaca College's Senior Project, it is required that a student develop an idea for a project, as well as the budget, goals, proposal, and design of the project itself. This project discussed in this presentation is developing a connection between an Arduino and the X-Ray Diffractometer owned by Ithaca College. The goal is to have the diffractometer and Arduino communicate easily and allow for data to be taken during the experiment easily. We wanted to make sure that students would be able to take, as well as save, data in the simplest way possible.

*Ithaca College Department of Physics & Astronomy

C71.00088: Assessing iOLab-based Laboratories in Online Instruction* EMMA KOLLER (Presenter), LOUIS LEBLOND, Department of Physics, Pennsylvania State University — We implement an online introductory mechanical physics laboratory course that features the Interactive Online Lab (iOLab) device and a class structure that encourages student engagement and collaboration. The students in the online class achieved a learning gain of $g = 0.55$ on the FCI. The end of class survey showed that the students overwhelmingly (93%) valued the lab portion of the course. However, we can only infer their mastery of the lab learning objectives from lab related questions on exams and lab reports. We present an ongoing study that seeks to understand student attitudes towards the labs, and the processes students use to complete them. We observe student help-seeking strategies, the amount of time they spend performing the lab, and student motivation. Student attitudes towards online physics labs will be accessed through the use of in-person interviews and a pre and post Colorado Learning Attitudes About Science Survey for Experimental Physics (E-CLASS). The overall goal is to form a more detailed picture of how students complete online physics labs to improve the quality of online physics instruction.

*We would like to acknowledge the Tombros Fellowship and a Schreyer Teaching Grant at Penn State University.

C71.00089: The Effects of Heat Exposure Over Various Time Intervals on the Performance Characteristics of Monocrystalline Silicon Photo-voltaic Cells MADALYNNE FORSTER (Presenter), HUNTER DAVIS, NOAH COX, JUSTIN L SMOYER, PAUL V QUINN, Physical Sciences, Kutztown University of Pennsylvania — With the rise of awareness for climate change and environmental protection, research into alternative energy sources has becoming increasingly important. One of the most popular forms of renewable energy is solar power. Most commonly built solar panels utilize a collection silicon photovoltaic cells to generate electricity. Our research specifically looks into the efficiency characteristics of monocrystalline silicon photovoltaic cells after they are exposed to intense heat for a predetermined amount of time. The cells were heated at temperatures of 190°C, 200°C, and 210°C, for times ranging from 10 minutes to 110 minutes. An analysis of our data shows an average increase in fill fraction with time for all three temperatures. These results indicate a permanent overall increase in efficiency of the cells compared to baseline values. This outcome proves that we do not need to significantly change the process of production of the cells in order to increase the efficiency.
C71.00090: Optimization of CoFeB Electrodes for Magnetic Tunnel Junctions  

GILLIAN BOYCE (Presenter), Florida State Univ, SUYOGYA KARKI, JEAN ANNE INCORVIA, University of Texas at Austin — A magnetic tunnel junction (MTJ) is the current standard for converting magnetic information into electrical information. It is formed by sandwiching an insulating barrier between two ferromagnetic electrodes. An external magnetic field is then used to switch the electrodes between parallel and antiparallel magnetic alignment. The focus of this research is to optimize the switching between magnetic states through the optimization of electrode thicknesses, especially when non-conventional barrier materials are used. The goal is to decouple the two FM layer switching fields, which allows read-out of two resistance states of the device. The method used is three-fold: First, MTJ stacks are grown using sputter deposition. Next, vibrating sample magnetometry is used to test for switching of magnetic alignment. Finally, atomic force microscopy is used to test for interfacial roughness, which could cause the layers to couple and prohibit antiparallel alignment. I will discuss our work developing a method for minimizing the coupling between the FM electrodes by focusing on understanding the interfacial roughness.

*Funding was provided by the NSF Research Undergraduate Experience hosted by the Center for Dynamics and Control of Materials at the University of Texas at Austin

C71.00091: Predicting and Synthesizing Photocatalytic Semiconductor Materials  

XAVIER QUINTANA (Presenter), Physics, Pennsylvania State University, NATHAN D KEILBART, JULIAN FANGHANEL, ISMAILA DABO, The Pennsylvania State University —  

The photocatalytic generation of hydrogen fuel is a promising way to store and utilize solar energy and mitigate carbon dioxide emissions. Water-spitting photocatalysts use solar energy to convert water into molecular hydrogen and oxygen. Yet, many of the photoactive materials required for water splitting are costly or inefficient. To accelerate the discovery of photocatalytic materials, a high-throughput computational screening protocol was developed, coupled with experimental synthesis and characterization, to select photoactive materials that can efficiently split water. Several candidates from the list were synthesized and their bandgaps and ability to produce hydrogen were characterized. Many of the compounds exhibited desirable photocatalytic water-splitting properties. This screening provides a framework from which viable photocatalytic materials can be discovered.

*The authors acknowledge financial support from the National Science Foundation under grant number DMREF-1729338 and the Research Experience for Undergraduates (REU) Program
C71.00092: Effects of Nanoparticle Size and Density on the Critical Current and Creep in (Y,Gd)BCO Films: Comparisons to Strong Pinning Theory* SARAH JONES (Presenter), Physics, Colorado School of Mines, ROLAND WILLA, Karlsruhe Institute of Technology, MASASHI MIURA, Graduate School of Science & Technology, Seikei University, SERENA M ELEY, Physics, Colorado School of Mines — Incorporating nanoparticle inclusions into superconducting films is a well-established route for boosting current carrying capacity. (Y,Gd)Ba$_2$Cu$_3$O$_7$ films containing various nanoparticles have been shown to demonstrate inexplicably slow rates of thermally activated vortex motion (creep, S). Understanding the microscopic source of these slow rates is key to determining how to reduce S in superconductors. In this project, we report on the effects of different sizes and densities of nanoparticle inclusions on the critical current and creep in (Y,Gd)Ba$_2$Cu$_3$O$_7$ films. Samples in this study all contain a low density of R$_2$Cu$_2$O$_5$ (R = Y,Ba) inclusions (naturally occurring during growth), and each contain either no other nanoparticles, BaHfO$_3$, BaSnO$_3$, or BaZrO$_3$ nanoparticles. The data presented was collected from low temperature magnetization measurements in fields of 0.3 T up to 35 T using a VSM at the NHMFL and a local commercial SQUID.

*Funding for this project was provided by the Mines Undergraduate Research Fellowship. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by the National Science Foundation Cooperative Agreement No. DMR-1644779 and the state of Florida.

C71.00093: Design Parameters of Liquid Crystal Elastomer Multi-Laminates* KELSEY LYNCH (Presenter), JOSELLE MCCRACKEN, TIMOTHY J WHITE, Chemical and Biological Engineering, University of Colorado, Boulder — Liquid crystal polymer networks or elastomers (LCEs) can be surface aligned into complex orientations that produce cooperative deformation and out-of-plane shape transformation.[1] When subject to thermal stimuli, thermotropic LCE films actuate and display significant weight lifting capabilities that scale with thickness.[2] Here, we investigate parameters that affect the mechanical output of LCE actuators including thickness, composition, disclination type, and geometrical packing. Specifically, we develop an LCE composition amenable to photoalignment processing that acts below 70°C. The mechanical response of this material (stroke and force displacement) are contrasted to canonical LCE material systems. The actuation output of the LCE is increased by lamination.[3] A multi-laminate LCE material actuator over 1mm in thickness is demonstrated, capable of lifting large objects (>1 lb).

* DARPA-SHRIMP
**C71.00094: Solid State NMR Physics Laboratory**

ROSA CARDENAS (Presenter), Univ of the Incarnate Word — We report on the progress of the newly developed physics laboratory at the University of the Incarnate Word (UIW). This laboratory is the first physics research laboratory at this institution. It includes a new solid state NMR experimental setup. The experimental setup is comprised of a 400 MHz variable temperature, cryogen free, superconducting magnet manufactured by Cryogenic. It also includes a Tecmag Redstone NMR Spectrometer. This spectrometer is very flexible and therefore many different samples may be analyzed. Field calibration was conducted by using Nuclear Magnetic Resonance (NMR) with liquid D2O. This allowed for successfully tracking the Te NMR signal of an iron-chalcogenide FeTeSe sample. The superconducting transition of different purity iron-chalcogenide FeTeSe samples will be analyzed in detail.

*Department of Defense HBCU/MI Equipment Grant

**C71.00095: Simulation of Efficient Perovskite Solar Cells**

MADISON J GUERRERO (Presenter), HONGKUN CAI, PROF WEINING WANG, Seton Hall University — While Perovskite popularity has skyrocketed since the efficiency reached 22% in 2018, there is still ample research to be done as to what characteristics and parameters affect the solar cell. In order to obtain a greater understanding of the mechanics of how a perovskite cell becomes more efficient, this project focuses on the simulation program wvAMPS and how parameters alter main characteristics such as Voc (open circuit voltage) and Jsc (short circuit current). The perovskite solar cells were obtained from National Renewable Energy Laboratory. The structure of the solar cell is Ag(120nm)orAu(100nm)/spiro-OMeTAD(180-200nm)/perovskite(550nm)/mesoporous-TiO_2(200nm)/compact-TiO_2(40-60nm)/FTO/glass. The measured solar cell parameters are: Voc = 1.06V, Jsc = 16.53 mA/cm^2, Fill Factor = 63.5% and Efficiency = 11.2%.

The simulation attempted to parallel the measured Perovskite solar cell. With given parameters, we were able to simulate a solar cell with a Voc = 0.93V, Jsc = 21.27 mA/cm^2, Fill Factor = 85.5% and Efficiency = 16.9%, which are very close to the measured parameters. We also varied the layer thickness to check how the device performance can be improved. These results will help determine how to optimize device structures for Perovskite solar cells.

*Clair Booth Luce
C71.00096: An Algorithm to Optimize the Search for Electromagnetic Counterparts to Gravitational Wave Events* PRIYADARSHINI RAJKUMAR (Presenter), ALESSANDRA CORSI, Texas Tech Univ, CHRIS COPPERWHEAT, DANIEL PERLEY, Astrophysics Research Institute, Liverpool John Moores University, — Our understanding of gravitational wave (GW) events is greatly enhanced by identifying and studying their electromagnetic (EM) counterparts. For nearby GW events with a small localization uncertainty, an effective strategy is to search for new transient sources in previously catalogued galaxies, whose properties are consistent with the GW data. Even with a limited field of view, it is plausible to discover the EM counterparts using an efficient observational strategy. But because many galaxies must be observed and the EM counterparts are faint and fade rapidly, a reliable automatic procedure is crucial to schedule observations efficiently. To meet these challenges, we designed an algorithm in Python that uses a catalogue of nearby galaxies and the three-dimensional GW localization map to create a prioritized list of galaxies based on GW error-map probability, observability, and absolute magnitude. We tested our algorithm with past GW events and, within a few minutes, obtained consistent results with previous observations. We conclude highlighting how this algorithm can more generally assist in formulating effective followup plans with various types of small field telescopes at a variety of wavelengths, including radio.

*NSF-funded and Caltech-led GROWTH program.

C71.00097: Machine learning for classifying the chiral phase transition in AdS/QCD* BEIXI HAO (Presenter), SEAN BARTZ, Indiana State University — AdS/QCD is a phenomenological application of the gauge/gravity duality to strongly-interacting nuclear matter, including the quark-gluon plasma (QGP). This work uses machine learning to classify the order of the chiral phase transition between ordinary nuclear matter and the QGP. Our machine learning method is a supervised-learning synthesis of four standard classification algorithms: classification and regression trees (CART), k-Nearest Neighbors (kNN), Support Vector Machines (SVM) with a linear kernel, and Random Forest (RF). It is trained on a subset of data with known behavior, and tested on the remaining data, with a 100% success rate. We also discuss the application of this machine learning method to the development of an AdS/QCD model featuring a critical point in the QCD phase diagram, which aligns with the current experimental program at Brookhaven National Laboratory.

*The authors wish to thank the Indiana State University SURE program for its support.

C71.00098: EARLY CAREER —
C71.00099: Development of a zinc manganese dioxide flow battery*  DAVID REYES-RAMIREZ
(Presenter), Mechanical Engineering, California State University Los Angeles — With larger penetrations of renewable energy on our electrical grid, there is a need for large-scale energy storage devices. A redox flow battery is an electrochemical device with great promise as a large-scale energy storage technology given the scalability of the technology and that power and energy output are decoupled. This study aims to incorporate the strengths of flow batteries with the abundance and relatively high safety of manganese dioxide batteries. However, manganese dioxide batteries historically suffer from poor reversibility. To improve reversibility, the effects of different electrolyte additives, as well as the synthesis of manganese nano-rods, were investigated. These solutions were then incorporated into a prototype flow battery to address the need for a safe and reliable energy storage device.

*Partnership for Research and Education in Materials

C71.00100: Achieving an efficient control of antiferromagnetic order in artificial layered iridates  LIN HAO (Presenter), University of Tennessee, Knoxville, DEREK J MEYERS, Brookhaven National Laboratory, JUNYI YANG, HIDEMARO SUWA, CRISTIAN BATISTA, University of Tennessee, Knoxville, MARK DEAN, Brookhaven National Laboratory, JIAN LIU, University of Tennessee, Knoxville — Antiferromagnetic (AFM) materials started to gain traction owing the advantages of reliability, ultrafast dynamics, etc. in spintronic applications. In our recent work, we investigated AFM order in layered iridates, which is a newly established Mott system similar to cuprates but features a strong spin-orbit coupling. By building the spin-orbit Mott insulators as SrIrO$_3$/$\text{SrTiO}_3$ superlattices, we gained controllability in the strength and sign of interlayer exchange interaction. This enables one to reach the 2D limit of a magnet, where the ordering temperature is only governed by magnetic anisotropy. The 2D antiferromagnet preserves a hidden SU(2) symmetry, which was first proposed in cuprates but never experimentally realized. Specifically, we unveiled that Dzyaloshinskii-Moriya interaction in the square-lattice magnet does not contribute to the spin anisotropy. The extremely strong 2D critical fluctuations enable us to achieve giant AFM responses to sub-tesla magnetic fields. The observed field-induced logarithmic increase of the AFM ordering demonstrates a new pathway for designing efficient AFM spintronics. These results were recently published on Phys. Rev. Lett. [119,027204, (2017)] and Nat. phys. [14, 806--810 (2018)].
C71.00101: Multimodal x-ray and electron microscopy of an Allende meteorite sample*
CHEN-TING LIAO (Presenter), JILA, University of Colorado, Boulder, YUAN HUNG LO, JIHAN ZHOU, ARJUN RANA, University of California, Los Angeles, CHARLES BEVIS, GUAN GUI, JILA, University of Colorado, Boulder, BJOERN ENDERS, Advanced Light Source, Lawrence Berkeley National Laboratory, KEVIN CANNON, University of Central Florida, DAVID A SHAPIRO, Advanced Light Source, Lawrence Berkeley National Laboratory, HENRY KAPTEYN, JILA, University of Colorado, Boulder, ROGER WIRTH FALCONE, Advanced Light Source, Lawrence Berkeley National Laboratory, CHRIS BENNETT, University of Central Florida, JIANWEI MIAO, University of California, Los Angeles, MARGARET MURNANE, JILA, University of Colorado, Boulder — Correlative multimodal microscopy that combines complementary nanoscale imaging techniques is essential for extracting comprehensive chemical, structural, and functional information of heterogeneous complex samples. Advanced electron microscopy provides atomic-scale spatial resolution with quantitative elemental composition, while x-ray microscopy can achieve high-resolution imaging of bulk materials with chemical, magnetic, electronic, and bond orientation contrast. In our recent work (Science Advances 5, eaax3009, 2019), we combine x-ray ptychography and scanning transmission x-ray spectromicroscopy with 3D energy-dispersive spectroscopy and electron tomography to perform structural and chemical mapping of an Allende meteorite sample as a model system. We use textural and quantitative elemental information to infer its mineral composition and discuss potential processes that occurred. This multimodal x-ray and electron microscopy of the same sample overcomes the limitations of individual imaging modalities and opens up a route to future multiscale microscopies of complex functional materials and biological systems.

*We gratefully acknowledge support for this work by STROBE: A National Science Foundation Science & Technology Center, under Grant No. DMR 1548924.

C71.00102: Rationale Design of Polymeric Materials for Biological and Energy Applications using Multiscale Simulation Methods*
VAIDYANATHAN SETHURAMAN (Presenter), DAVID CLARK MORSE, KEVIN D DORFMAN, University of Minnesota — Two broad areas are investigated in this poster: (i) *Self-assembly of Methylcellulose in Solution:* We employ coarse-grained molecular dynamics simulations to show that the current theories of stacked toroid model for fibril formation is valid only at certain polymer concentrations. Rather, we showed the existence of a nucleation mechanism and the importance of conformational fluctuations for systems containing randomly coiled chains. We also show how the conformational and structural characteristics change with grafting the backbone with flexible polymers; (ii) *Polyelectrolyte Complexation:* We utilize implicit solvent coarse-grained molecular dynamics to probe the influence of charge sequence along the polymer backbone, on their adsorption efficacy onto grafted polyelectrolytes. Our work show that adsorption is strongest when both the grafted and the free polyelectrolyte in the solution possess a block charge sequence architecture and is weakest when both the grafted and the free polyelectrolyte possess an alternating architecture. We then showed that the sequence dependence on adsorption efficacy is enthalpic in nature and not entropic. We also show the effect of influence of charge sequence on polydisperse polyelectrolytes.

C71.00103: Proximity effects in two-dimensional transition-metal dichalcogenide materials for quantum information science*

CHRISTOPHER LANE (Presenter), JIAN-XIN ZHU, Los Alamos National Laboratory — Significant strides have been made towards the storage and processing of quantum information. However, scalable robust material platforms are scarce. The two-dimensional (2D) transition-metal dichalcogenides provide a possible path forward due to their valley degrees of freedom, which may be probed by circularly polarized light. Unfortunately, these levels are commonly degenerate in energy. Therefore, to create a viable platform for valley-based qubits, it is crucial to break time reversal symmetry in a controllable manner, allowing for direct manipulation. Using state-of-the-art \textit{ab initio} techniques, we demonstrate that controllable valley splitting can be achieved through a magnetic exchange proximity effect generated by a ferromagnetic 2D material substrate. Furthermore, by introducing vacancies into the transition-metal dichalcogenide layer, long-lived two-level impurity states may be stabilized. This approach reveals a new path towards the rational design of new complex multilayer systems for direct application in quantum information technologies and spin-optoelectronic devices.

C71.00104: Simultaneous Study of Structure and Correlation-Driven Transitions via X-ray Standing Waves*

MATTHEW J. WAHILA (Presenter), GALO J. PAEZ, CHRISTOPHER SINGH, Physics, Applied Physics, and Astronomy, Binghamton University, NICHOLAS F QUACKENBUSH, National Institute of Standards and Technology, HANJONG PAIK, PARADIM, Cornell University, DARRELL SCHLOM, Materials Science and Engineering, Cornell University, TIEN-LIN LEE, Diamond Light Source, WEI-CHENG LEE, LOUIS F. J. PIPER, Physics, Applied Physics, and Astronomy, Binghamton University — The possibility of decoupling electronic phenomena from those of the lattice has been a hot topic when discussing correlated metal-insulator transition materials such as VO$_2$, NbO$_2$, or V$_2$O$_3$.[1] A mainly electronic transition could enable ultra-fast switching, thin film electronics, with little risk of the inevitable physical degradation associated with bulk structural transitions. However, the roles of structural (Peierls) and electron correlation (Mott) effects in driving these transitions continue to be debated in the literature.[2] Using x-ray standing waves (XSW) and high quality epitaxial thin films, we have now concurrently investigated both the structural and electronic transition within some of these correlated materials using a single technique, directly measuring their simultaneity or lack thereof for the first time. We discuss these results and their wider implications.

*This material is based upon work supported by the Air Force Office of Scientific Research under award number FA9550-18-1-0024.
Due to its position at the boundary between the light and heavy actinides, Pu has exotic physical properties that are complex and challenging to model. The difficulties in obtaining a full theoretical understanding for this elemental solid stem from the transitional characteristics of Pu-5f orbital electrons and understanding the role of the fluctuating magnetism in the electronic structure. Focusing on the δ-phase of elemental Pu, we perform a careful comparison of Fermi surface topology calculations using DFT and DFT+U methods. The de Haas-van Alphen (dHvA) frequencies at the Fermi surface and band masses are calculated in both magnetic and nonmagnetic states. We also analyze the effective mass enhancement due to 5f-electron correlation effects with DMFT as compared to the Gutzwiller approximation (GA). The comparison study will be helpful for future experiments to validate theoretical modeling.

**C71.00106: van der Waals photothermoelectric effect in atomic layer heterojunctions**

YUNQIU (KELLY) LUO (Presenter), Laboratory of Atomic and Solid State Physics, Cornell University, TONG ZHOU, Physics, University at Buffalo, State University of New York, MAHESH R NEUPANE, Sensors and Electron Devices Directorate, U.S. Army Research Laboratory, ALEX MATOS ABAIGUE, Physics and Astronomy, Wayne State University, RYAN BAILEY-CRANDELL, MICHAEL J NEWBURGER, IGOR LYALIN, Physics, Ohio State University, IGOR ZUTIC, Physics, University at Buffalo, State University of New York, ROLAND KAWAKAMI, Physics, Ohio State University — Two-dimensional (2D) van der Waals (vdW) heterostructures provide exceptional opportunities for new physics and devices due to their unprecedented ability to tune the electronic, optical, magnetic and spintronic properties by atomic layer stacking and electrostatic gating. Harnessing this versatility requires a fundamental understanding of light-matter interactions and establishing new functionalities for photon-charge and photon-spin conversions. Here, we report the first observation of a highly-tunable vDW photothermoelectric effect in dual-gated MoS$_2$/graphene junctions with a striking multiple-polarity switching of photocurrent as a function of junction bias and carrier density. In stark contrast to photovoltaic effects arising from excitonic absorption in MoS$_2$, the vDW photothermoelectric effect originates from photoexcitation of hot electrons in graphene and thermoelectric transport across the vdw junction. Systematic studies of photoconductance as a function of photon energy and intensity reveal vdw photothermoelectric effect as the dominant mechanism for photocurrent generation at room temperature, as opposed to excitonic absorption. These findings provide an important step for understanding and control of vdw-interface devices.

**C71.00107: New Approaches and Observations in Scaled Contacts for 2D FETs**

ZHIHUI CHENG (Presenter), NIST & Duke University & Purdue University, HATTAN ABUZAID, Electrical and Computer Engineering, Duke University, YIFEI YU, Materials Science and Engineering, North Carolina State University, SHREYA SINGH, Electrical and Computer Engineering, Duke University, LINYOU CAO, Materials Science and Engineering, North Carolina State University, CURT RICHTER, Physical Measurement Laboratory, National Institute of Standards and Technology, AARON FRANKLIN, Electrical and Computer Engineering, Duke University — Atomically thin 2D crystals are promising channel materials for extremely scaled field-effect transistors (FETs). For devices at the scaled regime, both channel and contact length must be scaled, with channel length being the distance from source to drain contacts and contact length being the length of the source/drain covering the 2D semiconductor channel. Contacting 2D materials at these scaled contact lengths (< 30 nm) has rarely been pursued or studied in depth. Moreover, the device community has not yet determined how contacts can be scaled without causing significant degradation in device performance; i.e., how long is the transfer length, below which current crowding effects appear? Here, we demonstrate new measurement approaches and results for determining the transfer length of MoS$_2$ FETs by physically scaling the contact length. We found that, contrary to previous reports, top contacts can be scaled to ~20 nm without obvious degradation in transistor performance. Our data from measurements of over 100 devices with different contact lengths statistically imply that contact resistance variation increases in the scaled contact regime. Our work illustrates the impact of current crowding in scaled contacts and the ultimate scalability of metal-2D contact interfaces.
C71.00108: Investigation into form factors for mechanical-resonance-based methods of information storage*  
CHRISTOPHER HAKODA (Presenter), CRISTIAN PANTEA, VAMSHI KRISHNA CHILLARA, Los Alamos National Laboratory — Non-traditional information storage has become increasingly ubiquitous as a means of providing interactive, environment-specific information. With this in mind, we have investigated potential form-factors for a PZT-based information storage method that has visibly indistinguishable features for improved security. By manipulating the poling of PZT transducers, we developed a frequency-dependent, embedded array of transducers which, when excited at the relevant frequencies, reveal an engineered velocity profile. This velocity profile is then measured using a scanning laser Doppler vibrometer and decoded. Since this storage method is capable of storing frequency-dependent information, it can also store multiple layers of information that can be easily separated by applying a fast-Fourier transform. These multiple layers can be used for storing additional information or further hiding the encoded data. Two potential form factors are simulated and discussed in this proceedings, one has a flat profile while the other has a cylindrical profile.

C71.00109: Spontaneous thermal Hall conductance in superconductors with broken time-reversal symmetry*  
FIRAT YILMAZ (Presenter), SUNGKIT YIP, Academia Sinica — The thermal Hall conductivities (THCs), $\kappa_{ij}$ s have extensively been studied in recent condensed matter experiments. THC can spontaneously become non-zero for a time-reversal symmetry (TRS) broken system, and have a contribution from topologically protected edge states. In this talk, we focus on an additional bulk effect, the impurity pair breaking mechanism (IPM) in superconductors (SCs). Previously, the THCs were calculated for the chiral p-wave[1-2] SCs for point impurities. Motivated by d-wave TRS broken SCs; URu$\text{Si}_2$, SrPtAs including Sr$_2$RuO$_4$ which is recently suggested to be also possibly, we calculate THCs at finite temperatures and for finite size impurities using the non-equilibrium quasiclassical Green's functions.

We find that the IPM is dominant in $\kappa_{xy}$ at finite temperatures when compared to the topological contribution except at very low temperatures. There are two experimental signatures of IPM: 1. a non-monotonic temperature dependence, 2. sign change as a function of temperature depending on the scattering process.

C71.00110: Do Levinthals arguments lead to a paradox for Si$_{20}$H$_{20}$?*  
DEB DE (Presenter),  
BASTIAN SCHAEFER, STEFAN A C GOEDECKER, University of Basel — Levinthal argued that the folding of a protein should require a time longer than the age of the universe. However, since it is experimentally well established that proteins do fold on a quite short time scale, these arguments are known as the Levinthal paradox. The paradox is resolved by folding funnel hypothesis. Here we will present a system whose global minimum is not embedded in a large funnel. The global minimum is virtually not accessible on a reasonable time scale. The potential energy surface of Si$_{20}$H$_{20}$ is considered for this study. The dodecahedron cage of Si$_{20}$H$_{20}$ is the theoretically established ground state. However it has never been observed experimentally. Based on an extensive exploration of possible reaction pathways of Si$_{20}$H$_{20}$ we show that there exists a huge number of intermediate structures that consist mainly of collapsed cages. Among all these reaction pathways that lead into the ground state, the system has to go through energetically flat regions before it reaches the Si$_{20}$H$_{20}$ ground state. This implies that there is no clear driving force towards this ground state that would give rise to a short directional reaction pathway that would lead rapidly into the ground state.

*This work was done within the NCCR MARVEL.

C71.00111: Understanding the acoustic emission from gas bubble dynamics: a signature of CO$_2$ leakage*  
HUNG DOAN (Presenter), Los Alamos National Laboratory — The identification and characterization of CO$_2$ leakage signatures in water and other fluids are of interest in the geophysical study of geysers and aquifers. As several DOE programs are investigating the feasibility of operationally injecting CO$_2$ into the subsurface, detecting and characterizing the signatures associated with the interaction of CO$_2$ with water shows important implications for monitoring large scale Carbon storage. This project proposes the development of a laboratory-scale test bench to carry out experimental studies of the acoustic emission emanating from gas bubble dynamics in a bi-phasic (water and gas mixture) fluid system. Different air bubble sizes, varying from 1 cm to 10 cm, are injected from the bottom of a water bath. As the bubbles migrate to the top, the vibrational response of those bubbles is captured by an acoustic pressure sensor placed within the fluid. The interaction is expected to be dependent on the size of the bubble, which can be characterized using the recorded acoustic signal. The result provides a non-invasive technique for characterizing the air bubble-size in the water/gas system and enables us to develop a framework for determining signatures pertaining to the presence of CO$_2$ in water.

*The project is funded by Los Alamos National Lab.
C71.00112: Experimental Demonstration of a Superconducting 0-π Qubit* ANDRAS GYENIS (Presenter), Princeton University — Encoding a qubit in logical quantum states with wavefunctions characterized by disjoint support and robust energies can offer simultaneous protection against relaxation and pure dephasing. Using a two-dimensional circuit-quantum-electrodynamics architecture, we experimentally realize a superconducting 0-π qubit, which hosts protected states suitable for quantum-information processing. Our multi-tone spectroscopy measurements reveal the energy level structure of the system, which can be precisely described by a simple two-mode Hamiltonian. The parity symmetry of the qubit results in charge-insensitive levels connecting the protected states, allowing for logical operations. The measured relaxation (1.6 ms) and dephasing times (25 μs) demonstrate that our implementation of the 0-π circuit not only broadens the family of superconducting qubits but also represents a promising candidate for the building block of a fault-tolerant quantum computer.

C71.00113: Long-lived Floquet phases in interacting three-dimensional topological semimetals via bicircular laser fields THAIS VICTA TREVISAN (Presenter), Ames Lab, ROBERT-JAN SLAGER, Harvard, PETER ORTH, Iowa State University — The use of carefully tailored light fields to manipulate quantum states of matter is an important technique in condensed matter physics. By coupling to the electronic degrees of freedom, they can induce electronic phases that were otherwise absent, for example, by selectively breaking a certain symmetry. One important example is the breaking of time-reversal symmetry by circulary polarized light, which can lead to a photo-induced Hall effect or the splitting of a three-dimensional Dirac node into Weyl nodes. Interestingly, it was recently showed that bicircular laser fields can also break spatial symmetries such as inversion or rotation symmetries, thereby inducing a charge (or spin) density wave order. Importantly, the density wave order can persist even after the light field is turned off, leading to a long-lived light-induced phase. This idea was recently explored in graphene, where it was shown to lead to a long-lived Floquet charge-density wave phase due to a dynamic synchronization transition. Here, we report our findings on coupling bicircular laser light to three-dimensional materials in order to induce spin and/or charge density wave phases. We specifically discuss the effects on topological phases of matter in Dirac and Weyl semimetals.

C71.00114: Band engineering for quantum simulation with superconducting circuits* CHRISTIE CHIU (Presenter), ANDREW HOUCK, Princeton University — Quantum simulation has been implemented on a variety of experimental platforms such as neutral atoms, ions, quantum dots, and superconducting circuits, each offering unique features. Superconducting circuits can and have been used to realize artificial photonic materials in a wide range of lattice geometries and graph connectivities, due to the flexibility of on-chip fabrication. In addition, photon-photon interactions are possible using nonlinearities such as superconducting qubits, leveraging the vast toolkit developed for quantum computation. Here I report on recent progress towards engineering flat bands for studies of strongly correlated many-body physics.

*This research was supported by the Princeton Materials Science Postdoctoral Fellowship and the ARO MURI program.
**C71.00115: Using Machine Learning to Classify Phase Behavior of Oil/Water/Surfactant Systems**  SHIYAN WANG (Presenter), NATHAN SCHULTHEISS, SANGTAE KIM, Purdue Univ — According to BP Statistical Review of World Energy in 2019, total oil production from the US in 2018 was about 15 million barrels per day (MBPD). Thanks to the booming shale oil production, United States has become the world’s top oil producer. In fact, estimates show that up to two thirds of conventional crude oil in mature fields remains unproduced due to the physics of fluid flow. The techniques of chemical enhanced oil recovery could overcome the physical force holding hydrocarbons, and turn these accumulations into oil reserve, which would enhance the US energy security and maintain economic growth. For the oil/water/surfactant system, the goal is to form a microemulsion phase achieving the lowest interfacial tension, which increases the capillary number and dramatically recovers the remaining oil fraction within the pore. Therefore, it is critically important to understand the phase behavior for the oil/water/surfactant systems. In collaboration with Pioneer Oil Company, our current effort is to optimize the selection of surfactants and the constituents of the surfactant blend, which turns to be a high dimensional problem. In addition to the conventional analysis, we employ machine learning techniques to solve the system as a multinomial classification problem.

**C71.00116: Resonant Raman Spectroscopy of the Chiral Antiferromagnet CoNb3S6**  NORA HASSAN (Presenter), THUC MAI, AMBER MCCREARY, National Institute of Standards and Technology, NIRMAL GHIMIRE, George Mason University, ANGELA HIGHT WALKER, National Institute of Standards and Technology — We report here the first full Raman characterization of the chiral antiferromagnet CoNb3S6; i.e. cobalt-doped NbS2. CoNb3S6 exhibits a large c-axis anomalous Hall effect (AHE) not entirely attributable to the small intrinsic ferromagnetic component (Co) along the c-axis [1]. This interesting behavior suggests that the enhancement in AHE may be because of a combination of magnetic field in the presence of the near-Fermi energy Weyl nodes as predicted by theory [2]. Neutron scattering experiments of CoNb3S6 [3] showed incommensurate peaks; however, it was not clear whether the peaks are due to a spin spiral or a spin density wave. Magneto-Raman spectroscopy represents an optimal method to differentiate these structures. Wavelength- and polarized-dependent Raman spectra collected at room temperature from CoNb3S6 flakes are analyzed. Experiments of temperature- and magnetic field-dependent Raman spectroscopy to seek magnon (spin wave) signatures detected no change in the spectral weight at the Neel temperature implying absence of spin density waves suggesting that the magnetic structure is helical.

C71.00117: Physics-based models and simulations of cancer drug response in solid tumors
AMINUR RAHMAN (Presenter), Texas Tech Univ, SOUPARNO GHOSH, University of Nebraska - Lincoln, ERDI KARA, EUGENIO AULISA, Texas Tech Univ — Over the past few decades, cancer related deaths have fallen significantly as noted by the National Cancer Institute. However, assessing cancer treatments is still predominantly a trial and error process. This approach may result in delays to administer the correct treatment, the use of more invasive procedures than necessary, or an increase in toxicity due to superfluous treatments. Although these procedures may end up saving the patient, the treatment may also have an adverse effect on their quality of life. Reliable mechanistic models of drug response can potentially be used to aid oncologists and doctors in deciding on an optimal treatment strategy for the patient. We develop a modeling framework for tumor ablation, and present coupled transport - population models of varying complexity. First, we present a radially symmetric drug diffusion and binary cell death model, which produces a theoretical dose for optimal efficacy to toxicity ratios. Further, we investigate inhomogeneous - anisotropic drug diffusion, and develop an algorithm to locate the optimal injection points. Finally, we derive stochastic tumor population models that can be coupled to transport models in our framework. Importantly, the mechanistic models outperform data-driven models in statistical tests.

C71.00118: A Patterning Approach to Untangling Critical Interface Phenomena with In-Situ Resonant Scattering
ISVAR CORDOVA (Presenter), MSD, Lawrence Berkeley National Lab, GUILLAUME FREYCHET, NSLS-II, Brookhaven National Lab, ROMAIN GENEAUX, UC Berkeley, CHENG WANG, ALS, Lawrence Berkeley National Lab — Resonant soft x-ray scattering (RSoXS) is a powerful spatiochemical mesoscale characterization tool that is often overlooked across the field of interfacial science. Herein, we present a simple, yet highly sensitive, patterning approach for interface characterization that takes advantage of the physical processes intrinsic to small angle resonant X-ray scattering in order to selectively probe and enhance signals from interfacial regions of a vast array of material systems. Using several case studies, we show how patterns with simple nanoscale features can be used to 1) decouple the bulk from the interface scattering signal, 2) extract interfacial morphology with sub-nm precision, and 3) collect site-specific x-ray absorption spectra (XAS).

First, as an operando demonstration, we leverage a custom in-situ cell compatible with many synchrotron X-ray beamlines and use it conduct an operando study of Ni/Ni(OH)2 core/shell electrode undergoing electrochemical cycling under aqueous conditions. Next, we apply the technique to study the femtosecond dynamics of a 1.5 nm SiO2 surface with a broadband XUV table-top source. Finally, we introduce the potential of this technique to study material interfaces under conditions critical to the future of the next generation of electronics.
C71.00119: Tuning block copolymer rheology and structure via low strength magnetic fields* KARTHIKA SURESH (Presenter), MICHELLE CALABRESE, Chemical Engineering and Materials Science, University of Minnesota — The control of block polymer (BCP) structural ordering is of significant scientific interest because of their wide applications including nanotemplates, drug delivery and biomineralization. BCP properties have been controlled using various external fields including electric, magnetic, and shear fields, and via plasticizing additives, interfacial effects, and thermal methods. To control ordering in BCPs using magnetic fields, previous studies had used field strengths (≥5T), liquid crystalline mesogens, high magnetic susceptibility anisotropy groups or combinations therein. Here, we show anomalous behavior upon application of low strength magnetic fields (≥0.1 T) in coil-coil BCPs. Magneto-shear rheology shows up to a six order increase in modulus upon the field application. This magnetic response is a function of temperature, concentration, field strength, ionic content and shear strain. A minimum molecular weight and block length are required for this liquid to gel transition via low strength magnetic field. In situ small angle scattering (SAXS and SANS) and imaging techniques showed field-induced orientation in the BCPs and this orientation direction can be tuned by changing the direction of field lines.

C71.00120: PHYSICS EDUCATION —

C71.00121: Can Fermi energy be estimated experimentally? CHETAN KOTABAGE (Presenter), Department of Physics, KLS Gogte Institute of Technology, ASHUTOSH ABHYANKAR, Department of Materials Engineering, Defence Institute of Advanced Technology — Fermions, particles with half integral spin, follow Fermi-Dirac distribution. For free electron gas at absolute zero, Fermi energy is the energy of highest occupied level by electron. For \( n \), which is density of free electrons, Fermi energy can be estimated by \( E_F = \frac{\hbar^2}{8m} \left( \frac{3\pi^2 n}{2} \right)^{2/3} \) [1]. Theoretical calculation of Fermi energy of a metal involves estimation of density of electrons utilizing number of valence electrons. Experimentally, Fermi energy can be estimated by measurement of density of electrons in Hall effect measurement at room temperature. The measurement at room temperature serves as a good approximation because of very less difference between electron distribution at 0K and 300K.

[1] Modern Physics, K. Krane Wiley
Unscientific determination of Fermi energy by heating and/or cooling a copper wire, C. Kotabage, A. C. Abhyankar, Resonance- Journal of Science Education, 24 (12), 1439-1443.
C71.00122: Two Content Pathways in Presenting Electromagnetism in Introductory Algebra-Based Physics Textbooks  
LIANG ZENG (Presenter), Department of Physics and Astronomy, The University of Texas-Rio Grande Valley, YI ZENG, Center for the Core Curriculum, Nanchang Institute of Technology, GUANG ZENG, Department of Educational Leadership, Texas A&M University-Corpus Christi — Vector cross products play a fundamental role in determining the directions of electromagnetism in introductory physics courses. After examining thirteen introductory algebra-based physics textbooks, we found authors adopt the following two content pathways in presenting the electromagnetic phenomena: Over 90% of the textbooks follow pathway one which presents only algebraic formulas and mnemonic techniques for right- and left-hand rules. Scarcely few follow pathway two, which presents vector cross products as a mathematical model and reinforces this model by presenting the specific cross product formula for each electromagnetic phenomenon. Physics instructors teaching college physics courses similarly present electromagnetism using these two content pathways. In light of Bloom’s taxonomy of educational objectives and constructivist learning theory, we recommend the second pathway.

C71.00123: Using Group Exams to Address Persistent Intuitively Appealing but Incorrect Student Reasoning*  
ALISTAIR MCINERNY (Presenter), LIUDMILA KRYJEVSKAIA, Physics, North Dakota State University — Many students tend to provide intuitively appealing (but incorrect) responses to some physics questions despite demonstrating (on similar questions) the formal knowledge necessary to reason correctly. While these inconsistencies are typically persistent even in active learning environments, we believe that adding a group component to the exam may engage students sufficiently to resolve these instances of inconsistent reasoning. In our study, students were given opportunities to revisit their answers to questions known to elicit strong intuitively appealing (but incorrect) responses in a collaborative group component of an exam immediately following a traditional individual component. Students discussed their responses with group members but were required to submit their own answers and reasoning. On this poster, we examine the effectiveness of a collaborative group exam approach in addressing and resolving inconsistencies in student reasoning and will compare the effectiveness of this approach to a more traditional peer instruction technique.

C71.00124: Incorporating realistic aspects of experimentation into senior physics labs  
KIRSTIN PURDY DREW (Presenter), Pennsylvania State Univ — Here we present design changes to the senior physics lab course at Penn State, which were implemented in order to increase student engagement with modeling, experiment design, and the writing process in our lab curriculum. The goal of these changes was to restructure the course to emphasize planning, prediction, and assessment of experimental data during an experimental process, in mimicry of the scientific research process, while still providing students with exposure to a breadth of experiments and experimental techniques which are historically a required part of the course. Both structural and content changes made in the course will be presented along with initial assessment of changes in student perceptions and critical thinking skills.
C71.00126: Machine Learning Towards Optical Spectrum Estimation Using Nanomaterial Thin Films*  
DAVOUD HEJAZI (Presenter), SHUANGJUN LIU, AMIRREZA FARNOOSH, SARAH OSTADABBAS, SWASTIK KAR, Northeastern University — Some of the major challenges in optical spectrum estimation include the necessity to create an array of thousands of identical photodetectors, or intricate mechanical systems that make the estimation system bulky and expensive. Using the spectral transmittance of an array of 11 solution-processed nanomaterial thin film filters fabricated from two layered semiconducting materials, Molybdenum-Disulfide and Tungsten-Disulfide, we have estimated the wavelength of any incoming light in a wide spectrum range. By applying machine learning techniques we have used the variations in spectral transmittance of nanomaterials as the alternative method for optical spectrum estimation. We have studied the efficacy of various machine learning algorithms including k-nearest neighbors, artificial neural networks, support vector machines, and Bayesian statistics in spectrum estimation problem and identified the key advantages and limitations of each algorithm for real-time applications such as accuracy and speed. Furthermore, we have modeled the temporal drift of filters' spectral transmittance over a period of one year and showed that it is possible to overcome the drift-induced inaccuracies over time using a modeled drift function.

C71.00127: Improve the synaptic performance of resistive switching devices through interface engineering*  
YU SHI (Presenter), RABIUL ISLAM, GUOXING MIAO, Electrical and Computer Engineering, University of Waterloo — Transition metal based resistive switching devices (like HfO\textsubscript{2}, TiO\textsubscript{2}) has been shown to be a good candidate for neuromorphic computing for its bio-inspired synaptic properties, however, the non-linear conductance change synaptic behaviour prohibits further improvement due to poor accuracy of neural network training. Here, we provide a way to eliminate the intrinsic non-linearity through electrode-oxide interface engineering, including oxygen profile control and oxide heterostructure stacking, which can improve the neural network training accuracy and shorten the training time.

*Transformative Quantum Technologies (TQT)
C71.00128: High Thermoelectric Performance in Hexagonal 2D PdTe$_2$ Monolayer at Room Temperature

BRAHIM MARFOUA, JISANG HONG (Presenter), Pukyong National Univ — Motivated by the recent fabrication of hexagonal PdTe$_2$ monolayer, we investigated the thermoelectric properties of the hexagonal and pentagonal PdTe$_2$ structures using two approaches. The pentagonal monolayer has not been synthesized yet. The hexagonal layer had an indirect bandgap of 0.17 eV while the pentagonal structure had an indirect bandgap of 1.18 eV. By applying the semi-empirical Wiedemann–Franz law to calculate the electronic thermal conductivity, we found that both hexagonal and pentagonal structures had very high ZT more than 3. However, the Wiedemann–Franz law underestimated the electronic thermal conductivity and this resulted in high ZT. Thus, we employed the Boltzmann transport equation for the electronic thermal conductivity. At high temperature ( > 500 K), the pentagonal PdTe$_2$ structure showed a better thermoelectric performance than the hexagonal structure. However, both structures displayed the same ZT of 0.8 at 300 K. We propose that the hexagonal PdTe$_2$ can be a potential high performance thermoelectric material at room temperature.

*This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF) (2019RA21B5B01069807).

C71.00129: Textile Thermoelectric Generator Based on Carbon Nanotubes

FARIBA ISLAM, NABILA FAIRUZ, AHMED ZUBAIR (Presenter), Electrical and Electronic Engineering, Bangladesh University of Engineering and Technology — Smart textile based on seamless device integration into clothing will dominate the wearable technology field in the near future. Carbon nanotubes (CNTs) are a favorable candidate for use in these flexible and wearable electronic devices due to tunability of their electrical and thermal properties, mechanical strength, and lightweight. The wearable devices demand wearable micro-sources of energy. Here, we propose a textile thermoelectric generator based on CNT that can utilize waste heat to generate power. The generator is fiber-structured to make it easily woven into clothing. We simulated a ~5 cm long fiber structured generator with p-n junctions at every 3 mm interval based on CNTs. To model CNTs, experimental data were used in our simulation. This generator generates a thermoelectric voltage of ~55 μV for just a 1 K temperature difference. The thermoelectric figure of merit, ZT for this CNT based device was smaller than previously reported materials. However, it is possible to fabricate CNT based devices with large ZT by proper doping and utilizing the Van Hove singularities in the density of states of CNTs.
C71.00130: Structural Phase Transition of Multilayer VSe$_2$  

XIONG WANG (Presenter), DIAN LI, XIAODONG CUI, Physics, The University of Hong Kong, CHUANHONG JIN, Materials Science and Engineering, Zhejiang University — Vanadium diselenide (VSe$_2$), a member of the transition metal dichalcogenides (TMDs) family, is emerging as a promising two-dimensional (2D) candidate for the electronic and spintronic device with exotic properties including charge density wave and ferromagnetism. The bulk crystal VSe$_2$ exists in a crystallographic form of 1T phase with metallic behavior. In this paper, we report a structural phase transition of multilayer VSe$_2$ from 1T to 2H, which occurs at about 650 K, accompanying a metal-insulator transition. The phase transition is verified by Raman spectra, as different polymorphs have different Raman signals related to different characteristic vibration modes. The electrical characteristics are also studied on VSe$_2$ nanoflakes, as the phase transition occurs along with the metal-semiconductor transition, which is consistent with the electronic band structure calculation. The results of in-situ selected area electron diffraction (SAED) is are accord with our simulated diffraction patterns, which is strong evidence of the structural phase transition. Moreover, we observe that the 2H phase is more thermodynamically stable than the 1T phase at the multilayer level.

C71.00131: Investigating the metal to insulator transition in crystalline NbO$_2$ for neuromorphic computing applications*  

GALO PAEZ FAJARDO (Presenter), MATTHEW J. WAHILA, JATINKUMAR RANA, Department of Physics, Binghamton University, BROOKS TELLEKAMP, National Renewable Energy Laboratory, WILLIAM A. DOOLITTLE, School of Electrical and Computer Engineering, Georgia Institute of Technology, LOUIS F. J. PIPER, Department of Physics, Binghamton University — The metal-insulator transition (MIT) of NbO$_2$ is promising for technological applications where a self-regulated resistivity is needed like in neuromorphic computing. Though the Mott nature (electron correlation) of the MIT of NbO$_2$ arises purely by comparison to VO$_2$, the actual transition mechanism in NbO$_x$-based memristors remains unclear mainly due to the degree of participation of multi-phases of niobium oxides, likely induced after electroforming. By investigating phase-pure, crystalline NbO$_2$, we avoid the uncertainty created in electro-formed NbO$_x$-based devices. Using surface sensitive techniques like LEED, HAXPES, and LEEM on NbO$_2$(440)/Al$_2$O$_3$(006) thin films, we show that the phase transition does not extend to the film surface. XPS of the crystalline NbO$_2$ reveals a second-order Peierls transition in the bulk, in agreement with DFT results, indicating electron correlation effects do not play a significant role. In addition, the observed temperature dependence of the Nb-Nb dimer distance which controls the NbO$_2$ resistivity suggests that the switching of future phase-pure NbO$_2$ memristors could be controlled by resistive heating in an analog rather than digital fashion.

**C71.00132: Magnetically driven carbon nanotubes for a highly efficient mechanical single cell damage.** VICTORIA GABRIELE (Presenter), KRZYSZTOF KEMPA, MICHAEL NAUGHTON, THOMAS SEYFRIED, Boston College — Magnetized carbon nanotubes have previously been demonstrated as excellent candidates for the nanospearing transfection technique. In the presence of the moderate, spacially varying magnetic field, these magnetic nanorods exert motion, capable of piercing cell membranes, and allowing for highly efficient drug delivery. Here we study the possibility of enhancing this nanospearing technique, by varying magnetic strength and its time-space patterns, in order to inflict a highly efficient and selective, single cell mechanical damage.

**C71.00133: Quasiparticle and Optical Properties of Bulk and Monolayer Zirconium Disulfide**

GABE LOPEZ-CANDEALES (Presenter), GREIS JULIETH CRUZ REYES, ZHAO TANG, PEIHONG ZHANG, Physics, University at Buffalo — Zirconium disulfide (ZrS2) is a member of layered transition metal dichalcogenide (TMD) family that has rich and versatile chemical and physical properties. Despite much recent renewed interest in ZrS2, especially in few-layer ZrS2 systems, an accurate and systematic understanding of the quasiparticle and optical of ZrS2 from monolayer to bulk phase is still lacking. In this work, we present a fully converged GW+BSE study of the quasiparticle and optical properties of monolayer and bulk ZrS2, aiming at illustrating the subtle interplay between structural and electronic properties and the importance of the convergence issues in 2D many-body perturbation calculations.

*This work is supported in part by the NSF (Grant Nos. DMR-1506669 and DMR-1626967).

**C71.00134: Ab-Initio Computations of Electronic and Related Properties of cubic Magnesium Silicide (Mg$_2$Si)**

DIOUM ALLÉ, Department of Physics, Cheick Anta Diop University (UCAD), Dakar, Senegal, BLAISE AYIRIZIA, YURIY MALOZOVSKY (Presenter), DIOLA BAGAYOKO, Department of Mathematics and Physics, Southern University and A&M College — We have performed *ab-initio*, self-consistent calculations of electronic, transport, and bulk properties of cubic magnesium silicide (Mg$_2$Si). Our computations employed the local density approximation (LDA) potential of Ceperley and Alder and the linear combination of atomic orbital (LCAO) formalism. We followed the BZW-EF method to reach the ground state of the materials, verifiable, without using over-complete basis sets. For a room temperature lattice constant, our calculated, indirect band gap, from $\Gamma$ to X, is 0.86 eV. We discuss the total and partial densities of states, electron and hole effective masses, and the bulk modulus.

*This work was funded in part by the Department of Physics de l’UCAD and l’UCAD, the National Science Foundation [NSF Award HRD-1002541], the US Department of Energy – National Nuclear Security Administration (NNSA) (Award Nos. DE-NA0001861 and DE- NA0002630), LaSPACE, and LONI-SUBR.
**C71.00135: Ab-initio Calculations of Electronic Properties of Tin Selenide (SnSe)**

YURIY MALOZOVSKY (Presenter), SHAIBU MATHIAS, DIOLA BAGAYOKO, Southern Univ & A&M Coll — We present results from *ab-initio*, self-consistent density functional theory (DFT) calculations of electronic properties of tin selenide (SnSe) in the *orthorhombic B16* crystal structure. We utilized a local density approximation (LDA) potential and the linear combination of atomic orbital (LCAO) formalism. Our calculations performed a generalized minimization of the energy to reach the ground state, as required by the second DFT theorem. This process ensures the full, physical content of our findings that include electronic energy bands, total and partial densities of states, and electron and hole effective masses.

*This work was funded in part by the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0003679), the National Science Foundation (NSF) (Award No. HRD-1503226), LaSPACE, and LONI-SUBR.*

**C71.00136: Calculations of third order nonlinear susceptibilities focused in two photon absorption on semiconductors.**

ALAN BERNAL (Presenter), Centro de Investigaciones en Optica, BRANDON FUREY, MICHAEL C DOWNER, University of Texas at Austin, BERNARDO MENDOZA SANTOYO, Centro de Investigaciones en Optica — We presented the calculation of nonlinear third order susceptibility focused on Two-photon absorption phenomena (TPA) on bulk crystal semiconductors. Our calculation considers the longitudinal gauge approximation to the interaction field, the non-local part of the crystal potential and the scissor operator as correction to LDA energies calculations.

**C71.00137: Observation of B 1s trion and A 2s trion in 2d limit**

TENGFEI YAN (Presenter), KE XIAO, XIAODONG CUI, department of physics, the university of Hong Kong — The distinct excitonic effect in two-dimensional (2d) layered material attracts lot of attentions in recent years. The largely reduced screening effect in 2d materials allows tightly bonding exciton. With gate tunable photoluminescence spectrum, we observe B 1s trion and A 2s trion in h-BN capsuled MoSe$_2$. The two states show much larger valley polarization compared with their low energy counterparts A 1s exciton and trion.

**C71.00138: Excited carrier relaxation in GaAs by mid-IR pump-probe spectroscopy**

ROISUL GALIB (Presenter), Mechanical and Aerospace Engineering, University of Virginia, JOHN A TOMKO, Materials Science and Engineering, University of Virginia, DAVID OLSON, ASHUTOSH K GIRI, JOHN T GASKINS, PATRICK HOPKINS, Mechanical and Aerospace Engineering, University of Virginia — Ultrafast laser spectroscopy is a versatile technique that is commonly used to both understand and manipulate carrier scattering mechanisms in semiconductors. We report the observation of excited carrier relaxation times in GaAs using optical pump mid IR probe spectroscopy. We find a sharp change in relaxation times occurs at the intervalley transitions of GaAs. Our results also show the relaxation times becomes faster with increasing photoexcitation fluence. These results provide direct evidence that excited carrier decay at greatly different rates based on their energy relative to the conduction band minimum. These findings provide additional insight into the energy-dependent nature and rate of phonon emission during electronic relaxation.
**C71.00139: Temperature dependent vibrational modes of TNT and CL-20 cocrystal in terahertz regime**  
ABDUR RAHMAN (Presenter), Physics & Technology, Edinboro University, TOWFIQ AHMED, ABUL AZAD, DAVID MOORE, Los Alamos National Laboratory — We employed terahertz time domain spectroscopy (THz-TDS), a non-invasive technique, in the range of 0.30 THz to 2.50 THz to measure the effective dielectric properties of a 1:1 molar ratio cocrystal of TNT and CL-20 in the temperature range 150K to 400K. We observed two distinguished absorption peaks at 0.80 THz and 1.3 THz at or below room temperature. The absorption peaks disappear at higher temperatures. We extracted the dielectric constants of the cocrystal using effective medium theories.

*Los Alamos National Laboratory’s LDRD program.*

**C71.00140: Point-of-care ultrahigh sensitivity magnetic lateral flow assay**  
MOHAMMAD KHODADADI (Presenter), Materials Science & Engineering, University of Houston, JOÃO TRABUCO, Chemical & Biomolecular Eng, University of Houston, LONG CHANG, Electrical & computer Engineering, University of Houston, KATERINA KOURENTZI, RICHARD WILLSON, Chemical & Biomolecular Eng, University of Houston, DMITRI LITVINOV, Electrical & computer Engineering, University of Houston — Today, many highly quantitative biomarker detection tools for medical diagnostics are readily available in state-of-the-art centralized clinical laboratories. However, there remains a critical need for inexpensive, versatile, and high-sensitivity diagnostic platforms which can bring the performance to the point of care (POC) or doctor’s office. Our team has developed an ultrasensitive point of care biosensor based on the miniaturized inductive detector of magnetic reporter nanoparticles ($10^{10}$ emu detection limit) in a test line of a lateral flow assay (like a pregnancy test). This technology represents a new general biosensor platform that can be broadly useful in various areas of molecular diagnostics, therapy monitoring, biomarker detection, and biomedical research. The biosensor prototype performance was evaluated using a standard hCG model system with well established LFA immunochemistry based on readily available, well-characterized, and inexpensive antibodies. The first target after proof of concept is to make a biosensing platform for detecting the recurrence of prostate cancer.

C71.00142: Obstacles to Undergraduate Research in Thin Film Semi-Conductor Characterization: The Creation of Inexpensive Hall Measurement Apparatus

OLUWASEKEMI ODUMOSU (Presenter), Ithaca Coll — The goal of my project was to grow and characterize thin semiconducting ZnO films grown on PET plastic via pulsed laser deposition (PLD) with a KrF laser. To characterize the electrical properties of these films, I had to create an automated Hall Measurement apparatus, as I did not have access to industrial equipment due to its unfeasible cost. The apparatus required a few components: I started by creating a Labview program to interface with an ArduinoMega, which operates a 16-switch relay. This relay was then connected to a nano-voltmeter, current source, and my sample film (which would be in a uniform magnetic field for some measurements). Labview would then compile the data into a .csv file, which my Python code would interpret and record measurements for the sheet resistance, bulk resistivity, semiconductor type, sheet carrier density, bulk carrier density, and hall mobility. The apparatus functions correctly, but improvements need to be made to get consistent data.

C71.00143: Thermoelectric effect in suspended Bi$_2$Se$_3$ grown by molecular beam epitaxy on GaAs(111)A

DONGUK KIM (Presenter), CHANUK YANG, JOON SUE LEE, YUN DANIEL PARK, Physics & Astronomy, Seoul National University — Bi$_2$Se$_3$ is well known as an efficient thermoelectric (TE) material. We report growth optimization of Bi$_2$Se$_3$ thin films and thermoelectric study of suspended Bi$_2$Se$_3$ beam structures. The Bi$_2$Se$_3$ thin films were grown on GaAs(111)A substrates by molecular beam epitaxy (MBE) and confirmed by (00n) series peaks of x-ray diffraction (XRD) that the material was grown along the c-axis of GaAs(111)A. Optimizing the desorption process of GaAs(111)A surface and growth conditions of GaAs buffer layers leads to low RMS roughness and less-defective structural aspect. Using the optimized Bi$_2$Se$_3$ films, we realize the suspended beam structures with minimal heat dissipation to GaAs substrate. The beam structures are fabricated by selective wet etching, and on the two membranes, platinum heaters and voltage channels are patterned to measure the thermoelectric effect, the conversion of temperature difference to electric voltage. Nanomachining technique enables to calculate the dimensionless figure of merit (ZT) of Bi$_2$Se$_3$ with minimal environmental factors.

C71.00144: High quality Tantalum pentoxide thin film growth and its application for low loss nonlinear waveguide* JIA-WEI LIU (Presenter), CHAO-HONG LIN, TE-KENG WANG, FU-YAN YAN, ZI-DE XIE, Department of Photonics, National Sun Yat-sen University, MIN-HSIUNG SHIH, Research Center for Applied Sciences, Academia Sinica, CHAO-KUEI LEE, Department of Photonics, National Sun Yat-sen University — Tantalum pentoxide ($\text{Ta}_2\text{O}_5$) of a large bandgap material has shown its potential for Si photonics due to its low absorption loss coefficient in visible to infrared regions, high Kerr coefficients, and nonlinear absorption (TPA/FCA) free. Development of large scale high optical quality thin film for integrated photonics is therefore desired. In this work, by using e-gun evaporation, large scale $\text{Ta}_2\text{O}_5$ thin film growth was performed. Beside the measurement of x-ray and Ramen pattern for identifying the structure, the AFM and SEM results all show the grown thin film with high quality. In addition, a low-loss and high-Q $\text{Ta}_2\text{O}_5$ based micro-ring resonator was fabricated and characterized. The propagating loss of 0.3 dB/cm was obtained and unloaded quality as high as 300000 was accordingly estimated. This is, in our knowledge, the largest unloaded quality for $\text{Ta}_2\text{O}_5$ waveguide. This all show that electron beam thermal evaporation (E-gun) grown $\text{Ta}_2\text{O}_5$ film is with great potential for photonic integrated circuit.

C71.00145: WITHDRAWN ABSTRACT
—

C71.00146: Dry surface cleaning of twisted bilayer graphene and angle dependent oxidation by UV irradiation. JIN HONG KIM (Presenter), MOHD MUSAIB HAIDARI, JIN SIK CHOI, KonKuk Univ — Since production of single layer graphene (SLG) by mechanical exfoliation, it has been focal to many researches thanks to its extraordinary electrical conductivity and surface to volume ratio. these characteristics of graphene have benefit for apply gas sensor devices. Recently, twisted bilayer graphene (tBLG) attracted much attention of its extra ordinary physical properties, especially for its twist angle opto-electrical dependant characteristic. specifically, the magic angle (~1.1°) which shows super conducting characteristics. Moreover, tBLG shows higher mobility and conductivity than SLG. However, stacking two layers of single crystalline SLG has been reported to show side effect of introducing interlayer impurities during transfer process. Furthermore, Impurities of graphene surface, such as PMMA residues, degrade electrical conductivity and mobility. Here we report a CVD synthesis of clean interlayer tBLG to containing various twist angles. Top layer of tBLG was cleaned and oxidized by angle dependency under UV irradiation at ambient condition and characterized by Raman and electrical properties. We suggest that UV cleaning is the most effective method for surface cleaning of graphene. Also, we expect a correlation between oxidation rate and twist angle.
C71.00147: High transmittance Er doped ZnO thin films as electrodes for organic light-emitting diodes  SHI YINGLI (Presenter), CHI-CHUNG LING, The University of Hong Kong — Transparent conducting oxides (TCO) have attracted great attention since the first demonstration in 1907 by Baedeker. TCO thin films with high transparency and electrical conductivity have been widely used in optoelectronic devices, such as thin-film transistors, perovskite solar cells and light emitting diodes (LEDs). Er doped ZnO films exhibit higher optical transparency (~95 %) than other reported metal elements doped ZnO TCO thin films. The effect of Er doping concentration on photoelectric properties of ErZO thin films was investigated in the range of 0-2.0 wt.%. The Er impurity substitutes the Zn site and Er\textsubscript{Zn} serves as charge donor in the ZnO crystal structure, thus resulting in the improvement of \textit{n}-type conductivity as compared with intrinsic ZnO thin films. The optimized ErZO thin films present the low resistivity of $3.4 \times 10^{-4} \ \Omega/$cm, high carrier concentration of $5.9 \times 10^{20} \ /$cm$^3$ and high visible optical transmittance (~93%) when the Er content is 1.0 wt.%. The ErZO thin films were used as transparent anodes to fabricate organic light-emitting diodes (OLEDs). Impressively, with the ErZO as anode, the current efficiency of the OLEDs device can reach as high as 86.5 cd/A, which was increased by 14% when compared with the reference OLEDs device (76.0 cd/A) using ITO as anode.

C71.00148: Thermally induced metal-to-insulator transition in NbO\textsubscript{2} thin films*  TOYANATH JOSHI (Presenter), ELI CIRINO, SOPHIE MORLEY, DAVID LEDERMAN, Department of Physics, University of California, Santa Cruz — Modification of the carrier dynamics in correlated oxide systems via epitaxial strain is a promising pathway for the practical realization of energy-efficient electronic devices. Here we present on the thermally induced metal-to-insulator transition (MIT) of epitaxial NbO\textsubscript{2} films grown on Al\textsubscript{2}O\textsubscript{3} substrates and the modulation of the MIT temperature via epitaxial strain from the substrate. The metal-insulator transition temperature increased from 910 K to 1066 K with increasing strain. An ultrathin 3.9 nm film consisting of a single strained layer with minimal structural defects yielded a bulk-like sharp transition. The substrate-induced strain offers a new degree of freedom to improve device functionality of MIT materials.

C71.00150: Structural Design and Manufacturing of Three-Dimensional Porous Superstructures with Additive and Subtractive Electrochemistry for Flexible Self-Powered Electronics and Electromechanical Devices*  
WEIGU LI, DONGLEI (EMMA) FAN (Presenter), University of Texas at Austin — The recent search for advanced materials with desired properties for the next-generation flexible energy and electronics has been focused on the unique class of three-dimensional (3D) porous superstructures made of 2D materials, such as graphene, graphite, and molybdenum disulfide.

In this work, we report an innovative and rational approach to create 3D metallic foams with tunable multi-level porosity by using a process consisting of an additive electrodeposition and subtractive electroetching. The resulted metallic foams can readily serve as catalytic templates for the growth of 3D hierarchically porous thin graphite. The 3D graphite is freestanding after selective etching of the metallic template. They provide enhanced mechanical properties and electrochemical performances when applied as supercapacitor electrode supports. They can be readily integrated with our wearable GF/polymer strain sensors developed recently and nanomotor manipulation systems into self-powered sensing and electromechanical devices, respectively.

*The research is supported by the National Science Foundation and Welch Foundation.
C71.00151: In-situ Raman investigation of Laser-Induced Graphene using Machine
Learning*  VIVEK JAIN (Presenter), ALEX TYRRELL, HUD WAHAB, LARS KOTTHOFF, PATRICK A
JOHNSON, Univ of Wyoming — High-quality graphene was laser-induced from precursors graphene
oxide and commercial polyimide. Laser annealing is a promising method to create graphene-
based devices including sensors, biomedical equipment and thin-film transistors. A Bayesian
optimization-based machine-learning strategy was used to predict optimal process parameters.
We custom-built our system to allow simultaneous laser patterning processing and in-situ Raman
spectroscopy characterizations. The Raman G/D ratio is a good indication of the quality of the
laser-induced graphene. Rapid and significant improvements in the G/D ratios were seen with the
machine-learning predicted process parameters. This experimental setup has enormous
potential in Autonomous Research Systems for new materials discovery and can be scaled up for
advanced-manufacturing patterned graphene-based electronics.

C71.00152: Optical phenomena of irradiation induced molybdenum disulfide*  KORY BURNS
(Presenter), ANNE MARIE ZHAO HUI TAN, University of Florida, ADAM GABRIEL, LIN SHOA, Nuclear
Engineering, Texas Agricultural and Mechanical University, RICHARD HENNIG, ASSEL AITKALIYEVA,
University of Florida — Irradiation introduces damage cascades, destroys the periodicity of the
lattice, and pushes the material away from equilibrium. In this contribution, we utilize heavy ion
and gamma irradiations to alter the optical properties of two-dimensional (2D) materials such as
MoS$_2$. Irradiation offers a pathway to introduce desired defect densities to any given material,
and, in case of low-dimensional materials, can be used to control physical properties. Defects
introduced using irradiation were characterized using transmission electron microscopy (TEM)
and photoluminescence (PL) measurements. We primarily focus our attention on the behavior of
valley excitons, as they dominate the optical response of the material even when the system is in
equilibrium and reveal the emergence of dark excitonic states in the K-valley. With this work, we
offer insight into how increased defect density can potentially engineer magnetism in 2D MoS$_2$.

*U.S. Department of Energy, Office of Science, Basic Energy Sciences, Award #DE-SC0019014
“Establishing defect-property relationships for 2D-nanomaterials”.
C71.00153: Non-Destructive Thickness Mapping of Wafer-Scale Hexagonal Boron Nitride Down to a Monolayer
ANDREA CROVETTO (Presenter), PATRICK WHELAN, DTU Physics, Technical University of Denmark, RUIZHI WANG, Department of Engineering, University of Cambridge, MIRIAM GALBIATI, DTU Physics, Technical University of Denmark, STEPHAN HOFMANN, Department of Engineering, University of Cambridge, LUCA CAMILLI, DTU Physics, Technical University of Denmark — Characterization of the thickness and continuity of wide band gap 2D materials with monolayer sensitivity over large areas has proven to be very challenging. A prime example is 2D hexagonal boron nitride (hBN). Optical contrast methods suffer from the lack of visible absorption in the material; Raman spectral signatures are weak and often not conclusive; and electrical measurements are not possible due to a high electrical resistivity. In this contribution, we will demonstrate an experimental method based on the ellipsometry technique, which makes it possible to map the thickness and continuity of large-area hBN monolayers and bilayers transferred to Si/SiO$_2$ substrates. The method has sub-monolayer thickness sensitivity, is relatively fast, non-destructive, and can be easily automated. The hBN thicknesses measured in this study have been confirmed by Raman spectroscopy, x-ray photoemission spectroscopy, and by a series of ellipsometry control experiments. We will present a workflow of our experimental procedure, so that other researchers can extend this characterization method to other 2D materials and hopefully accelerate their development.

C71.00154: Raman Enhancement effect using hexagonal Boron Nitride with a substrate*
JESSICA LEMOS (Presenter), ANDREJ DE CARVALHO GADELHA, CRISTIANO FANTINI LEITE, Physics, Universidade Federal de Minas Gerais, ELIEL GOMES DA SILVA NETO, Physics, Universidade Federal Fluminense — The Raman enhancement effect is a phenomenon for fundamental studies of both light-matter and matter-matter interactions and applications. Among the several Raman enhancement techniques, the surface-enhanced Raman scattering (SERS) has been the most studied. There are two different mechanisms for SERS effect, the first one is the electromagnetic mechanism when is the local electromagnetic fields around the metallic structures can be amplified. The second is the chemical mechanism which is lower understood, and its magnitude is smaller than the electromagnetic effect. The substrate surface is very important to control the necessary enhancement to make the technique as valuable as it has become. In this work, we study hexagonal boron nitride (hBN) a two-dimensional layered material with a substrate for a type of SERS, an insulator whose gap is approximately 5eV.

*Capes, CNPq and INCT(nanocarbono)
C71.00155: Dual comb spectroscopy for measuring the group velocity dispersion of optical fiber realized by fast locking of the beat note with a piezoelectric module*  
RYOSUKE TABUCHI (Presenter), Keio Univ, KANA ALYSSA SUMIHARA, Keio Univ / AIST, SHO OKUBO, AIST, MAKOTO OKANO, Keio Univ, HAJIME INABA, AIST, SHINICHI WATANABE, Keio Univ — Dual-comb spectroscopy (DCS) emerged a decade ago as a powerful tool for gas spectroscopy and metrology. DCS is based on two optical frequency combs (OFCs) with slightly different repetition rates. Using DCS, one can simultaneously obtain amplitude and phase of the light, resulting in the direct determination of complex refractive index. Thus, DCS promises for investigating the solid state materials. Here, we demonstrate an application of measuring the group velocity dispersion (GVD) of single-mode fiber (SMF) by using DCS. We constructed two Er-fiber-based OFCs and achieved the fast locking of the beat note by using PZT module based on Ref. [1]. The beat note was phase locked with the servo bandwidth of over 100 kHz and the integrated phase noise as 0.21 rad and we realized the DCS system. By using this system, we obtained a wavelength-dependent GVD of SMF and the GVD as -22.0 ps^2/km at 1550 nm with the standard deviation of 0.02 ps^2/km. It agrees well with the nominal value of the GVD. Thus, we conclude that our DCS works as a brilliant tool for solid state physics.

C71.00156: Heavy Mediator at Quantum Dot/Graphene Heterojunction for Efficient Charge Carrier Transfer to Enhance the Performance of the Optoelectronic Devices*  
RAPTI GHOSH (Presenter), Academia Sinica — The two-dimensional mediator with heavy effective mass possesses a large density of states that can be inserted at the two-dimensional heterostructure interface. In general, the 2D heterostructure interfaces suffer from enhanced depletion region which deteriorates the charge carrier transfer efficiency and hence the device performance. The insertion of the mediator reduces the depletion region and form type–II band alignment which speeds up the carrier dissociation efficiency and hence eventually enhances the carrier transfer phenomena. 2D ReS_2 as a mediator has been employed at the heterojunction of graphene and perovskite quantum dots which results in enhancing photosensitivity (> 10^7 A/W). Moreover, the device can withstand 100% longitudinal strain making it ideal for the future wearable optoelectronic device industry^1.

C71.00157: Nonlinear Refractive Index Measurement of E-beam Evaporation Ta$_2$O$_5$ film*

TE-KENG WANG (Presenter), CHAO-HONG LIN, JIA-WEI LIU, FU-YAN YAN, HAN-TING HOU, Sun Yat-sen University, MIN-HSIUNG SHIH, Research Center for Applied Sciences, CHAO-KUEI LEE, Sun Yat-sen University — Tantalum pentoxide(Ta$_2$O$_5$) has been realized as a promising material for waveguide due to its great linear optical properties, such as high refractive index, large bandgap and so on. Recently, the nature of athermal property and high nonlinear refractive coefficient exhibit its potential for Si photonics application. In this work, using e-gun deposition growth Ta$_2$O$_5$ thin film, high quality micro-ring resonator was fabricated. The propagation loss as low as 0.3/cm was characterized from the transmission spectrum. Additionally, the nonlinear refractive coefficient (n$_2$) was investigated by using all optical modulation technique. The n$_2$ of 1.42 x 10$^{-14}$ cm$^2$/W was estimated. Compared to the conventional materials for Si photonics, such as Si$_3$N$_4$, SiO$_2$ and so on, the larger n$_2$ value reveal the value for application.

C71.00158: Investigation of the Resistive Switching Mechanism in Li$_x$NbO$_2$ Memristors*

SEBASTIAN HOWARD (Presenter), LOUIS F. J. PIPER, MATTHEW J. WAHILA, CHRISTOPHER SINGH, WEI-CHENG LEE, Binghamton University, TIMOTHY M. MCCORNE, WILLIAM A. DOOLITTLE, ALEX WEIDENBACH, Georgia Institute of Technology, GALO J. PAEZ, Binghampton University — A complete understanding of the origin of resistive switching in memristors is necessary for implementation into neuromorphic computing applications. However, the resistive switching of memristors is typically attributed to a complex combination of processes (e.g., redox reactions, ionic transport, phase changes, etc.) post an electroforming step, which limits tunability and scalability of the device. Li$_x$NbO$_2$ analog memristors circumvent the electroforming step and demonstrate a promising new mechanism wherein the diffusion of Li$^+$ ions enables precise control of the resistive states [1]. Here we utilize synchotron-based x-ray spectroscopy techniques to examine the electronic strucure of Li$_x$NbO$_2$ memristors. We employ x-ray absorption spectroscopy (XAS) across the active to observe variations in the Li content. Additionally, we investigate the origin of non-volatility by probing the buried interface at the metal contacts via hard x-ray photoelectron spectroscopy (HAXPES). This work opens a new avenue of methodology for illuminating resistive switching mechanisms in memristors from a fundamental perspective.

*This material is based on the work supported by the Air Force Office of Scientific Research under Award No. FA9550–18–1–0024.
C71.00159: Tunable Dirac points and zero-energy modes in periodic curved graphene superlattices* JIANLI LUAN, SHANGYANG LI, TIAXING MA (Presenter), Beijing Normal Univ, LIGANG WANG, Zhejiang University, HAI-QING LIN, Beijing Computational Science Research Center — We combined periodic ripples and electrostatic potentials to form curved graphene superlattices and studied the effects of space-dependent Fermi velocity induced from curvature on their electronic properties. With equal periods and symmetric potentials, the Dirac points do not move, but their locations shift under asymmetric potentials. This shift can be tuned by curvature and potentials. Tunable extra gaps in band structures can appear with unequal periods. The existence of new Dirac points is proposed, such that these new Dirac points can appear under smaller potentials with curvature, and their locations can be changed even under a fixed potential by adjusting the curvature. Our results suggest that curvature provides a new possible dimension to tune the electronic properties in graphene superlattices and a platform to more easily study physics near new Dirac points.

C71.00160: On degradation and reliability testing GaN High-electron-mobility transistor (HEMT) PARVEEN KUMAR (Presenter), University of California, Merced — Gallium nitride (GaN) based high electron mobility transistors (HEMTs) have shown a lot of promise in high voltage, high power, and high radiation applications. However, the full realization of the III-nitride potential and large-scale adoption of this technology has been hindered by the existence of electrically active defects that manifest as deep levels in the energy bandgap. These deep levels can potentially act as charge trapping centers limiting device performance and long-term reliability. It is therefore imperative to monitor these traps in operational GaN HEMTs as close as possible to their real-world operational conditions. With that goal in mind, in this work, a suite of advanced thermal and optical-based trap spectroscopy methods and models are reported and expanded upon to directly probe and track traps in three-terminal operational of GaN HEMTs.
C71.00161: Stress/Strain Effects on Phonon Modes and Phonon Deformation Potentials in Monoclinic $\beta$-Ga$_2$O$_3$  
RAFAŁ KORLACKI (Presenter), MATHIAS SCHUBERT, University of Nebraska - Lincoln, ALYSSA MOCK, Naval Research Laboratory, SEAN KNIGHT, University of Nebraska - Lincoln, VANYA DARAKCHIEVA, Linköping University — Strain-induced shifts of phonon energies provide a powerful tool for modeling strain patterns in heterostructures and thin films. In the case $\beta$-Ga$_2$O$_3$, an emerging wide-bandgap semiconducting oxide, the low symmetry of its monoclinic structure is responsible for the high anisotropy and unusual ordering of phonon modes, while the effects of stress and strain on the phonon properties in general are not yet well understood. We present a rigorous, symmetry-based analysis on how the frequencies of optical phonon modes depend on the components of stress and strain tensors in monoclinic crystals, and we confront it with the results of density functional theory (DFT) calculations involving several distinct deformation scenarios, and the resulting shifts in phonon mode frequencies for $\beta$-Ga$_2$O$_3$. We derive sets of phonon deformation potential parameters for all phonon modes, including infrared-active ($A_u$ and $B_u$) and Raman-active ($A_g$ and $B_g$) modes. Additionally, we discuss how stress affects the order of phonon modes with $B_u$ symmetry.

C71.00162: Thermal and Magnetic Properties of Landau–Quantized Group VI Dichalcogenide Carriers in the Approach to the Degenerate Limit  
N J HORING (Presenter), Department of Physics, Stevens Institute of Technology, Hoboken, NJ 07030, USA, JAY D MANCINI, Department of Physical Sciences, Kingsborough College, CUNY, Brooklyn, New York 11235 — This work is concerned with determination of the thermal and magnetic behavior of the Group VI Dichalcogenides in a quantizing magnetic field. Our analysis treats the principal statistical thermodynamic functions (grand partition function and the ordinary partition function, as well as the grand potential, Helmholtz free energy and the entropy), providing the basis for calculation of the specific heat: Their dependencies on temperature and magnetic field strength are carefully examined, particularly in the degenerate regime and the approach to zero temperature. The joint dependence on magnetic field and temperature is also determined for the Dichalcogenide magnetic moment in the degenerate statistical regime, replete with de Haas–van Alphen oscillatory phenomenology and also above the zero–temperature limit.

C71.00163: Effect of electric potential fluctuations in Coulomb drag in double layer graphene systems  
RYAN A. BOGUCKI (Presenter), BEN HU, Department of Physics, Univ of Akron — We study theoretically the drag transresistivity in a graphene double layer system exhibiting electric potential fluctuations. The fluctuations are modelled as sinusoidal oscillations in the first layer, which induces a sinusoidal variation in the electron density in that layer, which in turn induces an electron density oscillation in the second layer. We calculate the drag resistivity as a function of average charge densities in each layer for various amplitudes of the electric potential fluctuations. Recent experiments have found that the drag transresistivity in graphene double layers systems exhibit a sign change when one layer is held at the charge neutrality point, and the average density of the electrons in the other layer is varied through the charge neutrality point. Our simple model is able to qualitatively reproduce these experimental results. We discuss extensions of the model which characterize more realistically the electric potential fluctuations that are caused by the presence of charge density impurities near the graphene layers.
**C71.00164: Thermal expansion coefficients of high thermal conducting BAs and BP materials**  
SHENG LI (Presenter), University of Texas at Dallas, KEITH TADDEI, Oak Ridge National Laboratory, XIQU WANG, University of Houston, HANLIN WU, University of Texas at Dallas, JOERG C. NEUEFEIND, Oak Ridge National Laboratory, DAVIS ZACKARIA, XIAOYUAN LIU, University of Texas at Dallas, CLARINA RELOJ DELA CRUZ, Oak Ridge National Laboratory, BING LV, University of Texas at Dallas — Recently reported very high thermal conductivities in cubic boron arsenide (BAs) and boron phosphide (BP) crystals could potentially provide a revolutionary solution in the thermal management of high power density devices. To fully facilitate such an application, the compatible coefficient of thermal expansion (CTE) between the heat spreader and the device substrate, in order to minimize the thermal stress, needs to be considered. Here, we report our experimental CTE studies of BAs and BP in the temperature range from 100 K to 1150 K, through a combination of X-ray single crystal diffraction and neutron powder diffraction. We demonstrated that the room temperature CTEs, $3.6 \pm 0.15 \times 10^{-6}/K$ for BAs and $3.2 \pm 0.2 \times 10^{-6}/K$ for BP, are more compatible with most of the semiconductors including Si and GaAs, in comparison with diamond, and thus could be better candidates for the future heat spreader materials in power electronic devices.

**C71.00165: OUTREACH AND ENGAGING THE PUBLIC** —

**C71.00166: Dying Fundamental Physics and Rising Digital Era of Engineering**  
PRITAM MANDAL (Presenter), Durgapur Women's College — From a study based on personal teaching experiences and one-to-one and in-group interaction with a large number of students (9th to 12th Grade and UG levels), teachers, research scholars and lab-experts across India, we found that most of the students in the science stream no longer “view” Physics as a branch of science to study the nature, rather Physics for them is a giant toolbox to design more sophisticated devices and medicines for “social use”. To most of them, knowing physics means becoming smarter at handling electricity, electronic gadgets, computers, smart-phones and apps. Most of the science students were found not driven to learn physics as a way to understanding and relishing the hidden deeper beauty of nature; for them the new wonderland is the “on-line” world. Given the trend in students’ attitude towards physics in current time, theoretical physics might severely suffer in near future. In this talk, I discuss the issues we found and the possible course of action to better cement the foundation of tomorrow’s fundamental physics.

**C71.00167: WITHDRAWN ABSTRACT** —

**C71.00168: PUBLIC POLICY** —
Research Integrity, the Responsible Conduct of Research, and Plagiarism Analysis
AARON MANKA (Presenter), National Science Foundation — Among its duties, the National Science Foundation (NSF) Office of Inspector General (OIG) is responsible for helping ensure the integrity of research programs at NSF. We investigate allegations of research misconduct (plagiarism, falsification, and fabrication) in NSF proposals and awards. We also handle allegations conflict of interests and violations of the confidentiality of NSF’s merit review to ensure the integrity of that process. We completed a review of how grantees implemented NSF’s requirement to provide responsible conduct of research training to undergraduate students, graduate students, and postdoctoral researchers. We have analyzed our plagiarism cases of the past decade to accumulate data and potentially identify institutional strategies for preventing and reducing plagiarism. We are also reviewing grants for characteristics of serial spending. I will briefly discuss these topics and present our results.

ENERGY RESEARCH AND APPLICATIONS —

Perovskite Electronic Ratchet for Energy Harvesting
JI HAO (Presenter), HAIPENG LU, JEFFREY L BLACKBURN, ANDREW FERGUSON, National Renewable Energy Laboratory — Hybrid organic-inorganic perovskite semiconductors (HOIS) have demonstrated great potential as absorbers in thin-film solar cells, but recently there is emerging research demonstrating their application as the electronic materials in transistors, diode, and optoelectronic devices due to their unique mixed ionic-electronic properties. Here we demonstrate a novel energy harvesting application based on both ionic and electronic transport in HOIS — Perovskite electronic ratchets. The electronic ratchet is a new type of energy harvesting device that can convert (rectify) a non-directional electrical signal into stable direct current through an asymmetric potential distribution across the device (i.e., the device acts as a charge pump). Here we demonstrate the first lead-halide perovskite electronic ratchet by manipulating the ion distribution within a transistor channel to realize an asymmetric potential distribution in the perovskite device. This asymmetric potential distribution allows the perovskite ratchet device to convert both electronic noise and unbiased, periodic alternating potentials into stable direct current. Such devices have the potential for providing low-voltage power in remote and portable applications.
**C71.00172: Ferrofluid-Based Generator Harvesting Waste Heat and Ambient Vibration**

XUEWEI ZHANG (Presenter), Texas A&M University, Kingsville — Ferrofluid is a stable colloidal suspension of permanently magnetized nanoparticles, in which Brownian motion keeps the nanoparticles from settling under gravity, and a surfactant is placed around each particle to provide short-range steric repulsion between particles to prevent particle agglomeration. Since magnetic field device has no limitations analogous to electrical breakdown in its electric field counterpart, ferrofluids have become an excellent choice for micro/nanoelectromechanical systems technology. On the other hand, ferrofluids have applications in the cooling of electronic devices, which has led to several designs of power generators using waste heat. In this work, we study a new version of ferrofluid generators harvesting both heat and vibration energy. A theoretical model based on fundamental physics principles is developed to evaluate the system's energy conversion efficiency (the ratio of generated power and the heat input). Further, we discuss the dependence of the output power on various design parameters (including the scale of the system) and methods to enhance the performance of the ferrofluid generator for potential aerospace applications.

**C71.00173: Thermoelectric properties of As-based 1111-Zintl compounds La\(_{1-x}\)Sr\(_x\)(Zn,Cd)AsO**

YUSUKE KIMURA (Presenter), National Institute of Advanced Industrial Science and Technology, Tokyo University of Science, KUNIHIRO KIHOU, HIROTAKA NISHIATE, National Institute of Advanced Industrial Science and Technology, HIDETOMO USUI, Shimane University, YUTO TOKUNAGA, Osaka University, TSUTOMU IIDA, Tokyo University of Science, KAZUHIKO KUROKI, Osaka University, CHUL-HO LEE, National Institute of Advanced Industrial Science and Technology, Tokyo University of Science — 1111-system with the ZrCuSiAs-type structure has attracted great attention not only as the high-Tc superconductors but the high-performance thermoelectric compounds. The highest ZT in 1111-system was found in BiCuSeO with the value of ZT to be 1.4 at 923 K [1], demonstrating the high potential of the 1111-system as thermoelectric compounds. Previously, we found that LaFeAsO\(_{1-y}\) exhibits large power factor with values of PF = 4.1 mW/mK\(^2\) at T = 75 K [2], demonstrating that As-based 1111-system can also be a candidate.

In this study, we focused on LaZnAsO and LaCdAsO (space group: P4 / nmm) compounds. Hole carriers were induced by Sr doping. Polycrystalline samples were synthesized by the solid reaction method. High dense samples were obtained by hot-press. As results, peak of the power factor of LaZnAsO was shift to high temperature comparing with LaFeAsO\(_{1-y}\), achieving the value of 0.118 mW/mK\(^2\) at T=747 K. Details of sample preparation as well as thermoelectric properties will be discussed in the conference.

C71.00174: Understanding pressure-driven thermoelectric properties of PdP$_2$ and PdAs$_2$ nanowires via band engineering

PRABAL BHUYAN (Presenter), Department of Physics, Gujarat University, Ahmedabad, India, YOGESH SONVANE, Department of Applied Physics, Sardar Vallabhbhai National Institute of Technology, Surat, India, P. N. GAJJAR, Department of Physics, Gujarat University, Ahmedabad, India, RAJEEV AHUJA, Ångströmlaboratoriet, Department of Physics, Uppsala University, Uppsala, Sweden, SANJEEV K. GUPTA, Department of Physics, St. Xavier's College, Ahmedabad, India — In the race of searching for alternative clean and sustainable energy sources, thermoelectric materials have shown potential hope by converting low-grade waste heat into electricity. The efficiency of thermoelectric devices is characterized by power factor or ZT. Therefore, enhancing ZT in nanowires for the thermoelectric application is highly desired. In recent work, we propose semi-metallic nanowire with asymmetry density of states near the Fermi energy as an alternative class of thermoelectric materials. We have considered the pentagonal structure of PdP$_2$ and PdAs$_2$ nanowires (NWs) and confirmed its dynamical stability by the phonon dispersion study. The PdX$_2$ structure shows the transition from semiconducting to semi-metallic behaviour at a compressive strain of 8% within sustainable pressure of 0.2~0.3GPa. The semi-metallic behaviour with the asymmetric density of states near the Fermi energy boosts Seebeck co-efficient value and therefore, ZT$_e$ value is enhanced for both the nanowires. Our study stimulates both nanowire synthetization feasibility and thermoelectric applications for the conversion of waste heat into electricity.

*We would like to thank Science and Engineering Research Board (SERB), India for providing high computing system (Grant no.: YSS/2015/001269).
C71.00175: Optimized Efficiency of a stochastically driven quantum dot Heat Engine*

MULUGETA BEKELE (Presenter), Addis Ababa Univ — We take a stochastically driven single level quantum dot embedded between two metallic leads at different temperatures which works as a heat engine. We analytically study the optimized efficiency that lies between the maximum efficiency and minimum efficiencies. The minimum efficiency either takes the efficiency value at maximum power or the lowest possible value which is zero. We study the optimized efficiency of a quantum dot heat engine according to the optimization criteria, to find their corresponding optimized quantities in an external magnetic field (stochastic driving force). Accordingly, we found 1) efficiency-wise optimized efficiency is better than efficiency at maximum power; 2) power-wise, the optimized power is smaller than its value at maximum power by 35% and 3) period-wise, is performs the task in a cycle twice that of the period at maximum power. We study the overall performance of the heat engine by introducing a figure of merit that takes into account the contribution of each of the above quantities as a function of Carnot efficiency. Based on the proposed figure of merit, the model shows that the 1st optimization criteria is 3 times better than the 2nd optimization criteria as a function of $\eta_C$.

C71.00176: Thermoelectric Properties of Solvothermal Grown Bismuth Telluride-Carbon Nanomaterials Composites

DANIEL CHOI (Presenter), National Research Council, KARIMA PERRY, CCDC Army Research Laboratory, PATRICK TAYLOR, CCDC Adlphi Laboratory Center, EVGENIYA LOCK, United States Naval Research Laboratory, SHASHI P KARNA, CCDC Army Research Laboratory — Current state of the art portable power source faces problems such as low-life, high production cost and weight penalty. As such, thermoelectric (TE) power generation and cooling have been considered as an alternative as low-cost, more efficient, environmentally responsible approach. One of more promising TE material of interest are alloys based on bismuth telluride ($\text{Bi}_2\text{Te}_3$) and thus much efforts have been made to improve TE properties by (1) reducing the materials’ dimension to nanoscale, and (2) incorporating other nanostructures such as graphene, to enhance electrical properties and thermal conductivity. This geometry offers a natural architecture for thermoelectric devices due to reduced thermal transport and enhanced electronic tunneling at the nanomaterial interfaces. Building upon this mechanism, we present thermoelectric properties of $\text{Bi}_2\text{Te}_3$ compositied with various carbon nanostructures. Our TE materials are synthesized via solvothermal method resulting in uniformly dispersed nanoplates interfaced with 1D and 2D carbon nanostructures. Our results not only show change in thermoelectric properties of $\text{Bi}_2\text{Te}_3$ upon incorporation of carbon nanostructures, but provide characterization of Bi2Te3-nanomaterial interface for development of next-gen, low power, portable power source.
C71.00177: Defects and band positions in the p-type transparent conductor CuI  ANDREA CROVETTO (Presenter), SERGIU LEVCENKO, HANNES HEMPEL, MARIN RUSU, THOMAS UNOLD, Helmholtz-Zentrum Berlin — While high-performance n-type transparent conductive materials (TCMs) have existed for decades, heavy p-type doping of wide band-gap materials has proven much more challenging. The simple cubic compound CuI was recently rediscovered for this application and is currently the p-type TCM with the highest figure of merit. However, the native defects responsible for p-type conductivity in CuI, as well as compensating defects limiting the maximum achievable doping levels, have not yet been identified experimentally. Furthermore, there is disagreement in the literature on the work function and absolute band positions of CuI relative to vacuum. In this experimental study, we employ temperature- and intensity-dependent photoluminescence to draw new conclusions on the defect landscape of CuI. We then employ a combined photoemission spectroscopy-Kelvin probe system to show that the measured band positions depend critically on surface phenomena. Finally, we demonstrate that terahertz spectroscopy is an ideal tool for characterizing the electrical properties of CuI reliably and non-destructively.

C71.00178: Computational Screening and Designing High-performance Solid Sorbents for CO₂ Capture Technology  YUHUA DUAN (Presenter), Natl Energy Technology Lab — CO₂ is one of the major combustion products which once released into the air can contribute to global climate change. Solid sorbents have been reported to be promising candidates for CO₂ sorbents due to their high CO₂ absorption capacities. With ab initio thermodynamic calculations, we proposed a theoretical screening methodology to identify the most promising CO₂ sorbent candidates from vast array of possible solid materials. The advantage of this method is that it identifies the thermodynamic properties of the CO₂ capture reaction as a function of temperature and pressure without any experimental input beyond crystallographic structural information of the solid phases involved. According to the requirements imposed by the pre- and post- combustion technologies and based on our calculated thermodynamic properties for the CO₂ capture reactions by the solids of interest, we were able to identify only those solid materials for which lower capture energy costs are expected at the desired pressure and temperature conditions. In addition, through investigating several mixed sorbent materials, we demonstrate that by mixing/doping different types of solids it’s possible for a sorbent to shift its turnover temperature to the range of practical operating conditions.
C71.00179: Improved optoelectronic properties in CdSe\textsubscript{x}Te\textsubscript{1-x} through controlled composition and short-range order* BISHAL DUMRE (Presenter), NATHAN J SZYMANSKI, VIJAYA ADHIKARI, INDIRAS KHATRI, Department of Physics and Astronomy, The University of Toledo, DANIEL GALL, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, SANJAY V. KHARE, Department of Physics and Astronomy, The University of Toledo — We employ first principles methods based on density functional theory and beyond to study CdSe\textsubscript{x}Te\textsubscript{1-x} alloys in the zincblende and wurtzite structures. From the cluster expansion formalism, we provide phase diagram showing consolute temperature of 325 K where zincblende-to-wurtzite phase boundary is found for Se concentrations of \( x = 0.5-0.6 \) owing to increasing ionic character of the Cd-anion bonds. Disordered CdSe\textsubscript{x}Te\textsubscript{1-x} configurations are modeled using special quasirandom structures, for which optoelectronic properties are computed with the hybrid HSE06 functional. Downward bowing in the band gap and effective hole mass of the zincblende structure is highlighted for its potential benefits in photovoltaics through increased net photocurrent. Absorption coefficient and reflectivity are also reported, showing promising results in zincblende CdSe\textsubscript{x}Te\textsubscript{1-x} as indicated by substantial optical absorption throughout all Se concentrations. Lastly, we identify the presence of short-range order in CdSe\textsubscript{x}Te\textsubscript{1-x} characterized by clustering among like atoms in order to minimize strain. The degree of clustering, which may be tuned by temperature, also controls the magnitude of the band gap.

C71.00180: A Multidimensional Approach to Structural Transformation Through Functionalization of Tellurene* GRACIE CHANEY (Presenter), DANIEL WINES, FATIH ERSAN, JARON KROPP, CAN ATACA, Univ of Maryland-Baltimore County — Two dimensional (2D) Tellurene (Te) structures have recently been synthesized, and have been shown to possess high mobility and stability. Using density functional theory (DFT) and molecular dynamics (MD), we investigated the stability and electronic structure of 2D, and phase sheets, and their hydrogen, oxygen, and fluorine functionalized counterparts. Our calculations show that bare - and -Te sheets are stable and have band gaps of 0.44 eV and 1.02 eV respectively. We see that H, O and F destabilize -Te; F and H cause -Te layers to separate into functionalized atomic chains; and O causes -Te to totally transform into a Te\textsubscript{3}O\textsubscript{2}-like structure. Also, we studied the coverage effects of different concentrations of H and O on and \( \beta \)-Te and found that the full coverage case results in the highest binding energy and stability for both adatoms. Finally, we examined the stability and binding nature of functionalized \( \beta \)-Te on a GaSe substrate. We noted that having O and H impurities not only enhances the stability of Te layer, but also results in a strong binding energy on GaSe substrate. Our results indicate that Tellurene monolayers and functionalized counterparts are suitable for future optoelectronic devices and as metallic contacts in nanoscale junctions.

*NSF DMR-1726213
C71.00181: Investigation of Au(111)/Li$_3$PO$_4$ Interface Structures using Neural Network Potential

KOJI SHIMIZU (Presenter), WEI LIU, Department of Materials Engineering, The University of Tokyo, WENWEN LI, YASUNOBU ANDO, National Institute of Advanced Industrial Science and Technology, EMI MINAMITANI, Institute for Molecular Science, SATOSHI WATANABE, Department of Materials Engineering, The University of Tokyo — Recently, the construction of interatomic potentials using first-principles calculation data and machine-learning technique has been widely tried because of higher reliability and low computational costs. In the present study, we have tried to construct the four-element neural network potential (NNP) [1,2] to investigate the Au(111)/Li$_3$PO$_4$ interface system, where the understanding of the interface structures and Li-ion distribution near the interface is of significance for the development of all-solid state Li-ion batteries and novel memory devices [3]. Using the constructed NNP, we then performed structure optimization with a large interface model of Au(111)/Li$_3$PO$_4$. In the meeting, we will discuss the calculated interface structures and the Li defect formation energies.

C71.00182: Strong interplay between Na- and O-related defects in Cu-based chalcogenides

KOSTIANTYN SOPIHA (Presenter), Ångström Solar Center, Division of Solid State Electronics, Uppsala University, SIGBJØRN GRINI, Department of Physics/Centre for Materials Science and Nanotechnology, University of Oslo, CHARLOTTE PLATZER-BJÖRKMAN, Ångström Solar Center, Division of Solid State Electronics, Uppsala University, LASSE VINES, CLAS PERSSON, Department of Physics/Centre for Materials Science and Nanotechnology, University of Oslo — Recent advances in thin-film photovoltaics became possible by controlling the incorporation of impurities. The most notable among them are alkalis in-diffusing from soda-lime glass and oxygen incorporating from various sources during the baseline processing. Herein, we investigate the interaction between Na and O in co-sputtered Cu$_2$ZnSnS$_4$(CZTS) by combining theoretical and experimental techniques. First, using secondary ion mass spectrometry (SIMS), we demonstrate that Na and O distributions in the absorber are correlated. Then, employing first-principles methods, we show that the correlation is driven by a strong ionic Na-O bonding that triggers the formation of NaO and Na$_2$O complexes. The remarkably high binding energies for these complexes are proven to cause Na-O clustering at all temperatures of the baseline processing. Hence, the overall character of the impurity profiles is explained through O immobilizing Na by forming the defect complexes and leading to the Na accumulation near the CZTS surface. This defect interplay paves the way for a more accurate impurity control needed for fabricating high-performance devices.

*This work is supported by SSF #RMA15-0030 and RCN #243642.
Energetic and vibrational properties of carbon monoxide adsorption on platinum nanoparticles under applied voltage*  

CIERRA CHANDLER (Presenter), ISMAILA DABO, Material Science and Engineering, Pennsylvania State University — Carbon monoxide poisoning is a significant limitation to the performance of platinum-based transition metals. Manipulating the size of the catalytic particles could help inhibit carbon monoxide adsorption and increase the life cycle of the catalyst. This study models the energetic and vibrational properties of carbon monoxide on platinum nanoparticles under applied voltage using the self-consistent continuum solvation (SCCS) model. We determine adsorption patterns as the function of nanoparticle size and site coordination. It is found that the local surface charge strongly affects carbon monoxide adsorption particularly along the (111) and (001) facets of the nanoparticle. These results could prove useful in optimizing electrocatalytic systems such as proton exchange membrane (PEM) fuel cells where trace amounts of carbon monoxide in the hydrogen fuel can poison the nanostructured platinum electrodes and decrease the durability of the fuel cell.

Evanescent field polarization for giant chiroptical modulation from achiral gold half-rings: Theoretical insight from simulations  

LUCA BURSI (Presenter), Department of Physics and Astronomy, Rice University, LAUREN A. MCCARTHY, KYLE W. SMITH, Department of Chemistry, Rice University, ALESSANDRO ALABASTRI, Department of ECE, Rice University, PETER J. NORDLANDER, Department of Physics and Astronomy, Rice University, STEPHAN LINK, Department of Chemistry, Rice University — Metal nanoantennas have been under intense investigation due to their strong light−matter interactions and significant polarization sensitivities determined by their nanostructure. For applications seeking to realize on-chip polarization-discriminating nanoantennas, efficient energy conversion from surface waves to far-field radiation is desirable. However, the response of individual nanoantennas to the particular polarization states achievable in surface waves, such as evanescent fields, has not yet been thoroughly studied. Here, we report the giant modulation of the visible light scattering predicted from gold half-ring, pinwheel, and other nanoantennas excited through total internal reflection of left- and right-handed circularly polarized light, by exploiting the distinct polarization properties of surface evanescent waves [ACS Nano, 12, 11657 (2018)]. This result provides a fundamentally different mechanism for chiroptical responses requiring a phase delay between transverse and longitudinal electric field oscillations, not found in free-space light. Specifically, we focus on the insight provided by theory, and in particular by the electromagnetic simulations, performed with COMSOL Multiphysics software, of the systems of interest and aspects of their chiroptical response.

WITHDRAWN ABSTRACT
C71.00186: Free Energy Landscape of Sodium Solvation into Graphite  ALI KACHMAR
(Presenter), QEERI, Hamad Bin Khalifa University, WILLIAM ANDREW GODDARD, Division of Chemistry and Chemical Engineering, Caltech — Sodium Ion Batteries (SIBs) are the most cost-effective alternative to current generation lithium ion batteries (LIBs), $^{[1,2]}$ but Na is known to deliver very low energy capacity for sodium intercalation compared to Lithium. We report here first principles moleculars dynamics aided by metadynamics $^{[3]}$ to obtain the free energy landscape including changes in the electronic coupling as a sodium ion in Dimethyl sulfoxide solvent intercalates into graphite, the first step in understanding how the local environment affects the free energy of solvation. We analyze the free energy landscape for all the possible sodium solvation scenarios, while quantifying their free energy barriers. Our simulations indicate that solvent plays an important role in stabilizing the sodium intercalation into graphite through shielding of the sodium while modulating the interaction of the solvent with the graphite sheets $^{[4]}$.

C71.00187: Catalytic growth of N-doped Multi-Layer Graphene/Carbon Composites for Supercapacitor Applications*  AYUSH BHARDWAJ (Presenter), ALEXANDER RIBBE, JAMES J WATKINS, Univ of Mass - Amherst — Multi-layer graphene (MLG) composites are excellent candidates for supercapacitor applications, but current approaches to device fabrication and the cost to produce graphene poses challenges for commercialization. Here, we use iron nitrate nonahydrate as a catalyst for the growth of graphene, melamine formaldehyde resin as a solid carbon source, and Pluronic F127 surfactant as a sacrificial porogen to enhance porosity and surface area. The MLG composites are produced via thermal carbonization. The resulting composites exhibit high surface area (2200 m$^2$/g) and significant nitrogen doping (4-5%), yielding specific capacitance values as high as 300 F/g at 0.5 A/g. The role of temperature and coordination between functional group of the carbon precursor & metal source has been investigated to understand MLG formation.

C71.00188: Determination of the Enthalpy of Adsorption of Hydrogen in Activated Carbon at Room Temperature*  ERNEST KNIGHT (Presenter), ANDREW K GILLESPIE, MATTHEW JOHNSON PROSNIEWSKI, DAVID STALLA, ELMAR DOHNKE, TYLER RASH, PETER PFEIFER, CARLOS WEXLER, Univ of Missouri - Columbia — A very important quantity for adsorption performance is the enthalpy of adsorption $\Delta H$. The determination of $\Delta H$ for weakly adsorbing gases (e.g., $H_2$) in carbonaceous porous materials is difficult, normally requiring measuring adsorption isotherms at two cryogenic temperatures and calculation of $\Delta H$ using Clausius-Clapeyron's (CC) equation. Here we demonstrate a calculation of $\Delta H$ based on ca. room temperature isotherms at 273K, 296K. CC requires absolute isotherms; however, excess adsorption is measured; conversion between these requires the adsorbed film volume. We show that the film volume can be estimated by fitting the excess adsorption with an Ono-Kondo model and the auxiliary use of a fixed point corresponding to the saturation film density (estimated 100±20 g/L) which seems to be remarkably sample- and temperature-independent, i.e., an adsorbate property. We find that for high-quality porous carbons the film volumes are ~40%, ~12% of the total pore volume at 77K, 296K, respectively. Using these, we calculate $\Delta H = 8.3±0.4$ kJ/mol at room temperature, an excellent agreement with the low-coverage cryogenic determination. The methodology proposed facilitates reliable calculations of the $\Delta H$ at room temperatures for weakly-adsorbing gases.

C71.00189: Thermal conductivity of hydrogen sorbent materials for onboard storage applications  NOEMI LEICK (Presenter), ROBERT BELL, National Renewable Energy Laboratory, TROY ALLEN SEMELSBERGER, Los Alamos National Laboratory, BRANDON BARNETT, JEFFREY R LONG, Lawrence Berkeley National Laboratory, PHILIP ANTHONY PARILLA, National Renewable Energy Laboratory, THOMAS GENNETT, Colorado School of Mines, Chemistry, National Renewable Energy Laboratory — Measuring the thermal conductivity (TC) of $H_2$-physisorption storage materials under system conditions are critical in designing the most practical onboard $H_2$ storage vessels. Furthermore, knowing the TC helps understanding how the heat associated with the sorption/desorption of $H_2$ is distributed throughout the storage material. In this work, we will show that the thermal properties of the powder materials can differ significantly from those of the bulk materials as heat transfer within a powder mainly occurs via: a) conduction through the solid particles and the gas within the interstices; and b) convection through the gas. To this end, we measured the TC on pellets of MOF-5 and powder Cu-MFU-4I with our state-of-the-art TC apparatus. We studied the behavior under He and $H_2$ pressures ranging from 0.03 - 80 bar, at temperatures ranging from 40 K - 380 K, and for different degrees of powder compaction. We will discuss that we measure an effective thermal conductivity that depends on the TC of the powder particles, on the powder compaction, the TC of the surrounding gas, the number of binding sites occupied, and the possible expansion or contraction of sorbents during the gas sorption/desorption which in turn all depend on temperature and pressure.
C71.00190: Thermal and Spectroscopic (IR, NMR) Studies of Ammonia Borane-Polyethylene Oxide Hydrogen Storage Composites: Effect of Catalyst*  
OZGE GUNAYDIN-SEN (Presenter), KRISHNA KHAREL, EMILY INGRAM, CAITLYN CLARK, Lamar University, RIQIANG FU, National High Magnetic Field Laboratory — Ammonia Borane (NH₃BH₃, AB) has been a potential candidate for chemical hydrogen storage due to its high hydrogen content (19.6 wt%). A downfall to the applicability of AB is its slow dehydrogenation kinetics and production of unwanted byproducts/gases. Studies show that introduction of a polymer, such as polyvinylpyrrolidone and polyacrylamide, can improve the performance of AB and decrease the release of harmful byproducts. Furthermore, catalytic additions such as, magnesium chloride (MgCl₂) and calcium chloride (CaCl₂), have proven to lower the activation energy (Eₐ), improve kinetics, and lower the hydrogen release temperature. This study explores thermal and vibrational analysis of pristine AB blended with polyethylene oxide (PEO) and individual additions of MgCl₂ and CaCl₂ as catalysts. Dehydrogenation kinetics were studied using a differential scanning calorimeter and the data was then compared with AB, bulk composites and analyzed. The results with CaCl₂ catalyst and high PEO content exhibited the most improved properties (i.e. lower Eₐ). In addition, evidence of the interactions between AB:PEO:Catalyst were given by Fourier-transform infrared and nuclear magnetic resonance spectroscopy.

C71.00191: The Impacts of Synthesis Routes and Phase-Purity on Water-Splitting Behavior in the Barium-Cerium-Manganese System  
DAN PLATTENBERGER (Presenter), ROBERT BELL, SARAH SHULDA, NICHOLAS STRANGE, PHILIP ANTHONY PARILLA, National Renewable Energy Laboratory, ANTHONY MCDANIEL, Sandia National Laboratory, MICHAEL TONEY, Stanford Linear Accelerator Laboratory, DAVID S GINLEY, National Renewable Energy Laboratory — Solar thermochemical hydrogen production (STCH) is a promising technology for solar fuels with high theoretical solar-thermal water-splitting efficiency. However, many candidate STCH oxides are complex ternary oxides, and they have the potential for secondary phase formation during synthesis and subsequent redox cycling. During synthesis, pervasive refractory impurity phases can occur, which impede the ability to develop a basic understanding of the STCH potential and complicate structural refinement of chemical expansion during isothermal reduction/oxidation. This work focuses on high phase-purity synthetic routes for known water-splitting oxides; in particular, BaCe₀.₂₅Mn₀.₇₅O₃ (BCM). These are approached by synthesizing both bulk ceramic and thin films, which are analyzed via in-operando synchrotron-based X-ray diffraction (XRD) to provide the highest quality structural refinements on BCM and other complex STCH oxides to date. The relationship between chemical shift and oxygen vacancy concentration is determined using a combination of flow-cell measurements and in-operando XRD during isothermal reduction and oxidation. In addition, key data for training computational simulations of vacancy formation and the effect of vacancies on structures is presented.
C71.00192: Frustrated Lewis Pairs with Applications in Hydrogen Storage  GLORY RUSSELL-PARKS (Presenter), BRIAN TREWYN, Colorado School of Mines, THOMAS GENNETT, National Renewable Energy Laboratory — Due to the abundance and large gravimetric energy density, hydrogen has been considered a potential source of energy.\(^1\) Major challenges with utilizing hydrogen for energy include efficient and safe storage and transportation of it. Frustrated Lewis pairs (FLPs) have recently proven their importance in hydrogen storage.\(^2\) In contrast to commonly known Lewis acid-base pairs, functionalizing the acid and base with bulky groups prevents them from binding to their counterpart causing them to be “frustrated”.\(^3\) The acid and base are held together by weak intermolecular forces without neutralization, which allows small molecules such as hydrogen to weakly bond to the Lewis acid and base in a heterolytic mechanism. FLPs as catalysts have unique characteristics including a wide range of compatible donors and acceptors.\(^2\) These attributes may assist with lowering the sorption temperature and pressure, reducing the activation energy barrier and potentially allowing for hydrogenation and dehydrogenation to occur. This work focuses on the novel synthesis and characterization of an FLP system.

C71.00193: Improving Cyclability of Metal Borohydrides for Hydrogen Storage via Non-Metallic Borohydride Additives.  ROBERT BELL (Presenter), NICHOLAS STRANGE, NOEMI LEICK, National Renewable Energy Laboratory & Colorado School of Mines, MICHAEL TONEY, SLAC Linear Accelerator Laboratory, THOMAS AUTREY, Pacific Northwest National Laboratory, THOMAS GENNETT, National Renewable Energy Laboratory & Colorado School of Mines — The theoretical ~15 wt% hydrogen content of magnesium borohydride is inaccessible for cyclical desorption/hydrogenation cycles at reasonable temperatures (<300°C) and pressures (<350 bar). However, a variety of additive compounds lower the Mg(BH\(_4\))\(_2\) hydrogen evolution temperature, changing the end state when hydrogen is released, and lowering the melting point of the system. These additives have included other metal borohydrides, metal hydrides, and organics (ether/glyme). Despite many of these additives lowering the liquidus temperature, desirable due to better mixing and higher theoretical kinetics in the melt, these systems often resulted in undesirable matrices upon re-cooling and cease to thermally cycle as expected. This work investigated an alternative family of additives, non-metallic borohydrides; a broad class of low melting point borohydrides. The temperature and hydrogen-evolution dependent phase diagram of these magnesium borohydride and non-metallic borohydride systems was investigated via calorimetry and in-situ diffraction analysis. Results of heat flow and temperature programmed desorption measurements demonstrate the improved thermal cyclability of these systems. The effect of non-metallic cation size on the behavior of these systems will be discussed in detail.
**C71.00194: Tailoring cations in a perovskite cathode for proton-conducting solid oxide fuel cells with high performance**  
MARCO FRONZI (Presenter), ICRE, Xi’an Jiaotong University, XI XU, LEI BI, Quingdao University, ENRICO TRAVERSA, University of Electronic Science and Technology of China — A rational design of a high-performance cathode for proton-conducting solid oxide fuel cells (SOFCs) is proposed in this study with the aim of improving the hydration properties of conventional perovskite cathode materials, thus leading to the development of new materials with enhanced proton migration. Herein, potassium is used to dope traditional Ba$_{0.5}$Sr$_{0.5}$Co$_{0.8}$Fe$_{0.2}$O$_{3-δ}$ (BSCF), which is demonstrated to be a beneficial way for improving hydration, both experimentally and theoretically. The theoretical study was needed to overcome practical limits that hindered direct hydrogen mobility measurements. The novel material Ba$_{0.4}$K$_{0.1}$Sr$_{0.5}$Co$_{0.8}$Fe$_{0.2}$O$_3$ d (BKSCF) shows a lower overall proton migration energy compared with that of the sample without K, suggesting that K-doping enhances proton conduction, which shows an improved performance by extending the catalytic sites to the whole cathode area. As a result, a fuel cell built with the novel BKSCF cathode shows an encouraging fuel cell performance of 441 and 1275 mW cm$^{-2}$ at 600 and 700 °C, respectively, which is significantly higher than that of the cell using the pristine BSCF cathode. This study provides a new and rational way to design a perovskite cathode for proton-conducting SOFCs with high performance.

**C71.00195: Solid-state NMR Studies of Non-Fullerene Acceptor-Based Organic Photovoltaic Active Layers**  
YAO WU, WEIGUO HU, THOMAS RUSSELL (Presenter), Univ of Mass - Amherst — The efficiency of organic photovoltaics has undergone remarkable increases in power conversion efficiencies (PCEs) recently achieving values in excess of 17% due, primarily, to the advent of non-fullerene acceptors (NFAs). To further increase PCEs, understanding and manipulating the morphology over broad range of length scales is necessary. The similarity in the chemical composition of the donors and NFAs limit current methods based on electron densities or refractive indices in discerning details of the morphology. To fill this gap we have used solid-state NMR (ssNMR) where donor and acceptor nuclei have distinct relaxation times that can be used to characterize the crystallinity, crystal size and state of mixing. Here, we present results on several donors and NFA combination where characteristics of the morphology were obtained. Donor and NFA blend film and their pristine films were studied by ssNMR. For PTB7:ITIC, the crystalline forms of ITIC show sensitive dependence on processing conditions. Furthermore, $T_1$ and $T_1ρ$ relaxation times were used to elucidate the phase separation behavior. For PM6:Y6, spin diffusion experiments based on the contrast between the $T_1ρ$ relaxation times of PM6 and Y6 are able to detect phase separation at a length scale of <15 nm.

*We thank ONR.*
C71.00196: Single-junction and Tandem Cu$_2$BaSnS$_4$ Solar Cells with a TaS$_2$ hole contact

ANDREA CROVETTO (Presenter), RASMUS NIELSEN, DTU Physics, Technical University of Denmark, ALIREZA HAJJAFARASSAR, OLE HANSEN, DTU Nanolab, Technical University of Denmark, BRIAN SEGER, IB CHORKENDORFF, PETER VESBORG, DTU Physics, Technical University of Denmark — Solar cells based on the wide band-gap Cu$_2$BaSnS$_4$ (CBTS) absorber have achieved open circuit voltages up to 1.1 V over a short development period, making CBTS an attractive material for tandem photovoltaic and photoelectrochemical cells. In this work, we explore an alternative CBTS growth route based on sulfurization of reactively sputtered oxide precursors, and we propose TaS$_2$ as an alternative back contact material. Compared to direct deposition of CBTS films from ceramic targets, reactive sputtering of oxide precursors can ultimately achieve a higher throughput and a lower cost, with the additional advantage that sulfur contamination of vacuum systems is avoided. The TaS$_2$ compound is selected as a prospective hole-selective contact due to its high work function and its metallic conductivity, which could prevent the losses associated with carrier transport across the semiconducting MoS$_2$ layer. By comparing CBTS solar cells with Mo and TaS$_2$ back contacts, the latter shows a significantly lower series resistance, resulting in a 10% relative efficiency improvement. Finally, we fabricate a proof-of-concept monolithic CBTS/Si tandem cell using a thin Ti(O,N) interlayer intended both as a diffusion barrier and as a recombination layer between the two subcells.

C71.00197: INSTRUMENTATION AND MEASUREMENT SCIENCE —

C71.00198: Development of a Surface Forces Apparatus Featuring Ultrafast Non-resonant Imaging for Measuring Contact Electrification* MATTHEW LIPPY (Presenter), ALEXANDER W BATALLER, North Carolina State University — The charging of surfaces via physical contact, known as contact electrification, is an off-equilibrium phenomenon that spans many lengthscales and can exhibit extreme energy focusing by conversion of diffuse mechanical energy into high energy x-rays. Due to the challenges of performing in-situ measurements of charge separation from buried interfaces, the fundamental mechanisms of contact electrification are still unknown. To make experimental advances in this field, we have developed a new multimodal platform that combines the angstrom precision of a surface forces apparatus with the interfacial access provided by a nonlinear optical measurement, i.e., second harmonic generation. Details of the instrument's design and operation will be presented, which will include preliminary experimental results that tests how contact electrification is affected by monolayer-levels of surface absorbents.

*This project was supported by the Julian Schwinger Foundation through grant JSF-18-09-01000.
C71.00199: Revealing signatures of topologically protected surface states with STM  AN-PING LI (Presenter), Oak Ridge National Lab — Owing to their bulk band topology, 3D topological insulators possess a massless Dirac dispersion with spin–momentum locking at the surface. The onset of a spontaneous magnetization or a broken time-reversal symmetry leads to the formation of an exchange gap in the Dirac band dispersion. In this work, we will present two salient examples to show that STM spectroscopy can be used to detect these signatures of topological surface states. The first is to measure spin–momentum-locked conduction on topological insulator Bi$_2$Te$_2$Se. A multi-probe STM with spin-polarized tips allows us to perform in situ transport measurement to differentiate surface conductance from the bulk and spin-up chemical potential from the spin-down. As a result, a spin-momentum-locked current is revealed which shows ultra-high mobility and polarization. The second is to detect topologically nontrivial magnetic states in MnBi$_2$Te$_4$. Quasi-particle interference patterns are used to probe local dispersions of both surface and bulk electronic structures. The theoretically predicted gaped surface states are evaluated with high spatial resolution. It is expected that tuning of the Fermi level in the exchange gap will result in the emergence of a quantum anomalous Hall effect.

C71.00200: Neutron Scattering at Missouri: Current Status and Future Prospects* HELMUT KAISER (Presenter), THOMAS HEITMANN, JOSEPH SCHAEPERKOETTER, PAUL MICELI, Research Reactor-MURR; Physics & Astronomy, Univ of Missouri, Columbia — The University of Missouri has been operating a nuclear research reactor for more than 50 years and thus has a long history in neutron scattering research. Currently, we have four neutron scattering instruments in service: a triple-axis spectrometer (TRIAX), an unpolarized neutron reflectometer (GANS), and two double-axis diffractometers (2XC and PSD). We will give an overview of the performance of the instruments and of the ongoing research projects. The PSD powder diffractometer has recently been upgraded with new electronics and software and with an expansion from 5 to 15 linear position sensitive He-3 detector tubes. We will illustrate the vast improvement of signal-to-background ratio and highlight ongoing research projects. Future plans to expand our suite of neutron instruments include a thermal neutron beam imaging station. We present a conceptual design and Monte Carlo calculations. The science case concerning Plant Imaging and Tomography will be discussed.

*Supported by NSF Grant No. DGE-1060091 and MURR
C71.00201: A robust software interface for a green astro-comb: remote control and automation* WILLA DWORSCHACK (Presenter), Physics and Astronomy, Lawrence University, AAKASH RAVI, Physics and Astronomy, Harvard University, DAVID PHILLIPS, Physics and Astronomy, Harvard | Smithsonian Center for Astrophysics, RONALD WALSWORDTH, Physics and Astronomy, Harvard University — Using the Doppler effect to search for exoplanets is a powerful technique. State-of-the-art spectrographs such as HARPS-N at the Italian National Telescope are the workhorse tools in such searches. Though their stability is excellent, it isn't sufficient to detect Earth-like planets around Sun-like stars due to the extremely small Doppler shifts associated with such systems (~100 kHz shifts of optical transitions). A visible wavelength, broadband 16 GHz laser frequency comb (astro-comb) can precisely calibrate spectra to resolve these Doppler shifts, but operation of this instrument requires maintenance and laser expertise. Here, we report on the successful development and implementation of a LabVIEW program that remotely operates an astro-comb and has automation features, relieving the need for on-site scientists at the Italian National Telescope on the Canary Islands and making this tool accessible to a larger community of researchers.

C71.00202: The Structure of Degassed Water-Enabled Oil-in-Water Microemulsions* KYLE WILLIAMS (Presenter), JOSE L BANUELOS, Physical Science, University of Texas at El Paso — Most anticancer agents are hydrophobic and their use on patients often requires an oil & drug delivery vehicle. The drug delivery vehicle tends to be the primary cause of side effects in patients. Growing evidence suggests that it may be possible to mix oil in water at higher concentrations if dissolved gases are removed from water. Understanding the structure of oil/water microemulsions could shed light on mechanisms of mixing. This project uses small-angle x-ray scattering, dynamic light scattering, and turbidity measurements to assess the structure of hydrophobic molecules mixed with degassed water. Results of nanostructure as a function of alkane molecule chain length and concentration will be presented. These results will be compared to the same measurements of biocompatible fatty acids. Determining the properties that enable their miscibility with an aqueous environment will be helpful for future drug delivery.

C71.00203: Increasing the Nanoparticle Size Detection Sensitivity of Dynamic Light Scattering using Wavelength Dependent Excitation*  
DANIEL GUZMAN (Presenter), HRISTO V IVANOV, BRYAN M AUGSTEIN, JEFFREY SIMPSON, Physics, Towson University — We report on the development of homebuilt Dynamic Light Scattering (DLS) instrumentation to measure the size of monodisperse (MD), spherical nanoparticles (NPs) of gold. HeNe and Ar-ion lasers constitute the excitation sources for the scattering experiment, while an avalanche photodiode detects the scattered light, and an autocorrelation card analyzes the resulting signal to provide a measurement of the translational diffusion coefficient, which allows for the determination of NP diameter. We characterized our instrumentation using commercially-produced gold NPs with diameters ranging from 10nm to 200nm in aqueous solution. The strong wavelength \( \lambda \) dependence of the scattered light intensity \( (1/\lambda^4) \) provides increased sensitivity for smaller excitation wavelengths. We present DLS measurements on gold NPs using excitation from both a HeNe laser \( (\lambda = 632.8\text{nm}) \) and a tunable Argon laser \( (457\text{nm} < \lambda < 515\text{nm}) \). The increased scattering from the shorter wavelengths should increase our sensitivity to smaller particles.

C71.00204: Application of edge detection techniques to ARPES data*  
LUIS PERSAUD (Presenter), CHRISTOPHER SIMS, GYANENDRA DHAKAL, FIROZA KABIR, MD MOFAZZEL HOSEN, YANGYANG LIU, SABIN REGMI, KLAUSS DIMITRI, MADHAB NEUPANE, Univ of Central Florida — Edge detection and similar image analysis techniques are commonly used in computer vision but have not been fully realized for the purpose of ARPES data analysis. Without applying any Image analysis, the interpretation of ARPES data is left to the eyes of researchers and can be tricky and unreliable due to many sources of noise and distortion from the experimental processes, as a result, some of the finer, defining, details required to classify a material can be missed. By applying edge detection techniques, we are able to highlight key features such as distinct, clustered bands and other fine details that may otherwise have been obscured by noise and other experimental artefacts. Here we show the implementations of various image processing techniques applied to ARPES data and how they not only aid the interpretation of results, but can also be looked upon as stepping stones for better data processing techniques and potential automation of the classification of quantum materials through ARPES.

Constructing New Patterns for Structured Illumination Microscopy

CHI MING KAN (Presenter), The University of Hong Kong — Ernst Abbe derived his famous formula of diffraction limit in 1873. The implication of this formula is that resolution of light microscopy is limited, which is in the magnitude of half of the wavelength of the light used in microscope. With the advancement in information theory and fluorescence techniques, going beyond theoretical limit stated by Abbe became possible. These methods are known as ‘super-resolution microscopy’ and one of them is structured illumination microscopy (SIM).

The basic idea of SIM is similar to that of Moiré pattern. By overlapping two finely spaced patterns, a slowly varying pattern of large fringes can be observed, in analogous to sound beats. By constructing a known finely spaced pattern, and illuminate it onto an unknown finely spaced pattern, fine details of unknown pattern can be reconstructed from the overlapped pattern observed with computer algorithms. Our group would like to explore and design new interference light patterns by manipulating optics and investigate whether a better lateral and axial resolution could be achieved.

Focused Ion Beam Pt for Cryogenic Resistive Thermometry

PORTIA ALLEN (Presenter), KIRSTEN BLAGG, MEENAKSHI SINGH, Colorado School of Mines — Local temperature measurements at cryogenic temperatures are important for studying thermal effects, both classical and quantum, in nanoscale devices. Resistive thermometry is a relatively simple way to obtain these measurements. However, most metals’ electron transport saturates at low temperatures, leading to constant resistances and making them ineffective for cryogenic thermometry. An exploration of Pt thermometers, deposited using a focused ion beam (FIB) system, reveals that they are very effective for low temperature thermometry. This is believed to be because of the carbon contamination of the Pt. A detailed analysis of the dependence of composition of the contaminants on deposition parameters and its effect on thermometer performance is presented here. Through this research, it is clear that FIB Pt offers a tunable, sensitive, template-free thermometer for nanoscale, cryogenic thermometry.

*We would like to acknowledge NSF DMR 1807583.

Medical Physics

Aggregation Dynamics of Blood Platelets

SURESH AHUJA (Presenter), xerox corporation — Platelet aggregation at sites of vascular injury is necessary for hemostasis and arterial thrombosis and occurs via platelet–platelet adhesion, tethering and rolling on the injured endothelium, a critical initial step in blood clot formation. In straight vessels, the presence of erythrocytes, red blood cells (RBCs) is known to push platelets toward walls, which may affect platelet aggregation and thrombus formation. Blood Cells for required optimizing coagulation. Model predictions on platelet to platelet collisions and of platelets to the capillary wall showed that platelet size, platelet Young’s modulus and shear rate are most significant variables controlling capillary aggregation and thrombus. Results are compared with available experimental results.
C71.00209: A Novel Energy-Resolved X-Ray Semiconductor Detector  TENGFEI YAN (Presenter), XIAODONG CUI, department of physics, the university of Hong Kong, CHUNLEI YANG, Chinese academy of sciences, Shen Zhen Institutes of Advanced Technology — The hyperspectral X-ray imaging has long been sought in various fields from material analysis to medical diagnosis. Here we propose a new semiconductor detector structure to realize energy-resolved imaging at potentially low cost. The device is designed based on the strong energy-dependent absorption of X-ray in solids. Namely, depending on the energy, X-ray photons experience dramatically different attenuation. An array or matrix of semiconductor cells is used to map the X-ray intensity along its trajectory. With known X-ray attenuation coefficient, the X-ray spectrum could be extracted from a Laplace like transform or a supervised machine learning. We conceptually demonstrated an energy-resolved X-ray detection with a regular silicon camera.

C71.00210: Improved Sensitivity of a Single-Sided Magnetic Particle Imaging Scanner*  JASON PAGAN (Presenter), AMANUEL NEGASH, Physics Dept, Univ of Mass - Boston, JUEHAO LIN, Engineering Dept, Univ of Mass - Boston, ALEXEY TONYUSHKIN, Physics Dept, Univ of Mass - Boston — Magnetic Particle Imagining (MPI) is the new frontier of medical imaging, capable of imaging the distribution of superparamagnetic nanoparticles (SPIOs) in an expeditious and sensitive manner. For instance, the accumulation of SPIOs in tumor tissue, serving as tumor markers, presents the MPI device as a practical means of imaging for in vivo cancer imaging. The single-sided design is beneficial for this application allowing imaging of larger subjects. In our design of a scanner we utilize a field-free line (FFL) geometry of the magnetic field zero, which has a potential advantage of an increased sensitivity over the traditional approach with field-free point (FFP). Our prototype device uses a single primary coil to generate a magnetic excitation field. The SPIOs response to the excitation is detected by a planar receive coil on the surface of the device. Due to a single-sided geometry, differentiating a small signal on a strong excitation background becomes a challenging task and further impinges the potential sensitivity gain, thus a new planar gradiometer coil configuration was developed. Results from the numerical simulations and experimental data imply the improved sensitivity of the device over the single coil design.

*This work supported by NIH under Award 1R15EB028535-01.
C71.00211: Retrospective quantitative harmonization in PET using deconvolution and optimal filtering

MAURO NAMÍAS, Medical Physics, Fundación Centro Diagnóstico Nuclear, DANIEL HUFF (Presenter), AMY J WEISSMAN, TYLER J BRADSHAW, ROBERT JERAJ, Medical Physics, University of Wisconsin - Madison — The reliability of longitudinal quantitative PET image analysis suffers if scans are acquired on different PET scanners. Here, we describe a post-reconstruction harmonization method that can be implemented to enable quantitative PET analysis across scanners.

First, images are unfiltered by Wiener deconvolution. Then, the differences in contrast recovery coefficients (CRC) from NEMA phantom scans are minimized by finding isotropic 3D Gaussian filters for each scanner/reconstruction setting combination with a downhill-simplex optimizer. After optimal filters are established, PET images to be harmonized are unfiltered using Wiener deconvolution, and then re-filtered with the determined optimal settings.

We demonstrate that the method minimizes differences in CRC values for a set of 7 heterogeneous reconstruction protocols acquired on 3 different PET/CT scanners. We apply our method retrospectively to 18F-FDG PET/CT scans of a cohort of metastatic melanoma patients to show that performing harmonization has a significant impact in assigning lesion response as measured by change in PET SUV metrics.

In conclusion, the described method for harmonization enables accurate quantitative PET image analysis for retrospective datasets, and has clinical impact in response assessment settings.

C71.00212: WITHDRAWN ABSTRACT

C71.00213: Magnetic Resonance Imaging Thermography with Uniform Gd Microstructures

JASON NOBLES (Presenter), KEVIN SMILEY, SARA GOLDMAN, JOHN STROUD, University of Colorado, Colorado Springs, KARL STUPIC, National Institute of Standards and Technology, ZBIGNIEWS J CELINSKI, JANUSZ HANKIEWICZ, University of Colorado, Colorado Springs — Magnetic resonance imaging is an important technique in imaging living tissue and composite structures. Many medical procedures now use MRI as a critical component including MRI guided thermal ablation therapy used to treat cancer. Such procedures require real-time, spatially and thermally accurate temperature maps.

We demonstrate an MRI temperature contrast agent consisting of uniform gadolinium microstructures dispersed within a media. We report on the performance of 6 micron wide, disk-shaped Gd microstructures passivated by a layer of chromium. A SQUID magnetometer was used to determine the mass magnetization of these disks. The temperature dependence of the mass magnetization was then correlated to the nuclear magnetic resonance linewidth broadening of water protons in the presence of Gd disks. We used this correlation to demonstrate the MRI image brightness of the Gd microstructures suspended in a tissue-mimicking phantom can be related to the temperature of the sample indicating these Gd disks are a good candidate for use as an MRI temperature contrast agent.
**C71.00214: Simple physical modeling for comparing respirator breathing resistance standards**  
DANA ROTTACH (Presenter), SUSAN XU, CAITLIN MCCLAIN, WILLIAM KING, NIOSH-CDC — Air purifying respirators are designed to reduce the number of hazardous particles respired by wearers. One barrier to respirator use is their inherent increase in breathing difficulty. The National Institute for Occupational Safety and Health (NIOSH) evaluates respirators using Standard Test Procedures (STP) for various factors, including measuring the breathing resistance as the pressure drop across the filter at a certain relatively high flow rate. The International Standards Organization (ISO) has a competing standard based on a 'Work of Breathing' (WOB) concept, which considers Pressure-Volume (PV) work for a series of sinusoidal simulated breaths with frequencies and magnitudes reflecting a variety of occupational scenarios, from resting to intense physical exertion. We compare the WOB and NIOSH breathing resistance limits using a simple linear model, which reflects the most common type of particulate filtering respirators. We find that the NIOSH result is more stringent than the ISO standard for most of the ISO work rates, Resting, W1, W2, and W4, but is less stringent for the moderately high W3 work rate. The effect of the non-linear flow characteristics associated with exhalation valves will be discussed along with the results of a less rigorous treatment.

**C71.00215: Deflector Cavity Design for Rapid 2-D Proton Beam Scanning**  
EMMA SNIVELY (Presenter), XUEYING LU, EMILIO NANNI, ZENGHAI LI, VALERY DOLGASHEV, GORDON BOWDEN, ANN V. SY, SAMI TANTAWI, SLAC - Natl Accelerator Lab — We investigate the design of a 2.856 GHz deflecting cavity to provide rapid 2-D beam scanning for hadron therapy. We consider geometries for both conventional TM$_{11}$ modes and TE$_{11}$-like modes. Designs are optimized for the case of sub-relativistic protons with 150 MeV kinetic energy using simulations in HFSS to characterize the full 3-D field profile. We discuss the challenge of maximizing the transverse shunt impedance while mitigating variations in the transverse voltage as a function of distance from the nominal beam axis. These changes in the effective transverse kick can lead to significant beam profile aberrations for non-relativistic particles.

*This research has been supported by the U.S. Department of Energy (DOE) under Contract No. DE-C02-76SF00515.*
C71.00216: Comparative Pharmacokinetics, Biodistribution and Dosimetry of $^{212}$Pb labeled Antibody vs Peptide vs Small Molecule  
NADER MOSHIRI (Presenter), Florida Atlantic University, GEORGE SGOUROS, Radiology, Johns Hopkins School of Medicine, THEODORA LEVENTOURI, Florida Atlantic University — We study the impact of carrier molecules in biodistribution and absorbed dose in normal tissue and tumors using $^{212}$Pb radionuclide. $^{212}$Pb ($T_{1/2} = 10.64$ hrs) decays to $^{212}$Bi ($T_{1/2} = 60.6$ mins) via β emission then finally stable $^{208}$Pb via α and γ decays. The effective $T_{1/2}$ could vary a lot depending on the carrier molecule. In this study, rats and mice data of $^{131}$I, $^{166}$Ho, $^{153}$Sm and $^{177}$Lu labeled DOTATATE, $^{111}$In and $^{212}$Pb labelled trastuzumab and $^{188}$Re-HEDP were utilized and fitted via SAAM II software. To calculate absorbed doses, the AUC of each organ was multiplied by the S values provided in MIRD scheme. RBE value of 5 was used to take into account the biological effect of the doses.

The highest level of radioactivity indicating the amount of absorbed dose was detected in bladder, pancreas, intestines, bone and kidneys for DOTATATE, while it was cleared out of the blood within a few hours post injection. In contrast to the peptide carrier, the antibody carrier, remained in the blood significantly longer with increased uptake in the liver after 78 hrs while decreasing everywhere else steadily. For the small molecule carrier HEDP, the main concentration was found in bone followed by kidney, thyroid, stomach, liver and blood. Quantitative analysis of effective doses is in progress.

C71.00217: Rotation- and reflection-encompassing multispectral nonlocal means denoising filter for magnetic resonance imaging*  
MUSTAPHA BOUHRARA, NIKKITA KHATTAR, RICHARD SPENCER (Presenter), National Institutes of Health - NIH — Image denoising is used extensively in medical image processing. Compared to other advanced filters, nonlocal means (NLM) shows excellent performance while being straightforward to implement. NLM takes advantage of structural redundancy in images by comparing local neighborhoods (local patches) around voxels throughout the whole image. The index voxel is then restored based on a weighted average of all voxels, with the weighting dependent on the degree of similarity. We have extended this by exploiting multispectral (MS) similarity in related images, obtained with a sequence of imaging parameters (1). In addition, we have developed an adaptive user-independent method to define similar voxels (2). The filter exhibits excellent edge preservation and noise reduction in magnetic resonance (MR) images and has been applied to improve parameter determination (3, 4). Here, we introduce a rotation- and reflection-encompassing implementation of our filter, motivated by the fact that patches may be similar only upon rotation. Our results demonstrate the improved performance as compared to our original implementation. This filter has wide applicability in imaging.

C71.00218: QUANTUM INFORMATION —
C71.00219: Deterministic single photon subtraction for engineering exotic non-classical states of light*  SUPRATIK SARKAR (Presenter), JINJIN DU, MICHAL BAJCSY, Institute for Quantum Computing, University of Waterloo — We present an analytical and numerical simulation study of deterministic single photon subtraction using Single Photon Raman Interaction (SPRINT) [1] in a three level Λ-type quantum emitter coupled with a chiral waveguide or cavity. This process of deterministic single photon subtraction is fundamentally different from the usual probabilistic single photon subtraction, which is inherently just the application of the annihilation operator on the incoming light field. Unlike probabilistic single photon subtraction, the photon subtraction probability relying on SPRINT is independent of the number of photons in the input field. We investigate the effects of the repeated application of the deterministic subtraction operator on photonic fields and the resulting changes in phase space statistics that lead to exotic non-classical states of light, such as states with negative Wigner functions and squeezed states. We also discuss the prospects of experimental implementation of this approach.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund.

C71.00220: Using Trapped Ion Chains for Realization of Quantum Error Correction  DAIWEI ZHU (Presenter), LAIRD EGAN, MICHAEL L GOLDMAN, MARKO CETINA, CRYSTAL NOEL, ANDREW REISINGER, DEBOPRIYO BISWAS, CHRISTOPHER ROY MONROE, Joint Quantum Institute, University of Maryland —

We are constructing a quantum processor based on a register of up to 32 trapped 171Yb+ ions, with high connectivity provided by high-fidelity entangling gates. Our goals are to implement an error-corrected logical qubit and to perform a range of quantum algorithms with a system size and gate depth that move beyond what has previously been demonstrated. Here, we report on the current status of our first-generation integrated system, including gate fidelity, hardware performance, and automatic control. We also present the progress toward implementing fault-tolerant logical qubits.
**C71.00221: Exploration of the Circularly Polarized Attosecond Pulse Generation Mechanisms by Polarization Gating**  CHON-TENG BELMIRO CHU (Presenter), Physics, Natl Taiwan Univ, XIAO-MIN TONG, Materials Science, Univ of Tsukuba, SHIH-I CHU, Physics, Natl Taiwan Univ — We perform a fully ab initio investigation of the generation of circularly polarized attosecond pulse of atomic H driven by polarization gating. The time-dependent Schrödinger equation is solved accurately and efficiently by means of the time-dependent generalized pseudospectral method. We investigate the physical mechanism of this process by solving the time-dependent Schrödinger equation in the integral form. In this way, the contribution of the wave function from different time segment to the induced dipole can be analyzed. The dynamic behavior during this process can be unveiled by the Bohmian trajectories of the dominant part of the wave function.

*This work was partially supported by National Taiwan University, the Ministry of Science and Technology and Ministry of Education of Taiwan.

**C71.00222: High resolution AC magnetometry NMR spectrometer development using diamond nitrogen-vacancy centers**  ZHIPAN WANG (Presenter), WILLIAM CASEY, NICHOLAS CURRO, University of California, Davis — Nitrogen-vacancy (NV) quantum defects in diamond are sensitive detectors of magnetic fields. Due to their atomic size and optical readout capability, they have been used for magnetic resonance spectroscopy of exceptionally low volume samples on diamond surfaces. Here we present our approaches to develop and construct a simple, low-cost NV-detected NMR spectrometer. The underlying theory and preliminary experimental data will be presented.

*The work was supported by the United States Department of Energy, Office of Basic Energy Sciences, Chemical Sciences, Geosciences and Biosciences Division for Grant DE-FG0205ER15693

**C71.00223: Microwave to Optical Transducer with Single Emitters**  VINODH RAJ RAJAGOPAL MUTHU (Presenter), WENFANG LI, JINJIN DU, RUBAYET AL MARUF, PRITAM PRIYADARSI, MICHAL BAJCSY, University of Waterloo — In this project, we aim to develop a quantum interface between microwave and optical photons. This is an essential component in realizing a hybrid quantum network where information needs to be interfaced between superconducting microwave circuits, which provide quantum information processing, and optical photons, which are suitable for long-distance communication. Our work investigates the potential of micro-fabricated devices with integrated optical and microwave cavities that use individual three-level solid-state emitters, such as NV centres, for the efficient conversion between the microwave and optical regimes. We present analytical and numerical simulation results that explore the required characteristics of the microwave and optical cavities to achieve high conversion efficiency between the microwave and optical regimes.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund.*
**C71.00224: Growth and characterization of Si/SiGe heterostructures towards scalable qubit architecture**

CEDRIC CORLEY (Presenter), Materials Research, IHP – Leibniz-Institut für innovative Mikroelektronik, YUJI YAMAMOTO, MARKUS ANDREAS SCHUBERT, FLORIAN BÄRWOLF, Technology, IHP – Leibniz-Institut für innovative Mikroelektronik, MARVIN ZÖLLNER, Materials Research, IHP – Leibniz-Institut für innovative Mikroelektronik, INGA SEIDLER, MALTE NEUL, LARS SCHREIBER, JARA-FIT Institute for Quantum Information, RWTH Aachen University, GIOVANNI CAPELLINI, WOLFGANG MATTHIAS KLESSE, Materials Research, IHP – Leibniz-Institut für innovative Mikroelektronik — Strained Si/SiGe Quantum Well (QW) structures are a promising material system for the realization of spin qubits based on spatially confined electrons. A major advantage for Si-based structures is their compatibility with mature Si-CMOS technology, providing high scalability. In this study we show a first step towards determining the relationship between the material properties (e.g. interface roughness and defect density) and qubit performance of these structures. In order to discuss the influence of the material properties of the QW, tensile strained Si QW embedded in Si$_{0.7}$Ge$_{0.3}$ layers with different types of SiGe buffer layers are fabricated on 200 mm Si substrates. The material properties are characterized by various methods (X-Ray Diffraction, Secondary Ion Mass Spectrometry, Scanning Transmission Electron Microscopy).

*The "SiGeQuant (High-definition crystalline Silicon-Germanium structures for Quantum Circuits)" project is supported by the Leibniz-Gemeinschaft (Senatsausschuss Wettbewerb, SAW) under the project number K124/2018.*

**C71.00225: WITHDRAWN ABSTRACT**

**C71.00226: Electric manipulation of a valley qubit in a silicon quantum dot**

PEIHAO HUANG (Presenter), Institute of Quantum Science and Engineering, Southern University of Science and Technology — In a silicon quantum dot, the valley states can be encoded as a qubit for quantum information processing. Here, we study theoretically the electric manipulation of valley qubit in a silicon quantum dot. The valley qubit frequency and electric manipulation speed are studied as a function of the location of interface steps and the applied electric field. We find that the applied electric field or the interface state can enhance the electric manipulation of the valley qubit. We further study the combined effect of QD confinement and interface steps on the electric manipulation of valley qubit. We will discuss the consequence of the results on the valley qubit based quantum information processing.
C71.00227: A Platform for Light-Hole Qubits in Group IV Semiconductors  PATRICK DEL VECCHIO, ANIS ATTIAOUI, SIMONE ASSALI (Presenter), OUSSAMA MOUTANABBIR, Ecole Polytechnique de Montreal — Si-compatible quantum devices have been exploiting either tensile strained Si or compressively strained Ge QWs, which are the only group IV systems that can currently be routinely obtained using SiGe as growth template and barrier layers. For quantum information, the former has been used as the building block for electron spin qubits, whereas the latter has been explored in new schemes for hole spin qubits. Herein, we present a third low-dimension system consisting of highly tensile strained Ge QW integrated on an optically active platform and discuss its basic properties experimentally and theoretically. The growth of tensile strained Ge QW is achieved using direct bandgap GeSn as barrier layers grown on silicon wafers. This heterostructure yields high tensile strain in Ge QW and band structure corresponding to a sizable LH-HH splitting exceeding 100 meV. Unlike compressively strained Ge, the top of the valence band is occupied by LH in tensile strained Ge. We also found a high LH g-factor anisotropy in Ge/GeSn QW, with g = 21.8 for in-plane B-field and g = 0.69 for perpendicular-to-plane field. These properties lay the groundwork to implement LH spin qubits with potentially easier manipulation due to the combined effects of the large Rashba-type SOI, and the spin ½ of LH.

C71.00228: Observation and stabilization of photonic Fock states in a hot radio-frequency resonator*  MARIO GELY (Presenter), MARIOS KOUNALAKIS, CHRISTIAN DICKEL, JACOB DALLE, RÉMY VATRÉ, Delft University of Technology, BRIAN BAKER, Department of Physics and Astronomy, Northwestern University, MARK JENKINS, GARY STEELE, Delft University of Technology — Detecting and manipulating single-photons at MHz frequencies presents a challenge as, even at cryogenic temperatures, thermal fluctuations are significant. In our work [1], we use a GHz superconducting qubit to directly observe the quantization of a MHz radio-frequency electromagnetic field. Using the qubit, we achieve quantum control over thermal photons, cooling to the ground-state and stabilizing photonic Fock states. Releasing the resonator from our control, we directly observe its re-thermalization dynamics with the bath with nanosecond resolution. Extending circuit QED to a new regime, we enable the exploration of thermodynamics at the quantum scale and allow interfacing quantum circuits with MHz systems such as spins or mechanical oscillators. The tool used to design such a circuit, QuCAT [2], the "quantum circuit analyzer tool in Python" will also be featured in this poster.

*European Research Council under the European Union's H2020 program [grant numbers 681476-QOM3D, 732894-HOT, 828826-Quromorphic, 785219 - GrapheneCore2], the Dutch Foundation for Scientific Research (NWO) through the Casimir Research School, the Army Research Office through Grant No. W911NF-15-1-0421.
C71.00229: Single-Photon Dispersive Readout of a Qubit with a Photodetector: Theory Beyond the Rotating-Wave Approximation* ANDRII SOKOLOV (Presenter), Universität des Saarlandes, Institute of Physics of the National Academy of Sciences of Ukraine, EUGENE V STOLYAROV, Institute of Physics of the Ukrainian Academy of Sciences — We propose to use a single-photon pulse and a photodetector for the dispersive readout of a qubit. The scheme avoids the shot noise errors. However, another source of errors makes it challenging to perform a single-photon readout. To boost its performance, we propose to detune the qubit and the resonator further than usual, while coupling them stronger. The Bloch-Siegert shift then should be taken into account. It is shown how it can improve the readout. We provide simple analytical estimates for the readout contrast. Results of more complicated calculations that take the qubit relaxation into account are also presented. A contrast more than 75% can be achieved in 1μs for ideal detector and photon source.

*Work of A.S. was partly supported by a DAAD scholarship (2016).

C71.00230: Study on the cavity photon induced dephasing of a transmon qubit in circuit QED due to the measurement microwave leakage JISOO CHOI, Korea Research Inst of Standards and Science (KRISS), Korea University, GAHYUN CHOI (Presenter), Korea Research Inst of Standards and Science (KRISS), GWANYEOL PARK, Korea Research Inst of Standards and Science (KRISS), Korea University, JINSU SON, Korea Research Inst of Standards and Science (KRISS), KWAN-WOO LEE, SOON-GUL LEE, Korea University, WOON SONG, Korea Research Inst of Standards and Science (KRISS), YONUK CHONG, Korea Research Inst of Standards and Science (KRISS), University of Science and Technology (UST) — Qubit coherence is one of key features in quantum computing. In circuit QED architecture, it is known that the cavity photon induces dephasing of the qubit even in the dispersive regime [1, 2]. In this study, we studied in detail the dephasing of a 3D transmon qubit generated by the measurement microwave tone. First, we observed that the intense measurement microwave tone decreases the dephasing time. In order to avoid the dephasing, we controlled the mixer leakage by applying dc-offset voltage. We observed clear dependence of the measurement microwave leakage and dephasing, so that we can optimize our measurement setup to achieve maximum T_{2*}. This calibration method is one of the standard features in our measurement system to preserve the qubit coherence.

C71.00231: Enhancement in the cross-resonance gate performance XUEXIN XU (Presenter), MOHAMMAD ANSARI, Forschungszentrum Juelich — We theoretically model an experiment on a superconducting circuit made of a capacitively shunted flux qubit (CSFQ) and a transmon both capacitively coupled to a bus resonator in dispersive regime. We apply external driving microwave pulses over all energy levels and consider the transitions they impose effectively within the computational subspace. More specifically we apply entirely microwave two-qubit gate, the so called cross-resonance, on CSFQ at sweet spot and away from it. Interestingly the two-qubit fidelity is largely enhanced at certain external flux away from the sweet spot. This enhancement takes place as the result of suppressed leakage out of computational subspace.
C71.00232: Spectrum and Coherence of the Current-Mirror Circuit* DANIEL WEISS
(Presenter), CHEONG YIU LI, Northwestern University, DAVID FERGUSON, Northrop Grumman - Mission Systems, JENS KOCH, Northwestern University — The current-mirror circuit [1] exhibits a robust ground-state degeneracy and wave functions with disjoint support for appropriate circuit parameters. In this protected regime, Cooper-pair excitons form the relevant low-energy excitations. Based on a full circuit analysis of the current-mirror device, we introduce an effective model that systematically captures the relevant low-energy degrees of freedom, and is amenable to diagonalization using Density Matrix Renormalization Group (DMRG) methods. We find excellent agreement between DMRG and exact diagonalization, and can push DMRG simulations to much larger circuit sizes than feasible for exact diagonalization. We discuss the spectral properties of the current-mirror circuit, and predict coherence times exceeding 1 ms in parameter regimes believed to be within reach of experiments.

*This research was supported by the Army Research Office under contract W911NF-17-C-0024.

C71.00233: Qubit fast reset with QubiC* GANG HUANG (Presenter), YILUN XU, Lawrence Berkeley National Laboratory, RAVI KAUSHIK NAIK, BRADLEY MITCHELL, Physics, University of California, Berkeley, DAVID SANTIAGO, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, Physics, University of California, Berkeley — Fast reset is a basic qubit control feedback loop where the hardware latency is critical. We develop the fast reset logic on the QubiC system by implementing the qubit status classification and the feedback loop in the FPGA firmware. The experiment setup and initial testing results are presented here.

*This work was supported by the Department of Energy under Contract No. DE-AC02-05CH11231.

C71.00234: Exploring 3D architectures and superconducting interconnects using highly conformal ALD and CVD: a BEOL-compatible process for superconducting MgB$_2$ DAVID J MANDIA, DEVIKA CHOUDHURY, Argonne National Laboratory, NEIL T ANDERSON, GREGORY S GIROLAMI, University of Illinois at Urbana-Champaign, JEFFREY W ELAM, ALI NASSIRI, ANGEL YANGUAS-GIL (Presenter), Argonne National Laboratory — The ability to fabricate 3D architectures and superconducting interconnects can be an enabling technology towards the scale up of quantum computing architectures. One of the key challenges is that physical vapor deposition methods, such as evaporation or sputtering, struggle to coat or infiltrate high aspect ratio structures, being traditionally limited to aspect ratios of 10:1 or lower. In this work we explore how to take advantage of the high conformality of ALD and some CVD processes to overcome this limitation. In particular, we have developed a BEOL-compatible, diborane-free process that is capable of growing superconducting magnesium diboride at low temperatures. This process has allowed us to demonstrate critical temperatures exceeding 20K in films that are just a few nm thick, and the formation of stable interfaces with oxide materials. Together with existing ALD processes for superconducting nitrides, we believe that this process can help us explore new device configuration, including the design of architectures with vertical junctions, or the development of superconducting interposers for advanced packaging applications.
C71.00235: Impact of noise reduction in measurement of a super conducting flux qubit at 4.2 K
DAISUKE SAIDA (Presenter), AIST, NARI WATASE, MDR Inc., TAKEHITO KAMIMURA, SHINGO
SOBUKAWA, HIROHITO WATANABE, NF Corporation, YUKI YAMANASHI, Yokohama National University
— A flux state of a super conducting flux qubit is evaluated at 4.2 K prior to measurement of
quantum state at mK. At the 4.2 K measurement, a customized rod, where a sample is attached,
is inserted in the Dewar vessel filled in the liquid helium. An elimination of artifact from an
experimental system is crucial. In order to prevent signal quality deterioration by environmental
noise, countermeasures have been taken by strengthening the electrostatic shield and
introducing the twisted pair wiring. Low noise voltage source (LP6016) for bias current control of
SQUID is also effective in suppressing signal fluctuation from SQUID. As a result, noise density at
50 Hz and 150 Hz in the measurement became 1/300 and 1/500 compared to the previous
experiment, respectively. We evaluated the flux state in the super conducting flux qubit through
an observation of signal in a readout-SQUID. This sample was fabricated by AIST Nb standard
process 2, where $J_c$ was 25 μA/μm$^2$. On a flux dependence of threshold current ($I_{th}$) in the
readout-SQUID, standard deviations ($\sigma$) of $I_{th}$ was 0.16. This indicates that we can control an
operating point of the readout-SQUID in an accuracy of the measurement with an order less than
1 μA. Further, $\sigma << 1$ was evaluated when we observed flux conditions in the qubit.

C71.00236: Search by Lackadaisical Quantum Walk with Nonhomogeneous Weights*
MASON RHODES (Presenter), TOM WONG, Creighton University — The lackadaisical quantum walk, a
quantum walk with weighted self-loops, speeds up dispersion on a line and improves spatial
search on the complete graph and periodic square lattice. In these investigations, each self-loop
had the same weight, due to each graph's vertex-transitivity. In this paper, we propose
lackadaisical quantum walks with self-loops of different weight. We investigate spatial search on
the complete bipartite graph, which can be irregular with partitions of size $N_1$ and $N_2$, which
naturally leads to self-loops having different weights $l_1$ and $l_2$, respectively. We prove that if the $k$
marked vertices are confined to one partite set, then with the typical initial uniform state over the
vertices, the success probability is improved from its non-lackadaisical value when $l_1 = kN_2/2N_1$
and $N_2 > (3-2\sqrt{2})N_1$, regardless of $l_2$. When the initial state is stationary under the quantum walk,
however, the success probability is improved when $l_1 = kN_2/2N_1$ without a constraint on the ratio
of $N_1$ and $N_2$. Next, when marked vertices lie in both partite sets, then for either initial state, there
are many configurations for which the self-loops yield no improvement in quantum search, no
matter what weights they take.

*This work was supported by T.W.'s startup funds from Creighton University.
C71.00237: Trimming Grover's Quantum Search Algorithm*  GRANT EBERLE (Presenter), GONZALO ORDONEZ, Butler University — Grover's quantum algorithm is a complicated search algorithm made to run on a quantum computer. The algorithm allows users to search a database for a word in a significantly shorter time than a conventional computer. Past experiments have attempted to run iterations of the algorithm on a quantum computer and failed because of the complexity. My research modifies and simplifies the theory of Grover's algorithm by utilizing results from previous work that studied the diffusion of wave functions across a hypercube. I have directly applied this diffusion process to an edited and simplified version of Grover's algorithm based on the premise of simplifying the connections and paths between q-bits represented on a hypercube. The algorithm I have created has been run and tested on the open-source quantum computer simulations provided by IBM on their IBM Q website. My results display a trimmed and practical version of Grover's quantum search algorithm.

*Funding was provided by the Butler University CHASE scholars program and the Butler University Department of Physics and Astronomy.

C71.00238: Quantum simulations and force sensing experiments with 2D arrays of 100's of ions*  ELENA JORDAN (Presenter), MATTHEW AFFOLTER, KEVIN A. GILMORE, National Institute of Standards and Technology Boulder, ATHREYA SHANKAR, University of Colorado, Boulder, ARGHAVAN SAFAVI-NAINI, ROBERT J. LEWIS-SWAN, JILA, NIST, and University of Colorado Boulder, MURRAY J HOLLAND, University of Colorado, Boulder, ANA MARIA REY, JILA, NIST, and University of Colorado Boulder, JOHN JACOB BOLLINGER, National Institute of Standards and Technology Boulder — We perform quantum simulations and quantum sensing with two-dimensional arrays of >100 trapped ions in a Penning trap [1, 2]. In our quantum sensing experiments, we measure small displacements of the ion crystal. Electric fields excite center-of-mass (COM) motion of the crystal. By measuring the motion-induced spin precession we can determine the amplitude of the COM motion and the strength of the exciting field [2]. Improvements in the phase stability of our coupling lasers enabled phase coherent detection protocols, resulting in a single measurement sensitivity of 50 pm for the COM motion that was far off-resonant with the trap axial frequency. 50 pm is about a factor 40 below the size of the ground state wavefunction. Further, we show results of electromagnetically induced transparency (EIT) cooling for the drumhead motion of the single-plane arrays [3, 4]. We present results that show simultaneous cooling of all the drumhead modes to close to the ground state of motion.

*We gratefully acknowledge NIST, Leopoldina (German Academy of Sciences), NSF, and DOE.

C71.00239: WITHDRAWN ABSTRACT —
C71.00240: QAOA Algorithms for Traveling Salesman Problem Revisited

CHANGYUAN LIU (Presenter), BigCompute — The traveling salesman problem is a traditionally NP-hard problem. Earlier quantum algorithm encodes the qubits based on vertices, while we encode the qubits based on edges, with a resources requirement halved. With edge encoding scheme, QAOA algorithm is demoed with small cases, on a classical enumlator, with the optimal solutions successfully found. The algorithm has polynomial complexity in terms of the number of quantum operations.

*N/A - Self supported

C71.00241: Implementation of excited state energy and its analytical derivatives for photochemical reaction simulations on NISQ devices

YOHEI IBE (Presenter), TAKAHIRO YAMAMOTO, YUYA O. NAKAGAWA, QunaSys Inc., KOSUKE MITARAI, Graduate School of Engineering Science, Osaka University, TENNIN YAN, QunaSys Inc., GAO QI, TAKAO KOBAYASHI, Mitsubishi Chemical Corp. — A primitive but still powerful form of quantum computers called Noisy Intermediate-Scale Quantum (NISQ) devices is about to be utilized for the real-world problems. NISQ devices have a few hundreds to thousands of qubits under highly precise control although they are not fault-tolerant.

A quantum chemistry calculation is one of the most promising applications of NISQ devices in the near future, and Variational Quantum Eigensolver (VQE) is the most featured algorithm to take advantage of NISQ devices in quantum chemistry. Recently, numerous algorithms based on the VQE are proposed for solving problems that are hard for classical computers, such as calculations of electronic excited states of large molecular systems.

However, VQE-type algorithms are in general based on the variational principle, which makes it difficult to predict their performances when applied to actual molecular systems due to their heuristic nature.

In this study, using the high-speed simulator Qulacs, we implement VQE-type algorithms to calculate several physical properties (analytical energy derivatives and oscillator strengths) required for photochemical reaction simulations and create their unified benchmark of various proposed methods for small molecules compared with results from the classical computation.
C71.00242: The Quantum Alternating Operator Ansatz on Max-k Vertex Cover  JEREMY COOK (Presenter), STEPHAN EIDENBENZ, ANDREAS BÄRTSCHI, Theoretical Division, Los Alamos National Laboratory — We study the performance of the Quantum Alternating Operator Ansatz (a generalization of the QAOA for problems with hard constraints) on the problem of Max-k Vertex Cover due to its modest complexity, while still being more complex than the well studied problems of Max-Cut and Max-E3LIN2. Our approach includes (i) a performance comparison between easy-to-prepare classical states and Dicke states, (ii) a performance comparison between two XY-Hamiltonian mixing operators: the ring mixer and the complete graph mixer, (iii) an analysis of the distribution of solutions via Monte Carlo sampling, and (iv) the exploration of efficient angle selection strategies. Our results are: (i) Dicke states improve performance compared to easy-to-prepare classical states, (ii) an upper bound on the simulation of the complete graph mixer, (iii) the complete graph mixer improves performance relative to the ring mixer, (iv) the standard deviation on the distribution of solutions decreases exponentially in p (the number of rounds in the algorithm), requiring an exponential number of random samples find a better solution in the next round, and (iv) a correlation of angle parameters which exhibit high quality solutions that behave similarly to a discretized version of the Quantum Adiabatic Algorithm.

C71.00243: Optimizer-aware Circuit Design for Error Unfolding in Variational Quantum Eigensolver  WIM LAVRIJSEN, MIROSLAV URBANEK, MEKENA L METCALF, JULIANE MÜLLER, BENJAMIN NACHMAN, DIANA CHAMAKI, COSTIN IANCU (Presenter), WIBE A DE JONG, Lawrence Berkeley National Laboratory — Quantum hardware suffers from errors and any measured output is thus a convolution of the intended result and some error distribution. The Variational Quantum Eigensolver has a classical optimizer step that takes the output from the quantum chip to determine the input parameters for the next iteration. Errors can prevent the optimizer from making progress; and if they are too large, make it impossible to calculate, let alone find, the global minimum. If the error distribution were known, it could be unfolded, but this is generally not the case, especially if the errors do not commute with the whole circuit. Exploiting ideas from randomized compilation, we introduce twirl gates into the circuit, generating logically equivalent circuits with the same number of gates and same output, but with different error behavior. The physical processes do not change, thus error rates remain the same as well. Using a Markov chain as error model, we apply a maximum likelihood fit to find those rates that produce migration matrices for unfolding consistent with all observed distributions. This results in improved output estimates of the quantum computer, and better defined uncertainties as input to the classical optimizer leading to faster convergence and a more robustly defined global minimum.
C71.00244: Benchmarking Noise Extrapolation with OpenPulse*  EUGEN DUMITRESCU (Presenter), RAPHAEL POOSER, Oak Ridge National Lab, JOHN GARMON, Virginia Tech — In order to augment digital qubit metrics, such as gate fidelity, we discuss analog error mitigability, i.e. the ability to accurately distill precise observable estimates, as a hybrid quantum-classical computing benchmarking task. Specifically, we characterize single-qubit error rates on IBM's Poughkeepsie superconducting quantum hardware, incorporate control mediated noise dependence into a generalized rescaling protocol, and analyze how noise characteristics influence Richardson extrapolation-based error mitigation. Our results identify regions in the space of Hamiltonian control fields and circuit-depth which are most amenable to reliable noise extrapolation, as well as shedding light on how low-level hardware characterization can be used as a predictive tool for uncertainty quantification in error mitigated NISQ computations.

*This work was performed with DOE ASCR funding under the Quantum Testbed Pathfinder program, FWP number ERKJ332.

C71.00245: Modeling Quantum Devices and the Reconstruction of Physics in Practical Systems*  HANG REN (Presenter), Nankai University, YING LI, Graduate School of China Academy of Engineering Physics — Modeling quantum devices is to find a model according to quantum theory that can explain the result of experiments in a quantum device. We find that usually we cannot correctly identify the model describing the actual physics of the device regardless of the experimental effort given a limited set of operations. According to sufficient conditions that we find, correctly reconstructing the model requires either a particular set of pure states and projective measurements or a set of evolution operators that can generate all unitary operators.

*This work was supported by National Natural Science Foundation of China (Grant No. 11875050) and NSAF (Grant No. U1730449).
YICHEN ZHANG (Presenter), Beijing University of Posts and Telecommunications, ZIYANG CHEN, Peking University, BINJIE CHU, CHAO ZHOU, XIANGYU WANG, YIJIA ZHAO, YIFAN XU, CHAO XU, HONGJIE WANG, ZIYONG ZHENG, YUNDI HUANG, CHUNCHAO XU, XIAOXIONG ZHANG, TAO SHEN, GE HUANG, YUNWU ZHENG, ZHAOXUAN FEI, WEINAN HUANG, MENG LIN ZHU, LUYU HUANG, BIN LUO, SONG YU, Beijing University of Posts and Telecommunications, HONG GUO, Peking University — Continuous-variable quantum key distribution (QKD) is a very attractive method for the physical layer protection of information transmission by secure distribution of private keys, as it uses standard telecom components that operate at room temperature and it has higher secret key rates (bits per channel use) over metropolitan areas. The longest distance of continuous-variable QKD field tests has reached 50 km, which is enough to support the construction of metropolitan networks. Here, we report the long-term performance of three nodes continuous-variable QKD network in Qingdao, which is the first continuous-variable QKD application demonstration with clear application scenarios over a long period of time through existing commercial optical fiber links. The average secret key rate achieves higher than 12.00 kbps over 71.03 km optical fiber line. The system has been running for 28 days stably with a reliable performance, which paves the way to deploy continuous-variable QKD in metropolitan settings.

*This work was supported by National Natural Science Foundation of China under Grants 61531003.

YICHEN ZHANG (Presenter), Beijing University of Posts and Telecommunications, ZIYANG CHEN, Peking University, CHRISTIAN WEEDBROOK, Xanadu, BIN LUO, SONG YU, Beijing University of Posts and Telecommunications, HONG GUO, Peking University — The continuous-variable quantum key distribution with entanglement in the middle, a semi-device-independent protocol, places the source in the untrusted third party between Alice and Bob, and thus has the advantage of high levels of security with the purpose of eliminating the assumptions about the source device. However, previous works considered the collective-attack analysis, which inevitably assumes that the states of the source has an identical and independently distributed (i.i.d) structure, and limits the application of the protocol. To solve this problem, we modify the original protocol by exploiting an energy test to monitor the potential high energy attacks an adversary may use. Our analysis removes the assumptions of the light source and the modified protocol can therefore be called source-device-independent protocol. Moreover, we analyze the security of the continuous-variable source-device-independent quantum key distribution protocol with a homodyne-homodyne structure against general coherent attacks by adapting a state-independent entropic uncertainty relation. The simulation results indicate that, in the universal composable security framework, the protocol can still achieve high key rates against coherent attacks under the condition of achievable block lengths.
**C71.00248: Resource-Adaptable Quantum Algorithms for Scalable Simulation of the Schwinger Model**
ALEXANDER SHAW (Presenter), Oak Ridge National Lab, NATALIE M KLCO, University of Washington, PAVEL LOUGOVSKI, Oak Ridge National Lab, JESSE STRYKER, NATHAN WIEBE, University of Washington — The Schwinger model (quantum electrodynamics in 1+1 dimensions) is a testbed for the study of field theories underpinning the Standard Model. Quantum computers are anticipated to enable unprecedented simulations of field theories. In this work, we give scalable and explicit digital algorithms to simulate the Schwinger model using fault-tolerant quantum computation. We upper bound a relevant metric of computational complexity, the number of T-gates, in terms of the simulation parameters, confirming that the time evolution can be simulated efficiently. Additionally, we give circuits that could be used in a nearer-term (NISQ) implementation of our simulation algorithms.

**C71.00249: Space-Time Mixing of Quantum Computing in an Entangled Atomic Chain and Time Crystals**
ANDREW VAN HORN (Presenter), CHENG-HSIAO WU, Missouri Univ of Sci & Tech — Experimentally observed space-time crystals are modeled here as a 1-D 4-State Cellular Automata (CA) under a specific set of “cyclic” state-transition rules, three of which are analyzed here. The generations of these specific CA rule sets have been previously shown to model the properties of the recently described space-time crystals due to the underlying mathematical model present in these rules. The rules are shown here to display three space-time symmetry rotations in the time crystals generated. Hence, the rotational symmetry property of the computational states of these CA generations is of physical significance to the rules governing space and time in a space-time crystal. The time-crystal generations are mapped onto the surface of a space-time sphere, where the non-Euclidean geometry allows for the interchangeability between space and time in producing space-time crystals.

**C71.00250: Employing Variational Principles to Define the Effective Hamiltonian of a Periodically Driven Qubit**
DANIEL ZEUCH (Presenter), DAVID PETER DIVINCENZO, Peter Grünberg Institut, Forschungszentrum Julich — The trajectory of a linearly driven qubit in the rotating frame can be determined using the effective Hamiltonian introduced in [1], which improves on the rotating wave approximation. By its definition, this Hamiltonian (i) is analytic in time and, (ii), yields an effective driven-qubit trajectory that coincides with the exact trajectory at equally-spaced points in time. In general, these effective trajectories are significantly smoother than the exact ones. The effective Hamiltonian is determined by an infinite sum whose convergence, however, is not always guaranteed [1]. As the requirements (i) and (ii) are fulfilled by a continuum of Hamiltonians, here we hypothesize that the effective Hamiltonian additionally satisfies, (iii), a variational principle that is motivated by the smoothed trajectories mentioned above. Our variational principles state that the integral of a certain function of the Hamiltonian, e.g., its positive eigenvalue, over the full pulse duration is minimized by the effective Hamiltonian of [1]. To find evidence for or against our hypotheses, we carry out variational calculations aimed at numerically minimizing the corresponding integrals.

C71.00251: Entangled Excitons via Spontaneous Downconversion  ARIEL SHLOSBERG (Presenter), University of Colorado, Boulder, MARK T. LUSK, Colorado School of Mines — A class of centrosymmetric molecules support excitons with a well-defined quasi-angular momentum. Cofacial arrangements of these molecules can be engineered so that quantum cutting produces a pair of excitons with angular momenta that are maximally entangled. The Bell state constituents can subsequently travel in opposite directions down molecular chains as ballistic wave packets. This is a direct excitonic analog to the entangled polarization states produced by the spontaneous parametric downconversion of light. As in optical settings, the ability to produce Bell states should enable foundational experiments and technologies based on non-local excitonic quantum correlation. The idea is elucidated with a combination of quantum electrodynamics theory and numerical simulation.

C71.00252: Practical route to entanglement-enhanced communication over noisy bosonic channels*  HAOWEI SHI, James C. Wyant College of Optical Sciences, University of Arizona, ZHESHEN ZHANG, Materials Science and Engineering, University of Arizona, QUNTAO ZHUANG (Presenter), Electrical & Computer Engineering, University of Arizona — Entanglement can offer substantial advantages in quantum information processing, but loss and noise hinder its applications in practical scenarios. Although it has been well known for decades that the classical communication capacity over lossy and noisy bosonic channels can be significantly enhanced by entanglement, no practical encoding and decoding schemes are available to realize any entanglement-enabled advantage. Here, we report structured encoding and decoding schemes for such an entanglement-assisted communication scenario. Specifically, we show that phase encoding on the entangled two-mode squeezed vacuum state saturates the entanglement-assisted classical communication capacity and overcomes the fundamental limit of covert communication without entanglement assistance. We then construct receivers for optimum hypothesis testing protocols under discrete phase modulation and for optimum noisy phase estimation protocols under continuous phase modulation. Our results pave the way for entanglement-assisted communication and sensing in the radiofrequency and microwave spectral ranges.

E. CARL-LUDWIG SIEGEL (Presenter), FUZZYICS — QC has been alive and well since WWII in artificial neural-network(ANN) artificial-intelligence(AI), vs computing-quanta since quantum-theory, if not Newcomb(1881)-Poincare(1911)-Weyl(1916)-...-Benford(1938)[benfordonline.net] digits log-law inverse[Antonoff/Siegel(2002)]: digits=bosons. What does QC mean? In ANN AI, not counting Turing(1936 machine plagarism of Lenz-Ising model(1911) of localized magnetism, starting with Rosen(SRI). In the 1980s Charles Rosen(Machine-Intelligence), Jacob Goldman(Xerox PARC), Irwin Wunderman(HP), Vesco Marinov and Adolph Smith(Exxon Enterprises/AI) and Edward Siegel realized that ubiquitous standard sigmoid on-site switching-function \( N/[1+\exp(-E/T)] \) Fermi-Dirac quantum-statistics trapping the ANN in non-optimal local-minima necessitating time and memory costly Boltzmann-machine followed by simulated-annealing to eliminate the +1 converting Fermi-Dirac quantum-statistics into Maxwell-Boltzmann classical-statistics. They realized this time and memory costly crutch could be eliminated by reversing sigmoid-function to \( N/[\exp(-E/T)-1] \) Bose-Einstein quantum-statistics["Eureka!"] and then taking the limit as \( N \) approaches infinity. Bose-Einstein condensation (BEC) ["Shazam!"] blindingly quick ANN AI QC (N)-BEC-machine.

KA WA YIP (Presenter), MOSTAFA KHEZRI, DANIEL A LIDAR, Univ of Southern California — We devise a quantum feedback error correction method to reverse the effect of thermal excitations in quantum annealing. Conditioned on the output signal \( I(t) \) from continuous measurement records, feedback is applied to an adiabatically evolving system in the hopes of increasing the ground state population at the end of the anneal. We propose an experimental setting for such continuous measurement and feedback in the case of superconducting flux qubits. We simulate the error correction performance of a system weakly coupled to a thermal bath based on methods like quantum trajectories and quantum bayesian updates. We also derive a feedback master equation for markovian feedback (feedback delay \( \tau \to 0 \)) and further give the timescale condition for feedback Markovianity. Realistic feedbacks are also subjected to non-negligible feedback delay, detector efficiency, and restrictions on the form of the feedback Hamiltonian due to experimental challenges. We therefore study the effectiveness of feedback correction under such limitations and explore how the optimized feedback delay time depends on the annealing schedule and limitations in other experimental parameters.

C71.00255: Constructing parsimonious control functions using B-splines with carrier waves* N. ANDERS PETERSSON (Presenter), Lawrence Livermore Natl Lab, FORTINO GARCIA, Applied Mathematics, University of Colorado, Boulder, JONATHAN L DUBOIS, Lawrence Livermore Natl Lab — We consider the optimal control problem for realizing logical gates in closed quantum systems, where the evolution of the state vector is governed by the time-dependent Schroedinger equation. The number of parameters in the control functions is made independent of the number of time steps by expanding them in terms of B-spline basis functions, with and without carrier waves. We use an interior point gradient-based technique from the IPOPT package to minimize the gate infidelity subject to amplitude constraints on the control functions. The symplectic Stromer-Verlet scheme is used to integrate a real-valued formulation of Schroedinger’s equation in time and the gradient of the gate infidelity is obtained by solving the corresponding adjoint equation. This allows all components of the gradient to be calculated at the cost of solving 3 Schroedinger systems, independently of the number of parameters in the control functions. The method is applied to Hamiltonians that model the dynamics of several coupled super-conducting qubits. We find that including judiciously chosen frequencies in the carrier waves of the basis functions can significantly reduce the number of parameters and lead to smoother control functions.

C71.00256: Learning Quantum Error Models* WILLIAM MOSES (Presenter), Massachusetts Institute of Technology MIT, COSTIN IANCU, WIBE A DE JONG, Lawrence Berkeley National Laboratory — In this abstract we propose a methodology for learning quantum error models from experimental data. This information is useful for characterizing the effectiveness of hardware, predicting how well a circuit should run in practice, and synthesizing corrected circuits that attempt to perform better by taking the error model into account.

We learn the error model by taking each gate in the original circuit and replacing it with a parameterized probability distribution over potential gates. For example, we could replace a Pauli X gate with a distribution having probability p of performing a random unitary and probability 1-p of performing the Pauli X. We then perform bayesian inference to deduce the most likely error model that gave us the desired error.

We test our methodology on experimental data, and evaluate the learned error models in its predictive power.

C71.00257: An information entropy interpretation of photon absorption by dielectric media*  
SUNG WOOK HAN (Presenter), Department of Physics, Jeonbuk National University, 
PUREVDORJ MUNKHBAATAR, Institute of Photonics and Information Technology, Jeonbuk National University, KIM MYUNG-WHUN, Department of Physics, Jeonbuk National University — We measured photon absorption in dielectric media and proposed the photon-version Beer–Lambert’s law to quantify the absorption. We used a Hong–Ou–Mandel interferometer and 810 nm twin-photons. We found that the depth ratio of the null point in the interference patterns of the interferometer agreed with the classical transmittance of the samples. We established a statistical model of the photon absorption process and proposed an information entropy interpretation to understand the meaning of the Beer–Lambert law. Comparisons of the results of the photon absorption experiments with classical experiments demonstrate the validity of our model and interpretation.

*We acknowledge the support of the National Research Foundation of Korea (grant number: 2016R1D1A1B03934648).

C71.00258: Simulating broken PT-symmetric Hamiltonian systems by weak measurement*  
MINYI HUANG, School of Mathematical Sciences, Zhejiang University, RAY-KUANG LEE (Presenter), Natl Tsing Hua Univ, LIJIAN ZHANG, College of Engineering and Applied Sciences, Nanjing University, SHAO-MING FEI, School of Mathematical Sciences, Capital Normal University, JUNDE WU, School of Mathematical Sciences, Zhejiang University — By embedding a PT-symmetric (pseudo-Hermitian) system into a large Hermitian one, we disclose the relations between PT-symmetric quantum theory and weak measurement theory. We show that the weak measurement can give rise to the inner product structure of PT-symmetric systems, with the pre-selected state and its post-selected state resident in the dilated conventional system. Typically in quantum information theory, by projecting out the irrelevant degrees and projecting onto the subspace, even local broken PT-symmetric Hamiltonian systems can be effectively simulated by this weak measurement paradigm.

C71.00259: Knowledge is the Foundation of the Functioning of the Physical World in QM: Everything Goes Through the Wave Function, Including Null Measurements, Expansion of On the Nature of the Change in the Wave Function in A Measurement in Quantum Mechanics [arxiv, 1995]  DOUGLAS SNYDER (Presenter), None — Nothing in quantum mechanics (qm) occurs without the involvement of the wave function (wf); the wf is non-physical. When a measurement is made of 1 quantity, a new wf accompanies the measurement wherein another quantity of the particle is uncertain due to the wf, eg, position requiring many superposed waves and momentum requiring only 1 wave. Many situations showing the indispensability of the wf are discussed. What prevents knowledge based on the wf from being acknowledged as the foundation of the physical world is the assumed unavoidable physical interaction (pi) between the measuring instrument and the physical entity measured in the change in the wf in a measurement. This is explored in part through Feynman's jolt of a photon on an electron in his 2 slit experiment with a light source between the 2 slits. The origin of this assumed unavoidable pi appears to be Bohr's description of complementarity. The source for Bohr appears the psychologist W. James who did not include this pi in his complementarity. Without this pi, the central role of the wave function and knowledge derived from it is clearly seen in quantum mechanics. With null measurements (no pi), the problem that appears to originate with Bohr cannot be avoided. It should not have been avoided in 1995.

C71.00261: How Knowledge Leads to the Demise of Schrodinger's Cat Through a Null Measurement (A Quantum Mechanical Measurement in Which There is No Physical Interaction Between the Measuring Instrument and the Entity Measured)  
DOUGLAS SNYDER (Presenter), None — The Schrodinger cat experiment (SCE) is presented. An alteration follows where the LACK of radioactive decay (rd) leads to the demise of the cat instead of the ACT of rd. The lack of rd is a negative (null) measurement (nm) (where there is NO physical interaction between the radioactive material and the Geiger counter). The nm is non-trivial because all knowledge about the radioactive material (rm) is derived from its associated wave function (wf) which itself has no physical existence. The wf is how we make probabilistic predictions regarding systems in quantum mechanics. Before the box in the SCE is opened, the wf for the rm is: psi_rm = 1/√2 [psi_rm does not decay + psi_rm does decay] which leads to the possibility of interference before the cat is observed. As Schrodinger wrote: “The psi_function of the entire system [including rm and cat] would express this by having in it the living and the dead cat (pardon the expression) mixed or smeared out in equal parts.” The wf is the foundation for knowledge since the probabilities are derived from the wf and the wf contains all the information concerning a system. This alteration of the SCE emphasizes that the lack of rd in the original SCE is also a nm that leads to the continued life of the cat.

C71.00262: A quantum mechanical interpretation of gravitational redshift of photon*  
DONALD CHANG (Presenter), Hong Kong University of Science and Technology — It was observed that electro-magnetic waves can undergo a frequency shift in a gravitational field. This effect is important for satellite communication and astrophysical measurements. Previously, this redshift phenomenon was interpreted exclusively as a relativistic effect. Recently we found this effect can also be explained based on a quantum mechanical consideration. We propose that, due to the quantum nature of the photon, its effective mass is not zero. In a gravitational field, the total energy of the photon includes both its quantum energy and its gravitational energy. Then, the condition of energy conservation will require a frequency shift when the photon travels between two points with different gravitational potentials. This result suggests that the gravitational redshift effect of a photon is essentially a quantum phenomenon. This new understanding has a strong implication; it suggests that some of the previous experimental tests of general relativity need to be re-interpreted.

*This work was supported by the Macro-science project of HKUST.

C71.00263: From Hopf fiberation to duality-entanglement relation  
YUSEF MALEKI (Presenter), Texas A&M Univ — We show that the entanglement-duality relation [Optica 5, 942 (2018)] can indeed be obtained, in its most generic form, from Hopf fiberation and stereographic geometry. We demonstrate that this relation is a natural consequence of the stereographic geometry, providing the first geometric approach to the notion of complementarity problem. We show that this geometry is duality-entanglement sensitive. This means that, it is sensitive to the wave nature, particle nature and entanglement nature of a single qubit.
C71.00264: Programming multi-level quantum gates in disordered computing reservoirs via machine learning and TensorFlow* GIULIA MARCUCCI, DAVIDE PIERANGELI, Univ of Rome La Sapienza, PEPIJN PINKSE, University of Twente, MEHUL MALIK, Herriott Watt University, CLAUDIO CONTI (Presenter), Univ of Rome La Sapienza — Novel machine learning computational tools open new perspectives for quantum information systems. Here we adopt the open-source programming library TensorFlow to design multi-level quantum gates including a computing reservoir represented by a random unitary matrix. In optics, the reservoir is a disordered medium or a multi-modal fiber. We show that trainable operators at the input and the readout enable one to realize multi-level gates. We study various qudit gates, including the scaling properties of the algorithms with the size of the reservoir. Despite an initial low slope learning stage, TensorFlow turns out to be an extremely versatile resource for designing gates with complex media, including different models that use spatial light modulators with quantized modulation levels.[1]

*The present research was supported by PRIN2015 NEMO project (2015KEZNYM grant), H2020 QuantERA QUOMPLEX (grant number 731473), H2020 PhoQus (grant number 820392), and Sapienza Ateneo (2016 and 2017 programs).

C71.00265: Quantum Boosting SRINIVASAN ARUNACHALAM, Physics, Massachusetts Institute of Technology, REEVU MAITY (Presenter), Physics, University of Oxford — Boosting is one of the most famous classical machine learning techniques (in theory and practice) that can construct a strong machine learning algorithm given access to a weak learning algorithm. It is natural to consider boosting in the quantum setting for the following reason: suppose we implement a quantum machine learning (QML) algorithm on a NISQ device, then the guarantees of the QML algorithm could be much worse than it was designed for, due to the noise in the quantum system. This motivates the question whether we can "boost" the performance of a weak QML algorithm (implemented on a NISQ machine) to a *strong* QML algorithm?

Classically the time complexity for boosting the performance of a weak learner for a concept class C is characterized by the VC dimension of C. Here, we ask if quantum techniques can provide an improvement over the well-known AdaBoost algorithm introduced by Freund and Schapire '93 (for which they were awarded the Godel prize in 2003). In this work, we introduce the first quantum boosting algorithm which is provably faster than classical Adaboost with time complexity that scales quadratically in the VC dimension of C.
**C71.00266: Layerwise learning for quantum neural networks**  
ANDREA SKOLIK, Ludwig Maximilian University of Munich, JARROD MCCLEAN, MASOUD MOHSENI (Presenter), Google Research, PATRICk VAN DER SMAGT, Machine Learning Research Lab, Volkswagen Group, MARTIN LEIB, Data Lab, Volkswagen Group — We introduce a layerwise learning strategy for parameterized quantum circuits. The circuit depth is incrementally grown during optimization, starting with a shallow circuit and adding depth until the required loss is attained. By training only varying subsets of the circuit’s parameters, we keep a fixed number of training parameters while increasing circuit depth until it is sufficient to represent the data. We then show that this approach avoids the problem of saddle points, or barren plateaus, of the error surface to a large extent due to the low depth of circuits, low number of parameters, and larger magnitude of gradients compared to training the full circuit. These properties make our algorithm ideal for execution on noisy intermediate-scale quantum (NISQ) devices. We demonstrate our approach on an image-classification task on handwritten digits, and show that the number of trained parameters can be decreased substantially while keeping gradient magnitudes larger than those of quantum circuits of the same size trained on a fixed architecture.

*This project has received funding from the European Unions Horizon 2020 research and innovation programme under the Grant Agreement No. 828826.*

**C71.00267: Magnetic and electrical field detection using NV-based AFM**  
WENTIAN ZHENG (Presenter), Peking Univ — We develop a homemade NV-based scanning microscopy to detect both magnetic and electrical field induced by tips we used. As for the magnetic field, the Ni tip is required to provide magnetic field and field gradient on the surface of diamond membrane. The ODMR shift is observed during the Ni tip moving around a NV center, and we observe isomagnetic circle by ODMR mapping which shrinks to about 20nm indicating the actual location of the NV center.

Besides, the sensor we made allow us to apply bias voltage between metal tip and diamond. And the electrical field can be also measured by ODMR and Pulsed ODMR shift. Our results show the electrical field up to 100V/um which maybe controls the charge state of the NV center.
C71.00268: Time resolved diamond magnetic microscopy of single transition metal magnetic nanoparticles* ABDELGHANI LARAOUI (Presenter), Department of Mechanical & Materials Engineering, University of Nebraska - Lincoln, VICTOR ACOSTA, Department of Physics & Astronomy, University of New Mexico — Understanding the magnetic properties of small transition metal magnetic nanoparticles (TMMNPs) can help in exploiting their useful properties such as high surface-to-volume ratio and tailorable surface chemistry for applications in catalysis, biosensing, and ultra-high-density magnetic recording. At size below 10 nm, surface effects play a major role in determining their magnetic properties. Symmetry breaking of the crystal structure at the particle surface, dangling bonds, and surface strain can alter their properties. Accurate measurements of magnetic properties of single TMMNPs would therefore shed light on their critical properties. However, measuring these properties of such small particles at ambient conditions presents a great challenge due to the lack of sensitivity of current nonperturbative magnetic imaging techniques. Here we show recent measurements using magnetic microscopy based on nitrogen vacancy centers in diamond to measure the static and dynamic magnetic properties of individual 2-10 nm TMMNP (CoPt and FePt). Histograms of critical parameters such as magnetic anisotropy, saturation magnetization, and magnetic relaxation are extracted and correlated with morphology data taken by AFM, SEM, and TEM.

*We acknowledge support from NSF-DMR award #1809800

C71.00269: Phase estimation in a multimode nonlienar interferometer.* NARAYAN BHUSAL (Presenter), JONATHAN P DOWLING, Louisiana State University, Baton Rouge — Simultaneous estimation of multiple phase shifts is very important in quantum metrology as it has implications for the single-shot quantum imaging. Multiparameter estimation has been already demonstrated in linear optics even though its performance is greatly limited by computational difficulty associated with matrix permanent. Here, we propose a scheme that uses nonlinear optical parametric amplification (OPA) to estimate multiple simultaneous phase shifts. The performance of our scheme is compared with the SNL and the Heisenberg limit (HL). We choose homodyne as the measurement strategy in our scheme. As photon loss is the biggest experimental limitation, we also investigate the effect of photon loss in the phase sensitivity.

*NB would like to thank Army Research Office (ARO) for the support.
C71.00270: Rare Earth Quantum Information Science Decoherence Times and Hosts  
GAVIN NOP (Presenter), JONATHAN SMITH, Iowa State University — We present a brief review of the current state of Quantum Information Science (QIS), with a focus on Quantum Information Processing (QIP) and the challenges posed by short decoherence times. Rare earth based systems have the potential to resolve many of the issues faced in QIS. Due to their 4f orbitals, rare earth atoms, when implanted into an appropriate host, demonstrate relatively high coherence times. We cover benefits and challenges regarding QIP, specifically quantum processing and optical quantum memory. We emphasize important results in recent experiments regarding rare earth-based quantum computers, and compare these results to the current state of the art in qubit design. Specifically, we perform electronic structure calculations for a rare earth ion-doped wide band gap crystal and control quantum states offered by the doped ion. G.N. is grateful for an assistantship in the US DOE Office of Science, Science Undergraduate Laboratory Internship program.

C71.00271: WITHDRAWN ABSTRACT  —

C71.00272: Experimental demonstration of the validity of the quantum heat-exchange fluctuation relation in an NMR setup.*  
SOHAM PAL (Presenter), T.S. MAHESH, BIJAY AGARWALLA, IISER Pune — We experimentally explore the validity of the Jarzynski and Wójcik quantum heat-exchange fluctuation relation by implementing an interferometric technique in liquid-state nuclear magnetic resonance setup and study the heat-exchange statistics between two coupled spin-1/2 quantum systems. We experimentally emulate two models—(i) the XY-coupling model, containing an energy conserving interaction between the qubits, and (ii) the XX-coupling model—and analyze the regimes of validity and violation of the fluctuation symmetry when the composite system is prepared in an uncorrelated initial state with individual spins prepared in local Gibbs thermal states at different temperatures. We further extend our analysis for heat exchange by incorporating correlation in the initial state. We support our experimental findings by providing exact analytical results. Our experimental approach is general and can be systematically extended to study heat statistics for more complex out-of-equilibrium many-body quantum systems.

*The authors acknowledge the startup funding, IISER Pune, the IndiaMax Planck mobility grant, Department of Science and Technology, India (Grant No. DST/SJF/PSA-03/2012-13) and the Council of Scientific and Industrial Research, India (Grant No. CSIR- 03(1345)/16/EMR-II).
C71.00273: Collective enhancements in charging quantum batteries via a quantum heat engine

KOBUKE ITO (Presenter), Graduate School of Engineering Science, Osaka University, GENTARO WATANABE, Department of Physics and Zhejiang Institute of Modern Physics, Zhejiang University — As a model of so-called quantum battery, a quantum system as an energy storage, we study the charging of many two-level systems via a quantum heat engine. Especially, we focus on the collective effects in the charging. We show that the collective charging outperforms in the amount of the stored energy, its fluctuation, and the charging speed in comparison to the individual one. In the collective charging, symmetry of the interaction between the engine and the battery causes emergent bosonic quantum statistics, which result in a collective high probability excitation.

C71.00274: Controlling quantum dot level spacing: moving beyond the constant interaction model

ZACHARY PARROTT (Presenter), JACKSON KUKLIN, BRADLEY LLOYD, MEGAN SMITH, MEENAKSHI SINGH, Physics, Colorado School of Mines — Proposed large scale implementation of gate defined semiconductor quantum dots requires effective means to tune each dot to desired tunnel coupling, capacitive coupling to gates, and coupling to sources of decoherence such as the phonon bath. These parameters are currently understood within the context of the constant interaction model that predicts a periodic level spacing based on a constant capacitance of each dot to the relevant gates. Yet, the actual capacitance of the dot is not a constant and depends on parameters including the electron number, voltage of the associated gates, and size of the dot, leading to a nonlinear level spacing. We show how taking these parameters into consideration enables greater control of each quantum dot. We also present a means to change the dot level spacing, thereby changing the coupling to the phonon bath, while maintaining desired tunnel coupling in a framework similar to virtual gating for cross capacitance. The results are relevant to minimizing decoherence in quantum dot qubits.

C71.00275: Auto-tuned quantum dots in silicon as a candidate platform for scalable quantum computing and quantum neuromorphic devices

BRADLEY LLOYD (Presenter), MEGAN SMITH, ZHEXUAN GONG, MEENAKSHI SINGH, Colorado School of Mines — Spin qubits in gate defined quantum dots in silicon present a robust architecture for quantum information processing due to long coherence times, tune-ability, and scalability. However, the fabrication of such qubits leads to strong device variability, making it challenging to scale up the number of qubits for quantum computing applications. To address this challenge, we present our new device design and an automation protocol development to tune individual qubits. This automation protocol works to counteract device variability, resulting in greater scalability and versatility for the device. From this versatility we will explore the potential of using these auto-tuned quantum dots as quantum neuromorphic devices by engineering a non-Markovian bath for one or more qubits.
Controllable interaction between superconducting qubits is desirable for scalability architectures and quantum simulation applications. We experimentally demonstrate a simple-design tunable coupler, achieving a continuous tunability and almost zero coupling strength. Based on the tunable interaction between two qubits via the coupler, we first construct two-qubit iSWAP and control-Z (CZ) gate by applying standard rectangular pulses. We then propose a new 'Dynamic-Total-Closing' (DTC) technology to implement the CZ gate, which adopts a graded flux pulse for the qubit to approach the avoided crossing slowly, meanwhile dynamically closing the qubit-qubit coupling with a special pulse shape during the approaching process (fidelity up to 98.4%). Furthermore, we also try iSWAP gate by parametrically oscillating coupler at the qubit-qubit detuning and cross-resonance gate by tuning coupler frequency to explore the influence of ZZ interaction.

C71.00277: WITHDRAWN ABSTRACT —

C71.00278: THz Sommerfeld Wave Propagation on Superconducting Niobium Wire for Millimeter-Wave Interconnects* BHARAT KUCHHAL (Presenter), Stanford Univ, EMMA SNIVELY, SLAC National Accelerator Laboratory, KEVIN MULTANI, HUBERT STOKOWSKI, AMIR SAFAVI-NAEINI, Stanford Univ, PAUL B. WELANDER, EMILIO NANNI, SLAC National Accelerator Laboratory — Although there has been a stupendous development of superconducting microwave circuits, scalability and transmission of quantum information remain important issues. One approach involves the transduction of quantum information from microwave to millimeter-wave frequencies prior to transmission. For efficient transmission of THz waves, the development of millimeter-wave interconnects is a vital challenge. In this pursuit, we propose to transmit Sommerfeld waves in the THz regime on the surface of a single superconducting Niobium wire connected between a pair of horn antennas and W-band (75 – 110GHz) waveguides. The Sommerfeld mode on single conductors in the THz frequency range have demonstrated very low losses with room temperature conductors. Compared to the room temperature, our calculations show an increase in conductivity of superconducting Niobium by two orders of magnitude, which indicates significantly lower losses are possible for links at a few Kelvin.

*Work supported by the U.S. Department of Energy under contract number DE-AC02-76SF00515.
**C71.00279: Disorder-free localization in the Kitaev Honeycomb Model**

ADRIAN CHAPMAN, Physics, University of Sydney, SAYONEE RAY (Presenter), Physics, University of New Mexico — We study operator propagation and scrambling in the two-dimensional Kitaev honeycomb model. An exact solution for this model allows us to calculate the infinite-temperature out-of-time-ordered correlator for Pauli observables, where we find that the infinite-temperature average over gauge sectors manifests as a disorder average for this quantity. This induces a localization effect for observables in the bond algebra of the Hamiltonian, while observables outside of the algebra completely scramble. We interpret our result in terms of the diffusion of Pauli strings, whose endpoints are localized yet whose interiors propagate freely. We further find that, in the ground state gauge sector of the model, operators do not localize. We further extend our analysis to the finite temperature regime using Monte Carlo Metropolis-Hastings methods.

*NSF FRHTP grant, Centre for Engineered quantum systems

**C71.00280: DATA SCIENCE**

**C71.00281: Combinatorial fabrication and spectroscopic analysis of Fe-Co-Cr ternary alloy thin film**

TADASHI NISHIO (Presenter), MASahiRO YAMAMOTO, Sci Univ of Tokyo, TAKUO OHKOCII, SPring-8, MASATO KOTSUGI, Sci Univ of Tokyo — The development of a high-throughput experiment is an important issue in materials informatics, especially for materials discovery. Recently, combinatorial deposition and high-throughput analysis are rapidly progressed [1]. However, the combination of material fabrication and property analysis still leaves much room for development. Particularly, a question is raised about whether comprehensive phase diagram mapping is the optimum solution for materials discovery. Here, we focus on exploring the phase transition for the materials discovery and combined the combinatorial wedged thin film deposition, the synchrotron-based micro-spectroscopic characterization, and the statistical analysis of experimental bigdata. X-ray absorption spectrum and magnetic circular dichroism (MCD) information were recorded by photoelectron emission microscopy. We obtained chemical components and magnetic contrast in each pixel of the image and analysed the histogram of MCD contrast as a variation of the chemical composition of Fe-Co-Cr. We fitted MCD histogram by Landau theory to discuss the ferromagnetic phase transition.

Normal mode analysis of a relaxation process with Bayesian inference ITSUSHI SAKATA (Presenter), YOSHINO NAGANO, YASUHIKO IGARASHI, SHIN MURATA, Univ of Tokyo, KOHJI MIZOGUCHI, Osaka Prefecture University, ICHIRO AKAI, Kumamoto University, MASATO OKADA, Univ of Tokyo — Relaxation processes provide many insights into atomic/molecular structures and the kinetics and mechanisms of chemical reactions. For the analysis, the extraction of modes that are specific to the phenomenon of interest is unavoidable.

In this study, to construct a data-driven technique for relaxation processes, we propose a framework to systematically extract normal modes from the viewpoint of model selection with Bayesian inference. Our approach consists of a well-known method called sparsity-promoting dynamic mode decomposition, which decomposes a mixture of damped oscillations, and the Bayesian model selection framework. We numerically verify the performance of our proposed method by using coherent phonon signals of a bismuth crystal and virtual data as typical examples of relaxation processes. Our method succeeds in extracting the normal modes even from experimental data with significant trends. Moreover, the selected set of modes is robust to observation noise, and our method can estimate the level of observation noise. From these observations, our method is applicable to normal mode analysis, especially for data with significant trends, which broadens the applicability of the data-driven approach in analyzing relaxation phenomena in material science.

Predicting Ionic Liquids Properties with Machine-Learning ZAFER ACAR (Presenter), MICHAEL MUNJE, PHU NGUYEN, Computer Science, California State University, Northridge, KAHCHUN LAU, Physics and Astronomy, California State University Northridge — Since the last decade, there has been a dramatic increase in the number of ionic liquids (ILs) synthesized, tested and utilized in various applications (e.g. energy storage, CO₂ capture, catalysis, lubricant additives, etc.). The intense interest has been due to the various novel properties that can be found in ionic liquids, such as tunable ionic conductivity, negligible vapor pressure, liquid phase within a wide temperature range, non-flammability at ambient condition, etc. Among these properties, the melting point (Tₘ) of ionic liquids (IL) are very important in various applications. However, the Tₘ can change considerably depending on the molecular structures of the anions and cations. In this study, we will explore the use of various machine learning methods to predict the melting points of various ILs that consists of several different cation and anion classes. In addition to melting point prediction, some of the related structures-properties studies of ILs will be discussed.

C71.00284: Interpretable modeling by linearly independent descriptor generation method

HITOSHI FUJII (Presenter), National Institute for Materials Science, TAMIO OGUCHI, Osaka University — For interpretable modeling, linear regression combining descriptor generation and selection operator, such as approach of Ghiringhelli[1] and Ouyan[2], is very effective. However, multicollinearity (MC) (and near multicollinearity) between descriptors that are problematic in linear regression analysis can reduce the quality of the descriptor selection. Therefore, we proposed the linearly independent descriptor generation (LIDG) method[3] that generates descriptors while removing MC. This approach can improve their approach.

In this presentation we will present some application examples.

C71.00285: Artificial Intelligence to detect gravitational waves from a network of detectors

THILINA SHIHAN WEERATHUNGA (Presenter), Department of Physics and Astronomy, University of Texas Rio Grande Valley — The application of artificial intelligence in astronomical data analysis is becoming more popular among the scientific community. In our recent work [1,2], we have shown the effectiveness of Particle Swarm Optimization (PSO), a well-known algorithm in the field of swarm intelligence, in addressing signal detection and parameter estimation problem related to gravitational waves from compact binary coalescences (CBCs). The fully coherent network analysis of data from multiple gravitational wave (GW) detectors is computationally expensive since it is associated with a high dimensional numerical optimization problem. In our previous work, we showed using a non-spinning 2.0 post-Newtonian order waveform and four gravitational wave detectors (two LIGO detectors, Virgo and Kagra) that PSO can achieve the same performance as a grid search with less than 200,000 templates for a component mass range of 1.0 to 10.0 solar masses at a network signal to noise ratio of 9. Currently, we are increasing the dimensionality of the optimization problem by adding spin parameters to the waveform and exploring the effectiveness of the algorithm.

C71.00286: Machine learning to predict microbial community traits driving carbon fixation*
JARON THOMPSON (Presenter), Colorado State University — Microbial communities are ubiquitous influencers of macroscopic environments, yet overwhelming complexity makes it difficult to decipher functional relationships between specific microbes and ecosystem properties. Integrating advances in DNA sequencing technology with computational approaches like machine learning (ML) could address this problem. In [Thompson et al, PLoS One, 2019], we applied neural networks, random forest models, and indicator species analyses to correlate microbiome data (16S rRNA gene profiles) with dissolved organic carbon (DOC) content after 44 days of plant litter decomposition. We analyzed 300+ soil microcosms, including 1709 total bacterial operational taxonomic units (OTUs), and performed multiple-model feature reduction. We are now leveraging Bayesian network structure learning to infer mechanistic interactions between microbial species abundance and DOC. After training a Bayesian network model using pine litter data, we predict DOC results of independent oak litter experiments and demonstrate that relationships between microbial species abundance and DOC are conserved across litter types.

C71.00287: ParaMonte: A high-performance parallel library for Monte Carlo optimization, sampling, and integration  FATEMEH BAGHERI (Presenter), AMIR SHAHMORADI, University of Texas at Arlington — At the foundation of predictive science lies the scientific methodology, which involves multiple steps of observational data collection, developing testable hypotheses, and making predictions. Once a scientific theory is developed, it can be cast into a mathematical model whose parameters have to be fit via observational data. This leads to the formulation of a mathematical objective function for the problem at hand, which has to be then optimized to find the best-fit parameters of the model or sampled to quantify the uncertainties associated with the parameters, or integrated to assess the performance of the model. Toward this goal, a highly customizable, user-friendly high-performance parallel Monte Carlo optimizer, sampler, and integrator library is presented here which, can be used on a variety of platforms with single to many-core processors, with interfaces to popular programming languages including Python, and Fortran/C/C++. In particular, we discuss the parallel implementation of a variant of Markov Chain Monte Carlo known as Delayed Rejection Adaptive Metropolis (DRAM) and its scalability.

C71.00288: COMPUTATIONAL PHYSICS —
Building a DLS Device to Measure In Situ Glycine Cluster Formation

HANNAH FEJZIC (Presenter), California State University, San Bernardino, BRUCE ALLEN GARETZ, OMAR GOWAYED, Chemical Engineering, New York University — Laser trapping nucleation uses optical tweezers focused at the air-solution interface to grow crystals. Research has shown that focusing a continuous wave (CW) laser at the glass-solution interface of a solution of glycine in deuterium oxide, does not lead to nucleation, but to laser-induced phase separation (LIPS) droplet formation. The LIPS droplet is about double the concentration of the initial solution, past the metastable zone. This droplet is believed to be made up of large, liquid-like clusters of glycine that are organized in a size gradient with larger clusters in the center of the solution. Minutes after the LIPS droplet relaxes over a few minutes, clusters in the LIPS droplet spontaneously organize into a critical nucleus. Microscopic demixing of the solution is believed to leads to the observed polymorph-selectivity for LIPS droplet-grown crystals. To better understand the LIPS droplet, a dynamic light scattering (DLS) device will be constructed to observe the LIPS droplet in situ. By measuring the hydrodynamic radius of the glycine particles in situ, one can better understand this crystal growth mechanism.

First-principles calculations study of electronic structure, optoelectronic, vibrational analysis, linear and nonlinear optical properties of 4,5-dibromo-2,7 dinitrofluorescien

JEAN BAPTISTE FANKAM FANKAM (Presenter), Department of Physics, University of Yaounde I — Theoretetical inverstigation on 4,5-dibromo-2,7 dinitrofluorescien at the RHF level and different DFT with the cc-pVDZ basis set with the help of Gaussian 09 suit of program software. We have firstly modeled and optimized the geometry of the structure and further, we have computed the frequencies' analysis to understand the thermodynamic, optoelectronic, linear and nonlinear optical properties. As far as this analysis is concerned, we have also been able to come out successful with a well calculated chemical reactivity and stability of the molecule through frontier molecular orbitals defined by the higher occupied and lower unoccupied molecular orbitals (EHOMO and ELUMO). Our results insinuate that this molecule has a potential application in linear and nonlinear optical materials, and optoelectronic devices due to his large hyperpolarizability and can be a promising compound for optical limiting applications. Presently, no experimental and theoretical values in literature were determined for the above properties are available, we are hopeful that our final results will provide important information for further studies of this compound in NLO materials and optoelectronic devices.

No finding
C71.00291: Computational Synthesis of 2D Materials: A High-Throughput Approach to Materials Design* TARA BOLAND (Presenter), ARUNIMA SINGH, Arizona State Univ — The emergence of two dimensional materials opened up many potential avenues for novel device applications such as nanoelectronics, topological insulators, field effect transistors, microwave and terahertz photonics and many more. To date there are over 1,000 theoretically predicted 2D materials. Only 55 2D materials have been experimentally synthesized. Computational methods such as density functional theory can be used to determine the suitable substrates to synthesize 2D materials. Using various 2D materials databases and van der Waals corrected density functional theory we investigate the suitability of 12 substrates to stabilize 2D growth. For materials which meet the criteria for suitable substrate-assisted synthesis methods such as chemical vapor deposition or mechanical exfoliation, the density of states is computed to characterize the electronic properties of these materials for device applications.

*The authors would like to acknowledge Research Computing at Arizona State University and XSEDE for providing HPC resources and storage that has contributed to the research results to be reported.

C71.00292: Predicting the properties of ultrathin magnetic $H_xCrS_2$ from first principles and machine learning* DANIEL WINES (Presenter), JARON KROPP, CAN ATACA, Univ of Maryland-Baltimore County — An air stable $H_xCrS_2$ layered material has been synthesized by soft chemical methods, which can be exfoliated down to ultrathin layers, providing a promising path for the synthesis of two-dimensional (2D) magnets\(^1\). Although a reliable synthesis method has been developed, the atomic structure is still unknown. Variables such as Cr vacancies and H impurities must be determined in order to understand the properties of this material for device applications. We used a combination of density functional theory (DFT), molecular dynamics (MD) and cluster expansion formalism to study the energetics as a function of Cr vacancies and H impurities. From here, we studied the stability, electronic and magnetic properties of these $H_xCrS_2$ structures and examined the effect of layering on these properties. In order to extend our calculations to a wider range of structures, we trained a machine learning algorithm with our DFT and MD calculated data to predict the properties of other $H_xCrS_2$ based materials outside our training set.

C71.00293: Novel Solid-State Electrolytes for Li Ion Batteries by Computational Design and High-throughput Ab Initio Calculation  WONSEOK JEONG (Presenter), Seoul National University, YOUNGHO KANG, Korea Institute of Materials Science, SEUNGWU HAN, Seoul National University — Solid-state electrolytes (SSEs) can alleviate many of the issues of Li-ion batteries arising from the utilization of the organic liquid electrolytes. Up to date, several SSEs have been proposed from previous experiments or computational screening from publicly available materials databases, however, none of those SSEs are fully satisfactory. In this work, we take one step further; instead of simply exploring a pre-existing materials database, we try to design new materials with aliovalent substitution of cations. This aliovalent substitution is known to facilitate kinetics of Li diffusion. We first screen potential host materials for generating new SSEs by aliovalent substitution, considering fundamental properties such as the presence of transition metals, thermodynamic stability, and band gap. Afterward, we crudely examine the potential energy surface (PES) around the Li ion at interstitial sites. The materials with the most smooth PES are then chosen for the possible candidate for the host material. Finally, we choose some materials from the candidate list and demonstrate that indeed they become a Li ion conductor after aliovalent doping. Starting from 42,337 structures, we find a number of SSEs with predicted Li ionic conductivity comparable to the state-of-the-art \( \text{Li}_{10}\text{GeP}_2\text{S}_{12} \).

C71.00294: COMPUTATIONAL STUDY OF THE INTERACTION OF A WATER MOLECULE WITH 2D-HBN(TWO-DIMENSIONAL HEXAGONAL BORON NITRIDE) AND WITH TI-2D-HBN  GREGORIO RUIZ-CHAVARRIA (Presenter), UNIVERSIDAD AUTONOMA CHAPINGO — After graphene synthesis in 2004 many two dimensional systems has been studied, since the possible applications of these are many. In this work I made a computational study of the interaction of a water molecule with two dimensional hexagonal boron nitride(2D-HBN). First the stability of the 2D-HBN is obtained using Density Functional Theory, Atomic Pseudopotentials,Born-Oppenheimer approximation and molecular dynamics. Next I cause this system to interact with a water molecule. In a second moment, I made a computational study the stability of the system 2D-HBN, but adding a Titanium atom, the system Ti-2D-HBN. Again I provoke the interaction between a water molecule and the Ti-2D-HBN system. I show the results of my calculations, and these are compared with other computational and experimental results.
C71.00295: Real-space Moiré potential, lattice corrugation, and band gap variation in a MoTe$_2$/MoS$_2$ heterobilayer*  WENTONG GENG, National Institute for Materials Science, VEI WENG, Department of Applied Physics, Xi’an University of Technology, TAKAHISA OHNO, JUN NARA (Presenter), National Institute for Materials Science — To have a first-principles description of the Moiré pattern in a transition metal dichalcogenide heterobilayer, we have carried out DFT calculations, taking full accounts of both atomic registry in and the lattice corrugation out of the atomic layers, on a MoTe$_2$/MoS$_2$ system which has a moderate size of superlattice larger than an exciton yet not large enough to justify a continuum model treatment. We find that the local potential in the midplane of the bilayer can serve as an excellent illustration of the Moiré pattern in the van der Waals heterostructure. In the Mo atomic planes, the array of local potential planar maximum (LPPM), rather than the local potential itself, makes the Moiré pattern more obvious. Significant lattice corrugation is found in both MoTe$_2$ (0.30Å) and MoS$_2$ (0.77Å) layers. The interlayer Moiré potential, defined as the LPPM difference between the Mo atomic planes, has a depth of 0.20 eV and changes in direct correlation to the band gap variation in the Moiré cell, which has an amplitude of 0.04 eV. Wrinkling of the MoTe$_2$/MoS$_2$ bilayer enhances the spatial variation of the local band gap by 5 meV; by contrast, its influence on the global band gap is within 1 meV.

C71.00296: Simultaneous Prediction of the Magnetic and Crystal Structure of Materials*  PHIL HASNIP (Presenter), ED HIGGINS, MATT I. J. PROBERT, University of York — The coupling between magnetic properties and crystal structure in many magnetic materials means that it is essential to take a holistic approach to predicting their structure. We present for the first time a genetic algorithm that performs a simultaneous global optimisation of both magnetic structure and crystal structure, and illustrate its utility in a range of systems including a complex interface structure between a half-metallic Heusler alloy and a semiconductor substrate.

C71.00297: Minimization studies of elemental carbon using LCBOP semi-empirical potential. PHILIP CHROSTOSKI (Presenter), CHATHURI SILVA, PHILIP FRAUNDORF, University of Missouri - St. Louis — Elemental carbon is interesting to study thanks to its material properties and structural diversity, which ranges from nanotubes through graphite to diamond. In our study of slow-cooled carbon droplets condensed in cool-star atmospheres, computational study with semi-empirical potentials is complementary to experiment and \textit{ab initio} work. We've used the long-range carbon bond-order potential to relax, via conjugate gradient, 1.8 g/cc liquid-like carbon tiled-cube and isolated-cluster systems with 13, 20 and 100 atoms, as well as tetrahedral nanodiamond clusters of 17, 22 and 29 atoms. Tiled-cube simulation nearest neighbor histograms show a bond defining gap between 1.7-2.0 Å. Coordination statistics then show a high percentage of sp and sp2 coordination. Ring sizes of 5 - 7 atoms form more prominently than others, with 5 and 6 atom rings especially abundant. Isolated cluster relaxations show a high amount of sp chains forming, and less ring formation than the tiled-cube simulations. We also see a volume increase for the isolated clusters, unlike comparable density functional theory (DFT) simulations. Our isolated diamond-cluster relaxations saw less surface reconstruction than with DFT.

C71.00298: Line integral approach for fiber-fiber interactions implemented in LAMMPS ANIRBAN PAL (Presenter), West Texas State Univ — Fiber networks are currently modelled using discrete bead-spring type molecular models or cylindrical discrete-element (DEM) models. Bead-spring models often suffer from issues arising from artificial friction originating at the bead-bead contacts, and DEM-type models suffer from high computational demands. Thus, there is a need for better models. Here, the cohesive interaction energy between straight fibers is expressed as a double integral. This double integral can be converted into a single integral that has two terms in its integrand: $g(r)$, which depends on the relative geometrical positioning of the fibers, and $V(r)$, which reflects the interaction energy. Although $V(r)$ is readily available in analytical form, $(can be of the lennard-jones type)$, $g(r)$, which is essentially a distance distribution function of point-pairs located across 2 fibers, requires computation. The method to compute $g(r)$ involves elliptic integrals and is computationally demonstrated in this work. An implementation of the resulting fiber-fiber interaction is demonstrated in LAMMPS, a popular molecular dynamics package, and its computational and scientific performance is evaluated.

C71.00299: First Principles Evaluations of the Spin-Orbit Couplings in Crystals* KENSUKE KURITA (Presenter), TAKASHI KORETSUME, Tohoku University — The spin-orbit coupling (SOC) plays a crucial role in many spin-related phenomena such as anomalous Hall effect and spin Hall effect. However, the strength of the SOC in solids and its relation to the isolated limit have not been well understood. Here, we quantify the atomic SOC in solids by constructing the tight-binding Hamiltonian from the Wannier functions obtained by the first-principles calculation. By calculating the atomic SOC in monatomic crystals and binary compounds systematically, we find that the strength of the atomic SOC is not the atom-specific property but depends much on the crystal structure and chemical composition. We show that its crystal dependence is well explained by the spread of the Wannier function.

C71.00300: Time-evolution of a Schrödinger electron driven by a localized oscillating potential

LIUBOV ZHEMCHUZHNA (Presenter), GODFREY GUMBS, Hunter college, M. LAWRENCE GLASSER, Clarkson University, ANDRII IUROV, Medgar Evers college, DANHONG HUANG, Air Force Research Lab — We have obtained a semi-analytical solution of the Schrödinger equation for a massive particle in the presence of a harmonic time-dependent \( \sim \cos (\omega t) \) single-point \( \sim \delta(x) \) potential. We present a detailed analysis for determining the dependence of the wave function on the amplitude and frequency of the oscillatory potential, and the chosen initial conditions for the particle wave function. We have considered separately when either the potential is negative and leads to a bound state or is positive thus yielding scattering. Our derived results could be interpreted as being related to the dynamics of an electronic Floquet state subjected to a localized laser-induced dressing field.

C71.00301: Theory of phonon glass behaviour in host-guest thermoelectrics with avoided crossing

BINGYU CUI (Presenter), Univ of Cambridge, MATTEO BAGGIOLI, Universidad Autonoma de Madrid, ALESSIO ZACCONE, University of Milan — An analytical model is developed to describe the phonon dispersion relations of thermoelectrics with the presence of heavy guest atoms (rattlers). The model also accounts for anharmonic effects in phonon damping. The spectrum of low energy states contains acoustic-like and (soft) optical-like modes, which display the typical avoided crossing, and which can be derived analytically by considering the dynamical coupling between host lattice and guest rattlers. Inclusion of anharmonic damping in the model allows us, for the first time, to compute the vibrational density of states (VDOS) and the specific heat, unveiling the anomalous boson peak (BP) relating to the glassy behaviour of phonons in the otherwise crystalline material. We discuss the dynamics of the BP as a function of the strength of the interaction between the soft modes and the anharmonic lattice, and of the energy gap between the two avoided-crossing branches. Moreover, we find a robust linear correlation between the BP frequency and the energy of the soft optical-like modes.

C71.00302: Giant effect of spin-lattice coupling on the thermal transport in two-dimensional ferromagnetic CrI₃  GUANGZHAO QIN (Presenter), University of South Carolina, ZHENZHEN QIN, Zhengzhou Univ, HUIMIN WANG, Nanjing University, MING HU, University of South Carolina — Recently, two-dimensional monolayer chromium triiodide (CrI₃) with intrinsic magnetism was discovered, which shows promising applications in many technologies from sensing to data storage where thermal transport play a key role. So far the effect of spin-lattice coupling on the thermal transport properties has not been explored yet. In this talk, I would like to present the giant effect of spin-lattice coupling on the thermal conductivity of monolayer CrI₃. The thermal conductivity is more than two orders of magnitude enhanced by the spin-lattice coupling. The effect is found to be especially stronger for the acoustic phonon modes, which dominates thermal transport with spin-lattice coupling. Deep analysis shows that the reason lies in the weakened phonon anharmonicity by spin-lattice coupling. The bond angle and atomic position are changed due to the spin-lattice coupling, making the structure more stiff and more symmetric, which lead to the weaker phonon anharmonicity, and thus the enhanced thermal conductivity. This study uncovers the giant effect of spin-lattice coupling on the thermal transport, which would deepen our understanding on thermal transport and shed light on future research of thermal transport in magnetic materials.

C71.00303: Resonantly enhanced polariton wave mixing and Floquet parametric instability  SHO SUGIURA (Presenter), MIKHAIL LUKIN, EUGENE DEMLER, Harvard University, DANIEL PODOLSKY, Technion — Recent experiments by Cartella et al. [1] demonstrated terahertz optical amplification in SiC insulator following a strong mid-IR pump that resonantly excited the SiC stretching mode. Motivated by these experiments we study the problem of light reflection from a slab of insulating material with a strongly excited polariton mode. We introduce a new theoretical approach for analyzing this system using the Floquet formalism, in which polariton oscillations provide periodic time modulation. We present an analytic solution of the Fresnel light reflection problem. We demonstrate discontinuous dependence of the reflection coefficient on the incoming photon frequency, which we attribute to the existence of unstable polariton modes. We interpret these instabilities as resonantly enhanced polariton parametric wave mixing. Our results provide a simple physical interpretation of light amplification observed in recent experiments by Cartella et al. [1]. Moreover, we argue that Floquet parametric instability could already be present in these experiments. Our approach utilizing the Floquet formalism is applicable to a broad class of systems.  

C71.00304: Response at finite temperature  OLLE HELLMAN (Presenter), Linkoping University — We present recent developments using the temperature dependent effective potential technique (TDEP) to model strongly non-harmonic materials. The method employs model Hamiltonians that explicitly depend on temperature. I will present applications pertaining to thermal conductivity, inelastic neutron spectra and phase stabilities. In addition, we investigate the cross-terms between anharmonicity and non-adiabatic electron-phonon coupling and its influence on transport properties.
C71.00305: Deep Spectral Coarse Graining: Learning Simple, Dynamically Consistent Protein Models*  
NICHOLAS CHARRON (Presenter), FELIKS NÜSKE, JIANG WANG, LORENZO BONINSEGNA, ANKIT PATEL, CECILIA CLEMENTI, Rice Univ — Coarse grain models of proteins offer promising gains in both computational efficiency for molecular simulations and the development of simple physical interpretations. Recent efforts have focused on formulating the development of coarse grained force fields as a supervised learning problem, taking advantage of deep learning techniques for handling highly non-linear multibody effects produced by imposing coarse grained representations. In this work, we present a deep learning method that utilizes spectral information from simulation data to preserve essential dynamics of the original system. Following a Koopman-motivated approach, we optimize the dynamical consistency between fine grain and coarse grain systems by forming a cost from the dynamical generator eigenequation. Through this method, we can recover coarse grain empirical free energy landscapes that preserve essential dynamical information from the fine grain system.

*This work was funded by NSF grants: CHE-1265929, CHE-1738990, PHY-1427654, Welch Foundation grant C-1570m and NLM training grant 5T15LM007093-27. The researchers acknowledge the support of the Rice Center for Theoretical Biological Physics and the Gulf Coast Consortia.

C71.00306: Crystalin Protine Structure Prediction Algorithm  
DANAE STEPHENS (Presenter), Brigham Young Univ - Provo — The accurate prediction of protine structures is a continuously ongoing process, with the traditional method being a two step process of creating restraints and constructing a basic structure from that. Recent advancements in Machine Learning and Neural Networks have provided new avenues to increase accuracy for these predicted protein structures. By utilizing a Neural Network to estimate molecular distances, and running basic torsion angle predictions, enables us to more accurately fold proteins and create accurate protein structure predictions for use. Hopefully this neural network will allow further research and utilization of proteins that we are currently unable to crystalize and study by traditional means.
C71.00307: Constructing the Neural Network Potential With the Energies of the Atom and Its Derivatives  
JISU JUNG (Presenter), WONSEOK JEONG, SEUNGWU HAN, Seoul Natl Univ — 
Neural Network Potentials (NNPs) are highly anticipated as a possible breakthrough to overcome the trade-off between accuracy and speed in atomistic simulations. NNP learns the potential energy surface from the reference first principle calculations. The most widely used first principle calculation is based on the density functional theory (DFT) with the plane-wave basis, which does not provide atomic energy. Thus it is not possible to directly train the NNP to learn target atomic energy from plane-wave DFT. To overcome this limitation Behler and Parrinello designed high-dimensional NNP such that it represents the atomic energy as the sum of total energy. However, the mapping of atomic energy from the total energy is not unique, and if not carefully considered, there could be a loss of information leading to errors. We call this ad-hoc mapping problem. In contrast, because a pseudo-atomic localized basis can define atomic energy by its decomposition formalism, it enables NNP to avoid the above problem. In this presentation, we demonstrate the advantages of training NNPs directly from atomic energy and its derivatives, free from the high dimensional structure.

C71.00308: Grain boundary structures of elemental metals using machine learning potential  
TAKAYUKI NISHIYAMA (Presenter), ATSUTO SEKO, ISAO TANAKA, Kyoto Univ — 
Global optimization algorithms, such as multi-start local optimizations and Bayesian optimization, have been useful to determine the microscopic structure and its grain boundary energy for a given macroscopic grain boundary model. Together with the global optimization algorithms, the density functional theory calculation and interatomic potentials have been employed to estimate the grain boundary energy. However, the former is computationally demanding, and the latter often lacks the predictive power for a variety of grain boundary structures. Recently, several machine-learning potentials have been proposed, which are expected to enable computing the grain boundary energy accurately with less computational costs. In this study, we investigate symmetric tilt grain boundary structures and their grain boundary energy surfaces in elemental metals using a combination of global optimization algorithms and linearized machine learning potentials [1]. We compare the grain boundary structures and grain boundary energy surfaces obtained from machine learning potentials and embedded atom method potentials to examine the accuracy and stability of our procedure.

**C71.00309: Machine Learning-Aided Development of Empirical Force-Fields for Glasses**

MATHIEU BAUCHY (Presenter), University of California, Los Angeles — The development of reliable, yet computationally efficient interatomic forcefields is key to facilitate the modeling of glasses. However, the parametrization of novel forcefields is challenging as the high number of parameters renders traditional optimization methods inefficient or subject to bias. Here, we present a new parameterization method based on machine learning, which combines \textit{ab initio} molecular dynamics simulations, Gaussian Process Regression, and Bayesian optimization. By taking the examples of silicate and chalcogenide glasses, we show that our method yields new interatomic forcefields that offer an unprecedented agreement with \textit{ab initio} simulations. This method offers a new route to efficiently parametrize new interatomic forcefields for disordered solids in a non-biased fashion.

*This work was supported by the National Science Foundation under Grants No. 1762292, 1826420, and 1928538.

**C71.00310: A theoretical study on crystallization of chalcogenides via neural network potential**

DONGHEON LEE (Presenter), KYEONGPUNG LEE, DONGSUN YOO, WONSEOK JEONG, KYUHYUN LEE, SEUNGWU HAN, Seoul Natl Univ — Phase-change materials (PCM) have attracted wide interests in fields such as data storage and neuromorphic computing. Ge-Sb-Te alloys are a representative PCM, which show large contrast of optical and electrical properties between crystalline and amorphous phases. Atomic scale modeling of PCM has relied on ab-initio molecular dynamics (AIMD), but its large computational costs have limited simulation size and time. Neural network potential (NNP) can deal with more than thousands of atoms upto microseconds, while accurate potential energy surface can be obtained by learning the data of density functional theory (DFT).

In this work, we suggest the accurate and effective training scheme to develop reliable NNP for chalcogenides (e.g. GeTe and Ge$_2$Sb$_2$Te$_5$). It seems that NNP trained in the conventional way moderately predicts the basic properties but rapidly crystallizes an amorphous phase without any incubation time. We then propose a simple descriptor to diagnose it and an active learning scheme to manage it. Dependence of crystallization kinetics upon temperature and density is investigated using about 4000-atom cells. It shows that incubation and crystallization time is dependent on temperature and pressure, qualitatively consistent with experiments.
C71.00311: Direct prediction of quantum accurate forces for multicomponent systems

SUBODH TIWARI (Presenter), Univ of Southern California, PANKAJ RAJAK, Argonne National Lab, KEN-ICHI NOMURA, AIICHIRO NAKANO, Univ of Southern California, FUYUKI SHIMOJO, Department of Physics, Kumamoto University, RAJIV KALIA, PRIYA VASHISHTA, Univ of Southern California — Phase-change materials (PCM) are routinely exploited in optical data storage, flexible devices and neuromorphic computing due to the extreme electro-optical contrast between crystalline and amorphous states. However, high-quality force-field models for molecular-dynamics (MD) simulations of PCM are not available, while quantum molecular dynamics simulation is limited by the small size of system. We have developed neural-network (NN) force fields for GeTe and Ge$_2$Sb$_2$Te$_5$, which are trained using atomic forces computed by density functional theory. Radial and angular feature vectors are designed and trained, which feature permutational and translational invariance and rotational covariance of forces. The accuracy of the NN force fields is validated by performing MD simulation involving up to 100,000 atoms and computing multiple structural and dynamical properties.

C71.00312: IFF-R Models to Accurately Simulate Stress-Strain and Failure Porpherties of Carbon Allotropes and Polymer Composites

JORDAN WINETROUT (Presenter), KRISHAN KANHAIYA, University of Colorado, Boulder, RAVINDRA PANDEY, GREGORY M. ODEGARD, Michigan Technological University, HENDRIK HEINZ, University of Colorado, Boulder — Stress induced mechanical failure of polymeric materials is a result of the breakage of covalent bonds. The occurrence of bond breakage and formation is only observed during reactions. This study focuses on the novel bond-breaking capabilities of the Interface Forcefield (IFF-R). Traditional IFF models simulated systems using harmonic potentials. The IFF-R model incorporates Morse potentials; thereby, eliminating the restoring force experienced by bonded atoms stretched at large distances. This enables accurate predictions of mechanical responses in a variety of periodic systems. This study shows moduli and strength predictions of a single-walled carbon nanotube, poly(acrylonitrile) crystal, cellulose β crystal, and steel FCC lattice to be comparable to experimental values. Mechanical property predictions using IFF-R models are realized magnitudes faster than reactive forcefield (ReaxFF).

*NSF
C71.00313: Enhanced Optical Properties of Single-Walled Carbon Nanotubes (via SP$^3$-Hybridization Defects) from Many-Body Perturbation Theory Based on Density Functional Theory Calculations  BRADEN WEIGHT (Presenter), ANDREI KRYJEVSKI, Department of Physics, North Dakota State University — The optical consequences of functionalized carbon nanotubes (CNTs) (via a pair of SP$^3$-hybridized functional groups attached to a carbon ring) have been explored in great depth due to their promise of superior electronic properties for tunable emission in infrared energies. These studies have relied on time-dependent density functional theory (TD-DFT) calculations to model the excited states of these particles, but very little work has been completed on multiple exciton generation (MEG) processes within these systems. Here we employ a novel method based in non-equilibrium, finite-temperature, many-body perturbation theory (MBPT) calculations that utilize output from density functional theory (DFT) to accurately model excited states of these systems. We solve the Boltzmann transport equation (BE), including phonon absorption/emission and biexciton formation/recombination terms [1,2]. With this approach we compute an array of CNTs of varying chirality and functionalization scheme. We see that SP$^3$-defect functionalization of pristine CNTs that had high-energy biexciton MEG thresholds ($E \approx 2.4E_g$) can be reduced to $2E_g$, which drastically increases their value as efficient multiple exciton sources.

C71.00314: Quasi-Diabatic Scheme for Non-adiabatic On-the-fly Simulations*  WANGHUAI ZHOU, ARKAJIT MANDAL, PENGFEI HUO (Presenter), University of Rochester — We use the quasi-diabatic (QD) propagation scheme to perform on-the-fly non-adiabatic simulations of the photodynamics of ethylene. The QD scheme enables a seamless interface between accurate diabatic-based quantum dynamics approaches and adiabatic electronic structure calculations, explicitly avoiding any efforts to construct global diabatic states or reformulate the diabatic dynamics approach to the adiabatic representation. Using diabatic dynamics methods, the QD propagation scheme enables direct non-adiabatic simulation with complete active space self-consistent field on-the-fly electronic structure calculations. The population dynamics obtained from both approaches are in a close agreement with the quantum wavepacket based method and outperform the widely used trajectory surface hopping approach. Further analysis of the ethylene photo-deactivation pathways demonstrates the correct predictions of competing processes of non-radiative relaxation mechanism through various conical intersections. This work provides the foundation of using accurate diabatic dynamics approaches and on-the-fly adiabatic electronic structure information to perform ab-initio non-adiabatic simulation.

C71.00315: Abstract Withdrawn  —
C71.00316: Dielectric Screening by 2D Substrates KEIAN NOORI (Presenter), NICHOLAS CHENG, FENGYUAN XUAN, SU YING QUEK, Natl Univ of Singapore — While electronic screening within 2D materials has been studied extensively, the question of how 2D substrates screen charge perturbations or electronic excitations adjacent to them still remains.

In this work, we use first principles calculations to study the fully non-local dielectric screening properties of 2D material substrates. Our calculations give results in good qualitative agreement with those from electrostatic force microscopy (EFM) and Kelvin probe force microscopy (KPFM) experiments, indicating that the experimentally observed thickness-dependent screening effects and reduced charge potential fluctuations are intrinsic to 2D materials.

2D material substrates can also dramatically change the HOMO-LUMO gaps of small molecule adsorbates. We suggest an easy and reliable method to predict the HOMO- LUMO gaps of small physisorbed molecules on 2D and 3D substrates, using only the band gap of the substrate and the gas phase gap of the molecule.

C71.00317: Universal metric for plasmonicity of excitations at the nanoscale LUCA BURSI (Presenter), RUNMIN ZHANG, Department of Physics and Astronomy, Rice University, KYLE D. CHAPKIN, NAOMI J. HALAS, Department of Chemistry, Rice University, PETER J. NORDLANDER, Department of Physics and Astronomy, Rice University — A promising trend in plasmonics involves shrinking the size of plasmon-supporting structures down to a few nanometers, thus enabling control over light–matter interaction at extreme-subwavelength scales. In this limit, quantum mechanical effects, such as nonlocal screening and size quantization, strongly affect the plasmonic response, rendering it substantially different from classical predictions. For very small clusters and molecules, collective plasmonic modes are hard to distinguish from other excitations, such as single-electrons ones. Using rigorous quantum mechanical computational techniques for a wide variety of physical systems, we describe how the plasmonic character of a nanostructure’s optical resonance can be quantified. We define a universal metric, the generalized plasmonicity index (GPI), which can be straightforwardly implemented in any computational electronic-structure or classical electromagnetic approach to discriminate plasmons from single-particle excitations and photonic modes [ACS Nano, 11, 7321 (2017); PNAS, 115, 9134 (2018)]. The GPI metric deepens our fundamental understanding of what is a plasmon down to the molecular limit of plasmon-supporting nanostructures and provides a rigorous foundation for further development in molecular plasmonics.
**C71.00318: Particle-in-cell simulation of plasmons**  
WEN JUN DING, Institute of High Performance Computing A*STAR, JEREMY LIM (Presenter), Science and Math cluster, Singapore University of Technology and Design, DO THI BICH HUE, National University of Singapore, XIONG XIAO, Institute of High Performance Computing A*STAR, MICHEL BOSMAN, National University of Singapore, LAY KEE ANG, Science and Math cluster, Singapore University of Technology and Design, LIN WU, Institute of High Performance Computing A*STAR — Plasmons are collective oscillations of the free electron gas density in conducting media such as metals. In many cases of interest, plasmons are typically characterized by solving the Maxwell equations, where the electromagnetic response can be described by the bulk permittivity. Motivated by the physical similarity of plasmas and oscillating conduction electrons, we present a particle-in-cell-based method of simulating plasmons. By solving for the instantaneous particle position and momentum, which are connected to the electromagnetic fields through current, we demonstrate the capability of this novel approach in elucidating information on the formation of the plasmons. Specifically, we demonstrate plasmon formation in gold nanorods through laser irradiation and single-electron excitation. Lastly we investigate the non-local effects of ultra-small nanoparticles approaching quantum limit.

**C71.00319: Heat transport between two critical one-dimensional systems**  
SONJA FISCHER (Presenter), LARS FRITZ, DIRK SCHURICHT, Univ of Utrecht — Heat transport can reveal information about interacting many-body systems beyond other transport probes. In particular, in one dimension it has been shown that the energy current is directly proportional to the central charge, thus revealing information about the degrees of freedom of critical systems. In this work, we explicitly verify this result in two cases for translationally invariant systems based on explicit microscopic calculations. More importantly, we generalise the result to non-translation invariant setups and use this to study a composite system of two subsystems possessing different central charges. We find a bottleneck effect meaning the smaller central charge limits the energy transport.

**C71.00320: Thermal conductivity prediction from basic properties using a developed artificial neural network**  
GUANGZHAO QIN (Presenter), University of South Carolina, HUIMIN WANG, Nanjing University, ZHENZHEN QIN, Zhengzhou Univ, MING HU, University of South Carolina — High-throughput screening and material informatics have shown a great power in material discovery including Li-battery materials, alloys, photocatalysts, and nanowires. In this talk, we will present the accurate thermal conductivity prediction from machine learning technique using a developed artificial neural network (ANN). With 231 datasets of the basic properties describing materials calculated from first-principles and the corresponding thermal conductivity from experimental measurements as training data, the constructed ANN is well trained by iterating to reduce the loss function. The trained ANN model for thermal transport successfully captures the general correlation between basic properties and thermal conductivity for different types of materials, which is predictive spanning 4 orders of magnitude of the thermal conductivity. The developed ANN model in our work for fast and accurately predicting thermal conductivity provides a powerful tool for the large-scale thermal material screening with targeted thermal transport property.
C71.00321: Exploring structure and magnetism of collapsed lanthanides

EVGENY PLEKHANOV (Presenter), CEDRIC WEBER, Physics, Kings College London — By using DFT within VASP [1] and DFT+DMFT within CASTEP codes [2], we study the collapsed phases of Tb, Gd, Dy, Sm, Nd and Y at extreme pressure up to 240GPa.

In Tb, Gd, Dy we show that the collapsed phases have a 16-atom orthorhombic structure (oF16) not previously seen in the elements, whereas in Nd we show that it has an eight-atom orthorhombic structure (oF8) previously reported in several actinide elements. oF16 and oF8 are members of a new family of layered elemental structures, the discovery of which reveals that the high-pressure structural systematics of the lanthanides, actinides, and group-III elements (Sc and Y) are much more related than previously imagined. Our electronic structure calculations of Tb, combined with quantum many-body corrections, confirm previous and recent experimental observations by using synchrotron x-ray diffraction (see the Ref.[3] and the references therein), and predict that the collapsed orthorhombic phase is a ferromagnet, nearly degenerate with an antiferromagnetic state between 60 and 80 GPa. We also discuss in detail the magnetic properties of the lanthanides studied.

C71.00322: DFT studies of graphene in carbon droplets condensed in stellar atmospheres

CHATHURI SILVA (Presenter), PHILIP FRAUNDORF, ERIC MAJZOUB, PHILIP CHROSTOSKI, University of Missouri - St. Louis — Elemental carbon at low (ambient) pressure sublimates to vapor near 4000K, but liquid carbon is reported after laser ablation. Some meteoritic carbon particles, formed in red giant atmospheres, show a “graphene-core”/graphite-rim structure likely from super-cooled carbon droplets that nucleated graphene sheets on randomly-oriented 5-member rings. Similar core-rim particles form by slow cooling of carbon vapor in the lab (HAL-02238804). Our computations target growth of carbon rings & graphene sheets at the experimental 1.8 g/cc density estimate, by relaxing random liquid-like configurations of 13/20-atom clusters in a supercell. Inter-atom distances characteristic of covalent vs. metallic interactions (with a gap in 1.7-2 Å range) allow us to identify covalent “bonds” with small separation. Local energy minima at T = 0K show sp² & sp coordination numbers, as in the literature. Ring sizes vary from triangle to heptagon, but pentagons are more abundant than hexagons, also consistent with previous reports. Work remains to see if pent-loops can nucleate the growth of faceted pentacones, as suggested by HRTEM imaging. Unlayered graphene sheets in a frozen matrix may be an effective diffusion barrier.

C71.00323: Abstract Withdrawn
C71.00324: Dark Matter and Baryons (Surplus Quarks) Generated by Nonequilibrium Confinement of Quarks*  LEIF MATSSON (Presenter), Department of Physics, University of Gothenburg — The emergence of baryons (surplus quarks) at Big Bang, required a nonequilibrium binding and superconductor-like condensation of quark-antiquark pairs before the electroweak (EW) symmetry breakdown. (Similar for leptons). As will be further shown, the formerly unknown dimensionless coupling to the Ginsburg-Landau like potential and the scale parameter in the EW theory then become microscopic functions of the massive quark and antiquark fields, thus defining the matter-antimatter asymmetry and the dark matter content in the Universe at correct orders of magnitude. The number of free parameters in the Standard Model has thereby been reduced.

Key words: Baryogenesis; Quark Confinement; Matter-Antimatter Asymmetry, Dark Matter; Black Holes.

C71.00325: Effect of Surface Defects on Field-Induced Hot-Carrier Chemistry in Dielectric Polymers*  SUBODH TIWARI (Presenter), THOMAS LINKER, Univ of Southern California, HIROYUKI KUMAZOE, FUYUKI SHIMOJO, Department of Physics, Kumamoto University, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Univ of Southern California — Performance of dielectric polymers under high electric field is limited by the electrical breakdown, which is commonly understood as an avalanche of processes such as carrier multiplication and defect generation. We model the hot-carriers transport in dielectric polymer, polyethylene, with excited-state quantum molecular dynamics simulations in presence of electric field, which reveal multiple microscopic processes induced by hot electrons and holes under an electric field. The key chemical damage occurs due to localization of holes at the surface of slab which weaken carbon-carbon bonds on the surface. Introducing surface defects alter the valence-band maximum (VBM) state in polyethylene leading to bond breaking at lower field. Further, we have isolated C-C bond lengths and VBM localization as a proxy for dielectric breakdown. Such proxies allow us to perform one simulation to understand the effect of defect rather than scanning the complete electric field range. Such quantitative and qualitative information can be incorporated into first principles-informed, predictive modeling of dielectric breakdown.

C71.00326: Simulation of the effect of electric field on the performance of ion separation and water desalination using a graphene-carbon nanotube membrane  
SAMANEH RIKHTEHGARAN (Presenter), LUC T WILLE, Florida Atlantic University — Using molecular dynamics (MD) simulations, a graphene-carbon nanotube membrane is exposed to external electric field with intensities $E = 0.1, 1, 10, \text{ and } 100 \text{ mV/Å}$ in order to separate $\text{Na}^+$ and $\text{Cl}^-$ ions from a salt water solution to produce fresh water. The results show that by increasing the strength of the applied electric field, the ion separation will be increased to 100% for $E = 100 \text{ mV/Å}$. It is found that the ion separation efficiency of this filter is already greater than 90% for $E = 10 \text{ mV/Å}$. Based on the results of this study, it is suggested that the graphene-carbon nanotube membrane can be used as a device of water desalination under the application of electric field.

C71.00327: Effects of surface transition and adsorption on ionic liquid capacitors  
HUIKUAN CHAO (Presenter), ZHEN-GANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology — Room temperature Ionic liquids (RTILs) are a type of synthesized electrolytes possessing superb electrochemical stability and low vapor pressure compared with conventional aqueous-based electrolytes, which offers significantly enlarged electrochemical window and ease of maintenance for capacitors. Experiments measuring capacitance in concentrated RTILs often found hysteresis indicating that an underlying phase transition might exist. Current theories explaining the hysteresis in terms of phase transition either assume RTIL mixtures with neutral solvents or omit ion-ion correlations in RTILs. In this study, a variant of an existing RTIL model [1] is established for solvent-free RTIL capacitors incorporating both ion-ion correlations and nonelectrostatic interactions. We first use the model to explore the spontaneous charge separation in the capacitors and find that this transition is a common feature for realistic choices of the model parameters for most RTILs. Next, we investigate the effects of preferential ion adsorption on this charge separation transition. The results show that preferential ion adsorption can be a useful design parameter for optimizing the energy storage of the capacitors.

C71.00328: Disintegration of Surfactant Micelles at Metal-Water Interfaces Promotes their Strong Adsorption*  
SUMIT SHARMA (Presenter), HIMANSHU SINGH, Ohio Univ — We have studied adsorption behavior of surfactant micelles at metal-water interfaces via fully atomistic simulations. We show that micelles experience a free energy barrier to adsorption. Near the metal surface, surfactant molecules in the micelles slowly rearrange leading to complete disintegration of the micelles. Disintegration of the micelles results in much stronger adsorption. After the disintegration, surfactant molecules adsorb by lying flat on the metal surface. By simulating adsorption of micelles treated as rigid bodies, we show that when the micelles remain intact, they have a weak tendency to adsorb.

*NSF CBET # 1705817
C71.00329: Targeted Synthesis Conditions of Layered Bismuth Oxychalcogenides Via Electrochemical Phase Diagrams* LAUREN WALTERS (Presenter), CHI ZHANG, JAMES RONDINELLI, Northwestern University — We investigated how density functional theory calculations of electrochemical stability can guide the experimental hydrothermal synthesis of bismuth oxychalcogenides. The target phases, which are layered thermoelectrics and exhibit electronic anisotropy, represent exciting materials for catalysis, photoluminescence, and energy applications. We coupled experimental synthesis with DFT-calculated multielement Pourbaix diagrams to identify target pH and potential synthesis regions that ultimately proved successful. We further investigated numerous degrees of freedom present in the reaction, such as mass ratio of reactants, temperature, and concentration of ions, to qualitatively understand how changes in the chemistry of the oxychalcogenides alter phase stability. Last we discuss how these materials can be driven towards target phase production.

*The authors were supported by the ONR MURI “Understanding Atomic Scale Structure in Four Dimensions to Design and Control Corrosion Resistant Alloys” under Grant No. N00014-16-1-2280 and the National Science Foundation’s MRSEC program (DMR-1720139) at the Materials Research Center of Northwestern University.

C71.00330: Resolution of the identity approximation applied to PNOF family of correlation calculations JUAN FELIPE HUAN LEW YEE (Presenter), National Autonomous University of Mexico, MARIO PIRIS, Donostia International Physics Center, JORGE M. DEL CAMPO RAMÍREZ, National Autonomous University of Mexico — PNOFi (i = 1-7) family of functionals deal with electronic structure correlation calculations by means of the reduced electron density matrix approach (1-RDM). The major advantage of a 1-RDM formulation is that the unknown functional only needs to incorporate electron correlation. PNOFi family of functionals provide an efficient way of including dynamic and static correlation as compared to wave function methods. However, a transformation from atomic orbital integrals to molecular orbital integrals has to be performed in order to computate the Coulomb and Exchange matrices in molecular orbital representation J_{OM} and K_{OM} respectively, which involves an overall fifth power time scaling factor. Resolution of the identity (RI) approximation reduces the scaling factor of both, J_{OM} and K_{OM} matrices, and lowers the global scaling to fourth power. As a consequence, less memory is required to perform PNOFi calculations with an overall speed up in the calculation. RI is applied directly in the evaluation of J_{OM} and K_{OM} matrices, thus, improvement would be valid for all PNOFi family, however, the PNOF5 functional has been used in this work. Impact of RI on the convergence, and the obtained error in the correlation energy is analyzed for selected large size systems.
C71.00331: Coherent states, Gram matrix, and Hofstadter butterfly with flat band
YOUJIANG XU (Presenter), HAN PU, Rice Univ — A method to construct flat band model is exhibited. If a Gram matrix built upon a set of vectors is regarded as a Hamiltonian of certain physical system, then we can control the ground state degeneracy by modifying the vectors. If the vectors are chosen to be certain subsets of coherent states, the resulting Hamiltonians describe single-particle lattice models with a gauge field. The massive degeneracy of the lowest band in these models is a universal property independent from the shape of lattice, which is controlled by the completeness of the subsets of coherent states. The excitation spectra show Hofstadter-butterfly-like patterns which vary when the lattice changes. The models also feature ground state wave functions in universal form, which is like Landau lowest levels, but the dynamics differs. Experimental realization of the models is promising.

C71.00332: Computational simulation of patterns in a reaction-diffusion model
MONICA VELASCO (Presenter), CESAR MINOLLI, JOHN PRIAS, Physical Sciences Doctoral Program, Interdisciplinary Institute of Sciences, University of Quindío — Recent studies in reaction-diffusion models has been oriented to produce patterns for studying polycrystalline materials as graphene oxide and among others, here in show optimized algorithm for obtaining patterns of a reaction-diffusion equation. The optimization of algorithm were carried out by using fortran code and the respective visualization was employing the Visit software. The results suggest that is possible to obtain theoretical patterns of reaction-diffusion equation as expected, which could be comparable with the experimental patterns of high resolution transmission electron microscopy (HR-TEM) in graphite oxide samples.

C71.00333: Finite-Temperature Correlation Functions Using the Quantum Minimally Entangled Typical Thermal States Algorithm
SHI-NING SUN (Presenter), ADRIAN TAN, Caltech, MARIO MOTTA, IBM, FERNANDO BRANDÃO, GARNET CHAN, AUSTIN MINNICH, Caltech — Finite-temperature correlation functions provide fundamental information about the excitations and response properties of quantum many-body systems. Recently, the quantum minimally entangled typical thermal states (QMETTS) algorithm was introduced for calculating thermal averages of certain observables on near-term quantum devices. However, due to the computational cost of the quantum imaginary time evolution (QITE) subroutine underlying the QMETTS algorithm, the calculation of general thermal quantities with QMETTS remains challenging. Here, we report the calculation of finite-temperature correlation functions of quantum spin models with QMETTS. We describe how to reduce the cost of calculations by exploiting Hamiltonian symmetries and other constraints to eliminate qubits and reduce measurements. Our work advances efforts to study finite-temperature properties of quantum many-body systems on quantum computers.
C71.00334: Electrostatic screening, dynamics and structure of [BMIM+]\([\text{BF}_4^-]\) and [BMIM+]\([\text{PF}_6^-]\) with confinement*  
SUEHYUN PARK (Presenter), JESSE G. MCDANIEL, Georgia Inst of Tech — Ionic liquids are spotlighted as electrolytes for batteries and supercapacitors. Such applications have nanoconfined systems, where deviation of electrostatic screening, dynamics, and structure of ionic liquids from bulk properties is caused. Although electrostatic screening is a fundamental interaction for any charged particles, electrostatic screening condition for ionic liquids is not discovered yet in confined systems. To fully utilize ionic liquids in electronic devices, it should be fully revealed how confinement alters physical properties of ionic liquids. Here, we conducted molecular dynamics simulations of [BMIM+]\([\text{BF}_4^-]\) and [BMIM+]\([\text{PF}_6^-]\) between two graphene sheets with gap of 1.5 to 4.5 nm. Confined ionic liquids show slower dynamics by 2 orders of magnitude compared to bulk dynamics and have nonmonotonic behavior in dynamics. In addition to dynamics, we observed that capacitance is independent of confinement length. To explain this confinement effect, we computed electrostatic screening condition derived from Stillinger-Lovett sum rules. Furthermore, we investigated polarization effect on electrolytes and electrodes in confined system.

C71.00335: Finite-temperature auxiliary-field Quantum Monte Carlo study of dynamical correlation functions in correlated fermion systems*  
HAO SHI, YUAN-YAO HE (Presenter), SHIWEI ZHANG, Center for Computational Quantum Physics, Flatiron Institute — We compute dynamical (imaginary-time) correlation functions in correlated fermion systems using the finite-temperature auxiliary-field Quantum Monte Carlo method. The sign problem is eliminated by introducing constraints in auxiliary-field space. We carry out a systematic benchmark study of dynamical correlation functions in the two-dimensional repulsive Hubbard model, for various interaction strengths, density, and temperatures. At high temperatures, essentially exact results are obtained independent of the form of the constraint, similar to calculations of static quantities [1]. With decreasing temperature, we discuss how the constraint can be optimized to improve the accuracy of dynamical correlation functions. In the context of studying the pseudogap behavior, we apply the method to compute the self-energy and spectral functions in the Hubbard model. References:

**C71.00336: Low-energy physics in the critical phase of the bilinear-biquadratic spin-1 chain**

MORITZ BINDER (Presenter), THOMAS BARTHEL, Duke University — We use an efficient density matrix renormalization group (DMRG) algorithm to compute precise dynamic structure factors for the bilinear-biquadratic spin-1 chain with Hamiltonian \( H = \sum_i \left[ \cos \theta (S_i^* S_{i+1}) + \sin \theta (S_i^* S_{i+1})^2 \right] \). Here, we focus on explaining the physics in the extended critical phase \( (\pi/4 \leq \theta < \pi/2) \) of the model. The phase transition from the Haldane phase to the critical phase is marked by the SU(3)-symmetric ULS point \( (\theta = \pi/4) \), where the elementary excitations are spinons that can be obtained from the Bethe ansatz solution. As we move deeper into the critical phase, the spinon continua contract, and new striking features appear at higher energies. In the vicinity of the transition point from the critical to the ferromagnetic phase, a dispersion with a surprisingly simple functional form emerges, suggesting integrability of the model in the limit \( \theta \to \pi/2^- \).

**C71.00337: Entanglement decomposition for the simulation of quantum many-body dynamics**

THOMAS BARTHEL (Presenter), Duke University — Nonequilibrium dynamics in quantum matter are at the frontier of current research. Efficient and precise simulation techniques are needed to improve our understanding of equilibration and thermalization, dynamical phase transitions, decoherence effects, quantum transport etc. A major obstacle is the growth of entanglement with time which generally implies an increased complexity of the quantum state. For instance, the computation costs of simulations based on tensor network states generally grow rapidly in time, limiting the maximum reachable times. I will show how this problem can be addressed through entanglement decomposition. We can follow the dynamics, starting from an initial state, until the entanglement has grown to a point where our simulation resources are exhausted. We then decompose the current state into lower entangled components and continue by simulating the evolution of these components, decomposing them again when needed. I will demonstrate a specific entanglement decomposition scheme for matrix product state simulations and discuss its efficiency for the study of dynamics in quantum magnets.

*Research supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award No. DE-SC0019449.
C71.00338: Counter-diabatic Spin Squeezing  ZEYANG LI (Presenter), Massachusetts Institute of Technology, BORIS BRAVERMAN, University of Ottawa, ENRIQUE MENDEZ, VLADAN VULETIC, Massachusetts Institute of Technology — Spin squeezing states (SSS) are atomic entangled states that can be used to enhance the atomic precision measurements beyond the standard quantum limit. Existing implementations relying on unitary evolution are primarily based on one-axis twisting induced through coherent cavity feedback. By adding an auxiliary driving Rabi field, our work can generalize this one-axis twisting to an equivalent two-axis twisting, which features robustness against technical imperfections, as well as the potential to reach higher squeezing and therefore greater metrological gain. Moreover, by optimizing the time-varying auxiliary field, we obtain a fast preparation of SSS with high metrological gain, which we call as counter-diabatic spin squeezing.

C71.00339: Quantum Many-Body Effects in Optical Kerr Media  GIULIA MARCUCCI (Presenter), DAVIDE PIERANGELI, CLAUDIO CONTI, Physics Department, Sapienza University of Rome — Nonlinear quantum optics is emerging as one of the most important research directions in photonics. These include quantum solitons (QSs), and highly nonclassical supercontinuum generation (SCG). We need new strategies to design nonlinear optical devices operating at low photon numbers and theory to describe how they work.

Following Drummond et al. [1], we adopt a phase-space analysis to map the second quantized field theory of optical propagation in nonlinear dispersive media into a system of two coupled stochastic nonlinear Schrödinger equations (SNLSEs). This mapping allows numerical simulations of QSs, quantum dispersive shock waves (QDSWs) and quantum rogue waves (QRWs) generation by the nonlinear box problem [2] at low photon number.

As recently proved [3], quantum control furnishes new opportunities. By combining SNLSEs and CRAB optimization, we look for the best control function to limit effects as quantum spreading of QSs, to maximize the spectral generation of QDSWs, and to enhance the peak intensity of QRWs.

We believe that this approach unveils essential insights into the design of new quantum sources.

C71.00340: Bosonic entanglement crossover from groundstate scaling to volume laws*
Qiang Miao (Presenter), Thomas Barthel, Duke University — The crossover behavior of eigenstate entanglement entropies from an area law or log-area law for low energies and small subsystem sizes to volume laws for high energies and large subsystems can be described by scaling functions. We demonstrate this for two bosonic systems. The harmonic lattice model describes a system of coupled harmonic oscillators and is a lattice regularization for free scalar field theories. For dimensions \(d \geq 2\), the ground state of this model displays an entanglement area law, even at criticality, because excitation energies vanish only at a single point in momentum space. In contrast, Bose metals feature a finite Bose surface with zero excitation energy. One hence finds log-area laws for the groundstate entanglement. For both models, we sample excited states. The distributions of their entanglement entropies are sharply peaked around subsystem entropies of corresponding thermodynamic ensembles in accordance with the eigenstate thermalization hypothesis. In this way, we determine the scaling functions numerically. Eigenstates for quasi-free bosonic systems are not Gaussian. We resolve this problem by considering appropriate squeezed states instead, for which entanglement entropies can be evaluated efficiently.

*Research supported by DOE grant DE-SC0019449

C71.00341: A New Graphical Method for Designing Exactly Solvable Models
Masahiro Ogura (Presenter), Kyoto Univ — Exactly solvable lattice spin models have played important roles in physics. Since Onsager's work, some lattice spin models were exactly solved by treated as free fermion models (FFMs). For example, the one-dimensional XY model, the one-dimensional transverse field Ising model, and the Kitaev's two-dimensional honeycomb lattice model (KHL) can be solved in this way ([1],[2]). Based on these facts, in this talk we will present a new method to obtain a series of solvable models that include the Jordan-Wigner transformation and the Kitaev's method of the KHL as special cases [3]. For any given well-behaved graphs, we can construct FFMs corresponding to them. We can also design a set of operators from them. Therefore, we can create a lot of exactly solvable Hamiltonians. By this method we will introduce new solvable models, containing three-dimensional lattice models and spin systems corresponding to a fractal-like graph.

C71.00342: Application of the Recursive Projection Method to Electronic Structure Calculation*  SHOHAM SEN (Presenter), Carnegie Mellon University, YANG WANG, Pittsburgh Super Computing, Carnegie Mellon Univ, TIMOTHY BREITZMAN, Air Force Research Laboratory, KAUSHIK DAYAL, Carnegie Mellon University — In this work, we focus on the mixing scheme used during the Self-Consistent (SC) process of solving the Kohn-Sham (KS) equations. The two most common mixing schemes used in practice are the “Simple Mixing” and the “Modified Broyden Mixing”, the former is a fixed point method while the latter is a Quasi-Newton method. A characterization of the former method is that it takes less computation time per iteration but required a lot of iterations to converge; the latter gives quadratic convergence hence fewer iteration but takes more computational time per iteration. It can be shown that Simple Mixing converges if the eigen-values of the Jacobian lie within some ellipse. Thus even if only a few eigen-values lie outside the ellipse, Simple Mixing will not converge. We proposed the “Recursive Projection Method” (RPM) modified for electronic structure calculation, where we estimate the subspace spanned by the eigen-vectors whose eigen-values lie within the ellipse, call this the “stable-subspace”. We perform Simple Mixing on the stable-subspace and Modified Broyden on the complementary subspace. We expect that this method will improve convergence for systems of large size.

*We thank the DOD MURI Project for their Financial Support

C71.00343: The Energy Landscape Governs Brittleness and Ductility in Glasses*  LONGWEN TANG, MATHIEU BAUCHY (Presenter), University of California, Los Angeles — Based on their structure, non-crystalline phases can fail in a brittle or ductile fashion. However, the nature of the linkages between structure and propensity for ductility in disordered materials has remained elusive. Here, based on molecular dynamics simulations, we investigate the fracture of several disordered phases (metallic glass, glassy silica, colloidal gel, etc.) with varying degrees of disorder. We find that that, in general, structural disorder results in an increase in ductility. By applying the activation-relaxation technique (an accelerated sampling method to identify transition states), we show that the degree of plasticity is controlled by the topography of the energy landscape.

*This work was supported by the National Science Foundation under Grants No. 1762292 and 1826420.
C71.00344: Interface of Hydrated Perfluorosulfonic Acid Electrolyte with a Platinum Catalyst: Structural Analyses with Dissipative Particle Dynamics Simulations* NOBUO TAJIMA (Presenter), JUN NARA, MANA, National Institute for Materials Science, TAKU OZAWA, HIROYA NITTA, KOSUKE OHATA, Engineering Technology Division, JSOL Corporation, TAKAHISA OHNO, MANA, National Institute for Materials Science — Dissipative particle dynamics (DPD) simulations were performed to study structures of hydrated perfluorosulfonic acids (PFSA) in contact with platinum surfaces. Two types of interfacial systems were simulated, where PFSA molecules interact with a cube and a slab of platinum, respectively representing a small catalyst particle used in a regular fuel cell and a platinum substrate popularly used in a model system experiment. The calculated results suggest that the two systems form a shell structure and a layer structure, respectively, of PFSA components near the platinum surfaces. The water component covers the platinum surfaces popularly in both systems, of which the coverage depends on the hydration levels of PFSA. Detailed analyses revealed that the water component networks are quite different in the two systems, which are three-dimensionally connected in the systems with a platinum cube, while disrupted by hydrophobic components in the systems with a platinum slab.

*This work was partly supported by MEXT within the priority issue 6 of the FLAGSHIP2020 project (Project ID: hp160226, hp170253, hp180187, and hp190178). The calculations were primarily performed on NIMS super computer and K-computer.

C71.00345: Universal properties of creep flow in amorphous solids MARKO POPOVIC (Presenter), TOM.W.J. DE GEUS, École polytechnique fédérale de Lausanne, ALBERTO ROSSO, LPTMS, CNRS, Universite Paris-Sud, Universite Paris-Saclay, 69 91405 Orsay, France, MATTHIEU WYART, École polytechnique fédérale de Lausanne — Amorphous solids, such as atomic glasses, colloidal suspensions, granular matter or foams, begin to deform plastically when exposed to external stress $\Sigma$. Steady state deformation rate $\partial_t \varepsilon$ of these materials in absence of thermal fluctuations is usually described as $\partial_t \varepsilon \sim (\Sigma - \Sigma_c)^\beta$ for stresses above critical stress $\Sigma_c$ and vanishes below it, while in presence of thermal fluctuations flow persists below $\Sigma_c$, but is exponentially suppressed. The transient plastic deformation rate, called creep flow, is much less understood despite its importance in practical applications. Creep flow often displays a power-law decay in time $\partial_t \varepsilon \sim t^{-\mu}$ after which it can either arrest or eventually yield at fluidisation time $\tau_f$. In recent years various numerical values and/or laws have been suggested for the exponent $\mu$ and time $\tau_f$ in particular experimental or numerical studies. We propose that mechanism underlying creep flow is the same as that of the steady state flow, which allows us to predicts parameters $\mu$ and $\tau_f$ of creep flow in terms of the steady state flow parameters, both in athermal and thermally activated systems. We successfully tested all our predictions using different mesoscopic elasto-plastic models of amorphous solids and found them to be consistent with published experimental results.

C71.00346: SHOCK COMPRESSION OF CONDENSED MATTER —
C71.00347: Effect of structural collapse on electron density distribution and magnetic properties of ThCr$_2$Si$_2$-type pnictides* MICHAEL SHATRUK (Presenter), VINCENT YANNELLO, JUDITH K ROTH, Florida State Univ, ALEXANDER A YAROSLAVTSEV, European XFEL, ANDREI ROGALEV, European Synchrotron Radiation Facility, VASILE O GARLEA, Oak Ridge National Laboratory — The structural phase transitions in the ThCr$_2$Si$_2$-type materials involve a gradual or abrupt (first-order) collapse along the tetragonal c axis. Despite many examples of such transitions in the AT$_2$X$_2$ structures, the direct experimental assessment of changes in the electron density redistribution between the A and [T$_2$X$_2$] layers upon the formation and breaking of the X-X bonding interactions is largely lacking. Earlier studies have revealed fascinating pressure-induced transitions in EuCo$_2$Pn$_2$ (Pn = P, As) which are accompanied by the change in the Eu oxidation state and the transition from the localized (4f) magnetism to itinerant (3d) magnetism. In the present contribution, we demonstrate that the changes in the electron concentration in the [Co$_2$Pn$_2$] layer defy the formal electron-counting rules that are often used for Zintl-like phases. X-ray absorption measurements offer the direct insight into the changes in the Eu oxidation state and magnetism and the associated redistribution of the electron density in the [Co$_2$Pn$_2$] layer. Calculations of the band structure and analysis of chemical bonding have provided a satisfactory interpretation for the observed changes in the X-ray absorption spectra.

*This research was supported by the National Science Foundation (DMR-1905499).

C71.00348: Combining theoretical and experimental methods to study some zircon-type orthovanadates at high pressure.* ALFONSO MUNOZ-GONZALEZ (Presenter), PLACIDA RODRÍGUEZ-HERNANDEZ, IMN and Dept. de Fisica, Universidad de La Laguna, TOMAS MARQUEÑO, ENRICO BANDIELLO, DANIEL ERRANDONEA, Departamento de Física Aplicada, Universidad de Valencia — Many studies of zircon-type orthovanadates under high pressure have been performed. Some of these experiments using methanol-ethanol-water as pressure transmission medium report a zircon-to-monazite phase transition. In this work, we will focus on the study of the zircon-to-scheelite phase transition of some orthovanadates, combining high pressure experimental hydrostatic studies and ab initio simulations. Our approach provides information on the structural, electronic, dynamical, and elastic properties of these compounds. From our simulations, we found that around the transition pressure the zircon phase becomes dynamically unstable due to the softening of one B$_{1u}$ silent mode. Our study of the elastic constants and the analysis of the generalized mechanical stability criteria show a mechanical instability also appears near the transition pressure. We will also report on the new high pressure phase that appear after the zircon-to-scheelite transition.

*We thank the financial support from MINECO under projects MALTA Consolider Ingenio 2010 network (MAT2015-71070-REDC and RED2018-102612-T), MAT2016-75586-C4-1/3-P and by Generalitat Valenciana under grant Prometeo/2018/123 (EFIMAT). E. Bandiello thanks the Generalitat Valenciana for his postdoctoral contract (Vall+D, APOSTD2017).
C71.00349: New developments in large volume static compression with in situ synchrotron x-ray diffraction at High Pressure Collaborative Access Team (HPCAT) at the Advanced Photon Source*  ROSTISLAV HRUBIAK (Presenter), GUOYIN SHEN, CURTIS KENNEY-BENSON, CHANGYONG PARK, ARUN BOMMANAVAR, YU SHU, Argonne Natl Lab, ITARU OHIRA, Geophysical Laboratory, Carnegie Institution of Washington, YOSHIO KONO, Geodynamics Research Center, Ehime University — The integration of x-ray diffraction measurements with physical properties characterizations in a large volume cell provides a unique opportunity to investigate in-situ correlation between the atomic structure and the macroscopic properties of matter at high pressure (P) and high temperature (T) conditions. The beamline 16-BM-B capable of near comprehensive large-volume sample characterization at high P and high T conditions in a Paris-Edinburgh (PE) cell by using a multitude of in-situ x-ray-based techniques. An overview of the currently supported techniques that are available to users, with emphasis on new developments, is presented. Available techniques include: double-stage PE for amorphous structural measurements above 100 GPa, ultrasonic echo, fluid viscosity, high P-T synthesis, x-ray absorption density measurement, powder diffraction, phase contrast radiography, liquid (im)miscibility, and thermoelectric properties measurements.

*This work was performed at HPCAT (Sector 16), Advanced Photon Source (APS), Argonne National Laboratory (ANL). HPCAT operations are supported by DOE-NNSA's Office of Experimental Sciences. The APS is a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by ANL under Contract No. DE-AC02-06CH11357.
C71.00350: Pressure induced phase transitions in topological crystalline insulator SnTe and its comparison with semiconducting SnSe: Raman and First-principles studies  SUKANYA PAL (Presenter), Indian Institute of Science - Dept of Physics, RAAGYA ARORA, Theoretical Sciences Unit, Jawaharlal Nehru Center for Advanced Scientific Research, SUBHAJIT ROYCHOWDHURY, New Chemistry Unit, Jawaharlal Nehru Center for Advanced Scientific Research, LUMINITA HARNAGEA, SAURABH KUMAR, Department of Physics, Indian Institute of Science Education and Research, SANDHYA SHENOY, Theoretical Sciences Unit, Jawaharlal Nehru Center for Advanced Scientific Research, D.V.S. MUTHU, Indian Institute of Science - Dept of Physics, KANISHKA BISWAS, New Chemistry Unit, Jawaharlal Nehru Center for Advanced Scientific Research, U.V. WAGHMARE, Theoretical Sciences Unit, Jawaharlal Nehru Center for Advanced Scientific Research, A K SOOD, Indian Institute of Science - Dept of Physics — We report Raman study of a topological crystalline insulator (TCI) SnTe and a normal semiconductor SnSe, as a function of pressure at room temperature along with first-principles density functional theory calculations. Under pressure, iso-structural transition is observed in SnTe as revealed by the anomalous softening of the strongest Raman mode up to 1.5 GPa. Further, SnTe undergoes structural transitions at ~ 5.8, ~ 12 and ~ 18.3 GPa. The 5.8 GPa transition is associated with a structural transition from ambient cubic (Fm-3m) to orthorhombic (Pnma) phase which is no longer a topological insulator. Above the transition pressure of 12 GPa another orthorhombic Pnma[GeS] phase is stabilized coexisting with Pnma phase. Above 18.3 GPa enthalpy calculations show a transition from orthorhombic Pnma to a more symmetric cubic (Pm-3m) structure. Our high-pressure study of SnSe on the other hand reveals that it undergoes two phase transitions: one from the orthorhombic (Pnma) structure to orthorhombic (Cmcm) structure at ~ 6.2 GPa and the other at ~ 12.9 GPa in which the Cmcm phase undergoes a semi-metal to metal transition. Density functional theory calculations capture the contrast in pressure dependent behaviour of topological crystalline insulator SnTe and a normal semiconductor SnSe.

C71.00351: WITHDRAWN ABSTRACT  —

C71.00352: Study of thermal properties of HMX in molten TNT.  NATALYA SUVOROVA (Presenter), DAVID M OSCHWALD, DENNIS K REMELIUS, LAURA SMILOWITZ, BRYAN HENSON, PAMELA BOWLAN, Los Alamos Natl Lab — Octol composed of 70 wt% of HMX and 30 wt% of TNT is one of the melt cast explosives that is widely used in many military applications, namely for shaped charges. Due to the presence of low melt TNT component octol exhibits complex thermal behavior. At the temperature above TNT melt, octol forms liquid-solid system that with further heating undergoes phase change and decomposition of its constituencies with release of thermal energy. In this presentation the thermal decomposition properties of octol were investigated via DSC/TG method and X-ray diffraction at various heating conditions. The thermal reactivity of heated octol was compared to other TNT- based melt cast compositions, such as Composition B and cyclotol.
C71.00353: Electrical and optical properties of tetragonal polymeric C60 under high pressure ZHONGYAN WU (Presenter), Department of Physics and HYU-HPSTAR-CIS High Pressure Research Center, Hanyang University, Seoul, 04763, South Korea, LIN WANG, Center for High Pressure Science & Technology Advanced Research, Shanghai 201203, China, ALEXANDER SOLDATOV, Department of Engineering Sciences & Mathematics, Lulea University of Technology, SE - 97187 Lulea, Sweden, JAEYONG KIM, Department of Physics and HYU-HPSTAR-CIS High Pressure Research Center, Hanyang University, Seoul, 04763, South Korea — C60 having unique icosahedral truncated structure is known to form polymer or dimer between fullerene cages under high pressure and temperature. In this work the electrical and optical properties of 2-dimensional tetragonal polymeric C60 were studied under high uniaxial pressure, p, to investigate the phase transformation. The electrical resistance value, R, decreased from $10^{10}$ to $5 \times 10^5$ Ω as a result of pressure cycling (with ramp pressure increase in each cycle) to a maximum pressure of 32 GPa by using a diamond anvil cell (DAC). A substantial drop in R after decompression (~$10^{10}$ Ω) was reached in a cycle with a ramp pressure of 22 GPa that we consider as a cross-over/phase transition p. A subsequent p-cycling to 32 GPa resulted in further (20 times!) drop in the R of the recovered sample and exhibited anomalies in R vs p behavior. The results of Raman measured after decompression showed that the ratio of the 2-dimensional T-phase to 1-dimensional O-phase decreased as increasing the cycling p. Raman-mapping of the recovered material showed Raman spectra inhomogeneities across the sample stemming from a non-hydrostatic pressure distribution in the DAC and the relationship between shear and normal stress.

C71.00354: Structural behavior of silicate liquids and glasses under extreme conditions by using synchrotron X-ray diffraction and Raman spectroscopy* YOUNG JAY RYU (Presenter), TONY YU, Center for Advanced Radiation Source, University of Chicago, FIONA BONNET, Geosciences, Universite Claude Bernard Lyon 1, VITALI PRAKAPENKA, SERGEY TKACHEV, Center for Advanced Radiation Source, University of Chicago, HEATHER WATSON, Physics and Astronomy, Union College, MARK L RIVERS, YANBIN WANG, Center for Advanced Radiation Source, University of Chicago — The behavior of silicate melts under high-pressure and high-temperature conditions is of primary interest in the field of geophysical, chemical, material science, and technological glass process industry, both for their fundamental properties and for their significant roles in thermal transport and chemical differentiation within Earth and other terrestrial planetary interiors. Recently, considerable progress has been achieved in understanding the structural differentiation of liquid and glass silicates by both theoretical predictions and various spectroscopic experiments, yet still many issues are puzzling and several challenges must be overcome to expand our understanding of silicate liquids and glasses. Here, we report spectroscopic properties of enstatite (MgSiO3), wollastonite (CaSiO3), diopside (CaMgSi2O6) and silica (SiO2). The local atomic structure of various silicates has been studied using synchrotron angle-dispersive X-ray diffraction combined with a multi-channel collimator. Atomic pair distribution functions (PDFs) were obtained from the X-ray data. Also, we have obtained the local vibrational modes by using Raman spectroscopy, providing additional structural information that cannot be obtained by X-ray diffraction.

C71.00355: Automated iterative forward analysis for pressure determination in dynamic compression experiments  
CONNOR KRILL, SUZANNE J ALI, Lawrence Livermore Natl Lab, JUNE WICKS, Johns Hopkins University, RAYMOND SMITH (Presenter), Lawrence Livermore Natl Lab — High powered laser compression experiments can provide insights into material behavior at solar and planetary cores - some of the most extreme conditions in the Universe. To fully understand material response at such extreme conditions, the pressure within the sample must be accurately determined. However, pressure cannot be measured directly. Experiments must measure the velocity of a sample and use knowledge of the equation of state to extract a pressure history. With new driver developments laser shot rate is increasing, going from once a day at NIF, to every few minutes at the Stanford Materials in Extreme Conditions (MEC) endstation and the near-term sub-Hz operation at the European X-ray Field Electron Laser (XFEL) facility in Hamburg. This increase creates a need for an automated process to convert experimentally measured velocities into pressure histories. The work reported here implements an automated iterative forward analysis using the HYADES hydrocode that can scale with the growth of modern laser facilities to accurately retrieve pressure histories from a broad range of experimental conditions. We discuss this work in the context of ramp compression of various materials on the OMEGA laser facility.

C71.00356: Liner Material Dependence on Penetration Ability of Metal Jet generated from Mini-Shaped Charge Devices against Iron Target  
FUMIKAZU SAITO (Presenter), Department of Applied Physics, National Defense Academy — New experimental data for the mass and density gradients of Cu and Zn metal jet using the original mass-estimation method are reported. The metal jets were generated by using shaped charges, which consist of conical Cu / Zn liners and PBX explosive charge. To compare the penetration ability of these two metal jets, Fe target-blocks were used as the target. At 3 CD (3 times charge diameter; ca. 100 mm from the shaped charge device), the breakup of Cu jet was observed, and the Cu metal segment at the jet tip was generated. On the other hand, the breakup of the Zn jet was not observed at 3 CD. The tip of the Zn jet exhibited a comet-like tail, which is unique compared to the morphology of the Cu leading jet. This result shows that the Zn jet tip reaches a state of liquid, and/or becomes a fine particle at the initial formation process. Against expectations, the penetration depth of the Zn jet against the Fe target placed at 5CD from the shaped charge device was higher than that of the Cu jet having a relatively large initial density. This result suggests that the penetration depth is more affected by the total mass of the metal jet and that the liner geometry to generate the jet mass effectively is differ depending on the material properties such as density and melting point.
HOSSAIN (Presenter), Univ of Delaware — Vacancy defects are ubiquitous in growing materials at the nanoscale. Yet their role in low-dimensional materials such as nanowires remains less understood. Here we report the observation of two mechanisms: elastic softening and stress localization that govern effective mechanical behavior of diamond and silicon carbide nanowires. They control different mechanical aspects of the nanowire at finite deformation. Elastic softening controls the effective mechanical properties such as stiffness in the linear regime of mechanical deformation, whereas stress-localization affects the effective toughness and strength of the nanowire. As a result, the condition for crack nucleation and the direction of crack growth are directly controlled by the stress-localization mediated by the higher-order elastic behavior of the lattice. With the increasing size of the defective regime, the nanowire shows softer effective elastic behavior that arises from the low-coordinated atoms forming the basis for the softening state of the defective regime. Results show that defect-size dependent effective stiffness is controlled by softening at the defective and surface regimes, whereas defect-size dependent toughness and strength are controlled by stiffening of the material by second-order elastic modulus.

MAURIZIO MATTESINI (Presenter), CAROLINA LÓPEZ-SÁNCHEZ, ELISA BUFORN PEIRÓ, AGUSTÍN UDÍAS VALLINA, Earth's Physics and Astrophysics, Univ Complutense — A key element to understand the mechanism of shallow-intermediate and very deep earthquakes is here provided by an accurate model description of the stress-strain curves of the subducting material, i.e. the metastable Olivine. Specifically, atomistic modeling was carried out through ab initio techniques for the Mg$_2$SiO$_4$ forsterite end-member at different pressure ranges. The achieved stress-strain relationships were finally compared to the Moment Rate Source-Time Functions (MRSTFs) and Fracture Energies values. We found that deep events have a common rupture pattern that differs substantially from that of shallow-intermediate earthquakes. This finding is in line with the different behavior observed in the stress-strain curves as a function of depth.

*This work has been partially supported by the Spanish Ministry of Economy and Competitiveness, Project CGL2017-86070-R. Part of this data has been provided by the Instituto Geográfico Nacional, Madrid (Spain) and by Incorporate Research Institutions for Seismology (IRIS).
C71.00359: X-Ray Absorption Spectroscopy Fingerprints for bcc and hcp Iron at Earth’s Core Conditions* MAURIZIO MATTESINI (Presenter), Department of Earth Physics and Astrophysics, University Complutense of Madrid, ANATOLY BELONOSHKO, Department of Physics, AlbaNova University Center, Royal Institute of Technology (KTH) — The shapes of Fe K-edge of X-ray absorption spectra (XAS) were theoretically computed at Core conditions by using a number of molecular dynamics snapshots from a previously equilibrated iron system at 360 GPa and 7000 K. Reference fingerprints for the different iron polymorphs, namely Fe-bcc and Fe-hcp, were thus obtained within the multi-scattering method and therefore proposed as specific spectroscopic fingerprints. It is shown that is possible to unfold the long-standing controversy about the structural complexity of iron at the Earth’s inner core conditions. Specifically, high pressure studies from static laser heated diamond anvil cell and dynamic compression can take advantage of the proposed spectroscopic fingerprints.

*This work has been partially supported by the Spanish Ministry of Economy and Competitiveness, Project CGL2017-86070-R.

C71.00360: Phase diagram of solid hydrogen SAM AZADI (Presenter), Physics, King’s College London — We present new results for the phase diagram of low-temperature high-pressure solid hydrogen, which are obtained using independent-particle and many-body wave function-based approaches. To discover the nature of phase III, density functional theory calculations within the meta-generalized gradient approximation by means of the strongly constrained and appropriately normed (SCAN) semilocal density functional are employed to investigate eleven molecular structures within wide pressure ranges of 100-500 GPa. The SCAN-DFT predicts two structures of C2/c and P6122 as the best candidates for phase III. We employ the diffusion Monte Carlo (DMC) method to verify the stability of competitive phases which requires an accurate description of exchange interaction. Our DMC results indicate that the optimised percentage of exact-exchange in many-body wave function equals to 40%. We name the corresponding exchange and correlation functional as PBE\textsubscript{1}. The PBE\textsubscript{1}-predicted phase diagram shows that the phase III of high-pressure solid hydrogen is polymorphic [1].

Coarse-grain simulation study of the shear-band deformation mechanism in molecular crystals

SERGEI IZVEKOV (Presenter), PATRICK G. LAFOND, JOHN K. BRENNAN, JAMES P. LARENTZOS, US Army Rsch Lab - Aberdeen — Computationally inexpensive particle-based coarse-grained (CG) models are crucial for simulations of mesoscopically slow cooperative phenomena such as plastic deformations in solids. Molecular crystals possessing complex symmetry present an enormous practical challenge for coarse-graining at molecularly resolved scales, where the molecule is mapped into a CG particle and beyond. In this paper, we present the successful bottom-up coarse-graining of a molecular energetic crystal, cyclotrimethylene trinitramine in the alpha phase (α-RDX), using the force-matching based multiscale coarse-graining (a.k.a. MSCG/FM) approach. The new MSCG/FM model offers a potentially powerful free-energy tool to analyze the lattice instabilities that lead to plastic response. A specific application of this model involves a study of the molecular-level mechanisms of shear microband formation, which is observed in the atomistic simulations of α-RDX under both static and shock-wave uniaxial compressions. These were hypothesized to contribute to plasticity, and potential shock initiation in RDX-based explosives.

Atomistic Predictions for Reaction Mechanisms, Kinetics, and Detonation Properties of the Insensitive Explosive LLM-105

ALEJANDRO H STRACHAN, BRENDEN HAMILTON (Presenter), Purdue Univ, BRAD STEELE, MATTHEW P KROONBLAWD, I-FENG W KUO, Lawrence Livermore National Laboratory — Understanding the mechanical and chemical characteristics of insensitive high explosives (IHEs) is key for the design of new insensitive materials with improved response. We explore high temperature reaction kinetics and identify reaction mechanisms for the IHE LLM-105 through all-atom molecular dynamics performed at two levels of quantum chemical theory and with classical reactive potentials. Short timescale DFT-MD simulations are used to cross-validate density functional tight-binding (DFTB) predictions, which in turn are compared against multiple ReaxFF parametrizations. High-throughput DFTB simulations are coupled with the Hugoniotstat technique to simulate shock loading and to characterize the Hugoniot curves for both unreacted LLM-105 and its products. DFTB predictions for the CJ state and detonation properties are in good agreement with ReaxFF-LG. Effects of pressure on reaction products and pathways are identified and isothermal-isobaric simulations are used to study reactions at CJ conditions. Prepared by LLNL under Contract DE-AC52-07NA27344. Approved for unlimited release, LLNL-ABS-793765.
C71.00363: Development of low-adiabat drives for Rayleigh-Taylor strength experiments* 
TOM LOCKARD (Presenter), Lawrence Livermore Natl Lab, MATTHEW P HILL, Atomic Weapons Establishment, ANDREW KRYGIER, ALEX ZYLSTRA, Lawrence Livermore Natl Lab, PETER GRAHAM, Atomic Weapons Establishment, PHILIP POWELL, DAMIAN C SWIFT, SHON T. PRISBREY, HYE-SOOK PARK, JAMES M MCNANEY, Lawrence Livermore Natl Lab — We have used the expansion of a shocked reservoir assembly across a gap to induce ramp loading, and hence infer strength from the growth of ripples at an interface. For multi-megabar loading, the reservoir comprises a sandwich of several materials, and the resulting load history has a large amount of structure, including shocks. This structure leads to a degree of shock heating, and some uncertainty in the heating that actually occurs. We report on progress in studies to improve the reservoir drive by reducing the shock heating, including the performance of the models used for the components of the experiment in hydrodynamic simulations.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

C71.00364: LASER SCIENCE —

C71.00365: Electron cyclotron emission with a helical wavefront in millimeter-wave regime from an electron accelerated by a circularly polarized wave YUKI GOTO (Presenter), Department of Applied Energy, Nagoya University, SHIN KUBO, TORU II TSUJIMURA, National Institute for Fusion Science, National Institutes of Natural Sciences — In this study, we calculated an Electron Cyclotron Emission (ECE) with a helical wavefront in the millimeter-wave regime from an electron accelerated by a Circularly Polarized (CP) wave. Recently, it has been shown that radiation from a charged particle with spiral motion has a helical wavefront. Since an electron cyclotron motion is also a type of spiral motion, the ECE should also have a helical wavefront. In particular, we attempt to generate the high power coherent ECE with a helical wavefront from a multi-electron system. Because the radiation with helical wavefront from a single electron is low power, the superposition of the electric field is necessary to detect the radiation. For this reason, the CP wave plays an important role to control the electron' rotation motion. We have confirmed in the calculation that the rotation phase of the electrons is controlled by an externally applied CP electric field. It was also confirmed by calculation where the radiation from such the electron has a helical wavefront. We will show the details of the calculation results at the meeting.
C71.00366: Evolution from Periodic Oscillation to Chaos in Q-switched Vortex Lasers of a Unit Topological Charge  YUAN-YAO LIN (Presenter), CHAO-YI WU, Natl Sun Yat Sen Univ — Recently direct vortex lasing from azimuthal symmetry breaking resonator were demonstrated both in continuous wave [1] and in Q-switched [2] operations. Regarding to the investigation of laser dynamics we rebuild the Q-switched vortex laser system following the same configuration reported in REF [2]. Produced Q-switched laser emits annular intensity pattern and its positive unit topological charage is quantified by spiral phase pattern sensed using a interferometer. Clear transition from periodic oscillation of every 2 pulses, 4 pulses and 6 pulses to completely disorders in pulse sequences can be identified in delay maps using the pulse-to-pulse duration as an observable. This spatial-temporal dynamic can be explained by Tang-Statz-DeMars model that describes the coherent coupling and nonlinear interactions of the off-axis multiple pass resonance modes. Moreover pumping a KTP crystal by this Q-switched vortex laser at the wavelength of 1064 nm, second harmonic wave at 532 nm exhibits unconventional intensity distribution other than a vortex with doubling topological charges because of the interactions among the resonating off-axis modes in fundamental wave.

C71.00367: Discrete evolution on temporal separation and phase difference for bound solitons in an Yb mode-locked fiber laser* CECÍLIA CAMPOS (Presenter), LUCAS B. A. MÉLO, LÚCIO H. ACIOLI, MARCIO H. G. DE MIRANDA, Departamento de Física, Universidade Federal de Pernambuco — Multiple pulse regime is a common feature in passively mode-locked fiber lasers (MLFL). They could either be equally spaced, randomly distributed or arranged in a state of close interacting pulses. The later is often called bound solitons and presents strong modulation in the optical spectrum, which contains information about average relative phase, Δφ, and temporal separation between the pulses, τ. In this work, we study how increments in the total intracavity energy act on τ and Δφ for an Yb MLFL. For this, we continuously monitored the optical spectrum and the autocorrelation as the pump power was increased. We observed a discrete nature of τ, which is in agreement with previous works that observed its quantization for Er-doped fiber lasers [1] and predicted the quantization of binding energy between bound solitons [2]. Our work provides a systematic experimental study capable of capturing the jumps in τ, besides reporting a discrete behavior that is also present in Δφ.

*We acknowledge support from CNPq, CAPES and FACEPE.

C71.00368: ATOMIC, MOLECULAR, AND OPTICAL PHYSICS —
C71.00369: Using Light to Simulate the Quantum Mechanics of the Simple Pendulum*
ENRIQUE GALVEZ (Presenter), JAKE FREEDMAN, YINGSI QIN, FABIO J AUCCAPUCLLA, KRISTINA WITTLER, Colgate University — We present experiments with a type of non-diffracting optical beams that satisfy a form the 2-dimensional Helmholtz equation that is identical to the Schrödinger equation for the simple pendulum. This form is known as the Mathieu equation. As a result the optical beams are in spatial modes that are related to the quantum solutions of the pendulum. The light intensity in the far field is proportional to the probability of the pendulum bob as a function of the angular position. Depending on the parameters of the problem we can select either states that describe the pendulum swinging or rotating. This system also allows us to investigate an array of interesting quantum phenomena: stationary states with non-classical analogs, wavepacket revivals and even cat states.

*This work was funded by NSF grant PHY1506321

C71.00370: Effects of Spin-orbit-coupling-induced Resonance in Ultracold Bosonic Systems
YUNCHENG XIONG (Presenter), LAN YIN, Peking Univ — We calculate renormalized two-body interactions using T-matrix method, which is the sum of all orders of ladder diagrams in the bare basis. Apart from corrections to three types of diagonal interactions, there emerge many off-diagonal ones. We interpret the divergence of T-matrix as SOC-induced resonance, with the aid of which, the contrast of density modulation in stripe phase in Rb87 can be enhanced by ten times of its original value and wavelength enlarged by two times so that the stripe phase may be observed directly with conventional absorption image technique. Besides SOC-induced resonance, we also recalculate the critical value for Stripe-Plane wave transition which is shifted by a small value. Finally, we find the correction to the density profile when Raman coupling $\Omega>4E_r$.

C71.00371: Phonon Stability and Sound Velocity of Bose Mixture Droplet  
QI GU (Presenter), LAN YIN, School of Physics, Peking University — When the mean-field energy is as small as the quantum fluctuation, the self-energies under Bogoliubov approximation do not necessarily include all the contributions of the same order. For quantum droplets of a Bose mixture, the lower Bogoliubov mode is unstable at small momentum. Considering all the same order self-energies, the excitation spectrum is qualitatively different from the Bogoliubov mode. We develop Beliaev's method to calculate the elementary excitation and phonon velocity accurate to the order of gas parameter $(na^3)^{1/2}$ in the homogeneous droplet. We discuss quasi-particles' Beliaev damping and find that density phonons are almost undamped. The sound velocity is found to be positive, which determines the nonzero superfluid critical velocity of droplet. In experiments, our results can be tested by measuring sound speed, superfluid critical velocity or collective mode.
**C71.00372: Quench-produced solitons in a box-trapped Bose-Einstein condensate**

ELI HALPERIN (Presenter), MICHELLE WYNNE C SZE, JOHN CORSON, JOHN L BOHN, JILA — We describe a protocol to prepare solitons in a quasi-1d box-trapped Bose-Einstein condensate using only a quench of the isotropic s-wave scattering length. A quench to exactly four times the initial scattering length creates one soliton at each boundary of the box, which then propagate in a uniform background density and collide with one another. No nonsolotonic excitations are created during the quench. We investigate the robustness of this procedure to the scattering length ramp rate and a mismatch of the final scattering length.

*This material is based upon work supported by the National Science Foundation under Grants No. PHY 1125844 and No. PHY 1806971.

**C71.00373: Manipulation of cold chiral molecules using electronic and rotational spectroscopy**

ALICIA HERNANDEZ-CASTILLO (Presenter), JOHANNES BISCHOFF, JU HYEON LEE, MARCO DE PAS, HENRIK HAAK, GERARD MEIJER, SANDRA I EIBENBERGER, Molecular Physics, Fritz-Haber Institute — The two non-superimposable mirror images of a chiral molecule are referred to as enantiomers; that is, structures that cannot be transformed into each other by pure translation or rotation. Many molecules of biological interest have a stereogenic center that determines their functionality. However, most physical properties of enantiomers are identical, thus, chiral analysis remains a challenge, and there is a need for fast and reliable methods that can differentiate and/or separate enantiomers. Recently, the enantiomer-specific state transfer method\(^1\) was developed. This method provides the means to populate or depopulate a rotational state of an enantiomer. We have designed, built, and characterized a compact spectrometer capable of performing chirped-pulse Fourier transform microwave and electronic spectroscopy. By combining optical methods with microwave spectroscopy, we seek to maximize the state-specific enantiomeric enrichment. We also implement more sensitive detection schemes such that small population changes can be detected. Recent experimental results and details on the new spectrometer will be discussed.

**C71.00374: Photoassociation of Fermionic \(^{87}\)Sr via the \(^{1}S_0 - ^{1}P_1\) Transition**

JOSHUA HILL (Presenter), THOMAS CHARLES KILLIAN, Rice Univ — The fermionic isotope of strontium, \(^{87}\)Sr, is of interest for the development of optical frequency standards and the study of quantum many-body phenomena. In many of these experiments, \(^{87}\)Sr is confined in an optical lattice. Detecting the presence of doubly occupied lattice sites is a valuable tool for studies of atomic gases in optical lattices, and this is typically done with photoassociation, in which two ground-state atoms in a scattering state are photo-excited to a molecular state. No resonance frequencies have been reported for transitions to molecular states of any excited electronic potential for \(^{87}\)Sr. Here we present results for photoassociation of \(^{87}\)Sr atoms via the \(^{1}S_0 - ^{1}P_1\) transition at 461nm (\(\Gamma= (2\pi*30.5)\)s\(^{-1}\)), and measurements of optical lengths for select photoassociation spectra.

*National Science Foundation; PHY-1607665
C71.00375: **Cold polar molecules in superfluid helium nanodroplets: Electrostatic deflection of imidazole, its complexes and fragments**  
BENJAMIN KAMERIN (Presenter), JOHN W NIMAN, VITALY V KRESIN, Physics, University of Southern California — Helium nanodroplet isolation is a unique method for investigating molecules and molecular structures captured in an inert, superfluid matrix. In particular, it is a highly productive tool for the study of very cold polar molecules and their assemblies. We recently demonstrated that beams of nanodroplets doped with polar molecules can be interrogated by electrostatic deflection, leading to remarkably large deflections on the order of millimeters. Here we apply this method to the imidazole molecule, which is a five-membered polar ring which plays an important role in biological processes. We are able to differentiate polar complexes of imidazole by their dipole moments, and identify their fragmentation pathways.

C71.00376: **Structures with local minima at low energies in above-threshold ionization electron spectra**  
DMITRY A. TELNOV, Dept. of Physics, St. Petersburg State University, Russia, SHIH-I CHU (Presenter), Center for Quantum Science and Engineering, and Center for Advanced Study in Theoretical Sciences, Dept. of Physics, National Taiwan University, Taiwan — We perform a theoretical and computational study of multiphoton above-threshold ionization (ATI) of several one-electron atomic (H and He\textsuperscript{+}) and diatomic (H\textsubscript{2}\textsuperscript{+} and HeH\textsubscript{2}\textsuperscript{+}) quantum systems. The driving laser fields are in the near- and mid-infrared frequency range and have moderate peak intensities corresponding to the Keldysh parameter slightly larger than unity. Our calculations reveal structures with local minima in the low-energy part of the ATI electron energy spectra if the targets are initially in the excited electronic states: 2s states for H and He\textsuperscript{+}, 1\sigma\textsubscript{u} state for H\textsubscript{2}\textsuperscript{+}, and 2\sigma state for HeH\textsubscript{2}\textsuperscript{+}. The effect is non-perturbative and depends on the frequency and intensity of the driving field. The structures in the ATI electron energy spectra have the same nature for all the systems under consideration. Although the ionization process is generally nonresonant, our analysis shows an important role of intermediate electronic energy levels between the initial state and the onset of the continuum. For the hydrogen atom initially in the 2s state, we identify the intermediate states with the principal quantum number n=3 as those responsible for shaping the structure with the local minimum in the low-energy part of the ATI electron energy spectrum.

*MOST and NTU (Taiwan)*
C71.00377: A relativistic single-particle potential for photoexcited electron orbitals of open-shell atoms  JAMES BOYLE (Presenter), Boyle, PLLC — A single-particle potential for the calculation of relativistic photoexcited electron orbitals is introduced. Based upon the earlier work of Qian et al. (Phys. Rev. A 33, 1751 (1986)) and Boyle (Phys. Rev. A 48, 2860 (1993)) for non-relativistic electron orbitals, this relativistic potential is defined to include exactly all of the first-order electron correlations that appear in the diagrammatic perturbation series of the dipole polarizability and that contain potential corrections in the intermediate state. Analytic relationships associated with initial state jj-couplings are also considered. For example, among other things, the ability to rewrite the defined relativistic potential for a final state as an average term plus a correction to the defined average is investigated and presented.

C71.00378: The Link between Artificial Neural Networks and Propagation in Random Media  GIULIA MARCUCCI (Presenter), DAVIDE PIERANGELI, CLAUDIO CONTI, Physics Department, Sapienza University of Rome — Random media (RM) with tailored optical properties are attractive for their many applications. Transmission channels (TCs) in RM can be effectively controlled, and their rich behavior is due to the multitude of interacting optical modes. We demonstrate that TCs in RM act as an untrained artificial neural network (ANN), as deep as the amount of perturbations. This lets us obtain a random optical machine (ROM), able to do computation by reservoir computing (RC).

TCs in RM can be modulated by tuning the transmission matrix (TM) through iterative algorithms that modify the input until a designed output is obtained. This approach treats RM as black boxes, i.e., it treats the TM as an ANN hidden layer of a reservoir computing (RC) strategy, a machine learning technique that left untrained the ANN internal part and optimizes weights only at input and readout.

By electromagnetic perturbation theory, we prove that weakly tampering the medium generates a new TM, given by the product between the previous TM and the perturbative one. We then design the ANN depth of our ROM by optimizing the amount of perturbations, moving from an extreme learning machine (unperturbed system) to untrained deep learning (many perturbations).

C71.00379: Infinite temperature adiabatic flows and quantum many-body scar states in a chaotic system  SHO SUGIURA (Presenter), Harvard University, PIETER W CLAEYS, Boston University, AN DYMARSKY, University of Kentucky, ANATOLI S POLKOVNIKOV, Boston University — Under any operation in many-body chaotic systems, quantum states usually experience dissipation. However, this dissipation can be drastically suppressed through the application of additional appropriate control fields, as is done in counterdiabatic driving. Here, we restrict control to few-body operations and draw flows of the optimal path for quantum control in a non-integrable Ising chain. We find that these flows are highly anisotropic; we can realize almost dissipationless driving in one direction while dissipation is hard to reduce in the perpendicular direction. This indicates that the choice of the path is crucial for quantum operations in many-body chaotic systems. Furthermore, states which are eigenstates of the counterdiabatic term are shown to exhibit small dissipation even without counterdiabatic fields, and are closely related to quantum many-body scar states and many-body dark states.
C71.00380: Atom-Light Interactions in Integrated Photonics: en Route to an Atomic Lab on a Photonic Chip*  HADISEH ALAEIAN (Presenter), ARTUR SKLJRAW, ROBERT LOEW, HARALD KUEBLER, TILMAN PFAU, University of Stuttgart — The integration of photonic structures with thermal atomic vapors on a chip provides efficient atom-light coupling on a miniaturized scale well beyond the diffraction limit hence, opening a new regime in the field of cavity quantum electrodynamics. In this talk, we present the results of our study on interactions of thermal Rb atoms with integrated SiN and Si Nano-devices. In the former case, the atoms are probed with a laser at the D$_2$ transition, whereas in latter the atoms are further excited to the 4D states with an additional excitation at telecom wavelength. Our studies on Si structures benefit from stronger mode confinement due to the large reflective index as well as a larger dipole moment. Moreover, we demonstrate novel measurements on the effects of Si surface potentials on Rb 4D states. Promising results on ring resonators pave the way towards further investigations of high-Q photonic crystal cavities in order to reach the strong coupling regime.

*IQST Young Investigator award and Baden Württemberg Foundation

C71.00381: An optical fiber simulator of three interacting atoms in one dimensional parabolic trap*  MIGUEL GARCIA-MARCH (Presenter), Univ Politecnica de Valencia, NATHAN L HARSHMAN, American University, THOMAS FOGARTY, OIST - Okinawa Institute of Science and technology, HEITOR DA SILVA, Federal University of Rio Grande do Norte, THOMAS BUSCH, OIST - Okinawa Institute of Science and technology, MACIEJ A LEWENSTEIN, ICFO - The Institute of Photonic Sciences, ALBERT FERRANDO, Universitat de Valencia — We introduce an optical fiber that simulates a system of three trapped ultracold and strongly interacting atoms in one-dimension. To simulate the contact interactions among the atoms, we consider a sharp and narrow jump in the refractive index. To this end, we consider here three thin metallic slabs. To simulate the parabolic trap we assume that the fiber has a graded refractive index profile. While the wave-nature of single quantum particles leads well-known analogies with classical optics, for interacting many-particle systems such analogs are not straightforward. We discuss: i) how by spatially modulating the incident field, one can select the atomic statistics, i.e., emulate a system of three bosons, fermions or two bosons or fermions plus a distinguishable particle; ii) how this system can produce classical non-separability resembling that found in the analogous atomic system.

The surface plasmon-polariton (SPP) waves guided by one-dimensional photonic crystals (1DPCs) are usually excited at the interface perpendicular to the direction of periodicity. In this work, we will present the formulation and the numerical results delineating the excitation of the SPP waves on the interface perpendicular to the direction of periodicity. Both the eigenvalue problem of finding and solving the dispersion equation and the problem of the excitation of the SPP waves will be discussed. The eigenvalue problem is solved using the rigorous coupled-wave approach. The results indicate the presence of the plasmonic bandgap that can help in designing the plasmonic optical filters.

References:

In present work, we resolve the unified equation of motion for a quantum system on the adiabatically changed Finsler manifold, suggested by Lipovka (2017), for the particular case of the hydrogen atom. The radial part for the equation of motion is obtained to model a hydrogen atom, where the electron and the nucleus rotate around a center of mass. By using this expression, the total energy of the system under consideration (charged particles and EM field) is obtained.

By expanding in series in the small parameter $\alpha = v/c$, the value of the anomalous magnetic moment of the electron is obtained. The value calculated by J. Swinger $= \alpha /2\pi=0.0011614$ is obtained as a particular case.
THOMAS VARBERG (Presenter), SAMUEL P GLEASON, DALIR H. P. KELLETT, PAUL P. REISCHMANN, Chemistry, Macalester Coll — We have recorded electronic spectra of tantalum hydride (TaH) over the region 605–665 nm. The spectra were recorded by laser excitation spectroscopy at Doppler-limited resolution using a continuous-wave ring dye laser. We have assigned and fitted a total of 12 different bands, which originate from one of three low-lying electronic states. Calculations by Mark Gordon’s group and previous experimental work in our group confirm that the Ω = 2 ground state is largely derived from a σ^2δπ, 3Φ_2 state. An Ω = 0^+ state, largely a mixture of ^3Σ− and ^3Π, lies only 76 cm⁻¹ above the Ω” = 2 ground state. By recording dispersed fluorescence, we found and characterized a total of six low-lying states of the molecule. The electronic states have been fitted by least-squares using a Hund’s case (c) Hamiltonian. We report term energies, vibrational frequencies, rotational and centrifugal distortion constants, and bond lengths for these states, which were found to be in good agreement with the computational results.

C71.00386: Floquet approach to the study of the dynamical Lamb effect* MIRKO AMICO (Presenter), ROMAN KEZERASHVILI, The Graduate Center, City University of New York — The dynamics of N qubits coupled to a harmonic oscillator with time-periodic coupling is investigated in the framework of Floquet theory. This system can be used to model nonadiabatic phenomena that require a periodic modulation of the parameters of the system. An example is the dynamical Lamb effect, the simultaneous excitation of the qubits and the harmonic oscillator out of the ground state due to the nonadiabatic change in boundary condition of the system. The time-dependent Schroedinger equation describing the system’s dynamics is solved within the Floquet formalism and two other equivalent methods that rely on a perturbative approach in the time- and Laplace-domain. Because of the periodicity of the problem analyzed, the Floquet formalism provides a framework where analytical and numerical results are closest to each other. Nonetheless, the time- or Laplace-domain perturbative approaches can be used in the presence of simple or complicated, respectively, aperiodic time-dependent terms in the Hamiltonian.

C71.00387: Symmetric Rotating Wave Approximation for the Generalized Two-Mode Two-Photon System Coupled with a Bosonic Field DAVID WU (Presenter), Caltech — We study the analytically approximated eigenenergies of the two-mode two-photon quantum Rabi model coupled with a Bosonic field. By equipping the previously established generalized symmetric rotating wave approximation (G-SRWA) method used on single-mode spin-boson systems with a unitary squeezing operator and applying it onto the two-mode two-photon system, we obtain a more generalized and simplified closed-form expression for eigenenergies of the system compared to other expressions derived using the functional Bethe ansatz method. We further investigate the effectiveness of the squeezing operator by examining the eigenenergies of the generalized resonant and nonresonant case for the two-level two-photon system. The accuracy of the updated G-SRWA method in the ultra and deep-strong coupling regimes reveals interesting symmetries within the mathematical structure of the two-level two-photon systems.
C71.00388: Topological Control of Extreme Nonlinear Waves  GIULIA MARCUCCI (Presenter), DAVIDE PIERANGELI, Physics Department, Sapienza University of Rome, AHARON J. AGRANAT, Applied Physics Department, Hebrew University of Jerusalem, RAY-KUANG LEE, Institute of Photonics Technologies, National Tsing Hua University, EUGENIO DELRE, CLAUDIO CONTI, Physics Department, Sapienza University of Rome — Controlling nonlinear optical processes is a significant challenge in photonics. Shock waves, rogue waves and solitons are widespread, from optics to hydrodynamics. Intense research is dedicated to advanced techniques for tailoring extreme waves and finding the conditions to induce transitions between different waves.

We develop a new strategy to supervise, modify and tune a laser beam in third-order nonlinear materials, when light propagation is ruled by the nonlinear Schrödinger equation (NLSE). We denote our approach topological control (TC) [1]. TC is based on the one-to-one correspondence between the number of wave packet oscillating phases and the genus of toroidal surfaces associated with the NLSE solutions by the Riemann theta function.

We prove that our method is experimentally realizable in a photorefractive crystal [1]. Specifically, we use the parametric time-dependence of photorefractive nonlinearity to shape the asymptotic wave profile. We tailor propagation coefficients, as nonlinearity and dispersion, to observe all the phases in the nonlinear wave evolution of a rectangular-shaped beam, and to control transitions from shock to rogue waves.

C71.00389: Theory of High-Energy Electron Thermionic Emission from Graphene  LIEMAO CAO (Presenter), YUEYI CHEN, LAY KEE ANG, YEE SIN ANG, Singapore University of Technology and Design — Graphene thermionic electron emission across high barrier involves energetic electrons residing far away from the Dirac point. In this work, we construct a full-band model beyond the simple Dirac cone approximation for the thermionic injection of high-energy electrons in graphene [1]. We show that the thermionic emission model based on the Dirac cone approximation is valid only in the graphene/semiconductor Schottky interface operating near room temperature but breaks down in the cases involving high-energy electrons. We further reveal a critical potential barrier height beyond which the Dirac cone approximation crosses over from underestimation to overestimation. In the high-temperature thermionic emission regime, the Dirac cone approximation severely overestimates the electrical and heat current densities by more than 50% compared to the more accurate full-band model. Our findings reveal the fallacy of Dirac cone approximation in the thermionic injection of high-energy electrons in graphene. The full-band model developed here can be readily generalized to other 2D materials and shall provide an improved theoretical avenue for the accurate analysis, modeling and design of graphene-based thermionic energy devices.

C71.00390: Generation of optical vortices from a spatial light modulator, vortex phase plate, and mode converter*  TING-HUA LU (Presenter), TENG-DE HUANG, Department of Physics, National Taiwan Normal University — First introduced in 1992 by Prof. Allen et al., light with orbital angular momentum (OAM), also called the Laguerre-Gaussian mode, possesses an OAM of per photon. Its twisted phase wavefront is a manifestation of the azimuthal phase term in its wavefunction, while the phase singularities along the beam axis are defined as the optical vortices. The twisted light which possesses OAM can be generated by laser cavities, spiral phase plate, metalens, and spatial light modulator (SLM). In this work, we utilize a vortex phase plate, mode converter, and spatial light modulator to generate high-order vector vortex beams. The mode converter is used to transform the vortex beam with circular symmetry into rectangular symmetry and form the vortex array. This is a convenient and powerful method to produce and control the optical vortex array of the vector superposed optical field, which is composed of different orders of crossed Hermite-Gaussian bases with opposite helicity of circular polarization. The SLM provides an extra degree of freedom to increase and control the order of the bases in the vector superposed optical field, which can induce optical vortices of different sizes and quantities.

C71.00391: Multipole Excitation of C_{60} Molecules in a Semi-Classical Approach  KRISHNA LAMICHHANE (Presenter), Physics, Diablo Valley College Pleasant Hill, CA — This work investigated the collective dynamic response of the 240 delocalized valence electrons of the C_{60} molecules to external stimulations such as electromagnetic radiation or scattering of the charged particle, using local current approximation (LCA), which is a semiclassical approach based on general variational principle. Here the bulk of the valence electrons is treated as a semi-classical fluid that exhibits both the translational and compressional vibrations. The coupling of these two modes has been studied and the results are in good agreement with the experimental data from photoionization experiments on C_{60}. The same semi-classical approach has been applied to study the energies of higher angular momentum resonance.

C71.00392: Ab Initio Potentials for Low-Energy Positronium Scattering  JESSE KINDER (Presenter), Oregon Institute of Technology — This poster presents ab initio potentials for positronium-atom and positronium-molecule interactions. Two methods are used to calculate the potential energy: self-consistent solution of the Hartree-Fock equations and solution of the Kohn-Sham equations at the level of the local density approximation. The total energy is computed for a wide range of positronium-molecule separations, molecular orientations, and basis sets. Comparing the two methods illustrates the importance of both electron-electron and electron-positron correlations in obtaining realistic potentials.

Low-energy positronium scattering may soon become experimentally feasible in facilities such as the positronium beam line at the University College in London. This goal of this study is to provide a starting point for the theoretical analysis of positronium scattering at low energies from first principles, to complement existing studies based on semi-empirical potentials.
C71.00393: New Atomic Model from the spectra of Hydrogen, Helium, Beryllium, Boron, Carbon, and Deuterium and their ions  
JANEEN HUNT (Presenter), APS — A cohesive unifying theory of the atom does not currently exist in Quantum Physics. In this research, the atomic spectra are allowed to determine the model for the atom based upon the finding of patterns of the Balmer-Rydberg formula in the first 20 ions and neutral atoms of the periodic table. From this data, the model postulates a standing wave of varying energy antinodes originating from the particles in the nucleus of each atom which is able to predict the ionization energies of these atoms. The transitions of the electrons in atoms are defined by the energies of each antinode represented by the difference in energy between each spectral line. The spectral patterns for H, He-I, He-II, Li-I, Li-II, Li-III, Be-I, Be-II, Be-III, Be-IV, B-I, B-II, B-III, B-IV, B-V, C-I, C-II, C-III, C-IV, and Deuterium are charted and the ionization energies are calculated from the data including general inferences this model predicts about the unification of atomic forces, electron transitions, heat, and electromagnetism. This model predicts that the nucleus of every atom is held together by energy in the form of a standing wave originating from the nucleus and surrounding it. This is the Sollism Theory of the atom.

C71.00395: Casimir Juggling  
CONNOR HAFEN (Presenter), DANIEL SHEEHAN, Univ of San Diego — Casimir forces can dominate system behavior at the nanoscale; increasingly, efforts are being made to control and exploit them [1-3]. Here we propose a simple method for contact-free, dynamic levitation, handling, and physical diagnosis of micron and sub-micron particles in vacuum using these forces. This ‘Casimir juggling’ should sidestep the negative effects of stiction and contact contamination. Analytic calculations and numerical modeling show particles can be levitated, transported and deposited with nanometer precision using kHz-MHz active-feedback Casimir probes. Standard laboratory techniques appear adequate to experimentally test this proposal.
C71.00396: Survey of Molecular Rotational Transitions for Millimeter-Wave Frequency Metrology.  MARK YEO (Presenter), ANTOINE ROLLAND, TOMOHIRO TETSUMOTO, Boulder Research Laboratory, IMRA America — User-defined, spectrally pure and tunable millimeter-wave oscillators, using emerging photonic technologies, enables the probing of pure rotational molecular transitions (from 30 GHz to 1 THz). This work promises to open new applications in frequency metrology, precision molecular spectroscopy, and trace gas sensing. Here we report a theoretical survey of a wide range of molecular candidates to compare their suitability for use in a rotational based clock. We will report calculations that lead to theoretical estimations of clock factors of interest such as line positions and strengths, and sensitivity to environmental perturbations. This work will provide an understanding of the utility of ultra-precise measurements of the rotational spectrum in blooming applications such as radio-astronomy and remote sensing, non-invasive sensing, wireless communications, and for THz frequency metrology.

C71.00397: WITHDRAWN ABSTRACT —

C71.00398: WITHDRAWN ABSTRACT —

C71.00399: Design of a viable radiation-balanced fiber laser or amplifier*  ARASH MAFI (Presenter), MOSTAFA PEYSOKHAN, ESMAEIL MOBINI, University of New Mexico — Recent advances in power scaling of fiber lasers are hindered by the transverse mode instability (TMI), which deteriorates the output beam quality. TMI is blamed on the overheating of the fibers. Anti-Stokes fluorescence (ASF) cooling of the rare-earth-doped gain material has been suggested as a potentially viable heat removal scheme. In this scheme, the fiber is pumped at a pump wavelength, which is longer than the mean fluorescence wavelength of the active ions. Therefore, the fluorescence removes some of the excess heat. It may be possible even to balance the ASF cooling against all other sources of heating and make a non-heating radiation-balanced laser (RBL). I will focus on the general scaling laws that govern the design of RBLs. I will show that the magnitude of the parasitic absorption plays an essential role in the feasibility of such designs, especially in a double-cladding setting, and the measures that need to be taken to achieve net heat-balancing in a viable RBL.

C71.00400: Uncovering the Role of Excited States of Dication in Controlling the Dissociative Double Ionization of Ethane  
GIHAN BASNAYAKE (Presenter), DUKE DEBRAH, WEN LI, Wayne State Univ — With the aid of newly developed coincidence detection imaging system, we demonstrate that the branching ratios of dissociative double ionization channels of ethane can be controlled by varying the ellipticity of the intense ultrashort laser pulses. The $\text{CH}_3^+$ formation channel and $\text{H}^+$ formation channel show a significant yield changes, producing the highest and lowest at ellipticity of 0.59 respectively. With the help of theoretical calculations, we attribute such a control to both angle dependent ionization and intensity dependent ionization to excited dication states.

C71.00401: High bandwidth, bidirectional microwave to telecom conversion using an electro-optic transducer operating at millikelvin temperatures*  
WILLIAM HEASE (Presenter), ALFREDO RUEDA, RISHABH SAHU, JOHANNES FINK, Institute of Science and Technology Austria — Long distance connectivity of superconducting qubits poses an interesting challenge because their fragile microwave quantum states need to be protected from thermal noise. A hybrid quantum network, which combines the advantages of microwave quantum information processing and the robustness of optical telecommunication, appears as the natural solution. In this context, coherent conversion between optical and microwave photons is the key ingredient. We present a triply resonant electro-optic modulator [1] as a bidirectional and low noise microwave to optics converter. Our system is based on a LiNbO3 whispering gallery mode resonator coupled to a superconducting 3D microwave cavity. Unlike electro-opto-mechanical systems, a low frequency mechanical mediator is not needed, allowing for a 10 MHz conversion bandwidth and low added conversion noise of less than 1 quanta for continuous wave optical pump powers up to 25 $\mu$W.

* Supported by European Research Council under grant agreement number 758053 (ERC StG QUNNECT), and by the European Union’s Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No 754411.
C71.00402: Towards cavity quantum circuit electromechanics with millimiter-sized silicon nitride membranes
SARWAN PEITER, ADRIAN SANZ MORA (Presenter), GARY STEELE, Delft University of Technology — Due to their extremely high mechanical quality factors, silicon nitride membranes are commonplace in optomechanical experiments conducted with light fields. However, to strongly couple optical radiation to the vibratory motion of such membranes down in the quantum regime is still a sought-after target in these experiments. We use here an original assembly to couple instead microwave radiation to a vibrating membrane of submillimiter dimensions, obtaining interaction strengths approaching state of the art values achieved in the optical realm. The assembly is based on a mechanically adjustable pressing frame through spring screws, that holds a chip with an integrated lumped element resonator antenna facing another chip hosting the membrane. The membrane is coated with a layer of metal so that the two chips couple capacitively to form a resonant circuit, the capacitance of which, and thus its resonance frequency, is modulated by the membrane vibrations. Besides its potential to challenge the foundations of quantum mechanics at unconventional mass and length scales, our electromechanical device may be well suited to study nonlinear phenomena in the framework of classical mechanics such as the emergence of chaotic dynamics in the weak damping limit.

C71.00403: Acoustic modes of superfluid helium in a cross geometry
VAISAKH VADAKKUMBATT (Presenter), THOMAS CLARK, Univ of Alberta, SWATI SINGH, University of Delaware, JOHN DAVIS, Univ of Alberta — Superfluid helium is a low-loss optomechanical element, and an acoustic quality factor value up to $10^8$ has been realized experimentally in a macroscopic quantum system using a cylindrical microwave cavity [1]. It has been predicted that three orders higher quality factor may be attained with improvements to the experimental system. With these parameters, superfluid helium is a potential candidate for detecting continuous gravitational waves [2]. Here, we study the acoustic modes of superfluid helium inside a cross geometry using a re-entrant microwave cavity that provides improved detection of the acoustic modes. The cross shaped geometry is also predicted to be more sensitive than a cylinder for detection of gravitational waves.

C71.00404: Coherent coupling completes an unambiguous optomechanical classification framework*  
XIANG LI (Presenter), California Institute of Technology, MIKHAIL KOROBKO, Universität Hamburg, YIQIU MA, California Institute of Technology, ROMAN SCHNABEL, Universität Hamburg, YANBEI CHEN, California Institute of Technology — Cavity optomechanics studies the dynamics of systems in which optical and mechanical degrees of freedom are coupled, e.g., optical resonators with movable/deformable boundaries and/or shapes. A system's behavior depends crucially on the nature of optomechanical coupling. In addition to the previously well-known dispersive (when real parts of optical eigenfrequencies depend on mechanical displacement) and dissipative coupling (when imaginary parts of optical eigenfrequencies depend on mechanical displacement), we identify coherent coupling as a new type of coupling (when neither depend on mechanical displacement) and show that the three together fit into a general, unambiguous classification framework. We discuss in detail a ring cavity with a movable mirror inside, a system that has pure coherent coupling without any dispersive or dissipative coupling.

The work of M.K. and R.S. was supported by the Deutsche Forschungsgemeinschaft (DFG) (SCHN 757/6-1).

C71.00405: Two-tone optomechanical instability and its fundamental implications for backaction-evading measurements*  
ITAY SHOMRONI (Presenter), AMIR YOUSSEFI, NICK SAUERWEIN, LIU QIU, Ecole Polytechnique Federale de Lausanne, PAUL SEIDLER, IBM Research-Zurich, DANIEL MALZ, Max-Planck-Institut für Quantenoptik, ANDREAS NUNNENKAMP, Cavendish Laboratory, University of Cambridge, TOBIAS J. KIPPENBERG, Ecole Polytechnique Federale de Lausanne — We report a new type of optomechanical instability that arises in two-tone backaction-evading (BAE) measurements of mechanical motion, a protocol designed to overcome the standard quantum limit. We demonstrate the effect both in the optical and microwave domains using different optomechanical systems, and find excellent agreement with theory. In contrast to the well-known parametric instability that occurs in single-tone, blue-detuned pumping, and results from a two-mode squeezing interaction between the optical and mechanical modes, the two-tone instability results from single-mode squeezing of the mechanical mode due to small detuning errors in the two pump frequencies. The instability can occur even with balanced intracavity fields and for both signs of detuning errors. The required tuning accuracy increases with pump power, putting an intrinsic limit on the sensitivity of BAE measurements and on other two-tone schemes.

C71.00406: Ultraviolet resonator integrated in a hollow-core fiber for Xenon plasma lasing*

JEREMY FLANNERY (Presenter), SEMA KURU, SUPRATIK SARKAR, VINODH RAJ RAJAGOPAL MUTHU, MICHAL BAJCSY, University of Waterloo — We integrate a cavity in a large-diameter hollow-core optical fiber based on inhibited coupling as a step towards realization of a fiber-integrated gas laser in the ultraviolet (UV) region. This is accomplished by attaching highly reflective photonic crystal (PC) membranes onto the ends of a fiber segment to form a Fabry-Perot cavity. The PC membranes are fabricated using e-beam lithography and reactive ion etching, which are then mounted on the fiber face using a micromanipulator stage. The presence of the PC holes allow for injection loading of atomic species into the fiber-cavity. Specifically, Xenon gas can be introduced through the perforated membrane into the hollow-core of the fiber to act as a gain medium for UV lasing when exposed to RF discharge.

*This research was undertaken thanks in part to funding from Canada First Research Excellence Fund.

C71.00407: Numerical Modeling of Optomechanical Sensors for Dark Matter Detection*

RUSSELL STUMP (Presenter), JACK MANLEY, SWATI SINGH, Univ of Delaware — Ultralight scalar dark matter can be represented as an atomic strain that can drive the acoustic breathing modes of an elastic body. We propose various laboratory-scale mechanical resonators for measuring the acoustic excitations at frequencies ranging from kilohertz (kHz) to Gigahertz (GHz)[1]. These devices include bulk acoustic wave resonators, phononic crystals, superfluid helium detectors and suspended sapphire micropillars. We use numerical modeling techniques to characterize each device’s performance as a dark matter detector. These techniques can be applied to an arbitrary mechanical resonator to measure its viability as a sensor for these signals.

*National Science Foundation grant PHY-1912480
C71.00408: Observation of dynamical quantum phase transitions in spinor condensates with no correspondence in ground-state phase diagram*  HAOXIANG YANG (Presenter), TIAN TIAN, LIYUAN QIU, HAIYU LIANG, YANBIN YANG, YONG XU, LUMING DUAN, Tsinghua University — Dynamical quantum phase transitions are closely related to equilibrium quantum phase transitions for ground states. Here, we report an experimental observation of a dynamical quantum phase transition in a spinor condensate beyond this conventional wisdom. We observe that the quench dynamics exhibits a non-analytical change with respect to a control parameter in the absence of a corresponding phase transition for the ground state there. We make a connection between this singular point and a phase transition point for the highest energy level in a subspace with zero spin magnetization of a Hamiltonian. We further show the existence of dynamical phase transitions for finite magnetization corresponding to the phase transition of the highest energy level in the subspace with the same magnetization. Our results open a door for studying dynamical phase transitions beyond the conventional ground-state phase diagram and using them as a tool to probe the phase transitions at higher energy eigenlevels of many-body Hamiltonians.

C71.00409: Hydrodynamics of shock waves in ultracold non-degenerate dipolar gases.*  REUBEN WANG (Presenter), ANDREW SYKES, JOHN L BOHN, JILA — The hydrodynamics of an ultracold, non-degenerate gas of harmonically trapped dipolar atoms is studied. We numerically simulate this system using direct simulation Monte Carlo methods in the regime where interactions are dominated by two-body collisions, as for instance can be achieved in ultracold gases of Dy or Er. We subject the gas to a short-pulse perturbation which is common in hydrodynamic studies of shock waves, emphasizing the anisotropies in hydrodynamic phenomena resulting from the anisotropic collision cross sections of the dipoles. This work extends observations of anisotropic rethermalization of a cold, dipolar gas previously seen in [1,2]. Here, shock wave hydrodynamics is studied in the less explored low-temperature regime, leading to a emergence of rich phenomena. This work was supported by the NSF.

C71.00410: Self-organization and stroboscopic dynamics of a driven Rydberg gas
KAI KLOCKE (Presenter), MICHAEL BUCHHOLD, Caltech — Motivated by recent experiments observing signatures of self-organized criticality (SOC) in driven Rydberg ensembles, we develop a Langevin description to explore how SOC can emerge from the microscopic interactions in experimental Rydberg setups. We demonstrate that drift and diffusion of atoms arising from an inhomogeneous trapping potential capture the stroboscopic evolution observed in experiments. The trap dynamics induces a continuous reorganization of the atoms, which pins the central density to a critical point and gives rise to scale invariant excitation avalanches. We further discuss how additional external driving can be used to extend and manipulate the SOC avalanche dynamics. This offers a detailed perspective on how avalanche dynamics can be controlled in driven Rydberg gases.

C71.00411: Photon blockade in the Tavis Cummings model
RAHUL TRIVEDI (Presenter), MARINA RADULASKI, KEVIN A FISCHER, SHANHUI FAN, JELENA VUCKOVIC, Electrical Engineering, Stanford University — We use the scattering matrix formalism to study single- and two-photon transport through the Tavis Cummings model as a function of the number of emitters coupling to the cavity mode. It is shown that for a resonant Tavis Cummings system, photon blockade at the output of the cavity mode worsens with the number of emitters while for a detuned Tavis Cummings system, photon blockade at the output of the cavity mode improves with the number of emitters. By explicitly calculating the two-photon scattering properties of this system in the thermodynamic limit of an infinite number of emitters, we show that the light emitted from Tavis Cummings system under excitation by a coherent drive transitions from bunching to anti-bunching as the emitters are detuned from the cavity mode. Finally, we analyze the impact of inhomogeneous broadening in the emitter frequencies on both resonant and detuned photon blockade through the Tavis Cumming system.

C71.00412: Point-coupling Hamiltonian for frequency-independent linear optical devices*
RAHUL TRIVEDI (Presenter), KEVIN A FISCHER, SATTWIK MISHRA, JELENA VUCKOVIC, Electrical Engineering, Stanford University — We present the point-coupling Hamiltonian as a model for frequency-independent linear optical devices acting on propagating optical modes described as continua of harmonic oscillators. We formally integrate the Heisenberg equations of motion for this Hamiltonian, calculate its quantum scattering matrix, and show that an application of the quantum scattering matrix on an input state is equivalent to applying the inverse of classical scattering matrix on the annihilation operators describing the optical modes. We show how to construct the point-coupling Hamiltonian corresponding to a general linear optical device described by a classical scattering matrix, and provide examples of Hamiltonians for some commonly used linear optical devices. Finally, in order to demonstrate the practical utility of the point-coupling Hamiltonian, we use it to rigorously formulate a matrix-product-state based simulation for time-delayed feedback systems wherein the feedback is provided by a linear optical device described by a scattering matrix as opposed to a hard boundary condition (e.g. a mirror with less than unity reflectivity).

C71.00413: Efficient numerical integration of the adiabatic master equation*
HUMBERTO MUNOZ-BAUZA (Presenter), DANIEL A LIDAR, Univ of Southern California — The capability to simulate open quantum systems under the adiabatic condition is critical for verifying the behavior of quantum annealers. While adiabaticity is a useful condition for theoretical analysis, straightforward numerical implementations of the adiabatic master equation (AME) suffer from the need to integrate an adiabatic but highly oscillatory quantum state over a very long period of time. We show that the AME in the adiabatic frame can be split in a way that prevents large superoperator evaluations and is amenable to geometric integration methods for split time-dependent problems.

C71.00414: A perturbative view from the master equation: Electromagnetically induced transparency revisited

XIN WANG (Presenter), Beijing Computational Science Res Ctr — We show that by treating the weak probe field as a perturbation to the strong coupling fields in the atomic system and using the perturbative method in a master equation, the features of linear response of phenomena of electromagnetically induced transparency (EIT) can be uniformly demonstrated, regardless of the details of atomic energy level configuration. We compare our estimation with both typical and atypical EIT-observed configurations and find that our model indeed provides a description of the sharp transmission window in central area of typical EIT curve.

It can also be inferred hereby that for various systems other than atomic gas, as long as the description of the system’s dynamics comes down to the simplified form of master equation, the corresponding EIT analogs and EIT-like phenomena can also be explained in this way.

C71.00415: Vacancies effect on the BEC critical temperature of an ideal Bose gas within an imperfect crystal

MIGUEL A. SOLIS (Presenter), Theoretical Physics, Institute of Physics, Universidad Nacional Autónoma de México, EMILIO I GUERRERO, Postgraduate in Physical Sciences, Universidad Nacional Autónoma de México — After we have shown [1] that an ideal Bose gas in one, two or three-dimensional crystal with one structural vacancy presents Bose-Einstein condensation (BEC) at higher finite critical temperature than that when the crystal is perfect; here we report the BEC critical temperature as a function of the number of random vacancies. The particle energy spectrum is obtained using finite difference numerical method, which we use to calculate the critical temperature as the temperature at which the isobaric specific heat has its maximum [2]. When our finite system is taken to the thermodynamic limit, the critical temperature starts at the one vacancy value, it increases reaching a maximum when we have about 17 % of vacancies and then decays almost linearly to zero when the crystal has been removed.

C71.00416: Quantum system chaos in a PT-symmetry breaking potential* CARLA QUISPE
FLORES (Presenter), Physics Department, Colorado School of Mines, INES DE VEGA, Department of
Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig Maximilian University of Munich,
RENAN CABRERA, Department of Chemistry, Princeton University, LINCOLN CARR, Physics Department,
Colorado School of Mines — We studied the dynamics of N bosons confined in a triple well potential
in phase space. The system is tackled by using the truncated Wigner approximation (TWA) and
exact diagonalization of Bose-Hubbard model including a perturbative PT-symmetry breaking
potential. We find a region in which the symmetry breaking develops smoothly with the control
parameters enabling to break many symmetries of the Hamiltonian and reduce energy
degeneracies. The model shows signatures of stationarity, chaos and mixing as a consequence of
the inter-particle interactions. Generation of entangled states and loss of purity is also observed
and monitored by the Meyer's measure of the impurity and the von Neumann entropy S. Finally,
the system chaotic behavior is conveniently tracked within the phase space by the growth rate of
the out-of-time ordered correlator.

C71.00417: Continuous protection of a quantum state from inhomogeneous dephasing
RAN FINKELSTEIN (Presenter), OHR LAHAD, OMRI DAVIDSON, EILON POEM, OFER FIRSTENBERG,
Weizmann Institute of Science — Room-temperature atomic vapors are known for their simplicity
and their potential scaling-up in applications. In spite of these benefits, laser-cooled atoms have
evolved to be the prevalent systems for studying strong and coherent light-matter interactions,
as the latter are unhindered by Doppler broadening.
Here we present several methods to overcome the effective decrease of both atom-photon
cross-section [1] and coherence time in vapors, and in fact in any inhomogeneously broadened
atom-like system.
The mechanism we study can be understood as the counteraction of the inhomogeneous
dephasing of two coupled states, where one state has enhanced sensitivity to the source of
dephasing. A far-detuned dressing field admixes a fraction $\Omega^2/\Delta^2$ of this "sensor" state into the
"protected" state, yielding a velocity-insensitive state and effective line-narrowing in two-color
transitions [2]. Finally, we apply this method to extend the lifetime of collective excitations stored
in a thermal atomic vapor. This method is continuous, in contrast to pulsed echo-based
techniques.

C71.00418: Combined spontaneous symmetry-breaking and symmetry-protected topological order from cluster charge interaction*  
CHEN PENG, Department of Physics, Renmin University of China, YUAN-YAO HE (Presenter), Center for Computational Quantum Physics, Flatiron Institute, RONG-QIANG HE, ZHONG-YI LU, Department of Physics, Renmin University of China — The study of symmetry-protected topological states in presence of electron correlations has recently aroused great interest as rich and exotic phenomena can emerge. Here, we report a concrete example by employing large-scale unbiased quantum Monte Carlo study of the Kane-Mele model with cluster charge interactions. The ground-state phase diagram for the model at half filling is established. Our simulation identifies the coexistence of a symmetry-protected topological order with a symmetry-breaking Kekule valence bond order and shows that the spontaneous symmetry-breaking is accompanied by an interaction-driven topological phase transition (TPT). This TPT features appearance of zeros of single-particle Green's function and gap closing in spin channel rather than single-particle excitation spectrum, and thus has no mean-field correspondence.

C71.00419: Quantum Monte Carlo Simulations of the Attractive SU(3) Hubbard Model on a Honeycomb Lattice*  
YU WANG (Presenter), HAN XU, School of Physics and Technology, Wuhan University, LEI WANG, Institute of Physics, Chinese Academy of Sciences — We perform the projector quantum Monte Carlo simulation of the half-filled attractive SU(3) Hubbard model on a honeycomb lattice, exploring the effects of SU(3) symmetry on the correlated attractive Dirac fermions. Our simulation indicates the absence of pairing order in the system and shows a quantum phase transition from the semimetal to charge density wave (CDW) at the critical point $U_c = -1.52(2)$. We demonstrate that this quantum phase transition belongs to the chiral Ising universality class according to the numerically determined critical exponents $\nu = 0.82(3)$ and $\eta = 0.58(4)$. With the increase of coupling strength, the trion formation is investigated, and the change in probability of the on-site trion occupancy infers the coexistence of on-site trionic and off-site trionic CDW states at half-filling.

C71.00420: Signatures of Majorana-like Quasiparticles in Few-body Lattice Models* JARED BLAND (Presenter), BIRGIT KAUFMANN, CHRIS H GREENE, Purdue Univ — There is a strong interest in number conserving systems that exhibit Majorana fermions as quasiparticles. We utilize a number-conserving analog of the Kitaev wire model due to Iemini et al. in the small-lattice limit to examine signatures of topological properties in small systems. This interacting model exhibits several signatures of topological regime, such as identical entanglement spectra for the ground states in distinct parity sectors. Additionally, the Hamiltonian is akin to the BCS Hamiltonian, suggesting Bogoliubov rotations and approximations, allowing us to further examine this model in this regard. In this work, we demonstrate these signatures of different topological order in small lattice sizes to find evidence of isolated Majorana quasiparticles.

C71.00421: Effect of Core Size on Vortex Interactions in Light* JASMINE ANDERSEN (Presenter), ANDREW A. VOITIV, Univ of Denver, MARK T. LUSK, Colorado School of Mines, MARK SIEMENS, Univ of Denver — Optical vortices are characterized by a helical wavefront with integer winding, also referred to as the topological charge, around the center of the vortex. These vortices exhibit dynamic behavior when implanted in different locations of a Gaussian beam, and it is possible to observe vortex-vortex interactions as the beam propagates. In the case of an oppositely charged vortex pair separated symmetrically about the beam axis, the vortices begin with a downward motion in the transverse plane and then accelerate toward each other. When the beam propagates, these vortices will at some point annihilate each other, without reemergence on the other side of the collision. The exact dynamics depend on the shape and size of the core. For smaller cores, the diffraction of the core has an effect on the dynamics and the annihilation distance is farther along the propagation axis. I will present our theoretical and experimental results including the impact of charge and core size on the vortex trajectories. I will also discuss the role of the underlying phase and amplitude gradients at the location of a given vortex on its motion as the beam propagates.

C71.00422: Finite Orbital Angular Momentum Pairing in Atomic Fermi Gases with Spin-Orbital-Angular-Momentum Coupling  
WANG LIANG-LIANG (Presenter), Westlake University — Fulde-Ferrell-Larkin-Ovchinnikov states represent superconducting states with finite momentum Cooper pairs and have become one of most sought-after exotic states of matter. The recent realization of a new type of spin-orbit coupling in ultracold atomic gases, namely the spin-orbital-angular-momentum coupling, provides a novel perspective to study Fulde-Ferrell-Larkin-Ovchinnikov states in orbital angular momentum space. In this letter, we demonstrate that the combined effects of spin-orbital-angular-momentum coupling and level detuning can induce an exotic Fulde-Ferrell-Larkin-Ovchinnikov phase, where Cooper pairs have finite center-of-mass angular momenta. This implies that vortex with high-vorticity can be generated without rotation or effective vector potential field. The orientation of the phase winding can be altered by adjusting the sign of level detuning.

C71.00423: Quantum Defects in Diamond: Identifying Nitrogen Isotopes of Nitrogen-Vacancy Centers*  
MORGAN CHAMBERLAIN (Presenter), Linfield College, SRIVATSA C VARDARAJ, ZEESHAWN KAZI, ELYSSA B ROEDER, KAI-MEI CAMILLA FU, University of Washington — Nitrogen-vacancy (NV) centers are point defects in diamond formed by one substitutional nitrogen atom and an adjacent vacancy. Low spectral diffusion is a necessary property for NV centers to be qubit candidates. To characterize differences between naturally formed and ion implanted NV centers, diamond samples were studied that contained both types. The ion implantation used $^{15}$N to be able to differentiate from the $^{14}$N naturally formed NV centers. This project focused on identifying the isotope of a single NV center, which is the first step toward understanding differences in their emissive properties. Code was developed to execute, and then automate, the three experiments necessary to identify the isotope of a single NV center: Continuous Wave Optically Detected Magnetic Resonance (CW ODMR), Rabi oscillations, and Pulsed ODMR. These experiments resolve the hyperfine interaction of the nuclear spin states. The code was implemented on a test sample, where it successfully identified the isotope of several NV centers. The next step in this project is to link the isotopes of NV centers to their emissive properties, with a goal of producing reliable qubits for quantum information processing circuits.

C71.00424: Dynamics of Inhalation  FELIX KRATZ (Presenter), JEAN-FRANCOIS LOUF, ANVITHA SUDHAKAR, NATHANAEI LJI, SUJIT DATTA, Department of Chemical and Biological Engineering, Princeton University — The process of inhalation relies on the complex interplay between muscular contraction in the thorax, elasto-capillary interactions in the individual airway branches, connectivity between different branches, and overall air flow into the lungs. Sophisticated pulmonary fluid dynamics models have been developed to elaborate the competition between capillarity, which tends to keep flexible branches closed, and elasticity, which favors opening, for single airway branches. However, a quantitative model combining the physiological opening process of flexible airway branches with the biomechanics and interconnected geometry of the lungs is still missing. To address this issue, we develop a statistical model of the lungs as a symmetrically-branched network of liquid-lined flexible cylinders coupled to a viscoelastic thoracic cavity. Each branch opens at a rate and a pressure that is determined by input biomechanical parameters, enabling us to test the influence of changes in the mechanical properties of lung tissues and secretions on inhalation dynamics. By summing the dynamics of all the individual branches, we quantify the evolution of overall lung pressure and volume during inhalation, and find good agreement with typical breathing curves obtained in the literature.

C71.00425: Charge Carrier Transport in Cuprous Oxide: A Puzzle  GARIMA AGGARWAL (Presenter), SANDEEP K. MAURYA, K. R. BALASUBRAMANIAM, Dept. of Energy Science and Eng, Indian Institute of Technology — Deciphering the carrier transport mechanism in Cu$_2$O has been elusive, as none of the classical scattering mechanisms seems to be operative. Towards this, we study electrical properties of Cu$_2$O, wherein samples are prepared via thermal oxidation (TO), pulsed laser deposition (PLD), and electrodeposition. These methods provide a large range of grain sizes (100nm to 5mm), type of grain boundaries (high & low angle), and intrinsic defect concentration (10$^{13}$ to 10$^{18}$ cm$^{-3}$). T dependent Hall measurement is used to study carrier concentration and hole mobility. We observe the presence of two acceptor levels; a normal and a split Cu vacancy for the first time experimentally. The mobility vs. T data exhibits a maximum at 200 K for polycrystalline samples, while, monotonically decreases for single crystal and textured PLD thin film in the entire T range of study (80 – 300 K). Grain boundary (GB) scattering mechanism explains the dependence of transport at T < 200 K for samples with high angle GB. We find that trap mediated scattering is dominant for single crystal and poly-crystal at T > 200 K. This suggests that instead of increasing grain size or doping, the neutralization of trap centres is the only possible way to increase the mobility and thereby, performance of Cu$_2$O based devices.

Session D01 DAMOP: Open Quantum Systems I  Igor Lesanovsky - Tag(s): Focus
2:30PM D01.00001: Discovering feedback strategies for open quantum systems via deep reinforcement learning [Invited] FLORIAN MARQUARDT (Presenter), Max Planck Institute for the Science of Light — Recent rapid advances in deep neural networks are helping to revolutionize science and technology. In this talk, I will describe how neural networks can discover from scratch feedback strategies to help control open quantum systems, by exploiting the toolbox of reinforcement learning. A few-qubit quantum memory can be protected against decoherence via quantum error correction strategies that have been autonomously constructed in this way. Additional illustrative examples from our recent research include reinforcement learning applied to systems from the domain of cavity quantum electrodynamics and to arrays of coupled modes.

3:06PM D01.00002: Integrability Meets Dissipation: Critical Dynamics of Open Driven Systems DANIEL PAZ (Presenter), MOHAMMAD MAGHREBI, Physics & Astronomy, Michigan State University — Driven quantum systems coupled to an environment are generally non-integrable and typically exhibit relaxational dynamics. We investigate the paradigmatic open Dicke model which describes collective light-matter interactions subject to dissipation. In a certain limit (at large detuning), this model is governed by an effective driven-dissipative Ising model in a transverse field, which is integrable in the absence of dissipation. In the limit of weak dissipation though, integrability is only weakly broken. We show that, in this regime, the system undergoes a dynamical crossover from relaxational dynamics to underdamped critical dynamics, each described by a distinct dynamical exponent. We identify these critical behaviors with the infinite-range classical (stochastic) and quantum (unitary) Ising models at finite temperature, respectively. These results are obtained through a non-equilibrium quantum-to-classical mapping in addition to an efficient numerical analysis that exploits the permutation symmetry.

3:18PM D01.00003: Dissipative generation of highly entangled states of light and matter* CATALIN-MIHAI HALATI (Presenter), AMENEH SHEIKHAN, PI, University of Bonn, HELMUT RITSCH, ITP, University of Innsbruck, CORINNA KOLLATH, PI, University of Bonn — We investigate the full quantum evolution of ultracold interacting bosonic atoms confined to a chain geometry and coupled to the field of an optical cavity. Extending the time-dependent matrix product state techniques to capture the global coupling to the cavity mode and the open nature of the cavity, we fully include the light-atom entanglement. We examine the long time behavior of the system beyond the mean-field elimination of the cavity field. We show that in the self-organized phase the steady state consists in a mixture of the mean-field predicted density wave states and coherent states with lower photon number, with a large entanglement between the atomic and photonic degrees of freedom. In the regime of large dissipation strengths we develop a variant of the many-body adiabatic elimination technique and obtain a highly entangled steady state with a fully mixed atomic sector. We observe numerically the crossover from the density wave state towards the fully mixed state.

3:30PM D01.00004: Boundary dissipation in Ising CFT  UMAR JAVED (Presenter), MICHAEL KOLODRUBETZ, University of Texas at Dallas — Boundary conformal field theory (CFT) is one of few exact analytical tools for the study of quantum non-equilibrium systems, yet so far has been primarily restricted to closed Hamiltonian systems. We study one of the simplest CFTs, namely the quantum critical Ising model with boundary dephasing along the direction of the most relevant boundary operator. Naïve scaling arguments suggest that such dissipation should be marginal. Numerically for large systems, we find that boundary spin in the presence of dissipation, with or without boundary field, depolarizes and reaches a nonequilibrium steady state (NESS). In the presence of RG-relevant boundary term, scaling functions appear unmodified, suggesting that the dissipation is marginally irrelevant in that case. In the absence of boundary field, we study modifications of the Zeno effect by Keldysh RG and numerical calculations of the two-time correlation function of the boundary spin. Finally, we comment on potential application to other CFTs

3:42PM D01.00005: On the nature of the non-equilibrium phase transition in the non-Markovian driven Dicke model  REX LUNDGREN (Presenter), ALEXEY V. GORSHKOV, Joint Quantum Institute, University of Maryland / National Institute of Standards and Technology, MOHAMMAD MAGHREBI, Department of Physics and Astronomy, Michigan State University — The Dicke model exhibits a phase transition to a superradiant phase with a macroscopic population of photons and is realized in multiple settings in open quantum systems. In this work, we study a variant of the Dicke model where the cavity mode is lossy due to the coupling to a Markovian environment while the atomic mode is coupled to a colored bath. We find a simple effective theory for this model allowing us to derive analytical expressions for various critical exponents, including those, such as the dynamical critical exponent, that have not been previously considered. We find excellent agreement with previous numerical results when the non-Markovian bath is at zero temperature; however, contrary to these studies, our low-frequency approach reveals that the same exponents govern the critical behavior when the colored bath is at finite temperature unless the chemical potential is zero. Furthermore, we show that the superradiant phase transition is classical in nature, while it is genuinely non-equilibrium. Finally, we consider finite-size effects at the phase transition and identify the finite-size scaling exponents, unlocking a rich behavior in both statics and dynamics of the photonic and atomic observables.
3:54PM D01.00006: Anomalous exceptional point and non-Markovian Purcell effect at threshold in 1-D open quantum systems*  
SAVANNAH GARMON (Presenter), Osaka Prefecture Univ, GONZALO ORDONEZ, Butler University, NAOMICHI HATANO, University of Tokyo — We show that when a quantum emitter is coupled near threshold to a generic 1-D continuum with a van Hove singularity in the density of states, a characteristic spectral configuration appears involving a bound state, a resonance state and an anti-resonance state, as well as several exceptional points (EPs). At one EP appearing below the threshold, the resonance and anti-resonance states coalesce while the bound state instead experiences an avoided crossing. Meanwhile, if one considers the limit in which the coupling $g$ vanishes, all three states converge on the continuum threshold itself. For small $g$ values the eigenvalue and norm of each of these states can be expanded in a Puiseux expansion in terms of powers of $g^{2/3}$, which suggests a third order EP occurs at the threshold. However, in the actual $g \to 0$ limit, only two discrete states in fact coalesce as the system can be reduced to a 2x2 Jordan block; the third state instead merges with the continuum. We further demonstrate the influence of the EP on non-Markovian dynamics characterizing the relaxation process of the quantum emitter in the vicinity of the threshold.

*This work is supported by JSPS KAKENHI Grant No. JP18K03466 and the Research Foundation for Opto-Science and Technology.

4:06PM D01.00007: Non-Markovian collective emission from macroscopically separated emitters  
KANUPRIYA SINHA (Presenter), Army research lab/Joint quantum institute, University of Maryland, PIERRE MEYSTRE, University of Arizona, PABLO SOLANO, MIT — We study the collective radiative decay of a system of two two-level emitters coupled to a one-dimensional waveguide in a regime where their separation is comparable to the coherence length of a spontaneously emitted photon. The electromagnetic field propagating in the cavity-like geometry formed by the emitters exerts a retarded backaction on the system leading to strongly non-Markovian dynamics. The collective spontaneous emission rate of the emitters exhibits an enhancement or inhibition beyond the usual Dicke super- and sub-radiance due to a self-consistent coherent timedelayed feedback.

4:18PM D01.00008: Analysis of matter-wave emission dynamics and polariton formation in a quantum-emitter array coupled to a band structure*  
ALFONSO LANUZA (Presenter), MICHAEL A STEWART, JOONHYUK KWON, YOUNGSHIN KIM, DOMINIK SCHNEBLE, State Univ of NY - Stony Brook — Recent progress on a spontaneous emitter for atomic matter waves [1] has enabled studies of exotic emission phenomena in bandgap materials. Here we present analytic solutions for the single excitation dynamics in a 1D sinusoidal lattice potential and a finite or infinite array of emitters. The calculated phenomenology ranges from non-Markovian decay into bound states for the case of one emitter, to the emergence of an additional band structure of polaritons for the case of infinite emitters.

*Supported by NSF PHY-1607633/1912546 and SUNY Ctr for QIS on LI.
4:30PM D01.00009: Generalized Theory of Pseudomodes for Exact Descriptions of Non-Markovian Quantum Processes  GRAEME PLEASANCE (Presenter), Univ of KwaZulu-Natal, BARRY M GARRAWAY, University of Sussex, FRANCESCO PETRUCCIONE, Univ of KwaZulu-Natal — In this talk we develop a general approach to analyzing the non-Markovian behavior of an open quantum system in a setting where the interaction is modelled by a generalized class of spectral density function. By introducing an auxiliary model in which the environment is replaced by a set of discrete bosonic modes exhibiting Markovian dissipative interactions, we prove the validity of the conditions allowing for a non-Markovian open system dynamics to be amended to a Markovian description, where the dynamics in the latter is governed by an exact master equation of Lindblad form. Initially we apply our result to obtain a generalization of the pseudomode method [1] in cases where the spectral density function has a Lorentzian structure. For many other types of spectral density function, we extend this result to show that an open system dynamics may be modelled physically using discrete modes which admit a non-Hermitian coupling to the system, and for such cases determine the equivalent master equation to no longer be of Lindblad form. For applications involving two discrete modes, we demonstrate how to convert between pathological and Lindblad forms of the master equation via [1].

4:42PM D01.00010: Stabilization of Fractional Quantum Hall States of Light: Effects of Fractionalization  PAVEL KURILOVICH (Presenter), JOSE LEBREUILLY, VLADISLAV KURILOVICH, STEVEN GIRVIN, Yale University — Recently, the possibility of realizing strongly-correlated states of matter with photons has started to become an experimental reality. In combination with artificial gauge fields this paves the way to simulation of fractional quantum Hall states with light. A major hindrance to such simulations is the inevitable dissipation of photons into the environment which creates holes in the correlated state. The leakage of light can be counteracted by a stabilization scheme in which lost particles are irreversibly refilled. We investigate the efficiency of such a scheme for the preparation of a photonic Laughlin state at half-filling. We explore the limitations imposed by the ability of holes in the Laughlin state to fractionalize into several spatially separated quasiholes. Quasiholes correspond to the absence of a fraction of a particle and thus cannot be refilled efficiently. We find that the fractionalization drastically restricts the steady-state fidelity of the Laughlin state and leads to a long relaxation time in the system.
Transport through a quantum critical system: A thermodynamically consistent approach*

CHRISTOPHER WÄCHTLER (Presenter), GERNOT SCHALLER, Institut of Theoretical Physics, Technical University Berlin — Quantum phase transitions are striking phenomena of many-body systems at low temperatures. The current experimental feasibilities enable us to bring such critical systems out of equilibrium in a controlled manner. Due to the vanishing energy gap above the ground state [1], appropriate methods have to be developed to study the dynamics and thermodynamical applications. We show for a class of critical systems connected to several non-Markovian heat baths that by combining the reaction coordinate mapping [2] and a polaron technique [3] it is possible to find analytic expressions of the reduced system dynamics in the vicinity of quantum critical points, which are consistent with the laws of thermodynamics. As an example we consider the Lipkin-Meshkov-Glick model in a transport setup, where the underlying phase transition manifests itself in the heat transfer statistics.

*We acknowledge financial support from Deutsche Forschungsgemeinschaft through project BR1528/8-2 and are thankful for stimulating discussions with A. Knorr, S. Restrepo, S. Böholing and especially V. M. Bastidas.

Deconstructing Effective Non-Hermitian Dynamics in Quadratic Bosonic Hamiltonians*

VINCENT FLYNN (Presenter), Dartmouth Coll, EMILIO COBANERA, SUNY Polytechnic Institute, LORENZA VIOLA, Dartmouth Coll — Unlike their fermionic counterparts, the dynamics of Hermitian, bosonic, quadratic Hamiltonians are governed by a generally non-Hermitian Bogoliubov de-Gennes Hamiltonian. This effective non-Hermiticity gives rise to two distinct dynamical phases: one with bounded evolution of observables in time, and one without. We elucidate the physical manifestations of the transitions between these two dynamical phases. We show how a generalized notion of $PT$ symmetry may be used to classify the mechanisms by which this transition can occur. By combining this understanding with tools from Krein stability theory, we derive an indicator of dynamical phase boundaries inspired by the notion of phase rigidity in non-Hermitian quantum systems. As an example, we fully characterize the dynamical phase diagram of a bosonic analogue to the Kitaev-Majorana chain under a wide class of boundary conditions, and further establish a connection between phase-dependent transport properties and the onset of instability. We discuss potential applications of our techniques to quadratic Lindblad dynamics.

*Research supported in part by US NSF through grant No. PHY-1620541.
Non-Hermitian Linear Response Theory  LEI PAN (Presenter), XIN CHEN, Institute for Advanced Study, Tsinghua University, YU CHEN, Capital Normal University, HUI ZHAI, Institute for Advanced Study, Tsinghua University — Linear response theory lies at the heart of quantum many-body physics because it builds up connections between the dynamical response to an external probe and correlation functions at equilibrium. Here we consider the dynamical response of a Hermitian system to a non-Hermitian probe, and we develop a non-Hermitian linear response theory that can also relate this dynamical response to equilibrium properties. As an application of our theory, we consider the real-time dynamics of momentum distribution induced by one-body and two-body dissipations. We find that, for many cases, the dynamics of momentum occupation and the width of momentum distribution obey the same universal function, governed by the single-particle spectral function. We also find that, for critical state with no well-defined quasi-particles, the dynamics are slower than normal state and our theory provides a model independent way to extract the critical exponent. We apply our results to analyze recent experiment on the Bose-Hubbard model and find surprising good agreement between theory and experiment. We also propose to further verify our theory by carrying out a similar experiment on a one-dimensional Luttinger liquid.

Session D02 DAMOP: Nonequilibrium dynamics in ultracold matter

Quantum Cherenkov Transition in Bose Polaron Systems  KUSHAL SEETHARAM (Presenter), Massachusetts Institute of Technology MIT, YULIA SHCHADILIOVA, Department of Physics, Harvard University, FABIAN GRUSDT, Department of Physics, Technical University Munich, MIKHAIL ZVONAREV, LPTMS, Universite Paris-Sud, EUGENE DEMLER, Department of Physics, Harvard University — We study the behavior of a finite-momentum impurity immersed in a weakly interacting Bose-Einstein condensate (BEC) of ultra-cold atoms near an interspecies Feshbach resonance. Using the time-dependent variational approach and a non-Gaussian transformation, we study both ground state properties and quench dynamics of the system after a sudden immersion of the impurity into the BEC. While in the subsonic regime dynamics corresponds to relaxation into the quasiparticle state, in the supersonic regime we observe rapid emission of Cherenkov phonons. This phenomenon manifests in several ways during real-time dynamics of the system and showcases a rich interplay between polaronic physics and Cherenkov physics. We see qualitatively different long-time behavior of average impurity speed and Loschmidt echo depending on the impurity-boson interaction strength. Aspects of the discussed dynamical behavior can be probed in experimental protocols.
2:42PM D02.00002: Tuning of Scattering Resonances by Time-Periodic Driving*  
CHRISTOPH DAUER (Presenter), AXEL PELSTER, SEBASTIAN EGGERT, Technical University of Kaiserslautern —  
Scattering by a short-range inter-particle potential with time-periodic modulation is investigated with Floquet theory without assuming any high frequency approximations. For a harmonic drive it turns out that strong resonances occur, which allow versatile tuning of the s-wave scattering length and the resonance width by adjusting frequency and driving amplitude. Our approach leads to a simple description of the effect in terms of a generalized Fano-Anderson model, which in turn identifies the physical origin and leads to an analytic quantitative description of the resonances. Results for general experimental situations of magnetic and optical driving using two coupled channels and including higher harmonics are discussed.

*Supported by the Deutsche Forschungsgemeinschaft (DFG) via SFB/TR185 "OSCAR"

2:54PM D02.00003: Quench dynamics of two-component dipolar Fermions in a Quasiperiodic potential*  
BRADRAJ PANDEY (Presenter), ELBIO DAGOTTO, University of Tennessee, Knoxville, SWAPAN K. PATI, TSU, jncasr —  
Motivated by the recent experiments in fermionic polar gases, we study the quenched dynamics of two-component dipolar fermions, in the presence and absence of a quasiperiodic potential. We investigate the localization of the charge and spin degree of freedom separately, by probing local and global dynamical observables [1]. To study non-equilibrium dynamics, we start with two different product states, doublons and a Neel state. We calculate the long time dynamics of the fermionic Hamiltonian using exact-diagonalization and matrix-product-state formalisms. In the case of doublons, we demonstrate the transition from delocalized to localized MBL phase. In the case of Neel state, by introducing strong enough disorder, we show that the localization of the spin degree of freedom is also possible along with the charge degree of freedom when on-site and long-range interaction couplings are equal in strength. Our predictions for localizations of both charge and spin degrees of freedom should be observed in experiments with fermionic dipolar atoms subject to a quasiperiodic potential.  

3:06PM D02.00004: Enabling ultrastrong-coupling phenomena with single-drive Jaynes--Cummings models  CARLOS SÁNCHEZ MUÑOZ, Oxford University, ANTON FRISK KOCKUM (Presenter), Chalmers Univ of Tech, ADAM MIRANOWICZ, Adam Mickiewicz University, FRANCO M NORI, RIKEN — We propose the effective simulation of light-matter ultrastrong-coupling phenomena with strong-coupling systems. Recent theory and experiments have shown that the single-atom quantum Rabi model can be simulated by the Jaynes-Cummings model with two additional classical drives. Here, we show that quantum nonlinear optical phenomena, relying on the counter-rotating terms of the quantum Rabi model, can be implemented by the Jaynes-Cummings and Tavis-Cummings models with only a single classical drive. We analyze three examples (one atom exciting two photons, frequency conversion, and one photon exciting two atoms) and show that they could be demonstrated with several currently available experimental quantum-optics systems, including superconducting circuits and trapped ions.

3:18PM D02.00005: Dynamics of the decay of dark solitons in superfluid Fermi gases* WOUT VAN ALPHEN (Presenter), Department of Physics, University of Antwerp, HIROMITSU TAKEUCHI, Department of Physics, Osaka City University, JACQUES TEMPERE, Department of Physics, University of Antwerp — Dark solitons are solitary matter waves which retain their shape while propagating at a constant velocity. They emerge in a wide variety of physical systems, including ultracold atomic gases. In superfluid Bose gases, dark solitons have been observed to decay into quantized vortices through the so-called snake instability mechanism. Recent experiments in superfluid Fermi gases have also interpreted soliton decay via this mechanism. However, using both numerical simulations and a perturbative analysis based on a low-energy effective field theory, we show that there is a qualitative difference between soliton decay in the BEC- and BCS-regimes of superfluid Fermi gases.

In the BEC-regime, the characteristic snaking deformations of the soliton plane are induced by fluctuations of the amplitude of the order parameter, while in the BCS-limit, fluctuations of the phase destroy the soliton core through the formation of local Josephson currents, without the occurrence of a snaking pattern. The difference between both mechanisms should be experimentally observable, providing an incentive to consider both past and future experiments from a new perspective.

3:30PM D02.00006: Operator complexity of adiabatic gauge potential  MOHIT PANDEY
(Presenter), Physics, Boston University, DRIES SELS, Physics, Harvard University, PIETER W. CLAEYS, ANATOLI S POLKOVNIKOV, DAVID K CAMPBELL, Physics, Boston University — Recently, there has been great interest in studying the growth rates of operator complexity and out-of-time-order correlators in many-body quantum systems. Here we characterize the complexity of the adiabatic gauge potential (AGP), which encodes the geometry of eigenstates when varying a control parameter in a Hamiltonian. For generic systems, the AGP is a highly non-local and entangled operator. We find that its Frobenius norm, which can be explicitly related to operator growth, shows remarkably different scaling with system size for integrable and non-integrable systems: polynomial versus exponential. Using the length of Pauli string operator as a measure of the AGP complexity, we compute operator weight distributions and the Shannon entropy to better understand the norm’s system size scaling.

3:42PM D02.00007: Transport in a bosonic superfluid point contact  SHUN UCHINO
(Presenter), Waseda Univ, JEAN-PHILIPPE BRANTUT, EPFL — We discuss heat and particle transport of a weakly interacting, low temperature Bose-Einstein condensate in a quantum point contact. We show that the presence of gapless phonon modes in the condensate yields a contact resistance at zero temperature and a corresponding nonzero DC conductance. As a consequence, we predict zero thermopower and Lorenz number at zero temperature, a breakdown of the bosonic Wiedemann-Franz law. The consequences on heat and particle transport measurements in bosonic two-terminal setups should be readily observable in existing experiments.

3:54PM D02.00008: Entanglement production by interaction quenches of quantum chaotic subsystems  JETHIN PULIKKOTTIL JACOB (Presenter), Washington State University Pullman, ARUL LAKSHMINARAYAN, Indian Institute of Technology Madras, SHASHI C. L. SRIVASTAVA, Variable Energy Cyclotron Centre Kolkata India, ARND BÄCKER, Technische Universität Dresden Germany, STEVEN TOMSOVIC, Washington State University Pullman — The entanglement production in bipartite quantum systems is studied for initially unentangled product eigenstates of the subsystems, which are assumed to be quantum chaotic [1]. Based on a perturbative computation of the Schmidt eigenvalues of the reduced density matrix, explicit expressions for the time-dependence of entanglement entropies, including the von Neumann entropy, are given. An appropriate re-scaling of time and the entropies by their saturation values leads a universal curve, independent of the interaction. The extension to the non-perturbative regime is performed using a recursively embedded perturbation theory to produce the full transition and the saturation values. The analytical results are found to be in good agreement with numerical results for random matrix computations and a dynamical system given by a pair of coupled kicked rotors.

**4:06PM D02.00009: The entanglement membrane in deterministic systems**  
TIANCI ZHOU  
(Presenter), Kavli Institute for Theoretical Physics, ADAM NAHUM, Physics, University of Oxford —  
In certain analytically-tractable quantum chaotic systems, the calculation of out-of-time-order correlation functions, entanglement entropies after a quench, and related dynamical observables, reduces to an effective statistical mechanics of an ‘entanglement membrane’ in spacetime. These tractable systems involve an average over random local unitaries defining the dynamical evolution. We show here how to make sense of this membrane in more realistic models, which do not involve an average over random unitaries. Our approach relies on introducing effective ‘pairing’ degrees of freedom in spacetime, inspired by the structure emerging in random unitary circuits. We also provide an efficient algorithm for determining the ‘line tension’ of the entanglement membrane in 1+1D models.

**4:18PM D02.00010: Nonequilibrium dual-boson approach**  
FENG CHEN (Presenter), MICHAEL GALPERIN, University of California, San Diego, MIKHAIL KATSNELSON, Institute for Molecules and Materials, Radboud University Nijmegen —  
We develop nonequilibrium auxiliary quantum master equation dual boson method (aux-DB), and argue that it presents a convenient way to describe steady states of correlated impurity models (such as single molecule optoelectronic devices) where electron and energy transport should be taken into account. The aux-DB is shown to provide high accuracy with relatively low numerical cost. Theoretical analysis is followed by illustrative simulations within generic two-level junction model, where the new scheme is benchmarked against numerically exact results.

*we acknowledge support by the National Science Foundation (grant CHE-1565939).*
4:30PM D02.00011: Modeling Collective Emission in Cavities by Phase Space Trajectories

TAO LI (Presenter), HSING TA CHEN, ABRAHAM NITZAN, JOSEPH E SUBOTNIK, Chemistry, University of Pennsylvania — We model N electronic two-level systems (TLSs) coupled to a multimode cavity by sampling independent trajectories in Wiger phase space with a Meyer-Miller-Stock-Thoss (MMST) mapping Hamiltonian. We show that this approach can not only provide us an intuitive physical interpretation of quantum electrodynamics (i.e. sampling electronic and photonic zero-point energies in phase space represents radiative self-interaction and vacuum fluctuations respectively), but also correctly describe many intriguing collective emission phenomena, including spontaneous emission for an array of TLSs in the singly excited manifold, Dicke's superradiance and subradiance when all TLSs are excited, and even the quantum statistics for the delay time in superradiance. We also discuss possible further improvements of this approach.

4:42PM D02.00012: The role of integrability in speeding up collective spin polarization.

TAMIRO VILLAZON (Presenter), Boston University, PIETER W CLAEYS, Trinity College, Cambridge, ANATOLI S POLKOVNIKOV, ANUSHYA CHANDRAN, Boston University — The central spin problem plays an important role in a variety of condensed matter systems, including quantum dots and nitrogen vacancy centers in diamond. We study an anisotropic central spin model with two classes of special eigenstates: bright and dark. We find these states to be robust against perturbations around two integrable points of the model. By driving of the central magnetic field, the structure of these eigenstates can be harnessed to access highly polarized many-body configurations. Using approximate shortcuts to adiabaticity, we develop a highly efficient and experimentally viable polarizing scheme.

4:54PM D02.00013: Quantum Weak Measurement Back-action Control On A Strongly Interacting BEC  
YUEHENG SHI (Presenter), Carleton College, STUART SZIGETI, Department of Quantum Science, Australian National University, ARJENDU KISHORE PATTANAYAK, Carleton College — The choice of weak measurement phase can affect the energy dynamics of a nonlinear quantum system. We report on progress towards controlling the measurement back-action on a strongly interacting Bose Einstein condensate (BEC) continuously monitored under phase-contrast imaging setup. We have derived the master equation using the fixed number state approximation. These have been reduced to a coupled set of differential equations of motions under Gaussian Approximation for the BEC. We use measurement phase dependent back-action in these equations for feed-back control. We discuss potential applications and experimental realizations.

5:06PM D02.00014: Unitary Subharmonic Response of Floquet Majorana Modes  
OLES SHTANKO (Presenter), University of Maryland, College Park, RAMIS MOVASSAGH, IBM Tj Watson Research Center — Detection and manipulation of Majorana fermions are essential for creating a topological quantum computer. To this end, we show that unpaired Majorana modes in Floquet systems can directly be visualized using the phenomenon of unitary subharmonic response. Namely, starting from highly non-equilibrium initial states, the unpaired Majorana modes exhibit boundary oscillations that have twice the driving period, are localized, and have up to exponentially long lifetimes with respect to the system’s parameters. While the lifetime is still limited in translationally invariant systems, we show how disorder can be engineered to stabilize the subharmonic response of Majorana modes. We also suggest a viable implementation in modern multiqubit systems, such as superconducting circuits and atomic systems.

5:18PM D02.00015: Real time dynamics of impurity and disorder scattering with interacting Fermion wave packets*  
SEBASTIAN EGGERT (Presenter), KEVIN JÄGERING, IMKE SCHNEIDER, BENJAMIN NAGLER, ARTUR WIDERA, University of Kaiserslautern, Germany — Recent advances for ultra-cold gases allow the controlled scattering by disorder and localized impurities using moving interacting Fermion wave packets in a trap after a quick displacement in position. We analyze the damping and scattering behavior from large scale numerical t-DMRG simulations in 1D as a function of interaction, displacement and disorder strength in a regime where a comparison with our experiments is possible. Attractive interactions make the wave-packets more susceptible for both single impurities and disorder scattering, which leads to a significant larger damping and quicker breakdown of the oscillations. Repulsive interactions have a much smaller effect, but overall a reduction of scattering can be observed. The corresponding experiments for 3D scattering show maximum stability and minimal damping near the unitary point.

Session D03 GSCCM: Materials in Extremes: Multiscale Models of Energetic Materials 107 - Mitchell Wood, Sandia National Laboratories - Tag(s): Focus
2:30PM D03.00001: Understanding the Role of Microstructure in Energetic Materials Using a Predictive Hierarchical Multiscale Simulation Approach* [Invited] JAMES P. LARENTZOS (Presenter), BRIAN C. BARNES, Weapons and Materials Reserach Directorate, US Army CCDC Army Research Laboratory, KENNETH W. LEITER, Computational and Information Sciences Directorate, US Army CCDC Army Reseach Laboratory, JOHN K. BRENNAN, SERGEI IZVEKOV, Weapons and Materials Reserach Directorate, US Army CCDC Army Research Laboratory, JAROSLAW KNAP, Computational and Information Sciences Directorate, US Army CCDC Army Reseach Laboratory, JOHN K. BRENNAN, SERGEI IZVEKOV, Weapons and Materials Reserach Directorate, US Army CCDC Army Research Laboratory — Composite energetic materials contain microstructural heterogeneities (i.e., crystal defects, voids, interfaces, etc.), where the community consensus is that this microstructure plays a critical role in the energetic material response. However, an understanding and characterization of its precise role for system design is lacking. This is due in part to the significant experimental challenges caused by the extreme conditions occurring at short time and length scales. Modeling and simulation are not hampered by these conditions; rather, limitations are due to the approximations made in the models and the available computational resources.

In this talk, new capabilities for investigating the role of microstructure in energetic material response through both explicit, large-scale and multiscale simulation approaches will be discussed. A hierarchical multiscale simulation approach that directly couples a coarse-grain particle level description of the chemistry and material heterogeneities (via dissipative particle dynamics simulation) to macroscale, finite element continuum simulations of an energetic material is established. The new methodology closes a gap in modeling capabilities for a key time and spatial regime in the multiscale material landscape (i.e., the mesoscale). The computational capabilities are demonstrated through at-scale comparisons of thermal cookoff and plate impact simulations with experiment to provide key insight into the role of microstructure on the response of the energetic material cyclotrimethylene trinitramine (RDX) to thermal and shock loading.

*This work was supported by the US Army CCDC Army Research Laboratory, the Office of Naval Research (BAA number 12-001), and a grant of computer time from the DOD High Performance Computing Modernization Program at the ARL, Navy, AFRL and ERDC DoD Supercomputing Resource Centers.
3:06PM D03.00002: Microstructure-informed, statistical approach for shock to detonation transition modelling in high explosives  
AHMED HAMED (Presenter), MARISOL KOSLOWSKI, Purdue Univ — Shock to detonation transition phenomenon (STDT) is a synergistic effect of different underlying mechanical, chemical, and thermal processes, where the racing between different modes of energy production and dissipation is the key factor. Accurate prediction of these far-from-thermodynamic-equilibrium phenomena dictates careful consideration of different entropic fluxes associated with various inelastic processes, along with their characteristic modes of transport. Hot-spot formation and initiation is the main paradigm to tackle STDT, which, in turn, is known to be heterogeneous in nature. Accordingly, mean-field approaches, which employ averaged-measures of microstructural properties, predict critical parameters for STDT regime that can deviate significantly from experiment. In the present study, we seek a statistical approach to represent the heterogeneity in the microstructure of polymer-bonded explosives, which better captures the sensitivity of hot-spot initiation to local variation in the microstructure. The reactive flow system of equations is solved in Lagrangian framework, within finite strain formalism. In addition, this thermo-mechanical-chemical model is supplemented by the Hugoniot equation of state for closure purposes and solved using finite-element technique.

3:18PM D03.00003: Mesoscale modeling of explosive mixtures containing TNT and HMX*  
H. KEO SPRINGER (Presenter), SORIN BASTEA, CRAIG M TARVER, Lawrence Livermore Natl Lab — Different energetic constituents can be combined to achieve desired explosive mixture properties. One example of an explosive mixture is Octol which is comprised of a less ideal constituent, TNT, and a more ideal constituent, HMX. Changes to HMX content in this mixture can alter its shock sensitivity and performance. However, the microscale reaction mechanisms underlying such changes are not well understood. In this study we perform mesoscale simulations to investigate different TNT-HMX mixtures. Simulations are performed with the multi-physics code, ALE3D. A coupled thermochemical code provides equation-of-state and chemical kinetic properties. Simulations are performed for TNT-HMX weight ratios of 25-75, 40-60, and 70-30 with 2 and 5% porosity. A range of shock pressures are considered. Non-reactive studies examining changes to the p-v response and temperature distribution will be discussed with comparisons to common mixture rules. Trends for the mixture reaction rate with varying HMX content and porosity will also be discussed. These studies are important for developing mixture reactive flow models when the constituents are mixed at length-scales below the reaction zone size.

Mesoscale Dynamic Damage Visualization and Simulation of Energetic Materials under Impact

JONATHAN DRAKE, WEINONG CHEN (Presenter), MARISOL KOSLOWSKI, Purdue Univ, KAMEL FEZZAA, APS, Argonne National Laboratory — Energetic materials may be subjected to impact. Under such loading conditions, local stress or strain concentrations may lead to the formation of hot spots and unintended reaction. To visualize the dynamic damage and reaction processes in polymer bonded energetic crystals under dynamic compressive loading, a high-speed X-ray phase contrast imaging setup was synchronized with a Kolsky bar and a light gas gun. Controlled compressive loading was applied on PBX specimens with a single or multiple energetic crystal particles and impact-induced, time-resolved damage and reaction processes were captured using the high-speed X-ray PCI. Numerical simulation models were built based on the experimental results and used to investigate the impact damage in PBX over a wider range of parameter variations.

Developing and validating thermomechanics models for explosives with experiments on commensurate scales [Invited]  

KYLE RAMOS (Presenter), FRANCIS L ADDESSIO, CLAUDINE ARMENTA, JOHN L. BARBER, CYNTHIA BOLME, MARC CAWKWELL, Los Alamos National Laboratory, LEORA DRESSELHAUS-COOPER, Lawrence Livermore National Laboratory, ARIANNA E GLEASON, SLAC National Accelerator Laboratory, ADAM GOLDER, ERNEST HARTLINE, BRIAN JENSEN, Los Alamos National Laboratory, HAEJA LEE, SLAC National Accelerator Laboratory, DARBY J LUSCHER, Los Alamos National Laboratory, CHRISTOPHER MEREDITH, Army Research Laboratory, PAULO A RIGG, Washington State University, RICHARD L SANDBERG, Los Alamos National Laboratory, MATTHEW H SEABERG, SLAC National Accelerator Laboratory, NICHOLAS SINCLAIR, Washington State University, GARY K WINDLER, Los Alamos National Laboratory — In both manufacturing and dynamic loading, the interplay between deviatoric stress, plastic strain, and heat generation at the mesoscale dictate the responses of plastic bonded explosives (PBX). In situ mesoscale insights are needed to quantify structure-property relationships, inform theory, and enable simulations. We have attempted such an effort and will present an overview of our progress so far.

Laser-driven shock, gas gun, and split-Hopkinson pressure bar experiments have been performed to span multiple orders of strain rate, using synchrotron and X-ray free electron laser radiation to measure time-resolved X-ray diffraction (XRD) and phase contrast imaging (PCI) in situ for single crystal and plastic bonded explosives. This range of strain rates enables investigation of coupling between crystal mechanics, thermal softening, and microstructure that governs explosive response.

Multiphase single crystal plasticity models have been developed. They consist of non-linear thermo-elasticity, Orowan expressions for slip rate using the Austin-McDowell model for dislocation velocity, and multiphase equations of state (EOS) imposing phase transitions through Gibbs free-energy. Constitutive equations were parameterized with density functional theory and atomistic calculations for EOS and elastic constants along with experimental measurements of anisotropic deformation mechanisms and rates. These models are capable of predicting anisotropy, grain size, and pressure dependent effects remarkably well.

Combining the new capabilities, mesoscale thermomechanics can be investigated from the average lattice response up to PBX microstructures. For the first time, XRD quantify average lattice response and allows for direct comparison of experiments and simulations through measured and computed diagnostics. Using the experimentally validated models, simulation can be compared to PCI of heterogeneous micorstructure effects such as void collapse and grain boundaries.
4:18PM D03.00006: Non-Schmid effect of pressure on plastic deformation in molecular crystal HMX

ANIRBAN PAL (Presenter), West Texas State Univ, CATALIN PICU, Mechanical Aerospace and Nuclear Engg., Rensselaer Polytechnic Inst — The energetic molecular crystal HMX is a key constituent in common plastic bonded explosives. Its plastic deformation under shock conditions is important in reaction initiation and detonation. Here, we study the effect of high pressure on dislocation slip using isothermal-isobaric atomistic simulations. We consider 2 slip planes, (011) and (101), that are reported to be most active under ambient conditions. For all slip systems considered, the effect of pressure is to increase the critical resolved shear stress for dislocation slip. Pressure may fully inhibit dislocation-based plasticity if the resolved shear stress is not increased in proportion. On the other hand, at sufficiently high shear stresses, the crystal loses shear stability. Therefore, in a broad range of shock conditions, plastic deformation takes place by a combination of dislocation glide in some slip systems and localization in some other systems, with dislocation activity being gradually inhibited as the shock pressure increases.

*This work was supported by the US Air Force Research Labs(AFRL/RWK).

4:30PM D03.00007: Atomistic mechanisms in the plasticity of energetic crystal HMX

MOHAMMAD KHAN (Presenter), ANIRBAN PAL, CATALIN PICU, Rensselaer Polytechnic Institute — The energetic molecular crystal cyclotetramethylene tetranitramine (HMX) is a key constituent in common plastic bonded explosives. Its plastic deformation under shock conditions is important in reaction initiation and detonation. In this work we identify, using atomistic simulations, the slip systems in b-HMX and compute the critical resolved shear stresses for dislocation motion. We also evaluate the mobility of dislocations in various slip systems and the likelihood of cross-slip. The implications of these results for the overall physical picture of plasticity in HMX are discussed.

4:42PM D03.00008: Anisotropic Thermal Conductivity and Elasticity of RDX Using Impulsive Stimulated Thermal Scattering*  JOHN LAZARZ (Presenter), SHAWN DAVID MCGRANE, ROMAIN PERRIOT, CYNTHIA BOLME, MARC CAWKWELL, KYLE RAMOS, Los Alamos National Laboratory — Anisotropy of single crystals plays an integral role in meso-scale behavior of materials. In energetic materials, the anisotropy of thermal conductivity and elasticity plays a key role in hot spot generation during dynamic loading, potentially leading to deflagration or detonation. Precise measurements are needed to validate predictive models of these materials during accident scenarios. Toward these goals, we are investigating single crystal orthorhombic 1,3,5-trinitroperhydro-1,3,5-triazine (RDX) using impulsive stimulated thermal scattering (ISTS). Here we present results of the experimentally determined thermal diffusivity and its comparison with the anisotropic values predicted by atomistic simulations, as well as experimentally measured anisotropic acoustic velocities.

*LANL Laboratory Directed Research and Development project 20180100DR.

4:54PM D03.00009: Dynamic fracture and frictional temperature rise in HMX-Sylgard microstructures under impact and vibration  AKSHAY DANDEKAR (Presenter), MARISOL KOSLOWSKI, Purdue Univ — Polymer bonded explosives are sensitive to impact and vibrations and can form critical hot-spots under certain conditions leading to ignition. Thus, understanding the behavior of PBXs under mechanical loading is crucial to avoid accidents during manufacturing, handling, and transport of these materials. In this study, the response of HMX-Sylgard samples is numerically studied using a finite element approach that includes dynamic damage coupled with temperature evolution due to frictional heat. At impact velocities close to 100 m/s several cracks develop and grow. Consequently, critical hot spots are observed in agreement with PBX. The maximum frictional temperature rise is found at particle polymer interfaces. The effect of crystal orientation of the particles including plasticity and orientation and cleavage planes is analyzed under vibration and impact in 3D simulations.

5:06PM D03.00010: Temperature- and pressure-dependent lattice constants of CL-20 polymorphs from ab initio molecular dynamics simulations*  IGOR SCHWEIGERT (Presenter), BENJAMIN DATKO, United States Naval Research Laboratory — Hexanitrohexaazaisowurtizane (CL-20) is a high-density nitramine compound with several known polymorphs. We're interested in using density functional theory (DFT) to predict the thermodynamic stabilities of various polymorphs at elevated temperatures and pressures. This presentation will describe DFT-based molecular dynamics simulations of temperature- and pressure-dependent lattice constants for the epsilon and zeta polymorphs and compare the results to available experimental data.

*This work was supported by the Office of Naval Research (ONR), both directly (project N0001416WX0003, Dr. Chad Stoltz) and through the U.S. Naval Research Laboratory (NRL).
5:18PM D03.00011: Material Diffusion and Combustion Process Modeling Using a Stochastic Particle-Based Framework  
NIKOLAI PETSEV (Presenter), XIA MA, BRYAN HENSON, BRAD EDWIN CLEMENTS, Los Alamos National Laboratory — We describe a novel mesoscale particle-based computational strategy for modeling non-isothermal reaction-diffusion problems. Importantly, this simulation framework gives the foundation for investigating the deflagration-to-detonation transition (DDT) in combustion, where the material transitions from burning at a rapid subsonic pace (deflagration) to the emergence of a shockwave (detonation). The basis for this approach is "smoothed dissipative particle dynamics" (SDPD), a stochastic thermodynamically-consistent approach for solving the fluctuating hydrodynamic equations of Landau and Lifshitz. Presently our new approach incorporates heat and mass transfer driven by conduction and diffusion, exchange of heat and chemical species due to thermal fluctuations, and source terms arising from the chemical reaction. In future work, this will be coupled to the fluctuating momentum equation, or included in multiscale molecular-continuum simulations, opening the possibility for simulations studying DDT in energetic materials, in addition to a broad range of other applications involving chemical reactions and concurrent mass and heat transfer.

Monday, March 2, 2020 2:30 PM - 5:06 PM

Session D04 DCP DCOMP DBIO DSOFT: Water Dynamics in Different Environments: Experiment and Theory II. Ice

2:30PM D04.00001: Interfacial water: from atmospheric ice nucleation to nano-confinement [Invited]  
ANGELOS MICHAELIDES (Presenter), Univ Coll London — Recent work from our research group in which we are trying to understand the intimate molecular level details of water freezing will be discussed. A particular emphasis will be placed on the role the surfaces of foreign materials play in accelerating the nucleation process [1-3] and on the dynamical nature of the nucleation event.

**3:06PM D04.00002: Atomic imaging of edge structure and growth of a two-dimensional hexagonal ice**  
RUNZE MA (Presenter), DUANYUN CAO, International Center for Quantum Materials, Peking University, CHONGQIN ZHU, Department of Earth and Environmental Sciences, University of Pennsylvania, YE TIAN, JINBO PENG, JING GUO, International Center for Quantum Materials, Peking University, JI CHEN, XIN-ZHENG LI, School of Physics, Peking University, JOSEPH S FRANCISCO, Department of Earth and Environmental Sciences, University of Pennsylvania, XIAO CHENG ZENG, Department of Physics, University of Nebraska–Lincoln, LIMEI XU, ENGE WANG, YING JIANG, International Center for Quantum Materials, Peking University — The formation and growth of water ice layers on surfaces and of low-dimensional ice under confinement are common occurrences. While structured water adlayers and 2D ice have been imaged, capturing metastable or intermediate edge structures involved in their growth is extremely challenging due to their fragile and short-lived nature.

Here we show that noncontact atomic force microscopy with a CO-terminated tip allows real-space imaging of the edge structures of a 2D bilayer of hexagonal ice grown on an Au(111) surface. We find a new edge type that coexists with the zigzag edge commonly observed in 2D hexagonal crystals, and freeze samples during growth to identify intermediate structures.

When combined with MD simulations, these allow us to reconstruct growth processes that in the case of the zigzag edge involve addition of water molecules to the existing edge and a collective bridging mechanism. Armchair edge growth, in contrast, involves local seeding and edge reconstruction and thus is in stark contrast to conventional views of ice growth. The growth mechanism we have uncovered might also occur at the surface of bilayer hexagonal ice and might support a bilayer-on-bilayer ice growth to 3D ice transformation.

RICCARDO DETTORI (Presenter), Department of Chemistry, University of California, Davis, MICHELE CERIOTTI, Laboratory of Computational Science and Modeling, École Polytechnique Fédérale de Lausanne, JOHANNES HUNGER, Max Planck Institute for Polymer Research, LUCIANO COLOMBO, Dipartimento di Fisica, Università degli Studi di Cagliari, DAVIDE DONADIO, Department of Chemistry, University of California, Davis — We introduce a nonequilibrium molecular dynamics simulation approach, based on the generalized Langevin equation, to study vibrational energy relaxation in pump-probe spectroscopy. A colored noise thermostat is used to selectively excite a set of vibrational modes, leaving the other modes nearly unperturbed, to mimic the effect of a monochromatic laser pump. Infrared pump-probe spectroscopy provides detailed information about the dynamics of hydrogen-bonded liquids. Due to the dissipation of the absorbed pump pulse energy, thermal equilibration dynamics also contribute to the observed signal. Disentangling this contribution from the molecular response remains a challenge. By performing non-equilibrium molecular dynamics simulations of hydrogen-bonded liquids, we show that faster molecular vibrational relaxation and slower heat diffusion are decoupled and occur on different length scales. Transient structures of the hydrogen bonding network influence thermal relaxation by affecting thermal diffusivity over a length scale of several nanometers. Energy relaxation is probed by analyzing the evolution of the system after excitation in the microcanonical ensemble, thus providing direct information about the energy redistribution paths at the molecular level and their time scale.
3:30PM D04.00004: Complete Lattice Vibration Dispersion Curves (36 Branches) for the Frozen (T=0K) Bernal-Fowler Hexagonal Close Packed Crystalline Ice with Four Water Molecules in One Primitive Unit Cell Containing 8 Protons and 4 Oxygen Nuclei*  

BIN JIE (Presenter), Physics Department, Xiamen University, CINDY TIANHUI JIE, Massachusetts Institute of Technology, CHIH-TANG SAH, Physics Department, Xiamen University — In 1969, Faure computed the lowest 12 branches of dispersion curves of lattice vibrational modes for Ice Ih, assuming the water molecule H$_2$O in the crystalline ice as point mass (PM), in order to analyze the experimental infrared and Raman spectra of ice. In 1973, Bosi-Tubino-Zerbi removed the PM approximation of H$_2$O in the 1933 Bernal-Fowler Hexagonal Close Packed (HCP) Primitive Unit Cell (PUC) containing 4 H$_2$O (8 protons and 4 Oxygen nuclei) in order to account for the experimental spectra in the low vibrational frequency (LVF) range. During 1969-2019 (50 years) theoretical and experimental spectra of hexagonal Ice Ih are lacking in the high vibrational frequency (HVF) range. Our 2013 melted-ice model for pure liquid water, demonstrated the dominance of the HVF modes in accounting for the abnormally high mobilities of positive and negative ions in pure liquid water. This talk gives the computed 36 branches of dispersion curves of Ice Ih at 0K, using six prime force constants, four values of which from isolated water molecule, further proving the connection of water’s crystalline solid phase and single molecule gas phase, by our 2013 melted-ice lattice model for the liquid phase of water.

3:42PM D04.00005: Probing interfacial water by H-sensitive and non-invasive scanning probe microscopy [Invited]  

YING JIANG (Presenter), Peking Univ — Water/solid interfaces are a central theme across an incredibly broad range of scientific and technological processes. Scanning probe microscopy (SPM) has been extensively applied to probe interfacial water in many interdisciplinary fields. However, there exist two longstanding limitations in the past two decades, which makes SPM fall short compared with conventional spectroscopic methods. First, H atoms of water molecule are very small and light, so it is very difficult to image them directly; Second, the water molecules are linked by weak H bonds, and it is highly possible to disturb the fragile water structure during the imaging process. In order to overcome these two grand challenges, we have developed a new-generation SPM based on a qPlus sensor, which is sensitive to H and non-invasive to water structure [1]. The key lies in probing the high-order electrostatic force between the quadrupole-like CO-terminated tip and the polar water molecules at large tip-water distances. In this talk, I will first discuss the application of this technique to determine the microscopic structure of metastable water clusters [1]. In addition, we have unraveled the detailed atomic structures of ion hydrates at interfaces and discover a magic-number effect on the transport of ion hydrates [2]. Finally, I will show the ability of visualizing the growth of a two-dimensional ice in real space with atomic resolution, by capturing various metastable and intermediate structures during the ice growth at the ice edges [3].

CHIH-TANG SAH (Presenter), Physics Department, Xiamen University, CINDY TIANHUI JIE, Massachusetts Institute of Technology, BIN JIE, Physics Department, Xiamen University — Our 2013 melted ice model extends the 1933 Bernal-Fowler Hexagonal Close Packed Ice crystal model to pure liquid water (0-100°C). The periodically-extended 2 trisector proton sites between 2 nearest neighbor oxygen nuclei, occupied or unoccupied by a proton, are the 2 physical spaces for the migrations of the 2 protonic fermion species, the protons and prohols. The physical space describes, in the statistically large sensible volume, the 2 protonic energy bands, for protons migrating among the unoccupied proton sites and prohols migrating among the occupied proton sites. The vibrational modes of the protons and oxygens give the 2 atomic phonon species: 12 oxygenic bosons in the low energy range and 24 protonic bosons in the high energy range. Electrical charge and inertia mass transports in pure liquid water, are carried by the protons, and dominated by the strong localized (local mode & self trap) interaction between the protonic fermions and protonic bosons, with noisy background from the oxygenic bosons. Our computed temperature variations (0–100°C) of the three parameters (the proton product and the two protonic mobilities) are in excellent agreement with the international handbook values.

4:30PM D04.00007: Nanoindentation of Ice I\textsubscript{h} - Atomistic simulations

PEDRO ANTONIO SANTOS-FLÓREZ (Presenter), UNICAMP - Universidade Estadual de Campinas, CARLOS JAVIER RUESTES, UNCUYO - Universidad Nacional de Cuyo, MAURICE DE KONING, UNICAMP - Universidade Estadual de Campinas — Using molecular dynamics simulations we study the mechanical response of ice I\textsubscript{h} through nanoindentation tests perpendicular to the basal plane. Using a smooth spherical tip represented by a repulsive potential we explore the deformation mechanisms and hardness estimates for ice as described by the all-atom TIP4P/Ice potential and the coarse-grained mW models. We assess the sensitivity to the tip radius and the penetration rate both for low temperatures as well as for conditions close to the melting point, where the formation of a quasi-liquid layer (QLL) on the surface becomes relevant. We find that during plastic deformation the main mechanism for stress relief for the low temperatures is the amorphization of the crystalline ice bilayers. On the other hand, for high temperatures the plastic deformation occurs by bilayer-by-bilayer melting, consistent with previous literature. Considering the difference between the behaviors of the mW and TIP4P/Ice models, we observe that the latter also involves the nucleation and motion of dislocations. This is consistent with recent observations concerning uniaxial deformations and provides further indications that the absence of explicit protons in the mW model gives rise to excessive ductility.
**4:42PM D04.00008: Sum Frequency Generation Spectroscopy of Ice/Air and Water/Air Interfaces from Ab Initio Deep Potential Molecular Dynamics**

MARCOS ANDRADE (Presenter), LINFENG ZHANG, ANNABELLA SELLONI, ROBERTO CAR, Princeton University — The interfaces of liquid water and ice with air abound on Earth and impact non-negligibly atmospheric sciences. Directly probing the structure of interfacial water is challenging, and the surface-specificity of Sum Frequency Generation (SFG) spectroscopy has offered important insights on both structure and dynamics of interfacial water and ice. *Ab initio* molecular dynamics (AIMD) could, in principle, aid interpret the experimental observations since it accesses both molecular and electronic structure of interfacial water. However, AIMD stumbles on the slow convergence of the SFG spectrum with simulation time. We here overcome this difficulty using Deep Neural Networks (DNN) to represent the *ab initio* potential energy surface. DNNs were also used to obtain molecular dipole moment and polarizability of water in agreement with first-principles methods, which allows a proper computation of the SFG spectrum of water/air and ice/air interfaces relying only on the dipole approximation. Our method can be easily extended to other interfaces and should enable *ab initio* level simulations of SFG spectra for a wide variety of systems.

**4:54PM D04.00009: How crystals form: a theory of nucleation pathways**

JAMES LUTSKO (Presenter), Universite libre de Bruxelles — Classical Density Functional theory is combined with fluctuating hydrodynamics to describe nucleation in general and crystallization in particular. The nucleation pathway is characterized as the most likely path connecting the initial homogeneous solution to the critical cluster[1]. Classical Nucleation Theory can be recovered with additional approximations[2]. Results for a Lennard-Jones system[3] show a two-step path with the formation of a dense fluid-like droplet followed by the development of order within. During ordering, the system passes through a metastable, subcritical phase that could be identified as a nucleation precursor. The precursor is a sub-critical crystalline cluster stabilized by completed crystalline shells and a wetting layer.

**D04.00010: Surface and bulk contributions to sum-frequency vibrational spectroscopy of single crystalline ice**

XU XIAOFAN (Presenter), Fudan Univ, YUEN-RON SHEN, Physics Department, University of California, Berkeley, CHUANSHAN TIAN, Fudan Univ — We study the bulk and surface contributions to the sum-frequency vibrational spectroscopy (SFVS) of ice I_h(0001) interfaces in the bonded OH stretching band at 223K. Using phase-sensitive SFVS with selected polarization combination and beam geometry, a pure electric quadrupole SF spectrum from bulk ice was obtained. Based on analysis of selection rule, an electric quadrupole sub-band near 3120 cm\(^{-1}\) originated from the bulk was found to constitute large portion in the reflected SF spectrum of vapor/ice interface. Via modification of ice surface by absorption of a monolayer of ethanol, the SF vibrational spectrum was significantly reduced at ~3170 cm\(^{-1}\), suggesting the surface is also important in the ice SF spectrum. These results not only reveal the importance of bulk contribution in SFVS spectrum of ice, but pave the way for investigation of ice surface, e.g. surface premelting, in practical environments.

2:30PM D05.00001: Investigating the Energy Transfer Dynamics in the Baseplate of Green Photosynthetic Bacteria using 2D Electronic Spectroscopy* ALEXA RAE CAROLLO (Presenter), Department of Chemistry, University of Colorado Boulder, CARRIE GOODSON, Department of Biology, Washington University in St. Louis, ROBERT E. BLANKENSHIP, Department of Biology and Department of Chemistry, Washington University in St. Louis, NIELS-ULRIK FRIGAARD, Department of Biology, University of Copenhagen, DONATAS ZIGMANTAS, Department of Chemical Physics, Lund University — The structure of the baseplate, a pigment-protein complex that mediates energy transfer in green photosynthetic bacteria, is not fully understood. The baseplate cannot be isolated from the chlorosome light harvesting antenna, but their spectral signatures can be separated with femtosecond two-dimensional electronic spectroscopy (2DES)[1]. In this work, 2D spectra of the baseplate in a mutant of Chlorobaculum tepidum, which was previously found to contain dimeric pigments[2], will be compared to 2D spectra of Chloroflexus aurantiacus to characterize the pigment interactions and energy transfer pathways in both samples.

2:42PM D05.00002: Probing quantum coherence in photosynthetic energy transfer in the presence of fluctuating environment with levitons and time-dependent nonequilibrium Green functions* PRIYANKA MONDAL (Presenter), BRANISLAV NIKOLIC, Univ of Delaware, ALEXANDER EISFELD, Max Planck Institute for the Physics of Complex Systems — The first few steps of photosynthesis in light harvesting complexes involve creation of exciton at chlorosome and its transport to reaction center, where the charge separation takes place. The transport of exciton from chlorosome to reaction center is highly efficient but the role of long-lived quantum coherence towards this efficiency is highly debatable. Here we present a prototype that uses a leviton voltage pulse to map a single exciton entering Fenna-Matthews-Olson pigment complex which is mapped as coupled quantum dots with attached leads, in presence of environmental fluctuation coming from molecular dynamics simulation. Our main result includes long-lived quantum beating in population dynamics and the dependency of quantum dephasing on exciton transport efficiency in fluctuating environment using time-dependent nonequilibrium Green functions approach.

Exploring electronic-vibrational coupling in chlorophylls and photosynthetic complexes by polarization-controlled 2D electronic spectroscopy* [Invited]

DONATAS ZIGMANTAS (Presenter), EGLE BUKARTE, ERLING THYRHAUG, Lund Univ/Lund Inst of Tech, DAVID PALECEK, University of Cambridge, ROEL TEMPELAAR, Columbia University, ANJA HAUFE, Goethe University Frankfurt, MARCELO ALCOCER, KAREL ZIDEK, Lund Univ/Lund Inst of Tech, THOMAS LA COUR JANSSEN, University of Groningen, DAVID BINA, The Institute of Plant Molecular Biology, JASPER KNOESTER, University of Groningen, CLAUDIA BUCHEL, Goethe University Frankfurt — Electronic-vibrational (vibronic) coupling has been suggested to play an important role in energy transfer and charge separation processes in photosynthesis. It is, however, highly elusive phenomenon to investigate. To this end we have employed polarization-controlled 2DES together with advanced Fourier analysis [1]. We use double-crossed polarization scheme, which extracts signals generated by excitation of coherences, involving transitions with different orientation of dipole moments. It allows for studying electronic and vibronically mixed coherences, and therefore enables to directly detect the presence of vibronic mixing (coupling).

In one study we investigated chlorophyll c molecule, where we found a clear evidence of mixing of the two lowest electronic states, Qx and Qy via vibronic coupling. Interestingly, we discovered at least two vibrational modes that are involved in the coupling. Since this type of coupling is expected to be rather general, vibronic mixing is expected in all chlorophyll-type molecules.

In another study we revisited coherence dynamics in the FMO complex at 77 K [2]. Applying the same experimental method and analysis techniques, and aided by theory, we find a very rich picture of the coherence signals. We determined that all long-lived coherences have clearly vibrational origin. While electronic coherences are also observed, they dephase on the ~100 fs time scale. Importantly, we further observe that specific vibrational coherences are excited via vibronically coupled excitonic transitions.

Finding ubiquitous vibronic coupling in photosynthetic pigments and complexes that contain them raises a question if its presence is the signature of smart Nature's design, or an unavoidable consequence of the photophysical properties of the porphyrin-type molecules.

3:30PM D05.00004: Matrix-product-state-based calculations of exciton-phonon dynamics for light-harvesting complexes*  R. KEVIN KESSING (Presenter), SALVATORE MANMANA, Institute for Theoretical Physics, Georg-August-Universität Göttingen, JIANSHU CAO, Department of Chemistry, Massachusetts Institute of Technology MIT — Excitonic systems with one to a few dozen sites are an important topic in contexts such as quantum optics, molecular spectroscopy or the dynamics of light-harvesting complexes. However, the dynamics are often strongly influenced by coupling to the external or internal vibrational modes, which presents a computationally much more challenging problem. We investigate the dynamics of excitonic oligomers with such non-perturbative coupling to a quantum bath using a symmetry-adapted state-of-the-art matrix-product-state (MPS) code[1] which has not been previously applied to this type of system. Using this accurate, unbiased method, we focus on studying spreading, coherence and entanglement behavior. The insights gained from these analyses help us better understand exciton dynamics in photosynthesis, e.g. in the purple bacteria light-harvesting complex LH2, which exhibits efficient energy transfer and a notable symmetric structure. [2]

3:42PM D05.00005: Vibronic Structure and Coherence in the Bacterial Reaction Center* [Invited]  JENNIFER OGILVIE (Presenter), VERONICA POLICHT, Univ of Michigan - Ann Arbor — Much of our current understanding of photosynthetic charge separation has been derived from studies of the bacterial reaction center (BRC) from purple bacteria. We report two-dimensional electronic spectroscopy (2DES) experiments on the BRC that reveal previously hidden excitonic and vibronic structure. Through analysis of the coherent dynamics of the BRC and careful comparison with monomeric bacteriochlorophyll we report vibronic coherence and identify resonances between a number of key intramolecular pigment vibrations and electronic energy gaps in the BRC. Such resonances have been proposed to play a functional role in photosynthetic energy transfer and charge separation.

*The authors gratefully acknowledge support from the National Science Foundation (grant # PHY-0748470). J.P.O. acknowledges support from the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award #DE-SC0016384.
Organic solar cell materials are a cheaper option to traditional silicon but lack the efficiency for which silicon is famous. Quantum computers can outperform the greatest supercomputer, but the short-lived coherences lead to classical-like behavior. Light-harvesting systems (LHS) serve as an example to both applications. LHSs absorb sunlight and convert it into an electrochemical gradient with near unity quantum efficiency and maintain long coherence times. Probing the exciton dynamics of these systems, one of which is the Photosystem II reaction center (PSII RC), can elucidate how these systems are able to transport excitons with approximately 99% efficiency. This revelation could propel solar-cell and quantum-computing research forward at unprecedented levels.

To do this, we have employed a projection-free version of the Generalized Quantum Master Equation (GQME) whose memory kernel is calculated using approximate methods, such as the Mean-Field Approximation (MFA) and the Linearized Semiclassical Method (LSC). This approach, verified against a Spin-Boson model and the well-studied LHS Fenna-Matthews-Olson (FMO) complex, is more computationally efficient and yields a high level of accuracy compared to exact methods such as the Quasi-Adiabatic Propagator Path Integral (QuAPI).

The discovery that quantum coherence might enhance biological processes such as photosynthesis is not only of fundamental importance but also leads to hopes of developing bio-inspired ‘green’ quantum technologies that mimic nature. A key question is how the time scale of coherent processes in molecular systems compare to that of the driving light source — the sun. Across the community, the coherence time quoted for sunlight spans at least two orders of magnitude, ranging from 0.6 to >10 of femtoseconds. This difference can potentially be significant in deciding whether the induced light-matter coherence is long enough to affect macro system behaviour. Here we revisit the historic calculations of sunlight coherence starting with the blackbody spectrum and then proceed to provide values for the more realistic case of atmospherically filtered light. We corroborate these values with interferometric measurements of atmospherically filtered sunlight in the visible spectrum, the wavelength range most relevant for photosynthetic organisms on Earth. This is the first step in our development of a novel sunlight emulator utilizing a train of ultrafast laser pulses.

4:42PM D05.00008: Quantum coherence in a photosynthetic dimer driven by incoherent sunlight* PEI-YUN YANG (Presenter), Beijing Computational Science Research Center, JIANSHU CAO, Massachusetts Institute of Technology MIT — In this work, we demonstrate noise-induced coherence in a model of a photosynthetic molecular dimer driven by an incoherent radiation field. Through perturbation theory associated with white noise approximation, the dynamics of the excitons is characterized by the dressed exciton states. The exciton coherence exhibits respectively quantum beats among the exciton states and quasistationary relaxation processes in two opposite parameter limits. We further examine the steady-state physics, where the exciton coherence can be classified into light-induced and trap-induced coherences that break detailed balance. At last, the steady-state population and energy fluxes in the dimer system are discussed.

*Pei-Yun Yang is supported by Beijing Computational Science Research Center

4:54PM D05.00009: Carotenoid-mediated light harvesting in plants Minjung Son, Gabriela Schlau-Cohen (Invited) GABRIELA SCHLAU-COHEN (Presenter), MINJUNG SON, Massachusetts Institute of Technology MIT — Plants absorb across the visible region of the solar spectrum followed by rapid and efficient collection of the photoenergy in lower-lying states. Previous experiments have been limited to the dynamics of the low-energy states, leaving the higher-energy states, including how they transfer energy downhill, unexplored. We describe ultrabroadband 2D electronic spectroscopy that enables us to map out the excited states and dynamics of the major antenna complex of plants across the visible region. By analyzing the vibrational wavepackets in the spectra, we identify a debated dark state on a single carotenoid, lutein 2, that mediates relaxation. This result reveals that the protein binding pocket controls the electronic structure of carotenoids, and therefore their function in photosynthesis.

Session D07 DQI: NISQ: Quantum Chemistry and Quantum Simulation

2:30PM D07.00001: Demonstration of a large-scale quantum chemistry calculations using the Sycamore quantum processor NICHOLAS RUBIN (Presenter), JARROD MCCLEAN, ZHANG JIANG, MATTHEW HARRIGAN, Google Inc., TYLER TAKESHITA, Daimler Research, RYAN BABBUSH, Google Inc. — Variational simulation of quantum chemistry is a likely first application for noisy intermediate scale quantum (NISQ) computers in the post supremacy age. We simulate a chemistry model that is significantly larger than previous implementations on any quantum computing platform. The model is optimized through a variational outer loop and a new iterative method using an approximate Hessian. Upon application of an error mitigation scheme based on pure-state n-representability conditions our experiments run on Google's Sycamore quantum processor achieve chemical accuracy. The model provides an efficiently verifiable circuit that has a large degree of entanglement and is a circuit primitive for broader fermionic simulation.
2:42PM D07.00002: Energy gap calculation on near-term quantum hardware with robust phase estimation* ANTONIO RUSSO (Presenter), ANDREW BACZEWSKI, BENJAMIN C MORRISON, KENNETH RUDINGER, Sandia National Laboratories — Can alternative approaches to phase estimation yield better results for chemical simulation on NISQ hardware? Robust phase estimation (RPE) calculates the difference in phases between two eigenstates of a unitary, provided oracular access to that unitary and the relevant eigenstates. In contrast to conventional phase estimation, it does not require a controlled-U and is naturally resistant to state preparation and measurement errors.

We evaluate the suitability of RPE on near-term hardware. In particular, we calculate the energy landscapes of H_2 and H_3 on extant quantum hardware (pre-compiling to emulate hardware with significantly higher fidelities). Resource requirements for larger molecules are considered.

*Sandia National Labs is managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a subsidiary of Honeywell International, Inc., for the U.S. Dept. of Energy's National Nuclear Security Administration under contract DE-NA0003525. 2:54PM D07.00003: Quantum simulation of molecular vibronic spectra on a superconducting bosonic processor: Part I* JACOB CURTIS (Presenter), CHRISTOPHER WANG, BRIAN LESTER, YAXING ZHANG, YVONNE GAO, JESSICA FREEZE, VICTOR BATISTA, PATRICK HENRY VACCARO, Yale University, ISAAC CHUANG, Massachusetts Institute of Technology, LUIGI FRUNZIO, LIANG JIANG, STEVEN GIRVIN, ROBERT SCHOELKOPF, Yale University — A promising and practical application of quantum machines is the simulation of quantum chemistry. Recent proposals have introduced problems naturally suited for bosonic platforms, such as the simulation of Franck-Condon factors [Huh et. al, Nature Photonics 9 (2015)]. These simulations require a wide range of Gaussian operations and non-Gaussian resources, such as arbitrary state preparation and photon-number measurement. Here, we present a blueprint for realizing these capabilities in a superconducting architecture consisting of long-lifetime cavity modes coupled to transmon ancillae. Driven four-wave mixing processes implement bilinear interactions such as single-mode squeezing and beamsplitters, which, when combined with resonant displacements, generate a complete set of Gaussian operations. Furthermore, we present a novel single-shot measurement scheme that extracts the binary decomposition of the photon number in each cavity mode.

Quantum simulation of molecular vibronic spectra on a superconducting bosonic processor: Part II

CHRISTOPHER WANG (Presenter), JACOB CURTIS, BRIAN LESTER, YAXING ZHANG, YVONNE GAO, JESSICA FREEZE, VICTOR BATISTA, PATRICK HENRY VACCARO, Yale University, ISAAC CHUANG, Massachusetts Institute of Technology, LUIGI FRUNZIO, LIANG JIANG, STEVEN GIRVIN, ROBERT SCHOELKOPF, Yale University — A promising and practical application of quantum hardware is the simulation of quantum chemistry. As one example, a programmable bosonic machine can be configured to obtain Franck-Condon (FC) factors associated with molecular vibronic spectra [1]. Implementing such an algorithm in the linear optical domain is experimentally challenging due to the imperfect initialization and detection of optical photons. In this talk, we present a superconducting bosonic processor that combines high fidelity non-Gaussian state preparation, a complete set of Gaussian operations, and a novel single-shot photon number resolving measurement scheme. We utilize this processor to extract FC factors for photoelectron processes in H₂O, O₃, NO₂, and SO₂, including those from vibrational excited states. We exemplify the efficiency of this approach by comparing the resources needed to perform our simulation with that of a qubit-based architecture.

Quantum computation of magnon spectra

AKHIL FRANCIS (Presenter), North Carolina State University, JAMES FREERICKS, Georgetown University, ALEXANDER F KEMPER, North Carolina State University — We demonstrate quantum computation of two-point correlation functions for a Heisenberg spin chain. Using the IBM Q 20 Tokyo machine, we find that for two sites the correlation functions produce the exact results reliably. For four sites, results from the quantum computer are noisy due to read out errors and decoherence. Nevertheless, the correlation functions retain the correct spectral information. This is illustrated in the frequency domain by accurately extracting the magnon energies from peaks in the spectral function.

3:30PM D07.00006: Improving chemistry calculations with virtual quantum subspace expansion*  MIROSLAV URBANEK (Presenter), WIBE A DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory — Accurate calculations in quantum chemistry require the use of large basis sets which amounts to a large number of molecular spin-orbitals. Each spin-orbital is typically mapped to a separate qubit. Many qubits are therefore necessary to achieve a desired accuracy. However, noisy intermediate-scale quantum computers have only a small number of qubits which limits the reach of quantum computing algorithms in quantum chemistry. A promising approach to overcome this problem is to use a quantum computer to solve only the classically hard part and a classical computer to solve the rest. A recently proposed virtual quantum subspace expansion (VQSE) method achieves this by modeling only the active space, that captures essential quantum effects, on a quantum computer. We report experimental results obtained using the VQSE algorithm to model small molecules. This work explores practical viability of hybrid quantum-classical methods in quantum computing.

*This work was supported by the Office of Advanced Scientific Computing Research, Quantum Algorithms Team Program, Office of Science, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

3:42PM D07.00007: Accuracy of the effective Hamiltonian in the quantum simulation experiments*  EVGENY MOZGUNOV (Presenter), Viterbi school of engineering, University of Southern California — Superconducting qubits and cold atom systems can simulate a variety of quantum Hamiltonians by implementing the couplings directly, as opposed to Trotterization of the quantum evolution and gate-based simulation. In this approach, the effective Hamiltonian is often calibrated experimentally to match the desired properties. We develop a rigorous mathematical foundation for the calibration of the building blocks to obtain a target effective Hamiltonian. The building blocks we consider are both superconducting circuits and cold atoms. For both approaches we provide an error estimate: the difference in the norm between the obtained effective Hamiltonian and the target. Our approach extends to time-dependent Hamiltonians via a version of adiabatic theorem.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.
3:54PM D07.00008: Hybrid quantum-classical simulations of correlated materials within Gutzwiller variational approach*  YONGXIN YAO (Presenter), Ames Laboratory and Department of Physics and Astronomy, Iowa State University, NOAH BERTHUSEN, Department of Electrical and Computer Engineering, Iowa State University, FENG ZHANG, CAI-ZHUANG WANG, KAI-MING HO, PETER ORTH, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — We develop a hybrid quantum-classical simulation framework that leverages existing noisy intermediate-scale quantum (NISQ) computing technology to study ground-state properties of correlated electron materials. It combines classical Gutzwiller variational embedding theory with state-of-the-art quantum computing algorithms to solve the effective multi-orbital embedding problem. The theory amounts to finding a self-consistent solution of coupled eigenvalue equations. The effective quasi-particle Hamiltonian is diagonalized efficiently using classical computers, while the ground state of the Gutzwiller embedding Hamiltonian is obtained using variational quantum eigensolvers implemented on quantum computing devices. This is feasible on NISQ devices and takes advantage of relatively shallow quantum circuits for error mitigation. The approach is applied to the periodic Anderson model and Hubbard models. Various variational ansatz and quantum noise forms will be compared on their numerical convergence and calculation accuracy.

4:06PM D07.00009: Improvements in quantum algorithms for quantum chemistry and condensed matter*  THOMAS O'BRIEN (Presenter), Lorentz Institute — The simulation of many-body systems in condensed matter and chemistry is a challenging task in which quantum computers promise to be of some use. While initial quantum algorithms for such purposes had costly requirements for coherence times or numbers of state preparations needed, a flurry of work in recent years has significantly reduced these costs and found new methods, opening the question whether quantum computers can become of use for this class of problems in the NISQ era. In this talk, I will overview a number of recently developed algorithms and algorithmic improvements, and some experimental implementations thereof, including methods for state preparation, error mitigation, partial state tomography, and derivative estimation on a quantum device.

*This research was funded by the Netherlands Organization for Scientific Research (NWO/OCW) under the NanoFront and StartImpuls programs, and by Shell Global Solutions BV.
4:18PM D07.00010: Quantum Chemistry as an application-inspired Benchmark on near-term quantum computers*  RAPHAEL POOSER (Presenter), TITUS MORRIS, ALEXANDER MCCASKEY, JACEK JAKOWSKI, TRAVIS HUMBLE, SHIRLEY MOORE, Oak Ridge National Lab — Near term quantum computing applications can inspire benchmarks and can serve as predictors for future machine performance as the hardware improves. We will present results from application-inspired benchmarks, including Quantum Chemistry. The quantum chemistry benchmark for noisy intermediate-scale quantum computers leverages the variational quantum eigensolver, active space reduction, a modified unitary coupled cluster ansatz, and reduced density purification as error mitigation. We demonstrate this benchmark on the 20 qubit IBM Tokyo and 16 qubit Rigetti Aspen processors via the simulation of alkali metal hydrides (NaH, KH, RbH), with accuracy of the ground state energy as the primary benchmark metric. We also show how to reduce the noise in post processing with specific error mitigation techniques. The adaptation of McWeeny purification of noisy density matrices dramatically improves accuracy of quantum computations, which, along with adjustable active space, significantly extends the range of accessible molecular systems. We demonstrate that for specific benchmark settings, the accuracy metric can reach chemical accuracy when computing over the cloud on certain quantum computers.

4:30PM D07.00011: Quantum simulation of the dynamics of the Fermi-Hubbard model on Sycamore  ZHANG JIANG (Presenter), Google Inc - Santa Barbara — Studying strongly correlated systems is among the many applications of a quantum computer. Here, we report such an experiment on the dynamics of the Fermi-Hubbard model using Google’s Sycamore quantum chip. I will discuss the physics that we learned from the experiment as well as the compilation and error mitigation tools that make the experiment possible. I will also walk you through the tutorial that we develop for the Fermi-Hubbard experiment.
Experimental realization of a nonlinear 3-wave mixing gate for quantum simulation*  
ALESSANDRO CASTELLI (Presenter), YUAN SHI, ILON JOSEPH, VASILY GEYKO, FRANK R GRAZIANI, STEPHEN BERNARD LIBBY, JEFFREY PARKER, YANIV J. ROSEN, JONATHAN L. DUBOIS, Lawrence Livermore Natl Lab — The ability to simulate an arbitrary Hamiltonian on a quantum device is an important step towards achieving universal quantum computing. We present a simulation of nonlinear 3-wave processes on a single qudit of the LLNL Quantum Design and Integration Testbed (QuDIT) resulting from iterative application of a gate developed to emulate these interactions. We describe our experimental protocol for realizing this simulation on the first three levels of a qudit and present results of average state population as a function of time. This experiment consists of a transmon-style qudit that is capacitively coupled to a superconducting 3D microwave cavity field. The qudit is addressed by a single-input RF signal that has been numerically optimized to perform 3-wave mixing unitary gate operations with fidelity of over 99%. We find that the average population of the qudit states evolve in a manner that matches the theoretically predicted quantum numbers of each wave in the 3-wave mixing process over many gate iterations.

Matrix product state simulations on a quantum computer  
MICHAEL FEIG (Presenter), HQS, Honeywell, ANDREW POTTER, University of Texas, Austin — Matrix product states (MPS) afford a compressed representation of many states that are relevant to physical systems. While many classical algorithms have been developed to compute the properties of physical systems using MPS as an ansatz, in many cases of practical interest these algorithms still require exponential resources (for example in the size of the system, or in the evolution time when out of equilibrium). We discuss near-term prospects for using small and non-error-corrected quantum computers to aid in MPS simulations.
5:06PM D07.00014: Quantum simulation of nonlinear three-wave interactions with engineered cubic couplings*  YUAN SHI (Presenter), ALESSANDRO ROBERTO CASTELLI, ILON JOSEPH, VASILY GEYKO, FRANK R GRAZIANI, STEPHEN BERNARD LIBBY, JEFFREY PARKER, YANIV J ROSEN, JONATHAN L DUBOIS, Lawrence Livermore National Laboratory — Quantum three-wave gates are building blocks for simulating lattice gauge theory, nonlinear optics, weak turbulence, and laser plasma interactions. Although the underlying cubic couplings are usually absent in the quantum hardware, we show that effective three-wave vertices can be generated using control pulse engineering. In particular, for a three-wave Hamiltonian whose conserved actions are positive, we show that its Hilbert space can be decomposed into a direct sum of $D$-dimensional subspaces. Within each subspace, the quantum states are readily mapped onto the memory of quantum computers, and the Hamiltonian matrix becomes tridiagonal. Such a Hamiltonian is realized on the LLNL Quantum Design and Integration Testbed (QuDIT), utilizing three levels of a qudit. The qudit is controlled by digitally synthesized microwave pulses, whose wave forms are optimized numerically. Less accurate but cheaper control pulses may also be generated by interpolation, when parameters of the Hamiltonian vary. The resultant three-wave gates are applied to simulate the temporal three-wave problem, and physically meaningful results are obtained despite noise in the quantum computer.

Session D08 DQI: Quantum Control and Quantum Gates 104 - Gregory Quiroz, Johns Hopkins University

2:30PM D08.00001: Simulated Randomized Benchmarking of Dynamically Corrected Cross-Resonance Gate*  RALPH KENNETH COLMENAR (Presenter), JASON PAUL KESTNER, Univ of Maryland-Baltimore County — We theoretically simulate a cross-resonance (CR) gate implemented by pulse sequences proposed in Phys.Rev. Lett. 118, 150502 (2017). These sequences allow mitigation of systematic noise to first order, but their effectiveness is limited by one-qubit gate imperfections. To improve the feasibility of such sequences, we make use of the fact that arbitrary Z rotations can be implemented virtually and with negligible error. We illustrate this by simulating randomized benchmarking for a system of coupled transmons and show that it is possible, under certain conditions, to improve the CR gate fidelity in the presence of quasistatic noise.

*This work was supported by the National Science Foundation under Grant No. 1620740
2:42PM D08.00002: Experimental protection of qubit coherence up to relaxation times by using an image drive* SYLVAIN BERTAINA, Inst Mat Microelectronique et Nanosciences de Provence, UMR7334, CNRS, Aix-Marseille Universite, Marseille, France, HERVE VEZIN, Laboratoire de Spectrochimie Infrarouge et Raman, UMR8516, CNRS, Universite de Lille, Villeneuve d’Ascq, France, IRINEL CHIORESCU (Presenter), Dept of Physics and The National High Magnetic Field Laboratory, Florida State Univ — The protection of spin coherence is an essential task in order to manipulate, store and read quantum information. It has been proposed to dynamically decouple (DD) qubits from their surroundings by applying a series of distinct pulses\(^1\). For nitrogen vacancy centers, such protection was achieved by using concatenated DD up to the second order of dressing\(^2,3\). We go beyond their specific case and demonstrate a new pulse protocol in a number of materials with different spin Hamiltonians and environments. We demonstrate the regime T2~T1 for temperatures ~40K. The protocol uses two coherent microwave pulses: one drives the Rabi precession while a low-power, circularly polarized (image) pulse continuously sustains the spin motion. The initial phase of the image drive allows tuning the spin dynamics by altering the Floquet modes. The technical implementation is simple and can be generalized to any type of qubit, such as superconducting circuits or spin systems.

2:54PM D08.00003: Complete quantum-state tomography with a local random field CHRISTIAN ARENZ (Presenter), Princeton University, RALF BETZHOLZ, JIANMING CAI, Huazhong University of Science and Technology — Single-qubit measurements are typically insufficient for inferring arbitrary quantum states of a multi-qubit system. We show that if the system can be fully controlled by driving a single qubit, then utilizing a local random pulse is almost always sufficient for complete quantum-state tomography. Experimental demonstrations of this principle are presented using a nitrogen-vacancy (NV) center in diamond coupled to a nuclear spin, which is not directly accessible. We report the reconstruction of a highly entangled state between the electron and nuclear spin with fidelity above 95%, by randomly driving and measuring the NV-center electron spin only.
3:06PM D08.00004: High sensitivity spectral characterization of local microwave fields using two-photon absorption processes of a transmon qudit*  

SPENCER TOMARKEN (Presenter), JONATHAN L DUBOIS, Lawrence Livermore Natl Lab — Optimal control methods for quantum information processing require precise knowledge of the local microwave amplitudes generated by control pulses arriving at the cryogenic stage of the quantum processor. We present a scheme for characterizing the spectral transfer function of a superconducting transmon qudit capacitively coupled to a 3D cavity resonator. We apply two simultaneous drive tones close to the transmon's 0-1 and 1-2 state transition frequencies while varying both the duration of the pulses as well as their relative detuning. Through measurement of the 0-, 1-, and 2-state occupations, we map out the 0 to 2 state two-photon absorption process. The relative occupation of the three lowest transmon levels provides a sensitive probe of the local microwave field over a large range of detuning. By comparing our measurement results to master equation simulations incorporating a spectral filter, we recover the amplitude-corrected transfer function over an approximately 200 MHz bandwidth.

*This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. This work was partially supported by LDRD grant 19-ERD-013, ASC Beyond Moore's Law quantum effort, and DOE ASCR quantum testbed pathfinder program.

3:18PM D08.00005: Implementation of the XY interaction family by calibration of a single pulse*  

DEANNA ABRAMS (Presenter), NICOLAS DIDIER, BLAKE JOHNSON, MARCUS P DA SILVA, COLM RYAN, Rigetti Quantum Computing — Near-term applications of quantum information processors will rely on optimized circuit implementations to minimize gate depth and therefore mitigate the impact of errors in noisy intermediate-scale quantum (NISQ) computers. More expressive gate sets can significantly reduce the gate depth of generic circuits. Similarly, structured algorithms can benefit from a gate set that more directly matches the symmetries of the problem. The XY interaction generates a family of gates that provides expressiveness well tailored to quantum chemistry as well as to combinatorial optimization problems; while also offering reductions in circuit depth for more generic circuits. Here we implement the full family of XY entangling gates in a transmon-based superconducting qubit architecture using a composite pulse scheme that requires calibration of only a single gate and maintains constant gate time for all members of the family. This allows us to maintain a high fidelity implementation of the gate across all entangling angles. The average fidelity of gates sampled from this family ranges from 95.67 ± 0.60% to 99.01 ± 0.15%, with a median fidelity of 97.35 ± 0.17%, which approaches the coherence-limited gate fidelity of the qubit pair.

*This work was funded by Rigetti & Co Inc., dba Rigetti Computing.
3:30PM D08.00006: Selective number-dependent arbitrary Hamiltonian engineering for a cavity CHIAO-HSUAN WANG (Presenter), University of Chicago, JOSÉ LEBREUILLY, KYUNGJOO NOH, STEVEN GIRVIN, Yale University, LIANG JIANG, University of Chicago — Cavity resonators are promising resources for storing and processing quantum information. Here we investigate a scheme to engineer the Hamiltonian for a photonic cavity using an ancilla qubit. In the strong dispersive coupling limit and number-split regime, one can drive the qubit near selective photon-number-dependent transition frequencies to address the individual photon number states of the cavity. By choosing control driving detunings much larger than the driving strengths, we propose a general approach to engineering a selective number-dependent arbitrary Hamiltonian for the cavity. The engineered Hamiltonian admits various applications including canceling unwanted cavity Kerr effect, creating higher-order nonlinearities for quantum simulations, designing quantum gate operations resilient to noise, and even realizing quantum error correction. Our scheme can be implemented with a coupled microwave cavity and transmon qubit in superconducting circuits systems.

3:42PM D08.00007: Implementing robust Holonomic quantum gates using dynamical invariant YINGCHENG LI (Presenter), YIDUN WAN, Fudan Univ — Holonomic quantum computing operates quantum systems using berry's phase, or more generally, Aharanov-Anandan phase. It is proved that quantum gates implemented by using these geometric phases are more robust against certain errors. While Holonomic gates have been realized in many systems, extra degrees of freedom are usually required. In this work, we propose a general dynamical invariant for 1 qubit and 2 qubit that is restricted in logical space that enables holonomic quantum computing without inverse engineering. In particular, a Holonomic CNOT gate can be implemented with extremely high fidelity. Moreover, an investigation in the aspect of geometry shows the Hamiltonians used to control the system all have monopole-type gauge field in parameter space, which provides a hidden mathematical structure that contributes to extra robustness.

3:54PM D08.00008: Superconducting cavity QED: box modes for quantum control of qubits RAINA OLSEN (Presenter), MOHAMMADREZA REZAEE, Aurora Quantum Technologies, ELIAHU COHEN, Bar-Ilan University, EBRAHIM KARIMI, University of Ottawa — Circuit QED uses two types of superconducting cavities: one-dimensional superconducting resonators that contain charge excitations, and two or three-dimensional regions of space between superconducting mirrors that contain photons. This latter type of cavity does not necessarily need to be enclosed. Any superconducting circuit acts as a cavity for the surrounding photonic modes with wavelengths on the order of the circuit geometry. Normally these are referred to as box modes, and treated primarily as a source of dissipation (except when a box mode frequency happens to be close to qubit frequencies). However, quantum transduction methods show that a system can be designed so that energy flows between modes at very different frequencies. We treat the problem of a superconducting qubit in a THz cavity by quantizing Maxwell's equations, showing that the driven system is described by the linearized Hamiltonian of cavity optomechanical systems used for quantum transduction.
4:06PM D08.00009: Adiabatic Quantum Control of Dissipative State Preparation  EMERY DOUCET (Presenter), TRISTAN BROWN, ARCHANA KAMAL, Univ of Mass - Lowell — Dissipative protocols for state preparation provide the ability to produce complex entangled states which are inherently robust to decoherence. Protocols based on parametric interactions are particularly powerful in this regard, with the potential for much superior performance compared to resonant schemes while simultaneously providing a large degree of flexibility and control over the stabilized state [1]. In this talk I will describe a scheme for preparing Bell states which employs only parametric qubit-qubit and qubit-resonator couplings. Both the amplitudes and phases of these couplings are tunable in situ, providing a natural avenue to implement time-dependent control of the state preparation dynamics. I will present numerical and analytical results on the application of time-dependent parametric controls while ensuring that the evolution is adiabatic, such that the system remains in the instantaneous dark state of the dynamics. Such fast time-dependent control is within reach of current experimental capabilities, and can enable a large (>10x) reduction in state preparation times. [1] E. Doucet, F. Reiter, L. Ranzani, and A. Kamal, arXiv:1810.03631 (2018).

4:18PM D08.00010: Investigating the speed limit of two-qubit entangling gates with superconducting qubits*  JOEL HOWARD (Presenter), Colorado School of Mines, JUNLING LONG, Physics, CU Boulder, MUSTAFA BAL, RUICHEN ZHAO, National Institute of Standards and Technology - Boulder, TONGYU ZHAO, Physics, CU Boulder, DAVID PAPPAS, National Institute of Standards and Technology - Boulder, ZHEXUAN GONG, MEENAKSHI SINGH, Colorado School of Mines — Fast two-qubit entangling gates are essential for quantum computers with finite coherence times. Due to the limit of interaction strength among qubits, there exists a theoretical speed limit for a given two-qubit entangling gate. This speed limit has been explicitly found only for a two-qubit system and under the assumption of negligible single qubit gate time. We demonstrate such speed limit experimentally using two superconducting transmon qubits with an always-on capacitive coupling. Moreover, we investigate a modified speed limit when single qubit gate time is not negligible, as in any practical experimental setup. Finally, we discuss the generalization to multiple qubit systems where the coupling to additional qubits can significantly increase the speed limit of a two-qubit entangling gate, thus requiring the co-design of the quantum computer from both theorists and experimentalists for optimal gate performance.

*NSF Grant: 1839232

4:30PM D08.00011: High fidelity quantum gates for NV center defect registers based on dynamical decoupling sequences  WENZHENG DONG (Presenter), FERNANDO A CALDERON, SOPHIA ECONOMOU, Virginia Tech — The spinful nuclei surrounding a defect such as the NV center in diamond are promising qubits for a modest-size quantum register. Recent experimental advances demonstrated control of the nuclear spins through microwave manipulation of the NV spin via dynamical decoupling ‘CPMG’ sequences. Here we show that more complex dynamical decoupling sequences improve the nuclear spin operations, i.e., gate fidelity, applicability range, and nuclear spin selectivity. We numerically show the efficacy of our method on NV centers in diamond, but our results are general and applicable to other types of defects in solids.
4:42PM D08.00012: Time-optimal robust controls for Molmer-Sorensen gates in large ion chains
ANDRE CARVALHO (Presenter), CLAIRE EDMUNDS, HARRISON BALL, MICHAEL HUSH, MICHAEL BIERCUK, Q-CTRL — Performing high fidelity entangling operations in multi-qubit systems is an essential requirement for the scalability of quantum information processing. In trapped-ion architectures, these gates are achieved through external driving fields that excite shared oscillator modes: Molmer-Sorensen (MS) gates are a widely used example. In this talk, we present numerically optimized modulation protocols which enable the realization of pairwise MS interactions in long ion chains. We demonstrate how these protocols achieve efficient decoupling of the motional modes employed to effect the entangling operation and provide robustness against fluctuations in experimental parameters. We then demonstrate a routine for time-optimization of the gates on chains of up to 10 ions. The novel gates are not only more robust and faster than standard MS gates, but also more flexible in the choice of experimental parameters.

4:54PM D08.00013: Probing the quantum nature of electronic transport by sub-nanosecond time-resolved measurements
JEAN OLIVIER SIMONEAU (Presenter), CHRISTIAN LUPIEN, BERTRAND M REULET, Universite de Sherbrooke — Mesoscopic microwave measurements are usually carried out in the frequency domain. However, for some experiments involving large bandwidths (including frequency-resolved measurements) or short timescales (e.g. subcycle waveforms), the time domain can be a more suitable or convenient measurement framework.[1] In this talk, we present ultrafast time-domain measurements of the noise emitted by a tunnel junction under DC and AC excitation. The measurements are done at 32 GSa/s with an analog bandwidth of $\Delta f = 10$ GHz. We show that, at fixed time lag, the excess noise is an oscillating function of the bias voltage. It is thus possible to control noise correlations through the bias voltage. We also present recent advances in phase-resolved probing of the photoassisted noise.

*We acknowledge technical help of G. Laliberté. This work was supported by the Canada Excellence Research Chair program, the NSERC, the CFREF, the MDEIE, the FRQMT via the INTRIQ, the Université de Sherbrooke via the EPIQ and the Canada Foundation for Innovation
5:06PM D08.00014: Optimizing pulses with geometric parameters for dynamically-corrected single qubit gate  
XIUHAO DENG (Presenter), Shenzhen Institute of Quantum Science and Engineering, Southern University of Science and Technology — We used geometric parametrization to solve for the constraints of the control pulses to implement dynamically-corrected single qubit gate for superconducting qubits. We considered errors due to: I) crosstalk with other qubits; II) strong coupling to TLS defect; III) coupling to low frequency noisy background, and so on. The errors to be corrected are modeled in perturbative and non-perturbative regime respectively, resulting in different geometric parameters. The pulses obtained using geometric parametrization could corrected the errors and, furthermore, could be optimized in such parameter space with the number of parameters much less than discrete temporal parameter space associated with traditional quantum optimal control numerical approach such as GRAPE. Hence, our optimization approach performs much faster. We compare our optimized pulses with those generated with GRAPE, differential evolution, and other numerical approaches.

5:18PM D08.00015: Robust and optimal control for SC qubits, two-qubit gates, and circuits  
HARRISON BALL (Presenter), PER LIEBERMANN, ANDRÉ CARVALHO, HARRY SLATYER, VICKTOR PERUNICIC, RAJIB CHAKRAVORTY, MICHAEL HUSH, MICHAEL BIERCUK, Q-CTRL — Superconducting quantum computers manifest distinct error processes at different levels of system complexity: from leakage or dephasing in individual transmon qubits to errors in two-qubit gates arising from dephasing, imperfect control signals, and unwanted cross-couplings. Quantum control at the physical-layer provides a pathway to combating these errors in today's quantum hardware. In this talk we describe error modelling of dominant error channels in superconducting circuits relevant for parametrically-activated or cross-resonance gates. Advancing on previous work, we present optimal and robust controls that reduce sensitivity to both leakage and dephasing errors by orders of magnitude, as well as other optimized controls to reduce hardware errors at higher levels of system complexity.

2:30PM D09.00001: Analyzing the efficacy and work extraction of a quantum Maxwell's demon*  
XINGRUI SONG (Presenter), Department of Physics, Washington University, St. Louis, MAHDI NAGHILOO, Electrical Engineering & Computer Science, Massachusetts Institute of Technology, KATER MURCH, Department of Physics, Washington University, St. Louis — In a quantum Maxwell's demon experiment, two major quantities are commonly investigated - the average work extraction \( \langle W \rangle \), and the efficacy \( \gamma \) which measures the violation of Jarzynski's equality when extracted information and feedback is not accounted for. Here, we carefully analyze the relation between these two quantities, and find that they are not maximized simultaneously, requiring different feedback protocols. Furthermore, we investigate Maxwell's demon protocols for higher dimensional Hilbert spaces finding even stronger violations of Jarzynski's equality. Our study further reveals the thermodynamic implications of the exponentially large state space available in quantum systems.

*This work was supported by the NSF grant No. PHY-1752844 (CAREER)

2:42PM D09.00002: Simulating a quantum heat engine on transmon qubits*  
NICHOLAS MATERISE (Presenter), ELIOT KAPIT, Colorado Sch of Mines — We devise a scheme to simulate a quantum heat engine using an array of flux-tunable transmon qubits. This device provides a one-to-one mapping to a fixed nearest-neighbor coupled, disordered Bose-Hubbard model, with precision control over transitions between the many body localized (MBL) phase and the thermal or superfluid phase [Nature 566, 51 (2019)]. Our approach expands on a previous MBL engine proposal [Phys.Rev.B 99, 024203 (2019)], where the adiabatic strokes involve transitions between the two nondegenerate ground states and first excited states of the MBL and thermal phases. We expect that this choice of energy levels reduces the likelihood of excursions to higher levels, especially in the case of the ground states, serving as a prototype for future investigations into studies of MBL as a thermodynamic resource.

*We acknowledge funding support from the National Physical Sciences Consortium graduate fellowship and NSF grant (PHY-1653820)
2:54PM D09.00003: Macroscopic Thermodynamic Reversibility in Quantum Many-Body Systems* PHILIPPE FAIST (Presenter), Freie Univ Berlin, TAKAHIRO SAGAWA, University of Tokyo, KOHTARO KATO, Caltech, HIROSHI NAGAOKA, University of Electro-Communications, Tokyo, FERNANDO BRANDÃO, Caltech — The resource theory of thermal operations, an established model for small-scale thermodynamics, provides an extension of equilibrium thermodynamics to nonequilibrium situations. On a translation-invariant lattice with local interactions, we show that ergodic states (i.e. states that have sharp statistics for any translation-invariant observable) can be reversibly converted to and from the thermal state with thermal operations and a small amount of coherence. This proves the emergence of an operationally well-justified thermodynamic potential for this class of states, which includes states that are not in equilibrium. As an intermediate result of independent interest, we show that the gap between the min- and max-relative entropies controls the amount of coherence that is present in the state and that if this gap is small, the state can be approximately reversibly converted to and from the thermal state with a small reference frame. Our results provide a strong link between the abstract resource theory of thermodynamics and more realistic physical systems that go beyond the i.i.d. setting.

*The authors are supported by JSPS KAKENHI, NSF, DOE, and SNSF.

3:06PM D09.00004: What is Quantum Thermodynamics? [Invited] SEBASTIAN DEFFNER (Presenter), Univ of Maryland-Baltimore County — We are the verge of a technological revolution. Over the last couple of years the first computational devices have become commercially available that promise to exploit so-called quantum supremacy. Even though the thermodynamic cost for processing classical information has been known since the 1960s, the thermodynamic description of quantum computers is still at its infancy. This is due to the fact that many notions of classical thermodynamics, such as work and heat, do not readily generalize to quantum systems. In this talk, we will outline a novel conceptual framework of an emerging theory, Quantum Thermodynamics, and illustrate its applicability, mindset, and questions with a few pedagogical examples.
3:42PM D09.00005: Entanglement transport and thermalization in an isolated quantum spin chain

SHUNJI TSUCHIYA (Presenter), RYOSUKE YOSHII, Department of Physics, Chuo Univ —
Entanglement transport is considered to be essential for understanding thermalization in an isolated quantum system. In this work, we study transport of entanglement entropy (EE) in the Ising model with the next-nearest-neighbor interaction as well as the transverse and longitudinal magnetic fields. We calculate EE in a spin chain which consists of a single spin at the edge (A) and the bulk part (B). We compare time-evolution of EE for two different initial settings: the one with entanglement between A and B and the other one without it. The propagation speed of EE can be estimated by the time at which the EEs starting from the two initial conditions show deviation. We find that EE propagates ballistically with a constant velocity and that the propagation speed is enhanced when thermalization occurs. We also calculate the propagation speed of EE from mutual information between A and a subsystem in B. The velocities calculated by the two different methods agree well. We will discuss the relation between propagation of EE and thermalization.

3:54PM D09.00006: Characterizing complexity of many-body quantum dynamics by higher-order eigenstate thermalization

KAZUYA KANEKO (Presenter), Univ of Tokyo, EIKI IYODA, Physics, Tokai University, TAKAHIRO SAGAWA, Univ of Tokyo — Characterizing quantum many-body chaos has attracted renewed attention in condensed matter physics, quantum information, and high-energy physics. There are two fundamental concepts regarding this problem. One is the eigenstate thermalization hypothesis (ETH) stating that individual energy eigenstates are thermal. The other is information scrambling, which is quantified by out-of-time-ordered correlators (OTOCs). We propose a higher-order generalization of the ETH, named by the $k$-ETH ($k=1, 2,...$), which provides a unified view on the above two concepts. The lowest order ETH (1-ETH) is the conventional ETH, and the second order ETH (2-ETH) is a sufficient condition of the decay of OTOCs at late times. Our basic idea is that chaotic dynamics share common properties with random unitary dynamics even at a higher level than conventional ergodicity. The $k$-ETH also implies a universal behavior of the $k$th-Renyi entanglement entropy of individual energy eigenstates. In particular, we show that the Page correction originates from the higher-order ETH. We numerically verified that the 2-ETH approximately holds for nonintegrable systems, but does not hold for integrable systems.

4:06PM D09.00007: Collective phenomena in quantum thermodynamics: from mitigation to amplification of the baths' action* CAMILLE LOMBARD LATUNE, ILYA SINAYSKIY, FRANCESCO PETRUCCIONE (Presenter), Univ of KwaZulu-Natal — An increasing number of papers in quantum thermodynamic have shown that collective effects can be beneficial for thermodynamic tasks. In order to understand better why and when such enhancements can happen, we analyse in details the energetic, entropic, and more generally thermodynamic consequences of collective coupling between an ensemble of identical systems (spin or atoms) and their bath.

We reach the conclusion [1] that collective coupling, through the coherences it intrinsically generates, effectively shield the ensemble from the bath's action, affecting dramatically the thermodynamic characteristic of the ensemble (energy, entropy, and free energy). Strikingly, in presence of two thermal baths, the combination of these mitigation effects can result in a great amplification of the baths' action. This is illustrated through a cyclic (Otto) thermal machine, resulting in a large output power enhancement. We also highlight that such enhancements are not systematic: depending on the value of the bath temperatures, the number of spins, and their dimension, either enhancement or degradation of performances can happen.

*South African Research Chair Initiative, National Research Foundation and NITheP.

4:18PM D09.00008: Thermalization of a qubit strongly interacting with a bosonic environment PATRICK ORMAN (Presenter), DEXTER GRANT MITCHELL, RYOICHI KAWAI, Physics, Univ of Alabama - Birmingham — When a quantum system is placed in a thermal environment, we assume that the system relaxes to the Gibbs state in which decoherence takes place in the system energy eigenbasis. However, when the coupling between system and environment is strong, the thermal state is not necessarily the Gibbs state, and the system density matrix does not have to be diagonal in the energy eigenbasis. The theory of einselection by Zurek suggests that decoherence takes place in the pointer basis rather than in the energy eigenbasis, which can be interpreted as continuous measurement by the environment. However, the actual matrix elements are not known. Based on the theory of environment-induced decoherence, we introduce a couple of propositions: (1) in the strong coupling limit, the Gibbs state is projected to the convex hull spanned by the pointer basis, which necessarily increases the system entropy, and (2) the transition from the Gibbs state to the pointer limit takes place along the projection line perpendicular to the convex hull. We justify these propositions by exact numerical simulation of a qubit interacting with an infinitely large bosonic environment through various coupling Hamiltonians.
Kinetics of many-body reservoir engineering

HUGO RIBEIRO (Presenter), FLORIAN MARQUARDT, Max Planck Inst for Sci Light — Quantum simulators based on superconducting circuits can be used to study many-body physics with microwave photons. In particular, lattice systems can be used to study the thermalization of an engineered condensed matter system to a cold reservoir. However, in stark contrast to naturally occurring condensed matter systems, most engineered quantum lattice systems do not have a well-defined chemical potential. Here, we show that it is possible to cool a reservoir engineered many-body system with a well-defined chemical potential if the coupling with the reservoir is a density-density type coupling. Specifically, we consider an array of single-mode microwave cavities with each site of the array coupled to a driven, lossy cavity. The lossy cavities will act as an engineered non-equilibrium bath that mediates transitions between the eigenstates of the array while simultaneously conserving the number of excitations. We show that the steady state of the system can be described via a modified Bose-Einstein distribution with a momentum-dependent temperature.

Topological effects in quantum thermodynamics

CHARLES STAFFORD (Presenter), Physics, University of Arizona, YIHENG XU, Physics, UC San Diego, FERDINAND EVERS, Physics, University of Regensburg — The thermodynamics of open quantum systems coupled to topological fields is analyzed. Both the Aharonov-Bohm effect for systems of charged particles and the Aharonov-Casher effect for systems of neutral spin-1/2 particles are considered, and a general definition for the flux of a physical observable is proposed. A proper treatment of the work done by the topological fields is necessary to ensure that the entropy of the system is a state function, and to avoid certain thermodynamic paradoxes. In particular, the flux of entropy in the system induced by the topological fields naively appears to diverge as the temperature approaches absolute zero, in violation of the 3rd law of thermodynamics.

Fluctuations in stored work bound the charging power of quantum batteries

LUIS GARCIA-PINTOS (Presenter), University of Maryland, College Park, ALIOSCIA HAMMA, ADOLFO DEL CAMPO, University of Massachusetts Boston — We investigate the connection between the charging power of a quantum battery and the fluctuations of the work stored in it. We show that in order to have a non-zero rate of change of the extractable work, the work fluctuations must be non-zero. This is presented in terms of an uncertainty relationship that bounds the speed of the charging process of any quantum system. Our findings also identify quantum coherence in the battery as a resource in the charging process, which we illustrate on a toy model of a heat engine.
Thermodynamics features of quantum memristors* LUCAS CÉLERI (Presenter), Universidade Federal de Goias, MIKEL SANZ, ENRIQUE SOLANO, University of Basque Country, GABRIEL LANDI, University of São Paulo — Quantum memristors are devices holding great promise as a platform for quantum computation, especially when considering neuromorphic quantum computation. These devices are characterized by their non-Markovian behaviour. Here we describe such devices as a kind of thermodynamic engine operated by a Maxwell demon, but, instead of work, the output of such engine is non-Markovianity (time correlations), that can be employed to power quantum computation, for instance. We are therefore able to provide a thermodynamic description of this device, thus paving the way for establishing the limits of its applicability for information processing.

Heat Transfer in Mesoscopic Systems GABRIEL WEIDERPASS (Presenter), State University of Campinas, GUSTAVO MONTEIRO, The City College of New York, AMIR O. CALDEIRA, State University of Campinas — In this talk, we present an analytical solution for the heat flux along a harmonic chain connecting two identical reservoirs at different temperatures, in the stationary regime. In this model, the end points correspond to Brownian particles with different damping coefficients. This analytical expression for the heat conductance in mesoscopic chains allows for direct comparison with experiments and shed some light on the validity of the Fourier law in one-dimensional quantum systems.

Monday, March 2, 2020 2:30 PM - 4:54 PM

Session D10 GIMS: Scattering and Diffraction 108 - Zahir Islam, Argonne National Lab
2:30PM D10.00001: Developing Wide Angle Spherical Neutron Polarimetry at Oak Ridge National Laboratory

Nicolas Silva (Presenter), Oak Ridge Assoc Univ, Chenyang Jiang, Tianhao Wang, Oak Ridge National Laboratory, Jillian Ruff, Oak Ridge Assoc Univ, Masaaki Matsuda, Fankang Li, Barry Winn, Lisa Debeer-Schmitt, Oak Ridge National Laboratory, Roger Pynn, University of Indiana — Spherical Neutron Polarimetry (SNP) analyzes complex magnetic structures through distinguishing contributions from nuclear-magnetic interference and chiral structure in addition to nuclear magnetic scattering separation. This analysis is achieved through determining all components in the polarization transfer process. Wide-angle SNP is being realized at Oak Ridge National Laboratory (ORNL) for multiple beamlines including: the polarized triple-axis spectrometer (HB-1) and general-purpose small angle neutron scattering instrument (CG-2) at the High Flux Isotope Reactor (HFIR), as well as the hybrid spectrometer (HYSPEC) at the Spallation Neutron Source (SNS). The SNP device consists of three units: incoming/outgoing neutron polarization regions, sample environment and a zero-field chamber. The neutron polarization regions use high- superconducting YBCO films, magnetic guide fields, and mu-metal to achieve full control of neutron polarization. The sample environment is an orange cryostat with a customized tail piece placed into the zero-field chamber. The device has been fabricated and demonstration experiments were run at the University of Missouri Research Reactor (MURR) and at HYSPEC.

2:42PM D10.00002: Kilohertz-Rate MeV Ultrafast Electron Diffraction for Time-resolved Materials Studies

Khalid M Siddiqui (Presenter), Materials Sciences Division, Lawrence Berkeley National Laboratory, Daniel B Durham, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, Fuhao Ji, Accelerator Technology and Applied Physics Division, Lawrence Berkeley National Laboratory, Andrew M Minor, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, Robert A Kaindl, Materials Sciences Division, Lawrence Berkeley National Laboratory, Daniele Filippetto, Accelerator Technology and Applied Physics Division, Lawrence Berkeley National Laboratory — Ultrafast electron diffraction (UED) enables direct insight into structural dynamics of solids. Relativistic MeV-scale electron beams yield access to high-momentum scattering and preserve beam coherence, yet their application at high repetition rates for high-sensitivity UED has been limited. We discuss the High Repetition-rate Electron Scattering (HiRES) instrument at Berkeley Lab and its first applications to UED of metallic films and quantum materials. HiRES employs a state-of-the-art photoinjector with RF bunch compression to generate high-brightness, relativistic 0.75 MeV electron pulses with up to $10^5$-$10^6$ el./pulse and with highest achievable coherence length of 10 nm. The resulting high momentum range ($\pm 10$ Å$^{-1}$) yields access over multiple Brillouin zones. The sub-500 fs electron pulses are provided at 0.1-250 kHz repetition rate, and combined with optical pumping via a 1.03 µm fiber amplifier enable UED of cryogenically cooled materials. We will show examples of first experiments including transient Debye-Waller dynamics in ultrathin metals at kHz repetition rate as well as studies of charge density waves in 2D materials.

*Work at LBNL was supported by the DOE Office of Basic Energy Sciences.
2:54PM D10.00003: Directive steerable emission from an opened chaotic cavity controlled through a reconfigurable metasurface*  
SAMUEL METAIS (Presenter), JEAN-BAPTISTE GROS, Institut Langevin, GEOFFROY LEROSEY, Greenerwave — Chaotic reverberating cavities have been demonstrated to have a large number of exploitable degrees of freedom[1] that can be controlled with a reconfigurable metasurface [2]. Following previous work on the emission of opened electromagnetic cavity in the GHz regime[3], we demonstrate here that a reconfigurable metasurface in a small volume cavity, 4*6*0.5 λ^3, allows us to control the emission through a large opening (3.5*5.5λ^2). Measuring the transmission between a single source inside the cavity and an outside antenna, we show that a simple partitioning algorithm allows us to reach very high directivity, as well as a steering capacity over 120°. We compare those results with known limitations on the performances of antenna [4] and conclude on the performances of our device.

*The author acknowledges funding from Greenerwave, ESPCI Paris Incubator PC'up, 75005 Paris, France which produces the metasurfaces.

3:06PM D10.00004: Spatially-Resolved Layer, Interface and Dopant Profiling Using Tabletop Coherent EUV Beams  
YUKA ESASHI (Presenter), MICHAEL TANKSALVALA, CHRISTINA L. PORTER, BIN WANG, NICHOLAS W. JENKINS, ZHE ZHANG, MATTHEW N. JACOBS, University of Colorado, Boulder, GALEN P. MILEY, Northwestern University, NAOTO HORIZUCHI, imec, JIHAN ZHOU, University of California, Los Angeles, ROBERT M KARL, CHARLES BEVIS, PETER JOHNSEN, JOSHUA KNOBLOCH, University of Colorado, Boulder, SETH L. COUSIN, KMLabs, EMMA CATING, MICHAËL HEMMER, CHENTING LIAO, MICHAEL GERRITY, HENRY KAPTEYN, MARGARET MURNANE, University of Colorado, Boulder — Next-generation devices, nanomaterials, quantum and magnetic materials necessarily have increasingly complex layers, dopants and 3D structures. As a result, non-destructive techniques that can image through visibly opaque layers with sensitivity to layer and interfacial composition are critical for synthesizing and optimizing these systems. We present a tabletop complex-imaging reflectometer illuminated by coherent high harmonic extreme ultraviolet (EUV) beams. Unlike most reflectometers that transversely average quantities such as film thicknesses over the sample, our reflectometer can attain diffraction-limited spatial resolution with high sensitivity to material composition by using coherent diffractive imaging (CDI). Our complex imaging reflectometer uses grazing-incidence CDI to generate high-resolution, high-fidelity phase and amplitude images of a sample at many incidence angles. The phase images are extremely sensitive to composition, allowing us to extract a 3D map of the sample. We demonstrate the ability to very sensitively probe diffusion at buried interfaces, layer thickness and dopant profiles in a non-destructive and spatially resolved manner, distinguishing our technique from others such as SIMS, Auger sputtering, or electron imaging.
3:18PM D10.00005: 3D-ΔPDF Investigations of Structural Phase Transitions* RAYMOND OSBORN (Presenter), MATTHEW KROGSTAD, STEPHAN ROSENKRANZ, Materials Science Division, Argonne National Laboratory — By exploiting a new generation of fast area detectors with wide dynamic range optimized for high-energy x-rays, it is possible to measure single crystal total scattering, $S(Q)$, over large volumes of reciprocal space encompassing thousands of Brillouin zones in under 20 minutes. This allows detailed investigations of the temperature evolution of both weak Bragg peaks from modulations in the long-range crystal structure and diffuse scattering from short-range fluctuations in the atomic order. $S(Q)$ can be transformed into real space to generate “difference” pair-distribution-functions (3D-ΔPDF), a powerful way of eliminating the average crystal structure to reveal subtle structural modifications and determine the correlation length of atomic fluctuations above and below $T_c$, all without detailed simulations.¹ I will show examples of 3D-ΔPDF applied to both long-range and frustrated short-range structural transitions in correlated electron systems and intercalation compounds.

*Work supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division

3:30PM D10.00006: Interferometric tracking of nanoparticle orientation with quantitative optical anisotropy imaging ZHIXING HE (Presenter), Physics, Virginia Tech, CHENGSHUAI LI, YIZHENG ZHU, Electrical and Computer Engineering, Virginia Tech, HANS ROBINSON, Physics, Virginia Tech — We introduce Quantitative Optical Anisotropy Imaging (QOAI), an interferometric spectral multiplexing technique that allows imaging and tracking of the orientation of individual nanoparticles at the microsecond timescale. In QOAI, incident light whose polarization is modulated in the spectral domain is scattered off particles and structures, interfered with a reference beam, and detected spectroscopically. The signal is directly proportional to anisotropies in the particle polarizability, and can therefore be used to extract both orientation and shape information about each individual particle, even at sizes well below the diffraction limit of conventional microscopy. We use this technique to categorize the aspect ratio of gold nanorods and to characterize their rotational diffusion near a solid interface. QOAI can be straightforwardly combined with existing particle tracking techniques so that position and orientation can be tracked simultaneously and can also be modified to provide quantitative measurements of the chirality of individual particles.

MAKOTO SCHREIBER (Presenter), MATTHIAS WOLF, Okinawa Inst of Sci & Tech — The atomic structure of amorphous materials has long been a mystery. Due to the lack of long-range periodical order, traditional techniques such as X-ray diffraction cannot be used to directly measure atomic coordinates. Through the analysis of pair-distribution functions, measurements of averaged structural features such as average bond lengths can be determined. By combining experimental data with simulations such as in reverse Monte-Carlo simulations, some models of 3D atomic structures can be determined. However it has not yet been possible to determine any local structure directly from experiment.

In this work, a type of image processing commonly applied in single particle cryo-electron microscopy is applied to a large set of nanobeam electron diffraction patterns. This produces a set of class-averaged patterns that represent dominant SRO structures within the material. This for the first time allows direct measurements on such structures and may eventually be extended to determine experimental 3D electron density distributions of SRO structure within amorphous materials.

EMMA SNIVELY (Presenter), MOHAMED A. K. OTHMAN, MICHAEL E. KOZINA, BENJAMIN K OFORI-OKAI, STEPHEN P. WEATHERSBY, SUJI PARK, XIAOZHE SHEN, XIJIE WANG, MATTHIAS C. HOFFMANN, SLAC - Natl Accelerator Lab, RENKAI LI, Tsinghua University, EMILIO NANNI, SLAC - Natl Accelerator Lab — We discuss the results of a THz-driven electron bunch compression experiment in which interaction between a quasi-single-cycle THz pulse and a relativistic electron beam in a parallel plate waveguide produced a beam energy chirp for velocity bunching. Measurements at the SLAC MeV-UED facility show a simultaneous reduction in the bunch length and timing jitter by up to a factor of 3, improving the overall timing resolution for applications like ultrafast electron diffraction and other beam-based ultrafast measurements. This technique employs unique advantages of all-optical beam manipulation, including the inherent synchronization which allows the compensation of electron beam timing jitter and the high field gradient which enables efficient chirping of the electron beam in a sub-millimeter interaction region.

*This research has been supported by the U.S. Department of Energy (DOE) under Contract No. DE-C02-76SF00515. The SLAC MeV-UED program is supported in part by DOE Basic Energy Sciences (BES) Scientific User Facilities Division and SLAC UED/UEM program development: DE-AC02-05CH11231. M. K. and M. C. H. are supported by the DOE Office of Science, BES, award no. 2015-SLAC100238-Funding.
4:06PM D10.00009: Laboratory Based Hard X-ray Photoelectron Spectroscopy  SUSANNA ERIKSSON (Presenter), BRANDON GILES, Scienta Omicron — Hard X-ray photoelectron spectroscopy (HAXPES) is generally used to study core topics in condensed matter physics. However with a worldwide increase in the number of HAXPES focused endstations, many other interest groups now recognize its broad appeal.

In a HAXPES experiment 2-10 keV X-rays are used to excite photoelectrons to study the chemical environment and electronic structure of materials non-destructively. In contrast to standard XPS, HAXPES is more sensitive to what is beneath the surface. This makes it an ideal technique for studying structured samples that cannot be analyzed using traditional XPS. Bulk sensitivity means that realistic samples can be investigated without the need for surface preparation.

Unfortunately, there are very few existing HAXPES systems. Most are predominantly located at synchrotrons, as the photoionization cross sections at high energies is small and necessitates large X-ray intensities.

This work shows a new laboratory based HAXPES instrument capable of delivering monochromated 9.25 keV X-rays in a focused 30x45 μm² X-ray spot with energy resolution <0.5 eV. Systematic reference measurements demonstrate the system’s capability. Application based results from various fields, including measurements of energy related materials, are also presented.

4:18PM D10.00010: Probing bulk electronic structure with a laboratory-based hard x-ray angle-resolved photoemission spectrometer*  JOSEPH D GRASSI (Presenter), Temple Univ, ARIAN ARAB, Paul Scherrer Institute, JAY PAUDEL, RAJ K SAH, WEIBING YANG, RAVINI U CHANDRASENA, Temple Univ, KEISUKE KOBAYASHI, Japan Atomic Energy Agency, ALEXANDER GRAY, Temple Univ — Hard x-ray angle-resolved photoemission (HARPES) employing multi-keV x-rays as the excitation source has recently emerged as a powerful tool for the direct measurement of momentum-resolved bulk electronic structure [1-3]. To date, comprehensive HARPES spectroscopic studies have only been feasible at large-scale national synchrotron facilities. Here, we describe a newly completed laboratory-based hard x-ray photoemission spectrometer system with HARPES capabilities. The system utilizes a high-flux (3E9 ph/s) high-resolution (<0.45 eV) monochromated Cr Kα x-ray source tuned to the intermediate hard/tender energy regime (5.4 keV), which enables bulk- and buried-layer/interface sensitivity (up to 10 nm deep) while still being sensitive to the valence-band states due to appreciable photo-ionization cross sections. We present a wide range of examples of angle-resolved investigations of solids, including core-level and valence-band spectroscopy, momentum-resolved band structure mapping, and element-sensitive x-ray photoelectron diffraction.

4:30PM D10.00011: Development of in-situ differential thermal analysis for crystal growth experiments*  
YURI JANSSEN (Presenter), JOSE NICASIO, KEMAR DUDLEY, BINGYING XIA, JACK SIMONSON, State Univ of NY - Farmingdale — Differential thermal analysis (DTA) can give valuable information on melting and freezing of mixtures that are used for flux or solution growth of single crystals for materials research, and increasing the success rate of crystal growth attempts. DTA is especially valuable as a tool for undergraduate research involving crystal growth, as it can quickly give a realistic and easy-to-understand picture at what is happening inside a growth crucible as it is hiding the cooling crystal-growth mixture from view. In the past, we have performed DTA in a dedicated instrument, with small crucibles containing exactly the same composition as the larger growth crucible in the larger growth furnace. Now we are performing in-situ DTA inside the growth furnace and on as-prepared growth samples, for different type growths and furnaces, quickly improving crystal growth performed by undergraduate students with limited time dedicated to lab, and, moreover, on very inexpensive equipment. Here, we will present results of these developments.

*This project was funded by contributions from the Office of the Provost, the CSTEP program, and the Physics Department at Farmingdale State College.

4:42PM D10.00012: Early stage of iron anodic oxidation measured by 25ms-resolution X-ray reflectometry  
HIROMASA FUJII (Presenter), Graduate School of Engineering Science, Osaka University, TAKASHI DOI, Research and Development, Nippon Steel Corporation, YUSUKE WAKABAYASHI, Graduate School of Science, Tohoku University — Anodic oxidation at metal/water interface is a general phenomenon that commonly takes place on many metals. Time evolution of the oxide thickness is proportional to log(t)[1]. However, early stage clearly deviates from log(t) and the mechanism has not been understood yet in spite of its fundamental importance[2]. To reveal the early-stage mechanism, precise structural basis is needed. Here we report 25ms-resolution X-ray reflectivity experiments[3] to investigate the early stage of anodic oxidation at Fe (100), (110) and (111) in pH 8.4 borate buffer solution as model materials. Experiments were performed at the BL13XU of SPring-8, Japan with a 25keV monochromatic X-ray. The film density in the early stage is lower than in the later stage by 13 %, which suggests that the film structure is a highly defective spinel oxide. Moreover, the growth rate in the early stage is found to be proportional to about $t^{-1.5}$ but in later stage is $t^{-1}$. The presumed mechanism based on the Point Defect Model[1] will be discussed in the presentation.

Session D11 APS/SPS: Undergraduate Research IV 110 - Chrisy Xiyu Du, Harvard University - Tag(s): Undergrad Friendly
2:30PM D11.00001: High-pressure pretreatment of rice straw for optimizing the fermentable sugar yield  
PRATHAM GUPTA (Presenter), BAHIRU TSEGAYE, CHANDRAJIT BALOMAJUMDER, Indian Inst of Technology Roorkee —  
Rice straw has proved to be a prospective source of renewable energy owing to high polysaccharic content and abundant availability. On hydrolyzing rice straw, fermentable sugars could be produced. In this research, organosolv was used to pretreat rice straw in high-pressure autoclave reactor under multiple conditions for removal of lignin and release of trapped polysaccharides. Rice straw composition was evaluated in accordance with the rules of the National Renewable Energy Laboratory. The temperature ranged from 130, 140 and 150 degrees Centigrade and time varied as 20, 30 and 40 minutes. Temperature and time have significantly impacted the quantity of sugar and lignin. Sugar yield at 140 degrees Centigrade and 30 minutes was discovered to be maximum. In this condition of pretreatment, it was observed that nearly all hemicellulose was solubilized, about 75% of lignin was removed and over 80% of cellulose was released. Removal of lignin promotes the release of cellulose from the matrix of biomass. Overall, this research demonstrated the potential for a high-pressure reactor to effectively remove lignin, enhancing fermentable sugar output.

2:42PM D11.00002: NSF IRES: Exploring the Effect of Temperature on a Plant's Photocyle by Observing the Blue-Light Photoreceptor Protein Arabidopsis Cryochrome*  
MAROOTPONG POOAM, CNRS, Photobiology Research Group, Sorbonne University, NYKIERA DIXON, Chemistry, Xavier University, MICHAEL HILVERT (Presenter), Physics, Xavier University, PETER MISKO, KRISTY WATERS, Biology, Xavier University, STEPHEN MILLS, Chemistry, Xavier University, SORIA DRAHY, CNRS, Photobiology Research Group, Sorbonne University, DOROTHY ENGLE, Biology, Xavier University, JUSTIN LINK, Physics, Xavier University, MARGARET AHMAD, CNRS, Photobiology Research Group, Sorbonne University — Cryochrome is a blue-light photoreceptor protein involved in both plant and animal circadian rhythms. When illuminated by blue light, the flavin cofactor of cryochrome is photoreduced, thus yielding the active state of the protein. This photoreduction and subsequent reoxidation can be observed spectroscopically. However, the effect of temperature on the photoreduction has not been extensively studied. Here, using a UV-Vis spectrophotometer, we demonstrate the effects of temperature on the photoreduction and reoxidation of purified Arabidopsis cryochrome 1 (AtCry1) and cryochrome 2 (AtCry2) proteins. It was hypothesized that at higher temperature, an increase in the rate of photoreduction and reoxidation would occur. However, our experimental results demonstrated that when comparing the reactions at 15°C and 25°C, temperature had no effect on the photoreduction of the flavin, but the rate of reoxidation was increased at the higher temperature. These results suggest increased activation in AtCry1 and AtCry2 at lower temperatures.

*This material is based upon work supported by the National Science Foundation under Grant No. (NSF #1658640).
2:54PM D11.00003: Temperature Dependence in Stochastic and Deterministic Models of the Circadian Rhythm of Cyanobacteria  THOMAS BAER (Presenter), ORRIN SHINDELL, Physics and Astronomy, Trinity University — The chemical reactions that lead to circadian rhythms in organisms are deterministically described in the limit where the number of cells is large. However, for each individual cell these reactions are stochastic as the number of molecules involved in them is small. Here, the circadian rhythms of cyanobacteria are considered. Using mathematical models of biochemical oscillations, we analyze the characteristic behavior of the deterministic system near a non-equilibrium phase transition. The control parameter that drives the transition is the temperature, which must be high enough for any biochemical oscillations to occur. We analyze the same set of reactions near the transition temperature in the stochastic limit and discuss features that emerge in the probability distributions of oscillation amplitudes and frequencies. We also comment on the thermodynamic connection between the small and large scale descriptions.

3:06PM D11.00004: Nano-optical imaging of bacteria on 2D materials* LIANA SHPANI (Presenter), Clark University, SHARAD AMBARDAR, DMITRI VORONINE, University of South Florida — Bacteria cause hazards via biofouling and develop resistance to antibiotic treatments. However, due to their small size, spectroscopic imaging and analyzing bacteria using conventional optical microscopy is challenging. Moreover, atomically thin 2D materials, especially transition metal dichalcogenides, with their wide range of applications in optoelectronics, have also shown promising biological applications. In this work, we developed a novel nanoscale imaging approach to characterize bacteria-substrate interactions. Untreated and antibiotic-treated bacteria were deposited on the junction of monolayer MoS$_2$-WS$_2$ materials on top of a Si substrate. The optical characterization with 532 nm laser excitation provided far-field photoluminescence (PL) and near-field tip-enhanced photoluminescence (TEPL) measurements. When the bacteria were placed on the 2D materials, a higher PL signal was observed compared to the pure material. The enhancement and the red shift of the PL signal can be accounted as strain caused by the bacteria on the 2D materials. These observations show promising results to prompt further studies to analyze interactions of different bacteria with TMDs.

*This work was supported by the National Science Foundation (NSF) grant DMR-1852269.
3:18PM D11.00005: Human Gene Expression and the Protein-Protein Interaction Network: Identification of Potential Disease Module Association to Differential Gene Expression for Patient-to-Drug Matching  AYDIN WELLS (Presenter), Northeastern University, DEISY MORSELLI GYSI, Center for Complex Network Research, ALBERT L BARABASI, Northeastern University — The relationship between human gene expression (GE) and precision medicine applications is central in understanding how patients are affected by and how to better treat a disease. Even though it is of extreme importance, this knowledge is still absent from almost any disease analysis resulting in misdiagnosis and mistreatment based on symptomatic and physical observation criteria devoid of high throughput sequencing technologies. By detecting disease modules in the protein-protein interaction (PPI) network, along with the identification of patient differential GE sets (DGE), we can suggest effective individual treatment options. Here, we collect public RNA sequencing data for a diverse population and arrange unique GE patient profiles. DGEs are computed using machine learning techniques and are identified within the PPI network, where disease modules can be pinpointed. Those modules can be used for disease classification specific to expression levels and cohort phenotype. By elucidating these interactions using network approaches with an individual patient’s features, human diseases can be identified not by peripheral approaches, but by a personal genetic diagnosis; essentially redefining disease diagnostics from a “one size fits all” philosophy, to a “one size fits you” reality.

3:30PM D11.00006: Focused Ultrasound as a Replacement for Endodontic Therapy*  TALISI MEYER (Presenter), JENNIFER CANFIELD, MICHAEL JORDAN, JASON WHITE, Simmons College — Focused ultrasound has exhibited promising results as a therapeutic modality in its ability to minimize the invasiveness of a number of medical treatments that are physically and mentally traumatic to the patient. We propose the investigation of its use for non-invasive endodontic therapy (a.k.a. a “root canal”), with the ultimate goal of removing microbial infection from the root canal system of a contaminated tooth.

To avoid thermal damage to adjacent healthy tissues, we considered using the mechanical effects created by ultrasound, specifically that of cavitation. To generate proof-of-concept data, we designed, constructed, and tested a series of ultrasound transducers that delivered sufficiently low frequencies operating below 300 kHz and pressures below -30MPa to induce cavitation in degassed water with less than 3ppm. Our initial experiments have shown that sufficient ultrasound energy can be transmitted through intact ex vivo human teeth to elicit nonlinear streaming in the root canal of intact ex vivo human teeth. We have also demonstrated the use of equivalent parameters to kill bacteria. We will further determine and refine the optimal ultrasound parameters for eliciting bactericide in the intact tooth.

*SARP (Formally SCARP of Simmons University)
3:42PM D11.00007: Enhanced magnetic hyperthermia of copper ferrite nanoparticles for biomedical applications*  
ENYA SILVA (Presenter), J. ROBLES, SARATH WITANACHCHI, Department of Physics, University of South Florida, ANH-TUAN LE, Faculty of Materials Science and Engineering, Phenikaa University, MANH-HUONG PHAN, Department of Physics, University of South Florida — Magnetic hyperthermia is a promising cancer treatment that has minimal side effects compared to chemotherapy and radiation therapy. The heating efficiency of magnetic nanoparticles is central to the effectiveness of magnetic hyperthermia as a treatment and, while Copper is a well-known thermal conductor, little research has been done regarding its ability to increase the heating efficiency of magnetic nanoparticles. In this experiment, the heating efficiency of different samples of Copper Ferrite nanoparticles was quantified by dispersing the nanoparticles in a solution and measuring the solution's temperature change over time in an alternating magnetic field. This method is common in the study of magnetic hyperthermia because it best replicates the experiment's clinical applications. This experiment yielded a value of about 300 W/g for the heating efficiency of Copper Ferrite, which is significantly higher than the value of about 80 W/g obtained for Iron Oxide nanoparticles from previous experiments. These results suggest that Copper is a viable option for increasing the heating efficiency of magnetic nanoparticles and that Copper Ferrite nanoparticles are viable candidates for magnetic hyperthermia therapy.

3:54PM D11.00008: Correlative photoluminescence and micro-Raman spectroscopy determining disorder from two-dimensional heterostructures to rare-earth minerals  
JOY J. MA (Presenter), TAO JIANG, JUN YAN, MOLLY A MAY, MARKUS B. RASCHKE, Physics, University of Colorado, Boulder — Atomic composition and structural arrangement determine the correlation of electronic and lattice degrees of freedom in solids. With combined photoluminescence (PL) and Raman spectroscopy, simultaneous insight into electronic properties and structural disorder can be gained. Here, we use micro-Raman imaging to study spatial heterogeneity in structural disorder in the rare-earth mineral gadolinite as determined from correlative peak position and spectral linewidth analysis. We find the disorder associated with spatial variability in light and heavy rare earth element content. We then use micro-PL to investigate the effect of a plasmonic nano-slit on the excitonic landscape in a two-dimensional heterostructure of transition metal dichalcogenides and identify plasmonic enhancement of both intralayer and interlayer exciton emission as well as strain-induced spectral variations. In summary, this work demonstrates the combination of micro-PL and micro-Raman imaging to understand electronic and structural properties and disorder in crystal materials.
4:06PM D11.00009: Electron emission from randomly-oriented and vertically-aligned carbon nanotubes synthesized directly on conducting surface* MATTHEW KURILICH (Presenter), Department of Physics and Astronomy, Middle Tennessee State University, ARUN THAPA, WENZHI LI, Department of Physics, Florida International University, SUMAN NEUPANE, Department of Physics and Astronomy, Middle Tennessee State University — Field emission properties of carbon nanotubes (CNTs) have been intensively studied for various applications. It is desirable to synthesize CNTs directly on conducting substrates to develop field emission displays capable of operating at low voltages and at room temperature. As compared to the randomly-oriented CNTs, vertically-aligned CNTs demonstrate improved field emission properties with greater electric field enhancement and lower turn-on/threshold electric fields. In this work, we compare the electron emission between randomly-oriented and vertically-aligned CNT emitters synthesized directly on stainless steel substrates. The surface morphology of these CNTs has been studied with electron microscopy and the defects are analyzed by the Raman spectroscopy. The vertical alignment of the CNT emitters benefits the emission process by reducing the screening effect and by streamlining the path of ejected electrons directly onto the anode.

*We would like to acknowledge the financial support from startup funds by the Middle Tennessee State University and the National Science Foundation (NSF) under Grant No. DMR-1506640.

4:18PM D11.00010: Tunable 3D Photonic Crystal Cavity for Coherent Coupling between Microwave Fields and Solid State Spins* ABHIJATMEDHI CHOTRATTANAPITUK (Presenter), HYEONGRAK CHOI, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — We present a theory and experiment of a three dimensional (3D) photonic crystal (PhC) cavity for the control of microwave fields with ultra-low loss. The cavity consists of an engineered defect in a woodpile photonic crystal made of low-loss alumina rods. We measure a large complete bandgap of 13% of the center frequency and a cavity quality factor exceeding 22,000. The architecture allows for easy mechanical tuning of the cavity and waveguide. Our design has a variety of applications including the coherent coupling of microwave photons with electron and nuclear spins in solids.

4:30PM D11.00011: Viscosity of a Crowding Medium Obtained Through Optical Trapping*
JAMES HOWARD (Presenter), JAVIER E HASBUN, SUVRANTA TRIPATHY, Univ of West Georgia — The dynamic viscoelasticity a cellular medium is mainly due to the crowding of a large number of interacting and non-interacting proteins. Our research presents how the viscosity of a medium is altered in the presence of globular proteins. Using an optical trap paired with a 980 nm infrared laser and Nikon inverted microscope we have developed a synthetic approach to calculate the viscosity of a medium. The method involves comparison of Equipartition theorem and Passive power-spectrum technique to determine viscosity. This approach has enabled us to calculate the viscosity of several water and glycerol concentrations. The method has been extended to investigate the viscoelasticity of the medium with various concentrations of globular Polyethylene glycol proteins.

4:42PM D11.00012: Computation of Forces and Torques on Clusters of Micron-Sized Spheres in Optical Tweezers  WYATT VIGILANTE (Presenter), JEROME FUNG, Ithaca Coll — Optical tweezers are a focused laser beam that exerts forces and torques on micrometer-sized particles. Calculations of optical forces on non-spherical particles whose size is comparable to the wavelength of the trapping beam are challenging. Here, we use a $T$-matrix code to calculate how clusters of spheres scatter light. The resulting $T$-matrix is exported to a software package that calculates optical forces and torques. We present calculations of optical forces and torques on clusters of two and three spheres. We discuss how the forces and torques depend on the orientation, size, and refractive index of the clusters.

4:54PM D11.00013: Nano-Optical Imaging of CVD Grown Lateral Heterostructures  RANA KAMH (Presenter), SHARAD AMBARDAR, HANA HRIM, DMITRI VORONINE, Univ of South Florida — Transition Metal Dichalcogenides (TMDs) have attracted a lot of attention due to their properties such as direct band gap, photoluminescence, and applications in electronics. Several combinations of TMD monolayer heterostructures have been fabricated and studied for their unique optical and electrical properties. Here we explore CVD grown WSe$_2$-MoSe$_2$ heterostructures with the presence of telluride in order to observe the effects that arise from the integration of this material in CVD growth. We characterize the resulting material using techniques such as Kelvin Probe Force Microscopy (KPFM), Atomic Force Microscopy (AFM), and Tip Enhanced Photoluminescence (TEPL), revealing the optical properties and surface topographies of the 2D heterostructures after exposure to telluride during growth. We observe alloying and quenching of the near field PL in the 2D lateral heterostructures and propose reasons for these effects after the incorporated material. The integration of telluride to 2D materials can provide potential applications in optoelectronic devices.
5:06PM D11.00014: Computer generated holograms for optical trapping using a Spatial Light Modulator* ANTHONY HEWITT (Presenter), Department of Physics & Astronomy, University of Delaware, KOOK SIANG GAN, RAINER DUMKE, Division of Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Department of Physics & Astronomy, Rowan University — The general experimental modeling of quantum behavior with a well-characterized and well-controlled quantum system is now a possibility using a Bose-Einstein condensate loaded into programmable optical potentials. Through the use of a spatial light modulator (SLM), these patterns can be dynamically modified in real time to further increase the scope of these modelling capabilities. Accurate focal-plane intensity patterns can be generated using an SLM with appropriate algorithms. We demonstrate that the Mixed Region Amplitude Freedom (MRAF) algorithm can generate a desired intensity ring in the focal plane of a lens. We plan to use the MRAF output as the initial guess for a second algorithm that uses Conjugate Gradient Minimization (CGM) to reduce convergence time and increase overall accuracy.

Monday, March 2, 2020 2:30 PM - 5:06 PM

Session D12 APS/SPS: Undergraduate Research V 112 - Ivy Jones, Marquette University

2:30PM D12.00001: Magnetohydrodynamic (MHD) Modeling of Kelvin-Helmholtz Instability and Associated Magnetosonic Wave Emission in Solar Coronal Mass Ejections (CMEs) SARA BUTLER (Presenter), HAVA TURKAKIN, Bucknell University — Interrupted telegraphy systems, regional power outages, and damaged satellites demonstrate a few of the consequences to earth technology by mechanisms that can be analyzed and prevented. The impact of solar wind on the earth and other objects in interplanetary space is relatively understudied, yet has far-reaching applications. Previous related studies have observed through close study of shear flow regions in the Solar-terrestrial environment, that Kelvin-Helmholtz Instability (KHI) and Magnetohydrodynamics (MHD) wave emissions along these boundaries may be a method by which energy is transported from flow. In order to gain a deeper understanding of the non-linear dynamics that distribute energy throughout the Solar Corona, we expand upon these previous studies to investigate the nonlinear evolution of KHI and MHD waves along the boundaries of coronal mass ejections (CMEs), large eruptions of the corona that have a significant effect on satellites, earth's power grids, and humans in space. We utilize different criteria for measuring efficiency, including 2-D/3-D magnetohydrodynamic modeling software. We also discuss in detail the implementation of this software in our analysis about the nature of MHD instabilities in astrophysical plasmas throughout the universe.
2:42PM D12.00002: Cradle-to-Grave Evolution and Explosiveness of the Magnetic Field from Bipolar Ephemeral Active Regions (BEARs) in Solar Coronal Holes*  CAROLINE NAGIB (Presenter), University of California, Los Angeles, NAVDEEP K. PANESAR, Lockheed Martin Solar and Astrophysics Laboratory, RONALD L. MOORE, ALPHONSE C. STERLING, NASA Marshall Space Flight Center — We report on the magnetic evolution of magnetic-explosion eruption production of each of seven BEARs observed in on-disk coronal holes in line-of-sight magnetograms and in coronal EUV images. One of these BEARs produced no eruptions. The other six BEARs display three kinds of magnetic-explosion eruptions: (1) blowout eruptions, (2) partially-confined eruptions, (3) confined eruptions. The seven BEARs are a subset of 60 random coronal-hole BEARs, with visually estimated emergence phases. In this work, we obtain a reliable determination of when the emergence phase ended by finding the time of the BEAR's maximum minority flux from a time plot. These plots show: (1) none of the seven BEARs had an inside eruption while the BEAR was emerging, and (2) for these seven BEARs, the visually-estimated emergence end time was never more than six hours before the measured time of maximum minority flux. Our findings support that a great majority of the explosive magnetic fields from BEARs in coronal holes are prepared and triggered to explode by magnetic flux cancellation, and that such flux cancellation seldom occurs inside an emerging BEAR.

2:54PM D12.00003: Magnetic and Electronic Structure of CuTeO4  ZUBIA HASAN (Presenter), Johns Hopkins University, THAO TRAN, Clemson University, TYREL MCQUEEN, Johns Hopkins University — Cu2+ based materials have been extensively studied over the past decades due to their importance in high temperature superconductivity as well as their potential as quantum spin liquids. Recently,1 CuTeO4 has been proposed as a candidate material that combines a geometrically frustrated triangular lattice with potential high temperature superconductivity upon doping. To date, CuTeO4 has only been made as a secondary phase while making other Copper Tellurates, under extreme hydrothermal conditions over months 2. We developed a novel method of synthesizing CuTeO4 in single phase form, enabling us to characterize its physical properties by magnetization, heat capacity, and neutron diffraction. CuTeO4 was initially predicted to have a quasi-2D Neel ground state. Our magnetic susceptibility data shows no long range ordering with an upturn at T=50K and an intriguing hump around T=120K indicative of low dimensional antiferromagnetic interactions. Heat capacity data shows no magnetic transition at T=50K, an inconsistency that needs to be explored further. With the bulk characterization to date, CuTeO4 seems to be a prime candidate for low-dimensional magnetism.

3:06PM D12.00004: Properties of Magnetic High-Entropy Alloys*  
VALERIA ROSA ROCHA (Presenter), ABBY M NASH, JOHN-PAUL E. CESARE, TROY MESSINA, Berea College — Magnetic high-entropy alloys are a promise for many fields. From cryogenic to aircraft and spacecraft applications, the possibilities are varied but one thing is necessary: we must have a better understanding of the properties of these materials in order to put them to good uses. Korman et al. made predictions for the Curie Temperatures (Tc) of HEAs of the form Cr\textsubscript{x}CoFeNiQ\textsubscript{x} with Q being Pd, Cu, Ag, or Au. In our study, we focused on the Pd alloys varying both Cr and Pd in order to check the accuracy of the Tc predictions. Using the ’’Treasure Maps’’ provided by Korman et al. we chose combinations of Cr and Pd that were predicted to have a Tc near room temperature. Based on our work, we found the maps to be very reproducible with the procedure used, which is further explained in this presentation.

3:18PM D12.00005: Magnetic Heat Capacity Characterization of Magnetite  
SILVIA SHERMAN (Presenter), STEPHEN A TSUI, California State University, San Marcos — We investigate the magnetic and thermal properties of magnetite using both vibrating sample magnetometry (VSM) and heat capacity measurement. Magnetite undergoes the Verwey transition, which is a structural phase transition near 120 K. The magnetization behavior vs. temperature differs between field cooled (FC) and zero field cooled (ZFC) measurements in the VSM, due to the preferential alignment of the magnetic spin moments with respect to applied magnetic field. The application of magnetic field also contributes to an enhancement in the heat capacity. In this study, we investigate the behavior of the heat capacity of different specimens of magnetite under these FC and ZFC conditions.

3:30PM D12.00006: H-T phase diagram of antiferromagnetic topological insulator MnBi\textsubscript{2}Te\textsubscript{4} under hydrostatic pressure to 2.5 GPa*  
RAKIN NUMAIR BATEN (Presenter), TIMOTHY A ELMSLIE, DERRICK VANGENNEP, JAMES J HAMLIN, Department of Physics, University of Florida, Gainesville, Florida 32611, USA — MnBi\textsubscript{2}Te\textsubscript{4} is a layered compound that is an intrinsic antiferromagnetic topological insulator. Metamagnetic transitions have been observed at 3.2 T and 7.8 T at ambient pressure. By compressing the unit cell with hydrostatic pressure and applying a magnetic field we can track these metamagnetic transitions and investigate the magnetic ordering. In this talk I will present transport data and temperature-field phase diagrams of MnBi\textsubscript{2}Te\textsubscript{4} single crystals up to 2.7 GPa and 9 T.

Modeling Hyperfine Coupling in Molecular Magnets

CONG HU (Presenter), Physics, Univ of Connecticut - Storrs, JIA CHEN, XIAOGUANG ZHANG, Physics, University of Florida — Nuclear or electron spins of magnetic molecules are promising qubit candidates. Electron spins are advantageous due to faster operational times, but they decohere faster due to stronger coupling to environment. This project investigates hyperfine couplings in four vanadyl complexes with long decoherence times as qubits by electron structure calculations. In all complexes, electron spins are localized on V$^{4+}$ ion. Using the analytic derivative method based on density functional theory, the Fermi-contact and spin-dipole interactions were calculated. Total hyperfine coupling to vanadium nuclear spin is compared to experiment; Using hybrid functional, good agreement can be achieved. Due to the localized nature of electron spins, the Fermi-contact interaction between an electron spin and hydrogen nuclear spin is only strong for the smallest complex. Hyperfine coupling to hydrogen nuclear spins as the main source of electron spin decoherence can be modeled by spin-dipole interactions.

Mössbauer spectroscopy of iron oxide nanoparticles containing both magnetite and maghemite

JEREMY WINSETT (Presenter), SAEED KAMALI, SUMAN NEUPANE, Middle Tennessee State Univ — Iron oxide nanoparticles are available in two common phases, including magnetite (Fe$_3$O$_4$) and maghemite (Fe$_2$O$_3$). Upon exposure to oxygen atoms, the magnetite phase readily oxidizes into the maghemite phase with the partial conversion of ferrous ions into ferric ions. We report on the approach to determine the ratio of magnetite and maghemite in iron oxide nanoparticles synthesized by the hydrothermal process. The crystallinity of these nanoparticles has been investigated by X-ray diffraction studies and transmission electron microscopy observations. The hysteresis loops of the iron nanoparticles demonstrated the “S-shaped” pattern corresponding to superparamagnetic behavior. The Mössbauer spectrum of the sample is compared with the theoretically predicted model to determine the contributions from magnetite and maghemite. Such characterization is necessary for the synthesis of magnetic nanoparticles of uniform size with potential for biomedical applications.

*We would like to acknowledge the financial support from startup funds by the Middle Tennessee State University.
4:06PM D12.00009: Computational Modeling of Magnetorheological Elastomers* TONG DANG (Presenter), ANDY T CLARK, Department of Physics, Bryn Mawr College, JIAJIA LI, Department of Physics, Fudan University, DAVID MARCHFIELD, KRISTEN S. BUCHANAN, Department of Physics, Colorado State University, XUEMEI CHENG, Department of Physics, Bryn Mawr College — Ultra-soft polydimethylsiloxane (PDMS) based magnetorheological elastomers (MREs) are composite materials of polymeric matrix with embedded micro- or nano- sized ferromagnetic particles. They are promising candidates for dynamic cell culture substrata due to their magnetic field dependent mechanical properties. In this work, we have used a two-step, multi-scale approach to model the complex magnetic reversal behavior of MREs. Micro-magnetic simulations were performed using MuMax3 to obtain a detailed description of the magnetic reversal process of individual Fe particles. The micromagnetic modeling results are then used as input parameters for a particle interaction model that includes dipolar interactions and elastic deformations. This model was used to study the magneto-mechanical interactions between a large collection of particles and their surrounding elastomer matrix, which provides insight into the complex magneto-mechanical interactions of MREs.

4:18PM D12.00010: CsPbBr$_3$ Perovskite Quantum Dots as Single Photon Sources* GEORGIA NELSON (Presenter), Department of Physics, Bryn Mawr College, GIORGIO ADAMO, CESARE SOCI, Division of Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Department of Physics & Astronomy, Rowan University — Cesium Lead Bromide (CsPbBr$_3$) Perovskites Quantum Dots (PQDs) are zero-dimensional semiconducting particles with tunable optical properties. We are interested in PQDs as possible single photon sources with applications in quantum computing and quantum cryptography. We have successfully fabricated CsPbBr$_3$ PQDs and measured their photoluminescence intensity as a function of wavelength. As temperature is varied from 77K to 293K, the central wavelength undergoes a blue-shift. The fabricated CsPbBr$_3$ PQDs are stable at 77K and 293K. Diluting the solution used in fabrication should allow us to create samples of individual, spatially-resolved quantum dots, which can then be verified with $g^{(2)}$ measurements.

*The authors acknowledge support from NSF-IRES 1559410.
4:30PM D12.00011: Quantum entangled breathers in Goldilocks quantum cellular automata

HALEY COLE (Presenter), MATTHEW JONES, Colorado Sch of Mines, LOGAN HILLBERRY, Physics, University of Texas Austin, MINA FASIHI, LINCOLN CARR, Colorado Sch of Mines — We conducted robustness studies of quantum entangled breathers (QEBs) to evaluate their stability. QEBs are an emergent dynamical structure appearing in a continuous time generalization of Goldilocks quantum cellular automata. This system is a qubit spin chain on which sites evolve according to a local unitary operator if and only if 2 or 3 sites in a 5 site neighborhood are spin-up. The QEB is a quantum entangled generalization of a discrete breather or excited bright soliton on a lattice, a famous and robust classical solution to nonlinear wave equations. We consider four sources of noise: uniform and non-uniform spatial noise in the state; uniform spectral noise in the state; perturbations to the closed system Hamiltonian; and open quantum system evolution including T\(_1\) and T\(_2\) decoherence processes. We find that QEBs present a robust signal of quantum complexity in a simple system that can be studied on a wide variety of quantum simulators.

*Funded by NSF.

4:42PM D12.00012: Synthesis and Characterization of Quantum Dots Based on Transition Metal Dichalcogenides

PEDRO JUAN RODRÍGUEZ FERNÁNDEZ (Presenter), Physics Department, University of Puerto Rico, Mayaguez, NALAKA A KAPURUGE, HUMBERTO GUTIERREZ, Physics Department, University of South Florida — Atomically transition metal dichalcogenides (TMDs) have attracted a significant attention due to their novel and promising physical properties. However, Quantum Dots (QDs) based on TMDs have been less studied. QDs present size-dependent optical and electronic properties due to quantum confinement of electrons and phonons. Consequently, they have potential applications in medicine, renewable energy, and electronics, among others. In this presentation we will describe a simple synthetic approach to produce TMD-based QDs as well as the study of their physical properties. The synthesis involves mechanical rupture of large TMD flakes using a high power ultrasonic horn, bath sonication and/or thermal reflux. Subsequently, QDs of different sizes are selected by centrifugation. The effect of different parameters such as ultrasonic power, time, solvent type and centrifugation conditions on the final size distribution were studied. The morphology of the TMD fragments was studies by scanning electron microscopy and atomic force microscopy. The optical response of the as-prepared materials was evaluated using optical absorption spectroscopy, photoluminescence and Raman spectroscopies.

4:54PM D12.00013: Single Hole Based Magneto-Impedance Biosensor for Particle Detection*

BAYLEE SENATOR (Presenter), Department of Physics and Engineering, West Virginia Wesleyan College, VALEY ORTIZ JIMENEZ, MANH-HUONG PHAN, Department of Physics, University of South Florida — GMI (giant magneto-impedance) sensors have been used for biomedical applications that require maximum sensor detection sensitivity for accurate magnetic field detection. To create better biosensors, Fe$_3$O$_4$ nanoparticles are applied to holes drilled into a ribbon-based GMI biosensor which should increase the sensor detection sensitivity. A focused ion beam is used to drill various sized holes – 3, 4, 5, 7, and 10 μm diameters – into soft ferromagnetic Metglas® 2714A ribbons. The sensor sensitivity of these samples is measured as-cast, with holes, and with iron oxide nanoparticles at frequencies between 50 and 175 MHz. The addition of iron oxide nanoparticles has shown to increase the sensor sensitivity of the samples while the GMI ratio decreases. In conclusion, the sensor detection sensitivity of ribbon-based GMI biosensors improves when the iron oxide nanoparticles are applied and measured between 110 and 150 MHz, therefore, creating biosensors with greater detection sensitivity. The maximum sensitivity measured for the ribbon as-cast was 60 %/Oe, this increased to 105 %/Oe when the iron oxide nanoparticles were applied.

Session D15 DFD DSOFT: Thin Films, Surface Flows, and Interfaces I

210/212

2:30PM D15.00001: Physical Limits of Marangoni-driven Patterning*  STEVEN STANLEY (Presenter), ROGER T BONNECAZE, University of Texas at Austin — Marangoni-driven patterning is a novel technique that harnesses photochemically-applied surface tension gradients to pattern thin polymer films. When heated, the polymer flows away from regions of lower surface tension and into regions of higher surface tension, thereby generating hill-and-valley patterns. This new technique offers potential advantages over traditional patterning methods in creating functional coatings and flexible electronics at the roll-to-roll scale. To understand the full scope of applications this new patterning method could serve, it is necessary to understand the fundamental limits of pattern aspect ratio and pattern periodicity, both key metrics in evaluating pattern quality. Here, we present a model for Marangoni-driven patterning and perform a nonlinear analysis to determine the physical limits of pattern aspect ratio and feature pitch for an equal line-space system.

*This work is supported by a grant from the National Science Foundation under Cooperative Agreement No. EEC-1160494.
ABHEETI GOYAL (Presenter), Fluids and Flows Group, Theory of Polymers and Soft Matter Group, Dept. of Applied Physics, Eindhoven University of Technology, PAUL VAN DER SCHOOT, Theory of Polymers and Soft Matter Group, Dept. of Applied Physics, Eindhoven University of Technology, FEDERICO TOSCHI, Fluids and Flows Group, Dept. of Applied Physics. Dept. of Mathematics and Computer Science, Eindhoven University of Technology — Understanding the phase separation dynamics in thin films is crucial for the performance of many optoelectronic and photovoltaic device because their functioning relies on a well-defined morphology. The morphology forms in the fluid stages of the production process, and to control and improve the performance of thin-film composites it is vital to predict it quantitatively. Typically, the dynamics of fluid-fluid demixing is modeled using relaxational phase field-type theories that ignore the role of hydrodynamics. We study the impact of hydrodynamics on the demixing of binary fluid mixtures in contact with a wetting substrate by comparing lattice Boltzmann simulations with a diffusion-dominated phase field theory. Special focus is on the impact of a short-range surface interaction that favours one of the two fluids, particularly important in the context of photovoltaics. We find that incorporating hydrodynamics is crucial to quantitatively predict the relevant length scales both in the early and late stages of demixing. Indeed, we find that hydrodynamic processes suppress any dependence of the associated growth exponents on the strength of the substrate interaction predicted by phase field theory. We attribute this to flow-induced transport that significantly speeds up coarsening.

ANDERS JOHANSSON (Presenter), HENRIK A SVEINSSON, Department of Physics, University of Oslo, KJETIL THØGERSEN, Department of Geosciences, University of Oslo, ANDERS HAFREAGER, Department of Physics, University of Oslo, EINAT AHARONOV, Institute of Earth Sciences, Hebrew University of Jerusalem, ANDERS MALTHE-SØRENSSEN, Department of Physics, University of Oslo — Geophysical processes are traditionally studied at the continuum level, but large scale molecular simulations now allow detailed studies of the underlying nanoscale mechanisms responsible for large scale behavior. An outstanding question in geoscience is the dynamics of water in thin water films in geological materials under high pressure. In this work, we demonstrate that molecular dynamics simulations provide new insights on creep in water-wetted silicates. We have performed nonequilibrium molecular dynamics simulations of the creep process in a pair of opposing quartz asperities under constant load. The results are compared with a microphysics-based model for thermally activated creep. The thermal activation energy and the time evolution of the system height agree with theory when there is a vacuum between the asperities. Replacing the vacuum with water drastically alters these results by introducing chemical effects which dominate the creep process. Pressure solution of silica and the formation of an amorphous gel at the asperity interface are found to greatly increase the creep rate.

*Notur grant NN9272K
3:06PM D15.00004: Nonlinear Interface Equation For Capillary Driven Flow in 3D Open Curved Trajectories* NICHOLAS WHITE (Presenter), SANDRA TROIAN, Applied Physics, Caltech — Capillary driven flow of wetting liquids in open V-grooves and interior corners is known to be an especially robust and rapid means of fluid transport in gravity free environments and in small scale systems where gravity plays a negligible role. Nowadays, such flows are routinely used for propellant management in space based systems, lab-on-a-chip devices and high performance chip with micro heat pipes. The low-order inertia-free model developed by Romero and Yost (1996) and Weislogel (1996) first elucidated the flow behavior of an incompressible Newtonian liquid in a straight V-groove whose length far exceeds the film thickness. Here we present an extension of this classic work to flow in 3D open and curved channels in which the trajectory radius of curvature is larger than the film thickness. Despite the complexity of trajectories allowed by this model, a first-order perturbation analysis of the governing conservation equation yields a surprisingly simple form of the nonlinear equation governing the behavior of the moving interface. This thin film equation can now be used to design deterministic flow trajectories for ultracompact microfluidic systems featuring arbitrarily curved 3D channel flows.

*Sponsored by a 2017 NASA Space Technology Research Fellowship (NCW).

3:18PM D15.00005: Theory of the two-dimensional paraelectric structural transformation of ferroelectric group-IV monochalcogenide monolayers* SALVADOR BARRAZA-LOPEZ (Presenter), JOHN VILLANOVA, PRADEEP KUMAR, Univ of Arkansas-Fayetteville — After the initial description of a thermally-driven two-dimensional structural transformation in group-IV monochalcogenide monolayers [1] and its subsequent experimental demonstration [2], an additional publication claimed that the transformation can be determined via a Landau model based on an unidirectional optical phonon mode going soft [3]. In this presentation, we disclose a quadratic dispersion of softening modes and analyze molecular dynamics data to understand the atomistic motions underlying the ferroelectric to paraelectric transformation in these atomically thin membranes. We are then able to characterize a hierarchy of critical temperatures Tc that are dependent on structural constraints. Additional dependencies of Tc on the assumptions used to set interatomic forces are discussed as well [4].

3:30PM D15.00006: Evolution of elastic moduli through a two-dimensional structural transformation* ALEJANDRO PACHECO-SANJUAN, Departamento de Ingenieria Mecanica, Universidad Tecnica Federico Santa Maria, TYLER BISHOP (Presenter), ERIN FARMER, PRADEEP KUMAR, SALVADOR BARRAZA-LOPEZ, Univ of Arkansas-Fayetteville — We use an analytical elastic energy landscape describing SnO monolayers to estimate the softening of elastic moduli through a mechanical instability occurring at finite temperature. Although not strictly applicable due to a quantum paraelastic phase in this material [1], this exercise is relevant as it establishes a conceptual procedure to estimate such moduli straight from a two-dimensional elastic energy landscape. As additional support for the existence of a quantum paraelastic phase, we use a qualitative WKB analysis [2] to estimate escape times from an energy well on the landscape. These results continue to establish a case for the usefulness of soft matter concepts in 2D materials and of the potential lurking of quantum effects in soft matter [3].

3:42PM D15.00007: Laser-induced strong Marangoni effect in deformation and manipulation of ferrofluid FENG LIN (Presenter), Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, TALARI VISHAL, Department of Mechanical Engineering, University of Houston, JUNYI ZHAO, Department of Electrical and Systems Engineering, Washington University in St. Louis, JOHN SCHAIBLEY, Department of Physics, University of Arizona, DONG LIU, Department of Mechanical Engineering, University of Houston, ZHIMING WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston — Optical manipulation of fluid or droplet has long been investigated for applications in microfluidics. The light-induced thermocapillary effect is one of the strategies in optical control of liquid. We demonstrate the laser-induced deformation of ferrofluid surfaces with ultra-violet to infra-red lasers. The surface deformation reaches the bottom and breaks the liquid, achieving the highest liquid rupture thickness for over 1000 μm. The deformation process and rupture are related to strong Marangoni effect, high laser absorption and low viscosity of ferrofluid. As applications of the laser-controlled ferrofluid, we show that a ferrofluid droplet in the capillary can be easily moved horizontally and vertically by the illumination of a laser beam. We also demonstrate that letters and patterns can be written on the black surface of ferrofluid thin film with a laser beam even with a common laser pointer. Laser manipulation of ferrofluid also makes it a controlling vehicle for varieties of liquid or droplets.
3:54PM D15.00008: Long-time evolution of interfacial structure in dewetting* MENGFEI HE (Presenter), SIDNEY ROBERT NAGEL, University of Chicago — When a solid plate is withdrawn from a partially wetting liquid, a liquid layer dewets the moving substrate. High-speed imaging reveals alternating thin and thick regions in the entrained layer in the transverse direction at steady state. To quantify the absolute thickness of these steady-state structures precisely, I have developed an interferometric technique taking advantage of a varying angle of incidence. This method allows us to measure the absolute thickness as well as the local slope of the thin film. A new technique of likelihood maximization is applied to detect interference fringes. The result shows that the thicknesses of both regions of the film scale with the capillary number, Ca. In addition, a new region is observed during onset which differs from the behavior predicted by previous models.

*The work was primarily supported by the University of Chicago MRSEC, funded by the National Science Foundation under Grant No. DMR-1420709 and by NSF Grant No. DMR-1404841.

4:06PM D15.00009: Flows at Molecular Scales: Probing and Manipulating Ultra-Thin Supported Liquid Films CECILE CLAVAUD (Presenter), LAURENCE TALINI, CHRISTIAN FRÉTIGNY, ESPCI Paris — A hydrodynamical description of a liquid down to molecular levels has to take into account the effects specific to these very small scales. At molecular distances from a solid wall, phenomena such as slip or confinement-induced molecular layering have been observed with liquids in both experiments and numerical simulations. The ability to predict those effects is crucial in many fields involving flows at small scales close to a solid, such as nanofluidics or flows in mesoporous media. However, a unifying picture of the different reported features is still lacking, partly because their manifestations critically depend on the chemical nature of both the liquid and the solid medium.

We have developed a fully non invasive optical technique [Phys. Rev. Lett., 114, 227801 (2015)] in order to characterize the dynamics of a liquid by measuring the spontaneous thermal fluctuations of its free surface. Liquid films lying on solid substrates are formed with a thickness down to 5 nm using a Marangoni (surface tension gradient induced) flow. Using this technique, we evidence disjoining pressure effects, and are able to probe flow properties of ultra-thin liquid films.
4:18PM D15.00010: Towards nanoscale confinement in TEM liquid cells*  KYLE SENDGIKOSKI (Presenter), University of Maryland, College Park, ALOKIK KANWAL, JAMES ALEXANDER LIDDLE, Physical Measurement Laboratory, National Institute of Standards and Technology, JOHN CUMINGS, University of Maryland, College Park — Liquid confinement below micrometer thicknesses is of interest to several scientific disciplines and is inherently challenging to study experimentally. More extreme confinement at the single-digit nanometer scale is possible through the use of self-assembled nanostructures such as carbon nanotubes. Bridging the gap between micro- and nanoscale liquid confinement has been achieved with two-piece liquid cells within a transmission electron microscope (TEM), but irreproducibility and difficulties maintaining uniform liquid layer thickness makes high spatial and spectroscopic resolution challenging. We report on improvements made to a monolithic, in-situ TEM liquid cell\(^1\) with sub 40nm liquid thickness that overcomes the common challenges encountered with two-piece TEM liquid cells.

4:30PM D15.00011: Chemical Vapor Deposition Growth of Nickel Sulfide for optoelectronic device applications  NIDHI . (Presenter), TASHI NAUTIYAL, Physics, Indian Inst of Technology Roorkee, SAMARESH DAS, C.A.R.E., IIT Delhi — Nickel Sulfide (Ni\(_2\)S\(_2\)), a Transition Metal Di-chalcogenide (TMDC) has become an interesting material for the scientific community owing to its intrinsically small bandgap within the mid-infrared range [1] and superior charge transport properties. Experimentally, it is challenging to characterize the quality of NiS\(_2\). Although it offers a great opportunity for nanoelectronic devices. However, very few efforts have been given for the growth of NiS\(_2\) thin film for device applications. To date, NiS\(_2\) has been grown by the solution process and hydrothermal method and used for energy storage device applications. Here, we grow the NiS\(_2\) thin film on SiO\(_2\)/Si substrate by the chemical vapor deposition (CVD) technique. Several spectroscopic studies reveal the high-quality crystalline nature of CVD grown NiS\(_2\) film. We also fabricated the field-effect device at the nickel sulfide platform with thickness up to few nanometers (~23 nm). The performance of the fabricated device is characterized at room temperature. Nickel Sulfide field-effect device shows the drain current up ~10\(^{-6}\) A with drain voltage from -2 to +2 V.

References

Colloidal particle migration in combined Poiseuille and electrokinetic flows away from or towards the microchannel walls has recently been shown to be due to the particle slip velocity with respect to the fluid. The particle migration was attributed to an electrophoretic lift-like force, analogous to the inertial lift forces in sedimentation flows. The migration of colloidal particles towards the walls for dilute colloidal particle suspensions with diameters < 1 micron led to the assembly of distinct colloidal bands within microchannels (100 – 300 microns wide x 34 microns deep x 4cm long). Band formation requires opposing Poiseuille and electrokinetic flows. Band formation also requires a minimum applied potential threshold at a given shear rate. Band formation is a function of particle size and volume fraction, particle and channel wall zeta potential, electrolyte concentration, and the minimum electric field thresholds change non-monotonically for particle mixtures. Here, we discuss the effect of manipulating particle properties and fluid inertia over broad parametric ranges to elucidate robustness of particle migration to and away from walls, and the formation of particle bands.

Lattice Boltzmann Method for Designing cellular solids for effective acoustic noise cancellation

Acoustic technology based on Passive Noise Cancellation (PNC) has emerged as an excellent noise reduction strategy for both small and large environments. In general, PNC primarily focuses on designing specialty cellular materials, that can effectively attenuate unwanted sounds by virtue of its intrinsic morphology. Here, we design sound-absorbing materials and establish that by tailoring their morphological features, we can achieve acoustic noise cancellation, effectively. Our approach harnesses Lattice Boltzmann Method (LBM) to simulate sound propagation in two-phase cellular viscoelastic materials and our simulation results are in good agreement with the analytical calculations. In particular, using LBM, we designed various morphologies for cellular viscoelastic solids and demonstrate that the higher frequency waves attenuate faster compared to lower frequency waves. Further, we extend our approach for designing indoor acoustics and use reverberation time to quantify PNC for these systems. Our findings can be used not only to design miniaturized noise-canceling acoustic gadgets but also to design specific sound-absorbing materials for large indoor systems.

Session D16 DQI: Fluxonium and Novel Superconducting Qubits II
2:30PM D16.00001: Tunable Current Mirror Qubits: Experimental Status* JAMES WENNER (Presenter), MOE S KHALIL, Northrop Grumman Corporation, DANIEL WEISS, JENS KOCH, Northwestern University, DAVID FERGUSON, Northrop Grumman Corporation — In the last few years significant progress has been made in the development of tunable current-mirror qubits. This novel qubit type is projected to exhibit high coherence due to its insensitivity to environmental noise. However, as a consequence of their noise immunity, tunable current-mirror qubits are also insensitive to control signals, requiring novel control approaches. This talk reviews the successful demonstration of current-mirror test structures that share the same ‘Mobius’ capacitance connectivity as current-mirror qubits. The collective modes of these test structures exhibit a mode frequency parity effect such that even modes are much higher in frequency than odd modes—an indicator that such circuits can generate a parity valve effect—strong double-vortex hopping relative to single-vortex hopping—a key requirement for generating noise insensitivity. This talk also describes design optimizations of current-mirror qubits, and gives a status report on coherence tests, including tests that utilize adiabatic protection sweeps.

2:42PM D16.00002: Phase-shift flux qubit with a ferromagnetic π junction* TARO YAMASHITA (Presenter), Department of Electronics, Nagoya Univ, KUN ZUO, YOSHIRO URADE, Center for Emergent Matter Science (CEMS), RIKEN, WEI QIU, HIROTAKA TERAI, Advanced ICT Research Institute, National Institute of Information and Communications Technology, AKIRA FUJIMAKI, Department of Electronics, Nagoya Univ, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — A flux qubit with high anharmonicity is an attractive choice for large-scale superconducting quantum circuits. However, one of the biggest challenges is the necessity of an external flux bias corresponding to half flux quantum to achieve flux-insensitive point with the longest coherence time for each flux qubit. In light of this, we developed phase-shift flux qubits by integrating a ferromagnetic π junction in the qubit loop providing spontaneous π phase shift, enabling flux-bias-free operations [1]. The developed qubit consists of a superconducting loop with three Al/AlO$_x$/Al junctions and an NbN/CuNi/NbN π junction [2] on an Si substrate. The qubit is shunted to a large capacitor and is capacitively coupled to a coplanar waveguide resonator made of NbN/TiN. Our results indicate that the phase-shift qubits are indeed at their flux-insensitive point without any external flux, with a relatively long coherence. In this talk, we will discuss the NbN-Al hybrid fabrication process and the results of the spectroscopy and time-domain measurements.

2:54PM D16.00003: Electrically-tunable phase-slip qubits  AHMED KENAWY (Presenter), Katholieke Univ Leuven, WIM MAGNUS, University of Antwerp, BART SOREE, imec — The simplest form of a flux qubit is constructed by interrupting a superconducting loop (e.g., a ring) with an insulating barrier, thus forming a Josephson junction. The tunneling of Cooper pairs across the insulating barrier allows for a coherent coupling of two macroscopic flux states with oppositely circulating currents. In a similar manner, one can interrupt the superconducting loop with a nanowire over which superconducting vortices are coherently exchanged, a mechanism referred to as quantum phase slips (QPSs), giving rise to phase-slip qubits. Here, we investigate the possibility of using a voltage-biased superconducting ring to realize a phase-slip qubit. Using time-dependent Ginzburg-Landau equations, we show that the bias voltage modulates the free energy barrier between subsequent flux states of the ring. For a small but non-zero barrier, we calculate the rate of QPSs as a function of bias voltage, and investigate the possibility of realizing electrically-tunable phase-slip qubits.

3:06PM D16.00004: Influence of charge fluctuations on Josephson phase-slip qubits*  CYRUS F. HIRJIBEHEDIN (Presenter), STEVEN WEBER, GABRIEL ORR SAMACH, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, DANNA ROSENBERG, KYLE SERNIAK, JONILYN YODER, WILLIAM OLIVER, ANDREW JAMES KERMAN, MIT Lincoln Laboratory — The Josephson phase-slip qubit (JPSQ) [1] is a superconducting circuit designed to emulate a quantum S=1/2, with a vector dipole moment that is nearly independent of applied effective field, even near zero. This property should enable the realization of full quantum vector spin interactions, including non-Stoquastic interactions that are of interest for quantum annealing and Hamiltonian quantum computing. We characterize the influence of charge fluctuations on the JPSQ, examining both discrete quasiparticle tunneling as well as drifts and jumps in the background charge offset. In addition, we describe methods for mitigating the influence of these effects to enhance operational robustness.

3:18PM D16.00005: Bifluxon: Fluxon-Parity-Protected Superconducting Qubit*  

KONSTANTIN KALASHNIKOV (Presenter), Rutgers University, New Brunswick, WEN TING HSIEH, Engineering Department, University of Massachusetts Boston, Boston, MA, WENYUAN ZHANG, WEN-SEN LU, PLAMEN KAMENOV, Rutgers University, New Brunswick, AGUSTIN DI PAOLO, ALEXANDRE BLAIS, Institut Quantique and Departement de Physique, Universite de Sherbrooke, Sherbrooke, Canada, MICHAEL GERSHENSON, Rutgers University, New Brunswick, MATTHEW T BELL, Engineering Department, University of Massachusetts Boston, Boston, MA — We have developed and characterized a symmetry-protected superconducting qubit that offers simultaneous exponential suppression of energy decay from both the charge and flux noise, and dephasing from flux noise [1]. The qubit is implemented as a superconducting loop formed by a Cooper-pair box (CPB) and a superinductor. Provided the offset charge on the CPB island is an odd number of electrons, the qubit potential corresponds to that of a cos (φ/2) Josephson element, preserving the parity of fluxons in the loop via Aharonov-Casher interference. Importantly, the protection can be turned on and off by controlling the CPB charge. In the protected state, the logical-state wavefunctions reside in disjoint regions of phase space, thereby ensuring protection against energy decay. By turning the protection on, we observed a ten-fold increase of the decay time, up to 100 μs. We will discuss strategies for mitigation of the charge noise effects by designing small arrays of cos (φ/2) elements.

3:30PM D16.00006: Blochnium: A flux-tunable qubit with flux-insensitive coherence times  

RAY MENCIA (Presenter), IVAN PECHENEHKSIIY, LONG NGUYEN, YEN-HSIANG LIN, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We introduce a flux-insensitive superconducting artificial atom nicknamed “blochnium", which is dual to a transmon. A blochnium circuit consists of a small-area Josephson junction shunted by a hyperinductance -- a micro-Henry range linear inductance whose impedance reaches above 160 kΩ. Using innovative circuit design and fabrication tricks, we significantly reduced the parasitic capacitance previously associated with such large inductances. The flux dispersion of the qubit transition is reduced to about 100 MHz while transitions to non-computational states can be tuned in the usual few-GHz range. Such a unique spectrum eliminates flux-noise induced dephasing during flux-controlled logical gates on coupled blochnium qubits, which in theory allows for gate fidelities better than 0.999.

3:42PM D16.00007: Novel Qubit Designs [Invited]  

LEV IOFFE (Presenter), University of Wisconsin — Lev ioffe has pioneered the field of topologically protected superconducting qubits, including the development of the rhombus qubit. This is a growing area within the superconducting community.
Rabi Oscillations in a Superconducting Nanowire Circuit

YANNICK SCHÖN (Presenter), JAN NICOLAS VOSS, MICHA WILDERMUTH, ANDRE SCHNEIDER, SEBASTIAN T. SKACEL, Karlsruhe Institute of Technology, MARTIN WEIDES, University of Glasgow, JARED H. COLE, Royal Melbourne Institute of Technology, HANNE ROTZINGER, ALEXEY V. USTINOV, Karlsruhe Institute of Technology — At feature sizes of nanometer scale, superconducting wires made from a material with high normal state resistance show a pronounced nonlinear microwave response. Disordered oxidized (granular) aluminum is a new material for superconducting quantum circuits, featuring not only a very high kinetic inductance but also microwave resonators with high quality factors [1,2]. Microscopically, it can be described as a disordered network of nano-scale aluminum grains, coupled via the Josephson effect [3].

We investigate the circuit quantum electrodynamics of superconducting nanowire oscillators. The sample circuit consists of a capacitively shunted nanowire with a width of about 20 nm and a varying length up to 350 nm, capacitively coupled to an on-chip resonator. By applying microwave pulses we observe Rabi oscillations, measure coherence times and the anharmonicity of the circuit. Despite the very compact design, simple top-down fabrication and high degree of disorder in the granular aluminum material, we observe lifetimes in the microsecond range. [4]

Ultrastrong coupling to parasitic modes in superconducting circuits with hyperinductors

IVAN PECHENEZHSKIY (Presenter), RAY MENCIA, ROMAN KUZMIN, LONG NGUYEN, YEN-HSIANG LIN, VLADIMIR MANUCHARYAN, University of Maryland, College Park — Parasitic modes are inevitable in any real-world circuit. The hope of any practical circuit design is that these modes are sufficiently above the frequency band of interest and do not participate in the low-frequency dynamics of the circuit. A notorious example is a large-value inductor. As the value of the inductance increases with the inductor length, so does the parasitic capacitance. Even in the simplest qubit circuit, in which a Josephson junction is shunted by a hyperinductor, the distributed nature of parasitic capacitance leads to multiple parasitic modes that couple ultrastrongly to the qubit. This ultrastrong coupling of the parasitic modes prevents a perturbation theory treatment of the qubit excitation spectra, while a complete quantum description of the underlying qubit circuit is computationally prohibitive. Progress can be made using an effective multi-mode Hamiltonian that fully reproduces the experimental data both below and above the lowest parasitic modes. This method allows the extraction of the bare qubit circuit parameters that are not renormalized by the presence of parasitic modes.
4:42PM D16.00010: Relaxation and decoherence of 2D fluxonium*  KARTHIK SRIKANTH BHARADWAJ (Presenter), FARSHAD FOROUGHI, Univ. Grenoble Alpes and Institut Néel, CNRS, 38000 Grenoble, France, ETIENNE DUMUR, Institute for Molecular Engineering, University of Chicago, Chicago IL 60637, USA, LUCA PLANAT, ARPIT RANADIVE, CÉCILE NAUD, OLIVIER BUISSON, NICOLAS ROCH, WIEBKE HASCH-GUICHARD, Univ. Grenoble Alpes and Institut Néel, CNRS, 38000 Grenoble, France — High anharmonicity and wide frequency tunability of the Fluxonium qubit make it an indispensable candidate for emerging quantum computers. Moreover fluxonium qubit in a 3D cavity or environment, when biased at sweet spot, shows very high relaxation time well above 1ms with a potential to achieve higher magnitude [1]. However, 2D and on-chip qubits are more favorable to scale up. The transition from 3D to 2D is not trivial as the coupling to the unwanted degrees of freedom increases a lot. In this work we coupled the fluxonium qubit to on-chip lumped element and distributed resonators. We have studied effect of different qubit parameters on the coherence times T1 and T2.

4:54PM D16.00011: A Rotary Echo Flux Qubit*  ALEXANDER K SIROTA (Presenter), DAVID FERGUSON, Northrop Grumman - Mission Systems, DAVID I SCHUSTER, University of Chicago, RYAN J EPSTEIN, Northrop Grumman - Mission Systems — Flux qubits can have long T1 decay times due to nearly disjoint support of their flux basis wavefunctions. However the coupling of flux noise to circulating currents can lead to short dephasing times. This talk describes a qubit that utilizes a rotary echo control technique to maintain long T1 times yet also generating insensitivity to flux noise below a cutoff frequency. As the majority of the flux noise is low frequency in nature, this generates a qubit design capable of achieving high coherence.

*This research was supported by the Army Research Office under contract W911NF-17-C-0024.

5:06PM D16.00012: Characterization and control of topologically protected charge-parity qubits: Part 1*  KENNETH DODGE (Presenter), YEBIN LIU, MICHAEL SENATORE, Syracuse University, FNU NAVEEN, SHAOJIANG ZHU, ABIGAIL J SHEARROW, ANDREY KLOTS, LARA FAORO, LEV B IOFFE, ROBERT F MCDERMOTT, Physics, University of Wisconsin - Madison, BRITTON L PLOURDE, Syracuse University — Superconducting qubits with topological protection against local noise hold the promise of significantly enhanced coherence times and higher gate fidelities than is possible with conventional qubits. We are developing one such protected design — the hybrid charge-parity qubit — that combines arrays of compact, high inductances and conventional Josephson junctions with individual flux control for tuning each plaquette to a regime with a pi-periodic Josephson energy. With this scheme, concatenating multiple pi-periodic elements further enhances the degree of protection. Here, we will describe our experimental characterization of one- and two-plaquette devices through spectroscopy and time-domain measurements.

*Supported by the U.S. Government under Grant W911NF-18-1-0106
Decoherence poses a major impediment to the implementation of large-scale quantum processing with superconducting qubits. There have been tremendous improvements in superconducting qubit coherence times over the past two decades, with current state-of-the-art coherence levels approaching the threshold for fault-tolerant quantum computing. Nevertheless, for scalability, high-fidelity qubit control and qubits protected from sources of noise at the hardware level are needed. We implement qubit protection with pi-periodic superconducting elements made from flux-biased plaquettes of kinetic inductors and Josephson junctions that allow only double Cooper pair tunneling. The amount of protection from noise in such plaquette-based qubits can be further increased by concatenating plaquettes. We describe the design and characterization of a plaquette-based qubit with an embedded SQUID switch.

*Supported by the U.S. Government under Grant W911NF-18-1-0106

Session D17 DQI: Focus Entanglement in Quantum Dot Arrays 203 - Patrick Harvey-Collard, Delft University of Technology - Tag(s): Focus
JOHN NICHOL (Presenter), University of Rochester — Among the different experimental platforms for quantum information processing, individual electron spins in semiconductor quantum dots stand out for their long coherence times and potential for scalable fabrication. The past years have witnessed substantial progress in the capabilities of spin qubits. However, coupling between distant electron spins, which is required for quantum error correction, presents a challenge, and this goal remains the focus of intense research. Quantum teleportation is a canonical method to transmit qubit states, but it has not previously been implemented in quantum-dot spin qubits. Here, we present a conditional quantum teleportation protocol for electron spin qubits in semiconductor quantum dots. We demonstrate this method, which relies on a recently-developed technique to distribute entangled states of spin qubits, through conditional teleportation of spin eigenstates, entanglement swapping, and gate teleportation. This method is a promising addition to the quantum-dot spin-qubit toolbox, and it will alleviate many of the challenges associated with long-distance coupling between spins and open the door to scalable spin-based quantum information processing.

*This work was sponsored the Defense Advanced Research Projects Agency under Grant No. D18AC00025 and the Army Research Office under Grant Nos. W911NF-16-1-0260 and W911NF-19-1-0167. ELEANOR CRANE (Presenter), Electrical Engineering, University College London, ALEXANDER SCHUCKERT, Department of Physics and Institute for Advanced Study, Technical University Munich, NGUYEN HUY LE, Advanced Technology Institute, University of Surrey, ANDREW JAMES FISHER, Physics and Astronomy, University College London — Spin qubits of donors in silicon show some of the longest coherence times recorded and promise seamless integration of quantum computing into current semiconductor fabrication. However, current entangling gate implementations rely on knowledge of the exact value of the exchange interaction between donors, which decays as a highly oscillating exponential, making high fidelity entangling gates in multi-qubit fabricated devices a challenge. In this work, we show how this constraint can be released by using Rydberg blockade entangling gates between orbital excited states of donors, which are robust against variations in the interaction strength. We obtain these results by calculating induced dipole interactions of shallow and singly ionised deep donors using the finite element method and by simulating the entangling gate pulse sequence in the presence of decoherence with a Markovian Lindblad Master equation. Our study paves the way for near-term large scale quantum computations with donors in silicon by lowering the precision requirements on single donor placement.

3:18PM D17.00003: Entanglement of encoded spin-qubits via curvature couplings to a superconducting cavity

RUSKO RUSKOV (Presenter), CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740, U.S.A. — We propose entangling operation and preparation procedures based on curvature couplings of encoded spin qubits to a superconducting cavity, exploring the non-linear qubit response to a voltage variation. For two-qubit (n-qubit) entangling gate we explore acquired geometric phases via a time-modulated longitudinal \( \sigma_z \)-coupling, offering gate times of 10s of ns. No dipole moment is necessary: the qubit transverse \( \sigma_x \)-coupling to the resonator is zero at full sweet spot. This approach allows always-on, exchange-only qubits, for example, to stay on their `sweet spots" during gate operations, minimizing the charge noise and eliminating an always-on static longitudinal qubit-qubit coupling. We calculate gate errors due to the diffusion noise and damping of the resonator, the qubit charge dephasing, and a static spin-dependent resonator frequency shift (via a `dispersive-like" curvature coupling). Using spin-echo-like error suppression at optimal regimes, gate infidelities \( 10^{-2} \)-\( 10^{-3} \) can be achieved. For entangling preparation, one uses designated resonators to perform joint n-qubit quantum measurements with entangling times of 10s of ns, exploring both longitudinal and dispersive-like curvature couplings. The proposed schemes seem suitable for remote spin-to-spin entanglement.

3:30PM D17.00004: Far-detuned two-qubit operation of the quantum-dot hybrid qubit coupled to a microwave resonator

JOSE CARLOS ABADILLO-URIEL (Presenter), CAMERON KING, University of Wisconsin - Madison, SUSAN NAN COPPERSMITH, University of New South Wales, MARK G FRIESEN, University of Wisconsin - Madison — The quantum-dot hybrid qubit has a natural spin-charge hybridization that provides an electric dipole that can be used to perform EDSR or to couple the qubit to cavity photons. This electric-dipole moment is maximized in the charge-like regime, at small detuning, and it is reduced by going to the far-detuned regime. In this latter regime, the qubit behaves as a spin qubit, with good coherence properties, yet with a small dipolar moment.

In this work, we explore this far-detuned regime. The control parameters of the quantum-dot hybrid qubit can be adjusted to form a sweet spot in the far-detuned regime, increasing the qubit coherence times enough to allow operation with a small dipolar moment. At this sweet spot, the qubit can be strongly coupled to a superconducting resonator, allowing two-qubit gates to be performed. We find that the optimal operation of two-qubit gates, in terms of gate speed and experimental feasibility, is obtained by exploiting sideband transitions, achieving a 99% two-qubit gate fidelity in the best case.
3:42PM D17.00005: Coherent transport of spin by adiabatic passage in quantum dot arrays*

MICHAEL GULLANS (Presenter), JASON PETTA, Princeton University — The coherent transport of spin in arrays of quantum dots is important for distributing quantum information, or realizing more efficient spin-readout, across the array. A natural strategy to achieve charge transport in quantum dot arrays is known as coherent transport by adiabatic passage (CTAP). The simplicity of this method motivates the search for spin-based analogs of CTAP (spin-CTAP) that may allow robust spin transport. We develop the theoretical framework of spin-CTAP using the Heisenberg exchange interaction in a linear array of quantum dots. Applying an AC exchange modulation according to CTAP pulse sequences allows adiabatic spin-transfer across arbitrarily large arrays of dots. By choosing a staggered static exchange profile, we can ensure that only certain spin configurations realize the transfer protocol across the array, while other states are blocked from spin-CTAP. We show how to use this feature to generate arbitrarily large Greenberger-Horne-Zeilinger (GHZ) states in the system. Our transfer and entanglement generation protocols are immediately applicable to current experiments in quantum dot arrays.

3:54PM D17.00006: Robust two-qubit entangling gates using shaped pulses in silicon double quantum dots*

UTKAN GUNGORDU (Presenter), JASON PAUL KESTNER, Univ of Maryland-Baltimore County — Addressibility of spin qubits in a silicon double quantum dot setup in the (1,1) charge configuration relies on the difference between Zeeman splittings of electrons. When the difference is not sufficiently large, rotating wave approximation breaks down. We consider a device working in this regime, with always-on exchange coupling, and describe how a CZ gate and arbitrary one-qubit gates which are robust against charge noise can be implemented by smoothly pulsing the microwave source, while eliminating the crosstalk stroboscopically. We find that the correction required to compensate the most significant errors due to rotating-wave approximation, which is analogous to Bloch-Siegert shift in two-level systems, can be implemented by using virtual local gates.

*This research was sponsored by the Army Research Office (ARO), and was accomplished under Grant Number W911NF-17-1-0287.

4:06PM D17.00007: Democratizing Spin Qubits

CHARLES TAHAN (Presenter), Laboratory for Physical Sciences — I've been building Powerpoint-based quantum computers with electron spins in silicon for 19 years. Unfortunately, real-life-based quantum dot quantum computers are harder to implement. Fabrication, control, and materials challenges abound. The way to accelerate discovery is to make and measure more qubits. Here, I discuss separating the qubit realization and testing circuitry from the materials science and on-chip fabrication that will ultimately be necessary. This approach should allow us, in the shorter term, to characterize wafers non-invasively for their qubit-relevant properties, to make small qubit systems on various different materials with little extra cost, and even to test spin-qubit to superconducting cavity entanglement protocols where the best possible cavity quality is preserved. Such a testbed can advance the materials science of semiconductor quantum information devices and even enable small quantum computers.
4:18PM D17.00008: Fabrication and Measurement of Arrays of Few-Donor Quantum Dots

RICK SILVER (Presenter), XIQIAO WANG, RANJIT KASHID, ALBERT RIGOSI, JONATHAN WYRICK, FAN FEI, PRADEEP NAMBOODIRI, National Institute of Standards and Technology — NIST is using atomically precise fabrication to develop electronic devices for use in quantum information processing and quantum materials research. We are using hydrogen-based scanning probe lithography (STM) to enable deterministic placement of individual dopant atoms with atomically aligned contacts and gates to fabricate single and few atom transistors, as well as coupled few donor/quantum dot devices for spin and charge readout.

Here, we extend the STM-patterning method to fabricate coupled arrays of few atom clusters having multiple donors per dot, including a functional 3×3 quantum dot array device. Using the Si(100)2×1 surface reconstruction lattices as a natural atomic ruler, we designed the separation between a dot and its nearest neighbor dots or source/drain leads to span the regime from weakly coupled to strongly coupled ~ 5 to 8 nm separation. Low-temperature transport measurements are used to investigate the electron levels and energy spectra formed in individual dots versus energy spectra across the array of dots that result from the hybridization of quantum states. Combining electrical measurement results with simulations, we analyze the tunnel and capacitance couplings within this device to explore the rich physics in dot-arrays.

*Funded by a DOE grant.

4:30PM D17.00009: Realizing Discrete Time Crystals in Quantum Dot Spin Arrays with Magnetic Field Gradients

BIKUN LI (Presenter), JOHN VAN DYKE, ADA WARREN, SOPHIA E. ECONOMOU, EDWIN BARNES, Virginia Tech — A discrete time crystal is a non-equilibrium phase of matter that arises from a combination of interactions, disorder, and periodic driving. Previous work showed that it is possible to realize this phase in quantum dot spin arrays with nearest-neighbor exchange interactions if the number of pulses per period is substantially increased. Here, we show that the same result can be achieved using a magnetic field gradient instead of additional pulses, significantly reducing the demands on experimental capabilities. Numerical simulations of the return probability and mutual information confirm the time crystalline structure, which survives over a broad range of parameters and perturbations. In addition, we derive a stroboscopic effective Hamiltonian that provides further insight into the nature of this phase and the quantum state preservation properties it features.

*This work is supported by DARPA Grant No. D18AC00025.
4:42PM D17.00010: Exploring Many-body Localization in Quantum Dot Systems* BIKUN LI, JOHN VAN DYKE (Presenter), ADA WARREN, SOPHIA ECONOMOU, EDWIN BARNES, Physics, Virginia Tech — Recent experimental progress in the design and control of quantum dot arrays has opened new possibilities for studying one-dimensional spin chains within a highly tunable platform. We theoretically investigate the realization of many-body localized phases in a quantum dot system, the latter naturally yielding the nearest-neighbor Heisenberg model subject to a magnetic field gradient. We demonstrate how strong gradients take the Heisenberg model into an effective Ising Hamiltonian, and calculate various experimental and theoretical signatures of many-body localization in these systems. These include the quantum Fisher information and energy absorption, which are shown to agree with other metrics recently discussed in the literature. Our results indicate that gate-defined quantum dots provide a promising platform on which to explore many-body localization and related phenomena such as discrete time crystal phases in a controlled setting.

*This work is supported by DARPA Grant No. D18AC00025.

4:54PM D17.00011: Fine-tuning electron entanglement in two-dimensional artificial atoms DUNG N PHAM (Presenter), SATHWIK BHARADWAJ, Department of Physics, Worcester Polytechnic Institute, Worcester, MA, L RAMDAS RAM-MOHAN, Department of Physics, Electrical & Computer Engineering, and Mechanical Engineering, Worcester Polytechnic Institute, Worcester, MA — The spatial correlation of few electrons confined in semiconductor quantum dots is of great interest for realizing solid state quantum computing devices. Tunability of inter-electron interaction in quantum dots through geometrical manipulations, and external fields facilitates an enhanced level of control of their electronic properties. To this end, there have been several proposals to define deterministic teleportation protocols for quantum information processing using these artificial atoms. However, for all application purposes it is important to fabricate devices operating at resonant entanglement values. Here, we develop an action integral formalism in coordinate space for solving few-particle wavefunctions in arbitrary confinements. We obtain the spatial entanglement values for a wide range of two-dimensional quantum dots with varying potentials. Spectroscopy of two-electron entanglement reveals several novel phenomena such as entanglement resonances due to anti-crossings of excited states, and electron cluster formation. We further investigate the dependence of entanglement on external electric and magnetic fields and discuss the fine-tuning of electron correlation for useful quantum processes.
Operating four singlet-triplet qubits in a two-dimensional array of GaAs dots

FEDERICO FEDELE (Presenter), ANASUA CHATTERJEE, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark., SAEED FALLAHI, GEOFF C GARDNER, MICHAEL MANFRA, Department of Physics and Astronomy, Microsoft Quantum Purdue, Birck Nanotechnology Center, Purdue University, West Lafayette, Indiana 47907, USA, FERDINAND KUEMMETH, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark. — Building small-scale spin-based quantum processors requires the ability to perform simultaneous, fast measurements in single- and two-dimensional qubit arrays, as well as overcome challenges like gate crosstalk, tuning in large parameter spaces, and pulse calibration. Here we present the simultaneous coherent manipulation and readout of a two-by-two singlet-triplet qubit array in GaAs, with a large multielectron dot coupler at the center. Using four independent charge-sensors read out via a frequency-multiplexed RF-reflectometry setup, we show coherent exchange oscillations, concurrently monitor the Overhauser field at the four sites of the array, and interlace different pulse operations. Finally, we establish a coherent exchange coupling between one qubit and the central multi-electron dot coupler, suggesting its use as a mechanism to provide on-demand connectivity within the array.

Session D18 GSNP: Flow of Dense Granular Materials and Suspension

205 - Jeremy Lechman, Sandia National Laboratories - Tag(s): Invited
Dense suspensions of hard particles in a simple liquid have become a model system in the soft condensed matter, granular materials, and rheology communities for the investigation of strongly non-Newtonian behaviors. A key aspect underlying the recent surge of activity has been the realization that, in addition to hydrodynamic interactions, frictional contact between particles can occur. In fact, friction forces were found to be essential in order to explain some of the most striking phenomena observed, such as an abrupt, essentially discontinuous onset of shear thickening, whereby the viscosity can jump up by over an order of magnitude as a critical shear rate is exceeded. So far, however, friction has typically been modelled as a parameter without considering its origin. Furthermore, a focus on the steady-state response has prevented most models from capturing transient phenomena, most notably the propagating jamming fronts associated with the transition from a shear-thickened to a solid-like, shear jammed state. Thus, there remain fundamental questions both at the nano-scale about the nature of the frictional interactions, and at the macro-scale about the relation between steady-state and transient dynamic phenomena.

This talk will discuss recent experiments and simulations that address these questions, focusing on the differences between discontinuous shear thickening (DST) and shear jamming (SJ). In particular, I will show how controlling the particles' shape, their surface chemistry, and the suspending solvent opens up new opportunities for designing the dynamic stress response of dense suspensions as they transform into a shear jammed state.

3:06PM D18.00002: Investigating viscous to inertial transitions in granular suspensions with internal imaging* [Invited] ARSHAD KUDROLLI (Presenter), Clark University — We discuss experiments that probe the rheology of fluid-saturated granular beds coupled with the micromechanics of their flow using refractive index matching (RIM) techniques. These studies are fundamental to problems of erosion, sedimentation, and biolocomotion in such mediums. We will first discuss a sedimented bed which is sheared in a conical rheometer geometry which allows us to examine the system over prolonged periods under steady driving conditions. The shear experienced as a function of prescribed shear rate can be measured in this system along with the motion of the granular phase and the fluid phase. This allows us to determine the granular and fluid component of shear above and below the bed. We demonstrate that the appropriate control variable for the onset of bed motion with increasing shear is in fact the granular packing of the bed rather than the strength or the duration of the applied shear. Then, we show that the velocity profile of the suspended phase which develops between the clear fluid phase on top and a dense creeping granular bed below can be obtained from the applied strain rate and the Krieger-Dougherty model for the effective viscosity. We shall also discuss the drag and the unsteady flow of the medium resulting from the motion of a large solid intruder through the medium. The differences in the flow and drag encountered versus those observed in a viscous fluid and in dry granular media will be discussed going from the frictional to the inertial regime. We will highlight the difficulties encountered in interpreting the encountered rheology simply in terms of inertial and viscous numbers even in cases where the grains are weakly sedimenting.

*Supported by NSF Grant CBET-1805398 and DOE Grant DE-FG02-13ER16401.

3:42PM D18.00003: Continuum modeling of flow and size-segregation in dense granular materials* [Invited] DAVID HENANN (Presenter), DAREN LIU, SHIHONG LI, HARKIRAT SINGH, Brown University — Dense granular systems that consist of particles of disparate size segregate based on size during flow, resulting in complex, coupled segregation and flow fields. In this talk, we study size-segregation phenomenology using discrete-element method simulations of dense, bidisperse particles and propose a continuum model for coupled size-segregation and flow in dense, bidisperse granular systems. In our discrete simulations, we consider four flow configurations: (1) gravity-driven flow down a long vertical chute, (2) annular shear flow, (3) gravity-driven flow down a rough, inclined surface, and (4) planar shear flow in the presence of gravity - all while varying system parameters, such as the flow rate, flow configuration size, fraction of large/small grains, and grain-size ratio. Selected discrete simulation data inform continuum constitutive equations for the relative flux of large and small particles. The segregation model accounts for two driving forces - shear-strain-rate-gradients and pressure-gradients. When coupled with the nonlocal granular fluidity model - a nonlocal continuum model for dense granular flow - we show that both flow fields and segregation dynamics may be simultaneously captured using the coupled, continuum model - across all considered flow configurations, driving conditions, and mixture properties.

Bedform dynamics: interaction, attraction and repulsion of dunes*

NATHALIE VRIEND (Presenter), KAROL A BACIK, Department of Applied Mathematics and Theoretical Physics, Univ of Cambridge, PAUL JARVIS, School of Earth and Environmental Sciences, University of Geneva — Bedforms are fascinating and captivating self-organising patterns; from wind-blown dunes on Earth and other planets to regular ripple patterns on riverbeds or coastal beaches. Loose sediment reorganizes when the aeolian (wind-driven) or aqueous (fluid-driven) forcing exceeds a critical value for mobilization of grains. The resulting sediment ripples can coarsen into larger-scale dunes. The migration speed of individual dunes depends inversely on their dimensions: the larger the dune, the slower it migrates.

Here, we present a unique, recirculating, laboratory experiment in which we create and trace aqueous dunes over long times. We examine the interaction between two dunes of different sizes, and present a phase space diagram with outcomes of the resulting interaction. Furthermore, we explore the feedback mechanism between a bedform and the flow providing the forcing, and identify a repulsion mechanism that ensures that bedforms do not coarsen without limit.

Granular materials are inherently heterogeneous, and it is therefore difficult to construct a continuum model that successfully spans all the way from creeping to well-developed flows. This deficiency has serious consequences for making predictions in geological and industrial flows, but also presents a very interesting challenge for physicists. Local rheologies, such as the $\mu(I)$ rheology, relate the local shear rate to the local stresses. However, they fail to describe creeping flows, non-trivial particle size scaling, and the influence of small vibrations on the flow. Recently, the development of nonlocal rheologies has made inroads into solving this problem by allowing the fluidity at any position in the flow to depend on a spatially-extended region. In my talk, I will describe several experiments on two-dimensional granular materials which bridge particle-scale, meso-scale, and continuum-scale approaches. We test the efficacy of local and nonlocal models for describing flows across various particle shapes, particle stiffness, packing fractions, shear rates, and geometries. Through a combination of photoelastic force measurements, boundary stress measurements, and particle-tracking, it is possible to both fully-characterize the flows and test the assumptions of nonlocal models. We find that a single set of material parameters is able to capture the rheology of a particular granular material under a variety of flow conditions. Our measurements confirm the prediction that there is a growing lengthscale at a finite yield stress ratio associated with a frictional yield criterion. Finally, we observe rearrangements of the force network extending into quasi-static regions of the flow where shear rates vanish, and propose connections between their dynamics and the mechanisms responsible for nonlocal behaviors.

Monday, March 2, 2020 2:30 PM - 5:30 PM

Session D19 GMAG: Topological Spintronics using Chiral Antiferromagnets

2:30PM D19.00001: Physics of domains and domain walls in topological magnets* [Invited]
LEON BALENTS (Presenter), University of California, Santa Barbara — We will discuss the energetics and dynamics of domains and the boundaries between them in two examples of topological magnets: antiferromagnetic Weyl metals, as exemplified by Mn3Sn, and quantum anomalous Hall states as is observed in twisted bilayer graphene. The two cases will be distinctly contrasted and compared, and implications for experiments outlined.

*The work on Mn3Sn was supported by the NSF CMMT program under Grants No. DMR1818533, and that on QAHE by the DOE, Office of Science, Basic Energy Sciences under Award No. DE-FG02-08ER46524.
3:06PM D19.00002: Large magneto-optical Kerr effect in the non-collinear antiferromagnetic metal Mn₃Sn [invited]  TOMOYA HIGO (Presenter), ISSP, University of Tokyo, HUIYUAN MAN, Department of Physics and Astronomy, Johns Hopkins University, DANIEL B GOPMAN, National Institute of Standards and Technology, LIANG WU, Department of Physics and Astronomy, University of Pennsylvania, TAKASHI KORETUME, Department of Physics, Tohoku University, OLAF M VAN T ERVE, United States Naval Research Laboratory, YURY KABANOV, National Institute of Standards and Technology, DYLAN REES, Department of Physics, University of California, Berkeley, YUFAN LI, Department of Physics and Astronomy, Johns Hopkins University, MICHI-TO SUZUKI, Institute for Materials Research, Tohoku University, SHREYAS PATANKAR, Department of Physics, University of California, Berkeley, MUHAMMAD IKHLAS, ISSP, University of Tokyo, CHIA-LING CHIEN, Department of Physics and Astronomy, Johns Hopkins University, RYOTARO ARITA, RIKEN-CEMS, ROBERT D SHULL, National Institute of Standards and Technology, JOSEPH ORENSTEIN, Department of Physics, University of California, Berkeley, SATORU NAKATSUJI, Department of Physics, University of Tokyo — There has been a surge of interest in antiferromagnetic (AF) materials due to their favorable properties for device applications including a vanishingly small stray field, faster spin dynamics, and more abundance in nature compared to their ferromagnetic counterparts. In fact, motivated by these intriguing properties, several breakthroughs have been made: an anisotropic magnetoresistance (even-function response under time-reversal (TR)) for detecting collinear AF ordering [1]. Another breakthrough is an odd-function response under TR in the non-collinear antiferromagnetic metal Mn₃Sn such as an anomalous Hall effect (AHE) [2] and anomalous Nernst effect (ANE) [3] at zero magnetic field. Moreover, recent studies have revealed that Mn₃Sn is a TR symmetry breaking Weyl metal possessing a large and controllable Berry curvature in momentum space [4].

In this presentation, we will mainly talk about the magneto-optical properties of Mn₃Sn [5]. We found that despite a vanishingly small magnetization (~2 mμ₆/B/Mn), Mn₃Sn exhibits a large zero-field MOKE (~20 mdeg), comparable to that in ferromagnetic metals. Our first-principles calculation has clarified that the ferroic ordering of cluster magnetic octupoles in the AF state causes the MOKE even in its fully compensated AF state. This large MOKE further allows imaging of the octupole domains, which are strongly related to other TR-odd responses induced by the Berry curvature. We will also show that Mn₃Sn thin films exhibit the large time-reversal-odd response as well as the bulk Mn₃Sn [6]. These findings provide an important step for the further development of spintronics devices using AF materials.

Mn$_3$Sn exhibits a substantial anomalous Hall effect (AHE) at room temperature, the magnitude of which reaches almost the same order of magnitude as in ferromagnetic metals irrespective of a small spontaneous magnetization of about 1 mT [1]. This large AHE originates from a significantly enhanced Berry curvature associated with the formation of Weyl points near Fermi energy [2]. A detailed comparison between angle-resolved photoemission spectroscopy measurements and density functional theory calculations revealed significant bandwidth renormalization and damping effects due to the strong correlation among Mn 3d electrons. Magnetotransport measurements provide strong evidence for the chiral anomaly of Weyl fermions[3]. All the above characteristic electronic properties of Mn$_3$Sn imply that the spin Hall effect could also take place in the Mn$_3$Sn.

Our SHE experiments showed that the non-collinear antiferromagnet Mn$_3$Sn has richer spin Hall properties than non-magnetic materials, that is, the SHE has an unusual sign change when its triangularly ordered moments switch orientation. Our observations demonstrate that a novel type of contribution to the SHE (magnetic SHE) and the inverse SHE (MISHE) can be dominant in some magnetic materials, including antiferromagnets. We attribute this magnetic mechanism in Mn$_3$Sn to the momentum-dependent spin splitting produced by the non-collinear magnetic order [4]. This discovery further expands the horizons of antiferromagnet spintronics and motivates a universal outlook on spin-charge coupling mechanisms in spintronics.

Mn₃Ge* [Invited] JONATHAN GAUDET (Presenter), YOUZHE CHEN, SAYAK DASGUPTA, GUY G MARCUS, Johns Hopkins University, JIAO LIN, Neutron Scattering Division, Oak Ridge National Laboratory, YANG ZHAO, WANGCHUN CHEN, NIST Center for Neutron Research, National Institute of Standards and Technology, MATTHEW STONE, Neutron Scattering Division, Oak Ridge National Laboratory, MUHAMMAD IKHLAS, TAISHI CHEN, TAKAHIRO TOMITA, Institute for Solid State Physics, Univ of Tokyo-Kashiwanoha, OLEG TCHERNYSHYOV, Johns Hopkins University, SATORU NAKATSUJI, Institute for Solid State Physics, Univ of Tokyo-Kashiwanoha, COLLIN LESLIE BROHOLM, Johns Hopkins University — The kagome hexagonal compound Mn₃Ge is a room temperature non-collinear antiferromagnet with anomalous transport properties associated with electronic Weyl nodes near the chemical potential. The coupling of its electronic transports with magnetic order presents important technological opportunities for which, I will describe our experimental efforts to understand the magnetism of Mn₃Ge through neutron scattering techniques. Using polarized neutron diffraction, we show the magnetic order is a k=0 co-planar anti-chiral state with weak ferromagnetism described by a Γ₉ irreducible representation with magnetization remarkably aligned perpendicular to an applied field. Using time-of-flight neutron spectroscopy, we find three collective excitations above distinct Γ-point anisotropy gaps. These can be modeled as the normal modes of an anti-chiral triangular spin plaquette where an out-of-plane mode anti-crosses an optical phonon near 15-18 meV. Away from the zone center, magnetic excitations form a broad maximum near 75 meV with a half-width at half maximum of 25(5) meV indicative of itinerant magnetism. We develop a field theory of spin waves, which accurately describes the long wavelength magnetic properties, and use it to determine an effective low energy spin hamitonian for Mn₃Ge.

*This work was supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0019331. JG acknowledges support from the NSERC Postdoctoral Fellowship Program. CB and YC were supported by the Gordon and Betty Moore Foundation under GBM-4532.
Despite the significant academic interest in them and their richness in nature, antiferromagnets have always been overshadowed by ferromagnets in real-life applications based on magnetism or spintronics. This is primarily due to the fact that antiferromagnet order parameters, in contrast to the ferromagnetic magnetization, are only weakly coupled to magnetic fields, and are hence difficult, in conventional view, to be manipulated. In this talk I will discuss a number of recent theoretical and experimental developments that counter this conventional wisdom, in a class of antiferromagnets that have stable noncollinear magnetic order. I will first explain a theory for the recent experimental discovery of time-reversal-symmetry-breaking counterparts of the conventional SHE and ISHE in the noncollinear antiferromagnet Mn3Sn, which we name as the magnetic spin Hall effect (MSHE) and the magnetic inverse spin Hall effect (MISHE), respectively. Then I will discuss the concept of spin density polarization, and how to use it to describe spin-Hall effects in a magnetic insulator as bulk effects, without using the spin current language. The talk will end with an exploration on the nontrivial orbital coupling between chiral antiferromagnets and external magnetic fields.

Session D20 DBIO GSNP: Physics of Social Interactions 301 - Orit Peleg, University of Colorado, Boulder - Tag(s): Focus, Undergrad Friendly
2:30PM D20.00001: Collective Behavior in Growth-Driven Systems* [Invited] YASMINE MEROZ (Presenter), Tel Aviv University — A variety of biological systems are not motile, but sessile in nature, relying on growth as the main driver of their movement. Groups of such growing organisms can form complex structures, such as the functional architecture of growing axons, or the adaptive structure of plant root systems. These processes are not yet understood, however the decentralized growth dynamics bear similarities to the collective behavior observed in groups of motile organisms, such as flocks of birds or schools of fish. Equivalent growth mechanisms make these systems amenable to a theoretical framework inspired by tropic responses of plants, where growth is considered implicitly as the driver of the observed bending towards a stimulus. Here we set the stage for the study of emergent growth-driven structures by developing a model for interacting growth-driven organs. Particularly, we analytically and numerically investigate the 2D dynamics of pairs of organs interacting via allotropism, i.e. each organ senses signals emitted at the tip of their neighbor and responds accordingly. In the case of local sensing we find a rich state space.

3:06PM D20.00002: Collective Aggregation via Directed Pheromone Signaling in Honeybee Swarms DIEU MY NGUYEN, MICHAEL IUZZOLINO, AARON MANKEL, ORIT PELEG (Presenter), University of Colorado, Boulder — While pheromones are a prevalent volatile communication signal in nature, the range and noise tolerance of information exchange is limited by the spatiotemporal decay of these signals. Using honeybees as a model organism, we study the communication network of honeybee swarms that locate their queen by tracking her pheromones. Specifically, how can honeybees that are far away from the queen locate her? Our results suggest that bees who locate her pheromones, stop at a certain distance from her, raise their abdomens and fan their wings, driving airflow across the Nasonov gland, which disperses pheromones to the rest of the swarm. We show that bees arrange in a specific spatial distribution with a characteristic distance between individuals and a characteristic direction in which individuals broadcast the signal. This dynamic structure recruits new broadcasting bees over time as the pheromones traveled a distance which is orders of magnitude the size of an individual. We connect our experimental results to an agent based model of volatile communication network, and characterize the advantage of this directional communication strategy vs. an axisymmetric one.
3:18PM D20.00003: Social context alters behavioral interactions in bumblebees  GRACE MCKENZIE-SMITH (Presenter), YAN WANG, JEAN CHO, TALMO PEREIRA, SARAH KOCHER, JOSHUA SHAEVITZ, Princeton University — Bumblebees are eusocial insects that rely on successful cooperation to carry out collective tasks which keep the colony running smoothly. Individual bumblebees must be able to correctly interpret and respond to social cues within a busy hive in order to properly fulfill their role. In this study, we investigate how social context alters behavioral interactions among bumblebee (*Bombus impatiens*) workers by probing the behavior of differently aged bees either alone or paired with another bee. We track the posture of bees over time using a deep learning algorithm and quantify variation in social behavior by clustering the dynamics of individual body parts in addition to relative positioning, bee-to-bee antennation, and locomotion. We find a number of interesting differences between bees of different ages and castes, including variation in the responsiveness of individual bees to novel social partners.

3:30PM D20.00004: Brownian motion of fire ants hinders raft formation  HUNGTANG KO (Presenter), DAVID HU, Georgia Inst of Tech — When flooded, fire ants aggregate and form rafts to avoid drowning. Finding neighbors and attaching to them is a critical first step for raft formation. In this study, we observe individual fire ants perform random walk on the water surface. We characterize this exploratory behavior by measuring the orientational and translational diffusivity. Brownian motion of fire ants can be considered as thermal fluctuations which in turn inhibit the assembly of small rafts. Our results suggest that this repulsive mechanism is balanced by the attractive surface tension effect in the formations of larger rafts.

3:42PM D20.00005: Behavioral plasticity in jackdaw flocks  NICHOLAS OUELLETTE (Presenter), Stanford Univ, HANGJIAN LING, University of Massachusetts, Dartmouth, GUILLAM E MCIVOR, JOSEPH WESTLEY, University of Exeter, KASPER VAN DER VAART, Stanford Univ, RICHARD T VAUGHAN, Simon Fraser University, ALEX THORNTON, University of Exeter — Bird flocks are a classic example of collective behavior, where the cohesive motion of the flock as a whole is presumed to arise purely from local interactions. Flocking models tend to assume that every individual is an identical agent that plays by the same rules, and these rules are usually assumed to be immutable. In reality, however, interactions may be influenced by many factors, such as external stimuli and social relationships. I will present evidence from field studies of jackdaws, a highly social corvid species, that indeed flocks of this single species display different interaction rules in different ecological contexts. During the roosting season, large flocks spontaneously form in the evening as the birds return to their roosts. In these transit flocks, individual jackdaws interact topologically with a fixed number of their neighbors. Jackdaws also gather together in mobbing flocks to drive away predators, and such flocks can be induced experimentally using a model predator and playbacks of scolding and recruitment calls. In these mobbing flocks, jackdaws interact metrically over a fixed physical distance. This change in interaction type leads to a clear ordering phase transition as a function of group density in mobbing flocks that is absent in transit flocks.
3:54PM D20.00006: Shared behavioral mechanisms underlie *C. elegans* aggregation and swarming* SERENA DING (Presenter), Imperial College London, LINUS SCHUMACHER, University of Edinburgh, AVELINO JAVER, University of Oxford, ROBERT G ENDRES, ANDRE BROWN, Imperial College London — In complex biological systems, simple individual-level behavioral rules can give rise to emergent group-level behavior. While collective behavior has been well studied in cells and larger organisms, the mesoscopic scale is less understood, as it is unclear which sensory inputs and physical processes matter a priori. Here, we investigate collective feeding in the roundworm *C. elegans* at this intermediate scale, using quantitative phenotyping and agent-based modeling to identify behavioral rules underlying both aggregation and swarming—a dynamic phenotype only observed at longer timescales. Using fluorescence multi-worm tracking, we quantify aggregation in terms of individual dynamics and population-level statistics. Then we use agent-based simulations and approximate Bayesian inference to identify three key behavioral rules for aggregation: cluster-edge reversals, a density-dependent switch between crawling speeds, and taxis towards neighboring worms. Our simulations suggest that swarming is simply driven by local food depletion but otherwise employs the same behavioral mechanisms as the initial aggregation. We further expand our work by examining swarming at very high densities.

*BBSRC grant to AEXB and RGE (BB/N00065X/1); MRC grant to AEXB (MC-A658-5TY30).

4:06PM D20.00007: Predicting residential segregation using statistical physics approaches* YUCHAO CHEN (Presenter), Physics, Cornell University, YUNUS A KINKHABWALA, Applied and Engineering Physics, Cornell University, MALLORY GASPARD, Center for Applied Mathematics, Cornell University, MATTHEW HALL, Policy Analysis and Management, Cornell University, TOMAS ALBERTO ARIAS, ITAI COHEN, Physics, Cornell University — We introduce a statistical physics based method to predict racial residential segregation in human populations. Such predictions are increasingly important for informing policy decisions as human populations become more diverse and mobile. Here, we demonstrate how to make such predictions by extending a novel statistical physics approach called Density-Functional Fluctuation Theory (DFFT) to multi-component time-dependent systems. This technique uses observations of fluctuations in the local density of neighborhood racial composition to extract functions that separately quantify social and spatial preferences/constraints to predict demographic changes. As a demonstration, we simulate a population distribution using a Schelling-type segregation model, and use DFFT to predict both steady-state probability distributions and migration events after changes in the environment, social interactions, or number of individuals. Should these results extend to actual human populations, DFFT could be applied to demographic data to quantify segregation between different groups of people and predict how such populations will respond to proposed demographic changes.

4:18PM D20.00008: Leader cells in collective chemotaxis: optimality and trade-offs
AUSTIN HOPKINS, BRIAN CAMLEY (Presenter), Johns Hopkins University — Clusters of cells can work together in order to follow a signal gradient, chemotaxing even when single cells do not. This behavior is robust over many cell types and many signals. Cells in different regions of migrating streams show different gene expression, suggesting cells specialize to leader and follower roles in collective chemotaxis. We use a simple mathematical model to find when specialization would be advantageous. In our model, leader cells sense the gradient with an accuracy that depends on the kinetics of ligand-receptor binding while follower cells attempt to follow the cluster's direction with a finite error. Intuitively, specialization into leaders and followers should be optimal when a few cells have much more information than the rest of the cluster, such as in the presence of a sharp transition from one chemical concentration to another. We do find this - but also find that high levels of specialization can be optimal in the opposite limit of a very shallow gradient. There is also an important tradeoff: clusters have to choose between speed in following a gradient and ability to reorient quickly.

*We acknowledge an IDIES Seed Grant and computational resources from the Maryland Advanced Research Computing Center.

4:30PM D20.00009: One fish, two fish, win fish, lose fish: Imaging and analyzing the fighting behavior of zebrafish in 3D
LIAM O'SHAUGHNESSY (Presenter), Vrije Univ (Free Univ), TATSUO IZAWA, Biological Physics Theory Unit, OIST Graduate University, ICHIRO MASAI, Developmental Neurobiology Unit, OIST Graduate University, JOSHUA SHAEVITZ, Physics and the Lewis-Sigler Institute, Princeton University, GREG STEPHENS, Vrije Univ (Free Univ) — Social interactions represent some of the most intriguing aspects of animal behavior, yet principled methods for quantifying the joint actions of two individuals are lacking. We detail a novel effort to measure and model social behavior in the 3D swimming dynamics of the adult zebrafish, Danio rerio. We describe a custom tracking apparatus consisting of multiple fast cameras, a large imaging volume, and a transparent interior cage to avoid reflection artifacts. We leverage advances in convolutional neural networks to develop 3D markerless bodypoint tracking of interacting fish, while maintaining organism identity. We focus on small groups, below any obvious collective limit, yet with a rich repertoire of interacting behaviors. Specifically, we examine stereotyped male-male fighting behaviors and analyze the dynamics using short segments of bodypoint configurations to identify ethological motifs directly from tracked data. We quantify longer-time dynamics as transitions between motifs, and we repeat our analysis in mutant fish with known social deficits.

*Project supported from the Human Frontier Science Program and OIST Graduate University. JWS was supported in part by the National Science Foundation, through the Center for the Physics of Biological Function (PHY-1734030).
4:42PM D20.00010: A Foraging Approach to Analyzing Infant and Caregiver Vocal Behavior
RITWIKA VALLOMPARAMBATH PANIKKASSERYSU (Presenter), GINA M. PRETZER, SARA MENDOZA, CHRISTOPHER SHERIDDE, CHRISTOPHER T. KELLO, AJAY GOPINATHAN, University of California, Merced, ANNE S. WARLAUMONT, University of California, Los Angeles — Previous research on infant vocal development suggests that human infants and adult caregivers search for sounds that have social value. We hypothesized that this could be a foraging process in a high-dimensional acoustic space where the resources are adapting to the forager's behavior. We studied day-long recordings of vocalizations in a naturalistic setting over the infants’ first year. We examined inter-vocalization time intervals and distance steps in an acoustic space defined by mean pitch and mean amplitude. Infant inter-vocalization intervals were shorter immediately following a vocal response from an adult. Adult intervals were shorter following an infant response and adult inter-vocalization pitch differences were smaller following the receipt of a vocal response from the infant. These findings are consistent with the hypothesis that infants forage vocally for social input. Increasing infant age was associated with changes in adult and infant inter-vocalization step sizes. The study represents a novel application of foraging theory to characterize infant-caregiver vocal interactions by assessing vocal exploration in terms of patterns of movement in acoustic space, which will allow this domain of behavior to be compared to other foraging behaviors.

4:54PM D20.00011: The Superorganism’s Circulatory System: Collective control of development through a socially exchanged fluid* [Invited] ADRIA C LEBOEUF (Presenter), Department of Biology, University of Fribourg — How can a distributed system like a social insect colony collectively decide how to allocate resources and mature over the long-term? Many but not all species of social insects engage in the social fluid exchange of trophallaxis. In species that perform ample trophallaxis, each individual within the colony is connected through the trophallactic network, including larvae. In carpenter ants, we’ve shown that components of trophallactic fluid can influence larval development, regulating the number of new adults produced. Furthermore, we find that some trophallactic fluid proteins have been co-opted from typical insect developmental pathways: as these proteins have become abundant in this social fluid, they show increasing signatures of adaptation such as repeated duplications and positive selection. Recent advances using long-term fluorescence imaging reveal how the content and timing of larval feeding through trophallaxis controls growth and developmental timing. Thus, in species that engage in this behavior, trophallaxis and trophallactic fluid present a means by which adults can regulate larval development according to the needs of the colony.

Session D21 GERA: Probing and Manipulating Energy Related Materials 302
2:30PM D21.00001: Stanford R. Ovshinsky Sustainable Energy Fellowship award talk: 
**Structural Evolution of Nickel Thiophosphate Electrode Materials** [Invited] VICKY DOAN-NGUYEN (Presenter), Ohio State University — Transition metal phosphorus trichalcogenides have demonstrated to be promising electrodes in secondary Li-ion batteries with relatively high initial gravimetric capacity, and NiPS3 is in class of materials [1]. With C2/m symmetry, layers consist of edge-sharing Ni–S octahedra with a third of the Ni sites substituted with phosphorus dimers. NiPS3 has a theoretical capacity of 865 mAh/g corresponding to 6 mol of Li ions. The dual mechanisms of Li insertion/extraction and conversion are not well understood and is of interest due to the potential for high capacity relative to that of intercalation–based host materials. To better advance our understanding of the chemical and structural changes that contribute to capacity fade and irreversibly trapping Li ions, we employ the pair distribution functions technique and density functional theory to investigate the local structure evolution of the parent layered structure of NiPS3. The intercalation mechanism of Li ions shows decreased capacity fade within an operating voltage window of 1.0 V - 3.5 V vs. Li/Li+, depending on mass loading. [1] R. Brec, D. M. Schleich, G. Ouvrard, A. Louisy, and J. Rouxel, Inorg. Chem. 18, 1814 (1979).

MICHAEL BERKOWITZ (Presenter), ALEXANDER MCLEOD, WILLIAM J ZHENG, LEO LO, DMITRI BASOV, Columbia Univ — Plasmonics is one of the most exciting and rapidly developing fields in the broad category of nanostructure engineering and plasmon polaritons offer a unique window into physics occurring at the nanoscale. As such, the ability to analytically predict and simulate both the dispersion and real-space propagation of plasmons in materials and fabricated nanostructures is of great interest to condensed matter physicists. There have recently been important strides in the field of simulating the aforementioned dispersion using the near-field response of materials [1] as well as the optical constants of the layers of layered heterostructures [2] to construct their P-polarized reflectivity and, consequently, the plasmonic dispersion relation. Here, we present a computationally efficient implementation of a generalized spectral method [3] for the simulation of the real-space propagation and interference of plasmons in the near-field for a material or heterostructure with a given set of optical constants and geometry.

3:18PM D21.00003: Identifying Local Variations in PV Material Properties via EBIC using In-Situ Light and Voltage Bias*  SEAN JONES (Presenter), Colorado School of Mines, HARVEY L GUTHREY, JOHN MOSELEY, NREL, BRIAN GORMAN, Colorado School of Mines — Understanding the relationship between microstructure and excess charge carrier collection is key to the improvement of photovoltaic devices. Electron Beam Induced Current (EBIC) is a technique which creates a high-resolution spatial map of this excess charge carrier collection; however, it can be difficult to interpret due to the complex local variations in structure and chemistry characteristic of thin film devices. In this work we exploit the response of a CdTe device to applied light and voltage bias during the EBIC measurement in order to extract parameters related to the cause of collection variations in the EBIC map, namely local doping density and built-in potential of the p-n junction. Our results indicate that these parameters can vary from grain to grain within the polycrystalline film and can strongly impact grain boundary recombination behavior as well as overall collection profiles. In addition to a discussion of the physics associated with this measurement, we also use our results as input to a PV device model to estimate the impact of local variation on device performance.

3:30PM D21.00004: The improvement of carbon quantum dots on the manganese-nickel phosphide for electrocatalytic hydrogen evolution reaction*  WEIWU CHEN (Presenter), ZHAOJUN QIN, ZHIMING M WANG, HAI-ZHI SONG, University of Electronic Science and Technology of China, ZHIFENG REN, University of Houston — Transition-metal phosphides are good electrocatalysts for hydrogen evolution reaction due to their high catalytic efficiency and low cost. Carbon quantum dots (CQDs) deposited on top of the surface could make the phosphides even better for HER by increasing the number of active sites and reducing the charge transfer resistance. Here we adopt a simple method to synthesize CQDs-modified manganese-nickel phosphide (CQDs/Mn\textsubscript{x}Ni\textsubscript{5-x}P\textsubscript{4}) for efficient and stable HER activity using inexpensive raw materials. In 0.5 M H\textsubscript{2}SO\textsubscript{4}, CQDs/Mn\textsubscript{x}Ni\textsubscript{5-x}P\textsubscript{4} requires a low overpotential of only 31 mV to achieve a current density of 10 mA cm\textsuperscript{-2}, as well as having a low Tafel slope of 41.0 mV dec\textsuperscript{-1}, a large exchange current density of 1.753 mA cm\textsuperscript{-2}, and good stability, making it comparable with the best transition-metal-based catalyst available. Moreover, CQDs/Mn\textsubscript{x}Ni\textsubscript{5-x}P\textsubscript{4} also displays high activity and stability in alkaline solution, revealing that the ancillary role played by CQDs could be beneficial in both acidic and alkaline conditions. Based on our results, we believe that CQDs have great potential to be applied to other materials with various morphologies and structures for designing high-performance HER catalysts.

Monolayer MoS$_2$ on TiO$_2$ nanorods for enhanced electrocatalytic hydrogen evolution reaction

ANH DUC NGUYEN (Presenter), THI HUE PHAM, TRI KHOA NGUYEN, YOUNG HAN SHIN, YONG SOO KIM, Physics, Univ of Ulsan — The core-shell nanostructures of TMDCs and another semiconductor has been attracted much attention due to high surface-to-volume ratio and excellent electrocatalytic hydrogen evolution reaction (HER). Furthermore, number of TMDCs layer is an important factor that remarkably have an influence on the catalytic activity, therein monolayer (ML) is basically requirement. Herein, we have fabricated 2D@1D nanostructure; core of TiO$_2$ nanorods and shell of monolayer MoS$_2$. Firstly, TiO$_2$ NRs was grown on graphite foil by hydrothermal method. Then, TiO$_2$ was conformally covered by ML MoS$_2$ using metal organic chemical vapor deposition. A density functional theory was used to investigate the influence of TiO$_2$ on hydrogen Gibbs free energy ($\Delta G_H$) of basal plane MoS$_2$. When ML MoS$_2$ composite with TiO$_2$, the $\Delta G_H$ is closer to 0 eV, indicating that basal plane of ML-MoS$_2$ become more catalytically effective for HER. The onset overpotential of 190 mV and Tafel slope of 102 mV/dec were obtained for this kind of hetero-structural, which are much lower than that of nanoscale pristine MoS$_2$, in agreement with theoretical simulation result.

Theoretical Study of Hydrogen storage with Ti doped B40 boron fullerene

PARAMITA HALDAR (Presenter), Birla Institute of Technology and Science — Hydrogen has been considered as one of the most promising energy carrier because of its abundance, cheap and environmental friendliness. It is necessary to develop high capacity hydrogen storage medium. Metal doping has been found to be an effective method to improve hydrogen adsorption ability. B40 fullerene has been considered as promising hydrogen storage material due to its large surface area. In this work hydrogen storage capacity with B40 fullerene doped with titanium (Ti) has been investigated by density functional theory. We have calculated the binding energies of Ti doped endohedrally and exohedrally at the hexagonal and heptagonal cavities. The binding energy calculation shows that the doping of Ti atoms outside the the hollow sites of the B40 structure is most stable. It is observed that the shape and stability of the B40 cage structure rapidly changes with increased number of doping atoms. HOMO-LUMO study predicts that the transport is mainly controlled by LUMO. 5 and 6 H$_2$ molecules are attached with Ti atoms on each hexagonal and heptagonal holes respectively. From the average hydrogen adsorption energies and nudged elastic band method study, it is observed that most of the interaction is physisorption with weak Vander Waals force interaction.
4:06PM D21.00007: Multi-technique characterization of atomic-layer-deposition-functionalized magnesium borohydride hydrogen storage materials  MARGARET FITZGERALD (Presenter), NOEMI LEICK, Colorado School of Mines, Golden, Colorado, KARL GROSS, H2Technology Consulting, LLC, Alamo, California, STEVEN CHRISTENSEN, National Renewable Energy Laboratory, Golden, Colorado, SVITLANA PYLYPENKO, Colorado School of Mines, Golden, Colorado — Hydrogen storage technologies are essential for the implementation of a cost-effective hydrogen economy. This talk focuses on novel, atomic layer deposition (ALD)-functionalized, magnesium borohydride (MBH) materials with the potential to store hydrogen at relatively low temperatures, moderate pressures, and energy densities greater than liquid or compressed hydrogen.¹ This ALD functionality shows improved hydrogen desorption from the neat MBH material, however the coating is not well understood. In order to better understand the mechanism of hydrogen adsorption and desorption with this coated MBH material, a thorough set of characterization techniques is needed, however the air- and beam- sensitivity of MBH materials present significant challenges. This talk defines these challenges and proposes potential solutions in order to conduct multi-scale, multi-technique characterization including ex-situ, identical location scanning transmission electron microscopy (STEM) and X-ray-spectroscopies. Combined with temperature programmed desorption (TPD), these studies reveal elusive interactions between the MBH materials and their coatings to further optimize the functionalization of MBH materials for hydrogen storage.

4:18PM D21.00008: Hydrogen permeation in V₇₅Fe₂₅ alloy investigated by in situ neutron diffraction* IN HWA CHO (Presenter), Dept. of Physics and Photon Science, Gwangju Institute of Science and Technology, YONG NAM CHOI, HEEJU LEE, Neutron Science Division, Korea Atomic Energy Research Institute, JAE-HYEOK SHIM, JIN-YOO SUH, Center for Energy Materials Research, Korea Institute of Science and Technology, HO JUN OH, SEONGHYUN HAN, DO YOUNG NOH, Dept. of Physics and Photon Science, Gwangju Institute of Science and Technology — in situ neutron diffraction measurements were carried out to investigate the hydrogen permeation path in V₇₅Fe₂₅ alloy. During heating under D₂, replacing H₂ to enhance neutron scattering length, the atmosphere at 3 bar, deuterium atoms began to permeate into V₇₅Fe₂₅ alloy at around 350 °C signified by the increased diffuse background signal. While the scattering feature of vanadium-iron solid solution in a BCC structure exhibits just a thermal expansion, a new Bragg peak corresponding to the α-V phase, in which deuterium atoms occupy tetrahedral interstitial sites of V randomly, appeared indicating that deuterium atoms are permeated to segregated vanadium clusters in V₇₅Fe₂₅ alloy. At room temperature, the hydrogen ordering in the vanadium clusters occurred, which is evidenced by a phase transition from α-V (cubic, solid solution) to β-V (monoclinic, hydride). Interestingly, we could conclude that additional hydrogen atoms occupy randomly octahedral sites surrounding ordered hydrogen atoms in the β-V of V₇₅Fe₂₅ alloy.

**4:30PM D21.00009: Extraordinary cycling stability of pristine nickel hexaaminobenzene MOF supercapacitors**

**FATIMA AMIR** (Presenter), **SEAN C WECHSLER**, Winthrop University —

Metal-organic frameworks (MOFs) are a newly emerging class of materials that have received enormous attention because of their unique features such as high surface area, rich microporosity, and tunable pores size. MOFs are very promising electrode materials for supercapacitors; however, the application of MOFs as supercapacitors electrodes has been hindered by their conventionally poor conductivity. To improve their conductivity, MOFs have been mixed with different conductive additives and binders. Very few pristine MOFs have been explored as electrodes materials for energy storage devices. Herein, we report for the first time the fabrication of pristine nickel hexaaminobenzene (Ni$_3$(HAB)$_2$) supercapacitors electrodes via electrophoretic deposition. The obtained MOF supercapacitor delivered an outstanding areal capacitance of 13.65 mF cm$^{-2}$ and an exceptional ultra-high cycling stability with a retention of about 81.2% after 50,000 cycles. Moreover, the Ni$_3$(HAB)$_2$ supercapacitors exhibited an excellent areal energy density of 920 μWh cm$^{-2}$ at an areal power density of 130 mW cm$^{-2}$.

**4:42PM D21.00010: Various Graphene-Based Composites For an Efficient and Durable Supercapacitor**

**DINESH SINGH** (Presenter), **LEONARDO VIVAS**, Department of Physics, University of Santiago Chile, **RAJESH KUMAR**, Department of Electrical and Electronic Information Engineering, Toyohashi University of Technology —

Recently invented graphene and its astounding properties, such as very high theoretical surface area, excellent thermal conductivity, superior mechanical properties, and ultra-high electron mobility have led it to explore its widespread applications in electronics, optics, biomedicine, energy harvesting and storage. Electrochemical double layer capacitor also called as Supercapacitors have attracted a great attention due to its fast charging, instant power delivery and ability to sustain millions of charge-discharge cycles at higher current densities. Graphene, having very high surface area is the most suitable candidate for the efficient energy storage and low cost of production is another benefit for widespread commercialization. Here we present the variety of graphene-based structures/composites and their applications as a high-performance supercapacitor. Various metals and transition metal oxides (such as Au, TiO$_2$, cobalt oxides and Ni encapsulated CNT etc.) based composites with graphene are synthesized by hydrothermal/microwave methods and their potential applications as a supercapacitor will be discussed and described.

*The support from the Millennium Institute for Research in Optics (MIRO) Chile is acknowledged.
**4:54PM D21.00011: High Performance Structural Electrochemical Double Layer Supercapacitors Using Graphene-Metal Nanoparticle-Polymer Composites**  
SHASHI P KARNA (Presenter), Weapons & Materials Research Directorate, APG, MD, 21005, CCDC Army Research Laboratory, ASHWINI K SRIVASTAVA, Department of Chemistry, Vidyanagari, Santacruz (E), Mumbai - 400098, India, University of Mumbai — Electrochemical double layer (ECDL) supercapacitors (SCs) offer a promising technology to address the ever-increasing demand on power and energy in modern technologies. Unlike batteries, which have high energy density, but low power densities, the SCs can provide very high power density, but generally have low energy density. This can, however, be surmounted by using Gr which can act as a high mobility electrode as well as efficient charge collector from the electrochemical double layer formed near its surface. Additionally, use of Gr as electrode material puts little or no penalty on weight and can be easily integrated in structural platform. Taking advantage of such novel properties of Gr, we have begun to develop Gr-Metal/metal oxide nanoparticle (MNP)-polymer (Poly) composite – based electrochemical super-capacitors. The resulting SCs, where Gr-MNP-Poly composite serves as the electrodes, charged through a capacitive double-layer mechanism, exhibit considerably high power density as well as energy density, not achievable by batteries. Results on the electrochemical properties of ECDL SCs formed with the use of Gr-PdNP, Gr-porous CuO, and Gr-AgNP and conducting polymer composites will be presented.

**5:06PM D21.00012: Tracking the capacitive energy storage process in layered MXene across length scales**  
PAUL KENT (Presenter), QIANG GAO, WEIWEI SUN, Oak Ridge National Lab, POORANDOKHT ILANI-KASHKOULI, Georgia State University, ALEXANDER TSELEV, University of Aveiro, NADINE KABENGI, Georgia State University, MICHAEL NAGUIB, Tulane University, MOHAMED ALHABEB, Drexel University, WAN-YU TSAI, ARTHUR BADDORF, JINGSONG HUANG, STEPHEN JESSE, Oak Ridge National Lab, YURY GOGOTSI, Drexel University, NINA BALKE, Oak Ridge National Lab — Intercalation of ions in layered materials forms the basis of electrochemical energy storage and conversion and is especially attractive due to the typically ultra-fast intercalation kinetics. Enhancing the energy stored and power delivered by these materials relies strongly on improved understanding of the intercalation chemistry of cations including the intricate interplay of cations, water, and electrode interactions as well as the role of confinement. Here we report a highly integrated study between experimental and modeling approaches to investigate the intercalation processes for aqueous Li⁺, Na⁺, K⁺, Cs⁺, Mg²⁺ into Ti₃C₂ MXenes. Experiments include microcalorimetry, atomic force microscopy and cyclic voltammetry whose results are directly linked to the results of ab initio modeling. Our integrated analysis allows for a complete understanding of energy storage processes highlighting the importance of the dynamics of cations and positionings and their role in capacitive energy storage properties. Our findings will expedite the evolutions of various energy related functional devices driven by the design of higher-performing membranes and two-dimensional materials.
By using a photonic curing system (PulseForge 1300, NovaCentrix), we have instantaneously synthesized manganese oxide thin films. Characterizations are done by using Scanning Electron Microscopy, X-ray Diffraction, and Raman Spectroscopy. Electrochemical characterization, i.e., cyclic voltammetry, charge-discharge cycling, and electrochemical impedance spectroscopy (EIS) were carried out in three-electrode cell configuration (where Hg-HgO, Pt-wire, and our sample are reference, counter and working electrodes respectively) with 1 M KOH as the electrolyte. The presence of redox peaks in cyclic voltammetry curves confirms the pseudocapacitive behavior of the sample while identical CV curves even at higher scan rates further suggest excellent rate capability and ideal supercapacitor behavior. The galvanostatic charge-discharge measurements (GCD) performed at 0.2 mA current resulted in initial specific capacitance as high as 11 mF/cm² for 2-pulses irradiated electrode. After performing GCD measurements for 100000 cycles, we found that the electrode retains as high as 89%, which shows that as prepared electrode possesses excellent stability and long lifetime.

Session D22 DBIO: Physics of Proteins: Peptides and Small Proteins 303 -

Wouter Hoff, Oklahoma State University-Stillwater - Tag(s): Focus
HAO DONG (Presenter), Kuang Yaming Honors School, Nanjing University — Molecular self-assembly provides a chemical strategy for the synthesis of nanostructures by using the principles of nature, and peptides serve as the promising building block to construct adaptable molecular architectures. Recently, a series of hepta-peptides with alternative hydrophobic and hydrophilic residues were reported to form amyloid-like structures, which were capable of catalyzing acyl ester hydrolysis with remarkable efficiency. However, it remains elusive about the atomic structures of the fibrils: what is the origin of the sequence-dependent catalytic activity? How does the ester hydrolysis catalyzed by the fibril? In this work, the atomic structure of the aggregates was determined by using molecular modelling and further validated by solid-state NMR experiments, where the fibril with high activity adopts twisted parallel configuration within each layer, and the one with low activity is in flat antiparallel configuration [1]. The polymorphism originates from the interactions between different regions of the building block peptides, where the delicate balance between rigidity and flexibility plays an important role. We further show that the p-nitrophenylacetate (pNPA) hydrolysis reactions catalyzed by two different fibrils follow similar mechanism, and the difference in microenvironment at the active site between the natural enzyme and the present self-assembled fibrils should accounts for the different catalytic activities. The present work provides atomic understanding of the structure and function of self-assembled fibrils formed with short-peptides, and thus sheds new insight on designing aggregates with better functions.

3:06PM D22.00002: Representation of the Conformational Ensemble of Peptides in Coarse Grained Simulations*  MEHMET SAYAR (Presenter), Koc University — Proteins/peptides can adopt to different environments by altering their conformation. Novel experimental techniques have enabled a quantitative characterization of this structural heterogeneity. In molecular dynamics simulations capturing this conformational ensemble quantitatively remains a major challenge. Even in atomistic simulations one has to find the best force field for the molecule of interest. With coarse grained (CG) simulations, where the aim is to reduce the degrees of freedom to reach the relevant length and time scales, representation of the conformational ensemble becomes even more problematic. Here, we revisit a recent CG model from our group, which was designed and tested for representing the aggregation driven conformational change of LKa14 peptide. We demonstrate here, that the structure/physics based approach used in the original parameterization of our CG model, strongly depends on the reference system chosen and excluded volume interactions. The updated model can recover the whole conformational ensemble in a quantitative manner, while maintaining the aggregation driven conformational transformation feature. This balanced parametrization leads to a sequence transferable CG model.

3:18PM D22.00003: Polarization of Intrinsically Disordered Proteins in the Presence of Charged Biopolymers: the Case of Tau Protein  ISABEL RUFFIN (Presenter), Physics, Duke University, CHRISTIAN APONTE-RIVERA, Mechanical Engineering and Materials Science, Duke University, MICHAEL RUBINSTEIN, Mechanical Engineering and Materials Science, Chemistry, Biomedical Engineering, Physics, Duke University — Tau protein is an intrinsically disordered protein known to be associated with the progression of neurodegenerative diseases. In cells, tau interacts with charged macromolecules, including high charge density polyanions such as RNA and microtubules. Although attraction between tau protein and negatively charged biopolymers is thought to play an important role in cell function, the mechanisms leading to attraction between tau protein and negatively charged biopolymers remain poorly understood. We study tau protein conformations and polarization using molecular dynamics simulations. First, we study the electrostatically driven collapse of tau protein, and connect the resulting conformation to features of its charge sequence. We then study how the conformations of tau protein change in the presence of a constant electric field and in the presence of a negatively charged biopolymer. With the latter, we quantify polarization induced attraction of tau protein to biopolymers. The implications of conformational changes of tau protein as it interacts with polyanions inside the cell will be discussed.
3:30PM D22.00004: Strategic incorporation of fluorinated prolines can lead to faster folding and stable proteins  AJAY MURALIDHARAN (Presenter), JR SCHMIDT, ARUN YETHIRAJ, University of Wisconsin - Madison — A single atom substitution in a proline residue of ribonuclease A can lead to accelerated folding into its 3D structure with increased thermostability. It has been suggested that this can be caused by stereo-electronic effects due to fluorination of amino acids. In this work we use quantum chemistry and QM/MM methods coupled with accelerated sampling to study the static and dynamic properties of proline containing peptides in water, with a focus on the effect of fluorination on the free energy surface and conformational properties. We compare the free energy surfaces of plain vs fluorinated dipeptides along the amide dihedral and the proline ring pucker reaction coordinates to examine the effect of fluorination. Finally, we characterize the important interactions in the system: namely intramolecular H-bonding, n -> pi* and gauche interactions in the presence of explicit solvent. We find that the experimental data can be understood from the change in the dihedral potential surface due to electronic structure differences due to fluorination. The impact of this on the conformational properties of peptides and self-assembly in solution is discussed.

3:42PM D22.00005: Low Temperature Protein Refolding Suggested by Molecular Simulation*  DANIEL KOZUCH (Presenter), Chemical and Biological Engineering, Princeton University, FRANK H. STILLINGER, Chemistry, Princeton University, PABLO GASTON DEBENEDETTI, Chemical and Biological Engineering, Princeton University — The function of critical biological materials, such as proteins, is intrinsically tied to their structure, and this structure is in turn heavily dependent on the properties of the solvent, most commonly water. As water is known to exhibit anomalous properties, especially at supercooled temperatures, it is natural to ask how these properties might impact the thermodynamics of protein folding. To investigate this question, we use molecular simulation to explore the behavior of a model protein, Trp-cage, as low as 70 K below the freezing point of the solvent. Surprisingly, we find that while the expected cold denaturation of the protein is observed at moderate supercooling, further cooling to more than 55 K below the freezing point leads to cold refolding of the protein. Structural and hydrogen bonding analysis suggests that this refolding is driven by desolvation of the protein’s hydrophobic core, likely related to the pronounced decrease in density at this temperature. Beyond their intrinsic fundamental interest, these results have implications for cryo-microscopy and cryo-preservation, where biological materials are often transiently subjected to these extreme conditions.

van der Waals Forces in Biomolecular Systems: from Solvation to Long-range Interaction Mechanisms

MARTIN STOEHR (Presenter), Physics and Materials Science Research Unit, University of Luxembourg, MATTEO GORI, PHILIP KURIAN, Quantum Biology Laboratory, Howard University, Washington, DC, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg — One decisive characteristic of the biomolecular machinery is the access to a rich set of coordinated processes within a small energy window. Most of these processes involve collective conformational changes and occur in an aqueous environment. Conformational changes of (bio)molecules as well as their interaction with water are thereby largely governed by non-covalent van der Waals (vdW) dispersion interactions. By virtue of their intrinsically collective nature, vdW forces also represent a key influence on collective nuclear behavior. Our understanding of vdW interactions in large-scale (bio)molecular systems, however, is still rather limited [Chem. Soc. Rev. 2019, 48, 4118]. Here, we employ the Many-Body Dispersion framework to investigate the vdW interaction in biomolecular systems and its spatial and spectral aspects. In particular, we show the role of beyond-pairwise vdW forces for protein stability and highlight the delocalized character of the protein-water vdW interaction. We further examine intermolecular electronic behaviors and reveal a coexistence of strong delocalization with spatially-separated yet correlated, local domains. This, ultimately, forms the basis for a potential, efficient long-range interaction mechanism for coordinated processes in biomolecular systems.

The Assessment of MD Force Fields with Respect to Alanine Conformations in Aqueous Solutions

SHUTING ZHANG (Presenter), Physics, Drexel Univ, REINHARD SCHWEITZER-STENNER, Chemistry, Drexel Univ, BRIGITA URBANC, Physics, Drexel Univ — The ability to reproduce conformational ensembles of the central alanine residue in GAG and AAA obtained from experimentally-derived φ- and ψ-dependent J coupling constants and amide I’ profiles is examined for six molecular dynamics (MD) force fields (Amber ff14SB, Amber ff99SBnmr1, Amber ff03ws, OPLS-AA/L, OPLS-AA/M, and CHARMM36). Compared to the empirical Gaussian model, which is constructed to best fit the experimental data, MD-derived Ramachandran plots produce overly constricted polyproline II (pPII) basin, an overpopulated antiparallel β basin, and an underpopulated transitional β basin. Our results show that Amber ff14SB best reproduces the experimental J coupling constants and yields the highest pPII populations of the central alanine residue in GAG (55%) and AAA (63%), in a good agreement with the the Gaussian model (59% and 76%). The comparison between experimental and MD-derived results for GAG in water is extended to various water/ethanol mixtures in order to further evaluate Amber ff14SB, CHARMM36, and OPLS-AA/M. Amber ff14SB again outperforms CHARMM36 and OPLS-AA/M in reproducing experimental J coupling constants and amide I’ profiles.

4:18PM D22.00008: Developing an explicit solvent model for protein aggregation* JUTTA LUETTMER-STRATHMANN (Presenter), Physics and Chemistry, University of Akron — Protein aggregation is responsible for amyloid formation and implicated in many neurological diseases. Since protein aggregation is a slow process, intermediate resolution protein models with implicit solvent have been developed to extend the time scale accessible to computer simulations. These models have been improved over many years and have become a valuable tool to support and interpret experimental work on protein aggregation. However, explicit solvent models are required to describe such processes as thermophoresis, which has recently become a tool to study fibril formation. In this work, we start from an off-lattice, mesoscale protein model with implicit solvent to develop an explicit solvent model that reproduces the equilibrium conformational and aggregation properties of the original model. To this end, we choose a solvent that is compatible with the protein model and perform simulations where the interaction parameters are adjusted during the simulation to match the desired properties. Applying the approach to short peptides in water, we find that solvent-solvent interactions are essential.

*Research Center Juelich and the University of Halle (DFG - SFB TRR 102)

4:30PM D22.00009: A kinetic analysis of local fluctuations in ubiquitin by combining the LE4PD normal modes and Markov state modeling* ERIC BEYERLE (Presenter), MARINA GIUSEPPINA GUENZA, Univ of Oregon — Following the conformational selection hypothesis, accurately determining the location and magnitude of fluctuations along a protein’s primary sequence is important in describing its mechanism of binding, so methods describing precisely the fluctuation dynamics of proteins can help reveal their biological function. Here, we model the fluctuation dynamics and kinetics of the protein ubiquitin using a coarse-grained description of the protein's dynamics, the Langevin Equation for Protein Dynamics (LE4PD), which decomposes the dynamics of a protein into dynamical pathways that explore mode-dependent free-energy surfaces. Using as input to the theory statistics from a molecular dynamics simulation, we calculate the timescales of the slow LE4PD modes using Markov state models. The predicted timescales of these LE4PD modes can be elucidated using the committor function, and a version of the string method is used to extract real-space fluctuations of the protein from the mode representation. We find the dynamics predicted by the slow LE4PD modes correspond to motion in important binding regions of the protein. We also show that the fastest LE4PD modes correspond to localized, conserved fluctuations along the protein's primary sequence.

*NSF Grant No. CHE-1665466, NSF Grant No. ACI-154856
4:42PM D22.00010: Non-additive effects of denaturing and protective cosolvents on protein stability* PRITAM GANGULY (Presenter), JOAN-EMMA SHEA, University of California, Santa Barbara — The conformational stability of the Trpcage protein, in the presence of pure and mixed solutions of two denaturants, urea and guanidinium chloride (GdmCl), and one protective osmolyte, trimethylamine N-oxide (TMAO), are studied using enhanced-sampling all-atomistic molecular dynamics simulations. We find that the pure and the mixed solutions of urea and GdmCl denature Trpcage as a whole, but remarkably, the helical segment 1NLYIQWL7 of Trpcage is stabilized in mixed GdmCl-urea solutions. For this helical segment, we find that urea "over solvates" the peptide backbone by reorganizing water molecules from the peptide side chains to the peptide backbone and GdmCl strongly dehydrates the side chains. The effects of urea and GdmCl on the solvation structure of the peptide are non-additive and urea depletes Gdm+ from the surface of the peptide in mixed urea-GdmCl solutions. An intricate thermodynamic balance between these non-additive effects stabilizes the helix in mixed urea-GdmCl solutions. Interestingly, we find that the protective osmolyte TMAO also depletes Gdm+ from the peptide-surface in mixed TMAO-GdmCl solutions and the mixture of TMAO and GdmCl is less effective than GdmCl solutions in counteracting the urea-denaturation of the helix.

4:54PM D22.00011: Short peptides assemble to produce enzyme-like catalysts.* [Invited] IVAN KORENDOVYCH (Presenter), Syracuse University — Design of a novel catalytic function in proteins and peptides, apart from its inherent practical value, is important for fundamental understanding of enzymatic activity. We will present applications of a minimalistic approach to design of artificial enzymes. We designed a series of short peptides that self-assemble into amyloid-like fibrils to act as Zn2+-dependent hydrolases. Zn2+ helps stabilize the fibril formation, while also acting as a cofactor to catalyze acyl ester hydrolysis and carbon dioxide hydration. These results indicate that amyloid fibrils are able to not only catalyze their own formation – they also can catalyze chemical reactions. Excitingly, the specific activities shown by these catalytic amyloids are on par with those shown by natural enzymes. Thus, amyloids might have served as intermediates in the evolution of modern-day enzymes. This work has implications for the design of self-assembling nanostructured catalysts including ones containing a variety of biological and non-biological metal ions.

Session D23 DBIO GSNP: Membranes and Channels 304 - Loren Hough, Univ of Colorado, Boulder
2:30PM D23.00001: Formation and Properties of Self-Assembled Nanoparticle-Supported Lipid Bilayer Probed Through Molecular Dynamics Simulations*  
HAOYUAN JING (Presenter), YANBIN WANG, PARTH RAKESH DESAI, Univ of Maryland-College Park, KUMARAN S. RAMAMURTHI, National Cancer Institute, National Institute of Health, SIDDHARTH DAS, Univ of Maryland-College Park  
— We have carried out coarse-grained molecular dynamics (MD) simulations to study the self-assembly procedure of a system of randomly placed lipid molecules, water beads, and a nanoparticle (NP). The self-assembly results in the formation of the NPSLBL, with the self-assembly mechanism being driven by events such as the formation of small lipid clusters, merging of the lipid clusters in the vicinity of the NP to form NP-embedded vesicle with a pore, and collapsing of that pore to eventually form the equilibrated NPSLBL system. Subsequently, we quantify the properties and the configurations of this NPSLBL system. We reveal that the equilibrated self-assembled NPSLBL system demonstrates a larger number of lipid molecules occupying the outer leaflet as compared to the inner leaflet. Secondly, the thickness of the water layer entrapped between the NP and the inner leaflet show similar values as that predicted by experiments. Finally, we reveal that the diffusivity of the lipid molecules in the outer leaflet is larger than that in the inner leaflet.

2:42PM D23.00002: Leveraging the physics of a barbecue lighter to genetically transform living organisms  
GAURAV BYAGATHVALLI (Presenter), SOHAM SINHA, YAN ZHANG, MARK P. STYCZYNSKI, Georgia Inst of Tech, JANET STANDEVEN, Biotechnology, Lambert High School, SAAD BHAMLA, Georgia Inst of Tech  
— Electroporation is a powerful method for delivering small molecules (RNA, DNA, drugs) across cell membranes by application of an electric field with a specific voltage and time constant, with applications ranging from synthetic biology to drug delivery. Leveraging the piezoelectric mechanism found within a common barbeque lighter, we develop a low-cost electroporator that we call an ElectroPen. This ElectroPen device costs 23-cents, weighs 13g, utilizes a 3D-printed case, and can be applied to genetically transform \textit{E. coli} bacteria. In this talk, we will discuss both the physics of a lighter, as well as the synthetic biology protocol we have developed for electroporation using this frugal device. Using high-speed videos, we will discuss how the inner components of a lighter achieve extraordinary accelerations of 3000g force to ultimately deliver voltage pulses of up to 2,000 volts with a decay constant of 5ms. Finally, we will discuss applications of this low-cost device in broadening participation in synthetic biology in high school science laboratories.

2:54PM D23.00003: Listening to lipid membranes*  
KISUNG LEE (Presenter), Center for Soft and Living Matter, Institute for Basic Science, GURBAN CHOMMANOV, School of Energy and Chemical Engineering, Ulsan National Institute of Science and Technology, STEVE GRANICK, Center for Soft and Living Matter, Institute for Basic Science  
— Fluctuations of giant unilamellar vesicle and cell membranes are detected with exceptional resolution. The motion of localized membrane (<1 μm cross-section) is resolved with 5 decades in both frequency (1 Hz - 100 kHz) and amplitude (0.01 nm - 100 nm). This allows to listen to surprises in underlying membrane mechanics.

*Korean Institute for Basic Science, project code IBS-R020-D1.
3:06PM D23.00004: Comparing microrheological methods for measuring lipid membrane viscosity* PHILIP JAHL (Presenter), RAGHUVEER PARTHASARATHY, Univ of Oregon — The fluidity of lipid membranes governs the motions of bound proteins and macromolecules. Despite this, measurements of the viscosity of a lipid bilayer remain challenging to perform and interpret. Two different microrheological methods for measuring bilayer viscosity have been developed in recent years, one involving tracking phase-separated domains in giant unilamellar vesicles, and the other involving tracking elliptical lipid-anchored tracer particles. The latter approach has so far been applied only to pore-spanning black lipid membranes. The membrane viscosity values obtained by these two methods differ by an order of magnitude, however, and it is unclear whether this indicates inaccuracy of one or both techniques, or whether it is due to the difference in membrane systems examined. To resolve this discrepancy, we applied both methods simultaneously to the same lipid vesicles, featuring both phase separated domains and bound elliptical beads. We show that when applied to identical systems these methods are in agreement. The elliptical tracer method is generally applicable to vesicles of arbitrary composition, and we use it to quantify the viscosity of bilayers composed of phosphatidylcholine lipids of different chain lengths.

3:18PM D23.00005: Regulated ensembles and lipid membranes* MARTIN GIRARD (Presenter), TRISTAN BEREAU, Max Planck Institute for Polymer Research — Cellular membranes are composed of lipid bilayers, amphiphilic molecules with polar headgroups and hydrophobic tails. Their composition is highly complex, involving hundreds of different lipid types and the regulation mechanism is still the subject of intense research. A recent experiment [1] has shown that cholesterol concentration increases with temperature in zebrafishes, as well as the demixing temperature, two results which appear to be contradictory results since cholesterol promotes mixing. Here, we show that many aspects of the zebrafish experiments can be replicated if one assumes a chemical reaction network for regulation of acyl tails. Effectively, this would mean that acyl tail saturation is loosely regulated by cells and mainly directed by cholesterol fraction. This view also explains trends seen along the secretory pathway between cholesterol concentration and acyl tail saturation.

3:30PM D23.00006: Stable fabrication of a various-sized nanopore by controlled dielectric breakdown in a high-pH solution for the detection of various-sized molecules  ITARU YANAGI (Presenter), RENA AKAHORI, KENICHI TAKEDA, Hitachi Ltd — For nanopore sensing of various-sized molecules with high sensitivity, the size of the nanopore should be adjusted according to the size of each target molecule. For solid-state nanopores, a simple and inexpensive nanopore fabrication method utilizing dielectric breakdown of a membrane is widely used. This method is suitable for fabricating a small nanopore. However, it suffers two serious problems when attempting to fabricate a large nanopore: the generation of multiple nanopores and the non-opening failure of a nanopore. In this study, we found that nanopore fabrication by dielectric breakdown of a SiN membrane under high-pH conditions (pH ≥ 11.3) could overcome these two problems and enabled the formation of a single large nanopore up to 40 nm in diameter within one minute.

3:42PM D23.00007: Monte Carlo simulation of pH activated conformational changes of coarse-grained sodium-proton antiporters  MOJGAN ASADI (Presenter), ARIEH WARSHEL, Univ of Southern California — Sodium-proton antiporters are membrane proteins present throughout the eukaryotic and prokaryotic domains that have a critical role in balancing cell pH and cell volume. The *Escherichia coli* antiporter *NhaA* has pH-dependent behavior. There have been many studies regarding the function of this antiporter (Alhadeff and Warshel, PNAS (2015) 112 (40) 12378-12383), but the conformational energy landscape of this system at varying pH is not well-known. In this study, we map the energy landscape between two pH levels for two different conformations of the wild antiporter and a mutated variant using MD with coarse-graining. By Monte Carlo simulation on the energy landscape, we show that the mutated variant changes the stability of the antiporter without blocking the transport, in agreement with experimental results (Calinescu et. al. J. Biol. Chem. (2017) 292(19) 7932–7941).

3:54PM D23.00008: Multichannel Flow Cell for a Nanopore Array Sensor  HAI HUY NGUYEN PHAM (Presenter), ITARU YANAGI, KENICHI TAKEDA, Hitachi Ltd — Solid-state nanopore has been attracting remarkable research interest owing to its extensive potential in biological sensing applications, the robustness, and the possibility of a large-scale integration. A reliability and measurement time are two important criteria for practical uses of a nanopore sensor. An integration of nanopores into an array and simultaneous measurement are an effective approach to increase accuracy and to reduce measurement time. Recently, we have developed 4x4 SiN membrane arrays. However, the flow cell in this system had a bottle neck of exploiting all 16 membranes due to a real estate issue of flow paths. Another bottle neck was the generation of the air bubble that could cause the electrical conductance error. In this study, the mechanism of those issues is investigated. A novel 16-channel flow cell made by a 3D printer is introduced. In this flow cell, the flow paths are arranged in both parallel and orthogonal direction to the membrane surface; and the distance between the membrane surface and the flow path is adjusted to prevent the generation of the air bubble. Nanopores were successfully yielded in all 16 membranes by dielectric breakdown technique.
4:06PM D23.00009: Interaction of Graphene Oxide with Model Bio-membrane: Insights into the Structure of the Membrane  PRIYA MANDAL (Presenter), SAJAL KUMAR GHOSH, Shiv Nadar Univ — Graphene oxide (GO) holds a similar structure of graphene with a range of oxygen functionalities such as carboxyl groups on the edges and, the hydroxyl and epoxies on the basal plane. Presence of oxygen-containing functional groups increases its water dispersity and facilitate its applications in many bio-fields including cell imaging, drug-delivery and bio-sensing. As the cellular membrane is the first target of any foreign molecule. Hence, the mechanism of interaction of GO with this membrane is very crucial to understand for extending the future applications of graphene-based materials. In present work, the x-ray reflectivity (XRR) and grazing incidence small-angle x-ray scattering (GISAXS) techniques have been used to extract the structural details of the GO-membrane complex. XRR study from lipid multilayers has shown a distinct effect of added GO on the position and shape of Bragg peaks obtained from the smectic liquid crystalline phases. GISAXS has provided the in-plane organization of the lipid molecules in the presence of GO in the membrane. The electron density profile obtained from the XRR analysis and the lattice deformation detected by the GISAXS study has provided the detailed molecular organization of the complex.

4:18PM D23.00010: Detection of streptavidin-labeled DNA using solid-state nanopores for target sequence detection  RENA AKAHORI (Presenter), ITARU YANAGI, KENICHI TAKEDA, Hitachi Ltd — In recent years, the demand for rapid and on-site target gene detection has been increasing. For example, it is important for covering the increasing GMO (Genetically-modified-organisms) testings, and for preventing the spread of infectious diseases at an early stage. The conventional techniques for target DNA sequence detection are based on PCR and qPCR. Although these techniques are widespread, they are time-consuming and will not be able to cover all required testings. By comparison, solid-state nanopores have a potential to provide a rapid and portable testing device that is electronic and does not need optics. For realizing target sequence detection with solid-state nanopores, it is a promising approach to label the target sequence with a large molecule and enlarge a current-blockade value when DNA including the target sequence passed through a nanopore. In this study, the possibility of streptavidin (SA) as a labelled molecule was investigated. As a result, we found that the passages of SA-labelled and non-labelled DNA through a nanopore can be clearly distinguished.

4:30PM D23.00011: Moving while you're stuck; a mechanical model of binding facilitated transport in biological systems  KANGHYEON KOO, SHANKAR LALITHA SRIDHAR, NOEL ANTHONY CLARK, FRANCK J VERNEREY, LOREN HOUGH (Presenter), University of Colorado, Boulder — Binding is broadly understood in many biological processes as a mechanism to localize molecules. Binding is also used to dictate particle motion through some biopolymer filters including the nuclear pore complex, the extracellular matrix and mucus membranes. In these cases, flexible polymers transiently bind to transported molecules. Here we describe a mechanical model to probe how binding and thermal motion can enable transport. A particle experiences random forces during binding and unbinding events while being constrained by attached tethers. This model provides insight into the mechanisms and design rules involved in binding-mediated transport in both biological and synthetic polymeric systems.
Towards high-sensitivity phase cancellation microscopy*  
DOMINIKA LYZWA (Presenter), VIJAY SINGH, ZAHID YAQOOB, PETER SO, Biological Engineering, Massachusetts Institute of Technology — Label-free optical imaging techniques, such as light scattering and birefringence have long been used for detection of neural activity [1]. Wide-field interferometric microscopy has also been used for this purpose, most recently by Ling et al. [2]. Current interferometric systems are limited because of low phase measurement sensitivity of $10^{-3}$, while a sensitivity of $10^{-5}$ is necessary.

High sensitivity phase measurements will allow single-shot optical sensing of neural action potentials via imaging of optical path length changes. Here, we present a high phase sensitivity, phase cancellation interferometry system. We want to use a deformable mirror to generate a flat phase. A Wollaston prism is employed to split the beam into two orthogonally polarized beams with phase control. These beams are recombined for interferometric detection. A state-of-the-art 1.6M electron well-depth camera will be used for recordings. We report the analysis of our system’s sensitivity and compare it to theoretical predictions.

Predicting optimal parameters for ion transport through nanopores and biological channels*  
WILLIAM GIBBY (Presenter), MIRASLAU BARABASH, DMITRY LUCHINSKY, PETER MCCLINTOCK, Department of Physics, Lancaster University — Understanding, predicting and optimising ionic transport properties of pores on an atomic scale remains a critical challenge to, nanotechnology and biophysics [1]. In general, pores are designed to fulfil two criteria: conduction of ions at a high rate; and the selectivity amongst ionic species. We have derived a statistical and linear response theory that calculates the occupancy and conductivity of nanopores for given parameters including: pore geometry and charge; type of competing ionic species; and bulk concentration [2]. We find resonant conduction under known conditions, resulting in the coexistence of resonance for one species and suppression for the other and can predict optimal parameters required to produce the desired function. Examples of applications to biological channels and nanopores will be discussed.

Monday, March 2, 2020 2:30 PM - 4:42 PM

Session D24 GSNP: Control of Noisy Nonlinear Dynamical Systems 401 -

Uwe Tauber, Virginia Tech - Tag(s): Focus
2:30PM D24.00001: Understanding the control process for non-equilibrium systems using scaling theory* [invited] PRIYANKA . (Presenter), UWE CLAUS TAUBER, MICHEL PLEIMLING, Department of Physics & Center for Soft Matter and Biological Physics, Virginia Tech — Control theory is a widely used tool in engineering to develop controlled, stable models of dynamical systems. The control of deterministic models has been extensively studied; however, studies on the control of non-equilibrium systems are less explored due to the presence of non-linearity and noise. I will focus on understanding the effect of both linear and non-linear control processes on the intrinsic dynamics as well as stationary properties of non-equilibrium systems. In particular, I will discuss the control of the following two systems: a) surface roughness in the KPZ growth process, and b) the dynamical states in a network model. In the KPZ growth process, control is achieved by manipulating a subset of Fourier modes, whereas, in the dynamical network, a metastable state is controlled using a closed feedback loop. In both cases, the control process limits the time and length scales within which the system behaves according to its intrinsic stochastic dynamics. These time and length scales show scaling behavior with the control parameter, and the associated scaling exponents are related to those of the unperturbed model.

3:06PM D24.00002: Molecular machinery: quantifying the energetic cost of controlling nanoscale biological systems* STEVEN LARGE (Presenter), DAVID SIVAK, Simon Fraser Univ — At microscopic scales, biological systems must maintain a high degree of organization in order to properly function. Ultimately, this organization is achieved by the concerted efforts of a collection of nanoscale molecular machines: protein complexes that perform specific functions within the cell. Quantifying the flows of energy, information, and material through such systems is a central challenge in understanding their dynamics and in vivo operation. Currently, a number of important questions related to the function of molecular machines remain unanswered: what design principles produce efficient machines? What fundamental physical limitations are placed on these nonequilibrium systems? In this talk I will discuss our recent efforts to address some of these questions, making use of tools from nonequilibrium thermodynamics to quantify the energetic costs of driving strongly fluctuating systems. In particular, quantifying the dissipation associated with driving a fluctuating system between different states leads to conditions for efficient operation. Among other things, we find that there is an energetically optimal speed for systems to move at.

3:18PM D24.00003: Effects of structural and cellular heterogeneity on the control of nonlinear biological oscillator networks*  NARASIMHAN BALAKRISHNAN (Presenter), Chemical and Biological Engineering, Northwestern University, NEDA BAGHERI, University of Washington — Circadian rhythms are biological processes that have a period of roughly 24 hours. In most animals, these rhythms are orchestrated by a specialized network of neurons that possess a regulatory system involving oscillatory genes and proteins. The dynamics of these regulatory networks are highly nonlinear. In this work, we study the functional consequences of structural and cellular heterogeneity (extrinsic noise) on the control of these oscillator networks. Structural heterogeneity refers to variation in size, topology and edge weights within the network of oscillators. We present two optimal control problems, those of modifying the phase of the population of these oscillators in either minimal time, or using minimum effort. We find there is a sweet spot relating heterogeneity and average coupling strength for which the control cost is minimal, and a limit to which heterogeneity enables greater controllability. Insights relating to heterogeneity also suggest evolutionary advantages heterogeneous populations may carry over homogeneous ones. Our findings also may help provide guidelines for the design of synthetic oscillator networks, a field of growing interest.

3:30PM D24.00004: Corazon espinado: microelectrode closed-loop control in cardiac tissue  CONNER HERNDON (Presenter), FLAVIO H FENTON, Georgia Inst of Tech — Proper contraction of cardiac muscle relies on the coordinated propagation of transmembrane voltage, and disturbances of this propagation can result in deadly cardiac arrhythmias. One such disturbance strongly associated with the onset of fibrillation is a dynamical instability known as alternans, a beat-to-beat alternation in action potential duration (APD) arising from a period-doubling bifurcation. The restitution hypothesis claims that a return map in APD can describe and predict alternans, and decades of work have shown it can successfully reproduce many experimental observations. The restitution hypothesis likewise predicts a method for suppressing the onset of alternans which has been confirmed by some computational simulations; however, few experiments have addressed these predictions due to its difficult implementation. In this talk, I will discuss our development of a closed-loop control scheme to experimentally address predictions made by the restitution hypothesis via high resolution microelectrode recordings of transmembrane voltages in zebrafish, frog, and rabbit hearts. I will present our results which conclusively show the appearance of alternans in opposition to predictions made by theoretical models and provide an improved model that describes the dynamics.
Induction of spatio-temporal spiral defects in an inhomogeneous stochastic May-Leonard system*  

SHANNON SERRAO (Presenter), UWE CLAUS TAUBER, 
Department of Physics and Center for Soft Matter and Biological physics, Virginia Tech — We study the induction of spiral defects in an inhomogeneous two-dimensional Monte Carlo toroidal lattice simulation of the stochastic three-species May-Leonard model with asymmetric predation rates. In an isolated setting, strongly asymmetric predation rates cause fast extinction from coexistence of all three species to a single surviving population. However, when spatially coupled to a fully symmetric May-Leonard patch, the spiral patterns from this stable region induce transient plane wave fronts and ultimately quasi-stationary spiral patterns in the asymmetric region. We quantitatively analyze the initial injection of plane wave fronts from the symmetric region and the subsequent formation of spirals, and explore the conditions for the stabilization of the weaker ecosystem. To this end, we study characteristic correlation lengths and oscillation frequencies, the shape and size of the spirals induced in the asymmetric region in comparison to the isotropic spirals in the symmetric regime, and the effects of varying system size and individuals' mobility.

*Research was sponsored by the Army Research Office and was accomplished under Grant Number W911NF-17-1-0156.

Extracting important parameters from dynamical systems models through coarse-graining*  

PRANAV KANTROO (Presenter), Computational Biology and Bioinformatics Program, Yale University, BENJAMIN B MACHTA, Department of Physics, Yale University — Known microscopic details often motivate models with large numbers of parameters. However, not all parameter combinations are relevant at large length-scales of observation. Some may affect coarse-grained system behavior sensitively, while others may have no discernible effect. Here we utilize the Fisher Information Metric formalism to identify which parameter combinations influence observables even for coarse-grained data. We first derive a general method for calculating this metric from a model whose data has been coarse-grained, and apply this to models coarse-grained by sparse-sampling observables in time. We make the resulting Fisher Information reparameterization invariant by transforming to a basis that measures how coarse-graining reduces observability. We then use this procedure to explicitly calculate the temporally coarse-grained Fisher Information Metric for several stochastic differential equation models. The expansion of the reparameterization invariant Fisher spectrum after coarse-graining separates relevant parameter combinations from irrelevant ones. We then draw concrete parallels between our formalism which uses coarse-graining of the Fisher Information, and the Renormalization Group framework.

4:06PM D24.00007: NUMERICAL INVESTIGATION OF SIGNAL AMPLIFICATION VIA VIBRATIONAL RESONANCE IN A CHUA’S CIRCUIT. JOHN LAOYE, TAIWO OLAKUNLE ROY-LAYINDE (Presenter), KEHINDE ADAM OMOTESO, RASAKI KOLAWOLE ODUNAIKE, Olabisi Onabanjo Univ — In this paper, we numerically investigated the occurrence of Vibrational Resonance in a modified Chua’s oscillator with a smooth nonlinearity, described by a cubic polynomial. Response curves generated from the numerical simulation at the low frequency reveal that the system’s response amplitude could be controlled by modulating the conductance parameter of the Chua’s circuit, rather modulating the parameters of the fast periodic force. Modulating the frequency of the fast periodic force slightly reduces the response amplitude; shifts the peak point to a higher value of the amplitude of the fast periodic force by widening the resonance curves. Within certain parameter regime of the high frequency ($\Omega \geq 100 \omega$), the system’s response gets saturated, and further increase does not affect its amplitude.

4:18PM D24.00008: Resonance Coherence Optimization of Structure Formation in Nanofilms Undergoing Thermocapillary Instability YI HUA CHANG (Presenter), SANDRA TROIAN, Applied Physics, Caltech — External temporal modulation of time periodic phenomena is a well-known method for inducing resonant behavior in mechanical or electrical systems. While temporal modulation has been used as an effective control mechanism for decades, there have been far fewer studies of external spatial modulation to enforce pattern uniformity and growth in the presence of noise. One such example involves a liquid film undergoing a spinodal instability subject to an externally imposed wavenumber close to the stability threshold of the unforced homogeneous system, which has been shown to induce resonance leading to a bifurcation in equilibrium film shapes. In this talk, we examine a linear instability in molten nanofilms undergoing thermocapillary growth leading to structure formation resembling 3D microlens arrays. Noisy initial conditions, however, are found to generate non-uniform peak heights which accelerate at different rates and significantly compromise pattern fidelity. Using a combination of weakly nonlinear analysis and numerical simulations, we demonstrate the existence of a resonant regime with high spatial coherence leading to microarrays with uniform pitch and height. This regime should provide optimal conditions for fabrication of micro-optical arrays.

4:30PM D24.00009: An elementary renormalization-group approach to the Generalized Central Limit Theorem and Extreme Value Distributions ARIEL AMIR (Presenter), Harvard University — The Generalized Central Limit Theorem is a remarkable generalization of the Central Limit Theorem, showing that the sum of a large number of independent, identically-distributed (i.i.d) random variables with infinite variance may converge under appropriate scaling to a distribution belonging to a special family known as Levy stable distributions. Similarly, the maximum of i.i.d. variables may converge to a distribution belonging to one of three universality classes (Gumbel, Weibull and Frechet). I rederive these known results following a mathematically non-rigorous yet highly transparent renormalization-group-like approach that captures both of these universal results following a nearly identical procedure.

Monday, March 2, 2020 2:30 PM - 5:30 PM
2:30PM D25.00001: Recent Progress on 3D Chiral Mechanical Metamaterials* [Invited]
MARTIN WEGENER (Presenter), Karlsruhe Institute of Technology — We review our recent progress on three-dimensional (3D) microstructured chiral mechanical metamaterials. These architectures have been made by state-of-the-art 3D laser nanoprinting and lately also by rapid multi-focus multi-photon 3D laser nanoprinting. For the latter, the metamaterials contain more than one hundred thousand unit cells and more than three hundred billion voxels.
Concerning the static regime, we will present novel architectures that allow to bring the push-to-twist conversion effects previously reported by us to much larger absolute values at larger numbers of unit cells. Specifically, the twist/strain can be tailored to linearly increase up to a characteristic number of unit cells, beyond which the twist/strain asymptotically decays inversely with the number of unit cells (unpublished).
Regarding the dynamic regime, we will review our recently published results on acoustical activity, the elastic counterpart of optical activity. Moreover, we will also present unpublished result on a different unit-cell design, for which the observed rotation angles approach the fundamental limit of 90 degrees per unit cell.

*This research has been funded via the Excellence Cluster “3D Matter Made to Order” (EXC-2082 – 390761711).

3:06PM D25.00002: 3D Acoustic Zero Index Metamaterial* CHANGQING Xu, King Abdullah Univ of Sci & Tech (KAUST), GUANCONG MA, Physics Department, Hong Kong Baptist University, YUN LAI, Physics Department, Nanjing University, YING WU (Presenter), King Abdullah Univ of Sci & Tech (KAUST) — In this talk, I will report our design of a three-dimensional (3D) acoustic double-zero-index medium (DZIM) made of a cubic lattice of metal rods. Despite of several realizations of 2D DZIM in the past, achieving such a medium in 3D has remained an elusive challenge. Here, we show how a four-fold degenerate point with conical dispersion can be induced at the Brillouin zone center, such that the material becomes a 3D DZIM with the effective mass density and compressibility simultaneously acquiring near zero values. To demonstrate the features of the DZIM, we have fabricated an acoustic waveguide filled with 3D DZIM to form a “periscope” with two 90° turns and observed nearly perfect tunneling of a normally incident planar wave through the waveguide.

3:18PM D25.00003: Micro-lattices for wide-band three-dimensional elastic wave attenuation  
NIKHIL GERARD (Presenter), MOURAD OUDICH, YUN JING, North Carolina State University — The past decade has witnessed the emergence of three-dimensional micro-lattices and state-of-the-art manufacturing techniques that have enabled their realization. The ability to fabricate bulk materials that are precisely architected at the microscopic scale is exhilarating to various scientific communities. This has thus greatly revived the yearning for futuristic multifunctional materials. From the perspective of mechanical wave propagation, this implies complete control over micro-structure that can be designed for exotic wave-based applications. In this work, we put forth new design strategies to engineer micro-lattices for desirable elastic wave bandgaps and discuss their experimental realization. The band gaps can be attributed to local resonance and Bragg mechanisms and can be precisely tuned via both unit cell geometry and the intrinsic material employed for its fabrication. Alongside being thin, lightweight and/or displaying a negative Poisson’s ratio, our micro-lattices are equipped with the capability of attenuating elastic waves in all directions over a wide frequency range and can facilitate novel elastic wave functional materials.

3:30PM D25.00004: Elastic Weyl Points and Surface Arc States in Three-Dimensional Mechanical Metamaterials*  
XIAOTIAN SHI (Presenter), RAJESH CHAUNSALI, University of Washington, FENG LI, South China University of Technology, JINKYU YANG, University of Washington — We investigate a novel Weyl mechanical metamaterial inspired by the discovery of Weyl semimetal. We propose a three-dimensional mechanical structure in analog to the AA-stacked graphene with chiral intralayer coupling, which carries Weyl points of topological charge ±1. We numerically confirm the existence of the elastic Fermi arc and the associated gapless topologically protected surface states. The full-scale numerical simulation on the hollow 3D mechanical structure demonstrates that the surface elastic waves are robust and directional, which can pass a corner or defect without reflections. The findings from our work can contribute to the novel ways of manipulating elastic energy in 3D structures for potential applications in vibration isolation, advanced sensing, and energy harvesting.

Demonstration of the Majorana-like bound state in an elastic bolted plate  

CHUN-WEI CHEN (Presenter), Aeronautics and Astronautics, University of Washington, NATALIA LERA, Departamento de Física de la Materia Condensada, Universidad Autónoma de Madrid, RAJESH CHAUNSALI, LAUM, CNRS, Le Mans Université, DANIEL TORRENT, GROC, Institut de Noves Tecnologies de la Imatge (INIT), Universitat Jaume I, JOSE VICENTE ALVAREZ, Departamento de Física de la Materia Condensada, Universidad Autónoma de Madrid, PABLO SAN-JOSE, Materials Science Factory, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), JOHAN CHRISTENSEN, Department of Physics, Universidad Carlos III de Madrid, JINKYU YANG, Aeronautics and Astronautics, University of Washington — With the unveiling of the topological non-trivial phases, abundant demonstrations of the bulk-boundary correspondence in various domains of physics have been conducted in recent years. More recently, higher-order topological insulators are realized to reveal not only the boundary states but also the zero-dimensional corner states. In this work, another uniquely zero-dimensional non-propagating state, specifically a mechanical analog of the Majorana bound state, is shown numerically and experimentally in a mechanical system. We implement topological binding by creating a Kekulé distortion vortex on a two-dimensional thin plate with local resonators mounted in a honeycomb arrangement. It is renowned that Majorana bound states are protected by particle-hole (PH) symmetry. Similarly, to show our mechanical Majorana-like bound state is insensitive to certain type of disorder, we design a local perturbation to mimic the PH symmetry. We confirm that the Majorana-like bound state is indeed robust against the PH-symmetric perturbations and maintains pinned to Dirac frequency of the undistorted lattices. We anticipate that this finding will enrich the topological non-trivial phases in bosonic systems and broaden the applications of the energy localization or energy harvesting.

Tuning of 2D Phononic Band Structures via Buckling Instability  

TEJAS DETHE (Presenter), SIDDHARTH SARKAR, Princeton University, MATEVZ MARINCIC, University of Ljubljana, ANDREJ KOSMRLJ, Princeton University — Dispersion relation of propagating elastic waves through phononic crystals, which are periodic elastic structures, can be represented with band diagrams akin to the electronic band structures and band structures in photonic crystals. Of special interest in these diagrams are band gaps, which correspond to frequencies of waves that cannot be transmitted through the bulk of the phononic crystals. The location of band gaps depends on the material properties and on the geometry and symmetries of phononic structures. The symmetries of compressed elastic structures can be drastically altered via the buckling instability, and we are exploring how that affects the phononic band structures. First, we systematically investigated band diagrams for uncompressed 2D phononic structures that belong to different crystallographic groups. We employed recently developed tools for electronic systems, to analyze which band crossings are topologically protected/prohibited. We use this information to analyze how band structures are affected by the buckling instability, which causes a phononic structure to move from one crystallographic group to another. Such tuning of band structures with external load could then be used to engineer tunable sound filters as well as mechanical sensors.
4:06PM D25.00007: Robust gapless edge states and unconventional topological band properties in a two-dimensional elastic Kekulé phononic lattice* TING-WEI LIU (Presenter), FABIO SEMPERLOTTI, Purdue Univ — The existence of back-scattering-immune edge states in topological metamaterials has opened a new path for mechanical waveguide design. Recently, a “Brillouin-zone-folding” strategy was proposed to easily realize non-trivial topological properties in two-dimensional phononic systems. However, due to the intrinsic characteristics of phonons, the resulting edge states are generally gapped, indicating coupling between counter-propagating edge states. We report on the design of an elastic phononic structure that embeds a Kekulé distortion pattern to create the analogue of a quantum spin Hall system which, with proper tuning, can achieve fully decoupled and gapless edge states. Using \textit{ab initio} numerical calculations, we also discover unconventional characteristics of the phononic band structure including a six-lobe pseudospin texture and Berry curvature. We also find that the existence of edge-states does not depend exclusively on the topological invariants of the adjacent bulk lattices but also on the relative translation of the unit cell pattern, therefore it is possible to obtain edge states on an edge dislocation of one bulk lattice.

4:18PM D25.00008: Valley Anisotropy and Valley Topological States in Elastic Metamaterials* SHUAIFENG LI (Presenter), Department of Aeronautics and Astronautics, University of Washington, INGI KIM, SATOSHI IWAMOTO, Institute of Industrial Science, The University of Tokyo, JIANFENG ZANG, School of Optical and Electronic Information and Wuhan National Laboratory for Optoelectronics, Huazhong University of Science and Technology, JINKYU YANG, Department of Aeronautics and Astronautics, University of Washington — Valley, as a new degree of freedom, has emerged as an efficient way in manipulating waves in electronics, photonics and phononics. We present the valley anisotropy by introducing asymmetrical metamaterials made of hard spiral and soft materials. We study the phononic band structure and valley pseudospin in these spiral elastic metamaterials. By numerical calculations, we show the deviated Berry curvature and valley Chern number. The adjustment of the geometrical parameters in the spirals allows an extreme tunability of the Berry curvature and valley Chern number, resulting in the topological transition. We exploit the adjustment of the geometrical parameters to demonstrate the formation of valley topological states unprecedented in conventional topological platforms. Lastly, we present the topologically protected transport of elastic waves in our anisotropic topological elastic metamaterials.

4:30PM D25.00009: Topological boundary modes in nonlinear mechanical lattices  DI ZHOU (Presenter), ZEB ROCKLIN, Georgia Inst of Tech — Mechanical lattices have been shown to possess interface modes lying in bulk band gaps. These boundary modes are protected by bulk topological invariants in which the geometric (Berry) phase is quantized by certain symmetries, the celebrated bulk-boundary correspondence. This relationship has been proved rigorously for linear mechanical systems, which can be mapped onto quantum systems, yet recent has demonstrated that the boundary modes extend into the nonlinear regime. In the present work, we investigate the topological protection of nonlinear normal modes. In particular, we consider a one-dimensional diatomic chain with spatial inversion symmetry, whose linear limit has a well-characterized topological invariant. By continuing the linear modes into the nonlinear regime via a mix of numerical and analytic methods, we characterize how nonlinear topological boundary modes emerge, paving the way to topological modes of strongly and inherently nonlinear systems.

4:42PM D25.00010: Programmable higher-order Euler buckling modes in hierarchical beams* MARIA-GABRIELLA TARANTINO, KOSTAS DANAS (Presenter), LMS, CNRS, Ecole Polytechnique — We present a numerical-aided experimental study on the buckling of hierarchical beams comprising multiple self-similar modules. Each module consists of multiple elemental beams and is arranged in series to form the hierarchical beam. We show, through a combination of experiments and computations, that these beams exhibit stable and realizable higher-order buckling modes. By contrast to the canonical Euler buckling problem, such modes emerge naturally in the proposed self-similar beams since they correspond to almost identical critical loads. By harnessing the imperfection sensitivity of the hierarchical structures, we 3D-print weakly imperfect polymer samples with a small geometric imperfection corresponding to the desired eigenmode. The ability to trigger higher-order buckling modes is found to depend on two main geometrical parameters which lead to scale coupling. Those are the slenderness of the macroscopic hierarchical beam and the slenderness of the lower-scale elemental beam. With increasing slenderness of the hierarchical beam, we observe a significant softening in the overall stress-strain response and patterns exhibiting curvature localization in the post-bifurcation regime.

4:54PM D25.00011: Programmable metastructures featuring adaptable stiffness based on local bistability*  JANAV P. UDANI (Presenter), ANDRES F. ARRIETA, Purdue Univ — We present a novel class of programmable structures displaying large stiffness adaptability from local changes of shape. We connect a series of locally bistable semi-spherical shells (domes) within structural element geometries to create highly programmable properties. We demonstrate the property programmability by manufacturing and testing the dome patterned metasheets and beam-like metastructures, the properties of which are adapted by changing the local state of individual domes. We present bending and in-plane stiffness curves characterizing the global response as a function of the local unit cell states. Our results reveal extreme adaptability of properties ranging from high stiffness to high compliance as a result of the local changes of stable states. The properties of the metastructures depend on the local bistable state adopted by the domes and the global connectivity of the metastructures, thus departing from constraints imposed by specific constitute material choice for obtaining adaptability. We demonstrate the applicability of these metastructures in compliant/soft robotics particularly to enable stiffening without compromising on shape reconfiguration, all while using a simplified single input control to shift between stable states.

5:06PM D25.00012: Navigating the landscape of nonlinear mechanical metamaterials for advanced programmability  EDER MEDINA (Presenter), Harvard University, PATRICK FARRELL, Mathematical Institute, University of Oxford, KATIA BERTOLDI, CHRISTOPHER RYCROFT, Harvard University — We consider a flexible mechanical metamaterial comprising an elastomeric matrix with an embedded square array of circular holes. First, we use the deflated continuation technique of bifurcation analysis to explore its complex energy landscape, characterized by multiple bifurcations from which stable and unstable branches emanate. We then investigate how this landscape can be exploited for real-time programmability. We find that the response of the system can be constantly reprogrammed by locally manipulating it to move it from one stable branch to another and that small targeted imperfections can be harnessed to enhance such programmability.

5:18PM D25.00013: Space-time phononic crystals with anomalous topological edge states*  YUANCHEN DENG (Presenter), MOURAD OUDICH, Mechanical and Aerospace Engineering, North Carolina State University, MOLEI TAO, School of Mathematics, Georgia Institute of Technology, YUN JING, Mechanical and Aerospace Engineering, North Carolina State University — We introduce a one-dimensional topological phononic phase system with a dynamic modulation of its intrinsic properties that keep the topological feature of the system unchanged, while it leads to a multiplication of the edges-state into the continuum at the subwavelength regime. We use this feature to access the functionality of exciting the edge-state in the Bragg regime using harmonic deep subwavelength acoustic wave where the wavelength is about 55 times the whole topological system's length. This remarkable property introduces a promising alternative to achieve wave manipulation at the deep-subwavelength scale.

2:30PM D26.00001: Controlled neighbor exchanges drive intermittency and cell streaming in epithelial tissues  

AMIT DAS (Presenter), DAPENG BI, Northeastern University — Cell neighbor exchanges are integral to tissue rearrangements in biology, including development and repair. Often these processes occur via topological T1 transitions analogous to those in foams, grains and colloids. However, in contrast to non-living materials the T1 transitions in tissues are rate-limited and cannot occur instantaneously due to finite time required to remodel complex structure at cell-cell junctions. Here we introduce this important biological constraint in a vertex-based model as an intrinsic single-cell property and study how this rate-limiting process affects the mechanics and collective behavior of cells in a tissue. We report in the absence of this time constraint, the tissue undergoes a motility-driven glass transition characterized by a sharp increase in the intermittency of cell-cell rearrangements. Remarkably, this glass transition disappears as T1 transitions are temporally limited. As a unique consequence of limited rearrangements, we also find that the tissue develops dynamically heterogeneous pockets of fast and slow cells, in which the fast cells organize into long streams with leader-follower interactions, maintaining optimally stable cell-cell contacts. We compare our predictions with existing in-vivo experiments on Drosophila pupal development.
**2:42PM D26.00002: Mechanical Instabilities in Growing Biological Systems: Wrinkling and Branching** [Invited] ANDREJ KOSMRLJ (Presenter), Princeton University — Morphological shape transformations in biological systems often arise from patterned biochemical processes, which can produce mechanical forces either directly via molecular motors or indirectly via differential growth of connected tissues. The growth mismatch produces internal stresses, which can be released via shape transformations and mechanical instabilities. In this talk I will focus on mechanical instabilities that cause the wrinkling of Vibrio cholerae bacterial biofilms and branching in developing lungs. Biofilms grown on agar substrates form wrinkled patterns, which are radial in the outer region and zig-zag herringbone in the inner region. We demonstrate that the wavelength of wrinkles as well as their spatiotemporal pattern can be predicted by a chemo-mechanical model that takes into account the diffusion of nutrients and their uptake by bacteria, growth of the biofilm, mechanical deformation of the biofilm and the agar substrate, and the friction between them. In the second part I will discuss the branching morphogenesis of lungs. We investigate how patterned differential growth between the inner epithelium and the outer mesenchyme tissue as well as the spatial pattern of smooth muscles lead to formation of new branches and their subsequent development. Experiments and mathematical model suggest that the patterned formation of stiff smooth muscles is very important for the proper development of new branches. In the absence of smooth muscles, the wrinkling instability of growing epithelium on the soft mesenchyme produces several ectopic branches. However, when stiff smooth muscles are formed, they suppress the wrinkling instability and new branches are formed only between the gaps of smooth muscles.

**3:18PM D26.00003: Quasi-realistic modelling of expanding epithelial cell monolayer**
YOUYUAN DENG (Presenter), HERBERT LEVINE, Rice Univ — An expanding epithelial cell monolayer on a 2-dimensional substrate exhibits intriguing mechanical patterns. The distribution of mechanical quantities over space and time thereby hints a picture integrating cell-cell and cell-substrate interactions. We propose a quasi-realistic model for this phenomenon. Specifically, we model cells as active constituents that would maintain force-equilibrium at the end of each motile step. The model cells contract with a tension-dependent speed, and protrude after reaching the maximum allowed contraction. Cell-substrate and cell-cell elastic adhesion bonds form, break and relocate stochastically, so as to capture contact inhibition as well as other effects. We bring forward this bottom-up approach to reveal the essential mechanisms leading to the macroscopic patterns.
3:30PM D26.00004: Symmetry breaking and axis formation in Hydra* [Invited] EVA-MARIA COLLINS (Presenter), Swarthmore College — During animal development, a near-uniform collection of genetically identical cells self-organizes to form an organism with a well-defined anterior-posterior body axis. Axial patterning is the earliest and most fundamental event that gives rise to the complexities of a full animal. The freshwater polyp Hydra is an excellent model system to study axial patterning due to its simple anatomy and incredible regenerative abilities. Hydra can regenerate from small tissue pieces or from cell aggregates. The physicists Alfred Gierer and Hans Meinhardt recognized Hydra's self-organizing properties > 40 years ago. However, the physical mechanisms underlying cell sorting, symmetry breaking, and axis specification in Hydra remained elusive as existing studies failed to distinguish between different driving mechanisms. In my talk, I will present our recent work that answers some of these questions. Our results challenge key assumptions in existing mathematical models of Hydra regeneration and require that we re-examine the mechanisms driving axis specification and pattern formation.

*This work was funded by NSF grant CMMI-1463572, the Research Corporation for Science Advancement, and the Gordon and Betty Moore Foundation.

4:06PM D26.00005: Configurations and dynamics of membrane-bound elastic filaments* WILSON LOUGH (Presenter), University of Wisconsin - Madison — Changes in the curvature and topology of cell membranes are responsible for numerous biological processes. Many of these changes are driven by interactions with thin filament-like protein structures which form on the membrane surface. While there are a number of proposed mechanisms, how exactly the filament-membrane interactions produce changes in curvature remains an open question. The feasibility of proposed mechanisms can be investigated by modeling the filament as a thin elastic rod which is confined to the membrane surface. The interplay between the geometries of the surface and the filament give rise to complex distributions of force and torque which are believed to play a crucial role in reshaping the membrane. We discuss the mechanics of surface-bound filaments and present a collection of analytical and numerical results.

*NSF: DMS-1661900
4:18PM D26.00006: Bacteria sense and respond to the mechanics of the surface to which they attach* VERNITA GORDON (Presenter), LIYUN WANG, JACOB BLACUTT, University of Texas at Austin — The attachment of bacteria to a surface is often a key initial step in the development of biofilms, communities of bacteria that are significant contributors to disease, fouling, and damage to the built environment. Understanding how bacteria sense surface attachment and, in response, begin the process of biofilm initiation, should give rise to new avenues to biofilm prevention as well as advance basic science. Here, we examine the relationship between substrate stiffness, mechanical deformation of the bacterial cell, accumulation of bacteria on the surface, and dynamics of an intracellular signal that control biofilms development. 

*Pseudomonas aeruginosa*, a widely-used model organism for biofilm development and a common hospital-acquired pathogen. We find that when the chemistry of a gel substrate is held constant but the effective elasticity is increased, more bacteria accumulate and signaling activates earlier. The response to the substrate mechanics at times greater than one hour after attachment depends on different cellular structures than at earlier times. Thus, the bacterial mechanosensing leading to biofilm development is likely a multi-step process involving more than one sensory element.

4:30PM D26.00007: Mechanical impacts of complex topology on epithelial cells* SUN-MIN YU (Presenter), BO LI, FRANCOIS AMBLARD, STEVE GRANICK, YOON-KYOUNG CHO, Institute of Basic Science, Center for soft and living matter — Although complex curvatures are general features of in-vivo tissues where the fundamental biological functions are performed in our bodies, no in-depth study on the impact of complex curvature has been provided yet. In the current study, we found that strong mechanical impacts of complex topology on the epithelial system. With a great advantage of a torus having positive, zero, negative Gaussian curvature in a single structure, we demonstrated that the cells on tori showed polarized architecture than that of a flat surface. In addition, the cells manipulate the cellular mechanical elements to gain physically stable conditions. The current study sheds light on the mechanical adaption of cells on complex topology by which the relevance can be expanded in the in-vivo biological processes such as tumorigenicity and morphogenesis, also can provide insights on the design of biomaterials, tissue engineering and organoid/organ-on-a-chips.

4:42PM D26.00008: Three-dimensional Packing of Curved Epithelia: Biology and Topology meet Physics  PEDRO GÓMEZ-GÁLVEZ, PABLO VICENTE MUNUERA, Seville University, SAMIRA ANBARI, Lehigh Univ, LUIS M ESCUDERO, Seville University, JAVIER BUCETA FERNANDEZ (Presenter), Lehigh Univ — Building and shaping tissues and organs relies on the ability of epithelial cells to efficiently pack together. In this context, we recently produced a major breakthrough by showing that epithelial cells display a previously undescribed geometrical shape when tissues are subjected to bending (curvature): the scutoid [1]. This discovery has opened the door to a deeper understanding of morphogenesis. Yet, the consequences of this new paradigm in terms of the 3D cellular organization remains largely uncharacterized. Here we address this problem using a combination of experiments, mathematical analyses, computer simulations, and biophysical approaches. In that context we derive the "Flintstones' Law" [2]: the thickness and curvature of epithelial tubes are linked to the cellular connectivity of the tissue via energetic cues. This principle explains how the topological and physical constraints inherent to living matter contribute to build functional complex shapes and lead to the self-organization of tissues.

4:54PM D26.00009: Topological analysis of multicellular structures  DOMINIC SKINNER (Presenter), BOYA SONG, JÖRN DUNKEL, Massachusetts Institute of Technology MIT — Recent advances in microscopy techniques make it possible to study the growth, dynamics and response of complex biological systems at single-cell resolution, from bacterial biofilms to tissues. When seeking to understand the formation and mechanical properties of these multicellular materials, the local spatial arrangement of their discrete cellular building blocks is of principal importance. To compare the similarity of crystals, we can compare lattice vectors or motifs, but when there is no crystal structure it is less obvious how one can reliably distinguish two amorphous yet structurally different materials. In this talk we introduce a topological distance between materials that needs only the coordinates of the centroid of each discrete object, and is based on the local graph structure around each centroid. Using this distance we will differentiate and classify structures formed from various ellipsoid and sphere packings, as well as biological cell data.
5:06PM D26.00010: Tissue-Tissue Interactions at Boundaries of Colliding Monolayers*
MATTHEW HEINRICH (Presenter), DANIEL COHEN, ANDREJ KOSMRLJ, JAKE STRAIN, Princeton University — Classic ‘wound healing’ studies in epithelial monolayers use a wound or barrier removal to induce and study collective migration, focusing on the migration rather than the ultimate collision and tissue healing. Here, we address this by comprehensively studying epithelial tissue-tissue interactions in homotypic tissues from the initial outgrowth of multiple tissues through collision until a single, mature tissue is formed. We show the boundary between two non-mixing tissues is directly modulated by their size, shape, and density, and the boundary varies over time until the newly fused tissue stabilizes. In addition to characterizing interactions and boundary dynamics between colliding tissues, we predict the resulting fused tissue forms using a simple computational model assuming isotropic growth, which is used to systematically design the final resulting “mosaic” from many growing tissues. Finally, we show that unexpected boundary dynamics occur at the confluence of three or more tissues coming together that can lead to surprising planar extrusions where one tissue pushes out between converging neighboring tissues resulting in long, stretched regions of tissues.

5:18PM D26.00011: Patterning Potential of Cell-cell signalling Molecules in Flowing Tissue
SUPRIYA BAJPAI (Presenter), Civil Department, IITB-Monash Research Academy, MANDAR M INAMDAR, Civil Department, Indian Institute of Technology, RANGANATHAN PRABHAKAR, Univ, Monash, RAGHUNATH CHELAKKOT, Department of Physics, Indian Institute of Technology Bombay — Cell motility and cell-cell signalling are expected to play important roles in determining the mechanics behind deformation and patterning in tissues. Modelling efforts have, thus far, treated these two processes separately. Experiments in recent years, however, suggest that both these processes could be tightly coupled.

Cell deformation depends on membrane and cytoskeletal elasticity, cell-cell adhesion and active forces. Cell-cell signalling occurs through signalling molecules. A large number of complex tissue behaviours are controlled by contact signalling. Such interactions can occur only between cells that are in physical contact, either directly at the junctions of adjacent cells or through cellular protrusions. It is as yet unclear how the spatial distribution these molecules or the kinetics of their interactions are influenced by the collective migration in tissues driven by cell motility.

We present a model which accounts for contact signalling between adjacent cells and between non-adjacent neighbours through long protrusions that occur along the direction of cell polarization. The spatial patterns that develop are observed to qualitatively depend on polarization of protrusions, cell motility and the relative strengths of adjacent and non-adjacent signalling interactions.

Monday, March 2, 2020 2:30 PM - 5:30 PM
2:30PM D27.00001: Development of a high-k gate stack for atomic-precision advanced manufacturing  
TZU-MING LU (Presenter), EVAN ANDERSON, DEANNA CAMPBELL, MICHAEL MARSHALL, PING LU, SCOTT W SCHMUCKER, LISA A TRACY, MITCHELL ROBISON, REZA ARGHAVANI, LEON N MAURER, ANDREW BACZEWSKI, DANIEL R WARD, SHASHANK MISRA, Sandia National Laboratories — Atomic-precision advanced manufacturing (APAM) is a process in which a scanning tunneling microscope is used to create atomically precise conducting channels in Si. Gating of APAM devices is typically achieved by patterning electrical gates in the same plane as the channel. Higher transconductance could be achieved by adopting a vertical metal-oxide-semiconductor gate stack. Here we report on the development of such a gate stack incorporating high-k dielectrics. The process flow is designed to be APAM compatible with an ultra-low thermal budget. We evaluate the quality of the gate stack using capacitance-voltage measurements. This work was supported by the Laboratory Directed Research and Development Program at Sandia National Laboratories and was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government.

2:42PM D27.00002: Phase Controlling in HfO$_2$ Bulk Single Crystal*  
XIANGHAN XU (Presenter), FEI-TING HUANG, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Contingent upon the miniaturization of semiconductor circuits, high-dielectric hafnium oxide (HfO$_2$) serves an alternative to silicon oxide. Surprisingly, the continued scaling comes with unexpected ferroelectricity at nanoscale HfO$_2$ in both pure and doped forms. These unusual findings are attributed to polymorphic nature including monoclinic, tetragonal, and orthorhombic phases and phase transitions in thin films, which is a big challenge in bulk crystal growth. Here, we show that utilizing the state-of-the-art laser floating zone technique allows the stabilization of the metastable phases at room temperature and pressure. We investigate the evolution of structural phases with various thermal treatments and doping. A comprehensive study on the structural transition pathway using in-situ transmission electron microscope (TEM) will be discussed. Our results provide insights for an alternative route for phase controlling of HfO$_2$ and the comparisons with thin films.

*The work at Rutgers University was supported by the NSF under Grant No. DMR-1629059.
The effect of air-anneal on two-level tunneling systems of ion-beam sputtered amorphous SiO$_2$*  

XIAO LIU (Presenter), MATTHEW ABERNATHY, THOMAS METCALF, United States Naval Research Laboratory, MASSIMO GRANATA, LORENZO MERENI, ALEX AMATO, CHRISTOPHE MICHEL, Laboratoire des Matériaux Avancés, GIANPIETRO CAGNOLI, Institut Lumière Matière, Université de Lyon — Reducing mechanical loss, or internal friction, in amorphous dielectric coating materials is practically important in many present-day applications, such as mirror coatings of gravitational-wave detectors or dielectric insulating layer in superconducting quantum bits. It is known that mechanical loss is dominated by atomic tunneling through potential barriers of double-well potentials below ~10 K and by thermal activation over the same potential barrier landscape. It has been found that extended air anneal reduces near-room temperature mechanical loss of ion-beam sputtered amorphous SiO$_2$. We measured elastic properties of ion-beam sputtered amorphous SiO$_2$ from 0.3 K to room temperature that includes internal friction, shear modulus and the relative change of speed of sound, and found that internal friction increases slightly accompanied by a large drop of thermal activation peak at higher temperatures. We discuss possible mechanisms for our observations.

*Work supported by the Office of Naval Research

Demonstration of two-dimensional hole gases (2DHG) in strained GeSn quantum wells*  

CHIA-TSE TAI, CHENG-YU LIN (Presenter), CHIA-YOU LIU, TZ-MING WANG, Natl Taiwan Univ, CHARLES HARRIS, TZU-MING LU, Sandia National Laboratories, JIUN-YUN LI, Natl Taiwan Univ — In this work, capacitively induced two-dimensional hole gases in undoped Ge/GeSn heterostructures were demonstrated. Ge/GeSn heterostructures with Sn fractions of 6%, 9% and 11% were grown by chemical vapor deposition with surface roughness below 3 nm. Hall bar devices were fabricated and characterized at 4 K. Density saturation was observed and the highest mobility was $1.9 \times 10^4$ cm$^2$/Vs. The dominant scattering mechanism is likely background impurity scattering. Shubnikov-de Haas oscillations and the quantum Hall effect were observed at B > 1 T, indicating high-quality material growth of Ge/GeSn heterostructures. Effective masses were extracted by the temperature-dependent SdH oscillations.

3:18PM D27.00005: High sensitivity neutron detectors based on hexagonal boron nitride epilayers*  
AVING MAITY (Presenter), SAMUEL GRENAUDIER, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ — Hexagonal boron nitride (h-BN) has emerged as a promising material for realizing high efficiency solid-state thermal neutron detectors. Here, we report the epitaxial growth of thick h-$^{10}$BN ($^{10}$B enriched) epilayers and demonstration of thermal neutron detectors with a record high detection efficiency. To increase the overall detection sensitivity, we have explored strategies in material growth and device processing to reduce the detector’s dark current, capacitance, and surface recombination field and realized h-$^{10}$BN detectors from 100 µm thick freestanding wafers with a detection area as large as 1 cm$^2$ and a detection efficiency as high as 59%. We discuss the detail design and implementation of horizontal h-$^{10}$BN detectors to overcome the detrimental effects associated with increased dark current, capacitance, and surface recombination with increasing detector size, through reduction in metal contact area of the detector and utilization of superior lateral transport properties of h-BN. This work lays the foundation for achieving highly sensitive large h-$^{10}$BN neutron detectors for practical applications.

*This research is supported by DOE ARPA-E (DE-AR000964). Drs. Jiang and Lin are grateful to the AT&T Foundation for the support of Ed Whitacre and Linda Whitacre endowed chairs.

3:30PM D27.00006: Defect effects on Electron Magneto-Transport in Quantum Wells*  
DANHONG HUANG (Presenter), Space Vehicles Directorate, Air Force Research Lab - Kirtland, ANDRII IUROV, Department of Physics, Medgar Evers College of City University of New York, FEI GAO, Nuclear Engineering and Radiological Sciences, University of Michigan, Ann Arbor, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College of the City University of New York — The point-defect effects on the electron magneto-transport in a multiple quantum-well system are investigated by employing a many-body theory. By working within the ladder approximation, our theory takes into account the local-field vertex correction to a bare polarization function of electrons. Moreover, both intralayer and interlayer screening to defect-electron interactions are included within the random-phase approximation. Furthermore, by studying defect charging dynamics, both capture and relaxation times of a point defect, as well as captured density of electrons, are computed as functions of temperature, electron density and different types of point defects. Finally, numerically calculated defect effects on energy-relaxation and momentum-relaxation times of are presented and analyzed for various defect and electron densities and different temperatures as well.

*DH would like to acknowledge the financial supports from the Air Force Office of Scientific Research (AFOSR) and the Laboratory University Collaboration Initiative (LUCI) program.
3:42PM D27.00007: Atomistic Simulations of the Cold Source Field-Effect Transistor for Sub-60 mV/decade Switching*  
RAPHAËL PRENTKI (Presenter), Physics, McGill University, MOHAMMED HARB, NanoAcademic Technologies, HONG GUO, Physics, McGill University — Sub-60 mV/decade subthreshold swing (S) transistors have been the object of considerable research efforts due to their low power dissipations. The cold source field-effect transistor (CSFET) achieves low S by suppressing thermionic emission in the OFF-state through source density-of-states engineering. This device has thus far only been investigated by simulations based on effective mass, k.p, and ballistic approximations. We report the first simulations of CSFETs based on combining the nonequilibrium Green's functions (NEGF) formalism with the tight-binding (TB) method, thereby capturing the atomistic details of the devices under nonequilibrium conditions. Specifically, we consider gate-all-around Silicon nanowire CSFETs grown in [100], [110], and [111] with diameters ranging from a few Å to a few nm. We find that vacancies and surface roughness have little influence on the performance of the device, which maintains a low S even in the presence of elastic scattering. Finally, we present both n-type and p-type CSFETs, thus substantiating the compatibility of CSFETs with complementary metal–oxide–semiconductor (CMOS) technology.

*Supported by Fonds de Recherche du Québec - Nature et Technologies (FRQNT) and the Natural Sciences and Engineering Research Council (NSERC) of Canada.

3:54PM D27.00008: Looking Back to Look Forward: How scarcity affects electronics cost and drives material research*  
SAMANTHA REESE (Presenter), ALBERTA CARPENTER, ROBIN BURTON, National Renewable Energy Laboratory — Typically discussions of electronics focuses on high value semiconductor products. However, without commoditized components such as resistors and capacitors and materials such as printed circuit boards and solder, electronic devices are not possible. As Moore's Law enables the internet of things (IOT) and allows data to become even more ubiquitous, the consumer electronics market is projected to experience an annual growth rate of 11.6% reaching $528 billion in 2023. This means more components are needed. Case studies will be presented showing how electronics manufacturing volume effects the raw material cost. An analysis of materials needed for commoditized component manufacturing will be shown, it will identify raw materials that could either cause significant cost increases to or even interrupt the component supply chain. The information can then be utilized to direct research into substitution materials or to suggest process improvement opportunities.

*This work was authored by the National Renewable Energy Laboratory (NREL), operated by Alliance for Sustainable Energy LLC, for the U.S. Department of Energy (DOE) under contract no. DE-AC36-08GO28308. Funding provided by U.S. Department of Energy Office of Energy Efficiency and Renewable Energy Advanced Manufacturing Office.
4:06PM D27.00009: Angular Characterization of Magneto Optical Kerr-Effect by Ellipticity Modulation in Ultrathin Samples  
FERNANDO RAMIRO-MANZANO (Presenter), JAUME MESEGUER-SÁNCHEZ, FERNANDO CANTOS-PRIETO, EFREN NAVARRO-MORATALLA, Crisol Lab. Institute of Molecular Science (ICMol), University of Valencia — Magnetism in 2D materials has become of paramount interest in the scientific community because of overcoming the limitations of the Mermin-Wagner theory, nevertheless, new puzzling questions have arisen. Establishing the thickness frontier between bulk ferromagnetism and few-layer antiferromagnetism or the determination of the spin model that the 2D magnets follow are some of the current unsolved questions. One of the most sensitive techniques for characterizing the magnetism is the polarization changes of ellipticity-modulated light when interacts with a magnetic material. This technique permits to characterize both the Kerr-rotation and magneto-circular dichroism with a sensitivity bellow 100 µrad. Here, we will show the peculiarities of the experiments and simulations of the angular response of Van der Waalls magnetic materials. In particular, the Fourier plane response is acquired and compared with the simulation of the magneto-optical behavior. The fit results could allow extracting important parameters such as the spin orientation.

4:18PM D27.00010: Designing and characterizing rare-earth upconverting nanoparticles as nanoNewton mechanical sensors.  
CLAIRE MCLELLAN (Presenter), STEFAN FISCHER, CHRIS SIEFE, JASON CASAR, DAYNE SWEARER, MASASHI FUKUHARA, Materials Science and Engineering, Stanford University, MIRIAM B. GOODMAN, Department of Molecular and Cellular Physiology, Stanford University, JENNIFER A. DIONNE, Materials Science and Engineering, Stanford University — Non-invasive nanoscale mechanical force sensors will enable the monitoring of nanoNewton-scale forces in biological and condensed matter systems. Due to their near-infrared excitation with visible emission and robust host lattices, rare-earth upconverting nanoparticles (UCNPs) are a promising technology for mechanical force sensing. When engineered correctly, UCNPs exhibit a ratiometric color response to applied pressure but maintaining brightness high enough to detect this ratiometric color change at the single-particle level remains an outstanding challenge in the field. To create bright and force responsive particles, we explore alkaline earth host lattices (CaLuF, SrLuF, BaLuF). All particles studied are sub-15nm in diameter, core-shell, and are doped with 30% Yb$^{3+}$ and 2.9% Er$^{3+}$. Ensemble measurements with a diamond anvil cell yield a red-to-green intensity ratio ($I_R/I_G$) pressure responses of 20 ± 1.2, 16.2 ± 0.5, 12.7 ± 0.8, and 40 ± 4% ($I_R/I_G$/GPa for CaLuF, SrLuF, BaLuF, and NaYF$_4$, the control sample, respectively. We find that SrLuF-based nanoparticles respond to mechanical pressures changes of 37 MPa or 27 nN of force. Using a custom confocal-AFM microscope, we explore the brightness of single UCNPs and are developing techniques to explore their force sensitivity.
4:30PM D27.00011: Porous Carbon Nanotube Ring Resonators for Gas Sensing Application
DAVID MCKENNA (Presenter), HENRY DAVIS, RJ CASS, RICHARD VANFLEET, ROBERT DAVIS, Brigham Young Univ - Provo — Using the carbon nanotube templated micro-fabrication (CNT-M) method we have formed and characterized porous micro-mechanical ring resonators for gas sensing applications. The tunable porosity of the CNT structures lends itself to high surface area to volume ratios. In the resonator, a high surface area to mass ratio coupled with a high quality factor (Q) can enable detection of gasses at very low concentrations. The gas concentration detection limit is proportional to the inverse of the Q of the resonator. Building on previous work with micro-cantilevers, here we present results of in-plane ring resonators designed to reduce clamping and thermoelastic losses. This in-plane mode has the added advantage of being less sensitive to manufacturing variations in the height of the resonator. We present our work characterizing the gas and time response of these resonators.

4:42PM D27.00012: Role of dimensionality on thermodynamic properties in layered sulfides* NATHAN KOOCHER (Presenter), JAMES RONDINELLI, Materials Science and Engineering, Northwestern University — Understanding thermal expansion of materials helps in assessing the capability, performance, and lifetime of materials operating in variable thermal conditions. Previously Ca$_3$Ti$_2$O$_7$ with the layered Ruddlesden-Popper (RP) structure (n=2 member of A$_{n+1}$B$_n$O$_{3n+1}$) was found to exhibit pressure-tunable negative thermal expansion (NTE) and a pressure-independent softening of the bulk modulus due to a quasi-two-dimensional vibration [Huang et al, Phys. Rev. Lett. 117, 115901 (2016)], whereas RP strontium titanates did not exhibit NTE [Huang et al, Chem. Mater. 30, 7100 (2018)]. Here, we evaluate structural, lattice dynamical, and thermodynamic properties of the barium zirconium sulfide family with layer thickness $n=1,2,$ and $\infty$ using the self-consistent quasi-harmonic approximation within density functional theory. We formulate layer thickness dependent models of the anharmonic lattice properties and discuss how they may be used for design of thermal expansion coefficients in other chemistries.

*This work was funded by the National Science Foundation through grant no. DMR-1720139.
4:54PM D27.00013: Elastic Constants of Boron Arsenide and Boron Phosphide Crystals
*SUSHANT MAHAT (Presenter), University of Illinois at Urbana-Champaign, SHENG LI, HANLIN WU, PAWAN KOIRALA, BING LV, University of Texas at Dallas, DAVID CAHILL, University of Illinois at Urbana-Champaign — We report experimental results for picosecond ultrasonics (PU) studies of boron arsenide and boron phosphide crystals with zinc blend structure. These materials have coefficients of thermal expansion similar to commonly used semiconductors like Si and GaAs, and the synthesis of BAs and BP single crystals with thermal conductivity as high as 1000 and 540 Wm⁻¹K⁻¹ respectively has made them into promising materials for thermal management applications. Using PU, we measure Brillouin scattering frequencies and calculate longitudinal and shear velocities along several directions of the BAs and BP single crystals. The crystal directions are determined using electron backscattering diffraction and associated Christoffel equations are used to solve for the elastic constants of the crystals. We report $C_{11}$, $C_{12}$, and $C_{44}$ values of 289.4, 113.5 and 159.0 GPa for BAs and 310, 87, and 160 GPa for BP, respectively. Furthermore, we also demonstrate the utility of PU in studying optical and acoustic attenuation in these crystals. The elastic constants and the attenuation measurements will help to predict thermal transport behavior in these materials.

5:06PM D27.00014: Microscopic model for contact electrification between solids and fluids
MORTEN WILLATZEN (Presenter), Chinese Academy of Sciences, LOK CHONG LEW YAN VOON, Physics Department, University of West Georgia, ZHONG LIN WANG, School of Materials Science and Engineering, Georgia Institute of Technology — Triboelectric charge transfer between materials is a well-known phenomenon since more than 2000 years that still causes dispute. Recent experimental evidence suggests electron transfer to be the main mechanism for contact electrification between dielectrics and metals, and the electron transfer is specified by the material bandstructures and Fermi levels [1]. We present a new microscopic formalism based on a tight-binding Hamiltonian to describe charge transfer between two materials. The model captures charge transfer dynamics on a femtosecond scale, reveals the influence of Coulomb interactions for charge transfer oscillations, and is able to predict charge transfer differences between materials whether structured or disordered solids and fluids. We demonstrate that charge transfer between fluids and solids is more effective than between two solids, that charge transfer between two similar materials is possible, and shed light on the differences between metal-dielectric and dielectric-dielectric contact electrification.

Due to their sizable bandgap and layer-dependent properties, the transition metal dichalcogenides (TMDs) are of interest for a variety of electronic and optoelectronic applications.\(^1\) While much research in the field of 2D materials has focused on the emergent properties as a result of confinement to two dimensions, further confinement into quasi-one-dimensional nanoribbons is expected to provide a further handle for tuning the electronic structure.\(^2,3\) In this work, we have employed a bottom-up gas-phase synthesis within carbon nanotubes to template the growth of TMD nanoribbons. By growing the materials within nanotubes we can create nanoribbons with variety of widths. The nanotubes also provide protection from degradation due to oxidation or solvents enabling the facile handling and study of air-sensitive materials.

**Session D28 GMED FIAP: Metrology in Medical Imaging**

Invited
The standard paradigm in medical imaging uses sophisticated imaging systems that take advantage of a variety of phenomena that create image contrast, and those images are subjectively interpreted by highly trained clinicians. The trend toward measurement-driven medicine motivates an effort to convert imaging systems into measurement systems which provide quantitative imaging biomarkers. The mission of the Radiological Society of North America’s Quantitative Imaging Biomarker Alliance is to improve the value and practicality of quantitative imaging biomarkers by reducing variability across devices, sites, patients, and time. The core of the effort is the adoption of the principles of metrology into image analysis methods so confidence intervals can be claimed on imaging/measurement performance. Physicists’ contribution to this effort includes developing new imaging biomarkers, creating simulations of the physical interactions of image formation (in silico phantoms), and creating methods for objectively quantifying the technical performance of the system. Examples of objectively assessed parameters that are direct substitutes for subjectively assessed parameters, as well as other parameters that are not readily extracted from standard imaging methods, will be described. Methods for assessing their performance as quantitative imaging biomarkers will be described.

*Professor Hall is a Vice-Chair of the Quantitative Imaging Biomarker Alliance and is supported through a contract between The University of Wisconsin and the Radiological Society of North America. Some of the data shown was obtained under funding by NIH grants R01HD096361, R01HD072077, and R01CA140271.
3:06PM D28.00002: Importance of Statistical Metrology Framework for Quantitative Imaging Applications* [Invited] NANCY OBUCHOWSKI (Presenter), Quantitative Health Sciences, Cleveland Clinic Foundation — Quantitative imaging is being increasingly used to diagnose disease, predict patients’ outcomes, and monitor and adapt treatment. In clinical trials, quantitative imaging often serves as a non-invasive endpoint which can provide results earlier than traditional patient outcomes.

The precision and bias of quantitative imaging measurements drive their utility at the bedside and in clinical trials. Precision describes the closeness of replicate measurements, while bias describes how the measurements differ from the true value [1]. These technical performance characteristics are important in order to understand patients’ measurements, as well as to plan and analyze clinical trials [2].

In this presentation we examine several clinical trials using quantitative imaging. We discuss how the technical performance characteristics of the imaging biomarkers are used to determine sample size, identify eligible subjects, estimate treatment effect, and interpret measurements and change in measurements over time.

*Dr Obuchowski is a statistical consultant for the Quantitative Imaging Biomarker Alliance, through a contract between The Cleveland Clinic Foundation and RSNA.

3:42PM D28.00003: Quantitative Imaging Applications for Radiography and Computed Tomography [Invited] SAM ARMATO (Presenter), Department of Radiology, University of Chicago — Post-acquisition mathematical analysis of medical images can range from simple image processing to complex computer-aided diagnosis. The intent of such manipulation can range from the enhancement of aspects of the image for improved human visualization to artificial intelligence. The tools available for image analysis span the fields of mathematics, statistics, and computer science and incorporate biophysical aspects of the medical image acquisition system. The extraction of quantitative information (or “features”) from medical images and the use of this information to assist radiologists in their medical decision-making process (termed “radiomics”) has expanded medical imaging from a subjective art to much more of an objective science. Radiography, as the most common imaging modality, and computed tomography (CT), as the predominant tomographic imaging modality, both benefit from a vast array of quantitative techniques. Applications include volumetry of tumors and other abnormalities, assessment of response to therapy, patient prognosis, and evaluation of disease severity.
Due to its unique physical decay properties, positron emission tomography (PET) was developed, commercialized and marketed as a quantitative imaging technique. The first commercial scanners sold in the 1970s targeted the clinical research market, in particular for neurology and cardiology applications. The 1980s saw the rapid development of a new PET tracer called 18-F fludeoxyglucose (FDG), which is an effective tracer to quantitatively measure absolute glucose metabolism (e.g. umol of glucose/min/100 gm of tissue) non-invasively. It was soon shown that FDG PET filled an unmet clinical need for both the diagnosis and treatment of cancer patients, and the 1990s saw a rapid growth of clinical PET. PET innovations in the 2000s included whole body PET scans (e.g. moving the patient bed so patients can be scanned from head to toes), and the hybridization of PET scanners with CT and MR for better anatomical location. Today, 95% of all clinical PET scans are whole body FDG oncology scans. However, in order to make the scan time shorter and the analysis and reading faster, surrogate measures of absolute glucose metabolism were developed. The most popular surrogate is the standardized uptake value (SUV), and this talk will cover the pros and cons of using the SUV as a quantitative measure and initiatives driven by PET physicists and clinicians to make it a better universal and quantitative measure. The latest quantitative PET innovations from industry will also be presented, including making the measure of absolute glucose metabolism practical in the clinic – effectively bringing PET full circle and back to its commercial beginnings.

Magnetic Resonance Imaging (MRI) is able to interrogate a wide range of physical parameters. Some of these are intrinsic to magnetic resonance, such as relaxation times, while others are universal, such as diffusion coefficients, temperature, or magnetic susceptibility. This talk will provide an overview of important quantitative imaging biomarkers (QIBs) in MRI, highlighting their current and future applications, the challenges in measurement science and implementation, and the current status and progress of QIBs towards widespread clinical adoption.

The path from bench to bedside of QIBs involves researchers from many disciplines, and provides numerous opportunities for physics to inform approaches and improve the reliability of imaging. Bench scientists ensure that QIBs can be traced to primary standards, developing measurement infrastructure to establish ground truth values for reference materials and objects, known as phantoms. The Quantitative Imaging Biomarker Alliance (QIBA) is composed of stakeholders including equipment vendor and pharmaceutical representatives, statisticians, clinicians, technologists, and physicists. QIBA develops and promulgates standards-based documents known as Profiles that harmonize data acquisition and analysis, and which utilize reference standards, both physical and digital, to assess end users’ ability to conform to the Profile. The use of QIBA Profiles in clinical trials and clinical practice, backed by sound measurement science, can improve reproducibility of results, enhancing patient care and outcomes.
2:30PM D29.00001: Spatial-temporal organization of bacterial suspensions under confinement* [Invited] IGOR ARONSON (Presenter), Biomedical Engineering, Pennsylvania State University — Suspensions of motile bacteria or synthetic microswimmers, termed active matter, manifest a remarkable propensity for self-organization and formation of large-scale coherent structures. Most active matter research deals with almost homogeneous in space systems and little is known about the dynamics of active matter under strong confinement. We present experimental and theoretical studies on the expansion of highly concentrated bacterial droplets into an ambient bacteria-free fluid. The droplet is formed beneath a rapidly rotating solid macroscopic particle inserted in the suspension. We observed vigorous inability of the droplet reminiscent of a supernova explosion. The phenomenon is explained in terms of continuum first-principle theory based on the swim pressure concept. Furthermore, we investigated self-organization of a concentrated suspension of motile bacteria *Bacillus subtilis* constrained by two-dimensional (2D) periodic arrays of microscopic vertical pillars. We show that bacteria self-organize into a lattice of hydrodynamically bound vortices with a long-range antiferromagnetic order controlled by the pillars’ spacing. Our findings provide insights into the dynamics of active matter under extreme conditions and significantly expand the scope of experimental and analytic tools for the control and manipulation of active systems.

*NSF PHY-1707900

3:06PM D29.00002: Trapping of microswimmers in vortex flows* SIMON BERMAN (Presenter), KEVIN A MITCHELL, University of California, Merced — We theoretically investigate the trapping of rigid, ellipsoidal microswimmers in externally-driven two-dimensional vortex flows. Surprisingly, for swimmers that swim perpendicular to their elongation direction, we find that trapping depends non-monotonically on swimming speed. We identify certain stable periodic solutions of the swimmer equations of motion as the cause of trapping in individual vortices. A bifurcation analysis of these solutions explains the dependence of trapping on swimmer speed, shape, and swimming direction. We propose heteroclinic bifurcations between swimming fixed points as a general mechanism for the creation of stable swimmer trajectories.

*Supported by NSF grant CMMI-1825379.
3:18PM D29.00003: Sensorimotor processing and navigation in confined microswimmers
SAMUEL BENTLEY, VASILEIOS ANAGNOSTIDIS, FABRICE GIELEN, KIRSTY WAN (Presenter), University of Exeter — All living organisms are environmentally intelligent. This is the fundamental distinction between life, and other forms of matter. Even unicellular organisms are capable of complex behaviours, for they can sense as well as respond to changes in the environment. Here, we study spontaneous and constrained motor actions in algal microswimmers, using motility as a dynamic read-out of behaviour and physiology. Previous studies have focussed on locomotion transients over short timescales ranging from milliseconds to minutes. We present a novel microfluidic platform which allowed us for the first time to monitor and analyse algal cell motility over hours, and even developmental timescales. We focus on two species, a biflagellate which exhibits a form of run-and-tumble, and an octoflagellate which exhibits a tripartite behavioural repertoire termed run-stop-shock. Excitability and stochastic transitions in swimming gait are projected onto a low-dimensional state space. We reveal how flagellar mechanosensitivity mediates repetitive boundary interactions, and discuss the discovery of a light-dependent quiescent regime. Finally, we conduct pharmacological perturbations within these microenvironments, to shed new light on the physiological origins of excitable flagellar dynamics.

3:30PM D29.00004: Topographical guidance of highly-motile cells using cell-sized features
JOERI WONDERGEM (Presenter), KOEN K SCHAKENRAAD, Leiden University, PATRICK WITZEL, University of Würzburg, MARIA MYTILINIOU, Leiden University, DAVID HOLCMAN, École Normale Supérieure, DORIS HEINRICH, Leiden University — Cells navigate complex environments where they encounter a variety of physical cues. The extracellular topography is such a cue, as a substrate of anisotropically placed, sub-micron sized pillars, was recently shown to induce directed cell migration, a process named topotaxis. Here, we focused on a larger scale, and studied the influence of cell-sized obstacles on highly-motile, persistent cell migration. Using engineered topographies, reminiscent of pores cells squeeze though in vivo, and tracking cell migration, we explored the effects of spacing and obstacle geometry on cell motility. We show that cells undergo long-range topotaxis over large distances by anisotropically placed cell-sized obstacles. Furthermore, we performed active particle simulations, a minimal model for cell motility, to investigate the physics needed to reproduce key features of cell motion in different topographies. Finally, we show that long-range topographic guidance is conserved in chemical gradients, and moreover, the cues, topotaxis and chemotaxis, abide to linear summation, guiding the cell in the direction of both cues combined. Hence, topotaxis offers an independent way to steer cells, which can be exploited as a tool for in vitro applications, like lab on chip diagnosis and tissue engineering.
3:42PM D29.00005: Quenching active matter using light: Light mediated motility in swarming Serratia marcescens*  ARVIND GOPINATH (Presenter), JUNYI YANG, University of California, Merced, ALISON PATTESON, Department of Physics, Syracuse University, PAULO ARRATIA, Mechanical engineering, University of Pennsylvania — Understanding the connection between external stimuli such as light and emergent response manifested in multicellular, collective and long-range motility of cells and cell-like active systems remains a challenge. Swarming, a mode of bacterial surface migration is characterized by emergent flows, persistent structures and collaborative collective motility. Here we present the effects of light on the collective motility in a dense and far from equilibrium active system – swarms of the bacteria Serratia marcescens. Using a experimental light-based technique, we induce and generate localized condensed domains differing in motility. We then study immobilization and quenching of flow inside these domains and map the response to light in terms of the light intensity and duration of exposure. Together these parameters determine the reversibility of the response, domain size and extent of the mobility impaired region as well as its temporal evolution. Complementing our experimental results, we propose and analyze a minimal Brownian dynamics model to study the escape of bacteria from the exposed region before they are completely immobilized and trapped.

3:54PM D29.00006: Submerged micro-structures generate a soft boundary effect on active nematic flows*  DIMITRIUS KHALADJ (Presenter), AMANDA TAN, LINDA S. HIRST, University of California, Merced — Actively driven bundled microtubule networks have become a useful framework to study energy driven defects in structured fluids. Moreover, the implementation of soft boundaries instead of hard side walls can be a useful strategy to control defect flow and dynamics. We study the behavior of an active nematic microtubule system confined by submerged complex geometries. From our preliminary work, we have observed that submerged 3D structures can influence defect dynamics. We also demonstrate that the soft barrier generated by the submerged structures form stagnation points near the boundary reminiscent of those seen for hard boundaries. With the assistance of micro fabrication, we investigate the spontaneous flows of this novel system under confined conditions i.e. in proximity to the boundary of the submerged structures. For this investigation, we used cylindrical pillars and rectangular trenches. We are also interested to learn if the submerged surfaces will impact chaotic mixing dynamics.

4:06PM D29.00007: Lattices by design: exploring long-ranged interactions with gradient sensing droplets*  ANTON MOLINA (Presenter), MANU PRAKASH, SHAILABH KUMAR, Stanford Univ — Many body interactions are ubiquitous and occur across length scales, giving rise to a vast diversity of phenomena ranging from frustration to pattern formation with important implications for the design of new materials. However, their behavior can be challenging to predict since the number of relevant configurations scales exponentially with the number of particles. Two-component Marangoni-contracted droplets have been shown to interact via long-ranged vapor mediated attractions, resulting in a dynamic behavior that resembles chemotaxis and a capacity to self-organize. Meanwhile, hydrophobic barriers can create well-defined potential energy wells that are impassable to droplets but transparent to a vapor gradient landscape. Here, we develop exotic lattice systems that exploit the tools of photolithography to fabricate arbitrary patterns of hydrophobic boundaries, enabling us to experimentally manipulate the geometry in which long-ranged degrees of freedom interact. The macroscopic nature of this system provides real time access to microstate configurations, providing the opportunity for mechanistic insights and the development of control strategies in complex, interacting systems.

4:18PM D29.00008: Arresting Active Spinning Particle Coarsening in Passive Media via Actuation Protocols  JOSHUA STEIMEL (Presenter), Univ of the Pacific, RYAN TOLLEFSEN, Oregon State, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Active matter systems are unique in the rich non-equilibrium dynamical behavior that emerges such as flocking, lanning, swarming, and vortexting. Such emergent behavior has been previously observed in complex hybrid active-inactive systems with in-plane rotating magnetic particles; where active particle attraction is induced by the activity of the particles and the mechanical properties of the passive media. When continuously actuated these active particles will aggregate and coarsen. We present a novel approach which allows the control of coarsening behavior and resultant characteristic domain size via modulation of the activity actuation protocol. By tuning the frequency at which the rotational direction of the active spinning magnetic particles is changed, either clockwise or counter-clockwise, the system can exhibit microphase separation behavior distinct from the macrophase separation of active and passive particles. Changing the rotational direction is effectively equivalent to reversing the torque and unloading the stress in the system. This limits the ability of active particle clusters to attract, can arrest the coarsening behavior, and decrease the characteristic domain size. Thus, allowing control of the structure of these hybrid active-inactive systems.
4:30PM D29.00009: Flocking Transition in a Self-propelled Particle Model Using Experimental Motility Conditions*  JELANI LYLES, PAUL YANKA (Presenter), CHIH KUAN TUNG, North Carolina A&T State Univ, DANIEL SUSSMAN, Emory University, M. LISA MANNING, Syracuse University — Flocking transition has been studied using self-propelled particle models for decades. In these models, the initial angular distribution is random, the step-by-step angular fluctuation is either a bounded flat noise or a Gaussian noise, and the magnitude of the velocity of each moving particle is thought to be a constant. Experimental study of sperm flocking show that an aligned initial condition promotes sperm to form large flocks, angular fluctuation follows an exponential decay, and the velocity distribution follows a Gamma distribution. Our research has focused on using a computational model to understand the effects from those differences between experimental observation and the traditional model conditions. We found that aligned initial condition does help sperm to form larger flocks when the system is at the transition, but not much effect elsewhere. No major difference was seen between exponential and Gaussian angular noise. The Gamma velocity distribution was found to lower the density of the flocks. Our results provide evidence to rethink adapting the conclusion from active matter models to experimental systems.

4:42PM D29.00010: Re-entrant self pumping in confined active fluids*  MINU VARGHESE (Presenter), ARVIND BASKARAN, MICHAEL HAGAN, APARNA BASKARAN, Brandeis Univ — Spontaneous flows in the form of swirls is ubiquitous in biological systems. Such active swirling/turbulent flows self organize into net pumping flows when confined appropriately. Studies on 2D systems suggest that self pumping results when the confinement length scale is smaller than the size of swirls that form spontaneously in the bulk. However, recent experiments have shown that when confined in 3D channels, the emergence of self pumping can be more sensitive to the aspect ratio of the channel than to the size of the channel itself. This is a phenomenon that is unique to 3D and to active fluids. In this talk, I will discuss the origin of this phenomenon using an active hydrodynamic theory.

*This project was funded by the Brandeis MRSEC, and supported by computational resources from XCEDE
4:54PM D29.00011: Tunable self-organization of swimming magnetic bacterial suspensions*
HIRAN WIJESINGHE (Presenter), CHRISTOPHER J PIERCE, ERIC MUMPER, BRIAN LOWER, STEVEN LOWER, RATNASINGHAM SOORYAKUMAR, Ohio State Univ - Columbus — When units of active matter are brought together, the properties of the new construct are not always equal to the sum of the properties of the components. Instead, at each level, new behavior and rules (i.e., emergent properties) appear. For instance, the emergence of spontaneous order in collections of disordered biological components, from suspensions of biofilaments to bird flocks, is widespread in nature. We present population-level self-organization in a flagellated magnetic bacterial suspension of *Magnetospirillum magneticum* (AMB-1) that is amenable to experimental control using programmable fields. A major hindrance to the understanding of the emergent properties in a typical biological system is its complexity due to competing inter-component interactions, biological and external constraints, non-equilibrium dynamics, as well as stochasticity. Detailed computational modeling of hydrodynamics and magneto-aerotaxis in these motile AMB-1 suspensions reveals the underlying mechanisms leading to their self-organization, by producing experimentally verifiable population-level dynamics. This approach can be generalized to other species and active matter systems in general.

*This material is based upon work supported by the National Science Foundation under grant ECCS 1710598.

5:06PM D29.00012: Dynamics of 2D Active Nematics Confined in an Annulus*
CHAITANYA JOSHI (Presenter), ZAHRA ZAREI, MICHAEL M NORTON, SETH FRADEN, APARNA BASKARAN, MICHAEL HAGAN, Brandeis University — Active nematics are a class of non-equilibrium systems with constituents that consume energy at the molecular level to generate motion. While the dynamics of a bulk 2D active nematic are turbulent, confinement can provide a systematic way of achieving control over the flow. An annulus confinement geometry is particularly interesting because it could generate self-driven circulating flows. Indeed, such states have been found in recent experiments. In this talk, we will discuss a theoretical and computational study of 2D active nematics confined to an annulus. By performing simulations and comparing results against experiments as a function of geometry, boundary conditions and activity, we identify the driving forces and factors that control net circulation. In addition, by comparing the spatiotemporal behaviors as a function of annulus geometry with those observed in a channel, we elucidate the effect of boundary curvature on emergent behaviors in an active nematic.

*This work is funded by the NSF MRSEC DMR-1420382 and DMR-1855914.
5:18PM D29.00013: Self-organization of bacterial active matter in space and time*  SONG LIU (Presenter), YILIN WU, Chinese Univ of Hong Kong — Simultaneous control of spatial and temporal organization of active matter is challenging and generally requires complex interactions. Here we found that tuning the rheological properties of bacterial active fluids enables large-scale spatial and temporal self-organization. Combining experiments with an active matter model, we explain the phenomenon in terms of the interplay between active forcing and viscoelastic stress relaxation. Our findings advance the understanding of bacterial behavior in complex fluids and demonstrate experimentally that rheological properties can be harnessed to control active matter flows.

Monday, March 2, 2020 2:30 PM - 5:30 PM

2:30PM D30.00001: How do cells control the length of their flagella?  PRATHITHA KAR (Presenter), Harvard University, THOMAS FAI, LISHIBANYA MOHAPATRA, JANE KONDEV, Brandeis University, ARIEL AMIR, Harvard University — Cells assemble a number of filamentous structures which have a specific length. The question of how cells control the length has been studied extensively in model organism *Chlamydomonas reinhardtii* which has two flagella of the same length.

Past studies have shown that when one of the flagella is severed, its length increases over time while, remarkably, the other flagellum shortens. Upon reaching a common length, the two flagella grow together until reaching their steady state length. Although we know the molecular players involved in the process, the mechanism is not well understood.

Previously, several models have suggested length-control to occur via the length-dependent assembly of the flagella. Here, we show that within a wide class of models, length-control of multiple flagella can only occur if the disassembly (depolymerization) of the flagella is length-dependent. We provide concrete examples to show how such length-dependent-depolymerization can occur within simple biophysical models.
How cells regulate the size of filamentous structures, networks and organelles, despite continuous turnover in their component parts, is a longstanding question. Recent experiments suggest that size control of many intracellular structures and organelles is achieved through depletion of a limiting subunit pool in the cytoplasm. While the limiting pool mechanism ensures organelle size scaling with cell size, it does not provide a mechanism for sensing and regulating individual organelle size.

Here we present a physical theory for non-equilibrium self-assembly and size regulation of subcellular structures, based on negative feedback between structure size and growth rate. This model provides a mechanism for robust size regulation of multiple structures in the presence of stochasticity and competition for resources. Using this model we predict size regulation of multiple organelles, filaments, and networks, in quantitative agreement with available experimental data. We also demonstrate how competition for subunit resources between multiple networks can lead to spontaneous cell polarisation.

Energy cost of protein gradient formation in cells  
ARNAB DATTA (Presenter), Brandeis Univ — Cells make protein gradients for various purposes, such as establishing position information in development or defining cell polarity in the process of cell division. Two classes of mechanisms for maintaining protein gradients in cells have been reported in the literature: i. those that combine protein diffusion and degradation, and ii. mechanisms that involve active transport of proteins by molecular motors. An example of the first mechanism is the Bicoid protein gradient in the Drosophila embryo, which provides positional information to the nuclei during development. A Smy1 gradient along actin cables in budding yeast cells regulates cable length and is formed by active transport of the proteins by myosin motors to the bud neck [1]. Establishing and maintaining these protein gradients require cells to expend energy. In this talk I examine different mechanisms of gradient formation in cells and estimate the energy costs associated with them. I also consider the scaling of the energy expenditure with cell size for the two different models of gradient formation, and discuss when one mechanism is energetically less costly than the other.

First passage times in multi-protein self-assembly

BHAVYA MISHRA (Presenter), MARGARET JOHNSON, TC Jenkins Department of Biophysics, Johns Hopkins University — Self-assembly of proteins is essential for various cellular processes such as signalling, and clathrin-mediated endocytosis. In general, proteins diffuse in a 3D solution and recruit other proteins. But they can also localize to a 2D membrane surface via lipids. In a recent study, we quantified how localization of proteins to a 2D surface from 3D solution reduces their search space and proteins can exploit this dimensionality reduction to trigger self-assembly. Here we show how localization can in many cases accelerate the assembly process, despite significantly slower diffusion on the 2D surface. We formulate the self-assembly of protein binding pairs as first-passage problems and calculate the mean time to approach the thermodynamic equilibrium. We can theoretically approximate the role of localization in slowing or accelerating the overall assembly process and the regimes where diffusion becomes a limiting factor. We validate these predictions against numerical solutions using reaction-diffusion simulations. These results highlight the role of diffusion versus binding rates and concentration in controlling time-scales of assembly.

Quantifying kinetics of multi-protein self-assembly, remodeling, and disassembly

YIBEN FU, MARGARET JOHNSON (Presenter), Johns Hopkins University — In the cell, multi-protein assemblies cannot persist forever and must ultimately disassemble through active or spontaneous processes. Protein assemblies involved in virion formation and clathrin-coat formation also appear to undergo dynamic remodelling which is critical for successful function. We show here using reaction-diffusion simulations how the kinetics of these assembly and disassembly processes can be sensitively tuned by the binding kinetics and cooperative interactions of the coat components and the molecules linking them to the membrane. We determine regimes where assembled structures can spontaneously remodel or disassemble. For stable structures, we then predict how enzymatic reactions can be exploited to locally destabilize links to the membrane and drive remodelling and disassembly. Using our recently developed NERDSS software, these models generate space and time-dependent predictions that can be compared directly with experiment. Our generalized computational methods can directly simulate a broad range of assembly processes at the cell-scale, providing a natural companion to quantitative cell biology.

3:30PM D30.00006: Theoretical principles of viral shell assembly and self-organization*

[Invited] ROYA ZANDI (Presenter), University of California, Riverside — Spherical crystals are elementary models of geometric frustration in materials, with important realizations in a range of systems from viral shells and fullerenes to particle- and molecular-coated droplets. Using continuum elasticity theory, we study the structure and elastic energy of ground states of crystalline caps conforming to a spherical surface. We find that the ground states consist of positive disclination defects and that the ground states with icosahedral subgroup symmetries in caps arise across a range of curvatures, even far from the closure point of complete shells. Further, we use Monte Carlo simulations to investigate the kinetic pathway of formation of viral shells (capsids) and find that the key for the formation of perfect icosahedral capsids is in the strength of elastic energy compared to the protein-protein interactions and the chemical potential of free subunits.

4:06PM D30.00007: Computational modeling to explain Hepatitis-B Virus capsid assembly, dimorphism, and disruption by antiviral drugs* FARZANEH MOHAJERANI (Presenter), BOTOND TYUKODI, Department of Physics, Brandeis University, CHRISTOPHER SCHLICKSUP, Department of Molecular and Cellular Biochemistry, Indiana University, JODI HADDEN, Department of Chemistry and Biochemistry, University of Delaware, ADAM ZLOTNICK, Department of Molecular and Cellular Biochemistry, Indiana University, MICHAEL HAGAN, Department of Physics, Brandeis University — Assembly of the outer protein shell (capsid) of a virus is an essential step in its lifecycle. Understanding the mechanisms underlying assembly and the factors that determine the final morphology will guide development of antiviral drugs that disrupt or redirect assembly processes. Hepatitis-B Virus (HBV) assembles from a single capsid protein, which adopts different conformations to form icosahedral capsids with different sizes containing 180 or 240 proteins, T=3 or T=4 respectively in the Caspar-Klug nomenclature. Despite intensive experimental and theoretical investigation, the assembly pathways and mechanisms that control HBV dimorphism remain unclear.

In this talk we will describe dynamical computer simulations of HBV assembly, using a model which is minimal and highly computationally tractable, but has parameters learned from atomistic simulation data of whole HBV capsids. The simulation results identify pathways leading to T=3 and T=4 capsid morphologies, and suggest key factors which control this dimorphism. We describe tests of the model against experimental data, and propose mechanisms of action for antiviral drugs that result in assembly of malformed shells in recent HBV experiments.

4:18PM D30.00008: Thermodynamic and kinetic aspects of polymorphism in core controlled assembly of virus-like particles* ALIREZA RAMEZANI (Presenter), Physics and Astronomy, University of California: Riverside, ORFEAS AGIS KARACHALIOS, PAUL VAN DER SCHOOT, Physics and Astronomy, Institute for Theoretical Physics, Utrecht University, ROYA ZANDI, Physics and Astronomy, University of California: Riverside — Motivated by recent experiments we investigate the phenomenon of polymorphism in core- controlled self-assembly of virus-like particles, where identical nanoparticles are encapsulated in capsids with different sizes. Our goal is to understand how protein concentration, stoichiometry and preferred curvature of capsids influence the prevalence of one shell size over another one. Using the equilibrium statistical physics and classical nucleation theory, we study how kinetic traps modify the state diagrams. We find that the free energy penalty associated with the rim proteins that have fewer favorable contacts with other proteins plays an important role in determining the capsid size. We show that in and out of equilibrium phase diagrams differ significantly and that kinetics favors the co-existence of capsids with different sizes at large stoichiometric ratios and/or protein concentration.

4:30PM D30.00009: RNA-mediated capsid nucleation of bacteriophage MS2 coat proteins confers RNA packaging selectivity TIMOTHY CHIANG (Presenter), REES F GARMANN, AARON GOLDFAIN, LANELL A. WILLIAMS, VINOTHAN MANOHARAN, Harvard University — Simple viruses, such as bacteriophage MS2, spontaneously assemble into a protein shell encapsulating a single molecule of genomic RNA. Infection of host cells by MS2 results in replication of the RNA and expression of viral coat proteins, which then package the cognate viral RNA with high selectivity despite the presence of competing host RNAs. How the MS2 coat proteins selectively self-assemble around their own RNA is poorly understood. Using interferometric scattering microscopy and quantitative gel electrophoresis, we show that the RNA-mediated nucleation-and-growth assembly pathway of MS2 coat proteins can drive preferential encapsidation of cognate RNA, and hence selective packaging.
4:42PM D30.00010: Role of C-Terminal "Arms" in the Assembly and Stability of SV40 Polymorphs*  CURT WALTMANN (Presenter), Materials Science and Engineering, Northwestern University, MONICA OLVERA DE LA CRUZ, Materials Science and Engineering, Chemistry, Northwestern University, ROI ASOR, URI RAVIV, Institute of Chemistry, The Hebrew University of Jerusalem — We study SV40 polymorphs by simulating the templated assembly process of VP1 pentamers. The simulations incorporate electrostatic effects and the connections formed between VP1 proteins by C-terminal flexible lateral units, termed here "arms". During assembly, VP1 pentamers connect to partial capsids before they bind to the template. The strength of these connections along with salt concentration can be manipulated leading to incomplete particles, T=1 particles, or aggregates of VP1 pentamers. In contrast to all other configurations, which are dynamic, the T=1 particles are static. The ability of VP1 pentamers to connect to other VP1 pentamers combined with the dynamic rearrangement of particles other than T=1 allows capsids to continue growing even when they are "pseudo-closed". The assembly mechanism described here is likely applicable to T=7 capsids.

4:54PM D30.00011: Linking Capsomere Elasticity with Virus Capsid Size and Patterning* LAUREN NILSSON (Presenter), JCS KADUPITIYA, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — Self-limiting spontaneous assembly of proteins gives rise to many structures, including virus capsids. Often copies of a single type of protein are capable of assembling into an empty shell. Higher T-number viruses of this type, such as Hepatitis B virus (HBV), present an interesting challenge to model. Though these capsids exhibit a ubiquitous icosahedral symmetry, they can display distinct tiling patterns resulting from individual capsomeres in quasi-equivalent states. In order to model the assembly of these capsids, rigid-body models either use multiple monomeric subunits with different geometries or pre-formed pentamers and hexamers with fine-tuned interactions. We introduce SOUFFLE, a molecular dynamics simulation method with elastic capsomeres, to investigate capsid assembly. The method is used to study a model T1 system as well as nucleating tiling patterns associated with T3 and T4 HBV capsids. The assembly of full T3 and T4 capsids using pentamers and hexamers pre-formed with elastic capsomeres is also probed. Based on tiling-patterns and assembly diagrams, we propose that the heterogeneity of HBV capsids can be attributed to relatively low bending modulus of its capsomeres (10-15 kB T).

5:06PM D30.00012: Bulk light-scattering measurements of viral capsid self-assembly around RNA.*  LANELL A. WILLIAMS (Presenter), Physics, Harvard, TIMOTHY CHIANG, REES F GARMANN, Applied Physics, Harvard, VINOTHAN MANOHARAN, Physics, Applied Physics, Harvard — Self-assembly is a vital part of the RNA virus life cycle. The assembly of viral coat proteins around viral RNA occurs both in vivo and in vitro, suggesting that viral capsid assembly may be driven by minimization of free energy. To better understand this process, we modify the interactions between coat proteins and between the coat proteins and RNA of MS2 bacteriophage in vitro by varying the ionic strength and pH, and we study the assembly using dynamic and static light scattering. From dynamic light scattering we determine the assembly yield and the size distribution of assembled products. From static light scattering, we measure the kinetics of assembly in bulk. By comparing the results from these two different techniques to each other and to results from gel electrophoresis, we infer features of the assembly pathway.

5:18PM D30.00013: Membrane tubulation induced by chiral crescent-shaped proteins  HIROSHI NOGUCHI (Presenter), Institute for Solid State Physics, University of Tokyo — In living cells, structures of biomembranes are regulated by various proteins. We studied the protein assembly and membrane remodeling using coarse-grained meshless membrane simulations. We revealed how chirality of crescent-shaped protein rods changes their assembly and tubulation. The achiral rods deformed the membrane tube into an elliptical shape by stabilizing the edges of the ellipse. In contrast, the chiral rods formed a helical assembly that generated a cylindrical membrane tube with a constant radius in addition to the elliptical tube. This helical assembly could be further stabilized by the direct side-to-side attraction between the protein rods. The chirality also promotes the tubulation from a flat membrane. These results agree with experimental findings of the constant radius of membrane tubules induced by Bin/Amphiphysin/Rvs (BAR) superfamily proteins.

Session D31 DSOFT GSNP DPOLY: Wetting and Adhesion of Soft Materials: Dynamics and Instability I  503 - Julien Chopin, ESPCI Paris - Tag(s): Focus
From dewetting to adhesion rupture - moving lines in dissipative, heterogeneous systems

ETIENNE BARTHEL (Presenter), MATTEO CICCOTTI, ESPCI Paris — Thirty five years ago, two theories for the pinning of elastic lines by heterogeneities have appeared almost simultaneously (Joanny & de Gennes, J. Chem. Phys. 81 (1984) 552; Rice, J. Appl. Mech 52 (1985) 571). Starting from these results, a large number of models and simulations have greatly advanced our understanding of complex line phenomena, and especially wetting hysteresis and fracture toughness of heterogeneous materials. However, these theories provide quasistatic pictures and they do not tell us much about what happens beyond the depinning threshold in the rather ubiquitous case where the response of the material itself is dissipative (e.g. viscous liquids or viscoelastic solids). In fact, even for homogeneous systems, evaluating the dissipation is still often a problematic question and the most simple cases - dewetting newtonian liquid or adhesion rupture for a linear viscoelastic solid - are far from being completely understood, especially when confrontation with experimental results is intended... Here we consider the dynamics of a front in a dissipative material moving on a heterogeneous surface at finite velocity. Based on recent numerical results for periodic substrates, we will first show how heterogeneities renormalize the dynamics of newtonian fluids near the dynamic wetting transition and actually obliterate some of the details of the wetting problem. We will then discuss the generalization to the case of dissipative soft solids.

Adhesion in Capillary Assembled Origami Structures

TIMOTHY J TWOHIG (Presenter), ANDREW CROLL, North Dakota State Univ — Adhesion plays an important and often overlooked role in capillary assembly driven thin-film origami systems. Strong adhesion to a substrate can completely inhibit capillary forces from assembling a structure, while weak film-film adhesion means a structure may not be stable in the assembled configuration. In this work, we experimentally study thin-film/substrate and thin-film/thin-film adhesive interactions in order to explore the interplay between capillary forces, thin-film elasticity, bending, and adhesion. We use elastocapillary scaling models to highlight how the basic underlying physics can provide guidelines for building stable thin-film origami structures.

Morphology of adhesive creases

MARTIN ESSINK (Presenter), ANUPAM PANDEY, Physics of Fluids Group, Faculty of Science and Technology, Mesa+ Institute, University of Twente, STEFAN KARPITSCHKA, MICHEL VAN LIMBECK, Max Planck Institute for Dynamics and Self-Organization, JACCO SNOEIJER, Physics of Fluids Group, Faculty of Science and Technology, Mesa+ Institute, University of Twente — When a soft elastic material is compressed beyond a certain critical strain, the free surface turns unstable and forms a crease. This corresponds to a sharp fold of the surface onto itself, leading to intricate morphologies as observed for growing tissues and swelling gels. Self-adhesion within the folded region is known to affect nucleation and hysteresis, but a detailed description has remained elusive. Here we resolve the geometry and mechanics of adhesive creases, combining numerical simulations, analysis and experimental results — with specific attention to the singular edge of the self-contact. It turns out that adhesive creases exhibit a universal shape that arises from a balance of elastic and surface energies. From this we derive a scaling theory for the intricate bifurcation scenario, explaining the hysteretic nucleation of adhesive creases.
3:30PM D31.00004: Energy Approach to Understand Contact Mechanics on Rough Surfaces
SIDDHESH DALVI (Presenter), Univ of Akron, ABHIJEET GUJRATI, TEVIS D.B. JACOBS, Mechanical Engineering and Material Science, University of Pittsburgh, LARS PASTEWKA, Microsystems Engineering, University of Freiburg, ALI N DHINOJWALA, Univ of Akron — Understanding the deformation of elastic solids on rough surfaces is crucial for soft-hard contacts at different scales of applications such as biomedical adhesives, tire traction, soft robotics and even micro- or nano-electromechanical devices. It has been experimentally demonstrated that the apparent work of adhesion for a soft material brought in contact with rough surfaces is lower than the intrinsic work of adhesion. During separation, there is energy loss commonly attributed to viscoelastic dissipation, termed as adhesion hysteresis. Here, with experimentally controlled elastic modulus, roughness and surface chemistry, we demonstrate that the reduction in work of adhesion is equal to the energy required to achieve conformal contact. Further, the energy loss during contact and removal is equal to the product of the intrinsic work of adhesion and the true contact area. These findings provide a simple mechanism to quantitatively link the widely observed adhesion hysteresis to roughness rather than viscoelastic dissipation.

3:42PM D31.00005: Interfacial tension measurement of reconstructive interfaces
Hideaki YokoYama (Presenter), Masayuki Saito, Univ of Tokyo-Kashiwanoha — New fabrication method of polymer brushes, “dynamic polymer brush”, was developed recently. In the system where amphiphilic diblock copolymers are added to hydrophobic elastomer, they avoid the elastomer surface in air, but, upon contact with water, spontaneously segregate to the elastomer/water interface and form highly dense polymer brush to lower the interfacial tension. This system is one of many reconstructive surfaces, which change the interfacial structures upon contact with water and hence direct evaluation of interfacial tension is difficult with conventional contact angle measurement. To measure interfacial tension of reconstructive interface, we developed a novel method using elastomer thin films floating on water. Thin films on water was observed by Brewster imaging and their size change was analyzed using the force balance of surface tensions, interfacial tension and elastic force of thin film. The interfacial tension between water and reconstructive elastomer directly measured by this method drastically decreases down to zero due to the dense PEG brushes appeared at elastomer/water interface.
3:54PM D31.00006: Capillary instability of soft cylinders: Dynamical selection of nonlinear states  
MINKUSH KANSAL (Presenter), ANUPAM PANDEY, Univ of Twente, MIGUEL ANGEL HERRADA, Universidad de Sevilla, JENS G EGGERS, University of Bristol, JACCO SNOEIJER, Univ of Twente  
— Surface tension plays a key role for phenomena involving liquid interfaces. A prime example is the Rayleigh-Plateau instability, causing a liquid jet to break into droplets in order to minimise the surface energy. Remarkably, a similar capillary instability was observed in soft solids. Here we reveal the intricate morphologies that can be encountered during the capillary collapse of an elastic cylinder, from minimisation of capillary and elastic energy. Subsequently, we show the dynamical selection of the wavelength, which also dictates the final nonlinear state. It is found that near the onset of instability, the shapes resemble a “cylinders-on-a-string” configuration, while as the solid gets softer “beads-on-a-string” are observed — in analogy to the breakup of viscoelastic liquids. Our analysis explains recent experimental and numerical observations, and highlights how surface tension can dictate the mechanics of solids - provided that the solids are sufficiently soft.

4:06PM D31.00007: How Aqueous Salt Solutions Affect Hydrophobic Surfaces  
ADELE POYNOR (Presenter), CAYTON HORNBERGER, GRACE ROHALEY, JULIANA SEBOLT, Allegheny Coll  
— The study of how salty water meets a hydrophobic surface is important because in nature water is rarely pure. In order to study this phenomenon, we need smooth and homogenous surfaces; however, salt solutions can damage our surfaces. We study this damage for a variety of self-assembled monolayers (SAMs) in different aqueous salt solutions, using contact angle measurements, scanning electron microscopy, surface plasmon resonance.

4:18PM D31.00008: Determination of Interfacial Strain on Single-Layer Graphene Due to Ice Adhesion*  
SUBASH KATTEL (Presenter), JOSEPH R MURPHY, SAMUEL PASCO, JOHN ACKERMAN, VLADIMIR ALVARADO, WILLIAM RICE, Univ of Wyoming  
— Adhesion between two dissimilar media produces a strain that changes the bond character of both materials at the interface, like ice-material interface. To explore the interfacial adhesion properties of ice, researchers apply an external stress directly to ice while measuring strain until adhesive or cohesive failure. This destructive approach masks the intrinsic forces as well as complicated interfacial physics occurring at the ice-material interface. Here, we use Raman spectroscopy to non-perturbatively and contactlessly measure ice-induced strain. To isolate this interface, we probe the vibrational modes of single-layer graphene (SLG) from 20°C to -30°C with and without ice. Along with the well-known temperature-dependent Raman shift of SLG, a clear, ~2 cm⁻¹ change in the 2D-frequency (2650 cm⁻¹) developed upon ice formation. We found that at the same temperature, a decrease in the Raman shift emerged between supercooled water and ice, which corresponds to 0.013% strain in SLG solely due to ice. The localized nature of the Raman probe allows for spatial mapping of the ice-coated SLG surface, enabling precise correlation with surface roughness evaluation and theoretical models.

D31.00009: Capillary imbibition in a square tube
TIAN YU, JIAJIA ZHOU (Presenter), MASAO DOI, BeiHang University — We study the wetting of a capillary with a square cross-section. When a square tube is brought in contact with bulk liquid, the liquid wets the corners of the tube and creates finger-like wetted regions. The wetting of the liquid then takes place with the growth of two parts, the bulk part where the cross-section is entirely filled with the liquid and the finger part where the cross-section of the tube is partially filled. In previous works, the growth of these two parts has been discussed separately. Here we conduct the analysis by explicitly accounting for the coupling of the two parts. We propose coupled equations for liquid imbibition in both parts and show that the lengths both increase in time following Lucas–Washburn’s law, but the coefficients are different from those obtained in the previous analysis that ignored the coupling.

Session D32 DPOLY DSOFT DBIO: Responsive Polymers, Soft Materials, and Hybrids I

2:30PM D32.00001: Silk-inspiration: hierarchy, assembly, and mechanics in polyurea-polypeptide hybrids
LASHANDA KORLEY (Presenter), DASEUL JANG, Univ of Delaware — Inspired by spider silk, we have designed a series of polymer-peptide polyurethane/ureas to explore the hierarchical arrangement critical to energy absorption and mechanical enhancement. We have developed chain-extended and non-chain extended peptide-polyurea hybrids with tunable secondary structure, modulating extensibility, toughness, and stiffness. The sheet-dominant hybrid materials were typically tougher and more elastic due to intermolecular H-bonding, while the helical-prevalent systems generally exhibited higher modulus. We have also explored the impact of a molecular design strategy that overlays a covalent and physically crosslinked architecture in these hybrids, demonstrating that physical constraints in the network hybrids influences hydrogen bonding and morphology. More recently, tailored physical associations within the soft and hard phases were engineered as a function of peptide content, leading to a rheological response dictated by block ordering and highlighting their potential as structural and injectable hydrogels. New efforts in silk composites that exhibit shape memory behavior, and 'green' pathways for silk-inspired materials are of current focus. These structural features have enabled new thrusts in injectable gels and responsive actuators.

*This work was supported by the National Science Foundation (NSF, DMR 1608441; NSF, OISE 1844463).
Ionic microgels are cross-linked polymeric networks that ionize and swell in a good solvent. The swelling behavior of the particles can be tuned by adjusting temperature, pH, and ionic strength, enabling applications to drug delivery and tissue engineering. Unlike spherical microgels, cylindrical microgels can swell in both radial and axial directions. Equilibrium swelling can be triggered by varying the balance between electrostatic and gel contributions to the osmotic pressure inside and outside of the particles [1, 2]. Within a cell model, we derive an exact statistical mechanical theorem for the electrostatic osmotic pressure of a cylindrical microgel to study the dependence of microion distribution and osmotic pressure on equilibrium size. To validate the theorem, we implemented Poisson-Boltzmann theory and molecular dynamics simulations. Combining our theorem with Flory-Rehner theory of polymer networks, we predict radial and axial equilibrium swelling ratios of cylindrical microgels as a function of salt concentration. Our results can help guide the design of smart, responsive particles.

*MOA acknowledges support of Shaqra University.

Soft materials are ideal for designing structures with useful properties. Especially, hydrogels have been extensively studied for their response to various external stimuli and reversibility. A gel under geometric confinements deforms anisotropically due to applied directional stresses, but otherwise it can be equilibrated and swollen by solvent homogeneously. In particular, wrinkling instability can be observed for line patterns of hydrogels bounded on a rigid substrate. Geometry and swelling ratio of the gel can decide a morphology – in the case of wrinkles, wavelength and amplitude - of the pattern. We controlled not only geometry factors of the micro patterns of hydrogel, but also the swelling ratio of the gel by varying the amount of Acrylamide (AAm) added during synthesis.

There has been much research on the effect of geometry on mechanical instability. However, in-depth studies on the material properties and constitutive law related to the swelling ratio of the gel have not been conducted. In this presentation, we propose modified nonlinear stress-strain relationship of our synthesized gels in scope of both continuum and molecular scales and compare it with our experimental results.
3:30PM D32.00004: Dynamics of 3D polymer gel with reversible linkers  SANTIDAN BISWAS (Presenter), VICTOR V YASHIN, ANNA BALAZS, Univ of Pittsburgh — We utilize the gel lattice-spring approach to develop the 3D computational model of polymer gels containing the temporary crosslinks. The polymer chains are assumed to incorporate the folded domains that encompass the reactive functional groups (cryptic sites). Under deformation, the domains unfold and expose the cryptic sites, which can then form labile bonds with the linker chains grafted to the network. Once the deformation is removed, the linkers detach from the cryptic sites, and unfolded domains go back to the folded configuration thus hiding the cryptic sites. The gel behavior under applied force is described by the equations of elasticity of the polymer network coupled to the chemical kinetics equations for the folding and binding transitions. The model equations take into account the effects of finite chain extensibility on the gel elasticity and mechanosensitive reaction rates. Elasticity of the transient network is introduced to the model through the Flory approach. We study the behavior of the system under uniaxial extension and compression, and determine the effect of temporary crosslinks on the bulk and shear moduli of the gel. We also compare the behavior of the gel with a similar gel not undergoing the transient binding of the linker chains.

3:42PM D32.00005: Phototunable Viscoelasticity in Hydrogels Through Thioester Exchange*  BENJAMIN CARBERRY (Presenter), VARSHA V RAO, KRISTI ANSETH, University of Colorado, Boulder — The extracellular matrix in which cells reside offers elastic and viscoelastic mechanical cues important for directing cell behavior. Recently, cellular responses to viscoelastic and elastic mechanical cues have been studied; however, questions remain as to how cells identify and transduce these cues differently, sparking a need for materials that can interrogate these properties separately. We present a cell culture substrate based on thioester exchange chemistry where viscoelasticity of the biophysical environment can be modulated in situ with light and the photoinitiated thiol-ene ‘click’ reaction. With this method, stress relaxation in thioester hydrogels with relaxation times ranging from 200,000-1,500,000s can be switched off in the presence of cells without change to the elastic modulus. NIH 3T3 fibroblasts cultured for 48 hr on viscoelastic substrates that transition to elastic substrates after 24 hr display cell morphology and YAP/TAZ expression similar to the elastic control. Phototunable viscoelastic thioester hydrogels provide a tunable materials system to investigate time-dependent cellular responses to viscoelasticity and should prove useful for understanding the dynamics of mechanoresponsive cellular pathways.

*NIH (DE016523)
**3:54PM D32.00006: Toughening mechanism of tough and self-healing physical hydrogels**
KUNPENG CUI (Presenter), JIAN PING GONG, Hokkaido University — Recently, we have developed a new class of tough and self-healing physical hydrogels composed of polyampholytes (PA). Those PA gels possess high toughness, stiffness, fatigue resistance and self-healing. However, the toughening mechanism of these gels is still unclear. In this work, we used real time small-angle X-ray scattering (SAXS) to study the toughening mechanism of PA hydrogels. We revealed that the high toughness of PA hydrogels is a synergistic effect due to multi-scale energy dissipation. We found that, this class of tough gels have a bicontinuous phase separation structure, consisting of a hard phase network and a soft phase network, of ~100 nm in scale. Upon loading, the microscopic deformation of phase structure is perfectly affine up to a quite large macroscopic uniaxial deformation range, followed by a wide nonaffine regime. In affine deformation regime, the breaking of ionic bonds dissipates energy, while in nonaffine deformation regime, hard phase rupture dissipate energy.

**4:06PM D32.00007: Anisotropic Hollow Microgels That Can Adapt Their Size, Shape, and Softness**
ANNE NICKEL (Presenter), ANDREA SCOTTI, RWTH - Aachen, JUDITH HOUSTON, European Spallation Source, JEROME CRASSOUS, RWTH - Aachen, JAN SKOV PEDERSEN, University of Aarhus, WALTER RICHTERING, RWTH - Aachen — We have recently shown how to create hollow, anisotropically shaped thermoresponsive microgels, polymeric networks with a solvent filled cavity that are swollen in a good solvent.[1] Sacrificial elliptical hematite silica particles were utilized as a template for the synthesis of a cross-linked N-isopropylacrylamide (NIPAm) shell. We characterized these microgels using a combination of light, X-ray, and neutron scattering. New form factor models, accounting for the cavity, the polymer distribution and the anisotropy, have been developed for fitting the scattering data. With such models, we demonstrated the existence of the cavity and simultaneously the anisotropic character of the microgels. Finally, the effect of temperature and shell thickness was investigated, showing that changes in size, softness, and aspect ratio are triggered. We believe that these hollow anisotropic microgels represent an attractive model system for fundamental physics (e.g. phase behavior or ordering phenomena) and a variety of applications especially in respect to their responsivity to temperature.

*Financial support from the SFB 985 “Functional Microgels and Microgel Systems” of Deutsche Forschungsgemeinschaft is greatly acknowledged.*
Ionic microgels are soft, permeable, colloidal particles made of crosslinked polymer networks that ionize and swell in a good solvent. Swelling of these particles is responsive to external stimuli and involves a balance of electrostatic and gel contributions to the single-particle osmotic pressure. The electrostatic contribution depends on the distributions of mobile microions and fixed charge on the polymer. Within the cell model, we derive the electrostatic contribution within Poisson-Boltzmann (PB) theory, by minimizing a free energy functional with respect to electrostatic potential, and extract the gel pressure from the pressure tensor. By varying the free energy with respect to microgel size, we also derive exact statistical mechanical relations for the electrostatic osmotic pressure for models of planar, cylindrical, and spherical microgels with fixed charge uniformly spread over their surface or volume. To validate these relations, we solve the PB equation and compute ion densities and osmotic pressures [1]. We show that microgel swelling depends on the electrostatic pressure profile inside the particle and discuss implications for interpreting experiments.

Tuning Diblock Copolymer Morphologies by Stimuli-Responsive Supramolecular Interactions  

Xiangyu Zhang (Presenter), Jing Zong, Dong Meng, Mississippi State Univ — Ability to tune the microstructures formed by block copolymers via easy-to-use physical approaches offers additional handles to the materials for practical applications. One common approach is through adding homopolymers, which induces morphological changes due to preferential partitioning of homopolymers into specific micro-domains. Recently, supramolecular forces that are chemistry-specific and stimuli-responsive have been exploited to enable stimul

Tuning Diblock Copolymer Morphologies by Stimuli-Responsive Supramolecular Interactions  

Xiangyu Zhang (Presenter), Jing Zong, Dong Meng, Mississippi State Univ — Ability to tune the microstructures formed by block copolymers via easy-to-use physical approaches offers additional handles to the materials for practical applications. One common approach is through adding homopolymers, which induces morphological changes due to preferential partitioning of homopolymers into specific micro-domains. Recently, supramolecular forces that are chemistry-specific and stimuli-responsive have been exploited to enable stimuli-switchable morphologies. To offer microscopic insights into this process, here we present a simulation study of diblock copolymers blended with homopolymers that are associative to one of the blocks through supramolecular forces. By manipulating the manner of associations, we investigate structural changes induced by supramolecular complexations, and to elucidate the differences from the counterpart van der Waals (VDW) force-driven systems. It is found that the homopolymer-receiving microdomain exhibits non-monotonic size changes accompanied by cluster formation as preferential partitioning occurs. Dynamics analysis suggests that both morphologies and supramolecular binding kinetics exert significant influence on the diffusion of homopolymers across the microdomains, implicative of the extent of “responsiveness” of such materials.
4:54PM D32.00011: On the solvation of elastin-like polypeptides in aqueous mixtures  YANI ZHAO (Presenter), Max Planck Institute for Polymer Research, MANJESH KUMAR SINGH, Mechanical Engineering, Indian Institute of Technology Kanpur, KURT KREMER, ROBINSON CORTES HUERTO, Max Planck Institute for Polymer Research, DEBASHISH MUKHERJI, Stewart Blusson Quantum Matter Institute, University of British Columbia — The collapsed or expanded state of a polymer is determined by the quality of the solvents: a polymer collapses in a poor solvent, whereas in a good solvent it opens up. While this standard understanding is generally valid, there are examples when a polymer collapses even in a mixture of two good solvents. This phenomenon, commonly known as co-non-solvency, is usually associated with smart polymers. Recent experiments have shown that biopolymers, such as elastin-like polypeptides (ELP), show co-non-solvency in aqueous-ethanol mixtures. In this work, we compare conformational behavior of ELPs in aqueous-ethanol and -urea mixtures using explicit solvent generic simulations. These results may pave ways for operational understanding and advanced functional designing of biocompatible materials.

5:06PM D32.00012: Chemomechanical origin of directed gel locomotions driven by internal chemical pulses*  QINGYU GAO (Presenter), LIN REN, Chemistry, China Mining University, IRVING R EPSTEIN, Chemistry, Brandeis University — Our previous work reported the directed locomotion of self-oscillating polymer gels in asymmetric environments, such as retrograde and direct wave locomotion, reciprocal migration, photophobic and phototropic movement. We now ask whether directed locomotions and their transitions can be generated only from intrinsic chemical dynamics and its modulation. We examine this question by simulating the locomotion of a responsive polymer gel in a homogeneous environment. We find that autonomous directional locomotion emerges in the absence of asymmetric interaction with the environment, and that a transition between modes of gel locomotion can be induced by adjusting the spatially uniform intensity of illumination or certain kinetic and mechanical system parameters. We find that the internal wave dynamics and modulation of the system act as the impetus for signal-driven active locomotion in a manner similar to the way in which an animal's locomotion is generated via driving by nerve pulses.

Competition between Hydrophobic and Electrostatic Interactions determine pH-responsive Supramolecular Self-assembly

SAIKAT CHAKRABORTY (Presenter),
Institute of Physics, Johannes Gutenberg University Mainz, CHRISTIAN M. BERAC, POL BESENIUS,
Institute of Organic Chemistry, Johannes Gutenberg University Mainz, THOMAS SPECK, Institute of Physics,
Johannes Gutenberg University Mainz

We present results from a molecular dynamics simulations study, inspired by experiments on pH-regulated self-assembly into filaments. Experiments are performed in aqueous media, with 1:1 binary mixture of amphiphilic peptide monomers having oppositely charged side chains. In neutral conditions, the monomers self-assemble into alternating copolymers. In acidic and basic conditions, selective screening of Coulombic interactions occurs. This leads to formation of homopolymers. Building on our model for homopolymers in implicit solvent, we introduce charges to mimic the two monomers. Our simulations reveal that the consideration of pH-dependent hydrophobic interactions is essential to observe pH-switch in polymerization. Further, assembly kinetics is analyzed, comparing simulations to experimental data which are obtained from circular dichroism spectroscopy. We relate both to appropriate growth models. While the nucleation and elongation are key mechanisms in simulations, fragmentation is important in experimental kinetics.

Session D33 DPOLY: Morphology Characterization: Frontier of Scattering and Microscopy

Computational Reverse-Engineering Analysis for Scattering Experiments (CREASE) on Amphiphilic Block Polymer Solutions

ARTHI JAYARAMAN (Presenter), DANIEL J BELTRAN, MICHEL WESSELS, Department of Chemical and Biomolecular Engineering, University of Delaware

In this talk we will present a new computational method titled ‘Computational Reverse-Engineering Analysis for Scattering Experiments’ or CREASE to interpret the intensity profiles obtained from small angle neutron scattering done on amphiphilic polymer solutions. For a given input comprised of scattering intensity profiles and information about the amphiphilic polymers in solution, CREASE uses a genetic algorithm that outputs the structure of the self-assembled micelles (e.g., core and corona diameters, aggregation number) and then through molecular reconstruction simulations describes the conformations of the amphiphilic polymer chains in the micelle (e.g., blocks’ radii of gyration, chain radii of gyration, monomer concentration profiles). The primary strengths of CREASE are its ability to analyze scattering profiles without an off-the-shelf scattering model and its ability to provide chain and monomer level structural information that is otherwise difficult to obtain from scattering and microscopy alone.
2:42PM D33.00002: Feature Engineering for Small-Angle Scattering Model Selection  YUKE WANG, Physics, Mathematics, Computer Science, University of Kentucky, TYLER MARTIN (Presenter), National Institute of Standards and Technology — While many soft-matter characterization techniques can be unambiguously interpreted to yield information about chemical and material structure, small-angle neutron and X-ray scattering (SANS and SAXS) data must be interpreted via a library of physical and phenomenological models. Complicating this task is the unavoidable phase problem, which causes scattering patterns to be non-unique and makes model selection a non-trivial task. Here we present our efforts in developing shallow- and deep-classifiers which, given a scattering dataset, suggest applicable models to the user. In particular, we will focus on our efforts in feature vector engineering i.e., the optimization of input parameters in order to maximize classification efficiency. We show that simple data transformations greatly increase our classification efficiency over a naïve model, allowing us to achieve greater than 99 % top-3 accuracy in the model-selection task. More broadly, these optimized feature vectors will enhance machine learning models for tasks other than model selection (e.g., error detection, automated experimentation, on-the-fly analysis). The ultimate goal of this project is to formalize feature vector design for small-angle scattering, thereby enabling the creation of bespoke machine-learning models.

2:54PM D33.00003: Identification of Frank-Kasper Phases in Conformationally Asymmetric Linear Block Copolymer Self-assembly  SEUNGBAE JEON (Presenter), TAESUK JUN, SEONGJUN JO, Yonsei University, HYUNGJU AHN, Pohang Accelerator Laboratory, BYEONGDU LEE, Argonne National Laboratory, DU YEOL RYU, Yonsei University — The quasicrystalline phases which were originally observed in metal alloys have emerged with block copolymers (BCPs) self-assembly providing a new potential in soft materials. Theoretical and experimental studies have revealed that conformational asymmetry (ε) of the different blocks provides a key mechanism to stabilize the Frank-Kasper (FK) σ and A15 phases in BCPs self-assembly. In this work, polydimethylsiloxane-b-poly(2,2,2-trifluoroethyl acrylate)s (PDMS-b-PTFEAs) were designed using flexible silicon-containing blocks and rigid fluorine-containing blocks to produce linear BCPs with a high conformational asymmetry. Evaluated value of ε was 2.20 which is higher than other BCPs reported in the literatures. A series of PDMS-b-PTFEAs were synthesized to produce compositionally asymmetric, PDMS-rich phases ranging from \( f_{PDMS} = 0.746 \) to 0.869. Using small-angle X-ray scattering, the FK σ and C14 phases were observed at \( f_{PDMS} = 0.80 \) and 0.85, respectively. Based on the fact that the stability of σ phase increases by the value of ε, we speculate that the stability level of the C14 phase as well as σ phase is due to the relatively high ε of PDMS-b-PTFEAs.
Combining Advanced Experimental Methods to Characterization of Polymer Nanocomposites* [Invited] KAREN WINEY (Presenter), University of Pennsylvania — Each characterization method provides specific information about a polymer sample over a limited range of length and time scales. A comprehensive understanding of polymer morphology and dynamics is best developed by combining a set of characterization methods to capture a broader range of lengths and times. This talk will highlight examples from our studies of polymer nanocomposites that have combined methods to develop detailed and quantitative descriptions of these complex polymer systems. Specifically, the dynamics in polymer nanocomposites include segmental and chain-scale motion of the polymer, as well as diffusion of the nanoparticles. We apply ion beam methods (elastic recoil detection and Rutherford backscattering) and single particle tracking methods, as well as more accessible methods such as temperature-modulated DSC and broadband dielectric spectroscopy methods, to probe the molecular weight dependence of the polymer and nanoparticles are revealed for nanoparticles of various sizes and nanoparticle-polymer interactions. These vignettes will also serve to illustrate the capabilities of the individual methods and demonstrate the exceptional value of combining these advanced experimental methods.

Deformation Mechanics during Drawing of Ultra-High Molecular Weight Polyethylene Fibers  CHRISTOPHER HENRY, GIUSEPPE PALMESE, NICOLAS ALVAREZ (Presenter), Drexel Univ — There has been extensive study of Ultra-high molecular weight polyethylene (UHMWPE) fibers owing to their remarkable tensile modulus and strength. It is understood that these properties are generated during the post drawing process. Questions remain however, regarding how the morphology of the polymer develops during processing, and how this leads to the observed properties. Basic information regarding strain rate, stress at failure, and the role of processing parameters is missing due to the difficulty of measurement with industrial processes. This information is critical to understanding the polymer response during drawing. In this study we use a modified extensional rheometer (VADER 1000) to perform the drawing process on a series of UHMWPE fibers spun at Drexel. We have shown previously that ASF crystalline structure is not limited to the isotropic states typically seen in literature. With the VADER 100, and this broad range of starting materials we can monitor true stress and strain throughout the draw, and discover the mechanical properties prior to, and at, the failure point. Small and wide-angle x-ray scattering is used investigate the crystalline morphology. With this information a fundamental understanding of the post-drawing will be developed.
3:54PM D33.00006: 3D Structure of Grain Boundaries in Tubular Network Block Copolymers

XUEYAN FENG (Presenter), AMANDA SUAREZ, DERRICK ONG, KAIQI YANG, HUA GUO, EDWIN THOMAS, Rice University — Multi-continuous microphases (such as double gyroid) have network structures with 3D interconnected, self supporting domains. The properties of the component in each domain are strongly expressed due to the geometrical continuity in all three dimensions. However, the occurrence of grain boundaries (GB), which interrupt the topological and geometrical order of the continuous ordered networks, will significantly affect their performance. Here, we examine GBs in a polystyrene-b-polydimethylsiloxane double gyroid system using high fidelity 3D reconstructions made by Slice and View scanning electron microscopy (SVSEM). Since large amounts of GB can be reconstructed, we employ machine learning to extract the shape/distribution of the GB. Also, two types of GBs are identified and described (grain-grain tilt and order-disorder-order boundaries). Different types of irregular nodes/topological loops/network connections within the GB region are identified. The local topological parameters, as well as curvature of the intermaterial dividing surface, node functionality distribution, strut length/orientation distribution and surface to volume ratio in the GB are analyzed and compared with the same set of morphological descriptors measured in the adjacent, ordered double gyroid grains.

4:06PM D33.00007: Local density and free volume inhomogeneities govern transport properties in reverse osmosis membranes

MICHAEL GEITNER (Presenter), TYLER CULP, Pennsylvania State University, JEFFREY D. WILBUR, STEVEN JONS, DuPont Water Solutions, MANISH KUMAR, The University of Texas at Austin, ENRIQUE D GOMEZ, Pennsylvania State University — Developing a mechanistic description of how microstructure affects membrane properties could lead to the development of next-generation materials for desalination. Quantification of the internal microstructure of fully-aromatic polyamide thin-films, which serve as the active layer in state-of-the-art desalination membranes, is a crucial component to developing such descriptions. Here, we studied a series of reverse osmosis membranes showing systematic increases in water permeance over currently available membrane materials without sacrificing water-salt selectivity. We quantified the internal morphology of the polyamide active layers via scanning transmission electron tomography, where 3D reconstructions were obtained and parameters, such as void fraction and surface area, were measured. Tomogram intensity analysis revealed the nanometer-scale density and free volume distributions, used in conjunction with the 3D polyamide models to model water transport properties in such materials. The combination of density and free volume distributions determined from electron tomography with water transport modeling has provided a robust approach towards the development of structure-property relationships in reverse osmosis membranes.
Three-Dimensional Imaging the Crystalline Structure of Polypeptoid Nanosheet with Atomic Resolution

XI JIANG (Presenter), Materials Sciences Division, Lawrence Berkeley National Laboratory, SUNTING XUAN, NAN LI, DAVID PRENDERGAST, RONALD ZUCKERMANN, Molecular Foundry, Lawrence Berkeley National Laboratory, NITASH BALSARA, The Department of Chemical & Biomolecular Engineering, University of California, Berkeley — Electron microscopy imaging of three-dimensional structures in soft materials with atomic resolution is challenging because soft materials are unstable under the electron beam, and techniques such as x-ray scattering or diffraction are not able to provide atomic resolution phase information in position space. The experiments were conducted on self-assembled crystalline polypeptoid nanosheets. Low-dose cryogenic electron microscopy micrographs were obtained from frozen hydrated crystalline nanosheets on the novel ultra-flat supporting grid at different tilting angles. A hybrid processing of crystallographic, tomography and single particle methods, developed for cryo-electron microscopy of biological macromolecules, was used to resolve the structure of crystals with atomic resolution in three dimensions. Our approach is robust and enable direct visualization of the arrangement of polypeptoid backbones and side chains in crystalline nanosheets. It also revealed the effect of side chain chemistry on the crystalline structure of polypeptoid nanosheets.

Pushing the resolution limits for imaging conjugated polymers in the transmission electron microscope

BROOKE KUEI (Presenter), ENRIQUE D GOMEZ, Pennsylvania State University — Transmission electron microscopy (TEM) of conjugated polymers has remained a challenge because resolution is limited by the electron dose the sample can handle. We have characterized beam damage in poly(3-hexylthiophene) (P3HT), poly(3-dodecylthiophene-2,5-diyl) (P3DDT), and poly[(5,6-difluoro-2,1,3-benzothiadiazol-4,7-diyl)-alt-(3,3’’-di(2-octyldodecyl)-2,2’:5’,2’’;5’,2’’-quaterthiophene-5,5’’-diyl)] (PffBT4T-2OD) via electron diffraction and electron energy-loss spectroscopy (EELS). Critical dose $D_C$ values were calculated from the decay of diffraction and low-loss EELS peaks as functions of dose rate, temperature, and beam size. At room temperature, $D_C$ first increases then decreases with increasing dose rate, whereas at cryogenic conditions this dose rate dependence is less pronounced and the overall $D_C$ increases; these results suggest that a significant mechanism for beam damage in conjugated polymers is diffusion of secondary free radicals. $D_C$ also increases with decreasing beam size. These new concepts in beam damage revealed strategies to push the resolution in the TEM, allowing us to image 3.6 Å π-π stacking in PffBT4T-2OD with 4D STEM, high-resolution TEM (HRTEM) at cryogenic conditions, and HRTEM at room temperature with antioxidants.

**4:42PM D33.00010: Observation of Elongated Nano Domains in Organic Photovoltaic Active Layers with Electric Field Treatment using Cross-Sectional Scanning Tunneling Microscopy and Spectroscopy.**

RABINDRA DULAL (Presenter), Physics and Astronomy, Univ of Wyoming,

AKSHAY IYER, UMAR GHUMMAN, Department of Mechanical Engineering, Northwestern University,

JOYDEEP MUNSHI, Department of Mechanical Engineering & Mechanics, Lehigh University, AARON WANG, Physics and Astronomy, Univ of Wyoming, GANESH BALASUBRAMANIAN, Department of Mechanical Engineering & Mechanics, Lehigh University, WEI CHEN, Department of Mechanical Engineering, Northwestern University, TE-YU CHIEN, Physics and Astronomy, Univ of Wyoming — The effects of the electric-field-assisted annealing on the bulk heterojunction nano-morphology in the P3HT/PCBM active layer of the organic photovoltaic cells (OPVCs) are presented here. It was widely accepted that the electric field will facilitate the P3HT, the polar polymer, to be better crystallized hence enhance the charge mobility and improve the OPVC performance. However, the effects on the nano-morphology in the active layer treated with the electric field are not well understood. Here, by utilizing the cross-sectional scanning tunneling microscopy and spectroscopy (XSTM/S), it is revealed that the electric-field-assisted annealing will facilitate the P3HT-rich domains formed elongated shape with the orientation close to the direction of the external electric field which is beneficial to the OPVC charge collection. On the other hand, it was also observed that the electric-field-assisted annealed samples showed smaller energy gaps and smaller energy off-set between the molecular domains which might negatively impact the charge separation efficiency. The XRD and SAXS results indicate that the smaller energy gaps might be caused by the molecular intermixing. These results point out competing factors affecting the OPVC performance.

**4:54PM D33.00011: Directly Visualizing Conformations of Bottlebrush Polymers in Bulk Films using Super-Resolution Optical Microscopy**

JONATHAN CHAN (Presenter), AVRAM KORDON, ZHE QIANG, MUZHOU WANG, Northwestern University — Bottlebrush polymers have advantageous photonic and mechanical properties that are well suited for applications such as coatings, pigments, and super-soft materials. This architecture consists of a polymer backbone densely grafted by side chains, whose steric repulsions result in rigid, elongated conformations. While the single-chain conformations of these polymers have been studied experimentally for isolated chains on surfaces and within dilute solutions, few studies have probed their conformations in bulk environments. In this work, we directly visualize individual bottlebrush polymers in a bulk environment populated by other bottlebrushes, by mixing dilute quantities of fluorescently-labeled chains with unlabeled polymers and imaging through super-resolution optical microscopy (SROM). Using SROM, we resolved individual chains within thin films of bulk polymers and found the tangent correlation functions (TCFs) of the backbone. These TCFs were fit to a worm-like chain model, and values for the persistence length were extracted to quantify rigidity. Changes to these conformations were observed with variations to architectural parameters such as side chain length and grafting density.
5:06PM D33.00012: Kinetically Controlled Morphology in Copolymer-based Hydrogels Crosslinked by Crystalline Nanodomains Determines Efficacy of Ice Inhibition* PABLO SEPULVEDA-MEDINA (Presenter), Univ of Akron, CHAO WANG, Chemical and Biomolecular Engineering, University of Delaware, BRYAN VOGLT, Chemical Engineering, Pennsylvania State University — Confinement of water within physically crosslinked hydrogels can alter the physics associated with the water within the hydrogel. When water is confined between hydrophobic nanodomains that act as physical crosslinks, crystallization of water can be dramatically inhibited. In prior work, the inter-nanodomain spacing was controlled by changing the fraction of hydrophobic segments in the polymer, which leads to an inverse correlation between water content and confinement extent. However, water content and confinement effect have not been decoupled. Here, we decouple confinement and water content through kinetically controlled nanostructure in a hydrogel crosslinked by crystalline nanodomains based on 2-hydroxyethyl acrylate (HEA) and n-octadecyl acrylate (ODA). Zone annealing of the dry copolymer alters the structure of the crystalline ODA domains that effectively crosslink the hydrogel. Despite these changes in the ODA structure, the average hydrogel water content was not significantly altered. However, the unfrozen water inside the hydrogel varies from 60 to 99 wt%, determined from DSC and in-situ WAXS. The antifreeze efficacy is found to correlate directly with the structure where smaller spacing leads to higher unfrozen water fraction.

*Work founded by NSF grant CBET-1606685.

5:18PM D33.00013: Morphological Investigations of Anion-Conducting Polymer-Catalyst Interface* NORA BUGGY (Presenter), Chemical & Biological Engineering, Colorado School of Mines, YIFENG DU, Polymer Science and Engineering, University of Massachusetts Amherst, MEI-CHEN KUO, Chemical & Biological Engineering, Colorado School of Mines, BRYAN COUGHLIN, Polymer Science and Engineering, University of Massachusetts Amherst, ANDREW HERRING, Chemical & Biological Engineering, Colorado School of Mines — The heterogeneous microstructure of the electrode in polymer electrolyte-based electrochemical devices is not well understood. This is due in part to complex interactions between the ion-conducting polymer (ionomer), catalyst particles, and carbon. It is known that interactions at the polymer-catalyst interface induce restructuring that propagates through the bulk morphology of the material [1]. This is potentially to the detriment of species transport in the electrode, ultimately affecting device performance.

To simplify the system, model interfaces of polymer thin films on silver surfaces are studied. A set of tunable block copolymers, post-quaternized to produce anion-conducting polymers, are used to investigate how different parameters influence interfacial morphology. Their synthesis has been optimized to achieve a variety of block lengths and ratios, each with a unique set of characteristics (ionic conductivity, water uptake) and morphologies. Films have been investigated using GISAXS and AFM. An understanding of the ionomer morphology at the ionomer-catalyst interface will provide key insight toward rationally designing block copolymers for the electrode.

Monday, March 2, 2020 2:30 PM - 5:30 PM
2:30PM D34.00001: Role of chain architecture and composition on dynamics and ionic solvation in polyether-based electrolytes*  PETER BENNINGTON (Presenter), DANIEL SHARON, MICHAEL WEBB, CHUTING DENG, JUAN DE PABLO, PAUL F NEALEY, SHRAYESH PATEL, University of Chicago — In recent years a great number of new polymer electrolytes have been developed towards improved performance and stability of energy storage devices. These new materials typically include polyether moieties to facilitate efficient ion transport. However, the presence of additional non-conducting groups influences the ability of polyethers to solvate ions and hopping between these solvation sites. We have examined a number of polyether-based electrolytes in linear, block, graft, and blend configurations to explore how chemical and physical interactions between different components affects ionic conductivity. Using a combination of impedance spectroscopy, vibrational spectroscopy, and atomistic simulations, we gain insight into the degree of ion conductivity, ionic interactions, and polymer dynamics of these materials. Both the polymer-polymer interaction strength and segmental mobility of non-solvating components show an effect on the overall conductivity and connectivity of ion solvation sites. These findings highlight the need for more complete models to account for various length scales of interaction in these nonuniform material systems.

2:42PM D34.00002: Self Diffusion Dynamics and Viscoelasticity of Fluorescently Labeled Polymerized Ionic Liquids*  QIUJIE ZHAO (Presenter), CHRISTOPHER EVANS, University of Illinois at Urbana-Champaign — Scaling relationships for viscosity and diffusion coefficient as a function of degree of polymerization (N) are well-characterized in neutral polymers. We have synthesized fluorescently-labeled polymerized ionic liquids (f-PILs) with a broad range of molecular weights to understand these relationships in dry, ionic polymers with a charge on every repeat unit. Fluorescence recovery after photobleaching (FRAP) is used to measure polymer self-diffusion coefficients ($D$) using the post-bleached fluorescence images and fitting the intensity to a Gaussian profile over time. The zero-shear viscosity was measured via rheology. In the shortest f-PILs, the ionic interactions between imidazolium and bis(trifluoromethane sulfonamide) have little effect on extending the terminal regime. However, the terminal region did extend to lower frequencies as N increased. Interestingly, the wide-angle x-ray scattering shows an amorphous halo and anion-anion peak, but no longer range ionic aggregate peak which we assign as the origin of the rheologial behavior. Scaling relationships with molecular weight will be discussed.

*This work is supported by the National Science Foundation under Grant No. 1751291.
2:54PM D34.00003: First consideration of density scaling of the dynamic and thermodynamic properties in polymerized ionic liquid.*  MALGORZATA MUSIAL (Presenter), ZANETA WOJNAROWSKA, SHINIAN CHENG, Instytut of Physics, University of Silesia in Katowice, ADAM HOLT, CHARLES M. ROLAND, Chemistry Division, Naval Research Laboratory, ERIC DROCKENMULLER, Université de Lyon 1, MARIAN PALUCH, Instytut of Physics, University of Silesia in Katowice — The density scaling idea is a general feature of glass-forming materials, e.g., van der Waals liquids and polymer melts. According to this concept, the data of dynamic properties collected in isobars and isotherms collapse to a single curve when expressed versus $TV^γ$, where $T$ is temperature, $V$ is specific volume, and $γ$ is scaling exponent being a material constant independent of thermodynamic conditions. Herein, we test, for the first time, the scaling concept of dynamic and thermodynamic properties for polymerized ionic liquid (PIL). Since, various types of interactions can exist in ionic materials (balance between Coulomb interactions, van der Waals forces, and hydrogen bonds), and one of the ions is structurally constrained as part of the polymer skeleton, the validity of scaling concept is not obvious. We find experimentally that density scaling of ionic conductivity does not work. Additionally, concerning scaling of the entropy, a master curve can be obtained by taking the scaling exponent to be a linear function of total entropy.

3:06PM D34.00004: WITHDRAWN ABSTRACT —

3:18PM D34.00005: Charging Neutral Polymer by Simple and Macro Ions in Solution
MANUELA FERREIRA (Presenter), BENXIN JING, YINGXI ELAINE ZHU, Wayne State Univ — It is recently reported that neutral polymers, such as poly(ethylene oxide) (PEO), could behave like weakly charged polyelectrolyte in highly polar solvents. We have examined the ion charging and resulting conformational structure of single PEO chains of varied molecular weight in water and mixed solvents by fluorescence correlation spectroscopy (FCS)-photon counting histogram (PCH) experiments. PCH results indicate that PEO becomes positively charged in LiCl-added solution, yet the measured electrical potential of PEO in LiCl solution decreases rapidly with the addition of multivalent polyoxometalate (POM) polyanion. The net charge of single PEO chains in solution shows strong dependence on the concentration ratio among Li+, POM, and monomer. FCS results show non-monotonic change of measured hydrodynamic size of single PEO chains in LiCl or LiCl-POM added solution with increasing ionic concentration, suggesting distinct ionic binding and screening effects. Further, the addition of a solvent with weak hydrogen-bond donor capabilities could further weaken the binding POM with PEO, but not so for the binding of Li+ cation with PEO. Therefore, the formation of PEO-Li+-POM complexes in different solvent mixture could lead to a facile process of PEO-based ionomers of tunable net charge.
3:30PM D34.00006: Addition of Zwitterions to Single-ion Conducting Ionomers*  WENWEN MEI (Presenter), AUGUST ROTHENBERGER, JOSH BOSTWICK, ROBERT HICKEY, RALPH H COLBY, Materials Science & Engineering, Pennsylvania State University — Applications of polymeric materials in energy-related areas are severely hampered by their limited conductivity at room temperature. The continuing pursuit of maximizing their room-temperature conductivity has driven novel design of polymeric systems. Ion aggregates are believed to be one of the major causes that stymies the ion conduction, due to the decreased mobile ion density and slowed segmental motion. Recently, much attention was drawn on additives that increase the dielectric constant due to its significant role in promoting conduction of small mobile ions such as lithium. Zwitterions are promising candidates for this purpose, owning to a large molecular dipole from covalently bonded cation and anion. Here, we studied a series of imidazolium-sulfonate zwitterions that are used as additives in single-ion conducting ionomers. Significant increases in both dielectric constant and ionic conductivity are reported. This work highlights the significance of zwitterion for promoting the conductivity, which benefits their further applications in a wide range of polymers.

3:42PM D34.00007: Polymer Electrolytes Containing Solvate Ionic Liquid and Beyond* [Invited] MASAYOSHI WATANABE (Presenter), Yokohama Natl Univ — Certain molten solvates of Li salts can be regarded as solvate ionic liquids (SILs). A typical example is equimolar mixtures of glymes and Li[TFSA][TFSA]==[NTf2]). The amount (activity) of free glyme is a trace in [Li(glyme)][TFSA], and thereby can be regarded as solvate ionic liquids. Unlike conventional electrolytes, the solvation of Li⁺ by the glyme forms stable and discrete solvate ions ([Li(glyme)]⁺) in the SILs. Polymer electrolytes composed of ABA-triblock copolymers and [Li(glyme)][TFSA] SILs are proposed to simultaneously achieve high ionic conductivity, thermal stability, and a wide potential window. Intriguing points of the polymer electrolytes are decoupled ion transport from segmental motion of the matrix polymer and the persistence of solvate structure in the polymeric phase. Recently, we find that Li⁺ hopping conduction, which cannot be explained by conventional Stokes law, emerges in certain highly concentrated molten solvate electrolytes. Li⁺ diffuses faster than the solvent and anion, and thus the evolution of Li⁺ hopping conduction is confirmed, which leads to a higher Li⁺ transference number. Possible application of these new electrolytes will be discussed.

**4:18PM D34.00008: The Overlap Concentration in Strong Polyelectrolytes**

MARK STEVENS (Presenter), JON BOLLINGER, GARY GREST, Sandia National Laboratories, MICHAEL RUBINSTEIN, Physics, Duke University — Understanding strong polyelectrolytes in solution is a major challenge for theory. We have simulated a strong polyelectrolyte in a salt free solution for monomer numbers \( N = 10 \) to 1600. We calculated the overlap concentration \( c^* \) and find that \( c^* \) scales as \( N^{-2.5} \). Moreover, not until very large \( N \geq 800 \) does the end-to-end distance at \( c^* \) approach the infinite dilution limit. The chains at large \( N \) are fully stretched at \( c^* \), while at small \( N \) substantial stretching occurs below \( c^* \). For large \( N \) the chains are also rodlike in that the form factor at \( c^* \) is almost that of a straight line for lengths corresponding from a few bond lengths to the end-to-end distance.

**4:30PM D34.00009: Salt Effect on Swelling of Polyelectrolyte Networks with Brush-like Strands**

MICHAEL JACOBS (Presenter), ZILU WANG, ANDREY DOBRYNIN, Polymer Science, University of Akron — We study effect of added salt, density of ionized groups and molecular architecture of the network strand on the swelling ability of networks with charged brush-like strands using a combination of the analytical calculations and coarse-grained molecular dynamics simulations. Analysis of the simulation results shows that in the salt-free case, when swelling of polyelectrolyte networks is controlled by a fine interplay between the osmotic pressure of counterions and nonlinear elasticity of the network strands, one can achieve a significant increase in the network swelling ratio by increasing the grafting density and degree of polymerization of the side chains. Addition of salt is manifested in the monotonic decrease of the network swelling ratio with increasing the salt concentration. At high salt concentrations, the electrostatic interactions between ionized groups are screened and swelling of the polyelectrolyte networks is similar to that of networks with neutral brush-like strands immersed in a good solvent. The computer simulation results are in a very good qualitative agreement with the developed theoretical model accounting for nonlinear elasticity of the network strands.

4:42PM D34.00010: Electrostatic Effects on Charged Block Copolymer Melts* YIHAO LIANG
(Presenter), BORAN MA, MONICA OLVERA DE LA CRUZ, Northwestern University — Electrostatic interactions can enrich the phase behaviors of charged block copolymer melts. However, due to limitations of simulation techniques and theoretic tools, the phase behavior of charged block copolymers remains elusive. In this talk we implement the event-chain Monte Carlo (ECMC) algorithm to describe charged block copolymer melts. ECMC is a new simulation technique which satisfies the maximum global balance and is good for systems with long relaxation time. Equipped with cell-veto method, ECMC can achieve O(N) time complexity for each cycle. Our work shows that ECMC is a promising approach to describe charged copolymer systems.

4:54PM D34.00011: Transference Numbers of Aqueous Polyelectrolyte Solutions TYLER LYTLE (Presenter), ARUN YETHIRAJ, University of Wisconsin - Madison — The demand for lithium-ion batteries with improved energy density and charging rates is growing, because of increasing use of consumer electronics and electrification of vehicles. However, lithium-ion batteries have several issues including long charging times. A potential route to circumvent this issue and increase the battery energy density is high transference number electrolytes. Lithium transference numbers using traditional liquid electrolytes are less than 0.5, which indicates the anion carries most of the current. In order to increase this transference number, it has been suggested to use polyelectrolyte solutions in which the polyanion mobility is less than the lithium ion mobility, but molecular-level understanding of counterion dynamics in polyelectrolyte solutions is underdeveloped. Our work uses molecular dynamics simulations of coarse-grained polymer models to elucidate how chain length, counterion size, and solution concentration affect the ion transference number in solution. These simulations show ion transference numbers depend non-monotonically on chain length, and smaller counterions have lower transference numbers. These simulation results can be used to guide experimental design of electrolytes with high lithium ion transference numbers.
5:06PM D34.00012: Hydration Phenomena in Sulfonated Poly(arylene ether sulfone) Membranes*  
CHENGYUAN WEN (Presenter), BRITANNIA VONDRASEK, JUDY RIFFLE, JACK LESKO, SHENGFENG CHENG, Virginia Tech — The hydration mechanism of ionic polysulfones remains poorly understood, which hinders their utility in water purification membranes. Differential scanning calorimetry (DSC), density measurements, and molecular dynamics simulations are combined to improve molecular-scale understanding of how water interacts with different parts of sulfonated polysulfones as water uptake is varied. The results reveal a threshold value of water uptake below which virtually all water molecules are located in the primary hydration shell of ions (Na$^+$ and SO$_3^-$) and polar groups (SO$_2$ and ether linkages). At higher water uptake, a significant fraction of the absorbed water molecules become more loosely associated with the polymer. This transition is indicated by the gradual appearance of a melting endotherm in DSC analysis, a maximum in measured density of the hydrated polymer, and appearance of water molecules with a bulk-like state in simulations. The simulation results further indicate that interactions between ions (Na$^+$ and SO$_3^-$) and polar groups, particularly SO$_2$, play an important role in the hydration behavior of sulfonated polysulfones.

5:18PM D34.00013: Dynamics at Internal Interfaces in Ionizable Polymer Blends*  
JAYME ALGER (Presenter), MANJULA SENANAYAKE, Department of Chemistry, Clemson University, Clemson, SC, United States,29634, GARY GREST, Sandia National Laboratories, Albuquerque, NM, United States,87123, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States, 29634 — Ionizable polymers have found a large number of applications in the water-energy nexus, enabled by the segregation of the polymers into ionic and non-ionic domains. The morphology of the ionic domains varies as a function of numerous factors, among them are the number of ionic groups, their distribution and the topology of the polymers. To understand the segregation process, we probe the evolution and dynamics of internal interfaces formed by blends of polystyrene (PS) and polystyrene sulfonate (PSS) below their entanglement length using atomistic molecular dynamic simulations for temperatures above the glass transition temperature of either polymer. Melts of PS and PSS blends with varying sulfonation fractions with Na$^+$ and N(CH$_3$)$_4^+$ counterions were followed as a function of time. The development of the internal interface of the charged and the non-charged polymers will be discussed. We will compare blends of PS and PSS which can globally phase separate with diblock copolymers of PS and PSS which phase separate only locally.

Session D35 DPOLY DSOFT: Biopolymers, Polymer Bioconjugates, and Their Self-Assembled Phases 507 - Thomas Angelini, University of Florida - Tag(s): Focus
2:30PM D35.00001: Asymmetric Lipid/Polymer Vesicles  
YUTING HUANG (Presenter), Harvard University — Lipid vesicles are aqueous volumes surrounded by a bilayer of lipid molecules, which are amphiphilic molecules with their head groups facing water and tail groups facing oil. These vesicles are simple models for cell membranes and can be used for drug delivery. Similarly, block copolymers are amphiphilic molecules that form vesicles by themselves or with lipids. Like lipid vesicles, polymer vesicles can also be used for drug delivery and cell membrane mimicry. One interesting type of lipid/polymer vesicle is the asymmetric vesicle, in which its bilayer is composed of two dissimilar lipid monolayers or a lipid monolayer and a polymer monolayer. Importantly, all eukaryotic cell membranes exhibit this type of asymmetry and asymmetry is also proposed to enhance mechanical properties of the membrane. Here, we use microfluidics to fabricate mono disperse and highly controllable asymmetric vesicles, which unlike the conventional methods that often end up with highly poly disperse samples. To achieve this, asymmetric vesicles are produced using water/oil1/oil2/water emulsions in a glass capillary device, with different lipids/polymers immersed in two different volatile oil phases. In future, we envision asymmetric lipid/polymer vesicles could open a new door in the drug delivery field.

2:42PM D35.00002: Polyelectrolyte dynamical self-consistent field theory  
SYLVIA LUYBEN (Presenter), ROBERT WICKHAM, Univ of Guelph — Recent experiments that examine the reconstitution of proteins into artificial triblock copolymer membranes have implicated a charge-driven reconstitution mechanism. As a first step to model the dynamics of this mechanism, we incorporate electrostatic interactions into dynamical self-consistent field theory. We begin with microscopic Langevin equations for interacting polyelectrolytes, solvent, and counterions. These equations are recast as a dynamical functional integral over collective field variables. We then make a saddle-point approximation, leading to a coupled set of dynamical mean field equations which includes the Poisson equation governing the electrostatic potential. Our approach reduces the interacting many-chain problem to a single polyelectrolyte chain in a dynamical mean force field. This simplification enables us to probe a broad range of length- and time-scales. We simulate the dynamics of insertion of a charged triblock copolymer (a model protein) into an oppositely-charged, self-assembled, triblock copolymer membrane.

Dynamics of self-interacting bio-inspired polymers in shear flows

HELMAN AMAYA-ESPINOSA (Presenter), Vice-presidency of Research, University of the Andes, ALFREDO ALEXANDER-KATZ, Department of Materials Science & Engineering, Massachusetts Institute of Technology, CAMILO APONTE-SANTAMARÍA, Faculty of Engineering, University of the Andes — Biopolymers interact with each other, triggered by external stimuli, to carry out key biological functions. Blood clotting is a perfect example of that. Triggered by the shear of the flowing blood, the giant von Willebrand factor (VWF) adhesive protein establishes specific interactions with several partners, including with itself via specific protein-protein auto-inhibitory interactions. However, the impact of such self-interactions on the flow-induced non-equilibrium conformational dynamics of such polymers remained unclear. We tackled this question by implementing Brownian dynamics simulations at a coarse-grained resolution of VWF-like self-interacting biopolymers. In the absence of specific interactions, we recapitulated previous estimates of the critical shear-rate upon which the polymer underwent a globular-to-stretched conformation. Introduction of specifically interacting points within the polymer increased the critical shear-rate roughly by an order of magnitude. Accordingly, our data demonstrate that the state of self-interacting biopolymers, under shear flows, can be effectively tuned by increasing either the number or the strength of self-interacting units. This information is highly useful to understand how specific-molecular interactions modulate VWF assembly.

Computational prediction of molecular shape through the assembly of sequence-controlled polymers

DAVINDRA TULSI (Presenter), DAVID SIMMONS, Univ of South Florida — Nature employs molecular sequence to control macromolecular shape in order to realize exquisite control over biological nanostructures such as protein assemblies, membranes and DNA complexes. Over the last decade, significant strides have been made in synthesizing artificial sequence-controlled polymers, potentially paving the way for synthetic materials mimicking biological nanostructures. Further advances are hindered by the fact that the relationship between sequence and molecular shape remains poorly understood. Here we employ molecular dynamics simulations to probe the relationship between sequence and molecular shape in model synthetic polymers. Results point to a conformation diagram that provides fundamental physical insights towards design of molecular building blocks for hierarchical assembly.
Bottom-up Coarse-grained Molecular Simulations of Peptoids with Enhanced Sampling*  
MINGFEI ZHAO (Presenter), University of Chicago, JANANI SAMPATH, CHRISTOPHER J MUNDY, Pacific Northwest National Laboratory, JIM PFAENDTNER, University of Washington, ANDREW L FERGUSON, University of Chicago — Peptoids are a class of synthetic polymers that have similar biocompatibility but high stability compared to peptides. Peptoids can both self-assemble into highly ordered nanostructures and direct the organization of inorganic components. Computational modeling is promising in helping discover and design peptoid-based nanomaterials. Atomistic peptoid models have been developed but only consider small systems due to high computational costs. To reach the time and length scale of peptoid assembly, we develop a coarse-grained (CG) model reparametrized from all-atom (AA) simulations by fitting CG bonded interactions through iterative Boltzmann inversion and nonbonded interactions through potential of mean force matching. We use Parallel Bias metadynamics to obtain good sampling in the cis/trans isomerization. The proposed CG model demonstrates excellent agreement with AA distribution functions and opens a new avenue to the computational inverse design of peptoid-based nanomaterials.

*This material is based upon work supported by the US Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences (BES), as part of the Energy Frontier Research Centers program: CSSAS--The Center for the Science of Synthesis Across Scales--under Award Number DE-SC0019288.

Solution Self-Assembly of Block Copolypeptoids with a Crystallizable Core-Forming Block  
NAISHENG JIANG (Presenter), University of Science and Technology Beijing, TIANYI YU, Louisiana State University, SHUO QIAN, Oak Ridge National Laboratory, IGOR KEVIN MKAM TSENGAM, VIJAY T JOHN, Tulane University, DONGHUI ZHANG, Louisiana State University — In this study, we investigate the solution self-assembly of coil-crystalline diblock copolypeptoids with one polypeptoid block having long n-alkyl side chains. Poly(N-methyl glycine)-b-poly(N-decyl glycine) (i.e. PNMG-b-PNDG) with lower volume fraction of the crystalline PNDG blocks were found to slowly self-assemble into one-dimensional long worm-like nanofibrils in methanol, which is induced by the crystallization of core-forming PNDG. Upon increasing volume fraction of PNDG, the final micellar morphology changed from worm-like nanofibrils to rigid short nanorods and then two-dimensional nanosheets. The molecular arrangement and self-assembly pathways of these anisotropic nanostructures were investigated by a combination of X-ray/neutron scattering and microscopic techniques to understand the underlying assembly mechanism. We believe the relationship between chemical composition, micellar morphology and self-assembly pathway provided here would not only benefit the rational design of polypeptoid-based nanostructures with tunable size, shape and morphology, but also shed lights on the crystallization-driven self-assembly of comb-shaped polymers bearing long aliphatic side chains in general.
3:42PM D35.00007: Transforming protein-polymer conjugate purification by tuning protein solubility* [Invited]  ALAN RUSSELL (Presenter), STEFANIE BAKER, Carnegie Mellon Univ, CORAY COLINA, University of Florida — Almost all commercial therapeutic and industrial proteins are purified by processes that include salting-out precipitation in ammonium sulfate. Protein-polymer conjugates are generally synthesized from already pure starting materials and the struggle to separate the conjugates from polymer, native protein, and from differently modified variants has vexed scientists for decades. Since ammonium sulfate precipitation is exclusively used as an initial step in crude protein purifications, it has had little relevance in the delicate purification of protein-polymer conjugates. We have discovered, however, that polymers grown from the surface of proteins have a transformational effect on the solubility of proteins in salt solutions. We generated a family of protein-polymer conjugates with a variety of polymers, grafting densities, and polymer lengths using surface-initiated atom transfer radical polymerization. Covalently attached polymers increased solubility of the conjugates in ammonium sulfate and completely prevented precipitation. Molecular dynamic simulations showed the impact was driven by an anti-polyelectrolyte effect. We then efficiently and simply purified mixtures of conjugates and native proteins.

4:18PM D35.00008: Characterization of Fiber Formation of Sugar-based Poly(D-glucose carbonate) Amphiphilic Block Copolymers in Solution* JEE YOUNG LEE (Presenter), Univ of Delaware, YUE SONG, KAREN L WOOLEY, Chemistry, Texas A&M University, DARRIN JOHN POCHAN, Univ of Delaware — Designing the new sugar-derived poly(D-glucose carbonate)s (PGC) is motivated by a need to develop sustainable materials in response to a long-term environmental impact of traditional petroleum-based polymers. Herein, the fiber assembly behavior of the PGC amphiphilic BCP with targeted block compositions, chain lengths and side chain chemistries are explored with kinetically controlled assembly pathways varying the solvent compositions. The kinetics of the fiber formation is characterized using cryogenic-TEM and SANS where we find the assembled fibers have a flat interface composed of fused disc subunits. The assembly behavior deviates from the traditional coil-based BCPs due to the inherent stiffness of the glucose backbone resulting a unique chain packing in response to a solvent quality change. To observe the relative chain behavior in the same assembly conditions, both hydrophilic and hydrophobic block equivalent homopolymers are studied using various scattering techniques to obtain polymer chain solution properties for a better understanding of the PGC block copolymer chains. These findings allow us to discover a robust fiber nanostructure that can be achieved by non-traditional polymers and their potential to be used in many engineering applications.

Computationally designed bundlemers for hybrid physical-covalent assembly of rigid polymers

NAIRITI SINHA (Presenter), Materials Science and Engineering, University of Delaware, GRETHE VESTERGAARD JENSEN, National Institute of Standards and Technology, DARRIN JOHN POCHAN, Materials Science and Engineering, University of Delaware — Peptide coiled coils present a diverse toolbox for constructing new polymers that display target nanostructures and properties. Computational prediction of coiled coil-forming peptides enables chain and material construction in which coiled coils, also known as ‘bundlemers’, are the modular building blocks. We use bundlemers that form robust antiparallel homotetramers to construct hybrid physical-covalent, supramolecular polymers. By end-functionalizing peptides with complimentary ‘click’ reactive groups, bundlemers are covalently linked to form polymers displaying desired length distributions and flexibility: a short organic linker between bundlemers yields absolutely rigid rods while a flexible linker yields semi-flexible fibers. Small-Angle Neutron Scattering (SANS) along with Transmission Electron Microscopy (TEM) have been used extensively to characterize the structure of the resulting polymers. Furthermore, recombinant expression of the peptides in *Escherichia Coli* was used to obtain deuterated bundlemer-forming peptides. This has facilitated contrast-matching experiments in SANS with which we have characterized the stability of bundlemers in solution and also investigated the alternating bundlemer assembly design of rigid rods.

Random Heteropolymer Self-Assembly into Protein-Like Nanoparticles

SHAYNA HILBURG (Presenter), Massachusetts Institute of Technology MIT, TING XU, University of California, Berkeley, ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology MIT — Single-chain polymer nanoparticles are currently of great interest due to their potential applications, yet their properties have only recently started to be elucidated. Here, we study self-assembled single polymer nanoparticles to gain molecular insights into their structure and dynamics using molecular dynamics simulations. In particular, we study a four-component synthetic heteropolymer that has been experimentally investigated previously. Prior experimental findings showed favorable interactions with native proteins in non-native environments and during protein folding. Simulations of single chains demonstrate a rich energy landscape for these polymers, evident from the structure and dynamics of the molecules in solution. Specifically, spatial arrangement of amphiphilic monomers is characterized and shows many parallels to biological proteins. Multiple time scales are seen in system dynamics, showing a large impact of component chemistry and sterics. By bridging the gap between angstrom-scale NMR and bulk characterization, all-atom simulations provide valuable insight into potential mechanisms for these heteropolymer's behavior.

*This work was supported by the Defense Threat Reduction Agency contract HDTRA11910011.*
Both living cell cytoskeleton and their extracellular matrix are constituted mainly by biopolymer matrices. The physical properties of these matrices are known to significantly impact cell behavior, such as cell morphology, migration, and stem-cell differentiation. However, cells also constantly reorganize these intracellular and extracellular structures during physiological processes; this is thought to also change the mechanics of these biopolymer matrices, which may then have an immediate impact on cell behavior. In this talk, I will present our recent progress on characterizing the drastic local nonlinear matrix stiffening induced by contraction of individual living cells inside a 3D biopolymer matrix, through direct micromechanical measurement. Moreover, I will introduce a method, called Nonlinear Stress Inference Microscopy, with which we can determine the cell-induced local matrix stress from nonlinear microrheology measurements inside various types of extracellular matrix in 3D. In addition, I will also introduce our recent progress on characterizing the significant role of cytoskeletal intermediate filament in determining nonlinear mechanics, strength, toughness, and stretchability of the mammalian cytoskeleton.

Monday, March 2, 2020 2:30 PM - 5:30 PM

Session D36 DMP: DMP Past Chair's Symposium: Tools That Explore Materials Physics 601/603 - Amanda Petford-Long, Argonne National Laboratory - Tag(s): Invited

In this talk, I will present our recent experimental results using the latest generation of monochromated aberration-corrected scanning and transmission electron microscopes (STEM). Four examples of how one can reveal the magnetic ordering and orbital ordering of materials with atomic size electron probes will be shown. We have also used the principle of detailed balance to morph the electron microscope in a primary thermometer and revealed the anharmonic behavior of materials at the nanoscale. Our efforts in studying the phonon dispersion of materials under the presence of different isotopic species will be also mentioned. Finally, current and future limitations in the experiments and requirements to reveal the magnetic moment (orbital and spin), charge ordering, crystal field splitting, spin-orbit-coupling, optical dichroism, and other physical phenomena associated with broken symmetries will be discussed.

*This research was supported by the Center for Nanophase Materials Sciences, which is a Department of Energy Office of Science User Facility, using instrumentation within ORNL’s Materials Characterization Core provided by UT-Battelle, LLC under Contract No. DE-AC05-00OR22725 with the U.S. Department of Energy, and sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory, managed by UT-Battelle, LLC, for the U.S. Department of Energy.
We have developed a powerful new method called ultrafast electron calorimetry that can uncover hidden phases in magnetic and charge density wave materials. By using time and angle-resolved photoemission spectroscopy to measure the dynamic electron temperature and full band structure as the laser excitation is varied, one can clearly identify when changes in state or couplings occur in a material. Recently we used this approach to coherently manipulate the structure, electron-phonon couplings, and state of the 2D charge density wave (CDW) material 1T-TaSe2. Instead of the two material phases normally accessible using temperature tuning (CDW and normal phases), ultrafast laser excitation expands the phase diagram to include at least two new phases: a new metastable CDW state, and an inverted CDW state. Moreover, the electron temperature, bandwidth, band gap and band shift are all modulated by the CDW breathing mode, and this modulation changes in phase as the material enters a new state. In addition to the ability to map the state of a material, we can use pulse sequences to coherently guide a material from one phase to another.

Combining STM, AFM, and Magnetotransport Measurements for In-Operando Studies of Quantum Materials*

JOSEPH STROSCIO (Presenter), National Institute of Standards and Technology — Research in new quantum materials require multi-mode measurements spanning length scales, correlations of atomic scale variables with macroscopic functions, and with ultimate spectral resolution only obtainable at ultra-low temperatures. In this talk I describe a multi-mode instrument achieving μeV tunneling resolution with in-operando measurement capabilities of scanning tunneling microscopy (STM), atomic force microscopy (AFM), and magnetotransport inside a dilution refrigerator operating at 10 mK. I illustrate the capabilities of this new instrument in the study of quantum Hall edge states in graphene devices. The edge states, a set of alternating compressible and incompressible strips, are formed at the electrostatic pn junction boundary geometrically defining the Hall bar. To comprehensively characterize these microscopic objects, we apply all capabilities of the new instrument using modalities of AFM, STM, and magnetotransport measurements at mK temperatures. The Kelvin probe force microscopy (KPFM) mode of AFM detects the chemical potential transitions when Landau levels are being filled or emptied as a function of back gate potential and show the same fidelity for Landau level spectroscopy as STS measurements. In particular, symmetry breaking states can be resolved at filling factors ν = ±1 inside the N=0 Landau level manifold, showing the lifting of the graphene four-fold degeneracy due to spin and valley. With KPFM we can map the dispersion of the Landau levels across the quantum Hall edge boundary as a function of density and spatial position, including resolving the ν = ±1 edge modes. The microscopic properties of quantum Hall edge states can now be correlated with macroscopic magnetotransport measurements.

Capturing In Operando Electronic Structure of Microscopic 2D Materials*

ELI ROTENBERG (Presenter), Lawrence Berkeley National Laboratory — Angle Resolved Photoemission Spectroscopy (ARPES) is a premier technique for determining the electronic structure of correlated and topological materials. Recently, we and several other groups have adapted ARPES to submicron dimensions through the development of nano-scale scanning X-ray beams, creating so-called nanoARPES endstations at synchrotrons around the world. This exciting technique now enables the in operando measurement of electronic structure for materials in applied fields and currents, as well as the ability to probe the effect of screening and strain on many body physics in confined geometries. In this talk, I will present recent results in which nanoARPES is applied to 2D materials and heterostructures at length scales below 200 nm. These include few layer graphene and transition metal dichalcogenide / graphene heterostructures. Work done in collaboration with Professors T. Heinz (Stanford U.), J. Katoch (CMU), S Ulstrup, J. Miwa, and Ph. Hofmann (Aarhus U.).

*This research used resources of the Advanced Light Source, which is a DOE Office of Science User Facility under contract no. DE-AC02-05CH11231.
4:54PM D36.00005: Nanoscale quantum sensing of quantum materials through a single spin magnetometer [Invited] CHUNHUI DU (Presenter), University of California, San Diego — We introduce single spin magnetometry based on nitrogen-vacancy (NV) centers in diamond as a new measurement platform to locally probe the magnetic properties of quantum materials with a nanoscale spatial resolution. Utilizing this measurement platform, we have demonstrated control and local measurements of spin chemical potential in a magnetic insulator yttrium iron garnet (YIG) at the ambient condition, which opens up new possibilities for nanoscale imaging of spin-related phenomena. In addition, we investigate the temperature-dependent microwave response of an exfoliated high-$T_c$ superconductor $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$ (BSCCO) flake, from which the superconducting phase transition and penetration depth can be obtained in a non-invasive fashion. Our results demonstrate the unique capability enabled by NV spin magnetometry in exploring the exotic local spin and charge behavior of emergent material systems.

Monday, March 2, 2020 2:30 PM - 5:30 PM

Session D37 DFD: Transitional Flows & Chaotic Dynamics: In Honor of Bruno Eckhardt 605 - Alexander Morozov, Univ of Edinburgh - Tag(s): Invited

2:30PM D37.00001: What do we learn from the finite lifetime of turbulence?* [Invited] NIGEL GOLDENFELD (Presenter), University of Illinois at Urbana-Champaign — In a seminal paper published in 2006, Bruno Eckhardt and co-workers presented evidence to support the remarkable speculation that turbulence in shear flows --- specifically pipe flow --- has a finite lifetime at all Reynolds numbers, without the divergence that would be expected if the laminar and turbulent state were not analytically connected. I discuss these findings and their later extensions in terms of extreme value statistics and finite-size scaling, and show that the finite lifetime in pipe flow does not necessarily contradict the notion that there is a sharp laminar-turbulence transition in the universality class of directed percolation.

*This work was partially supported by a grant from the Simons Foundation (Grant number: 662985, NG) and by the National Science Foundation (Grant NSF-DMR-1044901).
3:06PM D37.00002: Is space time? A spatiotemporal tiling of turbulence [Invited]  PREDRAG CVITANOVIC (Presenter), MATTHEW N GUDORF, HAN LIANG, Georgia Inst of Tech — We address the long standing problem of how to describe, by means of discrete symbolic dynamics, the spatiotemporal chaos (or turbulence) in spatially extended, strongly nonlinear field theories.

One way to capture the essential features of turbulent motions is offered by coupled map lattice models, in which the spacetime is discretized, with the dynamics of small-scale spatial structures modeled by maps attached to lattice sites. The discretization that we study, the "spatiotemporal cat," has a remarkable feature that its every solution is uniquely encoded by a linear transformation from the corresponding finite alphabet symbol lattice. A spatiotemporal window into system dynamics is provided by a finite block of symbols, and the central question is to determine the likelihood of a given block's occurrence. As spatiotemporal states that share the same sub-blocks shadow each other exponentially well within the corresponding spatiotemporal windows, the dynamical zeta functions are now sums over spacetime tori, rather than time-periodic orbits.

In the spatiotemporal formulation of turbulence there is no evolution in time, there are only a repertoires of admissible spatiotemporal patterns. In other words: throw away your integrators, and look for guidance in clouds' repeating patterns.

3:42PM D37.00003: Deep learning to discover the dimension of an inertial manifold and predict dynamics on it [Invited]  MICHAEL GRAHAM (Presenter), University of Wisconsin - Madison — One of the senior author's last conversations with Bruno Eckhardt concerned the connection of machine learning tools and ideas to dynamical systems and turbulence. This talk concerns one such connection. Many flow geometries, including pipe, channel and boundary layer, have a continuous translation symmetry. As a model for such systems we consider the Kuramoto-Sivashinsky equation (KSE) in a periodic domain. We describe a method to map the dynamics onto a translationally invariant low-dimensional manifold and time-evolve them using neural networks (NN). Dimensionality reduction is achieved by phase-aligning the spatial structures at each time, then putting them into an undercomplete autoencoder that maps the original dynamics onto a lower-dimensional inertial manifold where the long-time dynamics live. We infer the dimension of the manifold by tracking the autoencoder error vs. dimension—this drops by orders of magnitude once the proper dimension is reached. The spatial structure and phase are then integrated forward in time using a NN. This approach significantly outperforms Principal Components Analysis.
4:18PM D37.00004: The onset of turbulence: from invariant solutions to a directed percolation phase transition [Invited]  BJOERN HOF (Presenter), Physics, IST Austria — Flows through pipes and channels exhibit an abrupt transition from ordered laminar to high dimensional turbulent flow. At the lowest Reynolds numbers where this transition can be observed the resulting flows are spatio temporally intermittent and are composed of patches of turbulence surrounded by laminar fluid. As will be shown, in direct numerical simulations individual turbulent patches (i.e. stripes and puffs) can be continued to much lower Reynolds numbers where they originate from spatially localized periodic orbit solutions. I will further discuss experimental studies of interacting turbulent patches and how the competition between the decay and the proliferation of turbulence gives rise to a phase transition to sustained turbulence.

4:54PM D37.00005: Nonlinear invariant solutions underlying spatio-temporal patterns in thermally driven shear flows * [Invited]  TOBIAS SCHNEIDER (Presenter), Ecole Polytechnique Federale de Lausanne — Driven wall-bounded fluid flows transitioning to turbulence are spatially extended chaotic dissipative non-equilibrium systems that support a large variety of self-organized patterns with regular spatial and temporal structure. In linearly stable parallel shear flows, patterns such as long-studied spontaneously emerging turbulent-laminar oblique stripes remain only partly understood. On the contrary, thermal convection in a fluid layer between two horizontal plates kept at different temperature, exhibits patterns that can often be described via a sequence of bifurcations off a base state undergoing a linear instability. If a Rayleigh-Bénard convection cell is inclined against gravity, buoyancy forces drive hot and cold fluid up and down the incline leading to a shear flow. In this so-called inclined layer convection (ILC) system, the competition of buoyancy and shear gives rise to a large variety of complex spatio-temporal flow patterns.

We study the dynamics of ILC using a fully nonlinear dynamical systems approach based on a state space analysis of the governing equations. Exploiting the computational power of highly parallelized numerical continuation tools based on matrix-free Newton methods (www.channelflow.ch), we compute a large set of invariant solutions of ILC and discuss their bifurcation structure. Specifically, equilibria, travelling waves, periodic orbits and heteroclinic orbits will be shown to form dynamical networks that support moderately complex dynamics at intermediate angles of inclination. At high inclination angles, where shear forces dominate, localized patches of weakly turbulent convection within a background of straight longitudinal convection rolls are observed. We present exact invariant solutions capturing both the dynamics and the spatial localization of these so-called transverse bursts.

Monday, March 2, 2020 2:30 PM - 5:30 PM

Session D38 FHP: History of Materials Science 607 - Robert Crease, State Univ of NY - Stony Brook - Tag(s): Invited, Undergrad Friendly
2:30PM D38.00001: Overview of History of Materials Research [Invited] ARNE HESSENBRUCH (Presenter), Massachusetts Institute of Technology — How can one get a quick overview of the history of materials research in the last few decades? Maybe by examining session titles at the Materials Research Society meetings. What has changed, what has not?

3:06PM D38.00002: Bernadette Bensaude-Vincent Invited Talk [Invited] —

3:42PM D38.00003: From Hidden Utility to Heroic Machines [Invited] E. F. SPERO (Presenter), Materials Science and Engineering, Massachusetts Institute of Technology — How do scientists imagine (and possibly enable) futures through their practices of computation? How might particular tools and approaches transition from serving as hidden utilitarian elements to those that give rise to new subfields and styles of thought? This presentation takes a historical approach to the emergence of computation in macromolecular science, an interdiscipline focused on polymers that bridges physics, chemistry, and materials science and engineering. In this field today, there is a palpable enthusiasm for the power and speed of computation investing in the promise of big data to revolutionize what is possible within these disciplines. Employing tools of high-throughput simulation and new machine learning algorithms, scientists aim to close the gap between theory and experiment, and redefine what it means to create, designing new sustainable materials built with atomic precision. However, in the late 1950s when computation was yet a nascent tool, often used for verification of existing models (rather than one for creation) scientists studying the physical behavior of long chain molecules downplayed, mistrusted, or even openly disdained computational methods. Along with fellow panelists this presentation will open space for reflection on tools, methods, and imagination.

4:18PM D38.00004: Lynn W. Hobbs Invited Talk [Invited] —

4:54PM D38.00005: History of Materials Science Institutions [Invited] ROBERT CREASE (Presenter), State Univ of NY - Stony Brook — Materials science requires a diverse set of institutions to interact closely and flexibly in staging research events, and to allow different kinds of communities and facilities to intersect. These institutions, however, tend to drop out of the history of scientific research. This talk divides such institutions into five basic, though often overlapping, kinds: physical sites (laboratories), educational institutions, societies, funding agencies, and journals. The talk discusses the importance of these institutions and makes a brief survey of them.

Monday, March 2, 2020 2:30 PM - 5:06 PM

Session D39 DCOMP DMP DCP: First-principles modeling of excited-state phenomena in materials III: GW+BSE for Polaron and Optical Excitations 703 - Sahar Sharifzadeh, Boston Univ - Tag(s): Focus
2:30PM D39.00001: Polarons from first principles* [Invited]  FELICIANO GIUSTINO (Presenter), Physics, University of Texas at Austin — Polarons are among the most well-known quasiparticles in solid state physics, and are key to understanding fundamental concepts such as the electron mass enhancement in semiconductors and the formation of Cooper pairs in superconductors. Interest in polaron physics has been reignited by recent angle-resolved photoelectron spectroscopy studies, which revealed polaronic signatures in the band structures of several metal oxides and two-dimensional semiconductors. In this talk I will describe our recent work aimed at describing polarons and their spectroscopic signatures from first principles. In the first part of the talk I will outline a general many-body framework to compute and analyze polaron satellites in photoelectron spectra using the cumulant expansion approach [1,2]. I will discuss applications to titanium dioxide and europium oxide, and show that the calculations are able to reproduce very closely measured angle-resolved photoelectron spectra. In the second part of the talk I will address the question on how to compute the wavefunction of a polaron. I will describe a new approach to the polaron problem that overcomes some of the limitations of explicit supercell calculations [3]. This approach enables systematic calculations of wavefunctions and formation energies for both small and large polarons, and can be used to analyze the electron-phonon coupling mechanisms responsible for electron or hole self-trapping. I will illustrate these concepts using lithium fluoride and lithium oxide as examples, and I will discuss the connection with previous work on the polaron problem based on model Hamiltonians.

*Grant RL-2012-001 funded by the Leverhulme Trust; Grant DE-SC0020129 funded by the U.S. Department of Energy, Office of Science.

3:06PM D39.00002: Theory and First-Principle Calculation of Photoemission Spectra from Optically Excited States  TING CAO (Presenter), Department of Materials Science and Engineering, University of Washington and Geballe Laboratory for Advanced Materials, Stanford University, KESHAV M DANI, Femtosecond Spectroscopy Unit, Okinawa Institute of Science and Technology Graduate University, TONY F HEINZ, Department of Applied Physics, Stanford University and SLAC National Accelerator Laboratory — The behaviors of optically excited states, such as excitons, not only give rise to a variety of fascinating phenomena in condensed matter, but also play vital roles in modern optoelectronics and energy harvesting. In this talk, I will present our recent development on the theory and first-principle methods in the study of the photoemission spectra of low-dimensional materials. By performing calculations based on many-body perturbation theories, we show that, in monolayer transition metal dichalcogenides, the excitons hold unique energy dispersions and spectra weights in photoemission, which unveil the fundamental physical properties of these excited states. We further connect our theoretical works to experimental results and explore their potential applications in other systems.

YU JIN (Presenter), Department of Chemistry, University of Chicago, MARCO GOVONI, Materials Science Division and Center for Molecular Engineering, Argonne National Laboratory, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago — In order to predict the opto-electronic properties of several classes of functional materials, an accurate description of absorption and photoluminescence processes is necessary. Building on our previous work on calculations of absorption spectra from first principles [1], we present a method to compute photoluminescence spectra based on the solution of the generalized quantum Liouville equation, including electron-phonon interaction [2]. We present results for the photoluminescence spectra of organic/inorganic perovskites and of optically controllable defects in semiconductors.

**3:30PM D39.00004: Deep ultraviolet luminescence and charge-transfer excitons in atomically thin GaN quantum wells**

WONCHEOL LEE (Presenter), DYLAN BAYERL, NOCONA SANDERS, ZIHAO DENG, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — We investigate the electronic, excitonic, and optical properties of atomically thin GaN quantum wells embedded in AlN or AlGaN barriers using first-principles calculations based on density functional theory (DFT) and many-body perturbation theory. The strong quantum confinement results in deep ultraviolet luminescence. Also, the quasi-2D structural characteristic produces strongly bound excitons, which are even stable at room temperature. We also investigate the properties of pairs of atomically thin GaN wells, separated by polar AlN barriers. The perpendicular electrical polarization produces charge-transfer excitons, in which electrons and holes are spatially separated in the two different GaN wells. Compared to direct excitons, the reduced overlap of charge-transfer excitons enables exciton lifetime that are 3-4 orders of magnitude longer. By adjusting the separation distance between electrons and holes through variations of the well and barrier thickness we can control the exciton lifetime and the binding energy simultaneously.

*The work is supported by the University of Michigan College of Engineering Blue Sky Research Program. W.L. was partially supported by the Kwanjeong Educational Foundation Scholarship. Computational resources were provided by the DOE NERSC facility.
Analysis of diagonal $G$ and subspace $W$ approximations within fully self-consistent $GW$ calculations for bulk semiconducting systems*  

YASHPAL SINGH (Presenter), LIN-WANG WANG, Lawrence Berkeley National Laboratory — Fully self-consistent $GW$ (sc-$GW$) methods are now available to evaluate quasiparticle and spectral properties of various molecular and bulk systems. However, such techniques are computationally demanding and act as a bottleneck to include vertex function. In contrast, routinely used single-shot $G_0W_0$ approximation has an undesirable dependency on the choice of xc-functional. In this work, we consider AlAs, AlP, GaP, and ZnS as our prototype systems to perform sc-$GW$ calculations by expressing the full $G$ matrix using a plane-wave basis set. To reduce the computational cost, we present a framework within our sc-$GW$ scheme to consider diagonal $G$ and subspace $W$ approximations. We analyse our results obtained from the above techniques by comparing against our fully sc-$GW$ calculations and other similar approaches including experiments. The sub 2% difference in the values of the bandgap obtained from fully sc-$GW$ and subspace $W$ methods shows an encouraging direction to incorporate vertex function that could potentially improve overestimated sc-$GW$ bandgaps.

Spin-wave dispersion of Cu$_2$MnAl, Ni$_2$MnSn, and Pd$_2$MnSn based on quasi-particle self-consistent $GW$ method*  

HARUKI OKUMURA (Presenter), KAZUNORI SATO, Osaka University, TAKAO KOTANI, Tottori University — We calculated the spin-wave dispersion and the stiffness constants of three metallic ferromagnetic Heusler alloys: Cu$_2$MnAl, Ni$_2$MnSn, and Pd$_2$MnSn. We determined the ground state by the quasi-particle self-consistent $GW$ (QSGW) method. In conjunction with the Wannier function, we obtain transverse dynamical spin susceptibility based on linear response method. It is found that the ground states within the QSGW are reasonably calculated to reproduce spin-wave dispersion around Gamma point. In Cu$_2$MnAl, the magnetic moment in QSGW agrees with the experiment, but stiffness constant is underestimated. In Ni$_2$MnSn, the QSGW overestimates the moment, as seen in the itinerant ferromagnetic case as FCC Ni; however, the stiffness in QSGW agrees with the experiment. In Pd$_2$MnSn, the QSGW reproduces the spin-wave throughout the Brillouin zone, and the stiffness is close to the experiments. This agreement is due to the reasonable exchange splitting of Mn 3d in accordance with the large screened Coulomb interaction in QSGW.

4:06PM D39.00007: Self-consistent GW method for solids: efficient implementation*
ANDREY KUTEPOV (Presenter), Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — An efficient implementation of the self-consistent GW method in the FlapwMBPT code (https://www.bnl.gov/cmpmsd/flapwmbpt/) is presented. It features the evaluation of the polarizability and the self-energy which scales only linearly with respect to the system size. The total computational time scaling measurements show it to be between linear and quadratic up to 72 atoms in silicon supercells. Application to such materials as CoSbS (24 atoms), supercells of La2CuO4 (up to 56 atoms), and SmB6 (7 atoms) illustrate the potential of the approach in computational material science.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences as a part of the Computational Materials Science Program.

4:18PM D39.00008: Systematic QSGW calculations on the electronic structure of rare-earth nitrides*
KAZUNORI SATO (Presenter), Graduate School of Engineering, Osaka University, TAKAO KOTANI, Department of Applied Mathematics and Physics, Tottori University, KATSUHIRO SUZUKI, Graduate School of Engineering, Osaka University — Rare-earth (RE) based light emitting materials are distinguished for their narrow line width, small temperature dependence and insensitivity to the environment. These characteristic properties mostly come from localized nature of 4f-states. Therefore, for accurate prediction and design of RE related functional material, reasonable description of 4f-states is indispensable.

In this paper, we present systematic electronic structure calculations of RE nitrides by using quasi-particle self-consistent GW (QSGW) method. This method was implemented to ecalj package, and confirmed to give reasonable description of the electronic structure of several materials including f-electron systems [1, 2]. It is found that the present calculations reproduce previous LDA+U calculations [3] and calculated magnetic moments are reasonably described by the Hund's rule for most of the rare-earth nitrides. For example, SmN is calculated to be semi-metallic and predicted magnetic moments (S=2.50, L=4.96, J=2.46) are consistent to Hund's rule prediction.

*This work was partly supported by JST CREST (JPMJCR1812) and by JSPS KAKENHI (JP18H05212).
**4:30PM D39.00009: Jigsaw Puzzle Orbitals for Electronic Structure**

DIMITAR PASHOV, MARK SCHILFGAARDE (Presenter), Kings College London — We present the jigsaw-puzzle orbitals (JPOs), a recently developed basis set for solving the one-particle Schrödinger equation with an optimally constructed minimal basis set. We illustrate some of its advantages with QSGW bandstructure calculations. A significant improvement in self-energy interpolation is observed as well as physically intuitive dependency of the band gap on the projection range.

The better spatial localization of JPOs paves the way to efficient, real-space assembly of 1-particle matrices while simultaneously improving accuracy on wider energy window. The short-ranged functions both significantly less linearly interdependent and more accurate than traditional atom-centered basis functions.

**4:42PM D39.00010: First-principles Studies of Tl activated Scintillator Phosphor Materials: Towards an understanding of the Scintillation mechanism**

ANDREW CANNING (Presenter), MAURO DEL BEN, Lawrence Berkeley National Laboratory, JAROSLAW GLODO, Radiation Monitoring Devices Inc. — Tl doped halide scintillator phosphors are amongst the most commonly used gamma ray detector materials for medical imaging, high energy physics and nuclear materials detection applications (e.g. CsI:Tl, NaI:Tl). Even so the complete scintillation process in these materials is still poorly understood. In particular in recent years there has been great interest in co-doping these materials to try and improve their detection performance. We have performed first-principles studies based on GGA, hybrid functionals and the GW/BSE method in tandem with experiments to understand the scintillation mechanism in these materials and how it could be improved by co-doping. In particular we have looked at the Tl exciton optical emission states and energy transfer mechanisms from the gamma ray to the Tl. Recently there has also been interest in new Tl bulk scintillators such as TLYC (Tl2LiYCl6) which we have also studied.

*This work was supported by the Director, Office of Advanced Scientific Computing Research, Office of Science of the U.S. Dept. of Energy and used resources of the National Energy Research Scientific Computing Center (NERSC). Excitation Pathways in Resonant Inelastic X-ray Scattering from Many-Body Perturbation Theory

CHRISTIAN VORWERK (Presenter), Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany, FRANCESCO SOTTILE, LSI, Ecole Polytechnique, CNRS, CEA, Institut Polytechnique de Paris, Palaiseau, France, CLAUDIA DRAXL, Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany — Resonant inelastic x-ray scattering (RIXS) spectroscopy is a powerful tool to unravel the nature of elementary excitations in a wide range of crystalline materials. In the RIXS process, a core electron is excited through the absorption of an x-ray photon. Subsequently, a valence electron fills the core hole via the emission of a x-ray photon. The final many-body state contains an excited electron and a valence hole. Through resonant x-ray absorption and emission, RIXS offers an elemental and orbital selective probe of the electronic valence excitations. In this talk, we present a novel many-body approach to RIXS. We use explicit many-body excited states in the optical and x-ray region, as obtained from full diagonalization of the Bethe-Salpeter equation in an all-electron framework, to obtain an expression for the RIXS cross section. The RIXS cross section is expressed in terms of pathways between intermediate many-body states containing a core hole, and final many-body states containing a valence hole. We apply our in-depth analysis to the RIXS spectra of the flour K edge of LiF and carbon K edge of diamond. Our results show that the excitation pathways determine the spectral shape of the emission, and the importance of electron-hole correlation in the spectra.

Session D40 DCOMP DMP DAMOP DCP: Building the Bridge to Exascale: Applications and Opportunities for Materials, Chemistry, and Biology III

705 - Jack Deslippe, Lawrence Berkeley National Laboratory - Tag(s): Focus
Preparing for exascale: additive manufacturing process modeling at the fidelity of the microstructure* [Invited] JAMES BELAK (Presenter), Lawrence Livermore Natl Lab — In FY17, the USDOE Exascale Computing Project (ECP) initiated projects to design and develop simulation codes to use exascale computing. This application development is organized around computational motifs. Here, we present an overview of the motifs of computational materials science, from the “particles” using by molecular dynamics to the “grids” using by phase-field models and the various solution algorithms such as FFTs. Examples will be taken from the co-design centers ExMatEx and CoPA, as well as the application development project ExaAM. This project includes an integration of all the computational components of the metal additive manufacturing (AM) process into a coupled exascale modeling environment, where each simulation component itself is an exascale simulation. What has emerged is that exascale computing will enable AM process modeling at the fidelity of the microstructure. Here we discuss what this means, in particular, tight coupling of Process-Structure-Property calculations. Macroscopic continuum codes (ALE3D, Truchas and OpenFOAM) are used to simulate melt-refreeze, within which mesoscopic codes (Phase-field and Cellular Automata) are used to simulate the development of material microstructure. This microstructure is then used by polycrystal plasticity codes (ExaConstit) to calculate local material properties. The project is driven by a series of demonstration problems that are amenable to experimental observation and validation. We present our coupled exascale simulation environment for additive manufacturing and its initial application to AM builds.

*Work performed with Tim Germann, John Turner, the ExaAM Team, and under the auspices of the U.S. Department of Energy by LLNL, LANL and ORNL under contracts DE-AC52-07NA27344, DE-AC52-06NA25396, DE-AC05-00OR22725, and supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. Department of Energy Office of Science and the National Nuclear Security Administration.
3:06PM D40.00002: Enabling First Principles Multiscale-Multiphysics Simulations of Complex Thermo-Fluid Systems Through Exascale Computing* JOSEPH OEFELEIN (Presenter), KYLE SCHAU, Georgia Inst of Tech, RAMANAN SANKARAN, Oak Ridge National Laboratory — Understanding and controlling turbulence, aerothermodynamics, and propulsion processes in advanced thermo-fluid systems presents many challenges. A multitude of strongly coupled fluid dynamic, thermodynamic, transport, chemical, and heat transfer processes are intrinsically coupled and must be considered simultaneously in complex domains. These multiscale physics are not currently understood or modeled with sufficient accuracy. Without their inclusion, timely Research and Development of advanced systems will be significantly deficient. Exascale computing offers significant opportunities to treat these physics with unprecedented accuracy and speed. However, the foundational hybrid-CPU+GPU architectures present many challenges to exploit their full potential power. This presentation will highlight the inherent challenges associated with porting complex multiphysics solvers to these architectures and the approach taken to achieve optimal performance using the RAPTOR code framework developed by Oefelein et al. as an example application.

*This research used resources of the Oak Ridge Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC05-00OR22725.

3:18PM D40.00003: Generating a Comprehensive Map of Cancer Morphology in Whole Slide Tissue Specimens* JOEL SALTZ (Presenter), RAJ GUPTA, DIMITRIS SAMARAS, LE HOU, HAN LE, SHAHIRA ABOUSAMRA, REBECCA BATISTE, TIANHAO ZHAO, JINGWEI ZHANG, CHAO CHEN, TAHSIN KURC, State Univ of NY - Stony Brook — Advanced imaging technologies can capture extremely high-resolution images of tissue specimens, and quantitative analyses of cancer morphology using these images have shown value in a variety of correlative and prognostic studies. Our work on Summit will generate a comprehensive multi-scale mapping of cancer morphology with a dataset of more than 10,000 whole slide tissue images from over 20 cancer types. The work will use a collection of deep learning analysis pipelines we have developed to study, quantify and characterize tissue structure in diseased and normal tissue specimens. These analysis pipelines generate distributions of nuclei and cells and patch-level maps of lymphocyte distributions and segmentations of tumor regions. The analysis results will provide a first-ever representations of lymphocyte maps, nuclear characterizations and characterizations of tumor regions on a dataset of this scale. We expect that studies supported by these rich datasets will enable the development of biomarkers to predict clinical outcome and a better epidemiological understanding of cancer subtypes and how constituent cells contribute to cancer invasion and expansion.

3:30PM D40.00004: Operator Dynamics in Quantum Circuits with Subsystem Symmetry  
JASON IACONIS (Presenter), Physics, University of Colorado, Boulder, SAGAR VIJAY, Physics, Harvard University, RAHUL NANDKISHORE, Physics, University of Colorado, Boulder — Our understanding of quantum dynamics in many-body quantum systems has been revolutionized in recent years by the study of random quantum circuits. These models provide a tractable setting in which we can understand ideas such as thermalization, operator spreading and quantum chaos. Furthermore, it is known that a richer variety of phenomena can occur when such models are enriched with a set of symmetries. We will focus on a particularly exotic set of symmetries which act on lower dimensional sub-manifolds of our system, a situation which is relevant to the study of highly quantum ‘fracton’ phases of matter. I will discuss approaches we may take to simulate such quantum dynamics numerically in higher dimensional systems. In particular, we will see that a restricted class of automaton circuit dynamics can be efficiently simulated while retaining the essential attributes of generic quantum chaotic systems. This technique will allow us to understand the properties of circuits with subsystem symmetry and may provide a valuable new tool for future studies of chaotic quantum dynamics.

3:42PM D40.00005: Radiation-matter interaction in graphene molecules: implementation on Geant 4 and computational simulations  
CARLOS VIDAL (Presenter), JOHN PRIAS, HERNANDO ARIZA, Doctoral Program in Physical Sciences, Interdisciplinary Institute of Sciences, University of Quindio — The voxelized computational approximation of the graphene molecules for different amounts of carbon atoms was simulated, using computational programs with optimized Geant 4 type geometry. The computational simulation of radiation transport through matter with characteristic interactions in the Uv-Vis spectral range, were made for radiation sources, detectors and graphene molecules. The optimization of the theoretical Uv-Vis spectra obtained from Geant 4, was achieved through algorithms development on Matlab. A method for computational reconstruction of UV-Vis spectra was proposed. The results suggest that is possible observe the contributions of the conjugated pi and sigma bonds, in the UV-Vis characteristic spectra as expected. Also, it was found that the variation in the size of the graphene molecules, influence the height of the band associated with the sigma bond, in agreement with experiments broadly studied. As well as, the proposed methodology suggests Geant 4 as a potential tool to simulate radiation-matter interactions in graphene-based molecules.
3:54PM D40.00006: ExaTN - A Scalable Exascale Math Library for Hierarchical Tensor Network Representations and Simulations in Quantum Many-Body Theory and Beyond*

DMITRY LIAKH (Presenter), EUGEN DUMITRESCU, GONZALO ALVAREZ, TIFFANY MINTZ, ALEXANDER MCCASKEY, Oak Ridge National Lab — Tensor network theory has recently paved the path to efficient numerical simulations of two- and three-dimensional many-body Hamiltonians describing strongly correlated quantum particles, but it still requires efficient software infrastructure that scales well on leadership heterogeneous HPC systems. To address this need, we develop ExaTN: A scalable math library for processing hierarchical tensor representations. Our library enables the use of advanced hierarchical tensor network states capable of expressing local expectation values in strongly entangled quantum systems efficiently. ExaTN allows building arbitrarily complex tensor networks for which it exposes a set of high-level API functions which automate tensor optimization procedures. A highly modular design of ExaTN allows seamless switching of computational backends for the computer system of choice, from a laptop to a leadership GPU-accelerated HPC platform, like Summit. The internal task-based parallel runtime then assures a load-balanced execution of tensor processing workloads.

*This research was funded by the Oak Ridge National Laboratory LDRD project 9463 and used resources of the Oak Ridge Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC05-00OR22725.

4:06PM D40.00007: Porting ITensor to Julia*

MATTHEW FISHMAN (Presenter), KATHARINE HYATT, MILES STOUDENMIRE, Simons Foundation — In this talk, we present iTensors.jl, a ground-up rewrite of the C++ ITensor library in Julia. ITensor is a leading software package for simulating quantum many-body systems with tensor networks. Julia is a relatively young just-in-time (JIT) compiled language that is particularly well suited for scientific computing. We will discuss the advantages and disadvantages of moving from C++ to Julia, including ease of development and performance. We will also discuss new designs for the Julia version that are in development or planned, such as a rewrite of the sparse tensor library optimized with multithreading, new tensor contraction backends, automatic fermion sign support, GPU support, and automatic differentiation for the automated optimization of tensor networks.

*This work is supported by the Simons Foundation.
4:18PM D40.00008: Breaking the entanglement barrier: Tensor network simulation of quantum transport  
MICHAEL ZWOLAK (Presenter), National Institute of Standards and Technology, MAREK M RAMS, Jagiellonian University — The recognition that large classes of quantum many-body systems have limited - or efficiently representable - entanglement in the ground and low-lying excited states led to dramatic advances in their numerical simulation via so-called tensor networks. However, global dynamics elevates many particles into excited states, and can lead to macroscopic entanglement (seen both experimentally and theoretically) and the failure of tensor networks. Here, we show that for quantum transport - one of the most important cases of this failure - the fundamental issue is the canonical basis in which the scenario is cast: When particles flow through an interface, they scatter, generating a "bit" of entanglement between spatial regions with each event. The frequency basis naturally captures that - in the long time limit and in the absence of an inelastic event - particles tend to flow from a state with one frequency to a state of identical frequency. Recognizing this natural structure yields a striking - exponential in some cases - increase in simulation efficiency, greatly extending the attainable spatial and time scales. The concepts here broaden the scope of tensor network simulation into hitherto inaccessible classes of non-equilibrium many-body problems [see arXiv:1904.12793].

4:30PM D40.00009: Accelerate Science on Perlmutter with NERSC*  
CHARLENE YANG (Presenter), JACK RICHARD DESLIPPE, Lawrence Berkeley National Laboratory — Towards exascale computing, the National Energy Research Scientific Computing (NERSC) Center has procured a ~100 PetaFLOP/s supercomputer called Perlmutter. This talk will give an overview of its architectural details and discuss what Perlmutter can offer to the scientific community especially to Material Science and Chemistry. These offerings not only include cutting-edge hardware and technology but also highly optimized software stack and expert user support. The NERSC Exascale Science Application Program (NESAP) provides resources such as hackathons with performance engineers, early access to hardware, and NERSC-funded PostDocs to select application teams, and lessons learned from these teams are then disseminated to the general community. NERSC also collaborates with vendors and other High Performance Computing (HPC) developers on math libraries, performance models and tools, compiler development and performance portability. With an emphasis on Material Science and Chemistry, we will pinpoint the opportunities that Perlmutter and NERSC can bring for exascale and beyond.

*This research used resources of the National Energy Research Scientific Computing Center (NERSC), a U.S. Department of Energy Office of Science User Facility operated under Contract No. DE-AC02-05CH11231.
4:42PM D40.00010: Central Moment Lattice Boltzmann Method with Fokker-Planck Guided Collision for Non-Equilibrium Flows*  WILLIAM TAYLOR SCHUPBACH (Presenter), KANNAN PREMNATH, FARZANEH HAJABDOLLAHI, University of Colorado, Denver — Central moments-based lattice Boltzmann method (LBM), a recent approach for flow simulations, is generally based on the relaxation of various central moments to their equilibria under collision. The latter is usually constructed either directly from the Maxwell distribution function or by exploiting its factorization property. We propose a central moment LBM from a different perspective, where its collision operator is constructed by matching the changes in different discrete central moments under collision to the changes in the corresponding continuous central moments as given by the Fokker-Planck (FP) collision model of the Boltzmann equation. The resulting formulation can be interpreted in terms of the relaxation of the various central moments to “equilibria” that depend only on the adjacent, lower order post-collision moments. We designate such newly constructed chain of equilibria as the Markovian central moment attractors and the relaxation rates are based on scaling the drift coefficient of the FP model by the order of the participating moment. We will demonstrate the accuracy and robustness of our new formulation for simulations of a variety of flows using the standard D2Q9 and D3Q27 lattices and also present a comparison against other collision models.

*NSF CBET-1705630

4:54PM D40.00011: Nonlocal Coulomb interaction and spin freezing crossover: A route to valence-skipping charge order  SIHEON RYEE (Presenter), Department of Physics, KAIST, P. SÉMON, Brookhaven National Laboratory, MYUNG JOON HAN, Department of Physics, KAIST, SANGKOOK CHOI, Brookhaven National Laboratory — Multiorbital systems away from global half-filling host intriguing physical properties promoted by Hund’s coupling. Despite increasing awareness of this regime dubbed Hund’s metal, effect of nonlocal interaction is still elusive. Here we study a three-orbital model with 1/3 filling (two electrons per site) including the intersite Coulomb interaction $V$. Using the $GW$ plus extended dynamical mean-field theory, the valence-skipping charge order transition is shown to be driven by $V$. Most interestingly, the instability to this transition is significantly enhanced in the spin-freezing crossover regime, thereby lowering the critical $V$ to the formation of charge order. This behavior is found to be closely related to the population profile of the atomic multiplet states in the spin-freezing regime. In this regime, maximum spin states are dominant in each total charge subspace with substantial amount of one- and three-electron occupations, which leads to almost equal population of one- and the maximum spin three-electron state. Our finding unveils another feature of the Hund’s metal, and has potential implications to the broad range of multiorbital systems as well as the recently discovered charge order in iron-pnictides.
5:06PM D40.00012: Improved methods for demonstrating that AKLT systems are gapped*  
NICHOLAS POMATA (Presenter), TZU-CHIEH WEI, State Univ of NY - Stony Brook — We examine recent advancements in proving the gaps of AKLT systems [1,2], in particular those proposed by Abdul-Rahman et al. [1], which we have later extended so that it can be applied numerically in more general settings. We discuss how this has been used in proving the AKLT gap on a variety of "decorated" lattices in 2D, where the number $n$ of decorating spin-1 sites on each edge of the original lattice is two or larger [3]. Furthermore, we investigate whether the gappedness can be established for several decorated lattices with $n=1$. We will further explore how the method may be used to demonstrate the existence of the AKLT gap on several uniform lattices without decoration.

Session D41 GMAG DMP DCOMP: Emergent magnetism in correlated electron systems I  
707 - Chetan Dhital, Kennesaw State Univ - Tag(s): Focus

2:30PM D41.00001: Z2xZ2 magnetic domains and magnetic moment disproportionation in the spin-orbit Mott insulator Sr2IrO4 [Invited]  
BUMJOON KIM (Presenter), SUNWOOK PARK, HOON KIM, Physics, Pohang University of Science and Technology, J.-W. KIM, Advanced Photon Source, ALASKA SUBEDI, Centre national de la recherche scientifique — Sr2IrO4 is representative of the new class of materials dubbed “spin-orbit Mott insulators” which hosts a variety of unconventional magnetism that arise from spin-orbit entangled moments, or pseudospins. A prominent example is the possible realization of a Kitaev spin liquid when pseudospins are arranged in a honeycomb lattice. In this talk, I will discuss on a new aspect of pseudospins; they show propensity to spontaneously disproportionate and lead to rich magnetic structures where symmetrically equivalent sites are decorated with magnetic moments of different magnitudes. We start by showing that the observed Z2xZ2 domain structure cannot be explained by the known magnetic structure and necessarily requires mixing of two order parameters that belong to two different irreducible representations of the high symmetry phase, which in response to the magnetic moment disproportionation distorts to a low symmetry phase. We argue that this phenomenon may be found more generally in other systems with spin-orbit entangled magnetic moments and hence should be considered when solving for the magnetic structure.
Exploring magnetic frustration in a square-lattice metallic system: spin fluctuations in 15% Fe-doped CaCo$_2$As$_2$*

BENJAMIN UELAND (Presenter), Ames Laboratory, Ames, IA 50011, USA; BING LI, AASHISH SAPKOTA, Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames, IA 50011, USA; SANGEETHA NEDIADATH SATHYANADHAN, Ames Laboratory, Ames, IA 50011, USA, DAVID C JOHNSTON, ALAN IRA GOLDMAN, Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames, IA 50011, USA, TOBY G. PERRING, ISIS Neutron and Muon Source, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 OQX, UK, ANDREAS KREYSSIG, ROBERT MCQUEENEY, Ames Laboratory, Ames, IA 50011, USA; Iowa State University, Ames, IA 50011, USA — Magnetic frustration can arise in a square lattice of magnetic moments from competition between nearest-neighbor ($J_1$) and next-nearest-neighbor ($J_2$) exchange, with $\eta = J_1/2J_2$ governing the magnetic ground state. Remarkably, our inelastic neutron scattering (INS) measurements have shown that CaCo$_{1.86}$As$_2$ is a unique example of a metallic square-lattice system with nearly perfect frustration ($|\eta| \approx 1$) despite possessing A-type antiferromagnetic (AF) order below a Néel temperature of $T_N = 52$ K. Our recent neutron diffraction data on Ca(Co$_{1-x}$Fe$_x$)$_2$As$_2$ show that the A-type AF order is suppressed past $x = 0.12$, and here we give results from INS experiments made at $T = 6$ K on single-crystal samples of $x = 0.15$. Instead of the walls of magnetic fluctuations found for $x = 0$, we rather find ferromagnetic-like fluctuations emerging from zone centers that, depending on the energy, is quickly suppressed with increasing momentum transfer. We discuss our results in terms of the changing degree of frustration with increasing $x$.

*This research was supported by the U.S. DOE, BES, Division of Materials Sciences and Engineering under Contract No. DE-AC02-07CH11358. We gratefully acknowledge the Science and Technology Facilities Council (STFC) for access to neutron beamtime at ISIS.
3:18PM D41.00003: Nonreciprocal directional dichroism effect in Ni$_3$TeO$_6$ in the toroidal geometry

KIMAN PARK (Presenter), Chemistry, University of Tennessee, Knoxville, HEUNG-SIK KIM, Physics, Kangwon National University, MICHAEL YOKOSUK, Chemistry, University of Tennessee, Knoxville, JUNJIE YANG, Physics, Central Michigan University, JAEWOOK KIM, Physics, Rutgers University, MATEUSZ GORYCA, SCOTT CROOKER, National High magnetic Field Laboratory, Los Alamos, KRISTJAN HAULE, SANG-WOOK CHEONG, DAVID VANDERBILT, Physics, Rutgers University, JANICE LYNN MUSFELDT, Chemistry, University of Tennessee, Knoxville — We bring together high magnetic field techniques, optical spectroscopy, and first principles electronic structure calculations to reveal high-energy, broadband nonreciprocal directional dichroism in Ni$_3$TeO$_6$. We focus on the toroidal geometry where polarization is perpendicular to the chiral spin arrangement, and light is propagating orthogonal to both. We employ circularly polarized as well as unpolarized light to fully explore the symmetry properties and eigenstates of the system as well as potential for photonics applications. Due to the spectral range of our work, we demonstrate nonreciprocal effects in the Ni$^{2+}$ $d$-to-$d$ on-site excitations as well as the phonon side bands that appear on the leading edge of these structures. In addition to being a peculiar and fundamental light-matter interaction in low-symmetric crystals, nonreciprocal directional dichroism can support one-way transparency, optical rectifiers, and high fidelity holograms – just to name a few.

3:30PM D41.00004: Magnetic structure in square cupola compound Ba(TiO)Cu$_4$(PO$_4$)$_4$: $^{31}$P NMR Study

RAIVO STERN (Presenter), IVO HEINMAA, RIHO RÄSTA, Chemical Physics, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, KENTA KIMURA, TSUYOSHI KIMURA, Advanced Materials Science, University of Tokyo, Kashiwa, Japan — The magnetic structure of the antiferromagnetic square cupola compound Ba(TiO)Cu$_4$(PO$_4$)$_4$ single crystal is studied with $^{31}$P nuclear magnetic resonance techniques. The magnetic hyperfine shift $K$ shows a clear splitting at the Neel temperature $T_N = 9.5$ K, where the resonance splits into 2 lines when the external field is oriented along c-axis and into 4 lines when the field is along a-axis. In paramagnetic region $K(T)$ follows temperature dependence of the magnetic susceptibility $\chi(T)$. From $K$ vs $\chi$ plot we determined hyperfine field values $H_a^{hf} = 765$ mT/$\mu_B$ and $H_c^{hf} = 740$ mT/$\mu_B$ for magnetic field oriented along a- and c-axis, respectively. From the rotation of the single crystal in external magnetic field we determined 8 different orientations of K-tensor in paramagnetic region. In antiferromagnetic state at $T = 6$ K we found that the local field at phosphorus is mainly due to dipolar field of coppers. Here the rotation of single crystal shows 8 different orientations of the local field $B_{int} = 38 \pm 2$ mT. Experimental orientation of $B_{int}$ corresponds to the calculation of dipolar fields at phosphorus assuming magnetic quadrupolar configuration of magnetic moments $\Gamma_3(1)$.

3:42PM D41.00005: The Origin of Ising Magnetism in Ca$_3$Co$_2$O$_6$ Unveiled by Orbital Imaging

BRETT LEEDAHL (Presenter), MARTIN SUNDERMANN, ANDREA AMORESE, Max Planck Institute for Chemical Physics of Solids, ANDREA SEVERING, University of Cologne, HLYNUR GRETRARSSON, Deutsches Elektronen-Synchrotron (DESY), LUNYONG ZHANG, ALEXANDER KOMAREK, Max Planck Institute for Chemical Physics of Solids, ANTOINE MAIGNAN, Laboratoire CRISMAT, MAURITS HAVERKORT, Heidelberg University, LIU TJENG, Max Planck Institute for Chemical Physics of Solids —

One-dimensional CoO$_6$ chains in Ca$_3$Co$_2$O$_6$ arranged in a triangular lattice give rise to an Ising-like magnetism with an intriguing quantum tunneling staircase structure in its magnetization. To resolve the underlying local electronic configuration of the Co ions we applied $s$-core-level non-resonant inelastic x-ray scattering ($s$-NIXS), a new technique that is capable of imaging the shape of the 3$d$ orbitals in real space. The orbital shapes that we found established unequivocally that both Co sites (octahedral and trigonal prismatic) are in a 3+ valence state (i.e. 3$d^6$); the trigonal Co site has a high-spin configuration while the octahedral Co site is low spin. Interestingly, we directly ‘see’ that it is the complex $d_2$ orbital that is stabilized by the prismatic trigonal coordination, which naturally explains the Ising magnetism in the system. Utilizing this ability to image electron orbitals, and thus directly relating the orbital occupation with the local crystal structure—without the need for theoretical modeling—is essential for modeling magnetic properties. This is especially true in situations where one would like to make use of the delicate balance of competing interactions to stabilize a particular orbital state for a desired or optimized physical property.

3:54PM D41.00006: Finite, disordered chains of local and correlated moments in transition metal oxides*

JACK SIMONSON (Presenter), CRISTIAN FRANCO, State Univ of NY - Farmingdale, ALLISON WUSTROW, Colorado State University, ALICIA BACCARELLA, JAYLYN C UMANA, FRANCISCO BURGOS, State Univ of NY - Farmingdale, LUCIA STEINKE, University of Florida, ERIC DOORYHEE, Brookhaven National Laboratory, MEIGAN ARONSON, Stewart Blusson Quantum Matter Institute, JAMES NEILSON, Colorado State University — The structures of Bi$_2$CrAl$_3$O$_9$ and Li$_2$Mn$_2$(MoO$_4$)$_3$ are similar in that they both contain quasi-linear chains of octahedrally-coordinated atomic positions that are partially occupied by 3$d$ transition metals and partially occupied by a non-magnetic species. In the absence of long range occupancy ordering, this configuration gives rise to finite chains of moments with statistically varying lengths. We report the results of in situ diffraction experiments probing the synthetic pathways that yield high quality single crystals of these compounds. Ex situ UV/Vis diffuse reflectance spectroscopy measurements establish the magnitude of the charge gap and the local configuration of the magnetic species. Scaling of the magnetization at $T < 10$ K provides a probe to differentiate between independently fluctuating local moments and collective excitations along the chains.

**4:06PM D41.00007: Complex magnetism and magnetic compensation in metal tellurate (Mn,Ni)$_3$TeO$_6$**

CHOONGJAE WON (Presenter), Center for Complex Phase Materials, Max Planck POSTECH/Korea Research Initiative, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University — The two of metal tellurate, Ni$_3$TeO$_6$ and Mn$_3$TeO$_6$, have rhombohedral lattice (Ni = R$3$, Mn = R-3), and they shows antiferromagnetic ordering with spin-induced ferroelectricity. However, we grown (Mn,Ni)$_3$TeO$_6$ single crystal, and found monoclinic structure, such as Co$_3$TeO$_6$. From magnetic susceptibility, and specific heat measurements, we discover ferrimagnetic transition and magnetic compensation state. These results significantly different from both end-member Ni$_3$TeO$_6$ and Mn$_3$TeO$_6$ and require further investigations of its magnetic structure.

**4:18PM D41.00008: High-energy nonreciprocal directional dichroism in a chiral magnet**

MICHAEL YOKOSUK, University of Tennessee, Knoxville, HEUNG-SIK KIM, Physics, Kangwon National University, KENDALL HUGHEY, University of Tennessee, Knoxville, JAEWOOK KIM, Rutgers University, ANDREAS V. STIER, Los Alamos National Laboratory, KENNETH O’NEAL, University of Tennessee, Knoxville, JUNJIE YANG, Central Michigan University, SCOTT CROOKER, Los Alamos National Laboratory, KRISTJAN HAULE, SANG-WOOK CHEONG, DAVID VANDERBILT, Rutgers University, JANICE LYNN MUSFELDT (Presenter), University of Tennessee, Knoxville — Nonreciprocal directional dichroism is an unusual light-matter interaction that gives rise to diode-like behavior in low symmetry materials. The chiral varieties are particularly scarce due to the requirements for strong spin-orbit coupling, broken time reversal symmetry, and a chiral axis. We bring together magneto-optical spectroscopy and first principles calculations to reveal high energy, broad band nonreciprocal directional dichroism in Ni$_3$TeO$_6$ with special focus on behavior in the metamagnetic phase above 52 T. In addition to demonstrating this effect in the magnetochiral configuration, we explore the transverse magnetochiral orientation in which applied field and light propagation are orthogonal to the chiral axis and by so doing, uncover an additional configuration with a nonreciprocal response in the visible part of the spectrum. In a significant conceptual advance, we use first principles methods to analyze how the Ni$^{2+}$ d-to-d on-site excitations develop magnetoelectric character and present a microscopic model that unlocks the door to theory-driven discovery of chiral magnets with nonreciprocal properties.
4:30PM D41.00009: Probing Spin-Excitations above the Ground State of 1T-TaS$_2$  
ITAI SILBER  
(Presenter), Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, ITAMAR KIMCHI, Department of Physics, University of Colorado, DAVID E GRAF, National High Magnetic Field Laboratory, AMIT KANIGEL, Department of Physics, Technion-Israel Institute of Technology, YORAM DAGAN, Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University — Spin-spin interactions can lead to exotic ground states with emergent excitations in frustrated quantum magnets. Such a system is the transition metal dichalcogenide 1T-TaS$_2$. While the material is electrically insulating and exhibits no magnetic ordering down to milikelvin temperatures, the specific heat has a linear fermionic-type contribution that suggests a large band-width. We analyse the low temperature specific heat data and torque magnetometry measurements to isolate the contribution of the spin excitations to the magnetization from the large background response. The magnetic torque is strongly anisotropic and has a singular response at low magnetic fields which we attribute to a continuous disassociation of singlet pairs. This picture is also supported by the perfect collapse of the specific heat data at various temperatures and magnetic fields onto a universal curve predicted for singlets with a random distribution of antiferromagnetic coupling strengths. We interpret our data in the framework of a quantum spin liquid ground state having a large bandwidth with minority spins forming an array of singlet pairs with a continuum of coupling constants. Finally, despite the presumed large spinon Fermi surface we could not observe quantum oscillations of the magnetization.

4:42PM D41.00010: Competition of itinerant magnetic states in SrCo$_2$As$_2$ from RPA spin susceptibility*  
ANA-MARIJA NEDIC (Presenter), Iowa State University, MORTEN HOLM CHRISTENSEN, University of Minnesota, YONGBIN LEE, Iowa State University, RAFAEL FERNANDES, University of Minnesota, ROBERT McQUEENEY, LIQIN KE, PETER ORTH, Iowa State University — The square-lattice layered 122-type cobalt pnictides ACo$_2$Pn$_2$ (A=Ca, Sr, Eu; Pn=As, P) are metals with fascinating magnetic properties reminiscent of local moment frustration. Among those, SrCo$_2$As$_2$ and CaCo$_2$As$_2$ stand out due to the competing nature of their in-plane magnetic fluctuations. While CaCo$_2$As$_2$ exhibits A-type antiferromagnetic order with ferromagnetically ordered Co planes, inelastic neutron scattering has revealed signs of extreme frustration towards stripe-like antiferromagnetism. SrCo$_2$As$_2$ does not order down to T=0.05 K, but shows an intricate competition between ferro- and stripe-like magnetic fluctuations instead. While some of these observations can be rationalized with $J_1$-$J_2$-type local moment models, several experimental facts cannot be reconciled within such a local moment picture such an approximate description. Here, we perform a fully itinerant analysis of the magnetic properties of these materials based on a tight-binding model obtained from DFT calculations for the bandstructure. We report our findings on the static transverse spin susceptibility for the resulting multiorbital Hubbard model within the random-phase approximation RPA approximation.

4:54PM D41.00011: Quantum-to-classical correspondence in two-dimensional Heisenberg models*  TAO WANG (Presenter), XIANGSHENG CAI, Univ of Mass - Amherst, KUN CHEN, Rutgers University, NIKOLAI PROKOF’EV, BORIS SVISTUNOV, Univ of Mass - Amherst — The quantum-to-classical correspondence (QCC) in spin models is a puzzling phenomenon where the static susceptibility of a quantum system agrees with its classical-system counterpart, at a different corresponding temperature, within the systematic error at a sub-percent level. We employ the bold diagrammatic Monte Carlo method to explore the universality of QCC by considering three different two-dimensional spin-1/2 Heisenberg models. In particular, we reveal the existence of QCC in two-parametric models.

5:06PM D41.00012: Theoretical Prediction of Bulk Rashba Effect in Pyroelectric Antiferromagnet BiCoO₃*  KUNIHIKO YAMAUCHI (Presenter), ISIR-SANKEN, Osaka University, PAOLO BARONE, SILVIA PICOZZI, CNR-SPIN — Rashba effect, a type of spin-momentum locking phenomena, commonly occurs at interfaces or surfaces, while it is nowadays well established that Rashba-like band splitting may also occur in non-centrosymmetric (chiral, polar or ferroelectric) bulk materials. Here we are taking a step further by considering a noncentrosymmetric antiferromagnetic oxide as a playground for bulk Rashba effect. In ferroelectric and antiferromagnetic systems, i.e., multiferroic systems, spin-flipping symmetry operations may exist (such as a mirror symmetry operation) which behave as time-reversal symmetry, thus enforcing two-fold degeneracy at specific high-symmetric points and allowing bulk Rashba effect to emerge. As a prototypical example, ab-initio DFT calculations of antiferromagnetic BiCoO₃ in the polar structure reveal that a large Rashba-like spin splitting occurs at the conduction band bottom, having a large weight from Bi-p orbital states [1]. In this presentation, we also show that the spin texture of such a multiferroic can be modulated by applying a magnetic field.

*This work was supported by JSPS Kakenhi (No.17H02916 and 18H04227) and JST-CREST (No. JPMJCR18T1).
WAYNE ZHENG (Presenter), Ohio State Univ - Columbus — On some one dimensional (1D) and 2D non-bipartite lattices, we study both free and Hubbard interacting lattice fermions when there are some magnetic fluxes threaded or appropriate gauge fields coupled. On one hand, we focus on finding out the optimal flux which minimizes the energy of fermions at specific fillings. For spin-1/2 fermions at half-filling on a ring lattice with an odd number of sites, the optimal flux is determined to be ±π/2. We prove this conclusion for Hubbard interacting fermions by means of a generalized reflection positivity technique. It can further lead to some applications towards 2D non-bipartite lattices such as triangle and Kagome. At half-filling, the optimal flux pattern on the triangular lattice can be ascertained to be [π/2, π/2]. We find that chirality emerges in these optimal flux states. On the other hand, we verify these conclusions and further study other fillings away from half with the numerical exact diagonalization (ED) method and find that, when it deviates from half-filling, Hubbard interactions can even alter the optimal flux patterns on these lattices.

Magneto-Ionic Control of Heterostructures and Interfaces* [Invited] KAI LIU (Presenter), Georgetown University — Magneto-ionic approaches for modifying ion distributions in metal/oxide heterostructures offer exciting potentials to control material properties. Our recent studies show that such magneto-ionic effect, even though initiated at metal/oxide interfaces, can extend deep into the rest of the oxide films and drastically tailor their physical properties [1-4].

In antiferromagnetic systems, we have previously demonstrated a controllable positive exchange bias in GdFe/NiCoO [1], and that the oxygen migration can be reversibly driven by an electric field [2]. Recently, we have observed a strong exchange bias in Gd/NiCoO due to the magneto-ionic effect, above the Gd $T_C$. After electric biasing, up to 35% enhancement of the exchange bias is observed, which can be reset by field-cooling.

In studies of cuprates, we show a simple, scalable approach to tune superconductivity [4]. A thin Gd layer (up to 20 nm) deposited onto epitaxial YBCO films (100nm), is found to leach oxygen from deep within the YBCO and suppress the superconductivity. These effects arise from the combined impact of redox-driven electron doping and modification of the YBCO microstructure.

In ferromagnets chemisorbed with submonolayer oxygen, we have observed strong DMI induced by chemisorption at room temperature. The sign of this DMI and its surprisingly large magnitude are derived by examining the oxygen coverage dependent evolution of domain wall chirality. The large induced DMI has enabled direct writing of magnetic skyrmions.

Our findings demonstrate an effective solid-state ionic approach to control a wide variety of magnetic functionalities, opening up possibilities for electric gating.

### 3:06PM D42.00002: Tuning Electrochemical Response in Ion-Gel-Gated $\text{La}_{1-x}\text{Sr}_x\text{CoO}_{3-\delta}$ Films via Sr-doping and strain*

**Presenter**: Vipul Chaturvedi, William M. Postiglione, Chemical Engineering and Material Science, University of Minnesota, Biqiong Yu, School of Physics and Astronomy, University of Minnesota, Wojciech Tabis, Faculty of Physics and Applied Computer Science, AGH University of Science and Technology, Krakow, Poland, Sajna Hameed, Nikolaos Biniskos, School of Physics and Astronomy, University of Minnesota, Hua Zhou, Zhan Zhang, Advanced Photon Source, Argonne National Laboratory, Martin Greven, School of Physics and Astronomy, University of Minnesota, Chris Leighton, Chemical Engineering and Material Science, University of Minnesota.

Electrolyte gating has proven powerful for controlling electronic, magnetic, and optical properties of materials such as oxides. Understanding the true gating mechanisms (i.e., electrostatic vs. electrochemical), however, particularly in oxides, where O vacancy formation and diffusion is often facile, remains challenging. Here, we present a study of the Sr-doping and strain dependence of the ion-gel gate response of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_{3-\delta}$ (LSCO) films ($0 < x < 0.7$), using transport, magnetometry, and operando synchrotron X-ray diffraction. Consistent with prior work, small negative gate biases induce reversible electrostatic hole accumulation, whereas positive biases induce oxygen vacancies ($V_O$) [1,2]. The window of reversibility and bias threshold for $V_O$ formation are found to systematically decrease with $x$, consistent with higher electrochemical activity of Co$^{4+}$ than Co$^{3+}$; tensile strain similarly promotes electrochemical response. At sufficiently high $x$, a topotactic transformation to a brownmillerite phase occurs. These findings are placed in the context of prior literature and discussed in terms of $x$-dependent variations in $V_O$ formation enthalpy and diffusivity.

### 3:18PM D42.00003: Insight into the Electronic Phase Separation in Perovskite Manganites: The Role of Charge-Orbital Ordering in the Interface Region*

**Presenter**: Zhe Wang, Department of Physics, Fudan University, China, Ruqian Wu, Department of Physics and Astronomy, University of California, Irvine.

The electronic phase separation in perovskite manganites, with coexistence of ferromagnetic (FM) metallic and antiferromagnetic (AFM) insulating phase, provides possibilities for tuning their electronic and transport properties. However, the mechanisms that drive the electronic phase separation are still unclear. Using density functional theory calculations, we investigated the charge-orbital ordering (COO) in both the AFM and FM/AFM interface regions of $\text{La}_{1-x}\text{Sr}_x\text{MnO}_3$ (LSMO). We found that the interface region prefers a distinct COO phase compared with the AFM region, which facilitates the formation of FM/AFM domain boundaries. We further studied the thickness dependent COO phase transition in LSMO ultrathin film, and predicted its critical thickness of phase separation. The results are in well agreement with experiments. These findings suggest that the COO phase transition in the FM/AFM interface region plays a key role in the electronic phase separation. The influence of substrate strain and Sr doping level on the phase separation were also studied.

Engineering Magnetic Interactions in Complex Oxide Heterostructures

ALEXANDER MICHAEL KANE, MINGZHEN FENG, NOLAN AHLM, BINZHI LI, J. PAIGE BYERS, University of California, Davis, RAJESH V CHOPDEKAR, PADRAIC SHAFER, ALPHA T. N’DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, NIGEL D. BROWNING, Imaging Centre at Liverpool, University of Liverpool, VALERIA LAUTER, Neutron Sciences Directorate, Oak Ridge National Laboratory, APRUVA MEHTA, Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, ELKE ARENHOLZ, Cornell High Energy Synchrotron Source, Cornell University, YAYOI TAKAMURA (Presenter), University of California, Davis — Complex oxides possess a wide range of technologically relevant functional properties including ferromagnetism, ferroelectricity, and superconductivity. Furthermore, their interfaces exhibit unexpected functional properties not found in the constituent materials due to structural and chemical changes as well as electronic and magnetic interactions. These unique interfacial effects lead to fundamental differences compared to analogous metallic systems. For example, ferromagnetic (FM)/FM interfaces consisting of magnetically hard La$_{0.7}$Sr$_{0.3}$CoO$_3$ (LSCO) and soft La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO) display exchange-spring behavior where the hard layer pins the moments of the soft layer, however, the hard/soft magnetic interface does not coincide with the chemical interface. Rather, an interfacial LSCO layer forms that is characterized by magnetically active Co$^{2+}$ ions which couple to the soft LSMO layer. The full characterization of the structural and magnetic properties of the LSCO/LSMO bilayers involves synchrotron-radiation and neutron-scattering based techniques as well as high resolution transmission electron microscopy. We find that the proportion of the Co$^{2+}$ ion-rich LSCO layer and magnitude of exchange bias shift depends sensitively on parameters such as individual layer thicknesses, epitaxial strain state, $BO_6$ octahedral tilt pattern of the underlying substrate, and stacking order of the layers. These results demonstrate how the competing interactions in complex oxides enable intriguing opportunities to tailor functional properties for new, versatile, and energy efficient spintronic devices.

We are grateful to the support by NSF (DMR 1745450), UC MRPI (No. MR-15-328528), and the DOE SCGSR program. This research utilized DOE user facilities including ALS at LBNL, SSRL at SLAC, SNS at ORNL, and EMSL at PNNL.

4:06PM D42.00005: High temperature magnetism and charge ordering in multiferroic
(LuFeO$_3$)$_m$/((LuFe$_2$O$_4$)$_1$ $(m = 3, 7, 9)$ SHIYU FAN (Presenter), Physics and Astronomy, University of
Tennessee, Knoxville, HENA DAS, Laboratory for Materials and Structures, Tokyo Institute of Technology, Midori-ku, 4259 Nagatesuta, Yokohama, Kanagawa 226-8503, Japan, KEVIN ARTHUR SMITH, Chemistry, University of Tennessee, Knoxville, Tennessee, 37996, USA, ALEJANDRO R'EBOLA, JULIA MUNDY, School of
Applied and Engineering Physics, Cornell University, Ithaca, New York 14853, USA, CHARLES BROOKS, Kavli Institute at Cornell for Nanoscale Science, Ithaca, New York 14853, USA, MEGAN HOLTZ, School of
Applied and Engineering Physics, Cornell University, Ithaca, New York 14853, USA, RAMAMOORTHY RAMESH, Department of Materials Science and Engineering, University of California, Berkeley, California 94720, USA, DAVID ANTHONY MULLER, School of Applied and Engineering Physics, Cornell University, Ithaca, New York 14853, USA, DARRELL SCHLOM, Kavli Institute at Cornell for Nanoscale Science, Ithaca, New York 14853, USA, CRAIG J FENNIE, School of Applied and Engineering Physics, Cornell University, Ithaca, New York 14853, USA, STEPHEN A MCGILL, National High Magnetic Field Laboratory, Tallahassee, Florida 32310, USA, JANICE LYNN MUSFELDT, Chemistry, University of Tennessee, Knoxville, Tennessee, 37996, USA — We combined optical spectroscopy, magnetic circular dichroism, and first principles
calculations to uncover the microscopic origin of the high temperature magnetism in multiferroic
superlattices (LuFeO$_3$)$_m$/((LuFe$_2$O$_4$)$_1$, as well as the charge ordered state in the
$m = 3$ case.
Analysis of the dichroic spectra at characteristic energies reveals optical hysteresis loops of
different Fe centers. Comparison between coercivity vs temperature curves indicates the bulk
magnetization emanates mostly from the LuFe$_2$O$_4$ layer. Spectroscopic signature of the interface
demonstrates that the larger Lu distortion only selectively increases the local magnetization of
the Fe$^{2+}$ and Fe$^{3+}$ sites in the spin-up channel, which strengthens the exchange interaction,
increases the total magnetization in the LuFe$_2$O$_4$ layer and enhances $T_C$. Comparison between
the calculated and measured dichroic spectra affirms a non-polar charge ordered state in the $(3, 1)$ case. These findings provide a site specific technique to analyze the complex interactions in the
materials with multiple magnetic centers, and also broaden the possibilities in the hunt for novel
multiferroics with high $T_C$ and large magneto-electric coupling constant.

4:18PM D42.00006: Tunable Perpendicular Magnetic Anisotropy in Multiferroic Oxides
XUEZENG LU (Presenter), JAMES RONDINELLI, Department of Materials Science and Engineering,
Northwestern University — Here we present design rules to realize electric-field control of
perpendicular magnetic anisotropy (PMA) utilizing hybrid improper ferroelectricity by scaffolding
simple perovskite oxides into ultrashort period superlattices, (ABO$_3$)$_1$/((A'BO$_3$)$_1$, and in
multiferroic AA'BB'O$_6$ double perovskites. The study validates the strategy using first-principles
calculations and a single-ion-anisotropy model. We show a change of the magnetic anisotropy from the
in-plane to out-of-plane direction occurs in (BiFeO$_3$)$_1$/((LaFeO$_3$)$_1$ and a 50% decrease of
the magnetization along the out-of-plane direction occurs in LaYNiMnO$_6$ when a polar-to-
nonpolar phase transition is activated with strain. The origin of the PMA control is due to the
structural-tunable competitions among the $t_{2g}$ and $e_g$ orbital interactions on the magnetic ions
arising from relativistic spin-orbital interactions that are susceptible to changes in the oxygen
eohedral tilts with the transition. Our results allow us to search rapidly for other promising
multiferroics materials with voltage-controlled magnetic anisotropy for applications in low-energy
information storage and logic devices.
4:30PM D42.00007: Prediction of a Giant Magnetoelectric Cross-Caloric Effect Around a Tetracritical Point in Multiferroic SrMnO$_3$  ALEXANDER EDSTRÖM, CLAUDE EDERER (Presenter), Materials Theory, ETH Zurich — We study the magnetoelectric and electrocaloric response of strain-engineered, multiferroic SrMnO$_3$, using a phenomenological Landau theory with all parameters obtained from first-principles-based calculations. This allows to make realistic semi-quantitative and materials-specific predictions about the magnitude of the corresponding effects. We find that in the vicinity of a tetracritical point, where magnetic and ferroelectric phase boundaries intersect, an electric field has a huge effect on the antiferromagnetic order, corresponding to a magnetoelectric response several orders of magnitude larger than in conventional linear magnetoelectrics. Furthermore, the strong magnetoelectric coupling leads to a magnetic, cross-caloric contribution to the electrocaloric effect, which increases the overall caloric response by about 60%. This opens up new potential applications of antiferromagnetic multiferroics in the context of environmentally friendly solid state cooling technologies.

4:42PM D42.00008: Effects of Three-Dimensional Strain on LaCoO$_3$ Thin Films*  RONALDO RODRIGUEZ (Presenter), TOYANATH JOSHI, DAVID P BELANGER, DAVID LEDERMAN, Department of Physics, University of California, Santa Cruz — LaCoO$_3$ films grown on SrTiO$_3$ substrates are known to exhibit a net moment below T = 85 K while the same films grown on LaAlO$_3$ exhibit little to no moment [1]. The underlying mechanisms behind this net moment are poorly understood, but it is speculated that modulation of the Co-O-Co bond angle through epitaxial strain may play a key role. By growing LaCoO$_3$ films on SrTiO$_3$ substrates with a high angle (~ 7-9°) of miscut via pulsed laser deposition (PLD), we have been able to induce epitaxial strain along the in plane and out of plane film axes. In-situ reflection high energy electron diffraction (RHEED) detected layer-by-layer growth. Sample crystallinity and topography were measured using X-ray diffraction and atomic force microscopy, respectively. Magnetometry data were collected both parallel and perpendicular to the SrTiO$_3$ [100] surface, as well as parallel and perpendicular to 5 nm steps induced by the miscut of the substrate. In films of thickness ~3-10 nm grown on high angle miscut SrTiO$_3$ substrates, we measure a strong anisotropic magnetization in the plane where spins are realigned at low magnetic fields. Possible mechanisms will be discussed.

*This work was partially funded by the NSF REU program, grant #1659744.
Emergent antiferromagnetism in diamagnetically substituted pseudospin-1/2 iridate thin film  

JUNYI YANG (Presenter), LIN HAO, University of Tennessee, Knoxville, QI CUI, JIAQI LIN, Chinese Academy of Sciences, LUKAS HORAK, Charles University, JENIA KARAPETROVA, JONG WOO KIM, P. J. RYAN, Argonne National Lab, MARK DEAN, Brookhaven National Laboratory, JINGUANG CHENG, Chinese Academy of Sciences, JIAN LIU, University of Tennessee, Knoxville — Recent developments in 5d transition metal oxides have made it a fertile playground to explore exotic emergent phenomena due to the interplay among charge, orbital, spin degrees of freedom. A prominent example is the quasi-2D layered iridate systems where the electronic and antiferromagnetic states of the pseudospin-1/2 electrons are highly susceptible to changes in the structural degrees of freedom. In contrast, the 3D perovskite iridate SrIrO3 is a nonmagnetic semimetal, which is believed to be topologically protected. Recent study showed magnetic order emerges through chemical substitution with nonmagnetic ions, offering an intriguing planform to explore the cooperation between electronic correlation and strong spin orbit coupling beyond the 2D regime. However, bulk perovskite SrIrO3 only exists in polycrystalline form; thus, we have used epitaxial strain to stabilize nonmagnetic ion substituted SrIrO3 in single crystal quality thin film form. Combined with physical properties measurements and synchrotron-based x-ray diffraction and resonant x-ray magnetic scattering, we can resolve its G-type antiferromagnetic structure and further elucidate the structural modulation of its magnetic properties.

Weyl semimetal thin film Eu$_{1-x}$Sm$_x$TiO$_3$ on LSAT (001): field-polarized long-range order and interfacial ferromagnetism  

ZACH PORTER (Presenter), University of California, Santa Barbara, RYAN NEED, NIST Center for Neutron Research, KAVEH AHADI, University of California, Santa Barbara, YANG ZHAO, ZHIJUN XU, BRIAN JAMES KIRBY, JEFFREY LYNN, NIST Center for Neutron Research, SUSANNE STEMMER, STEPHEN WILSON, University of California, Santa Barbara — EuTiO$_3$ thin films have recently been reported to manifest complex magnetotransport phenomena upon carrier substitution, ranging from symmetry breaking anisotropic magnetoresistance to nonmonotonic anomalous Hall transport. Here we investigate the interplay between magnetism and transport behavior by studying the evolution of magnetic order in thin film samples of biaxially strained and electron-doped EuTiO$_3$ under an applied field. Neutron diffraction reveals that G-type antiferromagnetism is suppressed with the onset of in-plane field-polarized ferromagnetism for insulating, semimetallic, and metallic samples. However, polarized neutron reflectometry further reveals the onset of interfacial ferromagnetism at low fields far below the fully polarized state. The relationship between magnetic order and electron transport behavior associated with the Weyl semimetal phase in these films will be discussed.
Manipulating the magnetic ground state in complex oxides represents a main stream of research in condensed matter physics and materials science due to their fundamental importance. Here we report the emergence of an itinerant ferromagnetic state from a paramagnetic metallic CaRuO$_3$ through electrically induced protonation during ionic liquid gating. More importantly, this magnetic transition is accompanied with a structural expansion due to proton intercalation, and both which could be reversibly switched by external voltage. Despite the fact that the ruthenates remains metallic across the magnetic transition, we reveal that the ferromagnetic state is strongly correlated with a non-Fermi liquid toward Fermi liquid transition. The versatile magnetic state in protonated CaRuO$_3$ therefore strongly suggests that the electrically controllable protonation could sever as a novel pathway to manipulate the electronic and magnetic properties in complex oxides.

**Monday, March 2, 2020 2:30 PM - 5:18 PM**

**Session D43 DCOMP DMP: Electrons, Phonons, Electron Phonon Scattering, and Phononics I**

2:30PM D43.00001: **Gauge invariance of heat and charge transport coefficients** [Invited]  
STEFANO BARONI (Presenter), SISSA - Scuola Internazionale Superiore di Studi Avanzati, Trieste — Transport coefficients in extended systems have been recently demonstrated to be largely independent of the microscopic representation of the current density of the conserved quantity being transported (charge/mass/energy) [1]. This remarkable *gauge invariance* of transport coefficients has been leveraged to lay down a rigorous density-functional theory of heat transport [1], as well as a general approach to it, valid in the low-temperature regime, that nicely bridges the Boltzmann-Peierls kinetic model, that applies to crystals, and the Allen-Feldman one, that applies to glasses [2]. In the case of charge transport, a combination of gauge invariance and Thouless' quantisation of particle transport [3] allows one to express the electrical conductivity of an insulating fluid in terms of integer-valued, scalar, and time-independent atomic oxidation numbers, instead of real-valued, tensor and time-dependent Born charges [3]. In this talk I will review these concepts and report on some key applications of them to liquids and glasses.

3:06PM D43.00002: Microscopic derivation of coarse-grained, energy-conserving generalized Langevin dynamics  SERGEI IZVEKOV (Presenter), Weapons and Materials Research Directorate, U.S. Army CCDC Army Research Laboratory — Properly simulating non-equilibrium phenomena such as thermal transport in condensed matter systems requires the conservation of system's internal energy. This precludes application of the coarse-grained (CG) generalized Langevin equation (GLE) dynamics. Attempts to address this issue have been pursued phenomenologically for dissipative particle dynamics (DPD, a Markovian variant of the CG GLE dynamics) by introducing an energy conserving extension of DPD (DPD-E). We present here a rigorous microscopic derivation of energy conserving variants of the CG GLE dynamics by extending the CG equations of motion to include the GLE for certain internal energy observables of the microscopic system. The derivation is performed using the Mori-Zwanzig projection operator method with the recently introduced interpretation of the Zwanzig projection operator.¹ Our extension of the GLE dynamics to quasi-equilibrium conditions (necessary to observe heat transport), are based on the generalized canonical ensemble approach and transport equation method. We derive closed microscopic expressions for conductive heat transfer coefficients. After employing the Markov approximation, we compare the equations of motion to the published DPD-E equations.

3:18PM D43.00003: Cavity Control of Nonlinear Phononics*  DOMINIK JURASCHEK (Presenter), TOMAS NEUMAN, JOHANNES FLICK, PRINEHA NARANG, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University — Nonlinear interactions between phonon modes govern the behavior of vibrationally excited solids and molecules. We demonstrate here theoretically that optical cavities can be used to control the redistribution of energy from a highly-excited coherent infrared-active phonon state into the other vibrational degrees of freedom of the system. The hybridization of the infrared-active phonon mode and the fundamental mode of the cavity induces a polaritonic splitting that we use to tune the nonlinear interactions with other vibrational modes in and out of resonance. We show that not only can the efficiency of the redistribution of energy be enhanced or decreased, but also the underlying scattering mechanisms may be changed.

3:30PM D43.00004: A hydrodynamic description of the vibrational modes of ordered and disordered systems.* MATTEO BAGGIOLI (Presenter), Univ Autonoma de Madrid, ALESSIO ZACCONE, University of Milano — In ordinary crystals, Debye theory represents a very successful framework to characterize the dynamics of the vibrational excitations – the phonons, and to predict macroscopic quantities such as specific heat. Disordered systems and in general systems with dissipation provide a challenge to this description, which is manifested in several anomalous properties, e.g. the Boson Peak (BP) excess in the VDOS and the linear in temperature specific heat. Given the universality of these anomalies and their recent observation also in ordered single crystals with no disorder, a more general derivation (not necessarily relying on the presence of disorder) is needed. In this talk we provide such description using a hydrodynamic-effective field theory approach. We prove that a universal BP emerges naturally from the competition between propagation-elasticity and dissipation/diffusive damping. We also show a dependence of the BP in function of the material density which is in perfect agreement with the experimental data. Additionally, we show that the existence of hydrodynamic quasi-localized diffusive mode – the diffusons – can explain the linear in T specific heat in glasses and be therefore an alternative to the well-known TTLS theory.

3:42PM D43.00005: Angular momentum radiation from current-carrying molecular junctions* ZUQUAN ZHANG (Presenter), Department of Physics, National University of Singapore, JING-TAO LÜ, School of Physics and Wuhan National High Magnetic Field Center, Huazhong University of Science and Technology, JIAN-SHENG WANG, Department of Physics, National University of Singapore — We study the radiation of angular momentum (AM) from current-carrying molecular junctions using the nonequilibrium Green's function method. The dependence of the the radiation on the molecular geometry is taken into account with a real-space tight-binding model coupled to the electromagnetic field. We study the relation between rotational symmetry of the molecule and the light radiation. We analyze the resonant effects when the applied bias crosses over the energy levels of the molecule. Our study maybe useful for generating radiation with AM from molecular junctions by simply applying an electrical bias.

Ultrafast dynamics of hot carriers in bulk semiconductors and in accumulation layer: energy relaxation and screening effects.

JELENA SJAKSTE (Presenter), Laboratoire des Solides Irradiés, CNRS, Ecole Polytechnique, Institut Polytechnique de Paris — The rapid development of the computational methods based on density functional theory, on the one hand, and of the time- energy- and momentum- resolved spectroscopy, on the other hand, allows today an unprecedentedly detailed insight into the processes governing hot electron relaxation dynamics, and into the role of the electron-phonon coupling. Recently, we have demonstrated, for the relaxation of hot carriers in GaAs, the existence of two distinct relaxation regimes, one related with the momentum, and the other with energy relaxation. In this work, we will present our new results, both experimental and theoretical, on hot electron relaxation in silicon. Numerous additional experiments were performed with respect to previous work, and a new interpretation of the measured relaxation times is provided [1]. Moreover, we will present our recent results on the hot electron relaxation in InSe. InSe is a quasi-2D material which was shown recently to have potential interest for optoelectronics [2]. In this work, we will discuss our new results on the relaxation and cooling dynamics in doped InSe.

Finite temperature full multiple scattering calculation of ultrafast x-ray absorption spectroscopy

TUN SHENG TAN (Presenter), JOHN REHR, JOSHUA KAS, University of Washington — Recent advances in ultrafast time-resolved (TR) x-ray absorption spectroscopy (XAS) have allowed us to probe the interaction between electronic temperature (T\text{e}) and lattice temperature (T\text{i}) on the femtosecond time-scale. We present a finite temperature multiple scattering Green's function calculations of XAS, which accounts for the finite T\text{e} of the system, to describe these extreme conditions. The effect of temperature on lattice can be included at different levels of approximation such as using correlated Debye (CD) model or dynamical matrix. We apply the method to TR-XANES of an Fe-MgO layered heterostructure [1] and a copper system [2]. We are able to qualitatively reproduce the experimental results with FEFF using CD model. We also obtain estimates of T\text{e} based on a shift in the edge and T\text{i} based on the size of the Debye-Waller factor.

Variational Treatment Beyond the Mean-Field Approximation for the Half-Filled SSH model

STEPAN FOMICHEV (Presenter), MONA BERCIU, Stewart Blusson Quantum Matter Institute, University of British Columbia — The Su-Schrieffer-Heeger (SSH) model is a common approach to quantifying the effect of electron-phonon coupling on many-body behavior. Developed initially for polyacetylene chains, it assumes that the leading order effect of lattice motion is the modulation of the electronic tight-binding hopping amplitudes. While the SSH model successfully predicts Peierls distortion, the lattice is often treated semiclassically, as there is no known analytical solution for quantum phonons. Motivated by the successes of the momentum average approximation applied to a single Holstein polaron, and extensions to boson-modulated hopping and multiple phonon branches, we generalize the technique to a half-filled (one carrier per unit cell) one-dimensional SSH model. We begin by studying the SSH model in the Born-Oppenheimer approximation, and find that an expansion of the hopping amplitudes to second order in the atomic positions is needed for internal consistency. Using the Peierls distortion ansatz, we find that the acoustic and optical phonon branches emerge even at this mean-field level. We then systematically expand the variational space around this improved mean-field solution to study the nature of the ground state in the non-adiabatic limit.

Nanoscale Friction Control in Transition Metal Dichalcogenides

ANTONIO CAMMARATA (Presenter), TOMAS POLCAR, Department of Control Engineering, Czech Technical University in Prague — One of the main difficulties in understanding and predicting frictional response is the intrinsic complexity of highly non-equilibrium processes in any tribological contact.

To understand the physical nature of the microscopic mechanism of friction and design new tribologic materials, we conducted a systematic quantum mechanic investigation on prototipical Van der Waals MX₂ (M=Mo, W; X=S, Se, Te) Transition Metal Dichalcogenides. We combined structural and dynamic information from group theory and phonon calculations with electronic features using non-standard methods such us orbital polarization, bond covalency and cophonicity analyses. We propose a phonon-mode based method to identify possible sliding paths, to tune the corresponding sliding energy barriers and to characterize and control frictional/dissipation energy channels. We discuss how to extract information on the energetics of sliding from atomic force microscopy signals. We finally formulate guidelines on how to engineer intrinsic friction at the nanoscale in order to design novel materials with expected improved tribological properties.

The present outcomes can be promptly used to finely tune physical properties for the design of new materials with diverse applications beyond tribology.
4:42PM D43.00010: Electrical tuning of vibrational modes in transition metal dichalcogenides*

FLORIAN BELVISO (Presenter), Control engineering, Czech Technical University in Prague, TOMAS POLCAR, Engineering Materials, University of Southampton, ANTONIO CAMMARATA, Control engineering, Czech Technical University in Prague — Understanding frictional phenomena at nanoscale in layered materials is an important stage in order to control layer sliding, occurring in nanoelectromechanical devices.

To this aim, we studied the atomic scale tribological properties of transition metal dichalcogenides (TMDs) by using ab initio techniques.

We considered 6 prototypical MX$_2$ TMDs (M=Mo, W; X=S, Se, Te) with hexagonal P6$_3$/mmc symmetry, focusing on how some specific phonon modes contribute to the intrinsic friction. We described the exchange-correlation interaction energy within the DFT framework, including long range dispersion interactions in the Grimme formulation.

We identified and disentangled the electro-structural features that determine the intra- and inter-layer motions affecting the intrinsic friction by means of electro-structural descriptors such as orbital polarization, bond covalency and cophonicity.

We show how the phonon modes affecting the intrinsic friction can be adjusted by means of an external electrostatic field, the latter then acting as a knob to control intrinsic friction in layered materials.

The presented outcomes are a step forward in the development of TMD-based nanoelectromechanical systems.

**4:54PM D43.00011: Effect of the presence of small molecule of contaminants on nanofriction in layered MX\textsubscript{2} Transition Metal Dichalcogenides: An ab initio investigation**

JAMIL MISSAOUI (Presenter), Control Engineering, FEL, Czech Technical University in Prague, Czech Republic, TOMAS POLCAR, Engineering Materials & nCATS, FEE, University of Southampton, United Kingdom, ANTONIO CAMMARATA, Control Engineering, FEL, Czech Technical University in Prague, Czech Republic — The control of friction at the nanoscale plays a central role in nanoengineered devices such as nano-electromechanical systems, the latter more and more based on multi-layered Transition Metal Dichalcogenides (TMDs). In the present work, we study the intrinsic friction in MX\textsubscript{2} (M = transition metal, X = chalcogen anion) TMDs in the presence of small molecules of contaminants from the atmosphere.

We perform quantum mechanic calculations on layered MX\textsubscript{2} TMDs-based systems with the hexagonal structure in the presence of contaminants between adjacent layers. We combine outcomes from phonon calculations together with the characterization of the electronic features using non-standard methods like orbital polarization, bond covalency and cophonicity, in order to study how the vibrational frequencies of pristine material are affected by the presence of contaminants. We show how changes in the phonon frequency are related to the nanoscale friction between adjacent layers. We finally present guidelines on how to engineer intrinsic friction in TMDs at the nanoscale.

**5:06PM D43.00012: The Order of Longitudinal and Transverse Optical Phonon Modes in Monoclinic Oxides**

RAFAL KORLACKI (Presenter), MATHIAS SCHUBERT, University of Nebraska - Lincoln, ALYSSA MOCK, Naval Research Laboratory, SEAN KNIGHT, University of Nebraska - Lincoln, VANYA DARAKCHIEVA, Linköping University — In monoclinic crystals, as required by symmetry, the infrared-active phonon modes have their transition dipoles oriented parallel (A\textsubscript{u} modes) and perpendicular (B\textsubscript{u} modes) to the symmetry axis. In the absence of additional symmetry constrains, the B\textsubscript{u} modes are distributed within the monoclinic plane, the pairs of the transverse optical (TO) and longitudinal optical (LO) modes (TO-LO pairs) do not need to be parallel to each other, and this leads to the apparent violation of the TO-LO rule. The analysis of the limiting frequencies within the Born-Huang approach reveals that TO-LO pairs either belong to inner or outer phonon modes. Inner modes are nested within the outer modes. The directional limiting frequencies are bound to within outer mode frequency regions not occupied by inner mode pairs. Hence, an unusual phonon mode order can occur where both lower-frequency as well as upper-frequency limits for the directional modes can be both transverse and/or longitudinal modes. This behavior will be demonstrated in the results of first principles calculations of phonon modes for three different monoclinic crystals: β-Ga\textsubscript{2}O\textsubscript{3} (space group 12), CdWO\textsubscript{4} (space group 13), and Y\textsubscript{2}SiO\textsubscript{5} (space group 15), and compared with experimental results based on infrared spectroscopic ellipsometry.
2:30PM D44.00001: Relaxation Effects in the Electronic Structure of Twisted Bilayer Graphene: a Multi-Scale Approach*  NICOLAS LECONTE, SRIVANI JAVAJI (Presenter), JIAQI AN, JEIL JUNG, Physics, University of Seoul — We introduce a multi-scale approach to obtain accurate atomic and electronic structures for atomically relaxed twisted bilayer graphene. High-level exact exchange and random phase approximation (EXX+RPA) correlation data provides the foundation to parametrize systematically improved force fields for molecular dynamics simulations that allow relaxing twisted layered graphene systems containing millions of atoms making possible a fine sweeping of twist angles. These relaxed atomic positions are used as input for tight-binding band-structure calculations where the distance & angle-dependent interlayer hopping terms are extracted from ab-initio calculations & subsequent representation with Wannier orbitals. We benchmark our results against published force fields and widely used tight-binding models and discuss their impact in the spectrum around the flat band energies. We find that our relaxation scheme yields a magic angle of twisted bilayer graphene consistent with experiments between $1.0^\circ \sim 1.1^\circ$ using Fermi velocities $v_F=1.0 \sim 1.1 \times 10^6$ m/s. We present high-resolution spectral function calculations to compare with experimental ARPES.

2:54PM D44.00003: Real-Space Calculations of Dielectric Screening in Large Silicon Nanocrystals*  TIMOTHY LIAO (Presenter), KAI-HSIN LIOU, JAMES CHELIKOWSKY, University of Texas at Austin — The nature of dielectric screening in semiconductor nanocrystals (NCs) is an outstanding topic. We examine the screening of a point charge in hydrogen-terminated Si NCs. We consider NCs containing up to 5,400 atoms using pseudopotential-density-functional theory. We solve the Kohn-Sham equation in real-space using the PARSEC code. We compute the dielectric properties of a Si NC by replacing a Si nucleus at the center of the NC with a P nucleus while maintaining the electron number. We consider NCs of sufficient size to converge the dielectric properties to the bulk limit. We find the resulting screening functions are consistent with previous studies on smaller NCs. The ability to calculate dielectric properties of a large confined system allows us to consider charged defects in bulk Si in a straightforward manner without invoking a compensating background.

*Our work is supported by a subaward from the Center for Computational Study of Excited-State Phenomena in Energy Materials at LBNL, which is funded by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05CH11231, as part of the Computational Materials Sciences Program.

3:06PM D44.00004: Superconductivity in heavily boron-doped carbon materials*  YUKI SAKAI (Presenter), Oden Institute for Computational Engineering and Sciences, University of Texas at Austin, JAMES CHELIKOWSKY, Department of Physics, University of Texas at Austin, MARVIN L COHEN, Department of Physics, University of California at Berkeley — We investigate the superconducting properties of heavily boron-doped carbon materials composed of $sp^3$ hybridized atoms: cubic diamond, hexagonal diamond, and body centered tetragonal $C_4$ (bct $C_4$). We find that a high density of states (DOS) at the Fermi energy result in a high superconducting transition temperature ($T_c$) in all three materials. The high DOS is particularly realized when boron dopants are not placed at nearest neighbor sites. A $T_c$ above 60 K can be obtained for cubic diamond, although other allotropes can exhibit a $T_c$ of 40-50 K at 25 % boron-doping. We also discuss superconductivity in amorphous carbon.

Discriminating functional groups, atomic species and molecular geometries in organic molecules using real-space simulations of non-contact atomic force microscopy*  

DINGXIN FAN (Presenter), YUKI SAKAI, JAMES CHELIKOWSKY, University of Texas at Austin — Noncontact atomic force microscopy (nc-AFM) with a CO functionalized probe tip is a powerful tool for molecular structure characterizations. In many organic molecules, the visualization of individual atoms is a real possibility, save for the complexity of interpreting the nc-AFM images. In order to gain a better understanding of such experimental images, we employ a real-space pseudopotential constructed within density functional theory code, PARSEC, to simulate nc-AFM images. We are able to discriminate functional groups (such as -C≡C-, -CH\textsubscript{2} and -C=O groups) and heteroatoms (such as O, N and S atoms) in organic molecules by mapping our simulated images to experimental images. Also, we find that nc-AFM is capable of directly visualizing the orientation of organic molecules at various adsorption sites on metal substrates. This can be very useful for characterizing large long-chain organic molecules in heavy oils and asphaltenes.

*This work is supported by the Welch Foundation under grant F-1837 and the U.S. Department of Energy under DOE/DE-FG02-06ER46286. Computational resources were provided by the National Energy Research Scientific Computing (NERSC) and the Texas Advanced Computing Center (TACC).

Time-dependent magnons from first principles  

NICOLAS TANCOGNE-DEJEAN, FLORIAN G EICH (Presenter), ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter — We propose an efficient and not perturbative scheme to compute magnetic excitations for extended systems employing the framework of time-dependent density-functional theory. Within our approach we drive the system out of equilibrium using an ultra-short magnetic kick perpendicular to ground-state magnetization of the material. The dynamical properties of the system are obtained by propagating the time-dependent Kohn-Sham equations in real time and the analysis of the time-dependent magnetization reveals the transverse magnetic excitation spectrum of the magnet. We illustrate the performance of the method by computing the magnetization dynamics, obtained from a real-time propagation, for iron, cobalt and nickel and compare them to known results obtained using the linear-response formulation of time-dependent density-functional theory. Moreover, we point out that our time-dependent approach is not limited to the linear-response regime, and we present first results for non-linear magnetic excitations from first-principles in iron.
3:42PM D44.00007: A real-space pseudopotential method for magnetocrystalline anisotropy energies and the search for magnets without rare-earth metals*  

MASAHIRO SAKURAI (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin — We present a real-space pseudopotential formalism for calculating magnetocrystalline anisotropy energies within relativistic density-functional theory (DFT). Our method is implemented in our real-space pseudopotential DFT code, PARSEC, which is designed to run efficiently on massively parallel computing platforms [1]. We show that our formalism works well for prototypical transition-metal compounds, such as YCo5 and Mn2Ga, yielding an accurate magnetization and a magnetocrystalline anisotropy constant consistent with other density-functional methods. We illustrate how our methods can be applied to the search for permanent magnets without rare-earth metals [2,3,4]. In particular, we identified several ZrCo5 and Fe–Ni–B compounds as possible candidate materials that can provide high magnetocrystalline anisotropy energies along with sufficient saturation magnetization.

**3:54PM D44.00008: Ab initio calculations of electron and nuclear spin interactions in molecules and solids using a mixed pseudopotential-all electron approach**

KRISHNENDU GHOSH (Presenter), Mechanical Engineering, Univ of Michigan - Ann Arbor, HE MA, Chemistry, University of Chicago, VIKRAM GAVINI, Mechanical Engineering, Univ of Michigan - Ann Arbor, GIULIA GALLI, University of Chicago and Argonne National Laboratory — The interaction between electronic and nuclear spins in the presence of external magnetic fields can be described by a spin Hamiltonian (SH), with parameters obtained from first principles electronic structure calculations. We previously developed an approach [1] to compute these parameters, applicable to both molecules and solids, which is based on real space density functional theory (DFT) based all-electron calculations using finite elements. Here we improve the efficiency of our approach for the calculations of spin-defects in semiconductors by combining all-electron and pseudopotential calculations: for a small region around the defect we treat explicitly all the electrons, while the rest of the crystal is described using pseudopotential calculations. We present results for the nitrogen vacancy in diamond and for divacancies in silicon carbide, including hyperfine and zero-field splitting tensors, and we show that the results of the mixed approach are in an excellent agreement with those of all-electron calculations for the full crystals. Our strategy opens the way to accurate large-scale calculations of SH parameters for the prediction of spin defect qubits in complex systems.

**4:06PM D44.00009: Nonlocal Density Embedding Theory**

WENHUI MI (Presenter), MICHELE PAVANELLO, Department of Chemistry & Department of Physics, Rutgers University, Newark — By invoking a divide-and-conquer strategy, density embedding methods dramatically reduce the computational cost of large-scale, *ab-initio* electronic structure simulations of molecules and materials. The central ingredient setting density embedding apart from Kohn-Sham DFT is the non-additive kinetic energy functional (NAKE). Currently employed NAKEs are at most semi-local (i.e., they only depend on the electron density and its gradient), and as a result of this approximation, only systems composed of weakly interacting subsystems can be successfully tackled. The limitation of semi-local NAKEs originate from the natural nonlocality of the underlying KEDF. Recently, we advance the state-of-the-art by introducing fully nonlocal NAKEs in density embedding simulations for the first time. Benchmark analysis based on the S22-5 set shows that nonlocal NAKEs considerably improve the computed interaction energies and electron density compared to commonly employed GGA NAKEs, especially when the inter-subsystem electron density overlap is high. Most importantly, we resolve the long standing problem of too attractive interaction energy curves typically resulting from the use of GGA NAKEs.

Modeling device-level semiconductors and their interfaces by orbital-free DFT

XUECHENG SHAO (Presenter), KAILI JIANG, MICHELE PAVANELLO, Chemistry / Physics, Rutgers University-Newark — Orbital-Free Density Functional Theory (OFDFT) is one of most promising methods for large-scale quantum mechanical simulations as it offers a good balance of accuracy and computational cost. Million atom simulations are nowadays achievable with OFDFT because the noninteracting kinetic energy functional is approximated by an explicit functional of the electron density removing the need to employ orbitals and diagonalizations. The commonplace belief is that because of the underlying approximations, OFDFT can only approach metallic systems. However, newly developed functionals allow the quantitative description of semiconductors and semiconducting quantum dots. We present an implementation of OFDFT entirely in Python providing some useful abstractions to deal with molecules and materials. The simulations are extremely computationally efficient, delivering converged electronic structures for million-atom system sizes realizing experimentally observed devices. We present calculations of work functions and Schottky barriers for an array of realistically sized systems that are still completely out of reach of commonly employed Kohn-Sham DFT methods.

Session D45 DCOMP DSOFT GSNP DPOLY: Understanding Glasses and Disordered Systems Through Computational Models III 706 - Pengfei Guan, Beijing Computational Science Res Ctr - Tag(s): Focus
The density of states of the vibrational modes (VDOS) plays a central role in determining macroscopic physical quantities of solids, such as specific heat, thermal conductivity and the critical temperature towards a superconducting phase. Also, the VDOS is directly linked to the elastic and viscoelastic moduli of the solid. For glasses, the VDOS at low frequency is not simply behaving quadratically in frequency as predicted long ago by Debye, but presents an excess of modes above some frequency where the quadratic Debye law breaks down. Upon normalizing the VDOS by the Debye law a peak is visible, known as the boson peak (BP). Consensus is emerging to explain the origin of the BP in terms of a (Ioffe-Regel type) crossover between ballistic phonon propagation and diffusive-like propagation dominated by randomness and scattering. The diffusive propagation shows up in a damping coefficient which is quadratic in the wavevector [1]. A theoretical description leads to the possibility of studying the VDOS in semi-analytical form as a function of physical parameters [2].

In glassy polymers, the BP has been shown to anti-correlate with the bending rigidity of the polymer chain [3,4], in spite of the BP occurring in a band of the VDOS spectrum dominated by Lennard-Jones type interactions [5]. This can be explained as due to redistribution of modes across the spectrum. The BP is shown to scale with the square root of the shear modulus [4], as predicted by theory [2]. The BP also controls the nonaffine contribution to the viscoelastic moduli [6] and thus is the central input to numerical predictions of mechanics [7], recently also at the atomistic level [8], thus leading to material design principles.

3:06PM D45.00002: Revealing the low-temperature fast relaxation peak in a model metallic glass  PENGFEI GUAN (Presenter), Beijing Computational Science Research Center — The relaxation dynamics and its underlying atomistic mechanism are one of the most important and challenging issues in metallic glasses. Here, we first report a pronounced low-temperature relaxation peak in a model metallic glass, which is located at a much lower temperature than the typical temperature for the conventional $\beta$ relaxation reported in prior works. Through extensive molecular dynamics simulations, we unravel its intrinsic link with reversible atomic motions, which bridges the vibrational modes and the structural rearrangements governing a normal $\beta$ relaxation process. Moreover, through the study of the local geometrical anisotropy, we reveal the microscopic mechanism of the fast relaxation process and clearly demonstrate that the fast relaxation dynamics is a trigger to a cascade of critical relaxation modes (such as $\beta$ and $\alpha$ relaxation). Our findings are of fundamental importance, and further our understanding of the heterogeneous dynamic response of metallic glasses and the dynamic origin of their physical properties.

3:18PM D45.00003: Accuracy of Classical Potentials for Polyethylene Structures Away from Equilibrium*  KEARA G FRAWLEY (Presenter), LIHUA CHEN, HUAN D TRAN, NARESH N THADHANI, RAMAMURTHY RAMPRASAD, Materials Science and Engineering, Georgia Institute of Technology — Realistic simulations of polymers require a large number of atoms due to the anisotropic nature of their morphology. Although density functional theory (DFT) is considered highly accurate, it is too computationally expensive to handle large systems. Classical potentials used for molecular dynamics studies are trained on experimental or quantum mechanical equilibrium structures, and their accuracy away from equilibrium is not well known. This work is a comparative study of two widely used classical potentials—Optimized Potentials for Liquid Simulations (OPLS) and the reactive force-field (ReaxFF)—with respect to DFT. Their performance for polyethylene (PE), a simple model polymer, is benchmarked by comparing the classical energies, forces, and stresses against DFT. Additionally, a pressure-temperature phase diagram for PE is computed using OPLS and ReaxFF. Although the classical potentials do not perfectly capture the DFT and experimental behavior, the results are close enough to justify their use when large system sizes are required. Consequently, these results will be used for shock simulations involving far from equilibrium structures.

3:30PM D45.00004: Disentangling glassy polymer dynamics: combining simulations and machine learning
ANNA LAPPALA (Presenter), Harvard University — Glass-forming liquids are an example of non-equilibrium systems: upon cooling, a glass undergoes a transition from a liquid into an amorphous solid without apparent long-range order. The problem of the glass transition combines the concepts of self-organization, collective and heterogenous dynamics and poses an unsolved fundamental problem in condensed matter physics. We investigate the role of connectivity and topology in the glass transition of polymers, combining coarse grained molecular dynamics simulations with machine learning. ML allows us to quantify the relation between local structural properties of polymers and their topology using clustering of correlated motions of polymer chain segments as an example descriptor to create a training set, leading to the development of a data-based model.

3:42PM D45.00005: Amorphous polymers in their glass transition regime: Comparison of local and macroscopic small non-linearities
AUDE BELGUISE (Presenter), FRANÇOIS LEQUEUX, SIMM, ESPCI Paris, SABINE CANTOURNET, Centre des Matériaux, Mines ParisTech, HÉLÈNE MONTES, SIMM, ESPCI Paris — The mechanical behavior of amorphous polymers in their glass transition regime is linked to dynamical heterogeneities at a nanometric scale. To describe them, we developed a finite elements method where a sample is described as a set of domains each characterized by its own relaxation time $\tau_i$. The relaxation times are randomly distributed over the domains. We showed that this approach quantitatively describes linear relaxation measured on glassy polymers.

In this work, we focus on the onset of non-linearities where non-linear relaxation is accelerated in comparison to the linear case. We describe the non-linearity effect as a decrease in local relaxation times due to stress i.e. $\tau_i$ becomes $\tau_i f(\sigma)$. In a homogeneous case, the local law accelerating relaxation ($f(\sigma)$) can be identified by comparing linear and non-linear macroscopic responses. However, we show that the local and macroscopic non-linear laws are different due to dynamical heterogeneities. Comparing experiments and simulations, the local non-linear law $f(\sigma)$ can be identified. We show that its shape would be as $\exp(\sigma^n)$ with $n$ larger than 1.

3:54PM D45.00006: Atomic-scale understanding of highly conducting polymer electrolyte
SUNGYEB JUNG (Presenter), Department of Physics, Pusan National University, YEONHWA SONG, U HYEOK CHOI, Department of Polymer Engineering, Pukyong National University, JAE HYUN PARK, Department of Aerospace and Software Engineering, Gyeongsang National University, JAEKWANG LEE, Department of Physics, Pusan National University — Electrolyte is one of the key and most important components determining the performance of lithium-ion batteries. Until now, solid polymer electrolytes have attracted considerable attention due to the rapid development of the need for more safety and powerful lithium ion batteries. Despite their high stabilities and endurance, extremely low conductivity has hindered their applications. Here, we find that novel poly acrylic acid polymer-based electrolyte exhibits at least two orders of magnitude higher ionic conductivity compared with conventional solid polymer electrolytes. By combining molecular dynamic simulations with temperature dependent conductivity measurements, underlying mechanism will be addressed at the atomic scale in detail.
4:06PM D45.00007: Effects of Coarse-Graining on Molecular Simulations of Mechanical Properties of Polymers  TING GE (Presenter), Department of Chemistry and Biochemistry, University of South Carolina, MARK ROBBINS, Department of Physics and Astronomy, Johns Hopkins University — Conventional coarse-graining methods for polymers are typically based on matching equilibrium thermodynamic properties in the melt state, such as the average structural correlations or forces. It is not clear whether the resulting coarse-grained potentials can be used to simulate non-equilibrium properties of melts at high rates or the mechanical properties of low-temperature crystals or glasses. As a case study, we simulate polystyrene using models with different levels of coarse-graining but the same structural correlations at thermal equilibrium. The elastic modulus, yield stress, and strain hardening of polystyrene in the glassy state show a steady decrease with increasing degree of coarse-graining. This reflects that the configurational average of fine-grained structure leads to a smoother coarse-grained potential with lower energy barriers between local configurations. We find that the stress-strain curves with different degrees of coarse-graining can be collapsed with a simple rescaling factor in some cases, but too much coarse-graining leads to qualitative changes of the curves. We develop a multi-scale method that uses properly selected coarse-grained models to accelerate the simulation of mechanical response while fine-grained models to capture the accurate stress value.

4:18PM D45.00008: Ubiquity of Entropy-Driven Local Organization  ANDREI A. KLISHIN (Presenter), Univ of Michigan - Ann Arbor, GREG VAN ANDERS, Physics, Engineering Physics, and Astronomy, Queen's University — Soft-matter and biological systems of crowded objects exhibit local organization into preferred motifs. Locally organized motifs in soft systems can, paradoxically, arise from a drive to maximize overall system entropy. The emergence of entropy-driven local order has been directly confirmed in model, synthetic colloidal systems, however similar patterns of organization occur in crowded biological systems ranging from the contents of a cell to collections of cells. In biological settings it is unclear whether entropy acts to promote or inhibit local organization. Answering this is difficult because entropic effects are intrinsically collective, complicating efforts to isolate them. Here, we employ minimal models that artificially restrict system entropy to show that entropy drives systems toward local organization, even when the model system entropy is below reasonable physical bounds. By establishing this bound, our results suggest that entropy drives local organization in all crowded soft and biological systems of rigid objects.
4:30PM D45.00009: Measuring configurational entropy of glasses using population annealing*  
CHRIS AMEY (Presenter), Physics, Univ of Mass - Amherst, JONATHAN LEE MACHTA, Physics, Univ of Mass - Amherst, Santa Fe Institute — In this talk we present two methods to calculate the vibrational ($S_{vib}$) and configurational ($S_c$) entropies of glassy fluids in the context of population annealing Monte Carlo. The first method for obtaining $S_{vib}$ integrates the pressure of individual configurations from the fluid phase to the glass phase, and the second method introduces a hard shell constraining potential to individual particles at fixed packing fraction in the glassy regime and integrates the entropy to the highly constrained, ideal gas limit. From population annealing, we also obtain the total entropy, $S_{tot}$, and from it the configurational entropy, $S_c = S_{tot} - S_{vib}$. We present numerical data for large-scale population annealing simulations of binary hard sphere fluids with 30, 60, and 100 particles. Our results show that the two methods agree and that for even modest-sized systems, finite-size effects appear to be small.

4:42PM D45.00010: Statistical structural and dynamic heterogeneity as signature of glass transition  
YUNJIANG WANG (Presenter), DONG HAN, Institute of Mechanics, Chinese Academy of Sciences — Glass transition is a ubiquitous phenomenon in nature yet it remains highly elusive. The puzzle is that there lacks intuitive rationalization for the dynamic arrest upon liquid-to-glass transition and a structural rationale is highly anticipated. Here I introduce two parameters based on the Shannon Information Entropy concept which can be served as intuitive signatures of glass transition. The first one is the Shannon entropy on structures, which characterize the diversity of atomic-level structures that undergoes a striking variation across the glass transition, and explains the change found in the excess configurational entropy. The other dynamic Shannon entropy is associated with the variation in the activation barriers to local structural excitations on the underlying potential energy landscape. It is also found to change dramatically at the glass-to-liquid transition and therefore can be treated as another signature of the glass transition. The two parameters can be evaluated based on the recent advanced atomistic simulations techniques, which moves a minor step towards the eventual understanding of physics of glass transition.
4:54PM D45.00011: RFOT theory explains fragile-to-strong crossover in Wigner glasses

HYUN WOO CHO (Presenter), MAURO LORENZO MUGNAI, Department of Chemistry, University of Texas at Austin, THEODORE KIRKPATRICK, Institute for Physical Science and Technology, and Department of Physics, University of Maryland, DAVE THIRUMALAI, Department of Chemistry, University of Texas at Austin — Colloidal suspension with various degrees of softness exhibits rich glass forming behavior, normally observed in molecular glasses. For over a decade, many experiments have shown that glass transition of colloidal suspensions can be either strong or fragile depending on the softness of potential, thus making them ideal testing ground for the structural glass transition (SGT) theories. However, it is still debated whether the softness alone is responsible for such a drastic change in fragility and if the glass transition of the soft colloid with the broad range of fragility can be described using a unified theory. We carried out Brownian dynamics simulations for a binary mixture of micron-sized charged colloidal suspensions and elucidate that they exhibit continuous transition from fragile to strong behavior due to the variation of the softness of potential that is achievable by changing the monovalent salt concentration. We found that the prediction of the random first order transition (RFOT) theory quantitatively describes the universal feature of the glass transitions of the charged colloids, such as growing length scales associated with heterogeneous dynamics. Our predictions are amenable to experimental tests.

5:06PM D45.00012: Cluster Dynamic Mean Field Theory of Glass Transition

CHEN LIU (Presenter), GIULIO BIROLI, Physics, Ecole Normale Superieure, DAVID REICHMAN, Columbia University, GRZEGORZ SZAMEL, Colorado State University — Recently, the infinite dimensional theory of the dynamics of super-cooled liquids was established in [1,2,3], and showed to be related to the mode coupling transition (MCT) theory [4]. One of the main mean field predictions is the existence of a sharp dynamical transition, akin to the MCT transition, at a temperature $T_d$, i.e. as the temperature approaches $T_d$ from above, the relaxation time diverges. However, in three dimensional glass-formers this transition is smeared out and a smooth crossover takes place. We extend the infinite dimensional analysis by developing a cluster dynamic mean field theory (CDMFT) where clusters of particles interact in a mean field way, while correlations involving several particles are taken into account inside clusters. This allows us to progressively take into account correlations between particles and activated dynamical processes. In this talk we will present CDMFT and present results for three dimensional super-cooled liquids.

5:18PM D45.00013: Understanding $T_A$ from dynamic heterogeneity in metallic glass-forming liquids  
NANNAN REN (Presenter), PENGFEI GUAN, LIJIN WANG, Beijing Computational Science Research Center, LINA HU, Shandong University — How to generally describe the structural relaxation upon cooling is still mysterious for metallic glass-forming liquids with various dynamic fragilities. Here a scaling collapse of the temperature dependence of structural relaxation time, $\tau_\alpha(T)$, is achieved by introducing the characteristic temperature $T^*(\alpha_{2,max})$ and characteristic time scale $\tau^*(\alpha_{2,max})$ with any identical dynamic heterogeneity $\alpha_{2,max}$ in 12 metallic glass-forming liquids, which is consistent with our previous reports[1]. The scaled master curve $\tau_\alpha/\tau^*(\alpha_{2,max}) \sim T^*(\alpha_{2,max})/T$ experiencing a crossover behavior from Arrhenius to non-Arrhenius implies that $T_A$ is one of $T^*(\alpha_{2,max})$. It is further confirmed by the almost constant $\alpha_{2,max}(T_A)$ for all the systems studied here and achieving a general description of relaxation time, together with $\tau_A$ (the structural relaxation time at $T_A$). Our findings provide a new insight of $T_A$ from the perspective of dynamic heterogeneity and shed light on the glass forming of metallic liquids.

Session D46 GMAG DMP: Spin Liquids: Theory and Experiment 708 - Martin Mourigal, Georgia Inst of Tech - Tag(s): Focus
The search for the enigmatic quantum spin liquid (QSL) state has switched into high gear in recent years. Amazing experimental progress has resulted in several highly promising QSL materials such as ZnCu3(OH)6Cl2, YbMgGaO4, and NaYbO2, to list just a few. All of these quasi-two-dimensional materials are characterized by a broad continuum of spin excitations observed in neutron scattering experiments. Unfortunately, many, if not all, of these QSL candidates suffer from the presence of significant substitutional disorder which often tends to strongly broaden inelastic neutron spectra and thus calls into question the QSL interpretation of the experimental data. It is therefore incumbent upon the theoretical community to identify specific experimental signatures, more detailed than a “broad continuum” arguments, that evince the unique aspects of spin liquid states of magnetic matter.

In this talk, I focus on the prominent metal-like magnetic insulators – U(1) quantum spin liquids with spinon Fermi surface – excitations of which are represented by neutral spin-1/2 fermions (spinons) and emergent gauge fields. The gauge field mediates strong interactions between spinons. We argue that the full effect of this interaction becomes apparent when the spin liquid is partially magnetized by the Zeeman magnetic field. Under this condition, the spectrum of the spin liquid acquires a new transverse collective spin-1 mode, distinct from incoherent particle-hole excitations of the spinon continuum. Despite being located outside the spinon continuum, this novel collective excitation interacts with emergent gauge fluctuations which are responsible for partially damping it.

I will also discuss how this picture is modified by the spin-orbit interaction, and present a calculation of the ESR linewidth for one specific spin-orbit geometry.

Entangled Neutron Beams: A possible new avenue to exploring Quantum Materials

DAVID BAXTER (Presenter), Indiana Univ - Bloomington, COLLIN LESLIE BROHOLM, Physics, The Johns Hopkins University, ABU ASHIK M IRFAN, STEPHEN J KUHN, SHUFAN LU, GERARDO ORTIZ, ROGER PYNN, JIAZHOU SHEN, WILLIAM MICHAEL SNOW, Indiana Univ - Bloomington — We have recently demonstrated that the Larmor instrument at ISIS can be used to construct two and three-fold entangled states in a neutron beam [1]. Entanglement among the spin, energy, and trajectory degrees of freedom for neutrons was indicated by observing clear violations of both the Clauser-Horne-Shimony-Holt and Mermin contextuality inequalities in the same experimental setup. Moreover, the entanglement length associated with this experiment was 1 micron (as opposed to the cm length scales previously seen with neutron interferometer experiments [2]), and could be experimentally varied from several nm to several microns. We suggest that such a beam, with an experimentally controllable microscopic length scale, may represent a fundamentally new probe of correlated matter. Experiments are planned to demonstrate these methods to probe entanglement in quantum spin chains.

Thermal conductivity of the quantum spin liquid candidate EtMe₃Sb[Pd(dmit)₂]₂: No evidence of mobile gapless excitations

NICOLAS DOIRONLEYRAUD (Presenter), PATRICK BOURGEOIS-HOPE, FRANCIS LALIBERTE, ETIENNE LEFRANCOIS, GAEL GRISONNANCHE, SAMUEL RENE DE COTRET, RYAN T GORDON, LOUIS TAILLEFER, Universite de Sherbrooke, HENGBO CUI, REIZO KATO, RIKEN, SHUNSUKE KITOU, HIROSHI SAWA, Nagoya University — The search for highly mobile gapless spin excitations in quantum spin liquids (QSL) is currently attracting considerable attention. We examined this specific issue via thermal conductivity measurements on one of the most promising QSL candidates, the organic insulator EtMe₃Sb[Pd(dmit)₂]₂ (dmit-131). We performed heat conduction experiments down to 0.07 K on a total of 8 high-quality single crystals of dmit-131. Contrary to previous reports, our body of data consistently and reproducibly shows the absence of a T-linear contribution to the thermal conductivity of dmit-131 at low temperatures, showing that no spin excitation contribute to the heat transport. Consequently, the spin excitations in dmit-131 are localized and not mobile. Our data further reveal a strongly suppressed phonon conductivity, evidence that the phonons are heavily scattered by those localized spin excitations. Comparison with published data on numerous spin-liquid materials shows, in fact, that this is a widespread phenomenon and that it should be considered in any future theory of QSLs.
3:30PM D46.00004: Evidence of Frozen Moments at Low T in κ-(BEDT-TTF)$_2$Hg(SCN)$_2$Br*
TERESA LE (Presenter), ANDREJ PUSTOGOW, University of California, Los Angeles, JIERONG WANG, Physics, Nanjing University, AYSSA HENDERSON, Florida State University, JOHN A SCHLUETER, National Science Foundation, STUART BROWN, University of California, Los Angeles — Quantum Spin Liquids (QSLs) and the phenomena behind their manifestation continue to be a topic of debate in solid state physics. The charge transfer salt, κ-(BEDT-TTF)$_2$Hg(SCN)$_2$Br or (κ-HgBr), has been proposed as a “quantum dipole liquid” [1], possibly exhibiting the necessary properties for QSL emergence. We examine the magnetic properties of κ-HgBr using 13C NMR Spectroscopy. 1/T$_1$ measurements show a first order transition at T$_{MI} = 90$ K, a possible crossover at T = 20 K, and a pronounced peak at 5 K characteristic of freezing moments. Analysis of the NMR spectra reveals an onset of broadening at T$_{MI}$ which becomes more pronounced at low T reaching a FWHM of approximately 1350 ppm at T = 2.5 K. The behavior and magnitude of the linewidth with respect to temperature is indicative of coupling to electron moments which are gradually freezing as temperature decreases and agrees with the 1/T$_1$ behavior.

3:42PM D46.00005: Understanding Complex Magnetic Interactions Using Diffuse Neutron Scattering* JOSEPH PADDISON (Presenter), Oak Ridge National Lab — Many important magnetic materials have complex bond-dependent magnetic interactions, such as Kitaev and frustrated spin-liquid candidates [1,2]. Traditionally, spin Hamiltonians of such systems are determined by fitting to spin-wave spectra measured below the magnetic ordering temperature $T_N$. Unfortunately, this approach is often impractical in spin liquids, either because $T_N$ is unmeasurably low, or the ordering is poorly understood.

I discuss an alternative approach to parameterize the spin Hamiltonian that does not assume long-range magnetic order: fitting interaction models to diffuse magnetic neutron-scattering data measured above $T_N$. I demonstrate the sensitivity of this method for canonical models of bond-dependent interactions on triangular and honeycomb lattices. I discuss my results in the context of developments in reverse Monte Carlo refinement [3], pair distribution function analysis [4], and machine learning [5].

**3:54PM D46.00006: Effects of nuclear spins in the transverse-field Ising quantum magnet Ho$_3$Mg$_2$Sb$_3$O$_{14}$**  
MARTIN MOURIGAL (Presenter), ZHILING DUN, XIAOJIAN BAI, Georgia Inst of Tech, JOSEPH PADDISON, Oak Ridge National Laboratory, EMILY HOLLINGWORTH, University of California, Berkeley, FRANZ DEMMEL, SFTC, HAIDONG ZHOU, University of Tennessee  — Transverse Ising model is the simplest quantum model which can be realized in rare earth magnets with two-singlet crystal field ground state. Recent interests have been focused on non-Kramer ion based pyrochlore lattice where random transverse fields are introduced by lattice disorder. As all stable isotopes of all non-Kramers ion possess non-zero nuclear spins, the couplings between electronic and nuclear spins (hyperfine interactions) in these systems are usually nonnegligible, yet are little discussed so far. Here, we show that the tripod kagome magnet Ho$_3$Mg$_2$Sb$_3$O$_{14}$ offers us a new platform to study this effect because of a homogeneous transverse field brought in by the low symmetry of the lattice. Using neutron backscattering and specific heat measurements, we illustrate that nuclear spins dramatically alter the single-ion and collective behaviors of the system. Comparing to classical spin ice system such as Ho$_2$Sn$_2$O$_7$, our results highlight the crucial role played by hyperfine interactions in frustrated quantum magnets, and motivate further investigations of correlated nuclear spins.

*The work at Georgia Tech was sponsored by the Department of Energy under DE-SC-0018660.

**4:06PM D46.00007: Robust quantum spin liquid ground state in hydrogen-bonded organic Mott insulators**  
KENICHIRO HASHIMOTO (Presenter), Department of Advanced Materials Science, University of Tokyo, MASAAKI SHIMOZAWA, MINORU YAMASHITA, Institute for Solid State Physics, University of Tokyo, AKIRA UEDA, Department of Chemistry, Kumamoto University, HATSUMI MORI, Institute for Solid State Physics, University of Tokyo, TAKAHIKO SASAKI, Institute for Materials Research, Tohoku University  — κ-H$_3$(Cat-EDT-TTF)$_2$ is a hydrogen-bonded organic Mott insulator that provides a new class of quantum spin liquids (QSLs), where the strong coupling between the localized spins and the hydrogen atoms leads to a quantum paramagnetic and quantum paraelectric (QPE) state. Although this material has a 2D spin-1/2 triangular lattice, its anisotropy parameter $t'/t = 1.25$ is far from unity. This raises a question as to whether the geometric frustration of the triangular lattice is an important factor for realizing the QSL state in this system. Here, we investigate a series of κ-H$_3$(Cat-X)$_2$ (X = EDT-TTF, EDT-ST, EDT-d4-TTF, and EDSe-TTF), where the substitution of X affects the anisotropy of the triangular lattice as well as the hydrogen-bond dynamics. Our dielectric and thermal-transport measurements reveal that all the materials exhibit a QSL and QPE state in spite of the large $t'/t$ (for instance, $t'/t = 1.84$ for X = EDSe-TTF), indicating that the coupling between the π electrons and the hydrogen atoms plays an important role for stabilizing the QSL state. We also find that the QPE behavior is strongly enhanced in X = EDT-ST that is located near a regime where the hydrogen atoms are localized at low temperatures, suggesting the presence of a QCP related to the hydrogen-bond dynamics.
4:18PM D46.00008: Coherent spinon behaviour in quantum spin liquids at finite temperature  YUAN WAN (Presenter), Institute of Physics, Chinese Academy of Sciences, OLLIE HART, CLAUDIO CASTELNOVO, Theory of Condensed Matter group, Cavendish Laboratory, University of Cambridge — Realistic Hamiltonians for quantum spin liquids often exhibit a large separation of energy scales between their elementary excitations. At experimentally relevant temperatures, some excitations are in a low-temperature regime where they are sparse and hop coherently across the lattice, while others are thermally excited and behave as a dense, stochastic ensemble. We study the interplay of these quasiparticles in the case where it is driven solely by their nontrivial mutual statistics rather than by direct interaction energy terms. We consider toy models for Z2 quantum spin liquids, where the two species of excitation (dubbed spinons and visons) are mutual semions. The nontrivial statistical angle between the two species leads to interference effects that we study using a combination of numerical and analytical tools. In the limit of self-retracing paths, we are able to use a Bethe lattice approximation to construct exact analytical expressions for the time evolution of the site-resolved density profile of a spinon initially confined to a single site. We also highlight an intriguing feedback mechanism, akin to the Nagaoka effect, whereby the spinons become localised on patches of expelled incoherent visons, the typical diameter of which increases as temperature is reduced.

4:30PM D46.00009: Finite temperature dynamics of Coulomb spin liquids  SIDDHARDH MORAMPUDI (Presenter), CHRISTOPHER LAUMANN, Boston University, FRANK WILCZEK, Massachusetts Institute of Technology — Coulomb quantum spin liquids like quantum spin ice realize a phase of emergent quantum electrodynamics. However, the energy scales are very different resulting in features like a slow photon and a separation of scales between the spinon and photon. We compute the dynamics of spinons and photons at non-zero temperatures in multiple regimes realizable in neutron scattering and show characteristic changes as temperature is tuned across the different regimes.

4:42PM D46.00010: Schwinger boson approach to magnetically ordered quantum magnets  SHANG-SHUN ZHANG (Presenter), University of Tennessee, Knoxville, ESTEBAN GHIOLDI, Institute of Physics Rosario and National University of Rosario, YOSHITOMO KAMIYA, Shanghai Jiao Tong University, Shanghai, China, LUIS O. MANUEL, ADOLFO TRUMPER, Institute of Physics Rosario and National University of Rosario, CRISTIAN BATISTA, University of Tennessee, Knoxville — The quest for quantum spin liquids is producing a large number of magnetically ordered quantum magnets that exhibit anomalies in their dynamical spin structure factor. These anomalies include a strong renormalization of the single-magnon bands and a broad continuum of excitations, whose integrated spectral weight is larger than the weight of the single-magnon peaks. These observations call for novel approaches that can properly capture the effect of strong quantum fluctuations. By considering a Schwinger boson theory (large-$N$ approach) beyond the saddle-point approximation ($N = \infty$), we demonstrate that the inclusion of $1/N$ corrections is strictly necessary to remove unphysical modes (single-spinon poles) and to capture the true magnon modes, which emerge as two-spinon bound states (poles of the RPA propagator). Moreover, we show that for each Feynman diagram there is a counter-diagram that removes the unphysical single-spinon poles. The counter-diagrams are different for collinear and non-collinear orderings. Based on these results, we demonstrate that the large-$N$ approach can exactly reproduce the spin-wave theory in the large-$S$ limit.
4:54PM D46.00011: Theoretical proposal for novel experimental probe of fractionalized excitations in two-dimensional quantum spin liquids  WONJUNE CHOI (Presenter), Univ of Toronto, KI HOON LEE, Physics, Seoul National University, YONG-BAEK KIM, Univ of Toronto — Experimental smoking-gun signature for quantum spin liquids, highly entangled quantum paramagnets hosting fractionalized excitations called spinons, is a long-sought holy grail of modern condensed matter research. As spin excitations decay into a pair of fractionalized quasiparticles, conventional experimental probes do not have the resolving power for each individual fractionalized excitation. In fact, they only show a broad continuum for the pair of spinons. In this talk, we discuss a novel experimental protocol to identify the sharp coherent signals of each of the individual spinons to disambiguate quantum spin liquids from trivial paramagnets or magnon excitations.

5:06PM D46.00012: Effective theories for quantum spin clusters : State selection by singularity  SUBHANKAR KHATUA (Presenter), Institute of Mathematical Sciences, DIPTIMAN SEN, CHEP, Indian Institute of Science, GANESH RAMACHANDRAN, Institute of Mathematical Sciences — We state a general principle -- the low energy effective theory of a quantum spin cluster reduces to that of a quantum particle moving on the space of classical ground states. We demonstrate this mapping for a family of spin clusters where each pair of spins is connected by an XY antiferromagnetic bond. The simplest member of this family is a dimer-- it maps to a particle on a ring. The trimer, a cluster of three spin-S spins, is more complex -- it maps to a particle on two disjoint rings. Unlike the dimer and the trimer, the classical ground state space of the quadrumer, cluster of four spin-S spins, is non-manifold in nature -- consisting of three tori pairwise touching along lines. Particle moving on this space, successfully, captures the low energy spectrum of the quadrumer. The non-manifold structure leads to a remarkable effect -- the dynamics at low energies is not ergodic as the particle is localized around singular lines of the ground-state space. The low-energy spectrum consists of an extensive number of bound states around singularities. Physically, this manifests as an order-by-disorder like preference for collinear states. However, unlike order-by-disorder, this “order by singularity” gets better as we approach the classical limit.

5:18PM D46.00013: Density Matrix Renormalization Group Analysis of Quantum Spin Ice  MICHAEL FLYNN (Presenter), University of California, Davis, THOMAS BAKER, Universite de Sherbrooke, RAJIV RANJAN SINGH, University of California, Davis — One of the most studied systems in three dimensional many-body physics is a model of spins on the pyrochlore lattice dubbed quantum spin ice. The massive frustration of the model makes it a strong candidate for supporting a variety of exotic spin liquids with natural connections to lattice gauge theory. Here we initiate the use of the Density Matrix Renormalization Group (DMRG) to study the phase diagram of quantum spin ice, focusing on the transition from an XY antiferromagnet to a U(1) spin liquid. Using quasi-one-dimensional cylindrical cuts of the lattice, we compute the local spin properties of the phases and find that they converge remarkably quickly. With more effort, we extract the entanglement entropies and fit them to the Cardy-Calabrese scaling form to extract the central charge. Further discussions on detecting the photon of the U(1) spin liquid and more controversial aspects of the phase diagram may be included.
2:30PM D47.00001: Planar Hall driven torque in a FM/NM/FM system  
CHRISTOPHER SAFRANSKI (Presenter), IBM Tj Watson Research Center, JUN-WEN XU, ANDREW KENT, Center for Quantum Phenomena, Department of Physics, New York University, JONATHAN Z SUN, IBM Tj Watson Research Center — Electrical manipulation of magnetization is an intensely studied topic with goals of producing energy efficient nanodevices. The charge to spin current conversion in bilayers of magnetic and nonmagnetic materials is one area of investigation. Typically studied materials have been mostly limited to the generation of in-plane polarized spin currents. We investigate spin currents produced by the planar Hall effect in Co/Ni multilayers, which carry a polarization dictated by the FM magnetization direction. In a sample based on CoNi/Au/CoFeB, spin torque ferromagnetic resonance is used to measure the damping-like torque on the CoFeB layer. The response as a function of the applied field angle and current is consistent with the symmetry expected for a torques produced by the planar Hall effect. We find the strength of this effect to be comparable to that of the spin Hall effect. However, unlike the spin Hall effect, it can produce a partially out of plane spin polarization. Our results indicate that the planar Hall effect holds potential as a spin current source with a controllable polarization direction.
**2:42PM D47.00002: Exciton-phonon damping in the two and three-dimensional anisotropic XY model**

LEONARDO DOS SANTOS LIMA (Presenter), Centro federal de educacao tecnologica —
The effect of exciton-phonon interaction on spin transport properties and quantum information is analysed in the integer spin XY model with ion-single anisotropy in dimension \( d=2,3 \) in the square and cubic lattices and in the neighbourhood of a quantum critical point \( \Delta_c \) using the SU(3) Schwinger boson approach. For three dimensions, there is a quantum phase transition from the Néel phase to paramagnetic phase where recently, one has investigated the influence of this quantum phase transition on spin transport and obtained a strong influence of the line of separation among the phases on continuum spin conductivity.

**2:54PM D47.00003: Probing Spin-wave Excitations in Layered Chromium Trihalides with Nitrogen-Vacancy Magnetometers in Diamond**

RUOLAN XUE (Presenter), Harvard University, MARK JEN-HAO KU, Harvard - Smithsonian Center for Astrophysics, DAHLIA KLEIN, DAVID MACNEILL, Massachusetts Institute of Technology, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, RONALD L WALSWORTH, Harvard - Smithsonian Center for Astrophysics, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, AMIR YACOBY, Harvard University — Nitrogen-vacancy (NV) centers in diamond are highly sensitive, nano-scale magnetic sensors. NV magnetometry has demonstrated detection of spin-wave excitations in bulk magnets and has recently been used as a local probe to detect static magnetization in layered magnets. While monolayer and few-layer van Waals magnets have been discovered and their static properties investigated, spin-wave excitations in these materials remains unexplored. Understanding low-energy excitations in layered magnets is crucial to further elucidate dynamical properties of 2D spin systems and to explore applications of these materials. In this work, we report progress towards probing spin-wave excitations in chromium trihalides with NV magnetometry.
3:06PM D47.00004: Exceptional non-reciprocity in non-Hermitian spin dynamics  ALEXEY GALDA (Presenter), James Franck Institute, University of Chicago, VALERII VINOKUR, Materials Science Division, Argonne National Laboratory — We investigate topological structure of complex energy surfaces of non-equilibrium magnetic systems. We consider spin-transfer torque-driven single-spin model described by a non-Hermitian Hamiltonian. The spectrum of the Hamiltonian admits branch point singularities that appear as chiral exceptional points where both eigenvalues and eigenstates coalesce. The emergence of exceptional spectral points provides access to a wealth of topological effects unique to non-Hermitian spin systems, e.g. non-reciprocal spin dynamics. An implementation of an asymmetric spin-filter device based on this effect is proposed.

3:18PM D47.00005: Quantized ΔS=2 excitation spectra by confinement in an S=1 Ising spin chain under magnetic fields*  SEI-ICHIRO SUGA (Presenter), TAKAFUMI SUZUKI, Univ. of Hyogo — We calculate the dynamical spin-structure factor of the S = 1 Ising spin chain with negative single-ion anisotropy in transverse and longitudinal magnetic fields using the infinite time-evolving-block-decimation algorithm [1]. We show that when only a transverse magnetic field is applied, both the ΔS = 2 excitation continuum and one-magnon mode appear in the low-lying excitation. When a longitudinal magnetic field is further applied, the excitation continuum changes into quantized spectra. The quantized ΔS = 2 excitation spectra originate from the confinement of two domain walls, each of which carries ΔS = 1. The quantized excitation energies are explained by the zeros in the Airy function. [1] T. Suzuki and S. Suga, J. Phys. Soc. Jpn. 88, 053702 (2019).

3:30PM D47.00006: Spin dynamics in interacting ferromagnetic discs arranged on a Kagome lattice  MOJTABA TAGHIPOUR KAFFASH (Presenter), SERGI LENDINEZ, Univ of Delaware, WONBAE BANG, Northwestern University, AXEL HOFFMANN, Argonne National Laboratory, JOHN B. KETTERSON, Northwestern University, MATTHIAS BENJAMIN JUNGFLEISCH, Univ of Delaware — Artificial spin ice (ASI) consists of periodic arrays of nanomagnets in the shape of elongated elements where competing interactions between the elements lead to geometric frustration. Recently, non-Ising-like ASI have attracted great attention due to their exotic phase diagrams. One example is an array of ferromagnetic nanodiscs. Here, we report the experimental and theoretical characterization of angular-dependent spin dynamics in arrays of ferromagnetic nanodiscs arranged on a Kagome lattice. The arrangement consists of coupled discs that are 500 nm in diameter. The distance between the Kagome vertices is 76 nm. The magnetic field and microwave frequency dependence obtained by broadband ferromagnetic resonance reveals a rich spectrum of modes that is strongly affected by the microstate of the network. In the high-field range the magnetization is parallel to the applied field, while at low-fields vortices are formed. A comparison of the experimental data with micromagnetic simulations reveals that different subsections of the lattice predominantly contribute to the high-frequency response of the array. Furthermore, we find indications that nucleation and annihilation of vortex-like magnetization configurations in the low-field range affect the dynamics.
3:42PM D47.00007: Magnetization reversal driven by low dimensional chaos in a nanoscale ferromagnet* [Invited]  ERIC MONTOYA (Presenter), Department of Physics and Astronomy, University of California, Irvine, SALVATORE PERNA, Department of Electrical Engineering and Information Technology, University of Naples Federico II, YU-JIN CHEN, Department of Physics and Astronomy, University of California, Irvine, JORDAN A KATINE, Hitachi Global Storage Technologies, MASSIMILIANO D'AQUINO, Engineering Department, University of Naples "Parhenope", CLAUDIO SERPICO, Department of Electrical Engineering and Information Technology, University of Naples Federico II, ILYA KRIVOROTOV, Department of Physics and Astronomy, University of California, Irvine — Energy-efficient magnetization switching is an essential problem in the realization of practical nonvolatile magnetic storage [1] and magnetic neuromorphic computing [2]. In the past two decades, several efficient methods of magnetic switching were demonstrated including spin torque, magneto-electric, and microwave-assisted switching mechanisms. In this talk, we experimentally demonstrate that low dimensional magnetic chaos [3] induced by alternating spin torque can strongly increase the rate of thermally-activated magnetic switching of the free layer in a magnetic tunnel junction (MTJ)[4]. This mechanism exhibits a well-pronounced threshold character in spin torque amplitude and its efficiency increases with decreasing spin torque frequency. We present analytical and numerical calculations that quantitatively explain these experimental findings and reveal the crucial role played by low dimensional magnetic chaos near saddle equilibria in enhancement of the switching rate. This work shows that ac spin torque driven chaos can facilitate thermally-assisted switching of magnetization in a MTJ [5] and provides a new path towards improved energy efficiency of spin torque memory based on thermally stable MTJs. Furthermore, MTJs with superparamagnetic free layers are attractive for neuromorphic computing. Our results show that low dimensional can be used to tune the switching rate of such systems, and therefore, may lead to computing schemes that simultaneously harness stochasticity and deterministic chaos.

**4:18PM D47.00008: Effects of Low-Atomic-Number Dopants on Magnetic Relaxation in Epitaxial Fe Alloys**

DAVID SMITH (Presenter), YOUNGMIN LIM, MICHAEL CLAVEL, ZIJIAN JIANG, Virginia Tech, TIM HARTNETT, University of Virginia, MANTU HUDAIT, JEAN J HEREMANS, Virginia Tech, PRASANNA V BALACHANDRAN, University of Virginia, DWIGHT D VIEHLAND, SATORU EMORI, Virginia Tech — We investigate the dependence of magnetic relaxation on dopant concentration in epitaxial thin films of Fe$_{1-x}$V$_x$ and Fe$_{1-x}$Al$_x$ grown by magnetron sputtering. By substituting Fe with lighter elements, one can expect to observe a reduction in the Gilbert damping parameter due to reduced spin-orbit coupling. The magnetic properties of these alloys were determined using broadband ferromagnetic resonance. For low concentrations of V, we observe a reduction in magnetic relaxation (e.g., effective Gilbert damping), consistent with previous experimental [1] and theoretical [2] results. In contrast, introducing Al causes a monotonic increase in magnetic relaxation. We attribute these behaviors to a modification in the density of states at the Fermi level, as shown by our density functional theory calculations. Our results serve as an avenue for predicting how to reduce Gilbert damping for applications in energy-efficient spintronic devices.

**4:30PM D47.00009: Spin dynamics in La$_{0.67}$Sr$_{0.33}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-\delta}$ heterostructures**

JACOB WISSER (Presenter), Applied Physics, Stanford University, LAUREN RIDDIFORD, Stanford Univ, SATORU EMORI, Physics, Virginia Polytechnic Institute and State University, YURI SUZUKI, Stanford Univ — Spin polarization in superconductors has largely been studied via injection of spin-polarized electrical currents, with relatively little attention paid to spin currents generated via spin wave excitations. To this end, we have fabricated heterostructures of the cuprate superconductor yttrium barium copper oxide (YBCO) with the half-metallic ferromagnet lanthanum strontium manganite (LSMO) via pulsed laser deposition on (LaAlO$_3$)$_{0.3}$(Sr$_2$TaAlO$_6$)$_{0.7}$ (001) substrates. In this study, we fix the LSMO thickness at 30 nm and vary the YBCO thickness from 2-17 nm. We have verified that the YBCO superconducts with T$_c$ varying from 55-88 K depending on YBCO thickness (with a minimum thickness of 5 nm required for superconductivity). To characterize spin wave transport, we perform ferromagnetic resonance (FMR) as a function of temperature and YBCO thickness. We find that the resonance linewidth of bare LSMO increases with decreasing temperature, which is attributed to increased two-magnon scattering at lower temperatures. Additionally, with the addition of 17 nm of YBCO, we see a near doubling of the FMR linewidth at all temperatures, indicative of spin pumping into the YBCO and possibly the coexistence of spin polarization with superconductivity.
4:42PM D47.00010: Tuning the dynamic behavior of a bicomponent artificial spin ice*
SERGI LENDINEZ (Presenter), MOJTABA TAGHIPOUR KAFFASH, MATTHIAS BENJAMIN JUNGFLEISCH,
Department of Physics and Astronomy, Univ of Delaware — Artificial spin ices (ASI) are magnetic
metamaterials initially designed to mimic the frustrated behavior of crystalline spin ice systems
such as pyrochlore crystals. They show complex magnetic ordering and can exhibit exotic phase
diagrams. Unlike their crystalline counterparts, the ASI geometry can be designed and the state
of their constituent elements can be directly probed. Recent studies have focused on their
dynamics at high frequencies (GHz to tens of GHz), as they can be used as magnonic
metamaterials to modify the spin-wave properties by creating band gaps in the resonance
spectra. Previous works have shown that different geometries produce unique dynamic spectra.
Here, we performed angular-dependent broadband ferromagnetic resonance measurements on
a square ASI composed of different materials for each sublattice (NiFe and FeCo). Our
experiments show that the interaction between the sublattices results in unique spectra
attributed to the sublattices. By performing micromagnetic simulations, we identify the modes
observed in the experiment. Our results show that the interaction in the ASI can be tuned not
only by the geometry of the lattice, but also by the proper choice of the materials.

4:54PM D47.00011: Ab-initio spin-lattice dynamics based on the tight-binding method*
SIMON STREIB (Presenter), Department of Physics and Astronomy, Uppsala University, DANNY THONIG,
School of Science and Technology, Örebro University, MANUEL PEREIRO, ANDERS BERGMAN, ERIK
SJÖQVIST, Department of Physics and Astronomy, Uppsala University, ANNA DELIN, Department of
Applied Physics, KTH Royal Institute of Technology, OLLE ERIKSSON, Department of Physics and
Astronomy, Uppsala University — Recent experiments on ultrafast demagnetization have shown
that the magnetization dynamics on ultrafast timescales involves both magnetic and lattice
degrees of freedom. We present a method for the quasi-classical simulation of coupled spin and
lattice dynamics in metallic magnets based on a tight-binding (TB) model. The TB parameters are
fitted to ab-initio data and take the structure dependence of the material into account. From the
TB model we calculate both magnetic and lattice forces for the integration of the equations of
motion. We use the CAHMD package [1], which implements the TB model and the atomistic spin-
lattice dynamics. Our approach opens the door for a better understanding of the transfer of
angular momentum between magnetization and lattice already on the electronic structure level.
We demonstrate the feasibility of our method by simulations of chains and clusters.

program package for atomistic magnetization dynamics simulations. (Danny Thonig,

D47.00012: Enhancement of damping factor in Fe/Bi$_2$Se$_3$ heterostructures via topological surface states modification

LI NA (Presenter), RUI SUN, YANG XU, YUNBIN SUN, WEI HE, XIANGQUN ZHANG, ZHAOHUA CHENG, State Key Lab. of Magnetism, Institute of Physics, Chinese Academy of Sciences — Owing to the spin-momentum-locked surface state of topological insulators (TIs), the spin dynamics in ferromagnetic materials (FM)/TI heterostructures is expected to be significantly different with that in FM/non-magnetic heavy metals. Previous studies suggested that TI can modulate the spin dynamics of FM layer, however, the temperature dependence of damping factors is controversial. Here, we report spin dynamics in Fe/Bi$_2$Se$_3$ heterostructures by changing thickness of Bi$_2$Se$_3$ with and without topological surface state (TSS). Compared with that in Fe/Bi$_2$Se$_3$(3QL), where Bi$_2$Se$_3$ containing only bulk state without TSS, a significant enhancement of damping factor was achieved in Fe/Bi$_2$Se$_3$(9QL) by TSS of Bi$_2$Se$_3$. On the basis of ab initio electronic structure calculations, we confirm that the enhancement of damping factor is originated from the strong band hybridizations of Fe and Bi$_2$Se$_3$(9QL) near the Fermi level. Furthermore, by inserting Cu layer between Fe and Bi$_2$Se$_3$, the contribution of spin pumping and magnetic proximity effect to the overall damping factor was separated. Our work not only reveals the mechanism of TSS-induced damping factor, but provides a new freedom to tailor the damping factor of FM/TI spintronic devices as well.

Session D48 DCMP: Superconductivity: Transport Properties  Mile High
Ballroom 1A - Michael Osofsky, United States Naval Research Laboratory

2:30PM D48.00001: Analysis of thermal conductivity for pairing symmetry in high-\(T_c\) cuprate superconductors*

H.-T. KIM (Presenter), ETRI, MINGUEN CHOI, Dongguk U. — The pairing symmetry of high-\(T_c\) cuprate superconductors has been unsolved over 30 years. Most researchers have believed that the pairing symmetry is \(d_x^2-y^2\) (\(d\)) wave, nevertheless, several objections have been still suggested. Recently the objection was also disclosed [1]. We reanalyze the data of thermal conductivity, \(\kappa\), announced as experimental evidence of \(d\)-wave symmetry, which showed the presence of a finite value at nearest \(T=0\) K in a curve of \(\kappa/T\) vs \(T^2\) in thermal conductivity [2]. This is the metal characteristic coming from the nodes of the \(d\)-wave electronic structure of clover [2]. The characteristic of the curve of \(\kappa/T\) vs \(T^2\) increases a residual linear value of \(\kappa/T\) with going to \(T=0\) K, which does not describe the pairing symmetry characteristic of \(\kappa\). We redrew the curve of \(\kappa/T\) vs \(T^2\) to the curve of \(\kappa\) vs \(T\), deduced experimental data below 0.2 K unobservable by experiment through polynomial fitting, and discovered the behavior of the conductivity with nonlinear and no residual linear value. This is evidence denying \(d\)-wave symmetry, rather, supports s-wave symmetry. [1] arXiv:1710.07754. [2] M. Sutherland et al., Phys, Rev. B 67, 174520 (2003).

2:42PM D48.00002: DC Hall measurements in the strongly correlated Hubbard model*  
WEN WANG (Presenter), JIXUN DING, BRIAN MORITZ, Stanford University, EDWIN HUANG, University of Illinois at Urbana-Champaign, THOMAS DEVEREAUX, Stanford University — We investigate the DC Hall conductivity, an indicator of charge carrier properties, of the single-band Hubbard model in the zero field limit[1] using determinant quantum Monte Carlo (DQMC). Utilizing an effective expansion to lowest order, we observe a change of sign in the Hall coefficient as a function of temperature and interaction strength, which may signal a change in the topology of the Fermi surface. We relate the Hall coefficient to the frequency dependent resistivity, also obtained from DQMC following analytic continuation, to reveal the properties of charge carriers within the strange metal phase of the Hubbard model.

2:54PM D48.00003: Hall Conductivity in the Hubbard Model from Determinant Quantum Monte Carlo*  
JIXUN DING (Presenter), WEN WANG, YONI SCHATTNER, BRIAN MORITZ, Stanford University, EDWIN HUANG, University of Illinois at Urbana-Champaign, THOMAS DEVEREAUX, Stanford University — We extend determinant quantum monte carlo (DQMC) to allow for the addition of a constant magnetic field to the usual Hubbard model hamiltonian. We calculate the frequency and field dependent electrical Hall conductance for the single-band Hubbard model on a two-dimensional square lattice as a function of doping and temperature. Limiting cases of our results are compared with both those from recent experiments and an alternative theoretical technique.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-76SF00515.

3:06PM D48.00004: Resistance oscillations in the quantum metal phase of lithium intercalated TiSe$_2$  
MENGHAN LIAO (Presenter), HENG WANG, YUYING ZHU, MOHSIN RAFIQUE, XIANG XU, LEXIAN YANG, DING ZHANG, QIKUN XUE, Department of Physics, Tsinghua University — The nature of the metallic ground state, in the transition from a superconductor to an insulator at a temperature close to absolute zero, is still a mystery. In this work, we uncover quantum oscillations of this quantum metal or failed superconductor in a three-dimensional anisotropic superconductor—lithium intercalated TiSe$_2$. The quantum metallic state, hosting saturating resistance below the superconducting transition even after properly filtering of radio-frequency (RF) signals, depends sensitively on the lithium doping. Exactly in this metallic regime, we show that the resistance oscillates as a function of magnetic field with a period that changes gradually with temperature. We attribute this oscillation to flux effects imposed by the domains of a coexisting charge density wave (CDW). It suggests that a periodically perturbed superconductor, either by CDW or artificial patterning, may be key to realizing the quantum metal.
Transport properties of EuTiO$_{3-\delta}$ down to 50 mK

JIAMING HE (Presenter), JIANSHI ZHOU, Materials Science and Engineering program, Department of Mechanical Engineering, University of Texas at Austin — Tetravalent perovskite titanates garnered great attention due to its unique dielectric properties. Within the family, the electron-doped SrTiO$_3$ was found to be superconducting below 1 K; its superconducting transition temperature has a dome-shaped dependence with carrier concentration [1]. Low temperature transport properties of electron-doped SrTiO$_3$ can be described by Fermi liquid theory [2]. Cubic perovskite EuTiO$_3$ has identical Ti-O subarray as SrTiO$_3$. However, interaction between mobile electron spins and magnetic moments in Eu$^{3+}$ may dramatically change transport properties. So far, transport properties of EuTiO$_3$ at sub Kelvin temperatures have not been studied. We obtained high quality single crystal EuTiO$_3$ by floating zone method; oxygen deficiency is introduced by annealing the crystal at different temperatures. These samples are characterized by suite of measurements including resistivity, specific heat capacity, and Seebeck coefficient. The electron doping converts the crystal from semiconductor to metal. As revealed by the resistivity and the specific heat, EuTiO$_{3-\delta}$ exhibits filamentary superconductivity at 1.4 K.

Electronic phase diagram of Ta$_{1-x}$Mo$_x$S$_2$ and optimization of superconductivity in a charge density wave system

JOSE SALCEDO- PIMIENTA (Presenter), JUAN MENDOZA ARENAS, Departamento de Física, Universidad de Los Andes, JOSE GALVIS ECHEVERRY, Facultad de Ingeniería y Ciencias Básicas, Universidad Central, IAN FISHER, Geballe Laboratory for Advanced Materials, Stanford University, LUIS QUIROGA, FERNEY RODRIGUEZ, PAULA GIRALDO-GALLO, Departamento de Física, Universidad de Los Andes — Transition metal dichalcogenides are a family of quasi-2-dimensional quantum materials with a unique susceptibility to the variation of parameters such as pressure, chemical doping, disorder, etc. These materials have been extensively studied due to the wide variety of electronic ground states they can show. Of special interest are the compounds of this family that show charge density wave (CDW) ordering and superconductivity, since the exact mechanism for the stabilization and optimization of superconductivity in systems that show these two ground states is still an open question. In this talk we present experimental transport results in single crystals of the solid solution Ta$_{1-x}$Mo$_x$S$_2$. We observe a suppression of the CDW transition temperature with increasing Mo content, accompanied by a strong enhancement of the superconducting transition temperature. We discuss our results in the context of the evolution of the electronic and structural properties of this solid solution as we approach the MoS$_2$ compound, and their relationship to the possible existence of a CDW quantum critical point.

This project is funded by COLCIENCIAS (Grant No. 120480863414), and by Universidad de Los Andes. PGG thanks the support of the APS IRTA Program, and the L'oreal-UNESCO FWIS-Colombia program.
**3:42PM D48.00007: Thermoelectric Effects in Superconductor-Ferromagnetic Heterostructures**

KIRSTEN BLAGG (Presenter), PORTIA ALLEN, BRADLEY LLOYD, Colorado Sch of Mines, MICHAEL P LILLY, Sandia National Laboratories, MEENAKSHI SINGH, Colorado Sch of Mines — Superconductor-ferromagnetic (S-F) heterostructures have been predicted to show large thermoelectric effects at cryogenic temperatures with a figure of merit of ~1.8. Confirmation of these theoretical predictions requires S-F heterostructures, controlled temperature gradients, cryogenic thermometry, thermal conductivity measurements, and electrical transport measurements. To this end, we have developed an experimental platform for the measurements of thermal and electrical transport in nanoscale devices at cryogenic temperatures. S-F heterostructures have been fabricated using lithography, evaporation, and sputtering, providing precise control over interfaces, and a wide choice of materials and geometries. Heaters and resistive thermometers, patterned via focused ion beam assisted platinum deposition, have been calibrated and optimized for thermal transport measurements at cryogenic temperatures. Finally, the Seebeck coefficient of S-F heterostructures has been measured in the presence of a magnetic field. This measurement sets the stage for systematic examination of the effects of dimensionality, ferromagnet polarization, and interface quality.

**3:54PM D48.00008: Thermal Transport as a Probe of the Hidden Rashba Effect in the High Temperature Superconductor YBa_2Cu_3O_{6+x}**

BILL ATKINSON (Presenter), Trent Univ, ARNO P KAMPF, University of Augsburg — The high temperature superconductor YBa_2Cu_3O_{6+x} is an example of a Rashba bilayer material. The crystal structure comprises a stack of CuO_2 bilayers, and while each bilayer is inversion symmetric, the individual CuO_2 planes within the bilayers are not. This leads to a so-called hidden spin polarization, in which each layer making up the bilayer has a Rashba coupling constant with opposite sign such that the net spin polarization vanishes. In this talk, I will discuss the origins of the effect in YBa_2Cu_3O_{6+x}, and show that the measurement of the transverse thermal conductivity in an in-plane magnetic field allows one to make a sensitive measurement of the Rashba coupling.

*This work is supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada.*
4:06PM D48.00009: Giant Edelstein effect in the surface states of non-centrosymmetric superconductors  
YUHEI IKEDA (Presenter), YOUICHI YANASE, Physical Society of Japan — It is an important topic in the modern field of spintronics to control magnetic moments by using local electric current. One of the representative methods is the Edelstein effect [1]. However, for practical applications, e.g. magnetic domain switching [2], it is widely known that quite a large amount of electric current density is needed. Therefore, Joule heating created by a dissipative current is the main obstacle for efficient control of magnetization.

In this study, we theoretically demonstrate that the edge state of a non-centrosymmetric superconductor is a good candidate for efficient magnetization control. By using tight-binding calculations, we have found that, in d-wave superconductors, the coefficient of the magneto-electric effect in the edge state is about eighty times larger than in the bulk state. We also have found that its topological winding number is the key factor of this giant Edelstein effect.

4:18PM D48.00010: Effect of Zeeman Splitting on Andreev Reflection in Quantum Hall--Superconductor Heterostructures*  
JOSEPH CUOZZO (Presenter), XIANG HU, STUART N THOMAS, ENRICO ROSSI, Physics, College of William & Mary — We study the effect of Zeeman splitting on Andreev processes and non-local transport in heterostructures formed by two-dimensional systems in the superconducting and integer quantum Hall regime. We obtain analytic expressions for the dependence of the Andreev reflection probabilities on the Zeeman splitting in the narrow-contact and long-contact limits using an low-energy effective edge-state Hamiltonian within the Bogoliubov de-Gennes formalism. We find that introducing a higher-order, spin-dependent contribution to the renormalized drift velocity in the effective model is important to obtain accurate results. We then correlate the scattering wave function's penetration into the superconducting region with the observed Andreev reflection probabilities.

*Work funded by ARO Grant No. W911NF-18-1-0290

4:30PM D48.00011: Manifestations of spin-orbit coupling in a cuprate superconductor  
ZACHARY RAINES (Presenter), Physics, Yale University, ANDREW A ALLOCCA, T.C.M. Group, Cavendish Laboratory, University of Cambridge, VICTOR GALITSKI, University of Maryland, College Park — Exciting new work on Bi2212 shows the presence of non-trivial spin-orbit coupling effects as seen in spin resolved ARPES data [Gotlieb et al., Science, 362, 1271-1275 (2018)]. Motivated by these observations we consider how the picture of spin-orbit coupling through local inversion symmetry breaking might be observed in cuprate superconductors.

Furthermore, we examine two spin-orbit driven effects, the spin-Hall effect and the Edelstein effect, focusing on the details of their realizations within both the normal and superconducting states.
A cyclic superconducting quantum refrigerator for adiabatic magnetization cooling*

SREENATH KIZHAKKUMPURATH MANIKANDAN (Presenter), University of Rochester, FRANCESCO GIAZOTTO, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, ANDREW N JORDAN, University of Rochester — We propose a solid-state refrigeration technique using adiabatic magnetization/demagnetization cycles of a superconductor, acting as the working substance. The gradual cooling down of a substrate (normal metal) in contact with the working substance is predicted, where the excess heat is given to a hot, large-gap superconductor. The selective cooling of the normal metal is due to an effective thermal switching mechanism owing to the asymmetry of heat transport between N/N versus N/S junctions. We predict cooling of a 0.3cm^3 block of Cu by almost two orders of magnitude starting from 200mK, and down to about 1mK starting from the base temperature of a dilution fridge (10mK). The cooling powers at 200mK and 10mK for a 1cmx1cm interface are 25 nW and 0.06 nW respectively, which scales with the area of the interface.

Parity dependent supercurrent amplitude and phase of InSb/Al hybridized island*

JIYIN WANG (Presenter), Delft University of Technology, CONSTANTIN SCHRADE, Massachusetts Institute of Technology, VUKAN LEVAJAC, DAVID VAN DRIEL, Delft University of Technology, SASA GAZIBEGOVIC, ROY OP HET VELD, Eindhoven University of Technology, KONGYI LI, Delft University of Technology, JOON SUE LEE, MIHIR PENDHARKAR, CONNOR DEMPSEY, CHRIS J PALMSTROM, University of California Santa Barbara, ERIK BAKKERS, Eindhoven University of Technology, LIANG FU, Massachusetts Institute of Technology, LEO P KOUWENHOVEN, JIE SHEN, Delft University of Technology — Semiconductor nanowires coupled with superconductors are a promising platform to construct Majorana zero modes as well as to build up topological fault-tolerant quantum computers. In semiconductor nanowire/superconductor hybridized island, charging energies are introduced and thus even/odd parity of two Majorana zero modes exhibit as a two-level quantum system, which could work as topological qubits. By embedding such hybridized islands into superconducting circuit, not only can trivial Andreev bound states and Majorana bound states be distinguished via the supercurrent phase of the island, but also topological-qubit readout and operation can be performed by supercurrent measurement. Here, we insert an InSb/Al hybridized island into NbTiN superconducting circuit forming a superconducting interference device (SQUID). In such a device, we find switching current of the InSb/Al island depends on its parity and the corresponding superconducting phase also show parity-dependent behaviours. In this way, the parity of bound state residing in hybridized island can be read out, which paves the way for parity read out of Majorana superconducting qubits.

Session D49 DCMP: Superconductivity in Ruthenates

2:30PM D49.00001: Effect of strain on critical temperature and Pauli-limit critical field of Sr2RuO4 with separable pairing interaction

YUE YU (Presenter), Stanford Univ, STUART BROWN, University of California, Los Angeles, SRINIVAS RAGHU, Stanford Univ — We study the critical temperature and Pauli-limit critical field of Sr2RuO4 as a function of uniaxial strain. A three-band tight-binding model is studied that includes effects of spin-orbit and Zeeman couplings and a separable pairing interaction. We compare with the experiment results obtained assuming pairing in various channels (d-wave, extended s-wave and p-wave). We will highlight the relationship of Tc with Hc2 for different pairing symmetries.

2:42PM D49.00002: Development of new phase in ruthenium oxides using molecular beam epitaxy method

MASAHITO SAKODA (Presenter), MIZUKI HIGASHIIZUMI, SATOSHI TANDA, Hokkaido University — The ruthenium oxides are known to have the layered structure and the anisotropic superconductivity. Especially, Ca2RuO4 shows remarkable property change applied by electrical field or pressure. We focus on Ca2RuO4 and its related compounds to research new phase in order to develop noble physical properties. We prepare the samples using a molecular beam epitaxy system. The substrates are LaAlO3, SrTiO3, CaF2, and YSZ. The growth temperature is 500-800 °C. We used O2, O*, O3 as the oxide source. We measured the X-ray diffraction, energy dispersive X-ray spectroscopy, temperature dependence of electrical resistivity. We have succeeded in fabrication of Ca2RuO4 films. The temperature dependence of electrical resistivity depends on \( \rho \sim \exp(1/T^{1/2}) \) which is consistent with the report by bulk samples. At the day, We will report the challenge to fabricate the Ca2RuO4 films which show metallic or superconductivity. We also fabricated CaRuO3 and CaRu(O,F)3 films. It is confirmed that the magnetic transition temperature is suppressed in the higher F-doped range.

2:54PM D49.00003: Superconducting Sr$_2$RuO$_4$ thin film growth by controlling the structural defects  
JINKWON KIM (Presenter), Department of Physics and Astronomy, Seoul National University, JUNSIK MUN, Department of Materials Science and Engineering and Research Institute of Advanced Materials, Seoul National University, CARLA PALOMARES-GARCIA, Department of Materials Science and Metallurgy, University of Cambridge, JEONG RAE KIM, LINGFEI WANG, Department of Physics and Astronomy, Seoul National University, SEO HYOUNG CHANG, Department of Physics, Chung-Ang University, MIYOUNG KIM, Department of Materials Science and Engineering and Research Institute of Advanced Materials, Seoul National University, SUK BUM CHUNG, Department of Physics, University of Seoul, CHANGYOUNG KIM, Department of Physics and Astronomy, Seoul National University, JASON ROBINSON, Department of Materials Science and Metallurgy, University of Cambridge, YOSHITERU MAENO, Department of Physics, Kyoto University, TAE WON NOH, Department of Physics and Astronomy, Seoul National University — The layered perovskite superconductor Sr$_2$RuO$_4$ (bulk $T_c \sim 1.5$ K) has been studied extensively with its possible topological superconductivity and chiral gap function ($p_x \pm ip_y$) [1]. The superconducting Sr$_2$RuO$_4$ thin film has advantages not only for physical advances but also fruitful device application such as quantum computation [2]. However, superconducting Sr$_2$RuO$_4$ film growth has been limited since the superconductivity of Sr$_2$RuO$_4$ is extremely vulnerable to structural defects, especially out-of-phase boundaries (OPBs) [3]. In this presentation, we will present our Sr$_2$RuO$_4$ film growth focused on the suppression of OPBs. By optimizing substrates and growth condition, we achieved epitaxial Sr$_2$RuO$_4$ films with high crystallinity and smooth surfaces, confirmed by X-ray diffraction and atomic force microscopy and transmission electron microscopy. With reduced OPBs, Sr$_2$RuO$_4$ films exhibit superconductivity up to 0.8 K. Our work suggests a novel method to obtain superconducting Sr$_2$RuO$_4$ films enabling Josephson junction or spintronics device based on the Sr$_2$RuO$_4$.

3:06PM D49.00004: Mimicking superconductivity of Sr$_2$RuO$_4$ using SrRuO$_3$-SrTiO$_3$ superlattice  
BONGJAE KIM (Presenter), Physics, Kunsan National University, SERGII KHMELEVSKYI, Institute for Applied Physics, Vienna University of Technology, CESARE FRANCHINI, Faculty of Physics and Center for Computational Materials Science, University of Vienna, IGOR MAZIN, Naval Research Laboratory, KYOO KIM, Max Planck POSTECH/Korea Research Initiative — The putative chiral spin-triplet superconductivity in ruthenate is under intense controversy, where the various theoretical and experimental studies discuss the diverse alternative pairing symmetries. Currently, the investigation is solely focused on only one material, Sr$_2$RuO$_4$, and the field suffers from the lack of comparison target. Here, employing density functional theory-based analysis, we show that the heterostructure composed of SrRuO$_3$ and SrTiO$_3$ is inherent with all the key characteristics of Sr$_2$RuO$_4$, and eventually can host superconductivity. Furthermore, we show that the competing magnetic phases and associated frustration entangled with the superconducting state can be tuned by epitaxial strain engineering. This system offers an excellent platform for the study of superconductivity of the ruthenate system.
The unconventional superconductivity of Sr$_2$RuO$_4$ has been studied extensively due to the claim of unique $p$-wave pairing state, which is under recent scrutiny. One of the main difficulties of determining the pairing symmetry is the accurate estimation of relevant energy scales, which are competing. Small tuning of the microscopic parameters and the resulting evolution of pairing symmetry can offer more insight in the field, which is not easy from the experimental side due to the requirement of extremely clean sample and high-precision measurement. Here, based on the recent proposal of possible superconductivity in SrRuO$_3$-SrTiO$_3$ superlattice, we investigate the pairing symmetry of the system, which can be comparable target of Sr$_2$RuO$_4$. From a DFT calculation, we construct a tight-binding Hamiltonian and search for the pairing symmetry of the heterostructure by calculating the superconducting phase transition temperature. We also study the possibility of pairing transition by tuning the external parameters, which is attainable through epitaxial strain.
3:30PM D49.00006: Constraints on the superconducting order parameter in Sr$_2$RuO$_4$ from oxygen-17 nuclear magnetic resonance

*ANDREJ PUSTOGOW (Presenter), YONGKANG LUO, AARON CHRONISTER, YUE-SHUN SU, University of California, Los Angeles, DMITRY SOKOLOV, FABIAN JERZEMBECK, ANDREW P. MACKENZIE, CLIFFORD W. HICKS, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, NAOKI KIKUGAWA, National Institute for Materials Science, Tsukuba, Japan, SRINIVAS RAGHU, Stanford University, Stanford, ERIC BAUER, Los Alamos National Laboratory, Los Alamos, STUART BROWN, University of California, Los Angeles — The superconducting state of the quasi two-dimensional and strongly correlated perovskite Sr$_2$RuO$_4$ is considered to be a solid-state analogue to the superfluid $^3$He-A phase, with an odd-parity order parameter that breaks time-reversal symmetry. Recent experiments using in-plane uniaxial stress revealed a dramatic rise and peak of the transition temperature [1], related to a DOS enhancement [2]. Here we use $^{17}$O NMR spectroscopy to probe the nature of superconductivity in Sr$_2$RuO$_4$ and its evolution under uniaxial strain. A reduction of the Knight shift is observed below $T_c$ for all strain values, consistent with a drop in spin polarization in the superconducting state [3]. In unstrained samples, our results rule out a chiral $p$-wave order parameter. We discuss the issue of sample heating on a sub-millisecond time scale after the NMR pulse, which is particularly relevant to superconductors with a small transition temperature ($T_c \approx 1$ K).

Reduced spin susceptibility in superconducting Sr$_2$RuO$_4$ measured by polarized neutron diffraction

ALEXANDER PETSCH (Presenter), MENGZE ZHU, Univ of Bristol, YOSHITERU MAENO, Kyoto University, ZHIQIANG MAO, Tulane University, MECHTHILD ENDERLE, Institut Laue-Langevin, STEPHEN HAYDEN, Univ of Bristol — Superconducting Sr$_2$RuO$_4$ has previously been considered as an analogue of superfluid $^3$He-A [1]. But the picture of odd-order parameter superconductivity with chiral triplet-pairing got recently challenged by the observation of a drop in the $^{17}$O-NMR Knight shift below the superconducting transition [2]. Herein, we present new data on the magnetic susceptibility in Sr$_2$RuO$_4$ collected by polarized neutron scattering. Consistent with the observations in NMR, a reduction below the superconducting transition is observed. In relation to previous work [3] we propose a complicated field dependence alongside large residual susceptibilities at zero temperature, arising from orbital and spin-orbit contributions. Our results support singlet-pairing with a complicated gap-symmetry or triplet-pairing with an in-plane $d$-vector, where time-reversal symmetry is still broken [4].

Understanding reduced NMR signals in Sr$_2$RuO$_4$

AUSTIN LINDQUIST (Presenter), HAE-YOUNG KEE, Univ of Toronto — The superconducting order parameter of Sr$_2$RuO$_4$ has been a topic of recent interest, as new NMR experiments are in contradiction with the previously proposed $p_x \pm ip_y$ triplet superconducting state [1]. The multi-orbital nature of the Fermi surface, in combination with the Hund's and spin-orbit coupling, allows various types of superconducting order parameters. We propose inter-orbital spin triplet pairing based on the Hund's and spin-orbit coupling [2], and study the NMR signals with and without uniaxial strain. These results are compared with recent NMR experiments, and future experiments which can test the validity of the proposed pairing symmetry are also discussed.

Muon spin relaxation studies of time-reversal symmetry breaking superconductivity in Sr$_2$RuO$_4$ along with the application of uniaxial stress and disorder*

SHREENANDA GHOSH (Presenter), VADIM GRINENKO, FELIX BRÜCKNER, RAJIB SARKAR, Institute for Solid State and Materials Physics, Technical University of Dresden, Germany, JEAN-CHRISTOPHE ORAIN, ARTEM NIKITIN, DEBARCHAN DAS, ZURAB GUGUCHIA, Laboratory forMuon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, JOONBUM PARK, MARK E BARTER, Max Planck Institute for Chemical Physics of Solids, NAOKI KIKUGAWA, National Institute for Material Science, Japan, JAKE BOBOWSKI, Department of Physics, Graduate School of Science, Kyoto University, Japan, DMITRY SOKOLOV, Max Planck Institute for Chemical Physics of Solids, TAKUTO MIYOSHI, YOSHITERU MAENO, Department of Physics, Graduate School of Science, Kyoto University, Japan, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, HUBERTUS LUETKENS, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, CLIFFORD W HICKS, Max Planck Institute for Chemical Physics of Solids, HANS-HENNING KLAUSS, Institute for Solid State and Materials Physics, Technical University of Dresden, Germany — After extensive research, the idea regarding the symmetry of the superconducting order parameter of Sr$_2$RuO$_4$ is still lacking a consensus. Recently, NMR experiments have ruled out the well-discussed $p_x \pm ip_y$ state [1]. Nevertheless, complex two-component order parameters are conventionally indicated by time-reversal-symmetry breaking (TRSB) superconductivity. In order to lift the degeneracy between such components, application of uniaxial stress is a plausible method [2]. One key prediction for Sr$_2$RuO$_4$, a splitting of the superconducting and TRSB transitions under uniaxial stress has not been observed so far. We report a large stress-induced splitting between the onset temperatures of superconductivity and TRSB transitions observed by muon spin relaxation (μSR) measurements under uniaxial stress. To perform these technically challenging experiments, a customized uniaxial pressure cell was developed, which will be presented. We also discuss the effect of disorder on the superconducting and TRSB states by μSR, concerning the chirality of the order parameter.

Spin-orbital coupling and spin-triplet pairing symmetry in Sr$_2$RuO$_4$  

WANG (Presenter), McMaster Univ, ZHIQIANG WANG, James Franck Institute, Chicago University, CATHERINE KALLIN, McMaster Univ — Spin-orbital coupling (SOC) plays a crucial role in determining the spin structure of an odd parity pseudospin-triplet Cooper pairing state. We discuss how SOC lifts the degeneracy among different p-wave pseudospin-triplet pairing states in a widely used microscopic model for Sr$_2$RuO$_4$ combining a Ginzburg-Landau free energy expansion, a symmetry analysis of the model, and numerical weak-coupling renormalization group, as well as random phase approximation, calculations. These analyses are also used to critically re-examine previous numerical results on the stability of chiral p-wave pairing. The symmetry analysis can serve as a guide for future studies, especially numerical calculations, on the pairing instability in Sr$_2$RuO$_4$ and can be useful for studying other multi-band spin-triplet superconductors where SOC plays an important role.

*This research is supported by the National Science and Engineering Research Council of Canada (NSERC).

Strontium Ruthenate's Superconducting Symmetries from First-Principles Calculations

OLIVIER GINGRAS (Presenter), MICHEL COTE, Universite de Montreal, REZA NOURAFKAN, ANDRE-MARIE TREMBLAY, Universite de Sherbrooke — The normal state of Sr$_2$RuO$_4$ is well understood but its superconducting state is still a subject of major debates [1]. From a first-principles correlated multiorbital calculation, we construct the spin and charge fluctuation pairing interactions. These interactions depend on the proximity to an instability and on the size of the screened Hund's coupling. We present the leading gap function symmetries obtained by solving the frequency-dependent linearized Eliashberg equation for the case where spin-orbit coupling is neglected [2]. Close to magnetic instabilities, we find spin-singlet d-wave pairing. Away, where charge fluctuations increase, we observe the emergence of two even-parity spin-triplet states: an odd in frequency s wave and two degenerate momentum-independent states that pair electrons on different orbitals and are odd in orbital indices. These exotic states are compared with experiments. Moreover, we discuss and present the effects of spin-orbit coupling and uniaxial strain on the system.

4:42PM D49.00012: Effects of spin-orbit coupling on the superconducting pairing in Sr$_2$RuO$_4$

WEN HUANG (Presenter), Southern University of Science and Technology, YI ZHOU, Institute of physics, Chinese Academy of Sciences, HONG YAO, Institute for Advanced Study, Tsinghua University — In a superconductor with finite spin-orbit coupling (SOC), neither the orbital nor the spin angular momentum of a Cooper pair is good quantum number, but their sum is. We focus on two aspects of the SOC-influenced superconductivity in Sr$_2$RuO$_4$. In the first[1,2], we argue that the most frequently discussed p-wave state in the $E_u$ representation, which has Cooper pair angular momentum $|L_z,S_z\rangle = |\pm1,0\rangle$, must coexist with another pairing with $|L_z,S_z\rangle = |0,\pm1\rangle$. The two correspond respectively to the gap functions $(k_x,k_y)\hat{z}$ and $k_z(\hat{x},\hat{y})$ in the d-vector notation. If the latter dominates, the $E_u$ superconducting channel would favor a nematic rather than a chiral state. Moreover, in-plane uniaxial strains, which primarily perturb the orbital angular momentum $L_z$ of the Cooper pairs, split the components in the $|\pm1,0\rangle$ pairing linearly and those in the $|0,\pm1\rangle$ pairing quadratically. In the second[3], we show how SOC may inherently entangle spin-triplet and spin-singlet pairings in multi-orbital models of Sr$_2$RuO$_4$. Possible relevance to the recent experiments, such as the uniaxial strain and NMR Knight shift measurements, will be discussed. Refs: [1] Huang and Yao, PRL 121, 157002 (2018); [2] Huang, Zhou, and Yao, arXiv:1901.07041; [3] Huang, Zhou, and Yao, PRB 100, 134506 (2019).

4:54PM D49.00013: Emergence of high-temperature superconductivity in a Ca$_2$RuO$_4$ nanocrystals

HIROYOSHI NOBUKANE (Presenter), KOSEI YANAGIHARA, YUJI KUNISADA, YUNITO OGASAWARA, KAKERU ISONO, KAZUSHIGE NOMURA, KEITA TANAHASHI, TAKAHIRO NOMURA, TOMOHIRO AKIYAMA, SATOSHI TANDA, Hokkaido University — The search for high-temperature (high-$T_c$) superconductors is a fascinating topic in condensed matter physics. It is widely believed that high-$T_c$ superconductivity in cuprates emerges from doped Mott insulators. Recently, 4$d$ and 5$d$ transition metal oxides with a layer perovskite structure have attracted much attention because the possibility of the emergence of high-$T_c$ superconductivity has been recognized in several studies. Here we report the realization of high-temperature superconductivity in Ca$_2$RuO$_4$ nanofilm single crystals. We found that the induced bias current and the tuned film thickness cause a superconductor-insulator transition. We clarify two quantum critical phase transitions corresponding to the clean and dirty limits of the Harris criterion. Our results demonstrate the presence of two-dimensional high-temperature superconductivity in Ca$_2$RuO$_4$ nanofilm.
Possible 'symmetry-imposed' near-nodal superconducting pairing in Sr$_2$RuO$_4$

YU LI (Presenter), Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, WEN HUANG, Shenzhen Institute for Quantum Science and Engineering and Department of Physics, Southern University of Science and Technology — One key feature of the multi-orbital superconducting Sr$_2$RuO$_4$ is the presence of nodal or near-nodal quasiparticle excitations revealed in a wide variety of experiments. Typically, a nodal gap structure in a two-dimensional model would be inconsistent with the chiral or helical p-wave interpretations. However, we demonstrate that true gap nodes may emerge along certain high-symmetry directions on the quasi-one-dimensional Fermi surfaces, if the multi-orbital chiral or helical p-wave pairings acquire peculiar forms wherein the d$_{xz}$ and d$_{yz}$ orbitals develop k$_y$- and k$_x$-like pairings, respectively. Spin-orbit coupling $\eta$ induces a near-nodal gap of order ($\eta^2/W^2$)$\Delta_0$, where $\Delta_0$ is the gap amplitude and W roughly the bandwidth. Provided the aforementioned pairing is predominant, the near-nodal gap structure is robust upon the inclusion of other multi-orbital pairings that share the same symmetries. In light of the recent experimental progresses, our proposal suggests that two-dimensional p-wave pairings may still be viable candidate ground states for Sr$_2$RuO$_4$. A near-nodal helical p-wave order, for example, would also be consistent with the substantial drop in the NMR Knight shift under an in-plane magnetic field.

Session D50 DCMP: Ferromagnetic Order and Instabilities Mile High Ballroom

2:30PM D50.00001: Time-stable remanence in Dzyaloshinskii-Moriya Interaction driven Weak ferromagnets NAMRATA PATTANAYAK (Presenter), Department of Physics, Indian Institute of Science Educaion and Research (IISER), Pune, India — We observe that a number of Dzyaloshinskii-Moriya Interaction (DMI) driven weak ferromagnets (WFMs) including α-Fe$_2$O$_3$, MnCO$_3$ and NiCO$_3$ exhibit two distinct time scale in the magnetization relaxation process as explored through SQUID magnetometry. One of the time scales of relaxation is short and, therefore, leads to a quick decay while the other is ultraslow leading to the observation of a time-stable remanence [1]. Furthermore, the time-stable remanence also varies with the strength of the magnetic field in a very unexpected way. We propose that these unique features of remanence explored in systems of different length scales covering bulk single-crystal to nanocrystallites can be taken as the footprint of weak ferromagnetism. We also find that this time-stable remanence which is intrinsic to WFMs can considerably be tunable by nano scaling as explored in the room temperature WFM α-Fe$_2$O$_3$ synthesized in various shapes, size, and morphologies. Corroborated by the synchrotron XRD measurements the study has provided us crucial insights to optimize the magnitude of time-stable remanence in α-Fe$_2$O$_3$ which has a prominent role in antiferromagnetic spintronics [2].

2:42PM D50.00002: Ferromagnetic kinetic exchange interaction  
NAOYA IWAHARA (Presenter), National University of Singapore, ZHISHUO HUANG, KU Leuven, AKSELI MANSIKKAMÄKI, University of Jyväskylä, VEACHESLAV VIERU, Maastricht University, DAN LIU, Northwestern Polytechnical University, LIVIU CHIBOTARU, KU Leuven — Anderson’s superexchange mechanism is indispensable for the description and prediction of the magnetic interactions in localized spin systems. Within the framework, weak ferromagnetism originates from Goodenough’s mechanism and potential exchange when strong antiferromagnetic kinetic exchange interaction is suppressed. However, Anderson’s model and also its modified version, Zaanen-Sawatzky’s model, fail to catch an important ferromagnetic contribution. Here, we report ferromagnetic kinetic exchange mechanism arising from overlapping of magnetic orbitals and their strong covalency with the bridging orbitals. Contrary to the conventional weak ferromagnetic exchange mechanisms, the present one can be larger than the antiferromagnetic kinetic exchange interaction, resulting in strong stabilization of ferromagnetic state. Based on first principles calculations, we demonstrate that the present mechanism is responsible for strong ferromagnetism in several existing materials with diamagnetic metal bridges: Fe$^{3+}$-Co$^{3+}$-Fe$^{3+}$ and Cu$^{2+}$-Cr$^{6+}$-Cu$^{2+}$ complexes, quasi-one-dimensional Cu chain, La$_4$Ba$_2$Cu$_2$O$_{10}$, and Co chain, Ca$_3$Co$_2$O$_6$.

2:54PM D50.00003: Small Moment, Itinerant Ferromagnetism Discovered in Single Crystalline La$_5$Co$_2$Ge$_3$* 
SCOTT SAUNDERS (Presenter), LI XIANG, Iowa State University, RUSTEM KHASANOV, Paul Scherrer Institut, TAI KONG, Princeton University, QISHENG LIN, SERGEY L. BUD’KO, PAUL C CANFIELD, Iowa State University — Single crystals of monoclinic La$_5$Co$_2$Ge$_3$ were grown using a self-flux method and were characterized by room-temperature powder X-ray diffraction, anisotropic temperature and field dependent magnetization, temperature dependent resistivity, specific heat, and muon spin resonance. La$_5$Co$_2$Ge$_3$ has a Curie temperature ($T_C$) of ~3.8 K, as well as a clear loss of spin disorder scattering in resistivity data and a sharp specific heat anomaly. The magnetism associated with La$_5$Co$_2$Ge$_3$ has $\mu_{\text{eff}} = 0.92$ $\mu_B$ per mol-Co, $\mu_{\text{sat}} = 0.11$ $\mu_B$ per mol-Co, and a change in the entropy at $T_C$ of ~0.05 R ln2 per mol-Co making it a rare, itinerant, low $T_C$ compound.

LI XIANG (Presenter), SCOTT SAUNDERS, SERGEY L. BUD’KO, PAUL C CANFIELD, Iowa State University — A quantum phase transition is a phase transition that occurs at 0 K. For many second-order phase transitions, application of a magnetic field, doping or pressure can suppress the transition temperature and lead to a quantum critical point (QCP). However, avoided quantum criticality is often observed in intermetallic, ferromagnetic systems. The mechanism behind this phenomenon has been discussed intensively in recent years. Lately, we discovered a new ferromagnetic compound, La$_5$Co$_2$Ge$_3$, which has a Curie temperature $T_C \sim 3.8$ K. The physical properties under pressure and the pressure dependence of $T_c$ are studied up to $\sim 5$ GPa. We find that a ferromagnetic QCP is avoided by the appearance of a new, most likely magnetic, phase. Details of the $T$-$p$ phase diagram and the possible nature of the new phase will be discussed.

*This work was carried out at Iowa State University and supported by Ames Laboratory, US DOE, under Contract No. DE-AC02-07CH11358, by the Gordon and Betty Moore Foundation’s EPiQS Initiative and the W. M. Keck Foundation.

GOPI CHANDRA KAPHLE, Central Department of Physics, Kirtipur, Kathmandu, Nepal, Tribhuvan University, RAMESH DHAKAL (Presenter), SASHI NEPAL, RAM BABU RAY, Central Department of Physics, Tribhuvan University — Mn and Co based Heusler alloys found to exhibit interesting electronic and magnetic properties. We have investigated the effect of electronic and magnetic properties on Mn$_2$CoGa after doping Fe and Cr. Entire calculations were performed through plane wave pseudo-potential method using quantum espresso.

From the calculation it is observed that the band gap of Mn$_2$CoGa shifted (increases) on 25% doping of Fe (or Cr) to its pristine form due to the effect of which shifting the band gap on the right side and shows perfect half-metallicity character. The band gap is found to be 0.307 eV and 0.352 eV for Fe and Cr doping respectively which is also greater than the minority band gap in the pristine (0.113 eV). The decreasing rate of bandgap is more in case of Fe doping than Cr doping. This maybe due to exchange splitting and coulomb repulsion competition. At this case system follows the Slater Pauling’s rule and hence gives rise to integer magnetic moments. If percentage of doping increases non-integer value of total spin magnetic moment is observed indicating that half-metallicity were destroyed. Doping in higher degree drastically increases the Magnetic moments.

3:30PM D50.00006: Small angle neutron scattering study of magnetic length scales in disordered ferromagnetic Ni-V alloys.* SHIVA BHATTARAI (Presenter), HIND ADAWI, JEAN GUY L LUSSSIER, ALMUT SCHROEDER, Kent State Univ - Kent, KATHRYN LYNN KRYCKA, National Institute of Standards and Technology — We used small angle neutron scattering (SANS) to reveal magnetic microstructures in a disordered ferromagnet (FM) close to quantum critical point (QCP) where long range order is suppressed with critical temperatures Tc approaching zero. First results of the alloy Ni-V with low Tc are presented on well characterized polycrystalline samples that demonstrated the quantum Griffiths phase signatures for “random” magnetic inhomogeneities [1]. SANS data were collected at NG7SANS, NIST. Full polarization analysis was effective to resolve weak magnetic scattering from dominating nuclear scattering. Angular dependent spin-flip scattering identified magnetic short-range clusters. Angular dependent non-spin-flip interference term recognized long-range magnetic domain contributions. The disordered FM Ni-V presents short-range correlations coexisting with long-range correlations at low temperatures well below Tc in the quantum Griffiths regime close to the QCP.

*This research is supported by ICAM and used resources at NIST provided by the Center of High-Resolution Neutron Scattering (through partnership of NIST and NSF)

3:42PM D50.00007: Unveiling electronic correlation and ferromagnetic superexchange mechanism in van der Waals crystal CrSiTe₃* JIAJIN ZHANG, XIAOCHAN CAI, ShanghaiTech University, LEXIAN YANG, Department of Physics, Tsinghua University, HONGTAO YUAN, Nanjing University, YULIN CHEN, Department of Physics, University of Oxford, SHILEI ZHANG, ZHONGKAI LIU (Presenter), GANG LI, ShanghaiTech University — The recent discovery of intrinsic ferromagnetic order in atomically thin van der Waals crystal CrXTe₃ (X=Si,Ge) stimulates intensive studies on the nature of low-dimensional magnetism. By combining advanced many-body calculations with angle-resolved photoemission spectroscopy we investigate CrSiTe₃ single crystals and unveil the pivotal role played by the strong electronic correlations at both high- and low-temperature regime. Above the Curie temperature (Tc), Coulomb repulsion (U) drives the system into a charge transfer insulating phase. In contrast, below Tc the crystal field arranges the Cr-3d orbitals such that the ferromagnetic super-exchange profits, giving rise to the bulk ferromagnetic ground state with which the electronic correlations compete. The excellent agreement between theory and experiment establishes CrSiTe₃ as a prototype low dimensional crystal with the cooperation and interplay of electronic correlation and ferromagnetism. Ref. [1] J. X. Zhang et al., Phys. Rev. Lett. 123, 047203 (2019)

*This work is supported by grant from the National Key R&D program of China and the National Natural Science Foundation of China.
3:54PM D50.00008: Existence of ferromagnetism in a two-dimensional two species bosonic Hubbard model with the presence of confinement  KALANI HETTIARACHCHILAGE (Presenter), Department of Physics, Seton Hall University, V. G. ROUSSEAU, KA-MING TAM, MARK JARRELL, JUANA MORENO, Department of Physics, Louisiana State University — With recent experimental advances on cold atoms in atomic traps, the realization of exotic magnetic phases in the presence of confinement is an area of renewed interest. We investigate a two-dimensional bosonic Hubbard model with two species in the presence of a harmonic trapping potential. In particular, we focus on the appearance of a novel high entropy ferromagnetic phase at finite doping and polarization. We find that in the presence of confinement, this ferromagnetic phase appears in both hard-core and soft-core bosonic models. In the hard-core limit, we observe phase separation where the heavy species is localized in the center of the trap, and it is surrounded by the light species. In the soft-core limit, we observe that the light species gets trapped in the center of the lattice, and it is surrounded by the heavy species. We link our results with experimental observables relevant for magnetic phases of trapped cold atoms.

4:06PM D50.00009: Z3 ferromagnet to Valence Bond Solid transition in 1d  BRENDEN ROBERTS (Presenter), SHENGHAN JIANG, OLEXEI I MOTRUNICH, Caltech — We continue recent efforts to discover examples of deconfined quantum criticality in one-dimensional models. In this work we focus on the transition between Z3 ferromagnet and Valence Bond Solid (VBS) in a 1d chain with a Z3xZ3 global symmetry. We use a model with alternating projective representations on the sites of the two sublattices. This allows the model to connect to an exactly solvable point which has VBS character as SU(3)-invariant singlets. We find a direct transition from this phase to a ferromagnetically ordered phase breaking Z3 symmetry. Numerical evidence suggests a second-order or extremely weak first-order transition. We characterize the apparent criticality using entanglement scaling and the critical scaling of lattice operators.

4:18PM D50.00010: Physical properties of the van der Waals material Fe$_5$GeTe$_2$  ANDREW MAY (Presenter), Oak Ridge National Lab, DMITRY OVCHINNIKOV, University of Washington, QIANG ZHENG, RAPHAEL HERMANN, STUART CALDER, CRAIG A. BRIDGES, Oak Ridge National Lab, XIAODONG XU, University of Washington, MICHAEL MCGUIRE, Oak Ridge National Lab — van der Waals bonded materials that possess magnetic order at high temperatures are of great interest for integrating magnetic effects into engineered heterostructures. Of the cleavable materials studied so far, Fe$_{5-x}$GeTe$_2$ possesses the highest reported Curie temperature $T_C$ in the bulk and maintains a high $T_C$ in exfoliated flakes. This presentation will discuss the physical properties of Fe$_{5-x}$GeTe$_2$ single crystals, with an emphasis on the metastable nature of the compound and how magnetism on one Fe sublattice dominates the transport properties. The ability to tune the magnetism through cobalt doping will also be briefly discussed.

**4:30PM D50.00011: The effect of Ge substitution on optical properties of FeGa$_3$ single crystals**

AASHISH POUDEL (Presenter), IHOR SYDORYK, Ramapo College of NJ, Mahwah NJ, 07430, RODICA M MARTIN, Montclair State University, Montclair NJ, 07043, USA, CEDOMIR PETROVIC, REN WEIJUN, Brookhaven National Laboratory, NY 11973, USA, CATALIN MARTIN, Ramapo College of NJ, Mahwah NJ, 07430 — Studied initially for its large thermopower effect, the intermetallic semiconductor FeGa$_3$ has recently been shown to provide a suitable platform for studying electron correlations, such as metal-insulator transition, non Fermi liquid behavior and ferromagnetism. In particular, with Ge-doping at Ga site the ground state is tuned from a Kondo insulator to a paramagnetic and further to a ferromagnetic metal. Here we present optical reflectance measurements on single crystals of FeGa$_{3-x}$Ge$_x$, for different values of x. The temperature was varied between 300 K and 5 K, and the frequency ranged from 80 cm$^{-1}$ to 50 000 cm$^{-1}$. From Kramers-Kronig transformation we obtained various optical functions and discuss here the effect of Ge substitution on optical conductivity across all three proposed ground states.

**4:42PM D50.00012: Intrinsically weak magnetic anisotropy of cerium in potential hard-magnetic intermetallics**

ANNA GALLER (Presenter), SILKE BIERMANN, LEONID POUROVSKII, Centre de Physique Théorique, Ecole Polytechnique, France — We study the magnetic properties of the "1-12" family of prospective hard-magnetic Ce-Fe intermetallics using an *ab initio* dynamical mean-field theory approach to treat the complex many-electron physics of the Ce 4f$^1$ shell. By considering the hypothetical binary compound CeFe$_{12}$, as well as the realistic compositions CeFe$_{11}$Ti and CeFe$_{11}$TiN, we show that the localization of the Ce 4f electron is strongly sensitive to alloying and interstitials. The onset of heavy-fermion behavior accompanied by a significant reduction of the Ce-4f moment—and concomitantly its contribution to the magnetic anisotropy—is found to occur in CeFe$_{12}$ for a wide temperature range up to about 400K. This 4f delocalization is moderately reduced by Ti substitution on the Fe site and, unexpectedly, markedly increased by nitrogen interstitials. However, even for localized Ce-4f electrons their contribution to the magnetic anisotropy is rapidly suppressed with increasing temperature.

Thickness-dependent magnetic order in CrI$_3$ single crystals

YU LIU (Presenter), LIJUN WU, XIAO TONG, JUN LI, JING TAO, YIMEI ZHU, CEDOMIR PETROVIC

Brookhaven National Laboratory — Two-dimensional (2D) materials with intrinsic ferromagnetism provide unique opportunity to engineer new functionalities in nano-spintronics. One such material is CrI$_3$, showing long-range magnetic order in monolayer with the Curie temperature ($T_C$) of 45 K. Here we study detailed evolution of magnetic transition and magnetic critical properties in response to systematic reduction in crystal thickness down to 50 nm. Bulk $T_C$ of 61 K is gradually suppressed to 57 K, however, the satellite transition at $T^* = 45$ K is observed layer-independent at fixed magnetic field of 1 kOe. The reduction of thickness facilitates a field-driven metamagnetic transition around 20 kOe with out-of-plane field, in contrast to the continuous changes with in-plane field. The critical analysis around $T_C$ elucidates a three-dimensional (3D) long-range magnetic coupling in bulk CrI$_3$, then mean-field type interactions in microscale-thick flake, and evolves into 2D Ising-like ferromagnetism in monolayer.

*Work at Brookhaven National Laboratory was supported by US DOE, Office of Science, Office of Basic Energy Sciences under contract DE-SC0012704.

Magnetic-Competition-Induced Colossal Magnetoresistance in n-Type HgCr$_2$Se$_4$ under High Pressure

JIANPING SUN (Presenter), YUANYUAN JIAO, Institute of Physics, Chinese Academy of Sciences, SACHITH DISSANAYAKE, MASAAKI MATSUDA, Oak Ridge National Laboratory, YOSHIYA UWATOKO, Institute for Solid State Physics, University of Tokyo, YOU GUO SHI, YONGQING LI, ZHONG FANG, JINGUANG CHENG, Institute of Physics, Chinese Academy of Sciences — HgCr$_2$Se$_4$ is a well-known ferromagnetic (FM) semiconductor with $T_C = 106 \sim 120$ K$^1$ and it has received renewed interest recently. Here, we performed the first comprehensive high-pressure study on n-type HgCr$_2$Se$_4$ single crystals and surprisingly found that the FM metallic ground state is destabilized and gradually replaced by an antiferromagnetic (AF) insulating ground state under high pressure. Our combined magnetic susceptibility and neutron measurements under high pressure indicated that the AF order is most likely a spiral-type. On the other hand, the application of external magnetic fields can restore the FM metallic state again at high pressures, resulting in a colossal magnetoresistance as high as $\sim 3 \times 10^{11}$ % under 5 T and 2 K at 4 GPa. Our results demonstrate that HgCr$_2$Se$_4$ situates at a critical point where the competition between FM and AF exchange interactions can be easily tuned by pressure and magnetic field. Thus, our work provides a means for realizing novel state where the extremely large magnetoresistance can be obtained via switching between two distinct electronic ground states in a single-valent system$^2$.

Electronic band structures of FeGe driven by thermal-fluctuation

YANG XU (Presenter), ZIZHAO GONG, RUI SUN, LI NA, XINGQUN ZHANG, WEI HE, ZHAOHUA CHENG, State Key Lab. of Magnetism, Institute of Physics, Chinese Academy of Sciences — Fluctuation-induced first-order transitions have been discussed in superconductors, liquid crystals, and magnetic materials. Recently, chiral magnet, such as FeGe, were found thermal-fluctuation first-order transition above $T_C$, which forms fluctuation disordered state (FD) of magnetic structure. Here, we unveil the Fermi surface symmetry and the evolution of electronic structures across the transition temperature of helimagnetic-paramagnetic phase at $T_C$~274K by means of angle-resolved photoemission spectroscopy (ARPES) on high-quality FeGe(111) films epitaxially grown on Si(111) substrate. The evolution of electronic structures with temperature suggest that FeGe is a Stoner itinerant magnetism. In contrast to ordinary ferromagnetism, a small kink in the integral energy distribution curve (IEDC) at binding energy of 0.5eV in the regime of 274K≤$T_C$≤276K can be identified. This temperature range is the same with the range of FD measured by AC magnetic susceptibility. Therefore, the small kinks on IEDCs imply the contribution of Dzyaloshinskii-Moriya interaction (DMI) on electronic band structure. Our finding paves the path for the theory of the relationship between freedom of spin and electron in itinerant DM helimagnet.

Correlated Insulators in Twisted Double Bilayer Graphene

GREGORY WILLIAM BURG (Presenter), JIHANG ZHU, The University of Texas at Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ALLAN MACDONALD, EMANUEL TUTUC, The University of Texas at Austin — We present a combined experimental and theoretical study of twisted double bilayer graphene with twist angles near 1°. Consistent with moiré band structure calculations, we observe insulators at integer moiré band fillings one and three. Within windows of finite transverse electric fields, the first moiré conduction band is separated from neighboring bands, and we observe correlated insulators at 1/4, 1/2, and 3/4 band filling. The insulators at 1/4 and 3/4 filling emerge in a parallel magnetic field, whereas the resistance at half band filling is weakly dependent on parallel magnetic field. These findings suggest that correlated insulators are favored when a moiré flat band is spectrally isolated, with spin polarization at 1/4 and 3/4 band fillings, and valley polarization at 1/2 band filling.

Correlated states in twisted trilayer graphene

SHAOWEN CHEN, Columbia Univ, VALERIE HSIEH, University of California, Berkeley, MATTHEW A YANKOWITZ, Columbia Univ, KENJI WATANABE, TAKASHI TANIGUCHI (Presenter), National Institute for Materials Science, CORY DEAN, Columbia Univ — Twisted bilayer graphene near the “magic angle” of 1.1 degrees can host low energy flat bands. Here we show tunable band hybridization and correlated states in twisted trilayer graphene, realized by placing monolayer graphene on top of a bernal bilayer graphene. Twisted monolayer-bilayer (tML-BL) devices were fabricated in a dual gate geometry allowing independent tunability of the carrier density and perpendicular displacement field D. For twist angle between 1.4 and 2 degrees the low energy band structure mostly preserves the monolayer and bilayer subbands, with an energy offset tunable with displacement field. At D = 0 the charge neutrality point is semi-metallic with compensated electrons and holes. Mapping the Landau levels as a function of density, D and magnetic field reveals transition between subbands, with a gapped monolayer subband. For twist angle ~ 1.2 degrees, we observed evidence of a flat band and emergent correlated insulating states, which are asymmetrically tunable with displacement field due to the lack of mirror symmetry.

Coexistence of ultraheavy and ultrarelativistic Dirac quasiparticles in sandwiched trilayer graphene.*

CHENYUAN LI (Presenter), STEPHEN CARR, ZIYAN ZHU, EFTHIMIOS KAXIRAS, SUBIR SACHDEV, ALEX KRUCHKOV, Harvard University — Electrons in quantum materials exhibiting coexistence of flat bands piercing dispersive bands can give rise to strongly correlated phenomena, and are associated with unconventional superconductivity. It is known that in twisted trilayer graphene steep Dirac cones can coexist with band flattening, but the phenomenon is not stable under layer misalignments. Here we show that such a twisted sandwiched graphene (TSWG) - a three-layer van der Waals heterostructure with a twisted middle layer - can have very stable flat bands coexisting with Dirac cones near the Fermi energy when twisted to 1.5 degrees. These flat bands require a specific high-symmetry stacking order, and our atomistic calculations predict that TSWG always relaxes to it. Additionally, with external fields, we can control the relative energy offset between the Dirac cone vertex and the flat bands. Our work establishes TSWG as a new platform for research into strongly interacting phases, and topological transport beyond Dirac and Weyl semimetals.

3:06PM D51.00004: Periodically strained graphene lattice: flat bands*  SLAVISA MILOVANOVIC (Presenter), MISA ANDELKOVIC, LUCIAN COVACI, FRANCOIS M PEETERS, Univ of Antwerp — The conditions for the appearance of flat bands in periodically buckled graphene systems is determined. We use a tight-binding model to calculate the band structure of periodically strained graphene lattice. Three different strain configurations are considered: 1) triangular pseudo-magnetic field (PMF) mode - which is the first two-dimensional buckling mode where flat bands have been observed, 2) hexagonal buckling mode - as a common out-of-plane buckling mode in case of stacking different hexagonal lattices, and 3) herringbone buckling mode - as the lowest energy configuration in the case of large biaxial strains. We examine the band flattening versus the period of the buckling and the strength of the deformation and give predictions for the necessary conditions to access the regime of correlated phases. Our simulations show that the triangular PMF configuration is the most favourable for the appearance of flat bands due to the PMF-induced electron confinement. Similarly as in the case of energy levels of graphene quantum dots in the magnetic field, we find that flat bands show the same dispersion versus the strength of the deformation with energy separation that is inversely proportional to the buckling period.

3:18PM D51.00005: Experimental Discovery of High Dimensional Band Topology in Twisted Bilayer Graphene*  CHAO MA (Presenter), Yale University, QIYUE WANG, The University of Texas at Dallas, SCOTT MILLS, Stony Brook University, XIAOLONG CHEN, BINGCHEN DENG, SHAOFAN YUAN, CHENG LI, Yale University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, DU XU, Stony Brook University, FAN ZHANG, The University of Texas at Dallas, FENGNIAN XIA, Yale University — Recently twisted bilayer graphene (t-BLG) emerges as a strongly correlated physical platform near a magic twist angle, hosting the Mott-like insulating phases and unconventional superconducting behavior. Besides, band topology may be another critical element in strongly correlated twistronics. In this work, we performed a systematic nonlocal transport study and revealed the nontrivial high dimensional band topology in t-BLG. Pronounced nonlocal responses are observed both in the electron and hole superlattice gaps of t-BLG, which are robust to the interlayer electric field, twist angle, and edge termination. We elucidate that two high dimensional $Z_2$ invariants characterize the topology of the moiré bands. Our findings provide a new perspective for understanding the emerging strongly correlated phenomena in twisted van der Waals heterostructures.

3:30PM D51.00006: Flat bands and gaps in twisted double bilayer graphene  RODRIGO CAPAZ (Presenter), FRANCISCO CULCHAC, Federal University of Rio de Janeiro, LEONOR CHICO, Instituto de Ciencia de Materiales de Madrid, ERIC SUAREZ MORELL, Universidad Tecnica Federico Santa Maria — We present electronic structure calculations of twisted double bilayer graphene (TDBG): A tetralayer graphene structure composed of two AB-stacked graphene bilayers with a relative rotation angle between them. Using first-principles calculations, we find that TDBG is semiconducting with a band gap that depends on the twist angle, that can be tuned by an external electric field. The gap is consistent with TDBG symmetry and its magnitude is related to surface effects, driving electron transfer from outer to inner layers. The surface effect competes with an energy upshift of localized states at inner layers, giving rise to the peculiar angle dependence of the band gap, which reduces at low angles. For these low twist angles, the TDBG develops flat bands, in which electrons in the inner layers are localized at the AA regions, as in twisted bilayer graphene.

3:42PM D51.00007: Electric field tunable correlated insulating states and spin-polarized phase transitions in twisted bilayer-bilayer graphene  ORIOL RUBIES-BIGORDA (Presenter), YUAN CAO, DANIEL RODAN-LEGRAIN, JEONG MIN PARK, Massachusetts Institute of Technology MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science (Japan), PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — Understanding how strongly correlated materials behave has been a challenge for the last decades. The recent discovery of superconductivity and correlated insulators in magic angle twisted bilayer graphene (MAGTB) has paved the way to realizing strongly correlated phases of matter using twisted van der Waals heterostructures. We report here on a new correlated platform, twisted bilayer-bilayer graphene (TBBG), which consists of two sheets of Bernal stacked bilayer graphene rotated by a small angle. This system exhibits tunable correlated insulating states at different commensurate fillings. In particular, these insulating states can be switched on and off if an electric displacement field is applied across the sample. The magnetic field response of the correlated insulators in TBBG points towards evidence of spin-polarized ground states. Besides, TBBG shows multiple flat bands near charge neutrality for small twist angles. This results into different correlated states that can be tuned by electric field and are located at half-filling of each flat band. This work contributes to the study of twist-angle and electric-field dependent correlated phases of matter.
3:54PM D51.00008: Lifshitz transitions in magic-angle twisted bilayer graphene*
ZHENGUAN ZHANG (Presenter), SHUANG WU, EVA ANDREI, Rutgers University, New Brunswick — In magic-angle twisted bilayer graphene, the flat band fosters the emergence of rich physics associated with strong correlations. Here we report on magneto-transport measurements of a twisted bilayer graphene device(1.17°±0.02°). From Hall measurements, we extract the Hall number $n_H$, which provides information about the Fermi surface topology as a function of doping within the flat band. At low filling, $|n/n_0| < 2$, we find $n_H = n$ as expected for a system with closed Fermi pockets. Here $n_0$ is the carrier density corresponding to one electron per moire cell. Upon approaching fillings of 2 carriers per moire cell, $n_H$ follows the logarithmic dependence predicted for a Lifshitz transition at a van-Hove singularity. Interestingly on the high doping side of the transition the linear dependence is restored but with an offset, indicating that the Fermi surface shrinks by 2 carriers per moire cell and a correlation gap opens. Moreover, a singular dependence around $±3n_0$ is observed suggesting a Lifshitz transition but without a gap. As the field is increased above 4T a gap opens at $n/n_0 = 3$ signaled by the appearance of a Landau fan and quantized $R_{xy}$ plateaus. At the same time $n_H$ suggests yet another change in the Fermi surface topology.

4:06PM D51.00009: Chern insulators at odd fillings in magic-angle twisted bilayer
graphene* SHUANG WU (Presenter), ZHENYUAN ZHANG, EVA ANDREI, Rutgers University, New Brunswick — The interplay of magnetic field and the moire superlattice in magic-angle twisted bilayer graphene provides a rich playground for correlated electron physics. We report on magneto-transport measurements of a twisted bilayer graphene device(1.17°±0.02°). At high out-of-plane magnetic fields, we observe Landau fans at integer fillings with well quantized Hall plateaus: $\sigma_{xy}=ve^2/h$, corresponding to integer Chern numbers, $v\in \mathbb{Z}$. These are formally equivalent to the Chern bands of the Hofstadter butterfly formed by the single-particle spectrum of an electron in a periodic potential at high magnetic fields. At fillings of $n/n_0=-1$, we find $v=3$, while at $n/n_0=3, v=1$. Here, $n$ is the total carrier density. $n_0$ is the carrier density corresponding to one electron per moire cell. For these fillings, we find that the field dependence of the Hall number $n_H(B)$ extracted from the Hall resistivity, is non-monotonic indicating the opening of a gap at high fields($B>4T$). This finding is confirmed by measuring the field dependence of the thermal activation gaps for both in plane and out of plane magnetic fields. The linear field dependence of the gaps being consistent with Zeeman splitting, suggests the emergence of a spin-aligned ferromagnetic phase.

*Work supported by DOE-FG02-99ER45742, NSF DMR 1708158
4:18PM D51.00010: Nematicity in twisted bilayer graphene: impact of the moiré superlattice* RAFAEL FERNANDES (Presenter), University of Minnesota, J.W.F. VENDERBOS, Drexel University — Recent experiments have reported evidence that the threefold rotational symmetry of magic-angle twisted bilayer graphene is broken in several regions of the phase diagram, both in the normal state and in the superconducting state. Here, we theoretically investigate the coupling between electronic nematic and moiré superlattice degrees of freedom. Because the nematic transition is described in terms of a three-state Potts order parameter, we show that a true phase transition can still take place even in the presence of externally applied uniaxial strain. Moreover, the nature of the Potts-nematic transition is fundamentally altered by fluctuating strain modes associated with the domain walls separating AB/BA stacking regions of the triangular moiré superlattice. In particular, these fluctuations mediate an effective nemato-orbital coupling that not only renders the nematic transition mean-field and first-order, but also ties the orientation of the nematic director to certain soft directions in momentum space. Finally, we contrast our results to the more familiar case of Ising-nematic order in a tetragonal rigid lattice.

4:30PM D51.00011: Z2 topology and edge states of twisted bilayer graphene* CHAO MA, Department of Electrical Engineering, Yale University, QIYUE WANG (Presenter), Department of Physics, University of Texas at Dallas, SCOTT MILLS, Department of Physics, Stony Brook University, XIAOLONG CHEN, BINGCHEN DENG, SHAOFAN YUAN, CHENG LI, Department of Electrical Engineering, Yale University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, DU XU, Department of Physics, Stony Brook University, FAN ZHANG, Department of Physics, University of Texas at Dallas, FENGNIAN XIA, Department of Electrical Engineering, Yale University — Recently twisted bilayer graphene (tBLG) emerges as a new platform of strongly correlated electrons near a magic twist angle, which hosts many exciting phenomena such as the Mott-like insulating phase, unconventional superconducting behavior, and emergent Chern ferromagnetism. Besides the apparent significance of band flatness, band topology may be another critical element responsible for the strongly correlated phenomena (like in the fractional quantum Hall effect) yet receives much less attention. We demonstrate that, while an unusual symmetry of tBLG trivializes the Berry curvature, two Z2 invariants characterize the topology of the moiré Dirac bands. We further show that subtle gapless edge states can survive in the electron and hole superlattice gaps of tBLG and mediate universal nonlocal transport that are robust to the interlayer electric field, twist angle, and edge termination.

**4:42PM D51.00012: Topological Floquet engineering of twisted bilayer graphene**

MICHAEL SENTEF (Presenter), GABRIEL E. TOPP, GREGOR JOTZU, JAMES W MCIVER, LEDE XIAN, ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter — We investigate the topological properties of Floquet-engineered twisted bilayer graphene above the magic angle driven by circularly polarized laser pulses. Employing a full Moiré-unit-cell tight-binding Hamiltonian based on first-principles electronic structure, we show that the band topology in the bilayer, at twisting angles above 1.05 degrees, essentially corresponds to the one of single-layer graphene. However, the ability to open topologically trivial gaps in this system by a bias voltage between the layers enables the full topological phase diagram to be explored, which is not possible in single-layer graphene. Circularly polarized light induces a transition to a topologically nontrivial Floquet band structure with the Berry curvature analogous to a Chern insulator. Importantly, the twisting allows for tuning electronic energy scales, which implies that the electronic bandwidth can be tailored to match realistic driving frequencies in the ultraviolet or midinfrared photon-energy regimes.

**4:54PM D51.00013: Topological charge pumping by sliding moiré pattern**

MANATO FUJIMOTO (Presenter), Osaka Univ, HENRI KOSCHKE, Physics, Cologne Univ, MIKITO KOSHINO, Osaka Univ — We theoretically study the adiabatic topological charge pumping driven by interlayer sliding in the moiré superlattices. We show that, when we slide a single layer of the twisted bilayer system relatively to the other, a moiré pattern flow and a quantized transport of electrons occurs.[1] When the Fermi energy is in a spectral gap, the number of pumped charges in the interlayer sliding process is quantized to a sliding Chern number, which is related to the interlayer sliding degree of freedom and obeys a Diophantine equation analogous to the quantum Hall effect [2]. We apply the argument to the twisted bilayer graphene, and find that energy gaps above and below the nearly-flat bands has non-zero sliding Chern numbers. When the Fermi energy is in either of those gaps, the slide-driven topological pumping occurs perpendicularly to the sliding direction.

Artificial gauge field in Moiré superlattices

CE SHANG, ADEL ABBOUT, XIAONING ZANG, UDO SCHWINGENSCHLOEGL, AURELIEN MANCHON (Presenter), King Abdullah Univ of Sci & Tech (KAUST) — Moiré superlattices, originating from rotational alignment or/and lattice constants mismatch between the individual layers, open up new strategies for engineering electronic properties [1]. Gauge fields unveil one of the most ubiquitous concepts which describes many branches of physics, ranging from the standard model to the general theory of relativity. In recent years, artificial gauge field for engineered systems extend their proven quantum simulation abilities further, e.g., to quantum Hall physics or topological insulators [2,3]. Here, we propose a method to create a tunable, artificial gauge potential in a periodically modulated Moiré superlattice. By imprinting Peierls phase on the hopping parameters between neighboring lattice sites, we present the realization of a Haldane-like model and investigate the characterization of its topological band structure. As an application, we also provide a methodology to directly measure topological order in such system from a dynamical quench process.

Multiple topological phases in graphene via magnetoelectric proximity effect

HIROYUKI TAKENAKA (Presenter), SHANE SANDHOEFNER, ALEXEY KOVALEV, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — Topological antiferromagnetic (AFM) spintronics have been drawn special attention for the next generation of non-volatile, ultra-fast, and low-power memory and storage devices. The key to realize the spintronic applications is to manipulate the topological electronic states via switching the AFM order parameter. Here we propose a new approach to control the topological electronic states of a two-dimensional material by the proximity of a magnetoelectric antiferromagnet. Using density functional theory and tight-binding Hamiltonian approaches, we investigate an interface between graphene and AFM magnetoelectric Cr$_2$O$_3$ (0001). Due to the proximity effect, the interface electronic structure exhibits non-trivial band gap openings in the graphene Dirac bands asymmetric between the $K$ and $K'$ valleys. This gives rise to an unconventional quantum anomalous Hall effect (QAHE) and, in addition, the spin-polarized valley Hall effect (VHE). The quantum anomalous Hall effect (QAHE), the valley-polarized QAHE and the quantum valley Hall effect emerge in graphene across a 180 magnetic domain wall in chromia. We theoretically demonstrate that these topological properties are controlled by voltage through magnetoelectric switching of the AFM insulator with no need for spin-orbit torques.
2:30PM D52.00001: Eu intercalation in Highly Ordered Pyrolytic Graphite (HOPG)*  
CHRIS MASI (Presenter), AARON WANG, Univ of Wyoming, NATHAN GUISINGER, Argonne National Laboratory, TE-YU CHIEN, Univ of Wyoming — Recently, two-dimensional (2D) van der Waals (vdW) magnetic materials have been of significant interest. Beside the intrinsic magnetism in the 2D materials, synthesized 2D magnetic materials may provide a wider range of opportunities. To achieve this, we successfully prepared Europium (Eu) intercalated highly ordered pyrolytic graphite (HOPG) through thermal evaporation. The intercalation is evidenced by the atomic resolution scanning tunneling microscopy (STM) measurements. Observations of a shift in dI/dV spectra near the Eu intercalation site indicate the electron doping effect. Next step is to test the transport properties and seek for the magnetoresistance signal.

2:42PM D52.00002: First-principles study of electronic structures of two-dimensional Y₂C electride surfaces*  
GUNN KIM (Presenter), JUNSU LEE, GWAN WOO KIM, JINWOONG CHAE, Department of Physics and Astronomy, Sejong Univ — Electrides are attractive ionic compounds in which electrons confined to the narrow interior space in the material act as anions because of their exotic physical and chemical properties such as low work function and efficient electron transfer. In particular, in the case of two-dimensional electride, electrons gather at the interstitial space. In this talk, we report the electronic structure of a two-dimensional Y₂C surface using the first-principles study. We calculate the work function of Y₂C multilayers and analyze how the electronic structure of the material changes when the external electric field is applied. Finally, we discuss what happens to the electronic structure of the Y₂C surface if a Y (or C) atom is missing.

2:54PM D52.00003: The Moiré Superstructure of Graphene Intercalated with a Co Layer*
CLAUDIA CARDOSO (Presenter), DANIELE VARSANO, ANDREA FERRETTI, S3 Center, Istituto Nanoscienze, CNR, Consiglio Nazionale delle Ricerche — The moiré superstructure of graphene grown on metals can drive the assembly of molecular architectures, such as metal-phthalocyanine molecules, allowing for the production of artificial molecular configurations. A detailed analysis of the Gr/Co interaction upon intercalation (including the resulting moiré pattern) is performed here by density functional theory, providing an accurate description of the template as a function of the corrugation parameters. We pay special attention to the comparison with experimental photoemission data (X-ray Photoemission Spectroscopy, XPS). We then report on empty electron states in cobalt-intercalated graphene, studied by X-ray adsorption spectroscopy and angle-resolved inverse photoemission spectroscopy. The experimental data are compared with theoretical calculations to unveil the dispersion of empty states and the hybridization of graphene π bands at the Gr/Co/Ir(111) interface.

3:06PM D52.00004: A non-invasive SOI gating method for probing 2D transport on pristine chemically-terminated Si surfaces*
LUKE ROBERTSON (Presenter), BRUCE E KANE, University of Maryland, College Park — Silicon has a variety of surface terminations available to it in which surface states are passivated and where 2D electron inversion layers are possible through electrostatic gating. In the Kane lab, Si(111) surfaces are terminated with hydrogen using a simple wet-chemical treatment of high-purity, deoxygenated, aqueous NH₄F. Extremely high mobilities, in excess of 300,000 cm²/Vs [1], have been demonstrated in our previous generation devices, and further refinement of these techniques to preserve the pristine nature of these passivated Si surfaces is expected to yield even higher mobilities. To this end, we have developed a new technique to probe these pristine H-Si surfaces using a non-invasive SOI flip-chip gating assembly in which all critical device fabrication is performed on the SOI end. Additionally, our novel device architecture is fully process-compatible with existing UHV halogen-termination (Cl, Br, I) techniques providing a viable solution for 2D transport studies on these surfaces. Architecture details and 77K characterization of 4-terminal devices with newly-incorporated Au depletion gates will be discussed, as well as ongoing low temperature (4K and below) challenges.

*Laboratory for Physical Sciences
3:18PM D52.00005: Electronic Density of States of CrBr$_3$ studied by Scanning Tunneling Microscopy and Spectroscopy (STM/S)*

DINESH BARAL (Presenter), ZHUANGEN FU, ANDREI S. ZADOROZHNYI, RABINDRA DULAL, AARON WANG, NARENDRA SHRESTHA, JINKE TANG, YURI DAHNOVSKY, JIFA TIAN, TEYU CHIEN, Department of Physics and Astronomy, Univ of Wyoming — CrBr$_3$ is a van der Waals material exhibiting magnetism at the 2D limit. Despite the great attention on magnetic properties, the electronic properties of CrBr$_3$ are relatively unexplored. Here, the study of thin flakes of CrBr$_3$ exfoliated on Highly Ordered Pyrolytic Graphite (HOPG) surface was performed using STM/S. The atomic resolution topography, multi-peak $dI/dV$ measurements on the bulk CrBr$_3$ as well as at the monolayer limit will be presented and discussed. Topography agrees with the crystal structures while the multi-peak $dI/dV$ spectra agree extremely well with reported optical measurements. However, the observed energy gap extracted from the $dI/dV$ measurements is determined to be $\sim0.57$ eV, much smaller than the previously believed $\sim1.7$ eV observed by absorption spectrum. DFT calculated DOS failed to reproduce two peaks near the Fermi energy. Further studies are needed to explain the discrepancy. The mono- and bi-layer flakes depict degradation at the edges due to air exposure during sample transfer. These observations provide important information towards the fundamental understanding of CrBr$_3$.

3:30PM D52.00006: Two-dimensional conductive surface oxide on CrN(001) and Cr$_{1-x}$Al$_x$N(001) films

MARY E MCGAHAY (Presenter), DANIEL GALL, Rensselaer Polytechnic Institute — CrN is a Mott-Hubbard insulator but forms a conductive surface oxide with a sheet conductance $G_s = 5.9 \times 10^{-5}$ [Ω/sq]$^{-1}$ when exposed to oxygen. This is demonstrated by in situ transport measurements on epitaxial CrN(001) layers during a continuously increasing pressure $dp/dt = 0.05$ Pa/s of a 90% Ar - 10% O$_2$ mixture, suggesting the formation of a thin n-type doped layer through substitutional replacement of N surface atoms with O. Low-temperature transport measurements indicate incomplete carrier delocalization in the 2D conductive oxide. Alloying with AlN to form cubic Cr$_{1-x}$Al$_x$N(001) films results in similar conductive surface oxides for $x < 0.62$, an increase in the room temperature resistivity from $\rho = 0.070$ to 26 Ω-cm for $x = 0-0.46$, and an increase in the optical band gap from 0.8 to 4.0 eV for $x = 0-0.85$. Direct oxygen incorporation during reactive deposition in a Ar-N$_2$-O$_2$ mixture yields epitaxial CrN$_{1-x}$O$_x$(001) films with a sheet resistance that decreases by over two orders-of-magnitude from $4.4 \times 10^3$ to 7.5 Ω/sq with an increasing O$_2$ partial pressure $P_{O_2} = 0-0.060$ mTorr, and an insulator-to-metal transition at $P_{O_2} = 0.015$ mTorr. The overall results show that oxygen can be used to control transport in CrN, with potential applications in 2D electronics and thermoelectrics.
3:42PM D52.00007: Topological charge pumping in twisted bilayer graphene* YINHAN ZHANG (Presenter), YANG GAO, DI XIAO, Carnegie Mellon Univ —
We show that a sliding motion between the two layers of a \moire superlattice induces an electric current and realizes a two-dimensional version of the topological Thouless pump when the Fermi energy lies in one of the minigaps. Interestingly, a chiral charge pump, namely, a transverse current induced by the sliding motion, is possible in twisted homobilayers. This result is confirmed by a concrete calculation of the adiabatic current in twisted bilayer graphene. Our work reveals an interesting link between mechanical motion and electricity unique to \moire superlattices, and may find applications in nanogenerators and nanomotors.

3:54PM D52.00008: Edge states and no wetting layer in ultrathin Bi(110) films grown on graphene/6H-SiC(0001)* YANFENG LYU (Presenter), SAMIRA DANESHMANDI, SHUYUAN HUYAN, PAUL C. W. CHU, Texas Center for Superconductivity, University of Houston — Ultrathin Bi(110) films have attracted significant attraction recently as a potential candidate for two-dimensional topological insulators. Grown on different substrates, ultrathin Bi(110) films exhibit totally different topological properties. Clarifying charge doping from substrates and wetting layer existing or not will profoundly deepen our understanding of possible topological properties in ultrathin Bi(110) films, which are still under fierce debate. In this talk, we unambiguously demonstrate no wetting layer existing in epitaxial ultrathin Bi(110) films grown on graphene/6H-SiC(0001) using low-temperature scanning tunneling microscopy/spectroscopy (STM/S). Obvious moiré pattern and (6 × 6) reconstruction originating from SiC(001) are clearly observed on the three-monolayer Bi(110) islands, confirming sharp and clean interface between graphene and Bi(110). Gapless edge states are also detected on island edges and domain boundaries, showing a signature of topological nontrivial electronic states in ultrathin Bi(110) films.

4:06PM D52.00009: Superconductivity in monolayer graphene driven by Ca and K doping*

YUKIHIRO ENDO (Presenter), JEHONG JUNG, Department of Physics, Univ of Tokyo, TAKUSHI IIMORI, Institute for Solid State Physics (ISSP), The University of Tokyo, RYOTA AKIYAMA, Department of Physics, Univ of Tokyo, FUMIO KOMORI, Institute for Solid State Physics (ISSP), The University of Tokyo, SHUJI HASEGAWA, Department of Physics, Univ of Tokyo — Superconductivity (SC) induced in graphene has been attracting much attention recently [1, 2]. An example is Ca-intercalated bilayer graphene on SiC [1]. Our structural analysis has unveiled that Ca is intercalated in graphene-buffer interlayer [3], not in graphene-graphene interlayer as analogy of graphite intercalation. Because the position of Ca atoms is on the buffer layer, it can be expected to intercalate Ca atoms into monolayer graphene on SiC. In this study, we have fabricated three samples: Ca-intercalated monolayer graphene grown on SiC(0001), and K or Ca+K adsorbed one on it to change the carrier concentration. Transport measurements have been performed in situ in ultrahigh vacuum. The result shows SC transition at ($T_c =$) 5.5 K, 3.2 K and 1.6 K, respectively. This is the first report of SC in monolayer graphene which has Dirac electrons. The relation between the $T_c$ and the carrier density is different from that of the conventional SC. In the presentation, we will show the details of the experiments and discuss the mechanism of SC. This work was supported by JSPS KAKENHI Grant Number 18K18732, 18K19014, and JSPS fellows.

4:18PM D52.00010: Growth of Silicene on Iodine/Silver (111) studied by low temperature scanning tunneling microscopy

MICHAEL DREYER (Presenter), Physics, University of Maryland, College Park, JENNIFER DEMELL, ROBERT E BUTERA, Laboratory for Physical Sciences — Silicene is the 2D form of silicon. It grows readily on silver (111) as single layers or even bi-layers showing several surface reconstructions in scanning tunneling microscopy images. In an attempt to produce more insulated silicene sheets we grew ~ 0.5 ML of silicon on an almost fully iodine terminated Ag(111) single crystal. For the most part silicene seems to be forming underneath the iodine layer and appears as iodine terminated silicene. In several areas clean silicene sheets were observed. Topographic and spectroscopic data will be discussed.
**4:30PM D52.00011: Emerging electronic states in van der Waals hetero-bilayers** Xianghua Kong (Presenter), Hong Guo, McGill Univ — Bilayer heterostructures have received tremendous attentions in recent years. It is usually believed that electronic structures of stacked van der Waals (vdW) bilayers are simply superposition of their monolayer electronic structures. Here, we show that significant interlayer electronic hybridization occurs even for the most weak-interlayer coupled MoS$_2$/WSe$_2$ bilayer among MoS$_2$/WSe$_2$, MoSe$_2$/PtSe$_2$ and PtS$_2$/PtSe$_2$ bilayers. Several interface states originating from the interlayer S-Se or Se-Se hybridization are explicitly identified by our density functional theory calculations of up to 4000 atoms and confirmed by electrostatic force microscopy (EFM) imaging. In addition, our results also explained the found emerging states within the bandgap of the MoS$_2$/WSe$_2$ bilayer.

*This work is financially supported by the Natural Science and Engineering Research Council (NSERC) of Canada. We thank Compute Canada and the High Performance Computing Center of McGill University for substantial computational support which made this work possible.

**4:42PM D52.00012: Selective adsorption of Dy on intercalated epitaxial graphene** Cai-Zhuang Wang (Presenter), Minsung Kim, Myron Hupalo, Ames Laboratory, Michael C. Tringides, Department of Physics and Astronomy, Iowa State University, Pat A Thiel, Department of Chemistry and Department of Materials Science and Engineering, Iowa State University, Kai-Ming Ho, Department of Physics and Astronomy, Iowa State University — Manipulation of metal deposition and growth morphology on graphene is essential for promising applications of graphene, e.g., magnetic nanoislands for computer memory and stable nanoparticles for catalytic activity. In this study, we present an effective method to control the adsorption and nucleation property of metal ions on graphene via metal intercalation. We experimentally demonstrate that Dy adatoms show highly selective adsorption behavior on Dy-intercalated epitaxial graphene on SiC(0001) by scanning tunnelling microscopy. This adsorption selectivity is theoretically explained by comparing adsorption energies on graphene regions with different intercalation configurations using first-principles methods based on density functional theory. Our results show that the metal intercalation can be an effective way for the functional manipulation of graphene and enlarge the scope of graphene application.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Division of Materials Sciences and Engineering. 4:54PM D52.00013: Theory of Epitaxial Growth of Borophene on Layered Electride: Thermodynamic Stability and Kinetic Pathway*  XIAOJUAN NI (Presenter), HUAQING HUANG, KYUNG-HWAN JIN, University of Utah, ZHENGFEI WANG, University of Science and Technology of China, FENG LIU, University of Utah — Based on first-principles calculations, we propose that the layered electride can serve as an effective substrate, in place of metal substrate, to grow borophene. We first confirm the thermodynamic stability of B@Sr\(_{2}\)N heterostructures by energetics analysis. Then, kinetically, we identify the atomistic pathways for a preferred 2D growth mode with a mixed triangle-hexagon configuration over 3D growth on the surface of Sr\(_{2}\)N, indicating the feasibility of epitaxial growth of borophene on layered electrides. As a weak metal, the significantly reduced density of states from the electride at the Fermi level helps to retain the most intrinsic electronic and transport properties of borophene, a significant advantage over metal substrate. We envision that layered electrides provide an attractive family of substrates for epitaxial growth of a range of 2D materials that can otherwise only be grown on undesirable metal substrates.

*This work is supported by U.S. Department of Energy-Basic Energy Sciences (Grant No. DE-FG02-04ER46148).

D52.00014: Electronic structures of air-exposed few-layer black phosphorus by optical spectroscopy*  FANJIE WANG (Presenter), GUOWEI ZHANG, SHENYANG HUANG, CHAOYU SONG, CHONG WANG, QIAOXIA XING, YUCHEN LEI, HUGEN YAN, Fudan Univ — The electronic structure of few-layer black phosphorus(BP) sensitively depends on the sample thickness, strain and doping. Here, we show that it's also vulnerable to air-exposure. The oxidation of BP caused by air-exposure gives several optical signatures, including the broadening of resonance peaks and increased Stokes shift between infrared absorption and photoluminescence peaks. More importantly, air exposure causes blue shifts of all resonance peaks in infrared absorption and photoluminescence spectra, with more prominent effects for thinner samples and higher order subband transitions. Our study may provides a convenient and exotic way for band-structure engineering of few-layer black phosphorus through controllable air-exposure or defect creation.

Session D53 DMP: Novel Phases and Phase Transitions in 2D Materials

Mile High Ballroom 1F - Liuyan Zhao, Univ of Michigan - Ann Arbor - Tag(s): Focus
2:30PM D53.00001: Imaging spinons in a 2D gapless quantum spin liquid [Invited] MICHAEL F CROMMIE (Presenter), University of California, Berkeley — Two-dimensional triangular-lattice antiferromagnets are predicted under some conditions to exhibit a quantum spin liquid ground state whose low-energy behavior is described by a spinon Fermi surface. This “ghost” Fermi surface (in an otherwise insulating material) is a key concept for understanding spin liquids and their relationship to other quantum phases. Directly imaging the spinon Fermi surface, however, is difficult due to the fractional and chargeless nature of spinons. I will discuss how we have used scanning tunneling microscopy (STM) to image density fluctuations arising from a spin liquid Fermi surface in single-layer 1T-TaSe2, a two-dimensional Mott insulator. Quantum spin liquid behavior was observed in isolated single layers of 1T-TaSe2 through long-wavelength modulations of the local density of states at Hubbard band energies. These modulations reflect a spinon Fermi surface instability in single-layer 1T-TaSe2 and allow direct experimental measurement of the spinon Fermi wavevector, in good agreement with theoretical predictions for a 2D quantum spin liquid. Our results establish single-layer 1T-TaSe2 as an ideal platform for studying novel two-dimensional quantum spin liquid phenomena.

3:06PM D53.00002: Intrinsic magnetic topological insulators: MnBi$_2$Te$_4$ and beyond [Invited] YONG XU (Presenter), Department of Physics, Tsinghua University — Intrinsic magnetic topological insulators are novel states of quantum matter possessing both inherent magnetic order and topological electronic states, which offer a fertile playground to explore emergent quantum physics. The antiferromagnetic topological insulator MnBi$_2$Te$_4$ [1-4] is a rapidly rising star in the research field. The material is theoretically predicted to host rich topological quantum states (e.g., topological axion states, magnetic Weyl semimetal, and quantum anomalous Hall (QAH) effect). In addition to theoretical proposals, I will also introduce recent experimental findings, including the discoveries of antiferromagnetic topological insulator states [1,4], QAH effect [5], robust axion insulator and Chern insulator phases [6], high-Chern-number and high-temperature QAH effect [7], helical Chern insulator phase [8], etc. An outlook for future work will be given. Importantly, the working temperature of MnBi$_2$Te$_4$ is limited by its rather weak ferromagnetic exchange, making superior material candidates desirable. In this perspective, I will briefly report an unexpected theoretical finding of room-temperature ferromagnetism and large-gap QAH insulators in lithium-decorated iron-based superconductor materials LiFeX (X=S, Se, Te) [9], which is awaiting for experimental proof.

3:42PM D53.00003: Optically probing tunable topology in group V monolayers

GAOFENG XU (Presenter), TONG ZHOU, State Univ of NY - Buffalo, BENEDIKT SCHARF, University of Wurzburg, IGOR ZUTIC, State Univ of NY - Buffalo — Experiments on Bi monolayers on a SiC substrate reveal an interplay between a huge topologically nontrivial gap ~0.8 eV and strong spin-orbit coupling (SOC), leading to striking transport properties such as a robust quantum spin Hall effect (QSHE) [1]. With a suitable choice of substrates it is also possible to remove valley degeneracy and realize multiple Hall effects in a single materials system [2]. In contrast to transport properties, much less is known about how an optical response could yield topological signatures in these group V monolayers. By combining first-principles calculations for different substrates and a careful inclusion of strong SOC in effective models as well as the Coulomb interaction in these monolayers, we show that the changes in optical response reveal topological properties inherent to these systems. We explain how these findings offer new opportunities for proximitized materials [3].

3:54PM D53.00004: Topological aspects of the band structure of monolayer \beta-Sb in flat and buckled form: Nodal line to unpinned Dirac cones.

SANTOSH KUMAR RADHA (Presenter), WALTER R.L LAMBRECHT, Case Western Reserve University — Monolayer antimonene in the beta structure has a buckled honeycomb structure with a semiconducting band structure. DFT calculations show that a flat honeycomb structure is a metastable state which has been stabilized epitaxially on Ag. In the flat form of Sb, the Fermi level occurs near linear dispersion band crossings, formed by the intersection of two warped Dirac cones, one derived from p_z orbitals and the other from p_x, p_y orbitals. This conical intersection corresponds to a nodal line with a Lissajous pattern in k-space leading to an interesting Fermi surface with electron and hole pockets in different in-plane directions, in other words an in-plane angle dependent carrier polarity (goniopolarity). Tight-binding as well as DFT calculations show that the nodal line breaks up into six individual symmetry protected Dirac points in the slightly buckled form. These Dirac cones are unpinned and can be moved with increasing buckling until Dirac points of opposite winding number annihilate beyond a critical buckling angle. Band structure calculations in the quasiparticle self-consistent GW approximation including spin-orbit coupling show that a gap opens at the various Dirac crossings but lead to an indirect zero gap situation.
4:06PM D53.00005: *Ab initio* study of pressure-driven phase transition in FePS$_3$ and FePSe$_3$*

YEXIN FENG (Presenter), YUESHAO ZHENG, Hunan University — In spite of recent findings about the pressure-driven insulator-to-metal phase transition, and emerging superconductivity of FePS$_3$ and FePSe$_3$, the knowledge about the atomic structures of them is still vague. Here, we investigate the pressure-driven structural phase transitions of FePS$_3$ and FePSe$_3$ from 0 to 35 GPa by using *ab initio* calculations. We find that FePS$_3$ B-I structure transforms to FePS$_3$ B-II phase at about 5 GPa. Then above 17 GPa, FePS$_3$ B-III phase becomes energetically favored. For FePSe$_3$, with increasing pressure, FePSe$_3$ transforms to B-II phase at around 6 GPa and further to B-III phase at about 15 GPa. Our calculation results are consistent with experimentally observed high-pressure induced cell volume collapse, spin-crossovers and insulator-metal transition in FePS$_3$ and FePSe$_3$, which shed new light on understanding the high-pressure physics and phase transitions of FePS$_3$ and FePSe$_3$.

4:18PM D53.00006: Van-der-Waals layered ferroelectric CuInP$_2$S$_6$ I: a quadruple-well potential*

LEI TAO (Presenter), Chinese Academy of Sciences, JOHN A BREHM, Vanderbilt University, SABINE M. NEUMAYER, Oak Ridge National Laboratory, ANDREW O’HARA, Vanderbilt University, MARIUS CHYASNAVICHUS, Oak Ridge National Laboratory, MICHAEL SUSNER, Air Force Research Laboratory, MICHAEL MCGUIRE, SERGEI V. KALININ, STEPHEN JESSE, PANCHARAPAKESAN GANESH, Oak Ridge National Laboratory, SOKRATES T PANTELIDES, Vanderbilt University, PETRO MAKSYMOVYCH, NINA BALKE, Oak Ridge National Laboratory — CuInP$_2$S$_6$ (CIPS) is a van der Waals solid that is ferrielectric below room temperature and has polarization in the stacking direction. Using density-functional-theory calculations, we discovered that, instead of the usual double-well potential, CIPS features a unique quadruple-well potential, with two low-polarization and two high-polarization states, with the latter corresponding to large Cu displacements to the layer surfaces, where they bond to the adjacent layers.[1] The quadruple well is tunable by strain, which can eliminate one or the other of the polar states. Quantum molecular dynamics shed light on the nature of polarization switching in the CIPS environment. The predicted features have been verified by experiments utilizing scanning probe microscopy (next abstract, Maksymovych et al.). The new results and the propensity of CIPS for ionic substitution opens new opportunities to control and generate ferroelectric properties in layered materials.

4:30PM D53.00007: Van-der-Waals layered ferroelectric CuInP$_2$S$_6$ II: negative
electrostriction and pressure-induced switching*  

JOHN A BREHM, Vanderbilt University,
SABINE M. NEUMAYER, Oak Ridge National Lab, LEI TAO, ANDREW O'HARA, Vanderbilt University,
MARIUS CHYASNAVICHUS, MICHAEL SUSNER, MICHAEL MCGUIRE, SERGEI V. KALININ, STEPHEN JESSE, PANCHAPAKESAN GANESH, Oak Ridge National Lab, SOKRATES T PANTELIDES, Vanderbilt University, PETRO MAKSYMOWYCH (Presenter), NINA BALKE, Oak Ridge National Lab — Layered ferroelectric CuInP$_2$S$_6$ (CIPS) is highly unusual in light of its negative longitudinal piezoelectric coefficient the recently predicted quadruple-well potential (previous abstract, Brehm et al.). Here we show an even larger spectrum of peculiar behaviors, obtained via systematic analysis of nanoscale electromechanical properties with scanning probe microscopy [1]: giant negative electrostriction, coexistence of high and low polarization phases with four distinct polarization orientations, and intrinsic pressure-induced polarization switching. These properties derive from the quadruple potential well for polar displacements, verifying its existence. The combination of unique properties enable deeper insight from microscopic measurements, such as imaging of inhomogeneous strain distribution. More broadly, the peculiarities of CIPS are in large part engendered by its van der Waals structure, thus opening new prospects at the intersection of ferroelectric and 2D materials. [1] J. A. Brehm et al. “Tunable quadruple-well ferroelectric van-der-Waals crystals” Nature Mater., in press.

4:42PM D53.00008: Reversible electrical control of stacking order phase transition in few-layer graphene*  
HONGYUAN LI (Presenter), IQBAL UTAMA, SHENG WANG, WENYU ZHAO, SIHAN ZHAO, Department of Physics, University of California, Berkeley, XIAO XIAO, YUE JIANG, Department of Physics, The Chinese University of Hong Kong, LILI JIANG, Department of Physics, University of California, Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, ALEXANDER WEBER-BARGIONI, Lawrence Berkeley National Laboratory, ALEX ZETTL, FENG WANG, Department of Physics, University of California, Berkeley — The layer stacking order has profound effects on physical properties of two-dimensional (2D) van der Waals heterostructures. For example, graphene multilayers can have distinct electronic band structures and behaviors depending on their stacking orders. Fascinating physical phenomena -- such as correlated insulators, superconductors, and ferromagnetism -- can also emerge with a periodic variation of the layer stacking order, known as the moiré superlattice in van der Waals materials. In this work, we demonstrate that a reversible phase transition between different layer stacking orders can be induced globally in few-layer graphene by electrostatic gating. We directly image the gate-induced stacking orders phase transition with infrared near-field optical microscopy. We reveal that both the carrier doping and the vertical electrical field can drive the stacking order phase transition, but with different mechanisms, through a systematic study of dual-gated few-layer graphene. Our findings provide a reversible and non-invasive method to globally control the stacking orders of few-layer graphene, and they have important implications for the understanding of gate-dependent quantum phenomena in graphene moiré superlattices.

4:54PM D53.00009: Electronic Properties and Polarization Profiles of Janus Transition Metal Dichalcogenides*  
KAICHEN XIE (Presenter), TING CAO, University of Washington — In this talk, we will present our recent studies on the structural and electronic properties of Janus transition metal dichalcogenides by density functional theory calculations. For the structural properties, we identify a novel reaction path in the materials conversion from transition metal dichalcogenides monolayers to its Janus form. For the electronic properties, we calculate the electronic band structures and polarization profile of the Janus monolayer, and discuss how these electronic properties can be modified through interlayer interactions. We further connect our theoretical works to experimental measurements.

*This research was partially supported by NSF through the University of Washington Materials Research Science and Engineering Center DMR-1719797. T.C. acknowledges support from the Micron Foundation. **5:06PM D53.00010: Crystallography and Properties of Atomic Chirality in Two-dimensional Helical Crystal Tellurium**

CHANG NIU (Presenter), GANG QIU, Electrical and Computer Engineering, Purdue University, YIXIU WANG, Industrial Engineering, Purdue University, JINGKAI QIN, Electrical and Computer Engineering, Purdue University, JIE JIAN, HAIYAN WANG, Material Engineering, Purdue University, WENZHUO WU, Industrial Engineering, Purdue University, PEIDE (PETER) YE, Electrical and Computer Engineering, Purdue University — Chirality is a fundamental property of nature which is extensively studied in various of fields such as chemistry, material science and biology. In condensed matter physics, chiral crystals bring exotic optical, electrical and magneto properties due to the lack of mirror and inversion symmetry. Tellurium (Te) as one of the chiral materials is formed by van der Waals interaction between each one-dimensional helical chiral atom chains which determine the chirality of the whole crystal, and Te with opposite chiralities are described by different space groups: P3\(_1\)21 (right-handed) and P3\(_2\)21 (left-handed). Here we report that two dimensional tellurium twin flakes were identified with opposite chirality by electron crystallographic techniques (high-resolution transmission electron microscope image along different primary axes) and sulfuric acid etching method. These Te twin flakes offers an ideal platform to study the chirality-dependent material properties which can potentially be distinguished in electronic structure and transport properties. Our results pave a way for the research in fundamental properties of chiral materials in two-dimensional limit.

*The synthesis of 2D Te materials is supported by the National Science Foundation under Grant CMMI-1762698.

**Session D54 DCMP: Construction and detection of topological orders**

Mile High Ballroom 2A

**2:30PM D54.00001: A defect TQFT approach to fractons**

DAVID AASEN (Presenter), Microsoft Quantum, Microsoft Station Q, University of California, Santa Barbara, DANIEL BULMASH, University of Maryland, College Park, ABHINAV PREM, Princeton University, KEVIN SLAGLE, Physics, Caltech, DOMINIC WILLIAMSON, Physics, Stanford — We explore fracton phases from the perspective of topological quantum field theories. We argue that type I and type II gapped fracton models can be realized by a network of defects embedded into various 3+1D topological quantum field theories. The idea is that subdimensional excitations characteristic of fracton phases can appear due to mobility restrictions imposed by the defect network. We explicitly construct many well known examples of fracton phases and a few new models using the defect construction. As a byproduct the defect construction provides a generalized membrane-net condensate picture of fracton phases.

*This work was supported by a postdoctoral fellowship from the Gordon and Betty Moore Foundation, under the EPIQS initiative, Grant GBMF4304.
THOMAS SCHUSTER (Presenter), University of California, Berkeley, NATHANAN TANTIVASADAKARN, ASHVIN VISHWANATH, Harvard University, NORMAN YAO, University of California, Berkeley — Fractons are three-dimensional phases distinguished by the restricted mobility of their quasiparticles, and share many similarities to topological order in two dimensions. In this talk, we demonstrate that boundaries of well-known fracton models feature anomalous constraints arising from the emergent conservation laws that govern the bulk fracton order, in a manner similar to 2D topological orders such as the toric code. These constraints restrict the allowed boundary operators to those that commute with certain subsystem symmetry operations, determined both by the bulk fracton order and the direction of boundary termination. The constraints are anomalous in the sense that they cannot arise in any 2D local theory; we demonstrate this from a microscopic perspective, showing that the boundary operators' anticommutation relations are inconsistent with the constraints in any such theory. This gives rise to a rich phase diagram for the boundary theory, in correspondence with that of local 2D subsystem-symmetric systems.

ANDREY GROMOV (Presenter), Physics, Brown University — I will describe an effective field theory approach to the fracton order. In particular I will show how to construct a U(1) version of the Haah code from the principles of symmetry and gauge invariance.

HAN YAN (Presenter), Okinawa Inst of Sci & Tech — In this talk we reason that there is a universal picture for several different holographic toy model constructions, and a gravity-like bulk field theory that gives rise it. First, we observe that the perfect tensor-networks and hyperbolic fracton models are both equivalent to the even distribution of bit-threads on geodesics in the AdS space. Such picture is also a natural "leading-order" approximation to the holographic entanglement properties. Then, we argue that the rank-2 U(1) theory with linearized diffeomorphism as its gauge symmetry, also known as a case of Lifshitz gravity, is the bulk field theory behind such picture. The Gauss' laws and spatial curvature require the electric field lines along the geodesics to be the fundamental dynamical variables, which lead to geodesic string condensation. These results provide an intuitive way to understand the entanglement structure of gravity in AdS/CFT.

Localized representation and surface signature of Hopf insulators.
ALEKSANDRA NELSON (Presenter), Physik-Institut, University of Zurich, ARIS ALEXANDRADINATA, Department of Physics, University of Illinois at Urbana-Champaign, ALEXEY SOLUYANOV, Physik-Institut, University of Zurich — The Hopf insulator is a 3D topological insulator that can't be described in terms of a 10-fold classification. It also differs from fragile topological insulators. The main requirement for its existence is a two-rank Hamiltonian. In case when Hopf Hamiltonian has a trivial first Chern class, it obeys Z classification.

In our work, we address two questions. Firstly, we study the possibility for the Hopf insulator to possess localized Wannier representation and the existence of its topological obstructions. We propose that Wannier functions are exponentially localized and preserve the symmetries of the system. What obstructs the equivalence of the Hopf insulator to the atomic limit is the finiteness of the Wannier function width.

The second part of our work is related to the surface signature of the Hopf insulator. We claim that the surface states can be gapped out by surface potential without violating the symmetry or closing the bulk gap. However, surface states have a nontrivial first Chern number that equals to the bulk Hopf invariant. This bulk-edge correspondence can be explained by a new type of bulk-to-boundary Berry curvature flow originating from gauge-invariant magnetoelectric polarizability.

Lattice models that realize $\mathbb{Z}_n$-1-symmetry protected topological states for even $n^*$
LOKMAN TSUI (Presenter), XIAO-GANG WEN, Massachusetts Institute of Technology MIT — We study the lattice model of $\mathbb{Z}_n$-1-symmetry protected topological states (1-SPT) in 3+1D for even $n$. We write down an exactly soluble lattice model and study its boundary transformation. On the boundary, we show the existence of anyons with non-trivial self-statistics. For the $n=2$ case, where the bulk classification is given by an integer $m \mod 4$, we show that the boundary can be gapped with double semion topological order for $m=1$ and toric code for $m=2$. The bulk ground state wavefunction amplitude is given in terms of the linking numbers of loops in the dual lattice. Our construction can be generalized to arbitrary 1-SPT protected by finite unitary symmetry.

*LT is supported by the Croucher Fellowship for Postdoctoral Research. XGW is partially supported by NSF Grant No. DMS-1664412.
3:42PM D54.00007: Strong 3D planar subsystem symmetry-protected topological phases and their dual fracton orders*  TRITHEP DEVAKUL (Presenter), Princeton University, WILBUR SHIRLEY, Department of Physics, California Institute of Technology, JUVEN C WANG, Center of Mathematical Sciences and Applications, Harvard University — We classify subsystem symmetry-protected topological (SSPT) phases in 3+1D protected by planar subsystem symmetries: short-range entangled phases which are dual to long-range entangled abelian fracton topological orders via a generalized `gauging' duality. We distinguish between weak SSPTs, which can be constructed by stacking 2+1D SPTs, and strong SSPTs, which cannot. We identify signatures of strong phases, and show by explicit construction that such phases exist. A classification of strong phases is presented for an arbitrary finite abelian group. Finally, we show that fracton orders realizable via p-string condensation are dual to weak SSPTs, while those dual to strong SSPTs do not admit such a realization.

*This work is supported by the Charlotte Elizabeth Procter Fellowship at Princeton University. W.S. is supported by the National Science Foundation under award number DMR-1654340 and the Institute for Quantum Information and Matter at Caltech. 3:54PM D54.00008: Coupled wire constructions of 3D topological phases*  JOSEPH SULLIVAN (Presenter), Yale University — We present a general coupled wire construction in 3D in an effort to study novel topological phases of matter. Starting by stacking 1D quantum wires of free Dirac fermions into a rectangular array, interactions are added by introducing back scattering terms. The gapping terms are chosen to act on each plaquet of the array. By construction they mutually commute and hence completely gap out the bulk. The resulting theory is very rich, exhibiting many of the hallmarks of topological phases. We compute the ground state degeneracy on the 3 torus and study particular realizations which support fracton-like excitations.

*This work is supported by the NSF under award number DMR-1846109 and the Alfred P. Sloan research fellowship.
4:06PM D54.00009: Modeling Electron Fractionalization with Unconventional Fock Spaces

EMILIO COBANERA (Presenter), Department of Mathematics and Physics, SUNY Polytechnic Institute — It is shown that certain fractionally-charged quasiparticles can be modeled on D-dimensional lattices in terms of unconventional yet simple Fock algebras of creation and annihilation operators. These unconventional Fock algebras are derived from the usual fermionic algebra by taking roots (the square root, cubic root, etc) of the usual fermionic creation and annihilation operators. If the fermions carry non-Abelian charges like spin, then this approach fractionalizes the Abelian charges only. In particular, the mth-root of a spinful fermion is an operator that carries charge e/m and spin 1/2. While the exclusion statics is fixed by the root operation, there are several possible choices of quantum exchange statistics for fermion-root quasiparticles. These choices are tied to the dimensionality D = ... 1, 2, 3, of the lattice and the exchange statistics between fermions and fractionalized fermions. As an application of potential mesoscopic interest, I investigate numerically the hybridization of Majorana and parafermion zero-energy edge modes caused by fractionalizing but charge-conserving tunneling.

4:18PM D54.00010: Fractionalization and Anomalies in Symmetry-Enriched U(1) Gauge Theories

LIUJUN ZOU (Presenter), Perimeter Institute, SHANG-QIANG NING, University of Hong Kong, MENG CHENG, Yale University — We classify symmetry fractionalization and anomalies in a 3+1d U(1) gauge theory enriched by a global symmetry group G. We find that, in general, a symmetry-enrichment pattern is specified by 4 pieces of data: \( \rho \), a map from \( G \) to the duality symmetry group of this U(1) gauge theory, \( \nu \in H^2(\rho[G, U_T(1)]) \), \( p \in H^1(G, Z_T) \), and a torsor \( n \) over \( H^3(\rho[G, Z]) \). However, certain choices of \((\rho, \nu, p, n)\) are not physically realizable, i.e., they are anomalous. There are two levels of anomalies. The first level of anomalies, deconfinement anomalies, obstruct fractional excitations being deconfined. States with these anomalies can be realized on the boundary of a 4+1d long-range entangled state. In the absence a deconfinement anomaly, there can still be the more familiar ’t Hooft anomaly, which forbids certain types of symmetry fractionalization patterns to be implemented in an on-site manner. States with these anomalies can live on the boundary of a 4+1d short-range entangled state. We apply our results to some interesting physical examples.

4:30PM D54.00011: Coupled Wire Model of $\mathbb{Z}_2 \times \mathbb{Z}_2$ Orbifold Quantum Hall States*  POK MAN TAM (Presenter), Physics and Astronomy, University of Pennsylvania, YICHERN HU, Physics, University of Oxford, CHARLES L KANE, Physics and Astronomy, University of Pennsylvania — We construct a coupled wire model for a sequence of non-Abelian quantum Hall states occurring at filling factors $\nu = 2/(2M+q)$ with integers $M$ and even(odd) integers $q$ for fermionic(bosonic) states. They are termed $\mathbb{Z}_2 \times \mathbb{Z}_2$ orbifold states, which have a topological order with a neutral sector described by the $c=1$ orbifold conformal field theory (CFT) at radius $R^2 = p/2$ with even integers $p$. When $p=2$, the state can be viewed as two decoupled layers of Moore-Read (MR) state, whose neutral sector is described by the Ising $\times$ Ising CFT and contains a $\mathbb{Z}_2 \times \mathbb{Z}_2$ fusion subalgebra. We demonstrate that orbifold states with $p > 2$, also containing a $\mathbb{Z}_2 \times \mathbb{Z}_2$ fusion algebra, can be obtained by coupling an array of MR $\times$ MR wires together through local interactions. The corresponding charge spectrum of quasiparticles is also examined. The orbifold states constructed here are complementary to the $\mathbb{Z}_4$ orbifold states, whose neutral edge theory is described by orbifold CFT with odd integer $p$ and contains a $\mathbb{Z}_4$ fusion algebra.

4:42PM D54.00012: Properties of the Dice-Lattice and its Ribbons  RAHUL SONI (Presenter), NITIN KAUSHAL, ELBIO DAGOTTO, SATOSHI OKAMOTO, University of Tennessee, Knoxville — Previous theoretical studies established the existence of nearly flat bands with non-zero Chern numbers in the dice lattice using non-interacting electrons in the presence of spin-orbit coupling and magnetic field [1]. To pave the way towards the introduction of Hubbard correlation effects via numerical methods here we explore if the main properties of the dice lattice survive in ribbons where one direction is made much shorter than the other [2]. Surprisingly, we find a rich eigenvalue spectrum that continues to display flat bands even for the smallest ribbon such as the $N \times 2$. Real-space charge currents moving along the edges clearly develop. We observed the presence of non-zero Hall-conductance ($\sigma_{xy}^H$) and associated Quantum Anomalous Hall effect for all the ribbons investigated [3]. Time allowing, preliminary results for the effects of interaction ($U$) at half-filling on these ribbons will also be discussed using DMRG. In particular, for the $N \times 2$ system when no magnetic field is present the ground state is ferri-magnetic increasing $U$. The evolution of the edge currents with increasing $U$ will be presented.

Anyonic partial transpose

HASSAN SHAPOURIAN (Presenter), Harvard University, ROGER MONG, University of Pittsburgh, SHINSEI RYU, University of Chicago — A basic diagnostic of entanglement in mixed quantum states is known as the positive partial transpose and the corresponding entanglement measure is called the logarithmic negativity. Despite the great success of logarithmic negativity in characterizing bosonic many-body systems, generalizing the partial transpose to fermionic systems remained a technical challenge until recently when a new definition that accounts for the Fermi statistics has been put forward. In this talk, I will present our attempts to generalize partial transpose to anyons with fractional statistics. It turns out that there is a connection between the partial transpose and braiding statistics. As an application, I will show how the braiding matrix can be used to reproduce many-body topological invariants of 1D time-reversal symmetric topological superconductors.

Detecting Topological Order at Finite Temperature Using Entanglement Negativity*

TSUNG-CHENG LU (Presenter), University of California, San Diego, TIMOTHY HSIEH, Perimeter Institute for Theoretical Physics, TARUN GROVER, University of California, San Diego — We propose a scheme to diagnose finite temperature topological order using the long-range component of entanglement negativity, dubbed topological entanglement negativity. As a demonstration, we study the toric code model in d spatial dimension for d=2,3,4, and find that a topological ordered state at finite temperature has non-zero topological entanglement negativity, whose value is equal to topological entanglement entropy at zero temperature. To calculate entanglement negativity, we develop a general tool for any commuting projector Hamiltonians to derive the spectrum of a thermal state under partial transpose, allowing us to map the calculation of negativity to a classical statistical mechanics problem. Relatedly, using the idea of minimally entangled typical thermal states, we derive necessary conditions for the existence of finite temperature topological order in any CSS code Hamiltonians.

Aharonov-Bohm Effect without Using Vector Potential

XIANG LI (Presenter), Shanghai Jiao Tong University, HANS HANSSON, Stockholm University, WEI KU, Tsung-Dao Lee Institute — Aharonov-Bohm effect is a pure quantum effect that describes a phase shift of a quantum particle due to magnetic flux present in space inaccessible to the particle. Such a non-local effect appears to be impossible classically given the locality of coupling between a particle and magnetic field. Typically, this effect is accounted for via the use of a gauge-dependent vector potential, which extends to the entire space beyond the region with finite magnetic field and thus recovers the locality of the theory. This leads to a perspective of electromagnetic potential being more “fundamental” than the electromagnetic field in quantum mechanics, despite the gauge dependent nature of the vector potential. Here, we demonstrate that this effect can be completely accounted for by consideration of the gauge invariant magnetic field only, if the entire system is included in the analysis. This gauge invariant picture provides an alternative intuitive physical understanding that explicitly encapsulates the non-locality of quantum mechanics in the presence of magnetic field.
2:30PM D55.00001: Strain induced semimetal-insulator transition in monolayer 1T'-WTe₂
ZHAO CHENXIAO (Presenter), JINFENG JIA, Shanghai Jiao Tong Univ, JUNWEI LIU, department of physics, ust.hk — Monolayer 1T'-WTe₂ has exhibited clear quantized transportation originated from the quantum spin Hall phase, while the channel length with quantized conductance is restricted around 100 nm due to its semimetallic nature. To overcome this problem, it is crucial to find a way to engineer the electronic structure. Through a combined in-situ scanning tunneling microscopy/spectroscopy (STM/STS) and Density functional theory (DFT) study, we demonstrate that strain can effectively manipulate the band structure of monolayer 1T'-WTe₂ to realize a phase transition from a semimetal to an insulator upon application of a compressive strain along a axis or a tensile strain along b axis. Moreover, the topological edge states are found to be very robust against strains. Besides, we find that the out-of-plane distortions can also significantly change the band structure. Our results reveal the clear strain dependence of electronic properties and phases of monolayer 1T'-WTe₂, which provides an effective approach to realize the long-coherent quantized conductance for the further transport experiments verification.

2:42PM D55.00002: Finite-temperature spectroscopy in dirty helical Luttinger liquids*
TZU-CHI HSIEH (Presenter), Department of Physics, University of Colorado, Boulder, YANG-ZHI CHOU, Department of Physics, University of Maryland, College Park, LEO RADZIHOVSKY, Department of Physics, University of Colorado, Boulder — I will discuss a theory of finite-temperature momentum-resolved tunneling spectroscopy (MRTS) for disordered two-dimensional INTERACTING topological-insulator edges. The MRTS setup measures the spectral properties and THUS provides a complementary way (distinct from transport) to characterize helical Luttinger liquid edges of topological insulators. The (exact within bosonization) finite-temperature spectral function and the tunneling current of MRTS are derived in the presence of disorder and interaction. The theory provides a detailed analytical characterization of MRTS between helical edges, that should be of interest for corresponding experimental studies.

*Supported by the Simons Investigator Award through the James Simons Foundation (to LR)
2:54PM D55.00003: Atomically resolved study of the effect of back-gating on the band structure in monolayer WTe$_2$* YULIA MAXIMENKO (Presenter), YUEQING CHANG, LUCAS WAGNER, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign — Two-dimensional topological materials have generated a lot of excitement as systems potentially exhibiting quantum spin Hall (QSH) effect, ballistic 1D transport, and helical edge modes. Monolayer 1T’-WTe$_2$ has been demonstrated to be both a QSH insulator and a superconductor upon doping using electronic transport and photoemission spectroscopy on single crystal flakes and epitaxial films. Atomically-resolved scanning tunneling microscopy (STM) also demonstrated clear edge states on WTe$_2$ monolayer islands. Here, we report the first STM study of monolayer 1T’-WTe$_2$ with in-situ tuning of carrier concentration using back-gating. We demonstrate band structure changes in response to doping and back-gating and use first principle calculations to explain the observed effects.

*The STM studies were supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award #DE-SC0014335, and in part by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4860.

3:06PM D55.00004: Resolving the topological classification of bismuth with topological defects ABHAY NAYAK (Presenter), JONATHAN REINER, RAQUEL QUEIROZ, HUIXIA FU, Weizmann Institute of Science, CHANDRA SHEKHY, Max Planck Institute for Chemical Physics of Solids, BINGHAI YAN, Weizmann Institute of Science, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, NURIT AVRAHAM, HAIM BEIDENKOPF, Weizmann Institute of Science — Bulk boundary correspondence has been the cornerstone in the study of topological quantum materials. It has enabled the exploration of electronic bulk properties through the investigation of topological boundary modes. However, the growing diversity and profusion of topological classes has lead to ambiguity between classes sharing similar boundary phenomenology. This is the current status of bismuth, for which recent studies have suggested nontrivial classifications like strong or higher-order TI, both of which hosts 1D helical modes on their boundaries. Here, we use a novel approach to resolve the topological classification of bismuth by spectroscopically mapping the response of a topological lattice defect like screw dislocation using a scanning tunneling microscope. We find a 1D edge mode, bound to the step edges of bismuth, extending to the core of the screw dislocation without gapping out. This signifies that the edge mode binds to the topological defect, characteristic of a material with nonzero weak indices. This work paves the way for the identification of novel electronic topological phases through the study of boundary modes associated with topological defects.
Domain walls as possible realization of edge state coupling in a quantum spin Hall insulator  RAUL STÜHLER, ANDRÉ KOWALEWSKI, FELIX REIS, JOHANNES WEIS, JOERG SCHAEFER, Universität Würzburg, Germany, GANG LI, ShanghaiTech University, China, WERNER R HANKE, DIMITRI JUNGBLUT, BENEDIKT SCHARF, FERNANDO DOMINGUEZ TIJERO, EWELINA M HANKIEWICZ, RALPH CLAESSEN (Presenter), Universität Würzburg, Germany — The recently discovered monolayer system bismuthene/SiC(0001) is a promising candidate for the realization of a room temperature quantum spin Hall (QSH) effect. Previous experiments have established a large fundamental band gap (0.8 eV) and the existence of one-dimensional metallic edge states [1]. As expected for a QSH insulator, the electronic edge channels do not show any signs of backscattering from kinky edge sections that would manifest in interference phenomena. Notwithstanding, topological protection against defect scattering may become lifted when two helical edge channels are brought into direct proximity, resulting in quantum interference. By scanning tunneling microscopy we study phase-slip domain boundaries (DB) that form as result of bismuthene being a rt3 x rt3 R30° reconstruction on SiC(0001) as substrate. Kinks and disorder limit the longitudinal extent of these quasi one-dimensional topographic defects. By spectroscopic means we scrutinize quasi-particle interference along the DB that points towards a linear electronic dispersion strongly reminiscent of a Fabry-Pérot resonator. We discuss our findings as possible quantum interference between coupled helical edge states that are formed in the vicinity of a DB.

Drumhead surface state in ZrSiTe probed by scanning tunneling microscopy  BRANDON A STUART, SEOKHWAN CHOI (Presenter), JISUN KIM, Stewart Blusson Quantum Matter Institute, University of British Columbia, RAQUEL QUEIROZ, Department of Condensed Matter Physics, Weizmann Institute of Science, LUKAS MUECHLER, Center for Computational Quantum Physics, The Flatiron Institute, LESLIE Schoop, Department of Chemistry, Princeton University, DOUGLAS ANDREW BONN, SARAH A BURKE, Stewart Blusson Quantum Matter Institute, University of British Columbia — The family of materials ZrSiX (X = S, Se, Te) are topological nodal-line semimetals characterized by linear band crossings in 1-dimensional lines or loops in momentum space, rather than discrete points as in Dirac or Weyl semimetals. ZrSiTe has a non-symmorphic crystal symmetry, protecting nodal lines at high symmetry lines in the Brillouin zone (BZ). ZrSiTe is host to four nodal lines, two of which form loops in the BZ, one encircling gamma and the other encircling Z, and the other two forming lines that extend through the BZ. It was theoretically predicted that in the surface projection of ZrSiTe, the area between the nodal loops would contain a drumhead state, an exotic, topologically protected 2-dimensional surface state that links the nodal loops together [1]. Surface states have long been probed by scanning tunneling microscopy (STM) using quasiparticle interference (QPI) measurements, and have also been able to provide additional information on the topological nature of these states. Here, we show the first observed signature of electronic scattering within the drumhead state using low-temperature STM and QPI measurements.

3:42PM D55.00007: Symmetry dictated grain boundary state in a two-dimensional topological insulator MoTe$_2$  HYO WON KIM (Presenter), Samsung Adv Inst of Tech, SEOUNG-HUN KANG, HYUN-JUNG KIM, KISUNG CHAE, Korea Institute for Advanced Study, SUYEON CHO, Ewha Womans University, WONHEE KO, Oak Ridge National Laboratory, SANGJUN JEON, Chung-ang University, SUNG WNG KIM, Sungkyunkwan University, YOUNG-KYUN KWON, Kyung Hee University, YOUNG-WOO SON, Korea Institute for Advanced Study — Structural imperfections such as grain boundaries (GBs) and dislocations are ubiquitous in solids and have been of central importance in understanding the nature of polycrystals. In addition to their classical roles, the advent of topological insulators (TIs) offers a chance to realize distinct topological states bound to them. Although dislocations inside three-dimensional TIs are one of the prime candidates to look for, their direct detection and characterization is challenging. Instead, in two-dimensional (2D) TIs, their creations and measurements are easier and, moreover, topological states at the GBs or dislocations are intimately related to their lattice symmetry. However, such roles of crystalline symmetries of GBs in 2D TIs have not been definitively measured yet. Here, we present the first direct evidence of a symmetry-enforced Dirac type metallic state along a GB in 1T'-MoTe$_2$, a prototypical 2D TI. Using scanning tunneling microscopy, we show a metallic state along a grain boundary with non-symmorphic lattice symmetry and its absence along another boundary with symmorphic symmetry. Our large-scale atomistic simulations demonstrate hourglass like nodal-line semimetallic in-gap states for the former, whereas the gap opens for the latter, explaining our observation well.

3:54PM D55.00008: Scanning Tunneling Microscopy Imaging of Electronic Waves on the Surface of Molecular Beam Epitaxy Grown Ag$_2$Se*  SAMIRA DANESHMANDI (Presenter), YANFENG LYU, HANMING YUAN, CHING (PAUL) W CHU, Univ of Houston — Recently, silver chalcogenide systems are being studied as possible candidates for topological insulators (TIs). While experimental works have been reported only on the electronic transport of anisotropic Dirac fermions in silver chalcogenides, no local scanning tunneling microscopy (STM) studies have been done on these materials. Here, we report the synthesis of epitaxial Ag$_2$Se nanostructures using molecular beam epitaxy (MBE) method. Based on atomic-resolved STM images, a new monoclinic structure is proposed for the MBE grown Ag$_2$Se, which was not seen in this system before. The electronic structures of the Ag$_2$Se have been investigated by means of scanning tunneling spectroscopy (STS). To test the unique feature of topological surface states (TSSs), we conducted a low-temperature STM/S study on the surface states of Ag$_2$Se films. On the selenium (Se)-terminated surfaces, evidence for TSSs are observed in the quasi-particle interference patterns. The existence of standing waves strongly supports the surface nature of topological states. Our results may help resolve the current controversy on the topological nature of Ag$_2$Se.

*The work performed at Houston is supported by USAFOSR Grant FA9550-15-1-0236, TLL Temple Foundation, JJ&R Moores Endowment, and State of Texas through TCSUH.
JIANFENG GE (Presenter), Leiden University, KAIYUAN GU, Peking University, ADITYA MAHADEVAN, Harvard University, HAIMEI ZHANG, Wellesley College, JIAOXUAN GUO, HAO TANG, Peking University, JENNIFER E. HOFFMAN, Harvard University — Topological surface states are unconventional two-dimensional electronic states that are protected from backscattering and overcome surface barriers. Previous experiments have shown that topological surface states have an enhanced transmission and a reduced reflection at the common bilayer step edges on the (111) surface of topological semimetal antimony (Sb), indicating the presence of backscattering against bilayer step edges. We use scanning tunneling microscopy and spectroscopy to investigate Sb(111) surface, which exhibits novel monolayer step edges. We demonstrate that topological surface states transmit through these monolayer step edges perfectly without backscattering. Furthermore, we discover localized states on these edges resembling the helical edge states originating from higher-order topology.

*Experiments were supported by National Science Foundation DMR-1410480.

CHI MING YIM (Presenter), DIBYASHREE CHAKRABORTI, LUKE RHODES, Univ of St Andrews, SEUNGHYUN KHIM, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, PETER WAHL, Univ of St Andrews — Rashba spin-splitting enables manipulation of spins with electric fields, opening avenues to transformative device concepts. In most materials where Rashba-spin splitting has been observed, the underlying electronic structure is uncorrelated and therefore well described by electronic structure calculations. This is not the case for correlated systems, in which electronic repulsion is needed to be accounted for. Here, we report a scanning tunnelling microscopy, quasiparticle interference (QPI) study of the two-dimensional electron gas (2DEG) at the surface of PdCoO$_2$, a correlated oxide system reported to exhibit giant Rashba-like spin-splitting [1] Our QPI data reveal a complex quasiparticle scattering pattern which, in particular, consists of a rounded-hexagon shaped, hole-like scattering band that disperses with averaged effective masses of $\sim -13.0$ m$_e$ and $\sim -11.1$ m$_e$ along the G-K and G-M directions, respectively. Through comparison with tight-binding calculations, we also show that the scattering is well described once the spin-selection rules are accounted for. Observation of quantized states in a 5-nm wide terrace region confined by a set of parallel step-edges is also discussed.
**4:30PM D55.00011: Observation of backscattering induced by magnetism in the topological hinge state of bismuth**

BERTHOLD JAECK (Presenter), YONGLONG XIE, ANDREI BERNEVIG, ALI YAZDANI, Princeton University — We have investigated the effects of time-reversal symmetry breaking on the topological hinge state of bismuth. Using spectroscopic imaging and spin-polarized measurements with an STM, we have compared quasiparticle interference (QPI) occurring in the hinge state of a pristine bismuth bilayer with that occurring in the hinge state of a bilayer, which is terminated by ferromagnetic iron clusters. Our experiments on the decorated bilayer edge reveal an additional QPI branch that can be associated with spin-flip scattering across the Brioullin zone center between time-reversal band partners. The observed QPI characteristics exactly match with theoretical expectations for a topological edge state having one Kramer's pair of bands and, thus provide spectroscopic evidence for back scattering in the topological edge states of bismuth.

**2:30PM D56.00001: Van Hove singularity and stress-induced Fermi surface tuning in Sr$_2$RuO$_4$**

AARON CHRONISTER (Presenter), ANDREJ PUSTOGOW, University of California, Los Angeles, YONGKANG LUO, Huazhong University of Science and Technology, YUE-SHUN SU, University of California, Los Angeles, ANDREW MACKENZIE, CLIFFORD W HICKS, Max Planck Institute for Chemical Physics of Solids, ERIC BAUER, Los Alamos National Laboratory, NAOKI KIKUGAWA, National Institute for Material Science, Tsukuba Japan, STUART BROWN, University of California, Los Angeles — Application of in-plane uniaxial stress to the quasi-2D correlated material Sr$_2$RuO$_4$ results in pronounced changes to the physical properties; most familiar is a factor 2.5 increase in superconducting transition temperature. The normal state of Sr$_2$RuO$_4$ is also impacted. Specifically, the crossover temperature to standard Fermi Liquid properties can be tuned from T=30 K to almost 0 K with -0.44% strain. These anomalous properties are associated with the proximity of the Fermi energy ($E_F$) to a sharp singularity in the density of states, which can be tuned to $E_F$ and thus varies strongly on the scale of the Zeeman interaction and thermal energies. Reported here are $^{17}$O NMR hyperfine shifts over a wide range of stress, field, and temperature. Simple modeling of the results indicates that the difference between $E_F$ and the energy of the van Hove singularity plays a dominant role in the normal state properties for temperatures of order 300 K and below.

*Support from the National Science Foundation (DMR-1709304) and by the Laboratory Directed Research and Development (LDRD) programme of Los Alamos National Laboratory (20170204ER) is acknowledged.
2:42PM D56.00002: Density wave at the reconstructed surface of Sr$_2$RuO$_4$ and implications for quantum criticality  CAROLINA DE ALMEIDA MARQUES (Presenter), LUKE RHODES, Univ of St Andrews, VERONICA GRANATA, ROSALBA FITTIPALDI, ANTONIO VECCHIONE, CNR-SPIN, ANDREAS ROST, PETER WAHL, Univ of St Andrews — Many of the exciting properties of strongly correlated electron materials, including high-temperature superconductivity, are intricately linked to proximity to a quantum phase transition, a transition through which a material can be tuned as a function of an external control parameter other than temperature. Here, we propose that the reconstructed surface layer of Sr$_2$RuO$_4$ constitutes an ideal material to study the physics of quantum criticality. Using ultra-low temperature scanning tunneling microscopy, we observe the signature of a density wave in topographic images of the reconstructed surface of Sr$_2$RuO$_4$ which is linked with a sharp peak in the tunneling spectra, a few mV below the Fermi energy. We identify this peak as being the surface van Hove singularity (vHs) by comparing differential conductance ($dI/dV$) maps with a tight-binding model. Magnetic field splits the vHs peak, pushing one branch towards the Fermi energy. At 0T, the $dI/dV$ maps reveal a density wave with the periodicity of the reconstructed surface unit cell at the vHs peak energy. The energy at which this density wave occurs follows the field-split vHs. We discuss possible origins of this density wave as well as possible consequences for quantum criticality.

2:54PM D56.00003: QSGW+DMFT+BSE description of superconductivity in Sr$_2$RuO$_4$*  SWAGATA ACHARYA (Presenter), DIMITAR PASHOV, MARK SCHILFGAARDE, Physics, Kings College London — The nature of pairing in Sr$_2$RuO$_4$ continues to be widely debated, in particular, the possibility of a triplet origin of Cooper pairs. Its complexity, with multiple low-energy scales involving subtle interplay among spin, charge and orbital degrees of freedom, calls for advanced theoretical approaches which treat on equal footing all electronic effects. We present a novel approach, a detailed \emph{ab initio} theory, coupling quasiparticle self-consistent GW approximation with dynamical mean field theory (DMFT). We report that the superconducting instability has multiple triplet and singlet components. In the unstrained case the triplet eigenvalues are larger than the singlets. Under uniaxial strain, the triplet eigenvalues drop rapidly and the singlet components increase. This is concomitant with our observation of spin and charge fluctuations shifting closer to wave-vectors favoring singlet pairing in the Brillouin zone. We identify a complex mechanism where charge fluctuations and spin fluctuations co-operate in the even-parity channel under strain leading to increment in $T_c$, thus proposing a novel mechanism for pushing the frontier of $T_c$ in unconventional "triplet" superconductors.

Non-monotonic temperature dependence of the Hall coefficient in Hund's metals

MANUEL ZINGL (Presenter), Flatiron Institute, Center for Computational Quantum Physics, JERNEJ MRAVLJE, Department of Theoretical Physics, Institute Jozef Stefan, MARKUS AICHHORN, Institute of Theoretical and Computational Physics, Graz University of Technology, OLIVIER PARCOLLET, ANTOINE GEORGES, Flatiron Institute, Center for Computational Quantum Physics — A non-monotonic temperature dependence of the Hall coefficient has been reported for several strongly correlated materials, e.g. Sr$_2$RuO$_4$, Sr$_3$Ru$_2$O$_7$, LiFeAs and FeSe [1]. One common signature of these Hund’s metals is a strong orbital selectivity of electronic correlations. On the example of Sr$_2$RuO$_4$, where the Hall coefficient exhibits two sign reversals, we show that the behavior of the Hall coefficient is directly linked to the temperature dependence of the ratio of inelastic scattering rates between the different correlated orbitals [2]. In our picture the sign reversals reflect two important crossovers in the physics of this material: (I) from a high-T incoherent to a coherent regime at low-T associated with a remarkably large ratio of scattering rates, and (II) from inelastic to impurity-dominated scattering. This qualitative picture is supported by quantitative calculations using Boltzmann transport theory in combination with dynamical mean-field theory, taking into account the effect of spin–orbit coupling.

Fluctuation stabilised spin-density-wave order and the phase diagram of Sr$_3$Ru$_2$O$_7$

STEPHEN HAYDEN (Presenter), RICHARD WAITE, CHRIS LESTER, University of Bristol, UK, ROBIN PERRY, University College London, UK, SILVIA RAMOS, University of Kent, UK, DMITRY KHALYAVIN, FABIO ORLANDI, PASCAL MANUEL, ISIS, Rutherford Appleton Laboratory, UK — Sr$_2$Ru$_3$O$_7$ is a unique metal in which a magnetic field of about 8 Tesla can induce spin density wave (SDW) order [1]. There are two SDW ordered phases (A and B) with different incommensurate wavevectors. Here we use magnetic neutron diffraction to characterise the magnetic order as a function of magnetic field strength and direction. The order is observed for all field directions investigated. Our results suggest that the SDW is closely linked to Fermi surface nesting and is probably stabilised by magnetic fluctuations. Thus the SDW order explains many (magnetic, transport and thermal) anomalies in this material.

3:30PM D56.00006: Interplay between Spatially Modulated Nematic and Spin-Density Wave Order in Sr$_3$Ru$_2$O$_7$  JONATHAN CLEPKENS (Presenter), HAE-YOUNG KEE, Univ of Toronto — The anisotropic resistivity observed in Sr$_3$Ru$_2$O$_7$ [1] has led to a variety of theoretical studies proposing microscopic routes to a nematic phase in the material. However, the discovery of spin-density wave (SDW) order in the same region of phase space [2] has cast some doubt on this picture, even though there are open issues that cannot be understood within the SDW scenario. Here we study the interplay between spatially modulated nematic and SDW order from a microscopic viewpoint. Mean-field results illustrating the formation of the finite momentum nematic and SDW order will be presented. Implications towards the importance of bilayer coupling, spin-orbit coupling and the presence of a van-Hove singularity in Sr$_3$Ru$_2$O$_7$ will also be discussed.

3:42PM D56.00007: Metal-Insulator and Magnetic Phase Diagram of Ca$_2$RuO$_4$ from Auxiliary Field Quantum Monte Carlo and Dynamical Mean Field Theory*  HAO SHI (Presenter), Simons Foundation, HONGXIA HAO, Department of Chemistry, Brown University, ANTOINE GEORGES, ANDREW MILLIS, Simons Foundation, BRENTDA M RUBENSTEIN, Department of Chemistry, Brown University, QIANG HAN, Department of Physics, Columbia University — Layered perovskite ruthenium oxides exhibit a striking series of metal-insulator and magnetic-nonmagnetic phase transitions easily tuned by temperature, pressure, epitaxy, and nonlinear drive. In this work, we combine results from two complementary states of the art many-body methods, Auxiliary Field Quantum Monte Carlo and Dynamical Mean Field Theory, to determine the low-temperature phase diagram of Ca$_2$RuO$_4$. Both methods predict a low-temperature pressure-driven metal-insulator transition coincident with a structural transition and accompanied by a ferromagnetic-antiferromagnetic transition. The properties of the ferromagnetic state are dominated by the ruthenium xy orbital while properties of the antiferromagnetic state are dominated by the xz and yz orbitals. Differences of detail in the predictions of the two methods are analyzed. The work is theoretically important as an application of the auxiliary field quantum Monte Carlo method to an orbitally degenerate system with both Mott and Hund's physics and provides an important comparison of the dynamical mean-field and auxiliary field quantum Monte Carlo methods.

*Support by NSF, DOE, and the Alfred P. Sloan Foundation. The Flatiron Institute is a division of the Simons Foundation
3:54PM D56.00008: Spin-orbit interpretation of the Higgs mode in Ca$_2$RuO$_4$*  PAUL SARTE
(Presenter), California NanoSystems Institute/Materials, University of California, Santa Barbara, CHRIS STOCK, Univ of Edinburgh, BRENDEX ORTIZ, STEPHEN WILSON, California NanoSystems Institute/Materials, University of California, Santa Barbara — The role played by spin-orbit coupling in the determination of a system’s magnetism has recently been the subject of intense study, with particular interest being placed on magnets based on Ru$^{4+}$ and Ir$^{4+}$, revealing a wealth of novel emergent phenomena. Stemming from the complex interplay of comparable values for $J$ and $\lambda$, the parameterization for such phenomena has proven challenging. One particular example corresponds to the modeling of the low energy magnetic fluctuations, where conventional approaches often require complicated phenomenological Hamiltonians. Using the 4$d$ layered antiferromagnet Ca$_2$RuO$_4$ as a case study, we demonstrate that a mean-field multilevel spin-orbit exciton model employing a minimalist Hamiltonian captures the main features of the low energy magnetic excitation spectrum. Corresponding to a tetragonally-distorted $A$-centered antiferromagnetic unit cell, the model accounts for the softening and longitudinal polarization of the Higgs mode. The success of such a minimalist Hamiltonian in capturing such a rich spectrum for a 4$d$ magnet, suggests that the spin-orbit exciton model may be a suitable alternative to traditional approaches.

4:06PM D56.00009: Strain-mediated Mott transition in Ca$_2$RuO$_4$ induced by a dc current
ALFRED ZONG (Presenter), ANSHUL KOGAR, Massachusetts Institute of Technology MIT, HENGDI ZHAO, University of Colorado, Boulder, QIAN LI, Argonne National Laboratory, YIFAN SU, Massachusetts Institute of Technology MIT, SAMUEL D MARKS, Argonne National Laboratory and University of Wisconsin-Madison, GANG CAO, University of Colorado, Boulder, HAIDAN WEN, Argonne National Laboratory, NUH GEDIK, Massachusetts Institute of Technology MIT — In a Mott insulator, the delicate balance among several competing energy scales gives rise to a plethora of ground states, which may be tuned into one another by pressure, electric field, photoexcitation among other perturbations. Owing to many degrees of freedom present in the system, understanding Mott transitions remains difficult. Recently, Ca$_2$RuO$_4$ has emerged as a new platform for studying the insulator-to-metal Mott transition. A dramatic change in its structural and optical properties across the phase boundary allows a multimodal approach to investigate the transition in space and time. Here, we report *in situ* transport, optical, and X-ray microscopy measurements on current-induced Mott transition in Ca$_2$RuO$_4$. We find that lattice strain plays a central role in this spatially-inhomogeneous transition, whose temporal evolution is characterized by local fluctuations in temperature. The present work clarifies important aspects of the current-induced Mott transition and provides insights into future applications that harness such electromagnetic control.
4:18PM D56.00010: Tailoring the ferromagnetic easy axis of Ca$_2$RuO$_4$ via epitaxial strain

LUDI MIAO (Presenter), HARI NAIR, NATHANIEL SCHREIBER, JACOB RUF, MATTHEW FU, YONGHUN LEE, CELESTA CHANG, JACOB RUFF, DAVID MULLER, DARRELL SCHLOM, KYLE M SHEN, Cornell University — Magnetism in strongly correlated ruthenates has been a central topic in condensed matter physics, where the spin degree of freedom is has a strong interplay with lattice, charge and orbital degrees of freedom. For instance, the Mott insulator Ca$_2$RuO$_4$ (CRO) can be turned into a ferromagnetic metal under epitaxial strain or hydrostatic pressure. Here, we have grown coherently strained CRO thin films on various substrates including SrLaAlO$_4$ and YAlO$_3$ via molecular beam epitaxy and investigated the strain effect on their magnetic properties. We have used angle-resolved magnetoresistance measurements to characterize the ferromagnetic easy axes of these films, and found that they are also drastically different from CRO bulk, and show how the magnetic easy axes can be tuned as a function of epitaxial strain. Our results manifest the complex interplay between the spin, lattice and orbital degree of freedom in CRO, as well as demonstrate a practical approach to tailor the magnetic properties in strongly correlated oxide materials via epitaxial strain, in general.

4:30PM D56.00011: Imaging the current-driven metal–insulator transition in Ca$_2$RuO$_4^*$

GIORDANO MATTONI (Presenter), SHINGO YONEZAWA, Physics, Kyoto University, FUMIHIKO NAKAMURA, Education and Creation Engineering, Kurume Institute of Technology, YOSHITERU MAENO, Physics, Kyoto University — The flow of electric current is a powerful tool to alter the ground state of strongly correlated ruthenates, where novel material properties emerge in non-equilibrium steady states [1,2,3]. Despite the efforts to investigate these phenomena, the microscopic mechanism and the physical quantities responsible for the current-induced phase changes have not been clarified yet.

Here, I will present our recent results based on thermal imaging of single-crystal Ca$_2$RuO$_4$ while triggering its metal–insulator transition with the flow of direct current. By measuring the infrared thermal emission of the material and exploiting the different emissivity of the metallic and insulating state, we observe the formation of phase-separated regions which can be controlled and stabilised by current. We determine the correlation between current density and the metal–insulator transition, discussing the interplay between electronic effects and localised Joule heating. Our technique provides a fundamental step towards understanding the mechanism regulating current-induced phenomena in quantum materials.

**4:42PM D56.00012: Pump-probe Nano-spectroscopy of Mott Insulating Ca$_2$RuO$_4$**
ROCCO VITALONE (Presenter), AARON STERNBACH, BEN FOUTTY, ALEXANDER MCLEOD, Physics, Columbia University, CHANCHAL SOW, Physics, Kyoto University, FUMIHIKO NAKAMURA, Department of Education and Creation Engineering, Kurume Institute of Technology, YOSHITERU MAENO, Physics, Kyoto University, ABHAY PASUPATHY, DMITRI BASOV, Physics, Columbia University — Ca$_2$RuO$_4$ is a Mott Insulator that exhibits a temperature-induced insulator to metal transition occurring slightly above room temperature. Further, Ca$_2$RuO$_4$ exhibits a current-driven IMT at room temperature and current-induced diamagnetism below 50K. These discoveries, particularly the latter, imply that the application of current can expose a previously hidden state in Ca$_2$RuO$_4$. Motivated by the current induced transition, we conducted nanoscale pump-probe measurements to explore the phase diagram further. In our experiments, we study both the static and photo-induced response with nano-FTIR measurements to interrogate the dynamics of the spectral response throughout the mid-IR. The static spectra reveal a large phonon resonance of the in-plane stretching mode of the Ru-O bonds in the insulating state, while the metallic state demonstrates a flat, Drude like response. The photo-induced spectra reveal an initial suppression of the phonon mode and a noticeable increase in the Drude response at later times. We interpret the response as an initial injection of charge carriers that screen the phonon mode while their thermalization at later times leads to the Drude-like response.

*NDSEG Fellowship*

**4:54PM D56.00013: Magnetic phase tuning in Ca$_2$Ru$_{1-x}$Fe$_x$O$_4$: A structural perspective**
SONGXUE CHI (Presenter), FENG YE, Neutron Scattering Division, Oak Ridge National Laboratory, GANG CAO, Physics, University of Colorado Boulder, HUIBO CAO, JAIME FERNANDEZ-BACA, Neutron Scattering Division, Oak Ridge National Laboratory — The crystalline and magnetic structures of Ca$_2$Ru$_{1-x}$Fe$_x$O$_4$ (x=0.02, 0.05, 0.08 and 0.12) have been studied using neutron scattering and X-ray diffraction. The Fe-doping reduces the Ru-O bond length in both apical and planar directions. The smaller Ru(Fe)O$_6$ octahedra leads to its reduced distortion. The Pbca space group is maintained and so is the apical flattening. Warming has similar effect as Fe-doping in releasing the distorted octahedra except an abrupt change of flattening across the Neel temperature in x=0.08. Two types of antiferromagnetic orders, A- and B-centered phases with the same in-plane spin arrangement but different stack sequences, have been found. The Fe induced structure with relaxed octahedra seems to prefer the B-phase to the A-centered one, which is systematically overwhelmed and replaced as the Fe-doping increases. The nature of the magnetic phase competition and its connection to its host structure is discussed.
5:06PM D56.00014: Emergence of Competing Stripe Phase near the Mott Transition in Ti-doped Bilayer Calcium Ruthenates*  ASHISH GANGSHETTIWAR (Presenter), University of Texas at Austin, YANGLIN ZHU, Physics, Penn State University, JIN PENG, Tulane University, YU WANG, Physics, Penn State University, ZHANZHI JIANG, University of Texas at Austin, ZHIQIANG MAO, Physics, Penn State University, KEJI LAI, University of Texas at Austin — The physics of nanoscale phase separation is at the heart of strongly correlated materials, where multiple degrees of freedom such as charge, spin, lattice, and orbital are simultaneously active. Using microwave impedance microscopy, we spatially resolved the coexisting phases on a Ca₃(Ru₀.₉Ti₀.₁)₂O₇ bulk crystal during the metal-insulator transition. Different from a typical first-order phase transition where coexistence of the two terminal phases takes place, a new stripe phase oriented along the in-plane crystalline axes emerges inside both the G-type antiferromagnetic insulating state and paramagnetic metallic state. The effect of this electronic state can be observed in macroscopic measurements, allowing us to construct a phase diagram that takes into account the energetically competing phases. Our work provides a model approach to correlate macroscopic properties and mesoscopic phase separation in complex oxides.

5:18PM D56.00015: Nano-resolved insulator-metal domain textures in a polar bilayer ruthenate  ALEXANDER MCLEOD (Presenter), RAN JING, JEDRZEJ WIETESKA, Physics, Columbia University, LEIXIN MIAO, Materials Science and Engineering, Penn State University, BEN FOUTTY, Physics, Columbia University, RUI ZU, Materials Science and Engineering, Penn State University, GIULIANO CHIRIACO, QIANG HAN, Physics, Columbia University, DANilo PUGGIONI, JAMES RONDINELLI, Materials Science and Engineering, Northwestern University, ANDREw MILLIS, Physics, Columbia University, VENKATRAMAN GOPALAN, Materials Science and Engineering, Penn State University, ZHIQIANG MAO, Physics, Penn State University, NASIM ALEM, Materials Science and Engineering, Penn State University, ABHAY PASUPATHY, DIMITRI BASOV, Physics, Columbia University — The 4d transition metal oxides of the Caₙ₊₁RuₙO₃ₙ₊₁ perovskite family have recently garnered interest for their correlated electron physics and strong sensitivity to external stimuli like strain, temperature, and even electric current. The bilayer ruthenate Ca₃Ru₂O₇ exhibits a structural distortion producing a polar metal and, under Ti substitution for Ru, a correlated antiferromagnetic insulator. Through low-temperature nano-infrared imaging, we reveal a spontaneous striped texture of coexisting insulating and metallic domains in single crystals across their insulator-metal phase transition at T=70-100K. Under in situ uniaxial strain, we image anisotropic nucleation and growth of these domains, rationalized through on-demand control of a spontaneous Jahn-Teller distortion. Through high resolution transmission electron microscopy, we also reveal the detailed interplay between this textured phase coexistence and the displacive orientations, volumetric structures, and domain boundaries among polar twin domains in these crystals. These novel imaging methods afford new insights into strain- and structure-mediated manipulation of the insulator-metal transition in 4d metal oxides and the ubiquity of phase coexistence even in pristine single crystals.

Monday, March 2, 2020 2:30 PM - 5:30 PM
2:30PM D57.00001: Ultra-high sensitive gas sensor based on graphene/carbon nanotube barristor  
YOUNGGYU YOU (Presenter), DO-HYUN PARK, JUN-HO LEE, INCHUL CHOI, KonKuk Univ, SUNG-IL JO, GOO-HWAN JEONG, Kangwon Univ, ELEANOR CAMPBELL, University of Edinburgh, HYUN-JONG CHUNG, JHANG SUNG HO, KonKuk Univ — We have investigated switching characteristics in graphene/semiconducting single-walled carbon nanotube (SWCNT) junction device, so-called graphene/SWCNT barristor. We modulated the Schottky barrier between the graphene and the carbon nanotube by using top and bottom gate electrodes, and achieved on-off ratio of $10^8$ and the subthreshold swing of 74 mV/dec with high current density. In addition, we demonstrated the potential of our device as a NO$_2$/NH$_3$ gas sensor. Graphene/SWCNT barristor showed the $10^7$ % of sensitivity for the 100 ppm NO$_2$ gas, and $10^5$ % of sensitivity for the 100 ppm NH$_3$ gas. Also, our device is sensitive enough to detect NO$_2$ gas down to 25 ppb concentration with 400 % sensitivity.

2:42PM D57.00002: Circular nanoelectromechanical resonators based on hexagonal boron nitride graphene heterostructures  
ROHIT KUMAR (Presenter), DERIC W SESSION, HARRISON PAAS, RYUICHI TSUCHIKAWA, VIKRAM V DESHPANDE, University of Utah — 2D materials like graphene and h-BN, to name a few, when layered on top of each other offer a new class of metamaterials. Especially, the twisting degree of freedom between two layers has opened the window for new phenomenon not explored before. The mechanical properties of these heterostructures in the form of nanoelectromechanical systems (NEMS) have not been studied extensively. Their exceptional attributes like ultra-low mass, robustness and high tunability make 2D materials suitable for NEMS which holds promise for various technological applications viz. ultrafast sensors, actuators etc. We report fabrication and characterization of hexagonal-boron nitride (h-BN) graphene heterostructure based circular nanoelectromechanical resonators on sapphire substrates. The device is measured at cryogenic temperatures and exhibits multiple mode frequencies which are highly tunable with gate voltage. A continuum mechanics model is employed to analyze the transmission ($S_{21}$) data of fundamental mode. Parameters like built-in tension obtained from the fit are used to identify the indices (m, n) of higher mechanical modes observed for the device. NEMS could offer a way to study the electronic phenomena such as superconductivity in twisted bilayer graphene heterostructures.
2:54PM D57.00003: Advances in MEMS based Strain Engineering of 2D Materials*  MOUNIKA VUTUKURU (Presenter), ZHUOFA CHEN, ANNA K SWAN, Boston Univ — Strain on 2D materials is an exciting avenue to explore material properties as well as induce novel phenomena, such as strain-dependent electron-hole plasma (EHP) formation in MoS2, or pseudo-magnetic field generation in graphene. In this work, we successfully incorporate MoS2 and graphene with microelectromechanical systems (MEMS) to controllably introduce strain, while simultaneously observing 2-terminal transport and electro-optical changes. We fabricate suspended 2D material integrated MEMS devices using a novel polymer transfer microstructure without damaging the MEMS or the 2D film. By electrically powering our devices, suspended 2D materials undergo controllable, reversible uniaxial strain which we characterize by optical spectroscopy. Equipped with two-terminal contacts, we explore the conductance of suspended 2D materials while simultaneously straining the material in air, with the goal of achieving different strain gradients for accessing novel physics.

*This work is supported by NSF DMR grant 141108.

3:06PM D57.00004: Probing layered magnets with graphene van der Waals heterostructures  JESSE BALGLE (Presenter), Physics, Washington University in St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, ERIK HENRIKSEN, Physics, Washington University in St. Louis — Layered magnets are promising platforms for science and applications including novel quantum magnetic phases, nanoscale magnetic memory, and spintronics devices. However common bulk probes such as neutron and x-ray scattering or thermal probes are difficult or impossible to use to characterize these materials in the few-layer limit. We seek to develop new approaches for probing devices incorporating single-/few-layer magnets. Electronic transport in graphene can be influenced by both nearby and nonlocal scatterers. We have found that the resistance of graphene exhibits a nonmonotonic change with temperature when placed in contact with a material undergoing a magnetic phase transition. This is reminiscent of “critical resistivity” measurements in (anti-)ferromagnetic metals dating back over 50 years, which show that transport can be sensitive to spin-scattering. Motivated by these findings, we explore transport in graphene separated from layered magnets by thin hexagonal boron nitride (hBN). We find unusual nonmonotonic changes in graphene resistance persist even when the graphene is only in contact with hBN, suggesting that nearby magnetic materials impact transport. We show results for devices incorporating magnetic metals (Gd, Dy) as well as layered magnets α-RuCl3 and FePS3.
3:18PM D57.00005: NEGF simulations of metal contacts for graphene nanoribbon based device  
HANCHENG QIN (Presenter), WENCHANG LU, JERRY BERNHOLC, North Carolina State University — For nanoscale electronic devices, the precise atomic structure of the metal contact plays a significant role on the performance of the device. We use an accurate, DFT-based non-equilibrium Green's function method with variationally-optimized localized orbitals to study contacts between different metals and graphene and/or graphene nanoribbons (GNRs). For on-top metal contacts not chemically bound to graphene, we have found that Ti contacts have lower resistance than other metals, such as Au, Ca, Ir, Pt, and Sr. We will discuss channel length effects on the off-state current and the required minimum channel and metal-graphene contact lengths for applications. Other contact structures (side contacts with chemical bonds) will also be discussed.

3:30PM D57.00006: An ultra-high vacuum system for fabricating 2D material devices  
SHUAIFEI GUO (Presenter), Fudan University, SATORU MASUBUCHI, University of Tokyo, NAI ZHOU WANG, University of Science and Technology of China, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, XIANHUI CHEN, University of Science and Technology of China, TOMOKI MACHIDA, University of Tokyo, YUANBO ZHANG, Fudan University — Atomically thin two-dimensional (2D) materials exhibit a rich set of electronic properties that may impact future electronic and optoelectronic applications. Many 2D materials, however, are prone to degradation in the presence of trace amount of oxygen or water vapor. The study of the intrinsic properties of these 2D materials requires protection from degradation agents during sample fabrication process. To this end, we design and build an ultra-high vacuum (UHV) system, in which the entire sample fabrication is performed under a base pressure lower than $5 \times 10^{-10}$ mbar. We demonstrate the functionality of this UHV fabrication system by fabricating black phosphorus heterostructures completed with electrical contacts and gate electrode for transport measurements.

3:42PM D57.00007: Integration of 2D materials for Device applications [Invited]  
LAIN-JONG LI (Presenter), TSMC — Selected by Focus Topic Organizer (Deji Akinwande)
Towards the ideal diode: Half-metal spin-gapless semiconductor junctions based on 2D materials*  

ERSOY SASIOGLU (Presenter), THORSTEN AULL, Institute of Physics, Martin Luther University Halle-Wittenberg, STEFAN BLUEGEL, Peter Grünberg Institut, Forschungszentrum Jülich, INGRID MERTIG, Institute of Physics, Martin Luther University Halle-Wittenberg — Conventional semiconductor diodes have a junction barrier that electrons have to overcome and thus they have a threshold voltage \( V_T \), which must be supplied to the diode to turn it on. Using the half-metallic magnets (HMMs) and spin-gapless semiconductors (SGSs) we propose a new diode concept, which does not have a junction barrier and whose operation principle relies on unique spin-dependent transport properties of the HMM and SGS materials. We show that HMM and SGS materials form an Ohmic contact under any finite forward bias, while for the reverse bias current is blocked. Thus, the HMM-SGS junctions act as a diode with zero threshold voltage \( V_T \), linear current-voltage (I-V) characteristics as well as very high on/off ratio. We employ the nonequilibrium Greens function method combined with density functional theory to demonstrate the linear I-V characteristics of the proposed diode based on 2D spin-gapless semiconducting VS\(_2\) and half metallic Fe/MoS\(_2\) planar heterojunctions. Moreover, a reconfigurable magnetic tunnel diode [1] is also realized by vertically stacking the VS\(_2\) and Fe/MoS\(_2\) monolayers. [1] E. Sasioglu, S. Blügel, and I. Mertig, ACS Appl. Electron. Mater. 1, 1552–1559 (2019).

Improved broadband on-chip time domain terahertz spectrometer for van der Waals heterostructures  

ALEX POTTS (Presenter), JOSHUA O ISLAND, ERIC SPANTON, University of California, Santa Barbara, PETER KISSIN, Physics, University of California, San Diego, ANTHONY P MCFADDEN, LIAM COHEN, CHRIS J PALMSTROM, University of California, Santa Barbara, RICHARD AVERITT, Physics, University of California, San Diego, ANDREA YOUNG, University of California, Santa Barbara — Time domain THz spectroscopy is a powerful technique for studying low-energy excitations in quantum materials, but is typically restricted to samples physically larger than the electromagnetic diffraction limit (~0.3 mm). We present an on-chip THz time domain spectrometer based on transmission line-coupled photoconductive switches fabricated by aligned transfer of epitaxially grown ErAs superlattices. We benchmark our bandwidth and dynamic range, which shows significant improvement over radiation damaged silicon-based devices on silicon substrates, and anticipate the technique’s use in studying dynamics and non-equilibrium phases in exfoliable van der Waals materials and heterostructures.
Two-dimensional (2D) materials and heterostructures have emerged as promising candidates for post-Moore electronics due to their unique electronic properties and atomically thin geometry. I will start with our studies on 2D semiconductors with low lattice symmetry and type-II Weyl semimetals. In atomically thin Rhenium disulfide (ReS$_2$), we observed interesting low-symmetry-induced anisotropic transport and mechanical properties, and studied their electronic and optoelectronic applications.[1] In type-II Weyl semimetal Tungsten ditelluride (WTe$_2$), we observed planar-orientation-dependent negative longitudinal magnetoresistance (MR) which reveals important transport signatures of chiral anomaly and type-II Weyl fermions.[2] In the second part of my talk, I will show that 2D heterostructures could play important roles in future advanced memory, computing and optoelectronic applications. One example is robust memristors with good thermal stability based on a 2D heterostructure composed of graphene/MoS$_{2-x}$O$_x$/graphene, which show promising memory and neuromorphic applications. [3] Our latest results on the observation of ballistic avalanche phenomena in a thin 2D heterostructure made of black phosphorus and Indium Selenide (InSe), as well as their high-performance electronic and optoelectronic applications will also be presented.[4]

Graphene is a 2-dimensional plane of carbon and a zero-band gap material whose conduction and valence band meet at dirac point. This electronic band structure makes it possible that the graphene's fermi energy level is modulated with accumulated charges by ~0.5 eV [1]. In this study, the unique property of graphene, large modulation of fermi energy level, was used to realize a vertical transistor which is based on graphene/hexagonal boron nitride (hBN) heterostructure. This device controlled tunneling barrier height between graphene and hBN by modulating the graphene's fermi energy level, and $I_{on}/I_{off}$ up to $10^6$ was achieved at 300 K. We also confirmed that there was little change in performance of device at 300 K and 15 K.

Density Functional Theory (DFT) and Time-Dependent (TD) DFT allow us in principle to express observables as functionals of the density. Relatively efficient approximations exist for the ground state total energy, but major difficulties remain, for example to describe strongly correlated systems, or situations where long range correlation is important. For other observables, even less is known about how to build good density functionals.

One way of designing approximations is to use results of model systems. In this talk we will show how model results can be used in an in principle exact way, called “Connector Theory”, in order to describe observables and systems of interest. Within this approach, a quantity of interest is calculated for a model system as function of a parameter once and forever, and the results are stored. Under certain conditions, the result for an appropriate choice of parameter can then be used to replace a value of interest in a given real system. This choice of parameter is called “connector”.

We will discuss the principles and general properties of such an approach. Of course, in practice, the connector has to be approximated. We will show that formulating the problem in this way is a convenient starting point for approximations, and a strategy to build systematic approximations will be presented.

We will then focus more specifically on the use of the connector approach to design density functionals, both for DFT and TDDFT. Particular emphasis will be put on effects of non-locality in space and time, which are important to capture, e.g., image potentials or multiple excitations, respectively. Some discussion and results can be found in [1,2].

Nonadiabatic electron dynamics in time-dependent density-functional theory at the cost of adiabatic local density approximation.*

DMITRY GULEVICH (Presenter), YAROSLAV V. ZHUMAGULOV, ITMO University, ALEXEI V. VAGOV, ITMO University; University of Bayreuth, ILYA V. TOKATLY, University of the Basque Country, VASILI PEREBEINOS, University at Buffalo

— We propose a computationally efficient approach to nonadiabatic electron dynamics in time-dependent density functional theory (TDDFT) based on a representation of the frequency-dependent exchange correlation kernel as a response of a set of damped oscillators. The requirements to computational resources needed to implement our approach do not differ from those of the standard real-time TDDFT in the adiabatic local density approximation (ALDA). Our result offers an exciting opportunity to take into account temporal nonlocality and memory effects in calculations with TDDFT in quantum chemistry and solid state physics for unprecedentedly low costs. We present few simple approximations to nonadiabatic exchange-correlation kernels and their application to study nonadiabatic dynamics of electron liquid in semiconductor quantum wells and atoms.

Imitating beyond-DFT calculations via external on-site potentials

NITIN KUMAR (Presenter), Colorado School of Mines, STEPHAN LANY, National Renewable Energy Laboratory

— Density functional theory (DFT) based methods are the basis for the high-throughput calculations of structural and electronic properties currently used in most Materials-by-Design approaches for materials discovery. To improve the accuracy of such predictive theory, it is now necessary to bridge the gap between efficient, but approximate, DFT calculations, and accurate, but computationally expensive, “beyond-DFT” approaches, such as GW electronic structure and random phase approximation (RPA) total energy calculations. In this direction, we aim to reproduce the beyond-DFT level by using angular-momentum and energy-dependent external on-site potentials. The problem of fitting the potential parameters is equivalent to solving a multi-objective optimization problem. Using VO2 as a model system, we develop a workflow for potential fitting via machine learning, so to explore the extensive multi-dimensional search space for the highly non-linear objective function.
3:30PM D58.00004: First Principles Derivation of the Effect of Geometric Noise on Distributions of Electronic Properties using the Effective Stochastic Kohn-Sham Potential Method  JEREMY SCHER (Presenter), ARINDAM CHAKRABORTY, Syracuse University — Obtaining ensemble averages by sampling many conformations is vital for an accurate description of temperature-dependent properties of chemical systems. However, constructing distributions of $10^5 - 10^6$ samples is computationally challenging due to the high computational cost of performing calculations. In this work, we present a new approach called the effective stochastic Kohn-Sham potential (ESKS) method to address this challenge. Using the classical nuclear-nuclear repulsion energy as a metric, we derive statistical relationships between the distribution of nuclear-nuclear repulsion energies and the distributions of ground state quantum mechanical properties for a general chemical system. The results from this analysis show that the geometric noise experienced by molecules due to solvent interaction and thermal motion can be effectively captured by an effective stochastic operator. This allows for introducing a stochastic variable in the Kohn-Sham potential. Comparison of the analytical results with numerical DFT calculations on small molecules, semiconductor clusters, and large organic molecules will be presented. Both analytical and numerical results demonstrate the advantage of using an effective stochastic operator for performing large scale sampling of conformations.

3:42PM D58.00005: Towards Spectroscopic Accuracy for In-Silico Materials Design*  ADA SEDOVA (Presenter), Oak Ridge National Lab, ANUP PANDEY, Los Alamos National Lab, ANIBAL J. RAMIREZ-CUESTA, Oak Ridge National Lab — We present a new approach for enabling highly accurate prediction of non-equilibrium behavior of large supramolecular organic systems for in-silico design of novel functional materials. Using datasets of INS measurements of organic molecular crystals from the high-throughput, high resolution neutron vibrational spectrometer at SNS (VISION), we obtain essential information for achieving spectroscopic accuracy in density functional theoretical descriptions of the forces acting on large organic supramolecular assemblies with strong non-covalent bonds, using high performance computing and massively parallel DFT calculations. The work will pave the way for an ability to design and test new materials using high-confidence in-silico methods.

3:54PM D58.00006: Understanding the interplay between hole localization and reactivity in photoionized water clusters using real-time Time-Dependent Density Functional Theory*
VIDUSHI SHARMA (Presenter), MARIVI FERNANDEZ SERRA, Department of Physics and Astronomy, and Institute for Advanced Computational Science, Stony Brook University — Photocatalytic water-splitting on semiconductor surfaces is of topical interest for renewable energy applications, and yet, the molecular intermediates and their mutual interactions underlying photocatalysis remain poorly understood. In this work, we examine the scope of rt-TDDFT-based methods for analyzing ultrafast processes in photoexcited systems. We study the response of a prototypical molecular system consisting of chains of H-bonded (H_2O)_n molecules (n=2-5) under photoionization. The time evolution of the photogenerated hole is captured by rt-TDDFT Ehrenfest dynamics. We use a generalized gradient approximation (GGA-PBE) for nonadiabatic electron-ion dynamics, justified by comparing dynamic hole densities computed at PBE with those at higher PBE0 level of the theory. We also compare results from rt-TDDFT dynamics with those from adiabatic Born-Oppenheimer molecular dynamics at the GGA level, elucidating the importance of incorporating explicit nonadiabatic effects in excited-state phenomena. The H-bond cooperativity effects in (H_2O)_n^+ chains are identified, emphasizing their role in facilitating hole localization. Finally, we also uncover new connections between the test system and the H-bond network formed at water-semiconductor interfaces.

4:06PM D58.00007: Approaches for Non-Adiabatic Functional Approximations in TDDFT*
LIONEL LACOMBE, NEEPA MAITRA (Presenter), Rutgers University, Newark — Several examples of electron dynamics in the non-perturbative regime highlight the need to go beyond the adiabatic approximation to achieve even a qualitatively reasonable description. This includes charge-transfer dynamics out of the ground-state, resonantly-driven dynamics, and cases of pump-probe spectroscopy. We discuss different approaches to develop functionals that build in memory into new non-adiabatic exchange-correlation functionals. In one, we develop density-matrix coupled exchange-correlation approximations, starting from an exact expression for the time-dependent exchange-correlation functional. In another, a time-dependent extension of the adiabatic connection formula is developed to take advantage of coupling-constant integration.

Plasmon dispersion and the role of the exact constraints on exchange-correlation kernels within time-dependent density functional theory

ADRIENN RUZSINSZKY (Presenter), BIMAL NEUPANE, SHIQI RUAN, SANTOSH ADHIKARI, SANTOSH NEUPANE, NIRAJ K. NEPAL, Physics, Temple University — Small-wavevector excitations in Coulomb-interacting systems can be decomposed into the high-energy collective longitudinal plasmon and the low-energy single-electron excitations. The random phase approximation (RPA) is exact in the high-density limit but can capture the plasmonic dispersion reasonably even for densities with $r_s > 1$. The work by Tatarczyk et al. [1] found that the impact of the exchange-correlation kernels is significant and modifies the plasmon dispersion curve. There is however a large difference in the construction and performance of the kernels investigated earlier. Our current work for the jellium model introduces recent model exchange-only and exchange-correlation kernels and discusses the relevance of some exact constraints [2,3] in the construction of the kernel. This work could give a further hint toward a better plasmon dispersion in realistic metals where anomalous behavior was observed with RPA.

*Work is supported by National Science Foundation under Grant No. DMR–1553022.

Nonlocal energy optimized (NEO) kernel for the formation energies of alloys and surface energies of metals

BIMAL NEUPANE (Presenter), NIRAJ NEPAL, SANTOSH ADHIKARI, ADRIENN RUZSINSZKY, Temple Univ — Semi-local Density Functional Theory (DFT) includes the self-interaction error and misses the long-range van der Waals interaction. One possible remedy of these failures is the direct Random Phase Approximations (RPA). RPA stands on the highest rung of Jacob’s ladder of density functional approximations and includes the occupied and unoccupied Kohn Sham orbitals. However, the direct RPA is limited by neglecting the short ranged-correlation captured by an exchange-correlation kernel. Kernels based on the uniform electron gas model have shown some improvement over RPA and are computationally as affordable as RPA itself within PAW/pseudopotential codes. In this work, we are using the nonlocal energy-optimized (NEO) exchange-only kernel [1,2] to assess the formation energies of some intermetallic alloys and surface energies of some metals. These physical examples were chosen because they require a very delicate interplay of the short and long-range correlation in the kernel-corrected RPA and therefore a sophisticated way to construct the model kernel.

*National Science Foundation under Grant No. DMR–1553022.
The ground-state equilibrium properties of copper-gold alloys have been explored with the state-of-the-art random phase approximation (RPA) [1]. The PBE, PBE revised for solids, and revised Tao-Perdew-Staroverov-Scuseria functionals by Perdew et al. predict too-low formation energies, while the SCAN slightly overestimates it. The inclusion of thermal correction or the long-range dispersion provides a negligible contribution to the formation energies estimated with semilocal density functional theory. The spin-orbit coupling improves the formation energies of PBE only by 7-8 meV, while it intensifies the overestimation of SCAN. We found that the nonlocality present in RPA is able to describe the transition between two delocalized electron densities (bulk elemental constituents to crystallized alloys), as required to provide accurate formation energies without any further corrections.

4:54PM D58.00011: Non-Adiabatic Quantum Molecular Dynamics Investigation of Hot Carrier Dynamics in Dielectric Polymers under High Electric Fields.* THOMAS LINKER (Presenter), SUBODH TIWARI, Collaboratory for Advanced Computing and Simulations, University of Southern California, HIROYUKI KUMAZOE, SHOGO FUKUSHIMA, Department of Physics, Kumamoto University, RAJIV KALIA, AIICHIRO NAKANO, Collaboratory for Advanced Computing and Simulations, University of Southern California, RAMAMURTHY RAMPRASAD, School of Materials Science and Engineering, Georgia Institute of Technology, FUYUKI SHIMOJO, Department of Physics, Kumamoto University, PRIYA VASHISHTA, Collaboratory for Advanced Computing and Simulations, University of Southern California — Non-Adiabatic Quantum Molecular Dynamics (NAQMD) is a powerful tool typically used to model excited state electron-phonon dynamics under optical excitation. In this work we have ported NAQMD to study excited hot charge carriers involved in dielectric breakdown of organic polymers under high electric fields. Organic polymers offer many advantages over inorganic dielectrics, but they are severely limited by breakdown under the application of high electric fields. There also remains no mechanistic method for quantitative prediction of the breakdown field in polymers, unlike inorganic materials. Here we performed a systematic study of different electric fields on hot carrier dynamics and resulting chemical damage in a slab of archetypal polymer, polyethylene. We found a critical transition occurring near the experimentally reported intrinsic breakdown field marked by strong localization of electronic states at the slab surface and emergence of hot carrier C-H vibrational resonance. Such a localization transition may provide a critically-missing prediction method for computationally screening dielectric polymers with high breakdown fields.

Electron-nuclear coupling in non-equilibrium dynamics plays a fundamental role in condensed matter physics, defining behavior from phase transitions to chemical reactions. Recently the dynamics of these processes have been able to be experimentally resolved in the time-domain, requiring a theoretical framework beyond the Born-Oppenheimer approximation to describe [1]. While approaches such as the multi-configuration time-dependent Hartree method have been successful at describing excited state dynamics of relatively small systems, the cost to precompute potential energy surfaces and non-adiabatic couplings becomes a significant bottleneck for larger systems. In this talk we develop a trajectory based variational ansatz which treats the electronic system at the level of time-dependent density functional theory, while simultaneously incorporating a nonadiabatic quantum mechanical description of the nuclei. This method is compared to multi-trajectory Ehrenfest dynamics in the resolution of nuclear effects within the optical spectrum of small molecules.

Localized and collective magnetic excitations in the magnetic topological insulator Sn$_{1-x}$Mn$_x$Te*  

ROBERT MCQUEENEY (Presenter), Iowa State University, DAVID VAKNIN, SANTANU PAKHIRA, Ames Laboratory, DANIEL M. PAJEROWSKI, Oak Ridge National Laboratory, DAVID C JOHNSTON, Iowa State University, DEBORAH SCHLAGEL, Ames Laboratory — The nature of the magnetism dilute magnetic topological insulators (MTIs), controlled by atomic disorder and/or clustering and the competition between short- and long-range magnetic interactions, is not well understood. MTIs that develop ferromagnetic (FM) long-range order can host dissipationless electronic transport via the quantum anomalous Hall effect. We studied the magnetic excitations in a prototypical MTI, Sn$_{0.95}$Mn$_{0.05}$Te, using inelastic neutron scattering. Neutron diffraction and magnetization data indicate that our Sn$_{0.95}$Mn$_{0.05}$Te sample has no FM long-range order. However, we observe slow, collective FM fluctuations (<70 μeV), indicating proximity to FM order. We also find a series of sharp peaks originating from excitations of antiferromagnetically coupled Mn-Mn dimers with J$_{AF}$ = 230 μeV. These dimers sit at next-nearest neighbor positions on the FCC sublattice, suggesting that Mn substitution is not completely random. The simultaneous presence of collective and localized components indicate that some Mn ions contribute to FM order and some form strongly-bound dimer singlets.

Topological insulator interfaced with ferromagnetic insulators: Bi$_2$Te$_3$ thin films on magnetite and iron garnets  

CHI-NAN WU (Presenter), VANDA M PEREIRA, SIMONE G ALTENDORF, SHENG-CHIEH LIAO, CHENG-EN LIU, ALEXANDER KOMAREK, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MENGXIN GUO, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, HONG-JI LIN, CHIEN-TE CHEN, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, MINGHWEI HONG, Department of Physics, National Taiwan University, Taipei, Taiwan, JUEINAI KWO, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, LIU TJENG, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — We have grown Bi$_2$Te$_3$ thin films on Y$_3$Fe$_5$O$_{12}$(111), Tm$_3$Fe$_5$O$_{12}$(111), Fe$_3$O$_4$(111), and Fe$_3$O$_4$(100) by molecular beam epitaxy with minimal chemical reaction at the interface. Electrical transport measurements were performed to study the magnetism induced by the proximity effect in the topological insulator in conjunction to the ferromagnetic insulators. We observed the anomalous Hall effect on these heterostructures. Magnetoresistance measurements at low temperature reveal a suppression of the weak antilocalization, indicating a possible topological surface state gap opening induced by the magnetic proximity effect. However, we did not observe any obvious x-ray magnetic circular dichroism (XMCD) on the Te M$_{45}$ edges. The results suggest that the ferromagnetism induced by the magnetic proximity effect via Van der Waals bonding in Bi$_2$Te$_3$ by is too weak to be detected by XMCD, but still can be observed by electrical transport measurements. This is consistent with published density-functional theory results on topological insulator/magnetic insulator heterostructure showing that only a small band gap of 9 meV is induced by the magnetic proximity effect.
Tailoring Hybrid Anomalous Hall Response in Engineered Magnetic Topological Insulator Heterostructures

PENG CHEN, YONG ZHANG, School of Information Science and Technology, ShanghaiTech University, QI YAO, School of Physical Science and Technology, ShanghaiTech University, THORSTEN HESJEDAL, Department of Physics, University of Oxford, SHILEI ZHANG, School of Physical Science and Technology, ShanghaiTech University, XUFENG KOU (Presenter), School of Information Science and Technology, ShanghaiTech University — Magnetic topological insulators (MTIs) have greatly broadened the research scope of topological quantum materials. Introducing MTIs into the field of spintronics defines a new trend of magnetic-based logic and memory applications. Engineering the anomalous Hall effect (AHE) in emerging MTIs has great potentials for quantum information processing and spintronics applications.

In this talk, we will present the MBE growth and exotic transport properties of Bi2Te3/MnTe heterostructures. RHEED, XRR and TEM have revealed the high quality and atomically flat interface of the film. Through transport measurements, we observed pronounced AHE signals from both layers combined together. The evolution of the resulting hybrid AHE intensity with the top Bi2Te3 layer thickness manifests the presence of an intrinsic ferromagnetic phase induced by the topological surface states at the heterolayer-interface. Surprisingly, we find the polarity of AHE can be switched by adjusting the Fermi level position of the Bi2Te3 layer via effective Sb-doping. Such flexibility in controlling the AHE strength, which depend on the specific band structure (i.e., Berry curvature), in our MTI heterostructures therefore opens up a multitude of opportunities to explore MTI-based spintronics devices.

Molecular Beam Epitaxy Growth and Magnetization Characterization of Fe-doped Bi2Se3

ZHENG REN (Presenter), HE ZHAO, HONG LI, BRYAN RACHMILOWITZ, ILIJA ZELJKOVIC, Boston College — Bi2Se3 is a prototypical 3D topological insulator (TI), which hosts gapless surface states protected by time-reversal-symmetry (TRS). When TRS is broken by doping with magnetic elements, this system can realize exotic electronic states, such as the quantum anomalous hall states (QAHS) (Rui Yu et al., Science 329 , 61 (2010)). We grow Fe-doped Bi2Se3 thin films on SrTiO3(001) substrates by molecular beam epitaxy (MBE), and characterize them using a combination of low-temperature scanning tunneling microscopy/spectroscopy (STM/S) and magnetization measurements. We find a large difference between the Fe concentration in the topmost layer determined from STM topographs and that inferred from magnetization measurements. Moreover we find an intriguing magnetic anisotropy of the thin films, different from that observed in their bulk counterparts. Our findings provide a fresh insight into the idea of doping Fe into Bi2Se3 as a route towards achieving QAHS.

*We gratefully acknowledge the funding from the Army Research Office, grant W911NF-17-1-0399.
Optically manipulating ferromagnetism in Cr-doped topological insulators (TIs)*

ADRIAN LLANOS (Presenter), Department of Applied Physics, Caltech, CHIEN-CHANG CHEN, MARCUS L TEAGUE, Department of Physics, Caltech, XIAOYU CHE, PENG ZHANG, LEI PAN, KANG L. WANG, Department of Electrical Engineering, University of California Los Angeles, NAICHANG YEH, Department of Physics, Caltech — Optically manipulating ferromagnetic materials has been shown to be a promising route to opto-spintronic applications. Using a combination of optically-enabled transport measurements and scanning tunneling spectroscopic (STS) measurements in the presence of circularly polarized (CP) light, we found an enhancement of magnetization in 10% Cr-doped (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3} bilayer heterostructures which consisted of a pure layer (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3} on top of a 10% Cr-doped (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3} layer. Measurements of the anomalous Hall resistance revealed an increase in $R_{xy}$ and a decrease in longitudinal resistance $R_{xx}$ in the bilayer magnetic TI system under CP light (wavelengths $\lambda = 1600 \sim 1700$ nm). In contrast, both $R_{xx}$ and $R_{xy}$ were suppressed under CP light for uniformly Cr-doped (Bi\textsubscript{x}Sb\textsubscript{1-x})\textsubscript{2}Te\textsubscript{3}. To understand the microscopic origin of these results, we performed spatially resolved STS studies on the surface state of magnetic TIs as a function of temperature and magnetic field. We further conducted optically-assisted STS studies to spatially map out the CP light-induced spectral changes to the surface state. The physical implications from correlating the spatially resolved STS under CP light with findings from macroscopic $R_{xx}$ and $R_{xy}$ will be discussed.

Magneto-transport properties of bulk-insulating topological insulators (Bi,Sb)$_2$Te$_3$ on thulium iron garnets

CHUN-CHIA CHEN (Presenter), SHANG RONG YANG, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, YU-TING FANCHIANG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei 10617, Taiwan, WEI-JHIH ZOU, MENGXIN GUO, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, CHAO-KAI CHENG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei 10617, Taiwan, SHENG-WEN HUANG, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, KENG-YUNG LIN, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei 10617, Taiwan, KO-HSUAN CHEN, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, MINGHWEI HONG, Graduate Institute of Applied Physics and Department of Physics, National Taiwan University, Taipei 10617, Taiwan, JUEINAI KWO, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan — Breaking time-reversal symmetry in topological insulators (TIs) via magnetic proximity effect attracted intense studies. The spin dynamics of magnetic insulators (MIs) interfacing with TIs has been investigated by ferromagnetic resonance,

High-temperature ferromagnetic topological crystalline insulating state induced by proximity effect in a EuS/SnTe heterostructure

RYOTA AKIYAMA (Presenter), KAZUKI WATANABE, Univ of Tokyo, YUTA TOMOHIRO, TAKERU SHIMANO, Institute of Material Sciences, Univ of Tsukuba, RYO ISHIKAWA, Ulvac, KAZUHIRO AKUTSU, KAZUKI IIDA, Comprehensive Research Organization for Science and Society, SHINJI KURODA, Institute of Material Sciences, Univ of Tsukuba, SHUJI HASEGAWA, Univ of Tokyo — Ferromagnetic topological insulators attract much attention because they enable us to realize the quantum anomalous Hall effect (QAHE), possibly useful for low-energy-consumption devices by using the chiral edge state. However, the temperature for QAHE is still low mostly due to degradation of crystallinity by doping magnetic atoms. To prevent it, using ferromagnetic proximity effect is one of the solutions [1,2]. We made and measured a EuS/SnTe heterostructure. As a result, intriguingly, the perpendicular magnetization (PM) reaches minimum at ~100 K and then increases with increasing temperature and keeps up to room temperature. A similar behavior was reported in EuS/Bi$_2$Se$_3$[1], and the explanation is that after disappearance of bulk magnetization in EuS ($T_C$=17 K), the direction of the interface magnetization becomes perpendicular from oblique with increasing temperature. On the other hand, when we use a trivial insulator PbTe: EuS/PbTe, the PM monotonically decreases with increasing temperature. This suggests that the anomalous interface ferromagnetism is induced by the non-trivial nature in SnTe. [1] F. Katmis et al., nature 533, 513 (2016). [2] R. Akiyama et al., arXiv 1910.10540 (2019).

Ultrafast momentum-resolved study of electron-phonon coupling in an antiferromagnetic topological insulator

HARICHARAN PADMANABHAN (Presenter), VLADIMIR A STOICA, HUAIYU WANG, Pennsylvania State University, NATHAN KOOCHER, MINGQIANG GU, Northwestern University, XIAOZHE SHEN, MING-FU LIN, SLAC National Accelerator Laboratory, SENG HUAT LEE, ZHIQIANG MAO, Pennsylvania State University, AARON LINDENBERG, XIJIE WANG, SLAC National Accelerator Laboratory, JAMES RONDINELLI, Northwestern University, VENKATRAMAN GOPALAN, Pennsylvania State University — Elementary electronic and lattice excitations and their mutual interactions form the foundation of our understanding of condensed matter systems. In the context of topological insulators, the electron-phonon coupling determines in addition, the robustness of dissipationless surface states at finite temperatures. In this work, we consider the first discovered intrinsic antiferromagnetic topological insulator, MnBi$_2$Te$_4$, a system that is predicted to exhibit the quantum anomalous Hall effect [1]. We study the momentum-resolved electron-phonon coupling in this material at its inherent femtosecond timescale using ultrafast electron diffraction and coherent phonon optical spectroscopy. We find that electrons are strongly coupled to in-plane zone-boundary Eg optical phonons, resulting in a highly nonequilibrium phonon population for several hundreds of femtoseconds after excitation. The nonequilibrium phonon system subsequently relaxes by phonon-phonon coupling to zone-center transverse acoustic phonons. We simulate how the strongly coupled Eg phonons modulate the exchange interaction and magnetism using DFT calculations.

Pressurizing an antiferromagnetic topological insulator candidate

PRISCILA ROSA (Presenter), SEAN THOMAS, ERIC BAUER, JOE D THOMPSON, FILIP RONNING, Los Alamos National Laboratory — Intrinsic magnetic topological insulators hold the potential of hosting quantum anomalous Hall states, chiral Majorana fermions, and topological magnetoelectric effects. We have identified Zintl antiferromagnet Eu$_5$In$_2$Sb$_6$ as a candidate material which displays remarkable insulating behavior. Our previous results showed the presence of colossal magnetoresistance in this system, which is consistent with the presence of magnetic polarons. Here we investigate the effects of applied hydrostatic and uniaxial pressure on Eu$_5$In$_2$Sb$_6$ single crystals in an effort to drive the system through a topological phase transition. Our results show an exceptionally large decrease in resistivity under applied hydrostatic pressure as well as uniaxial pressure along the c axis.

*Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering.
4:18PM D59.00010: Spin-to-charge conversion on the edge of quantum spin Hall insulator
YASUFUMI ARAKI (Presenter), Japan Atomic Energy Agency, TAKAHIRO MISAWA, The University of Tokyo, KENTARO NOMURA, Tohoku University — We present our theoretical work on dynamical spin-to-charge conversion at the edge of a quantum spin Hall insulator (QSHI), namely a two-dimensional topological insulator with helical edge states. Interconversion between spin- and charge-related quantities has been a key idea in making use of magnetic materials, especially in the context of spintronics. QSHI is a typical system showing a universal charge-to-spin conversion behavior, namely the quantum spin Hall effect, whereas the spin-to-charge conversion therein is still not clearly understood.

We here investigate the many-body dynamics of the electrons under the magnetization dynamics at the QSHI-ferromagnet(FM) junction. We analytically treat the electron dynamics in terms of the Floquet-Keldysh formalism, and compare the spin injection rate from the FM into the QSHI and the charge current induced along the edge. Whereas the edge current seen in the previous works is reproduced, we find that it is not proportional to the spin injection rate, especially when the exchange interaction at the junction is strong enough. This relation implies that the spin-to-charge conversion in this system cannot be considered as the inverse spin Hall effect, while it can be rather seen as the inverse Edelstein effect.

4:30PM D59.00011: Exchange interactions between topological and meta-magnetic insulators
YING WANG (Presenter), Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907, USA, purdue university, VALERIA LAUTER, Thin Films and Nanostructures, Oak Ridge National Laboratory, JACEK K. FURDYNA, XINYU LIU, Department of Physics, Notre Dame University, LEONID ROKHINSON, Physics department and Birck Nanotechnology Center, Purdue university — The hallmark of 3D topological insulators(TIs) are topological surface states(TSS) protected by the time-reversal symmetry. One of the important goals is the ability to manipulate surface electron states and to lift the topological protection of TSS for the emergence of novel physical phenomena. Gapping of TSS has been demonstrated in TIs with bulk doping using the magnetic impurities and via exchange coupling to insulating magnetic or antiferromagnetic materials. Here we report an experimental study of exchange coupling in EuSe/Bi$_2$Se$_3$ and EuSe/Bi$_2$Se$_3$/EuSe heterostructures grown by MBE. Bi$_2$Se$_3$ is a typical TI and EuSe is a meta-magnetic insulator with a rich phase diagram of paramagnetic, antiferromagnetic, ferrimagnetic and ferromagnetic phases at low temperatures. Polarized neutron scattering experiments indicate enhanced exchange interaction between EuSe and Bi$_2$Se$_3$ and we observe finite in-plane magnetization at the interface even above the Néel temperature ($T_N$~5K) of EuSe. In transport measurement, we observe modulation of longitudinal and Hall resistance as a function of the magnetic field, which may be explained by the formation and re-arrangement of magnetic domains at the interface.

*Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy
We investigate the topological magneto-electric effect (TME) in Bi$_2$Se$_3$ topological insulator (TI) thin films, with a perpendicular exchange field applied to the top and bottom surfaces in the anti-parallel configuration. Here the system is in the axion insulator phase, which allows a direct probe of the quantized topological $\theta$-term of the axion electrodynamics. The $\theta$-term is a TI bulk property which gives the coefficient of proportionality between an applied electric field and the induced magnetization. We first consider an infinite slab and extract $\theta$ in a tight-binding framework, under the condition of weak electric field. In the second part of the work, we consider systems which are finite in one or more dimensions. By analyzing the dependence of $\theta$ on the system size and the strengths and profiles of the exchange fields on the two surfaces, we determine when the TME is expected to be quantized. Furthermore, we investigate possible deviations from exact quantization in the regime where the exchange field on one of two surfaces is progressively enhanced beyond a critical value. Our study sheds light on the fundamental issue of whether TME in a TI is completely determined by the bulk properties or it can be affected by how time-reversal symmetry is broken at the surfaces.

**4:54PM D59.00013: Electrically Tunable Anomalous Hall Effect in Topological Crystalline Insulator Films**

PENG DENG (Presenter), PENG ZHANG, XIAOYU CHE, KANG-LUNG WANG, Electrical and Computer Engineering, University of California, Los Angeles — Introducing ferromagnetism into topological crystalline insulator SnTe could lead to the high-Chern-number quantum anomalous Hall effect. Here we report the observation of magnetic proximity effect in heterostructures formed by the SnTe (111) and 2 quintuple layers thick Cr-doped (BiSb)$_2$Te$_3$ (CBST). Owing to the charge transfer between CBST and SnTe, the Fermi level of the latter can be tuned by adjusting the Bi/Sb ratio in the former. An anomalous Hall resistance as large as 0.08 $h/e^2$ is revealed. The transferred charges modify the electric field perpendicular to the film and change the critical thickness of topological phase transition in SnTe. Such property makes SnTe useful in realizing the topological transistor.
Large-Gap Quantum Anomalous Hall effect in a Magnetically doped Type-I Topological Heterostructure

ANH PHAM (Presenter), PANCHAPAKESAN GANESH, Oak Ridge National Lab — Current method of doping a topological insulator (TI) with magnetic element has only yielded low temperature quantum anomalous hall effect due to the small exchange energy of dopants and uncontrollable shifts in the Fermi-level due to band-bending effects [1]. To overcome the band-bending effect, Fermi-level can be pinned by creating a Type-I type TI/insulator band offset, while the magnetic exchange energy can be increased by searching over different potential magnetic dopants that remain neutral. Given the recent successes of growing high-quality TI-films on Cr$_2$O$_3$ heterostructure [2], we study different magnetically doped TI/Cr$_2$O$_3$ heterostructures using a combination of density functional theory and k.p modelling. We find Sb$_2$Te$_3$ to form a type-I interface with Cr$_2$O$_3$I, thereby making the heterostructure insulating, meanwhile maximizing the Zeeman energy due to the segeration of the dopants at the interface, suggesting possible room-temperature QAHE. We also compare our interfacial magnetism model with available experiments.

This research were financially supported by the Oak Ridge National Laboratory’s Laboratory Directed Research and Development project (Project ID: 8988).

Monday, March 2, 2020 2:30 PM - 5:30 PM

Session D60 DMP: Topological Materials: Topological Superconductors and Majorana States

WEI LI (Presenter), Tsinghua University — A possible topological superconductor 2M-WS$_2$ has been discovered and its superconducting transition temperature is ~ 8.8 K. By using low-temperature scanning tunneling microscopy, we have made direct observation of a clean Majorana zero mode in this transition metal dichalcogenide. The observed Majorana zero mode well separates in energy from the Caroli-de Gennes-Matricon bound states inside the vortex-core, therefore providing a good platform for the future quantum computing.

3:06PM D60.00002: Applications of a Novel Quantum Interband Index in Condensed Matter: Topological Insulators, Optical Selection Rules, and Beyond*  THARINDU WARNAKULASOORIYA FERNANDO (Presenter), TING CAO, Physics, University of Washington, CONGJUN WU, Physics, University of California, San Diego — The physical significance of a novel gauge-invariant interband index $T$ proposed in [1] is not immediately clear in condensed matter systems. In this talk, we present numerical calculations of the index $T$ in various systems. Calculations of $T$ in loops around valleys of the Haldane model for the anomalous quantum Hall effect give distinct integer numbers with behavior partly reminiscent of different types of Chern numbers (such as spin or valley). For loops containing more/less than 1 Dirac point, our calculations reveal perplexing results including a link to the sign of local Berry curvature. We further connect this index to recently discovered optical selection rules [2-4] and demonstrate other physical effects related to $T$.

3:18PM D60.00003: Bulk superconductivity in FeTe$_{1-x}$Sex via physicochemical pumping of excess iron  LIANYANG DONG (Presenter), University of California, Santa Barbara, HE ZHAO, ILIJA ZELJKOVIC, Boston college, STEPHEN WILSON, JOHN W HARTER, University of California, Santa Barbara — The iron-based superconductor FeTe$_{1-x}$Sex has attracted considerable attention as a candidate topological superconductor owing to a unique combination of topological surface states and bulk high-temperature superconductivity. The superconducting properties of as-grown single crystals, however, are highly variable and synthesis dependent due to excess interstitial iron impurities incorporated during growth. Here we report a novel physicochemical process for pumping this interstitial iron out of the FeTe$_{1-x}$Sex matrix and achieving bulk superconductivity. Our method should have significant value for the synthesis of high-quality single crystals of FeTe$_{1-x}$Sex with large superconducting volume fractions.
3:30PM D60.00004: Molecular Beam Epitaxy Growth of Superconducting Sn\(_{1-x}\)In\(_x\)Te (0 ≤ x ≤ 0.67) Thin Films  MAKOTO MASUKO (Presenter), Department of Applied Physics, Univ of Tokyo, RYUTARO YOSHIMI, Center for Emergent Matter Science, RIKEN, ATSUSHI TSUKAZAKI, Institute for Materials Research, Tohoku University, MINORU KAWAMURA, KEI TAKAHASHI, Center for Emergent Matter Science, RIKEN, MASASHI KAWASAKI, Department of Applied Physics, Univ of Tokyo, YOSHINORI TOKURA, Center for Emergent Matter Science, RIKEN — Topological superconductivity has attracted increasing interest for not only its novel properties but also the possible application to quantum computing. One way to realize topological superconductivity is to induce superconducting gap in the surface states of topological insulators (TIs) by the proximity effect. To maximize the superconducting proximity effect, all-telluride based heterostructures consisting of TI (Bi,Sb)\(_2\)Te\(_3\) and Te-based superconductor (SC) may be a promising candidate. As the first step toward TI/SC heterostructures, epitaxial growth of Te-based SC is required.

In this work, we report the thin film growth of rock-salt type SC Sn\(_{1-x}\)In\(_x\)Te (SIT) by means of molecular beam epitaxy. By finely tuning the amount of Te supply especially in the high-doping region, we have achieved In-doping up to x = 0.66, which exceeds bulk solubility limit under ambient pressure x ~ 0.5. In the transport measurements, we have observed superconductivity in SIT thin films, and \(T_c\) shows dome-shaped dependence on x with the highest \(T_c\) = 4.25 K at x = 0.55. Our result may lead to the TI/SC heterostructures and interfacial topological superconductivity.

3:42PM D60.00005: Proximity-induced superconductivity in SnTe thin films*  BRYAN RACHMILOWITZ (Presenter), HE ZHAO, HONG LI, ALEXANDER LAFLEUR, Boston College, JOHN SCHNEELOCH, RUIDAN ZHONG, GENDA GU, Brookhaven National Lab, ILIJA ZELJKOVIC, Boston College — Superconducting topological crystalline insulators (TCIs) are theorized to host new types of topologically protected surface states distinct from those at the surface of superconducting Z\(_2\) topological insulators (TIs). While superconducting proximity effect has been widely used to induce superconductivity in Z\(_2\) TIs, the efforts to induce superconductivity in TCIs have been hindered by growth difficulties. Here we report the synthesis of heterostructures of a prototypical TCI SnTe(111) and high temperature superconductor Fe(Te,Se) using molecular beam epitaxy. Utilizing low-temperature scanning tunneling microscopy and spectroscopy as function of temperature and magnetic field, we show strong evidence of induced superconductivity at the surface of SnTe. Our work provides a new platform for studying emergent phenomena in superconducting TCIs.

*We gratefully acknowledge the support from the Army Research Office Grant No. W911NF-17-1-0399 and the NSF Grant No. 1654041
3:54PM D60.00006: Fractional disclination charge in two-dimensional \(C_n\)-symmetric topological crystalline insulators* TIANHE LI (Presenter), PENGHAO ZHU, University of Illinois at Urbana-Champaign, WLADIMIR A BENALCAZAR, Department of Physics, Pennsylvania State University, TAYLOR L HUGHES, University of Illinois at Urbana-Champaign — Robust fractional charge localized at disclination defects has been recently found as a topological response in \(C_6\) symmetric 2D topological crystalline insulators (TCIs). We thoroughly investigate the fractional charge on disclinations in \(C_n\) symmetric TCIs, with or without time-reversal symmetry, and including spinless and spin-1/2 cases. We find the disclination charge is fractionalized in units of \(e/n\) for \(C_n\) symmetric TCIs; and for spin-1/2 TCIs, with additional time-reversal symmetry, the disclination charge is fractionalized in units of \(2e/n\). Utilizing band representation theory, we construct topological indices of the fractional disclination charge for all 2D TCIs that admit a (generalized) Wannier representation. Moreover, we use an algebraic technique to generalize the indices for TCIs with non-zero Chern numbers, where a (generalized) Wannier representation is not applicable. Our results provide a quantitative and intuitive understanding of fractional charge at defects for 2D \(C_n\)-symmetric TCIs.

*This work is supported by NSF grants EFMA-1627184 (EFRI), DMR-1351895, the MRSEC program under NSF Award Number DMR-1720633 (SuperSEED) (TL, PZ, TLH), and Eberly Postdoctoral Fellowship at Penn State (WAB).

4:06PM D60.00007: Tuning the Edge States of Topological Crystalline Insulator Bismuthene via Substrate Effects* CHUTIAN WANG, YUEFENG YIN, Materials Science and Engineering, Monash University, MICHAEL FUHRER, Physics and Astronomy, Monash University, NIKHIL MEDHEKAR (Presenter), Materials Science and Engineering, Monash University — One of the key challenges in design of devices bases on topological materials is to conveniently turn the surface and edge states on and off. Two-dimensional (2D) topological crystalline insulators (TCI) are ideal materials for achieving this switch, as their edge states can be turned on/off by applying a symmetry-breaking field. However, it remains unresolved how 2D TCI phases can be integrated in experimental devices due to the difficulty in synthesis and the complex interactions between TCI and underlying substrates. In this theoretical study based on first principles calculations and Wannier tight-binding models, we show that the edge states of TCI bismuthene can be stabilized on some substrates (e.g. h-BN and SiC) when the stacking pattern does not break mirror symmetry. We can achieve fine tuning of the edge states of bismuthene by applying strain or an external electric field. This research provides guidelines for selection of appropriate substrates for the experimental realization of topological edge states and the methodology to tune the edge states in 2D TCIs.

*This work is supported by ARC Centre of Excellence in Future Low-Energy Electronics Technologies (CE170100039).
4:18PM D60.00008: Searching for ideal topological crystalline insulators and topological superconductors in Pb-Sn-In-Te system  GENDA GU (Presenter), RUIDAN ZHONG, YANGMU LI, QIANG LI, TONICA VALLA, JOHN TRANQUADA, Brookhaven National Laboratory — The discovery of 3D topological insulator materials and topological superconductor open up a new research field in the condensed matter physics. In order to search for the topological superconductor, we have grown a large number of the single crystals of Pb-system (Pb-Sn-In-Te) topological crystalline insulator and their topological superconductor. We have measured the physical properties on these single crystals by various techniques. We have studied the effect of crystal growth condition, impurity and composition on the bulk electrical conductivity of these single crystals. We try to find out which composition and crystal growth condition is the best for the ideal topological insulator, topological crystalline insulator and topological superconductor. We have got the bulk topological superconductor with $T_c=5K$.

4:30PM D60.00009: Superconducting proximity effect in InAsSb surface quantum wells with in-situ Al contacts*  WILLIAM SCHIELA (Presenter), WILLIAM MAYER, JOSEPH YUAN, MEHDI HATEFIPOUR, Department of Physics, New York University, WENDY L SARNEY, STEFAN P SVENSSON, ASHER LEFF, US Army CombatCapabilities Command, Army Research Laboratory, TIAGO DE CAMPOS, Department of Physics, University at Buffalo, KAUSHINI S WICKRAMASINGHE, MATTHIEU DARTIALH, Department of Physics, New York University, IGOR ZUTIC, Department of Physics, New York University, WENDY L SARNEY, STEFAN P SVENSSON, ASHER LEFF, US Army CombatCapabilities Command, Army Research Laboratory, TIAGO DE CAMPOS, Department of Physics, University at Buffalo, KAUSHINI S WICKRAMASINGHE, MATTHIEU DARTIALH, Department of Physics, New York University, IGOR ZUTIC, Department of Physics, New York University — We demonstrate a robust superconducting proximity effect in InAs$_{0.5}$Sb$_{0.5}$ quantum wells grown with epitaxial Al contacts, which has important implications for mesoscopic and topological superconductivity. Unlike more commonly studied InAs and InSb semiconductors, bulk InAs$_{0.5}$Sb$_{0.5}$ supports stronger spin-orbit coupling and a larger g-factor. Through structural and transport characterization we observe high-quality interfaces and strong spin-orbit coupling. We fabricate Josephson junctions based on InAs$_{0.5}$Sb$_{0.5}$ quantum wells and observe a strong proximity effect. These junctions exhibit products of normal resistance and critical current, $I_cR_N = 270\mu V$, and excess current, $I_{ex}R_N = 200\mu V$, at contact separations of 500nm. Both of these quantities demonstrate a robust and long-range proximity effect with highly-transparent contacts.

*This work was partially supported by NSF DMR 1836687, the US Army research office, US ONR N000141712793, NSF ECCS-1810266, the University at Buffalo Center for Computational Research, and the ARO/LPS Quantum Computing Graduate Research Fellowship (QuaCGR BAA W911NF-17-S-0002).
4:42PM D60.00010: Topological Properties of Superconducting PdTe  RAMAKANTA CHAPAI (Presenter), Louisiana State University, Baton Rouge, PERAM SREENIVASA REDDY, National Cheng Kung University, Taiwan, LINGYI XING, Louisiana State University, Baton Rouge, DAVID E GRAF, National High Magnetic Field Laboratory, Tallahassee, FL, AMAR B. KARKI, WEIWEI XIE, JOHN DITUSA, Louisiana State University, Baton Rouge, TAY-RONG CHANG, National Cheng Kung University, Taiwan, RONGYING JIN, Louisiana State University, Baton Rouge — PdTe is a superconductor with $T_c \sim 4.5$ K. We have investigated its normal-state electronic properties via both first principles calculations and magnetic torque measurements by applying magnetic field up to 35 Tesla. Detailed analysis of the de-Haas van Alphen (dHvA) oscillations allows us to identify four frequencies: $F_\alpha = 64$ T, $F_\beta = 658$ T, $F_\gamma = 1155$ T, and $F_\eta = 1867$ T. Using the Lifshitz-Kosevich equation to fit the experimental data, the effective masses are obtained with $m^*_\alpha = 0.305m_0$, $m^*_\beta = 0.288m_0$, $m^*_\gamma = 0.415m_0$, and $m^*_\eta = 0.451m_0$ ($m_0$ is the free electron mass). By constructing the Landau fan diagram for each band, we extract the Berry phase, which is non-trivial for the $\alpha$ and $\gamma$ bands. These experimental findings are consistent with the calculated results. This suggests that PdTe is a topological superconductor.

4:54PM D60.00011: Tuning topological hinge states of Bi by edge adsorption: first-principles study*  IVAN NAUMOV (Presenter), PRATIBHA DEV, Howard University — Recent studies have shown that bismuth is a crystalline topological insulator and, additionally, hosts two different second-order band topologies that are protected by twofold and the threefold rotational symmetries [1,2]. These second-order topologies manifest themselves in one-dimensional hinge states in samples whose shape preserve the corresponding rotational symmetry [1,2]. Using first-principles calculations we show that the hinge states can be significantly tuned by H and N adsorption. We discuss the changes in their dispersion curves, real-space charge distributions and spin texture. Our findings may have practical applications in future electronic devices.

5:06PM D60.00012: The edge theories of 2D fermionic symmetry protected topological phases

SHANGQIANG NING (Presenter), CHENJIE WANG, Department of Physics, The University of Hong Kong, QING-RUI WANG, ZHENGCHENG GU, Department of Physics, The Chinese University of Hong Kong — Abelian Chern-Simons theory, labeled by the so-called $K$ matrices, have been quite successful in characterizing and classifying Abelian fractional quantum hall effect (FQHE) as well as symmetry protected topological (SPT) phases, especially for bosonic SPT phases. However, there are still some puzzles in dealing with fermionic SPT phases. In this paper, we utilize the Abelian Chern-Simons theory to study the fermionic SPT phases protected by Abelian total symmetry $G_f$ that is a central extension of bosonic symmetry $G_b$ by fermion parity symmetry $Z^f_2$. In particular, we study the edge theories with the proper anomalous symmetry action on the edge fields for various examples. Moreover, we also discuss the construction of edge theories with central charge $n - 1$ for Type-III bosonic SPT phases protected by $(Z_n)^3$ symmetry.

5:18PM D60.00013: Selective Control of Surface Spin Current in Topological Pyrite OsX$_2$ (X= Se, Te) Crystals

YUEFENG YIN (Presenter), Materials Science and Engineering, Monash University, MICHAEL FUHRER, Physics and Astronomy, Monash University, NIKHIL MEDHEKAR, Materials Science and Engineering, Monash University — The development of next-generation spin-based nanoelectronic devices requires effective control and detection of spin polarization. Recently topological materials have shown promising potential in this field due to their unique spin textures. Here we report the discovery of highly anisotropic surface spin textures in the (001) surfaces of topological pyrite OsX$_2$ (X = Se, Te) crystals using first principles calculations and Wannier tight-binding models. The surface spin textures of topologically nontrivial OsX$_2$ features a transition from in-plane to out-of-plane spin polarization in the momentum space and are protected by local crystalline symmetries. The energy screening of bulk bands leads to selective filtering of the magnitude and orientations of the surface spin polarization. These results provide new physical insights for manipulating spin degree of freedom in spin logic devices and could inspire new strategies of search nonmagnetic materials hosting exotic spin properties.

2:30PM D61.00001: Effect of pressure on the competing phases in FeSe and BaFe$_2$As$_2$:

Insights from specific heat measurements and beyond* [Invited] ELENA GATI (Presenter), LI XIANG, SERGEY L. BUD'KO, PAUL C CANFIELD, Iowa State University, Ames Laboratory —

Understanding the phase interplay in iron-based superconductors is considered to be crucial for unravelling the mechanism behind their superconductivity. In this talk, we focus on new insights into the phase interplay under pressure of two members, FeSe and BaFe$_2$As$_2$, from specific heat under pressures [1] up to ~ 2.5 GPa.

For FeSe [2], we show that superconductivity is bulk and competes with magnetism, whenever present. In addition, we conclude that, whenever magnetism is present, magnetic and superconducting fluctuations exist across wide ranges of pressure above their respective, bulk transition temperatures.

For Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ [3], we argue that the behavior of the nematic transition under pressure is intimately linked to changes of the Fermi surface topology. We complement these data by presenting the first study of elastoresistance under pressure [4] on BaFe$_2$As$_2$, which might allow to study the interplay of nematicity and superconductivity under pressure.

3:06PM D61.00002: Electronic phase diagram of FeSe$_{1-x}$Te$_x$ under high pressure  
KIYOTAKA MUKASA (Presenter), KOHEI MATSUURA, YUICHI SUGIMURA, MUKU OTANI, MINGWEI QIU, MIKIHIKO SAITO, YUTA MIZUKAMI, KENICHIRO HASHIMOTO, Department of Advanced Materials Science, University of Tokyo, JUN GOUCHI, YOSHIYA UWATOKO, Institute for Solid State Physics, University of Tokyo, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo — FeSe has the simplest crystal structure among the iron-based superconductors and is known to have a nonmagnetic nematic order. When selenium is substituted by the isovalent element, sulfur, the nematic phase is suppressed and a nematic quantum critical point without magnetism appears. On the other hand, under pressure, a dome-shaped magnetic phase is induced and the superconducting transition temperature rises from 9 K to 37 K. In this study, we focus on FeSe$_{1-x}$Te$_x$ in which selenium is substituted by tellurium. In order to clarify the relationship between the nematic phase and the superconducting phase, we have synthesized bulk single crystals of FeSe$_{1-x}$Te$_x$ (0 < x < 0.22) by using the chemical vapor transport method. The temperature dependence of the electrical resistivity was measured on the FeSe$_{1-x}$Te$_x$ crystals under pressure up to 8 GPa using a constant loading cubic anvil high-pressure apparatus. As a result, we have established the three-dimensional electronic phase diagram; temperature against pressure and Te-substitution. The obtained phase diagram indicates that the tellurium substitution shifts the pressure-induced magnetic phase to a lower pressure side, which is in contrast to the sulfur substitution case.

3:18PM D61.00003: Multiple Magnetic Phases Hiding in Plain (and Out-of-Plane) Sight in Coexistence with Superconductivity in LaFeAs$_{1-x}$P$_x$O 1111 System*  
RYAN STADEL (Presenter), Northern Illinois Univ, DMITRY KHALYAVIN, PASCAL MANUEL, ISIS, Rutherford Appleton Laboratory, RAFAEL FERNANDES, MORTEN HOLM CHRISTENSEN, University of Minnesota, KEITH TADDEI, HFIR, Oak Ridge National Laboratory, CLARINA RELOJ DELA CRUZ, ASHFIA HUQ, SNS, Oak Ridge National Laboratory, SAUL LAPI DUS, APS, Argonne National Laboratory, DANIEL PHELAN, DUCK YOUNG CHUNG, MATTHEW KROGSTAD, RAYMOND OSBORN, STEPHAN ROSENKRANZ, Material Science, Argonne National Laboratory, OMAR CHMAISSEM, Northern Illinois Univ — Following the discovery of the microscopic co-existence of antiferromagnetic spin density waves and superconductivity in Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and the low temperature structural re-entrance to the magnetic C$_4$ tetragonal phase in Ba$_{1-x}$Na$_x$Fe$_2$As$_2$, an effort was made to seek similar phases in the related LaFeAs$_{1-x}$P$_x$O 1111 system. Previous work had reported two superconducting domes as well as two distinct magnetic regions. While the low doping magnetic phase had been well characterized by neutron diffraction, the higher doped magnetic region had been deduced from short range $^{31}$P-NMR measurements. We present a detailed phase diagram with nuclear and magnetic structural characterization based on a combination of x-ray and neutron diffraction, as well as magnetic temperature dependence thoroughly mapped by muon spin resonance. This work demonstrates three distinct magnetic phases evolving from in-plane orthorhombic to in-plane tetragonal to out-of-plane tetragonal permeating the entire phase diagram from the parent LaFeAsO to superconducting LaFeAs$_{0.2}$P$_{0.8}$O.

*Work at the Materials Science Division at Argonne National Laboratory was supported by the US Department of Energy, Office of Science, Materials Sciences and Engineering Division.
3:30PM D61.00004: Wang-Landau simulations of the coupled magnetic and nematic transitions in disordered iron-based superconductors*  ANZUMAAN CHAKRABORTY (Presenter), Department of Physics, Missouri University of Science and Technology, WILLIAM J MEESE, RAFAEL FERNANDES, School of Physics and Astronomy, University of Minnesota, THOMAS VOJTA, Department of Physics, Missouri University of Science and Technology — In many iron-based superconductors, nematicity and magnetism are found to be closely related and occurring at comparable temperatures. While many works have discussed the character of these coupled transitions in clean systems, the impact of disorder, like random strain, has not been elucidated. Here we perform Monte Carlo simulations of an appealing model that captures these two transitions, namely, the 2D anisotropic Ising-O(3) model. For sufficiently large anisotropy in the exchange coupling, there is a direct first-order transition from the paramagnetic tetragonal phase to the low-temperature phase that displays both spin and nematic (Ising) orders. This transition splits into two separate transitions as the anisotropy decreases, giving rise to a nematic intermediate phase. We study both clean and disordered systems and compare conventional algorithms, such as Metropolis and Wolff, to an implementation using the Wang-Landau algorithm. The latter avoids the supercritical slowing down associated with the first-order transitions, providing an efficient way to probe the complicated free energy landscapes near the multi-critical point. Phase diagrams are obtained and compared to experimental results.

*Work supported by the NSF under Grant numbers DMR-1506152 and DMR-1828489.

3:42PM D61.00005: Coexistence of long-range magnetic ordering and superconductivity in FeSe/EuTiO$_3$ heterostructure  CHONG LIU (Presenter), HYUNGKI SHIN, RYAN ROEMER, KE ZOU, Stewart Blusson Quantum Matter Institute, University of British Columbia — Spin degree of freedom has played a key role in unconventional superconductivities. FeSe monolayer superconductors, with the highest transition temperature in Fe-based superconductors, remain not magnetically ordered, while spin density waves and nematicity have been observed in bulk FeSe. We grow heterostructures of FeSe on (001) antiferromagnetic EuTiO$_3$ (ETO) using molecular beam epitaxy. Transport measurements showed clear anomalous Hall effect in both ETO and FeSe/ETO samples. Simultaneously, superconducting transition was also observed in FeSe films on ETO. Our work provides a new platform for the interplay of spins and superconductivity, which may promote integration of superconductors in new spintronics.
Quasi-elastic scattering from short-range magnetic order in FeTe$_{1-x}$Se$_x$ compounds

GUANGYONG XU (Presenter), ZHIJUN XU, National Institute of Standards and Technology, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory, ROBERT J BIRGENEAU, University of California, Berkeley — We report neutron scattering measurements on single crystals of FeTe$_{1-x}$Se$_x$. Superconductivity (SC) and antiferromagnetic (AFM) order in these compounds can be tuned together by varying Se compositions and/or excess Fe. We show that in systems where long-range magnetic order develops, superconductivity is completely suppressed. The long-range magnetic order is static with long life-time. On the other hand, when the magnetic order is short-range and the system exhibits behaviors of a mixed phase or phase separation between AFM and SC, the energy profile of the magnetic order appears to be quasi-elastic with energy widths around 0.2 meV. We discuss the evolution of the quasi-elastic magnetic scattering with temperature and doping, and their implications on the understanding of the spin-glass/SC mixed phase in FeTe$_{1-x}$Se$_x$ systems.

*The work at Brookhaven National Laboratory and Lawrence Berkeley National Laboratory was supported by the Office of Basic Energy Sciences (BES), Division of Materials Science and Engineering, U.S. Department of Energy (DOE), under Contracts No. DE-SC0012704 and No. DEAC02-05CH1123, respectively.
Elastoresistance of CaK(Fe,Ni)$_4$As$_4$*  ANNA BOEHMER (Presenter), Karlsruhe Institute of Technology; Ames Laboratory, WILLIAM MEIER, MINGYU XU, GIL DRACHUCK, Ames Laboratory, Iowa State University, PAUL WIECKI, Karlsruhe Institute of Technology, SERGEY L. BUD'KO, Ames Laboratory, Iowa State University, CHRISTOPH MEINGAST, Karlsruhe Institute of Technology, FEI CHEN, MORTEN HOLM CHRISTENSEN, RAFAEL FERNANDES, University of Minnesota, PAUL C CANFIELD, Ames Laboratory, Iowa State University — Elastoresistance describes the resistance change induced by an elastic deformation. In the well-known compound BaFe$_2$As$_2$ with clear nematicity, a diverging elastoresistance has been taken as a measure of the nematic susceptibility [1]. In contrast to BaFe$_2$As$_2$, the related CaK(Fe,Ni)$_4$As$_4$ orders antiferromagnetically as a so-called spin-vortex crystal (SVC) [2], which does not entail any nematicity. Here, we have determined the elastoresistance of CaK(Fe$_{1-x}$Ni$_x$)$_4$As$_4$ ($x=0-0.05$), spanning the phase diagram from a superconducting sample with $T_c=35$ K and no magnetic order, to a sample with magnetic order at a high $T_N=51$ K having $T_c=10$ K. The nematic susceptibility for SVC order is analyzed theoretically via a Ginzburg-Landau expansion and compared with the elastoresistance data. Implications on the place of CaK(Fe,Ni)$_4$As$_4$ in the wider material class and the factors contributing to elastoresistance are discussed.

*Work at Ames Laboratory was supported by the U.S. DOE, BES, DMSE. Ames Laboratory is operated for the U.S. DOE by Iowa State University under Contract No. DE-AC02-07CH11358. WRM was supported by the Gordon and Betty Moore Foundation's EPIQS Initiative through Grant GBMF4411.
**4:18PM D61.00008: Prediction of Antiferromagnetism in Chromium Analog (BaCr$_2$P$_2$) of Iron Pnictide Confirmed by Synthesis**  
RADI JISHI, JOSE RODRIGUEZ (Presenter), Physics and Astronomy, California State University Los Angeles, TIMOTHY HAUGAN, MICHAEL SUSNER, Aerospace Systems Directorate, Air Force Research Laboratory — We have performed density-functional theory (DFT) calculations for BaCr$_2$P$_2$. It is a chromium analog to the parent compound BaFe$_2$As$_2$ for a series of iron-pnictide superconductors. By combining evolutionary methods with DFT, we predict that BaCr$_2$P$_2$ has the same crystal structure as its iron-pnictide analog[1]. DFT also predicts Neel antiferromagnetic order over the chromium sites. A simple hopping model over a square lattice of chromium atoms that includes only the principal 3d$_{xz}$ and 3d$_{yz}$ orbitals suggests that such checkerboard antiferromagnetic order is due to residual nesting of the Fermi surfaces that is obscured by a Lifshitz transition[1]. The DFT prediction has been confirmed experimentally after the synthesis of polycrystalline samples of BaCr$_2$P$_2$. X-ray diffraction recovers the predicted crystal structure to high accuracy, while magnetic susceptibility and specific-heat measurements are consistent with an antiferromagnetically ordered state at temperatures below $T_N \sim 60$ K [1].

*This work was supported in part by the Air Force Office of Scientific Research and by the National Science Foundation.

**4:30PM D61.00009: Novel Fe-based superconductor LaFe$_2$As$_2$ in comparison with traditional pnictides**  
IGOR MAZIN (Presenter), Naval Research Laboratory (currently at George Mason University), HARALD JESCHKE, MAKOTO SHIMIZU, NAYUTA TAKEMORI, University of Okayama — The recently discovered Fe-based superconductor (FeBS) LaFe$_2$As$_2$ seems to break away from an established pattern that doping FeBS beyond 0.2 e/Fe destroys superconductivity. LaFe$_2$As$_2$ has an apparent doping of 0.5 e, yet superconducts at 12.1 K. Its Fermi surface bears no visual resemblance with the canonical FeBS Fermiology. It also exhibits two phases, none magnetic and only one superconducting. We show that the difference between them has nonetheless magnetic origin, the one featuring disordered moments, and the other locally nonmagnetic. We find that La there assumes an unusual valence of +2.6 to +2.7, so that the effective doping is reduced to 0.30-0.35 e. A closer look reveals the same key elements: hole Fermi surfaces near the $\Gamma$-Z and electron ones near the X-P lines, with the corresponding peak in susceptibility, and a strong tendency to stripe magnetism. The physics of LaFe$_2$As$_2$ is thus more similar to the FeBS paradigm than hitherto appreciated.
4:42PM D61.00010: Biaxial Strain Tuning of Strong Electronic Correlations in CsFe$_2$As$_2$  PAUL WIECKI (Presenter), AMIR-ABBAS HAGHIGHIRAD, THOMAS WOLF, ANNA BOEHMER, Karlsruhe Institute of Technology — CsFe$_2$As$_2$ is an iron-based superconductor with $T_c \approx 2.3$ K and a large Sommerfeld coefficient of 180 mJ / mol K, indicating strong electronic correlations at low temperature [1]. In addition, CsFe$_2$As$_2$ shows a coherence-incoherence crossover, reminiscent of heavy fermion systems [2,3]. In this contribution, using transport and x-ray diffraction measurements, we demonstrate that in-plane biaxial tension strain, applied by gluing the sample to a rigid substrate with a large mismatch in thermal expansivity, can modify the low-temperature electronic correlations as well as the coherence-incoherence crossover temperature in this material.

4:54PM D61.00011: Emergent electronic properties of FeTe by strain tuning  SOUMENDRA PANJA (Presenter), CRAIG V TOPPING, CHI MING YIM, CHRISTOPHER TRAINER, University of St Andrews, North Haugh, St Andrews, Fife KY16 9SS, United Kingdom, SUPA, School of Physics and Astronomy, DORINA CROITORI, VLADIMI TSURKAN, ALOIS LOIDL, Center for Electronic Correlations and Magnetism, Experimental Physics V, University of Augsburg, D-86159 Augsburg, Germany, PETER WAHL, University of St Andrews, North Haugh, St Andrews, Fife KY16 9SS, United Kingdom, SUPA, School of Physics and Astronomy, ANDREAS ROST, School of physics and astronomy, SUPA, School of Physics and Astronomy, University of St Andrews, North Haugh, St Andrews, Fife KY16 9SS, United Kingdom; Max Planck Institute — FeTe is an ‘11’ non-superconducting parent compound with properties significantly different from those of other iron-based high-temperature superconductors. Most discernible is the double stripe antiferromagnetic order with the $(\pi,0)$ propagation vector contrary to the more typical $(\pi, \pi)$ order. That these properties can be significantly tuned by tensile strain has for example been shown by thin film experiments in which superconductivity was stabilised at 13K. In our research programme we explore the magnetic and superconducting phase diagram under uniaxial strain along [110]. We complement direct imaging of magnetic order by spectroscopic imaging STM with low-temperature magnetoresistivity measurements in force cell. We discuss the possibility of stabilising $(\pi, \pi)$ order both on the surface and in bulk under experimentally accessible strains and the potential to stabilise superconductivity in Fe$_{1+x}$Te via this route.
Unconventional charge density wave order in the pnictide superconductors $\text{Ba(Ni}_{1-x}\text{Co}_x\text{)}_2\text{As}_2$ and $\text{Ba}_{1-x}\text{Sr}_x\text{Ni}_2\text{As}_2$*  

SANGJUN LEE (Presenter), XIAOLAN SUN, XUEFEI GUO, University of Illinois at Urbana-Champaign, JOHN COLLINI, CHRIS ECKBERG, JOHNPIERRE PAGLIONE, University of Maryland, College Park, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — $\text{BaNi}_2\text{As}_2$ is a structural homologue of the pnictide high temperature superconductor parent compound, $\text{BaFe}_2\text{As}_2$, in which the Fe atoms are replaced by Ni. Superconductivity is highly suppressed in this system, reaching a maximum $T_c = 2.3$ K upon Co doping, compared to 24 K in its iron-based cousin, and the origin of this $T_c$ suppression is not known. Using x-ray scattering, we present the discovery of CDW order in $\text{BaNi}_2\text{As}_2$ and its evolution upon Co and Sr doping. The chemical doping suppresses the CDW, paralleling the behavior of antiferromagnetism in iron-based superconductors. Our study demonstrates that pnictide superconductors can exhibit CDW order which may be closely related to the $T_c$ suppression in this system. We also present the response of CDW in $\text{Ba}_{1-x}\text{Sr}_x\text{Ni}_2\text{As}_2$ under external strain and discuss how it relates to the strong nematic susceptibility recently discovered in these compounds via elastoresistivity measurements.

*X-ray work was supported by DOE grant DE-FG02-06ER46285 and crystal growth was supported by AFOSR grant FA9550-14-1-0332. P. A. and J. P. acknowledge Gordon and Betty Moore Foundation EPIQS grants GBMF4542 and GBMF4419, respectively.
Emergence of Fulde-Ferrell-Larkin-Ovchinnikov phase in FeSe in the BCS-BEC crossover*

SHIGERU KASAHARA (Presenter), YUKI SATO, Kyoto Univ, SALVATORE LICCIARDELLO, MATIJA ĆULO, High Field Magnet Laboratory (HFML-EMFL) and Institute for Molecules and Materials, Radboud University, STEVAN ARSENJEVIC, Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, THOM OTTENBROS, High Field Magnet Laboratory (HFML-EMFL) and Institute for Molecules and Materials, Radboud University, TAKAHITO TOMINAGA, Kyoto Univ, JAKOB BÖKER, ILYA EREMIN, Ruhr-Universität Bochum, JOACHIM WOSNITZA, Hochfeld-Magnetlabor Dresden (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, TAKASADA SHIBAUCHI, Univ. of Tokyo, NIGEL HUSSEY, High Field Magnet Laboratory (HFML-EMFL) and Institute for Molecules and Materials, Radboud University, YUJI MATSUDA, Kyoto Univ — The Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase, predicted more than a half-century ago, is a highly exotic state of fermionic condensate, in which oscillations of the order parameter emerge in real space. Yet, quest of the FFLO phase has been a challenge for a broad range of scientists, including solid-state, ultracold atomic and high-energy physics. Here, via thermal transport measurements in intense magnetic fields up to 33 T, we present compelling evidence for a distinct high-field superconducting phase in an iron-chalcogenide superconductor FeSe for the field $H \parallel ab$-plane. A discontinuous downward jump in the quasiparticle thermal transport indicates the presence of a first-order transition line within the superconducting phase. We attribute the high-field phase to the FFLO phase, where planar nodes are formed. We discuss the importance of the extremely small Fermi energies, strong spin-orbit coupling and multiband nature for the FFLO phase in FeSe.

Session D62 DMP: Nanostructures and Metamaterials III Mile High Ballroom 4C - Antoinette Taylor, Los Alamos Natl Lab - Tag(s): Focus
2:30PM D62.00001: Topological structures of and for light* [Invited] KOBUS KUIPERS (Presenter), Quantum Nanoscience, Kavli Institute of Nanoscience Delft — Topology is an invaluable tool to elucidate the properties of physical systems. Typically, it refers to instances where an entity has so-called topological protection, which means that the entity cannot disappear if small changes are made to the system. In this lecture I will address two illustrations of topological protection in light fields.

The first relates to optical singularities, which can have a topological charge. I will experimentally show that the charge of both phase- and polarization singularities plays a role in how they are distributed in space and also in the way they are created and annihilated. The second relates to the behavior of light in photonic nanostructures of which the properties have a non-trivial topology. We experimentally investigated the propagation of edge states between topologically non-trivial photonic crystals. I will show how the propagation direction is related to the far-field optical spin of the modes. Time allowing I will address the heterogeneity of the spatial distribution of the near-field optical spin of the mode, which is of importance to quantum optical application of these states.

* I would like to acknowledge funding from the European Research Council (ERC Advanced Grant No. 340438-CONSTANS).

3:06PM D62.00002: Topological phases of electromagnetic waves in superlattices of negative- and positive- epsilon materials AKIHIRO OKAMOTO (Presenter), Department of Physics, Tokyo Institute of Technology, YOSUKE NAKATA, Graduate School of Engineering Science, Osaka University, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Recently, a new topological invariant is proposed to classify electromagnetic waves in an isotropic medium with positive or negative permittivity and permeability, and various interface modes such as surface plasmons are interpreted as topological boundary modes [1]. We expect similar topological phases of electromagnetic waves even for metamaterials.

To this end, we consider the electromagnetic waves in a 1D multilayer consisting positive- and negative- epsilon layers, studied in [2]. Depending on the ratio of layer thicknesses and the values of the dielectric constants of the constituent layers, the spectra changes, and the dispersion opens a gap at the origin depending on the spatial average of the dielectric constant. We associate this with a change in the topological number proposed in [1]. In addition, we find that interface states appear at an interface between different topological phases as expected.

3:18PM D62.00003: Diverged photonic spin hall effect in Weyl Photonic metamaterial
WENHUI A. WANG (Presenter), Singapore University of Technology and Design, WENLONG GAO, University of Birmingham, SHENGYUAN YANG, Singapore University of Technology and Design, SHUANG ZHANG, University of Birmingham — Weyl semimetal is gaining increasing attention due to the unprecedented physical observables including the chiral magnetoresistance effect in condensed physics matter. In optics however, observables besides the detection of Weyl node and the Fermi arcs are still in lack. In this work, we discover that when circularly polarized beams are reflected by a Weyl medium, a handedness dependent spin hall effect can be realized due to the topological properties of the scattering matrix arises from the Weyl node. The scattering properties of the Weyl node could dramatically influence the trajectory of the light in real space resulting in a handedness dependent Imbert-Fedorov shift. More importantly, the shift is shown to be diverging in approximate to the Weyl node. Our discovery creates a whole new and readily available platform realizing diverged spin hall effect of optical Weyl medium.

3:30PM D62.00004: Optically tunable topological photonic structures [Invited] NATALIA LITCHINITSER (Presenter), MIKHAIL SHALAEV, WIKTOR WALASIK, Duke University, HOUCHEN LI, Nankai University, JIANNAN GAO, Duke University — Photonic topological insulators offer the possibility to eliminate backscattering losses and improve the efficiency of optical communication systems. We combine the properties of a planar silicon photonic crystal and the concept of topological protection to demonstrate dynamically controlled transmission in a topological photonic crystal that exhibits the valley Hall effect.

4:06PM D62.00005: Non-Hermitian landau damping and bulk Fermi arc in superlattice-gate-tuned graphene plasmons MINWOO JUNG (Presenter), Department of Physics, Cornell University, HANAN HERZIG SHEINFUX, ICFO-Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, FENGYU LIU, Department of Electrical and Computer Engineering, University of Maryland, FRANK KOPPENS, ICFO-Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, GENNADY SHVETS, School of Applied and Engineering Physics, Cornell University — Landau damping, in which a plasmon emits an electron-hole pair, has been considered as a hindering factor for low-loss nanophotonic applications of graphene surface plasmon-polaritons (GSP), and is usually avoided by Pauli-blocking at high doping. In contrast to this simple view against landau damping, here we unravel its ironic utility and show how significantly this loss mechanism can extend the existing framework of graphene nanophotonics. Given a properly designed spatial pattern, landau damping becomes a key element for exotic non-Hermitian band structure engineering of GSPs, without damaging their quality factor severely. We propose that periodic damping textures can be assigned by field-effect gating through a combination of two electrodes; a metagate, thin and periodically punctured, provides a superlattice photonic crystal structure to GSPs, and a backgate, placed far below the metagate, controls local carrier densities on graphene selectively on the regions above holes in the metagate. This setting allows us to use the backgate voltage as a switch for the bulk Fermi arc, a topological signature of an exceptional point pair in the band structure. Our work thus opens up a new regime of graphene plasmonics involving open systems and non-Hermitian topological physics.
4:18PM D62.00006: SAW interdigitated transducers as topological mechanical metamaterial

SEAN MCHUGH (Presenter), Resonant Inc. — A lattice model is developed to describe the mechanical displacement of and current through each electrode of a surface acoustic wave (SAW) interdigitated transducer (IDT). Each electrode of an IDT is treated as a mass connected mechanically to its neighbors with a spring and electrically with a capacitor. Simulations for the electrical admittance of a typical SAW IDT are performed and compared with the results of an accurate FEM simulation. The utility of this lattice model is demonstrated by simulating the admittance of an IDT structure known as a hiccup resonator, which has a mode in the center of the band gap. It is shown here that this mode is a topologically protected edge state described by the 1D Su-Schrieffer-Heeger (SSH) model. Hiccup resonators have been used in commercial products for decades, and as such it may considered the first mass-produced topological mechanical metamaterial.

4:30PM D62.00007: A polarization-actuated plasmonic circulator

TZU-YU CHEN, CHENBIN HUANG (Presenter), Natl Tsing Hua Univ — We show both by simulation and experiment, a plasmonic structure functions as a nanoscopic optical circulator when the input laser beam is properly polarized. Moreover, depending on the helicity of the spin angular momentum carried by the light, the circulation direction of surface plasmons could be correspondingly controlled.

*Ministry of Science and Technology in Taiwan (MOST) 106-2112-M-007-004-MY3.

4:42PM D62.00008: Integration of single layer MoSe2 with photonic rings for electrically switchable routing of light

ROBERT SHREINER (Presenter), KAI HAO, AMY BUTCHER, ALEXANDER A HIGH, University of Chicago — Semiconducting transition metal dichalcogenide monolayers exhibit pronounced optical signatures in the visible and near-infrared regimes due to strong excitonic resonances, which can be modulated significantly through electrostatic doping. When interfaced with such tunable dielectric environments, nanophotonic devices inherit gate-dependent functionalities. Here, we demonstrate an electro-optical switch composed of a titanium dioxide ring resonator fabricated on monolayer molybdenum diselenide. Gate-varying measurements reveal electrically tunable cavity transmission, suggesting future application in on-chip photonic circuitry.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1746045.
Diffraction of elastic waves is considered for a system consisting of two parallel arrays of thin (subwavelength) cylinders that are arranged periodically. The embedding media supports waves with all polarizations, one longitudinal and two transverse, having different dispersion relations. An interaction with defects mixes the in-plane longitudinal and transverse modes. It is shown that the system supports bound states in the continuum (BSC) that have no specific polarization, that is, there are standing waves localized in the scattering structure whose wave numbers lies in the first open diffraction channels for both longitudinal and transverse modes. BSCs are shown to exists only for specific distances between the arrays and for specific values of the wave vector component along the array. An analytic solution is obtained for BSCs containing coupled elastic waves with different dispersion relations. For distances between the parallel arrays much larger than the wavelength, the existence of BSCs is explained by a destructive interference similar to the interference in a Fabri-Perot interferometer.

5:06PM D62.00010: Strong nonreciprocal transmission self-induced by nonlinear PT-symmetric metamaterials  CHRISTOS ARGYROPOULOS (Presenter), BOYUAN JIN, University of Nebraska - Lincoln — Self-induced nonreciprocity based on optical nonlinear effects is a more appealing technique compared to other ways to achieve nonreciprocal response due to the absence of any kind of bias based on magnets, currents, or time modulation. We demonstrate strong self-induced nonreciprocal transmission by using a new compact nonlinear parity-time (PT) symmetric system based on epsilon-near-zero (ENZ) metamaterials photonically doped with gain and loss defects [B. Jin and C. Argyropoulos, “Nonreciprocal Transmission in Nonlinear PT-Symmetric Metamaterials Using Epsilon-near-Zero Media Doped with Defects,” Adv. Opt. Mat., p. 1901083 (2019)]. The strong self-induced nonreciprocal transmission arises from the extreme asymmetric field distribution achieved upon excitation from opposite incident directions combined with the boosted nonlinear effects at the nanoscale. The transmittance from one direction is kept exactly unity while the transmittance from the other direction is decreased to very low values, achieving very high optical isolation. The presented work can have a plethora of applications, such as nonreciprocal ultrathin coatings for the protection of sources or other sensitive equipment from external pulsed signals, circulators, and isolators without the use of bulk magnets.
5:18PM D62.00011: High-efficient harmonic generation via Plasmonic Tamm states
YINXIAO XIANG (Presenter), West Virginia Univ, CHENGLIN DU, Physics department, Nankai University, FAN SHI, YI LIANG, West Virginia Univ, WEI CAI, Physics department, Nankai University, CHENG CEN, West Virginia Univ — Plasmonic Tamm states in nanoscaled plasmonic waveguides can increase the electric and magnetic field intensity separately by three orders of magnitude via the spatial confinement and phase-matching. Theoretical or numerical models about plasmonic Tamm states have been proposed in metal-insulator-metal plasmonic waveguides and graphene plasmonic crystals. In this work, we experimentally realized plasmonic Tamm states by combining a nanoantenna with a plasmonic Tamm structure. The field enhancement was characterized by our home-made multi-photon microscope, in which highly efficient second and third harmonic generations were both observed. Our work demonstrates a promising potential for electromagnetic nanofocusing and nanosensing.

Session D63 DMP: Theory and Computation of Hybrid Perovskites Mile
High Ballroom 4D - Aron Walsh, National Renewable Energy Laboratory - Tag(s): Focus

2:30PM D63.00001: A Theoretical Study of Structure Property Relations in Photovoltaic Perovskites*
JORDAN COWELL (Presenter), NICHOLAS C. BRISTOWE, Materials for Energy and Electronics, University of Kent — Perovskite materials are a great example of systems with a multitude of structure-property relationships. For example, metal insulator transitions in the nickelates and manganites can be linked to breathing and Jahn-Teller distortions which allow for charge and orbital ordering, respectively. This study examines the relationship between atomic structure and electrical band-gaps in the promising photovolatics material A2Au2X6 (A = Cs, Rb, K, X = I, Cl), through first principles calculations based on DFT. We find that there is a complex competition between various structural degrees of freedom in the material, which can be manipulated through chemistry and pressure, and that each of the structural modes can strongly tune the band gap. For example, in the Rb2Au2I6 double perovskite, we predict that, contrary to expectation, hydrostatic pressure produces a polar phase. We argue that this is due to a) the cooperative coupling of the Jahn-Teller and tilt modes which are both reduced with pressure, and b) the competitive coupling of tilting and polar modes. We finally discuss the effect of each of these modes and chemical changes on the band gap, and how the polar mode could be helpful to separate photo-excited carriers via the photoferroic effect.

**2:42PM D63.00002: Improved Accuracy Tight Binding Model for Finite Temperature Electronic Structure Dynamics in Methyl Ammonium Lead Iodide (MAPbI3)**  
DAVID ABRAMOVITCH (Presenter), Department of Physics, University of California, Berkeley, LIANG TAN, Molecular Foundry, Lawrence Berkeley National Lab — Halide perovskites are promising photovoltaic and optoelectronic materials. However, computing electronic properties and dynamics at finite temperature is challenging due to nonlinear lattice dynamics and prohibitive computational costs for ab initio methods. Tight binding models decrease computational costs, but current models lack the ability to accurately model instantaneous atom displacement and reduced symmetry at finite temperature. We present a parameterized tight binding model for MAPbI3 capable of predicting instantaneous electronic structures for large systems based on atomic positions extracted from classical molecular dynamics. Our tight binding Hamiltonian predicts instantaneous atomic orbital onsite energies and hopping parameters accurate to 0.1 to 0.01 eV compared to DFT across the orthorhombic, tetragonal, and cubic phases, including effects of temperature, reduced symmetry, and spin orbit coupling. This model allows for efficient calculation of instantaneous and dynamical electronic structure at the length and time scales required to address coupled electronic and ionic dynamics, as required for predicting temperature dependence of carrier mass, band structure, free carrier scattering, and polaron transport and recombination.

**2:54PM D63.00003: Materials Property Database for Hybrid Organic-Inorganic Perovskites and Application to Stability and Electronic Structure of (PEA)\(_2\)PbI\(_4\)\(^*\)**  
XIXI QIN (Presenter), XIAOCHEN DU, SVENJA JANKE, RAUL LAASNER, TIANYANG LI, MANOJ KUMAR JANA, Duke University, CONNOR CLAYTON, Carnegie Mellon University, CHI LIU, Duke University, SAMPREETI BHATTACHARYYA, University of North Carolina at Chapel Hill, JULIANA MENDES, North Carolina State University, JUN HU, University of North Carolina at Chapel Hill, DOVLETGELDI SEYITLIYEV, North Carolina State University, RUYI SONG, Duke University, MATTI ROPO, University of Turku, FRANKY SO, KENAN GUNDOGDU, North Carolina State University, WEI YOU, YOSUKE KANAI, University of North Carolina at Chapel Hill, DAVID B. MITZI, VOLKER BLUM, Duke University — Hybrid organic-inorganic perovskites (HOIPs) are attracting significant attention as new semiconductor materials, due to their inherent tunability by varying both the organic and the inorganic components. However, keeping track of the dramatically increasing volume of materials data related to HOIPs is challenging. We here present an open database, "HybriD\(^3\)" (Design, discovery and dissemination (D\(^3\)) of data related to hybrid materials, https://materials.hybrid3.duke.edu), aiming to collect, curate, and make available materials data related to HOIPs. The database is open to the community and designed to accept community input for a broad set of data, i.e., experimental and computational, related to in principle any materials property. We demonstrate the use of the database for the widely investigated material phenethylamine lead iodide, (PEA)\(_2\)PbI\(_4\), for which several crystal structure refinements have been reported in past work. Using density functional theory including van der Waals effects, we identify the lowest-energy structure among them and provide the electronic band structure at a high level of theory (hybrid density functional theory including spin-orbit coupling).

3:06PM D63.00004: First-principles Study of Water Insertion Process on MAPbI$_3$ Surface

MD. ABDULLAH ASAD (Presenter), Okayama Univ, MASAKI HADA, Tsukuba Research Center for Interdisciplinary Materials Science, University of Tsukuba, KYOSUKE SATO, YOICHI HASEGAWA, RYOTA NAGAOKA, RYUJI MISHIMA, TAKEHI NISHIKAWA, YOSHIFUMI YAMASHITA, YASUHIKO HAYASHI, KENJI TSURUTA, Okayama Univ — We computationally investigate an insertion process of water into the methylammonium lead halide perovskite (MAPbI$_3$), which has been attracting considerable interest during recent years due to its high performance in solar-cell application [1]. The rapid decomposition of MAPbI$_3$ reaction with water has been recognized to be a major obstacle to outdoor applications [2]. To overcome this drawback process, it is important to identify the initial stage of water insertion into the MAPbI$_3$. The first-principles calculation based on the density-functional theory is performed to investigate the water insertion process on outer surface layer of MAPbI$_3$ slab model. Using the Nudged Elastic Band method, we find that the initial insertion process follows the three steps; approaching, re-orienting and finally sinking into the perovskite layer. This process requires approximately 0.60 eV to overcome an energy barrier, which agrees with an in situ X-ray diffraction (XRD) measurement of the reaction threshold of water molecules with the MAPbI$_3$ crystal at room temperature [3].

3:18PM D63.00005: Theory of Layer Edge States in 2D Halide-Perovskites

JISOOK HONG (Presenter), DAVID PRENDERGAST, LIANG TAN, Lawrence Berkeley National Laboratory — Halide perovskites are one of the most promising candidate materials for photovoltaic and optoelectronic applications. Compared to the 3D organic-inorganic hybrid perovskites, the 2D layered perovskites exhibit greater tunability of band gaps and exciton binding energies, while solving the well-known stability issue of hybrid perovskites at the same time. Recent experimental observations suggest that extrinsic localized edge states are present in 2D layered perovskites. [1-3] The edge state facilitates extremely efficient electron-hole dissociation and long carrier lifetimes as much as those of 3D perovskites. However, the phenomenon has not been thoroughly investigated in a first-principles theoretical framework. In this talk, we will discuss electronic structures and the origin of the edge states studied using first-principles calculations. Understanding the mechanism for edge state formation and their role in carrier separation will pave the way for controlling the edge states in future applications such as efficient photovoltaic devices and high-performance photodetectors.

Halide perovskites (HaPs) exhibit intriguing optoelectronic properties that cannot yet be fully explained on a microscopic level. Understanding the characteristics of HaPs is possible with well-established conventional theoretical calculations, such as density functional theory (DFT), but their applicability to large-scale simulations is often limited by their computational costs. Here, building on previous work [1] we put forward a tight binding (TB) approach as a computationally efficient tool to model large-scale system sizes and calculate optoelectronic properties of HaPs. Parametrizing the TB model with DFT calculations and unifying it with force-field molecular dynamics, we compute dynamic band gap distributions for several HaPs as well as their dependence on temperature. This helps resolving confluences of small Urbach energies and large amounts of nuclear disorder in HaPs around room temperature.

**3:54PM D63.00008: Structural and transport studies from air-stable hybrid perovskite thin films**

RANDY BURNS (Presenter), Department of Physics and Astronomy, University of Missouri - Columbia, SIPHELO NGQOLODA, CHRISTOPHER ARENDSE, THEOPHILLUS MULLER, Department of Physics, University of Western Cape, SORB YESUDHAS, DEEPAK K SINGH, SUCHISMITA GUHA, Department of Physics and Astronomy, University of Missouri - Columbia — Traditionally, MAPbX$_3$ (X = Br, I, or Cl) hybrid organic-inorganic perovskite films have been deposited with spin coating techniques which cause degradation under ambient atmospheric conditions. We demonstrate the feasibility of stable MAPbI$_3$ thin films grown by a facile two-step low-pressure vapor deposition process in a single reactor. Absorption measurements confirm excellent stability after three weeks. In confluence with the absorption data, synchrotron x-ray diffraction experiments reveal good structural stability on the timescale of several months. Temperature dependent transport measurements show sharp inflection points of the resistance curve at distinct temperatures. One inflection point occurs precisely at the expected tetragonal to orthorhombic transition, however, another inflection deviates significantly from the expected tetragonal to cubic transition. Consequently, we conducted temperature dependent laboratory-based x-ray diffraction measurements that also suggest a transition below the commonly reported tetragonal/cubic transition temperature. Concerning device application, the MAPbI$_3$ films were incorporated into solar cells that maintained the majority of their efficiency and energy yield on the timescale of weeks.

**4:06PM D63.00009: Frenkel-Holstein Hamiltonian Applied to Quaterthiophene-based 2D Hybrid Organic-Inorganic Perovskites**

SVENJA JANKE (Presenter), Mechanical Engineering and Material Sciences, Duke University, MOHAMMAD B. QARAI, Chemistry, Temple University, VOLKER BLUM, Mechanical Engineering and Material Sciences; Chemistry, Duke University, FRANK SPANO, Chemistry, Temple University — In two-dimensional hybrid organic-inorganic perovskites (HOIPs), both the organic and inorganic components can contribute to the electronic properties at the electronic frontier levels and hence open up a wide area for design of new materials with high tunability. For development of new devices like solar cells or light emitting diodes, the understanding of electronic excitations and their photophysical signatures plays a fundamental role. Here, we show by the example of quaterthiophene-based lead-halide HOIPs that the organic contribution to 2D HOIP absorption spectra can be theoretically appreciated employing a Frenkel-Holstein Hamiltonian that treats electronic coupling and electron-phonon coupling on equal footing. We relate changes in the spectra to structural changes in the organic layer that in turn are caused by variation of the halide anion. Specifically, we find that the strength of the excitonic coupling on the organic component decreases when the halide anion is varied from Cl to Br to I. Our research opens up a potential pathway for predicting optoeletronic properties of newly designed 2D HOIPs.

*Supported by the German Science Foundation (DFG), grant number 393196393 and NSF DMR-1729297.
Layered (so-called two-dimensional, 2D) hybrid organic-inorganic perovskites (HOIPs) can be created by combining a wide range of possible inorganic components with an even broader range of organic molecules, offering considerable flexibility to fine-tune their synthesizability and properties. This talk focuses on computational predictions of the electronic (carrier, i.e., electron- and hole-like) energy levels of new 2D HOIP materials. Such predictions pose a considerable challenge due to high required levels of theory and large unit cells (hundreds of atoms) associated with typical 2D HOIPs. We here use high-precision, all-electron hybrid density functional theory including spin-orbit coupling, showing that this combination provides descriptions of the quantum-well like energy level alignment in lead halide based oligothiophene perovskites in excellent agreement with experiments. We then employ the same approach to predictively address the electronic properties of a broad range of further 2D HOIPs, including lead-free (Ag-Bi) based ones. As a final point, we show that the details of the atomic structure used to predict electronic properties matter significantly, even in a qualitative sense, by determining energy level alignments and, therefore, which component (organic or inorganic) forms the band edges. A complete structural understanding of a given target 2D HOIP is thus essential for faithfully predicting the properties that can be leveraged within this promising new semiconductor materials space.

This work is enabled by the very large community of developers and users of the FHI-aims code as well as by close collaborations with leading experimental colleagues, particularly the group of David B. Mitzi (Duke University).

4:54PM D63.00011: Compounds with high macroscopically-averaged symmetries and low local symmetries: The consequence of lone-pair nematicity on electronic properties*

XINGANG ZHAO (Presenter), ZHI WANG, ALEX ZUNGER, University of Colorado, Boulder — The knowledge of the appropriate unit cell for a compound is crucial for many physical studies e.g. band structure theory. Traditionally, one prefers to use the smallest cell consistent with the global symmetry, e.g. monomorphous cells containing a single structural motif. It is well known that at high temperatures local displacements have the well-known thermal origin due to dynamically thermal fluctuation. But besides thermal effects, some compounds have non-thermal intrinsic local displacements already at low temperatures (LT) due to the preference of chemical bonding for stabilizing certain low-symmetry structural motifs requiring for their representation larger than minimal unit cells. By calculating in DFT the relaxed total energies of numerous cubic phases of ABX₃ compounds (X=oxygen or halogen) we identify special cases where the energy per formula unit decreases due to atomic displacements as the cubic cell size increases. Examples include cubic CsMX₃ (M=Sn, Pb; X=Br, I), and PbMO₃ (M=Ti, Zr, Hf) etc. These intrinsic, LT polymorphous networks are interesting because their properties (band gaps, etc.,) can be very different than those gleaned from their macroscopic averaged counterparts represented as a minimal unit cell.

*Supported by NSF-DMREF.

5:06PM D63.00012: Ligand Design Rules for Improving 2-D Organic-Inorganic Hybrid Halide Perovskite Moisture Stability

STEPHEN SHIRING (Presenter), BRETT SAVOIE, Purdue Univ — Organic-inorganic hybrid halide perovskites are promising semiconductor materials due to their long carrier lifetimes, diffusion lengths, and tunable band gap. Two-dimensional (2-D) Ruddlesden-Popper halide perovskites are particularly interesting from an optoelectronics device standpoint due to broad range of organic ligands that can be incorporated into the perovskite lattice and ease of fabrication. However, a major challenge for perovskite optoelectronics is their sensitivity to moisture, leading to chemical instability and device reliability issues. Here, we show that judicious choice in selection of the surface cation for a 2-D perovskite prevents water from penetrating into and dissolving the inorganic layer. We use molecular dynamics simulations to elucidate general design rules for designing water-proofing surface cations, showing that the length/size of the surface ligand alone is not sufficient to suppress water penetration. Our results provide insight into the stability-enhancing mechanism and provide a path for designing perovskites with improved properties.
Interfacial Electromechanics Predict Phase Behavior of 2D Hybrid Halide Perovskites

CHRIS PRICE (Presenter), University of Pennsylvania, JEAN-CHRISTOPHE BLANCON, ADITYA MOHITE, Chemical and Biomolecular Engineering, Rice University, VIVEK SHENOY, University of Pennsylvania — Quasi-two dimensional mixed-cation hybrid halide perovskites (q-2DPK) have improved structural stability and device lifetime over their 3D perovskite counterparts. The addition of a large organic A’ cation to the bulk AMX$_3$ structure gives the q-2DPK chemical formula A’$_2$A$_{N-1}$M$_N$X$_{3N+1}$ and introduces new synthetic degrees of freedom through the composition index N. Ordered lamellar structures form via coordinated M-X bond breaking and peculiar critical phase behavior emerges as a function of N. We propose a thermodynamic model parametrized by first-principles calculations to generate a phase diagram for the q-2DPK. We find that the difficulty in synthesizing phase-pure samples in the high-N composition range arises from the energetic competition between electrostatic interactions of opposing interfacial dipole layers and mechanical relaxation of interfacial stress. Our model shows quantitative agreement with experimental observations and explains the non-monotonic evolution of the lattice parameters with composition index N. This model is generalizable to the entire family of q-2DPK and can guide the design of optoelectronic and photovoltaic materials with enhanced environmental stability and reduced excitonic degradations to carrier transport.

Session D64 DMP: Emerging Phenomena & Defects in Transition Metal Oxides and 2D Materials

Mile High Ballroom 4E - Alexandru Bogdan Georgescu, Simons Foundation -
Tag(s): Focus
Effect of local correlation and nonlocal exchange*  HRISHIT BANERJEE (Presenter), Insitut für Theoretische Physik–Computational Physics, Graz Univ of Technology, OLEG JANSON, Institute for Theoretical Solid State Physics, IFW Dresden, KARSTEN HELD, Institut für Festkörperphysik, TU Wien, TANUSRI SAHA-DASGUPTA, Condensed Matter Physics and Materials Sciences, S. N. Bose National Centre for Basic Sciences, MARKUS AICHHORN, Insitut für Theoretische Physik–Computational Physics, Graz Univ of Technology — Motivated by the puzzling report of a ferromagnetic insulating state in LaMnO$_3$/SrTiO$_3$ heterostructures, we calculate the electronic and magnetic state of LaMnO$_3$, strained to a SrTiO$_3$ square substrate. We use 3 different computational approaches: (a) density functional theory (DFT) with Hubbard U(DFT+U), (b) DFT + dynamical mean-field theory (DMFT), and (c) DFT + Hartree Fock (HF) as a hybrid functional. While the first two approaches include local correlations and exchange at Mn sites, treated in a static and dynamic manner, respectively, the last one takes into account the effect of nonlocal exchange at all sites. We find in all three approaches that the compressive strain induced by the square substrate of SrTiO$_3$ turns LaMnO$_3$ to a ferromagnet with suppressed Jahn-Teller distortion, in agreement with experiment. The hybrid calculations result in a ferromagnetic insulating solution, as observed in experiment. This insulating behavior is found to originate from an electronic charge disproportionation. Our conclusions remain valid when we investigate LaMnO$_3$/SrTiO$_3$ within the experimental setup of a superlattice geometry using hybrid functionals. DMFT calculations show the presence of a paramagnetic insulating state.

Ultimate strength measurements on freestanding SrTiO$_3$ thin films
VARUN HARBOLA (Presenter), Physics, Stanford University, SAMUEL CROSSLEY, PRASTUTI SINGH, RUIJUAN XU, HAROLD HWANG, Applied Physics, Stanford University — The last two decades have seen enormous growth in the field of nanoengineering and nanomechanics using thin sheets owing to the variety of 2D materials available to us (2D Mater. 5, 032005 (2018)). With new advances in thin film growth techniques(Nat. Mater. 15, 1255–1260 (2016)), a new class of functional oxide thin films which are freestanding can be produced and readily incorporated in such nanomechanical implementations. However functional oxides are rigid and brittle in bulk, so it becomes imperative to verify the feasibility of nanomechanical deformations by investigating the breaking strength of these thin films. Here we report measurements of the ultimate strength of SrTiO$_3$ thin films using an atomic force microscope (AFM) by impinging upon a freestanding drumhead with an AFM tip. We demonstrate that in the sub-20 nm thickness regime of these thin films, SrTiO$_3$ can withstand an elastic extension of ~ 6% which is more than an order of magnitude higher than that for bulk. Furthermore, we also show that the fracture point of these films with respect to applied force is robust thus demonstrating their potential for use in nanomechanical platforms and devices.
Local modification of superconductivity in few unit cell thick high-\(T_C\) \(\text{Bi}_{2}\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}\) superconductor

SANAT GHOSH (Presenter), Tata Institute of Fundamental Research (TIFR), JAYKUMAR VAIDYA, University of Virginia, SAWANI DATTA, RAM PRAKASH PANDEYA, DIGAMBAR A. JANGADE, KALOBARAN MAITI, A. THAMIZHAVEL, MANDAR M DESHMUKH, Tata Institute of Fundamental Research (TIFR) — High temperature superconductors are interesting systems to study from the point of views of basic understanding about the origin and the nature of their superconducting properties as well as their numerous applications. Here we report transport studies on one of the high \(T_C\) cuprate superconductors namely \(\text{Bi}_{2}\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}\), an easily exfoliable Van der Waals material having superconducting transition temperature of 85K. In thin layers of this material, we have found that one can tune its superconducting property locally. This can have many potential device applications like patterning 2D superconductors for making high temperature Josephson Junctions and superconducting quantum interference devices.

*We acknowledge funding from Department of Atomic Energy and Department of Science and Technology of India.

Proving High Temperature Superconductivity in Monolayer \(\text{Bi}_{2}\text{Sr}_{2-x}\text{La}_x\text{Cu}_6\text{O}_{6+\delta}\)

HENGSHENG LUO (Presenter), LIGUO MA, YIJUN YU, PENG CAI, Fudan Univ, DONGJOON SONG, National Institute of Advanced Industrial Science and Technology, RUIDAN ZHONG, Brookhaven National Lab, JIAN SHEN, Fudan Univ, GENDA GU, Brookhaven National Lab, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, XIANHUI CHEN, physics department, University of Science and Technology of China, YUANBO ZHANG, Fudan Univ — Dimensionality plays a fundamental role in cuprate high-temperature superconductivity; all high-temperature cuprate superconductors adopt a layered crystal structure, and much of high-temperature superconductivity theory is based on purely two-dimensional (2D) models. A monolayer Bi2201 contains only a single layer of CuO\(_2\) plane, and therefore represents a cuprate superconductor in the ultimate 2D limit. Here, we exfoliate La doped Bi2201 (Bi\(_{2}\)Sr\(_{2-x}\)La\(_x\)CuO\(_6+\delta\)) single crystals down to monolayer (i.e. half unit cell) for transport measurements. We are able to tune the doping level of Bi2201 by annealing the sample in vacuum or ozone, and study the strongly correlated electronic states in Bi2201 over the entire phase diagram in a single sample. In addition, we probe the electronic structure of monolayer Bi2201 at atomic scale using scanning tunnelling microscopy and spectroscopy.
3:18PM D64.00005: Single-domain to Multi-domain Transition Due to Phase Separation in (La$_{1-y}$Pr$_y$)$_{1-x}$Ca$_x$MnO$_3$ Thin Films*  ASHKAN PAYKAR (Presenter), A. BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — The perovskite manganite (La$_{1-y}$Pr$_y$)$_{1-x}$Ca$_x$MnO$_3$ exhibits complex electronic and magnetic behaviors caused by a phase competition between its ferromagnetic metallic (FMM) and charged order insulating (COI) phases. While La$_{0.67}$Ca$_{0.33}$MnO$_3$ ($x=0.33, y=0$) undergoes a transition from a paramagnetic insulator to a pure FMM below 250 K, (La$_{0.4}$Pr$_{0.6}$)$_{0.67}$Ca$_{0.33}$MnO$_3$ ($x=0.33, y=0.6$) shows electronic phase-separation between FMM and COI phases at temperatures approximately below 120 K. Thin films of (La$_{1-y}$Pr$_y$)$_{1-x}$Ca$_x$MnO$_3$ ($x=0.33, y=0, 0.5, 0.6$) were grown on (110) NdGaO$_3$ (NGO) using pulsed laser deposition. Among these thin films, (La$_{0.4}$Pr$_{0.6}$)$_{0.67}$Ca$_{0.33}$MnO$_3$ also shows a single-domain to multi-domain transition in the FMM regions as they percolate at low temperatures. This domain transition is partially due to the in-plane uniaxial magnetic anisotropy caused by the anisotropic substrate strain exerted by (110) NGO. To check if phase separation also plays a role in the domain transition, we measured the temperature dependence of the coercive field ($H_c$) for $y=0$ and $y=0.5$ thin films. These films show a monotonic increase in $H_c$ with lowering temperature showing that phase separation and a percolation of the FMM regions is required for the domain transition.

3:30PM D64.00006: Effects of epitaxial strain and oxygen underdoping on order parameter competition in manganite/cuprate thin-film heterostructures*  CHAO C ZHANG, HAO ZHANG (Presenter), Department of Physics, University of Toronto, ANH NGUYEN, THOMAS GREDIG, Department of Physics and Astronomy, California State University Long Beach, MIN GU KANG, RICCARDO COMIN, Department of Physics, Massachusetts Institute of Technology, JOHN Y.T. WEI, Department of Physics, University of Toronto — To distinguish the role of magnetism from other factors that affect superconductivity in c-axis La$_{2/3}$Ca$_{1/3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-\delta}$ (LCMO/YBCO) heterostructures, we grow and characterize various perovskite/YBCO/perovskite trilayers, using ferromagnetic LCMO, paramagnetic LaNiO$_3$ (LNO), and orthorhombic PrBa$_2$Cu$_3$O$_{7-\delta}$ (PBCO) as the sandwiching layers. LCMO and LNO trilayers show similarly large superconducting $T_c$ reductions with decreasing YBCO layer thickness, whereas this $T_c$ reduction is not seen in the PBCO trilayers. Our results indicate that epitaxial strain has a stronger effect on the $T_c$ of LCMO/YBCO heterostructures than any long-range magnetic proximity effect present. Using this system, we also study how the $T_c$ reduction varies with oxygen underdoping by deoxygenating the cuprate layer. [1] We discuss our results in the wider context of multiple competing orders, in particular the recent observation by resonant x-ray scattering of robust charge-density-wave order in LCMO/YBCO multilayers. [2]

Creating Emergent Phases in Transition Metal Oxides

MILAN RADOVIC (Presenter), Photon Science Division, Paul Scherrer Institut — Transition Metal Oxides (TMOs) exhibit unique and multifunctional physical phenomena directly related to the spin and orbital degrees of freedom of metal d-states and their interplay with the lattice. Importantly, the isostructure of TMOs permits realization of hetero-structures generating at their surfaces and interfaces new physical matters that radically differ from those of the constituent bulk materials. Through two examples, novel and fascinating properties emerged in TMO based hetero-structures and routes to control them will be presented:

1. Altering orbital ordering and band filling of the 2DEG at titanates surfaces. Employing Angle-Resolved Photoemission Spectroscopy (ARPES) we found ways to manipulate the 2DEG and, consequently, to tune electronic properties of titanates surfaces (SrTiO3, TiO2-anatase and CaTiO3).

2. Tuning electronic phases in ultra-thin NdNiO3 (NNO) films via the strain and the proximity to a magnetic layer. Our study reveals that substrate-induced strain tunes the crystal field splitting, consequently changing the Fermi surface, nesting conditions and spin-fluctuation strength. All of them thereby effect and control the Metal Insulator Transition (MIT). In addition, we found that the ferromagnetic metallic (FM-M) state can be induced while MIT is quenched in ultra-thin NNO via the proximity to the magnetically ordered manganite buffer layer.

Overall our studies establish different approaches to manipulate the properties of the two-dimensional electron gas and electronic phases in NNO signifying perspectives of TMO for novel applications.
Electrically Controlled Intrinsic Tunneling in Dynamically Phase Separated Manganites* AMBIKA SHAKYA (Presenter), A. BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — (La$_{1-y}$Pr$_y$)$_{1-x}$Ca$_x$MnO$_3$ (LPCMO) thin films grown on (110) NdGaO$_3$ (NGO) substrates show clear evidence of micrometer scale electronic phase separation. A static phase separated state is observed at low temperatures while at high temperatures (approximately above 50 K) a dynamic (fluid) phase separated state (DPS) is formed. It has been shown that in the DPS state, the ferromagnetic metallic (FMM) regions can be reorganized using a non-uniform external electric field. We used microstructured gold contact patterns on LPCMO thin films to apply a non-uniform electric field and simultaneously measure the resistance vs. temperature ($R$-$T$) behavior. The $R$-$T$ graph shows a temperature independent resistance plateau at low temperatures (from about 20 K - 50 K). This behavior is a signature of tunneling. We further confirmed this tunneling behavior using current vs. voltage ($I$-$V$) measurements at low temperatures. Warming the sample up to a temperature of dynamic phase separation leads to redistribution of the FMM regions due to the non-uniform electric field between the gold electrodes. This redistribution changes the $I$-$V$ characteristics from tunneling to ohmic behavior. Hence, the properties of these magnetic devices can be modified using non-uniform external electric field.

Electronic and magnetic properties in three-component manganite films – the role of ordered interfaces and ionic size effects* CAITLIN KENGLE (Presenter), MAITRI WARUSAWITHANA, DAKOTA BROWN, JAMES PAYNE, THOMAS PEKAREK, University of North Florida — The mixed-valent manganite, La$_{1-x}$Sr$_x$MnO$_3$, with $x=1/3$ has been widely studied for its colossal magneto-resistive properties arising from the double exchange interaction. This material can be grown in thin-film form as a random alloy or an ordered superlattice. Here we grow films replacing 50% of the La with Y to make La$_{1/3}$Y$_{1/3}$Sr$_{1/3}$MnO$_3$ as both random alloys where La, Sr, and Y randomly occupy the A-site and ordered superlattices where the supercells comprise of single unit cells of LaMnO$_3$, YMnO$_3$, and SrMnO$_3$ stacked in sequence. While electronically La and Y are very similar, as both tend to be in a 3+ oxidation state in the crystal, we find contrastingly different electronic transport. The Y-substituted films exhibit a suppression of the metal-to-insulator transition compared to that of La$_{1/3}$Sr$_{2/3}$MnO$_3$. While the suppression is observed in both the ordered superlattice and the random alloy, we find it notably more amplified in the random alloy sample. We will discuss how ionic size effects and ordered interfaces affect the electronic and magnetic properties of these samples.

*This work was supported by NSF Grant No. DMR-16-26332. Select films were grown at Platform for the Accelerated Realization, Analysis, and Discovery of Interface Materials (PARADIM).
4:42PM D64.00010: Superconductivity in a Metal/Quantum Dimer Heterostructure*  ELI GERBER (Presenter), JIAN-HUANG SHE, Cornell University, CHOONG HYUN KIM, Seoul National University, CRAIG J FENNIE, MICHAEL J LAWLER, EUN-AH KIM, Cornell University — Recently we proposed a new approach to engineering exotic superconductors based on a metal/quantum spin ice heterostructure. However, pyrochlore materials are difficult to grow and current models of their spin fluctuation spectra remain incomplete. In contrast, weakly-interacting spin dimer compounds such as Ba3Mn2O8 are experimentally tractable and their spin correlations can be calculated explicitly. In this work we focus on a new example of such a setup, the spin dimer compound Ba3Mn2O8 in heterostructure with electron-doped Ba3Sb2O8, and predict interfacial p+ip pairing at a few Kelvin. We also provide criteria for materializing the heterostructure using ab initio calculations. Hence we present a concrete proposal based on a controlled calculation predicting p+ip superconductivity in a metal/quantum dimer heterostructure.

*The authors acknowledge support through the NSF MRSEC program (DMR-1719875) and the Materials Innovation Platform grant DMR-1539918.

4:54PM D64.00011: Investigation of the Defect-Tolerance of Chalcogenide Perovskites*  JIANG LUO (Presenter), ZHAOHAN I ZHANG, Washington University in St. Louis, BOYANG ZHAO, HUANDONG CHEN, JAYAKANTH RAVICHANDRAN, University of Southern California, ROHAN MISHRA, Washington University in St. Louis — Chalcogenide perovskites, such as BaZrS3, have been proposed as defect-tolerant materials — that can maintain their electronic properties even in the presence of defects. When combined with their novel electronic structure, they have been proposed as promising materials for application in solar cells and optoelectronic devices; however, a systematic investigation of the defect tolerance of such perovskites is missing. We have used BaZrS3 as a prototype chalcogenide perovskite and investigated its defect tolerance to intrinsic point defects using a combination of density-functional-theory calculations, spectroscopic and transport measurements. Based on the calculations, we find that most defects lead to shallow levels. However, we find that the sulfur vacancies have low formation energy. They lead to a deep transition level that is spatially localized to act as a non-radiative recombination center. Results of transport measurements with specimens annealed with S-rich and S-deficient conditions will be presented. Our work demonstrates that critical control over the chalcogen stoichiometry is necessary to improve the performance of these chalcogen perovskites.

**5:06PM D64.00012: Variation of defect states with the number of layers in 2D materials**

DAN WANG (Presenter), RAVISHANKAR SUNDARARAMAN, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — The high sensitivity of two-dimensional (2D) materials to surroundings makes layer number an important consideration in designing devices for opto-electronic and quantum applications. However, the theoretical prediction on the variation process of defect level with increasing layer number is challenging due to the high computational cost. Here, we used a recently developed continuum model[1] to explore the layer-dependent effects. The scheme removes the defect-free layers from the density-functional-theory (DFT) calculations and captures their effects on the defect by replacing the electrostatic effect of the defect-free layers with a continuum dielectric function. Application of this method to defects in multilayer hBN (from monolayer to five-layer and bulk) reveals that defect levels become shallower with increasing layer number due to the increased dielectric screening, and the reduction process of ionization energy is highly dependent on the level of theory (DFT or many-body perturbation theory) as a result of the presence of self-interaction error and the absence of non-local screening effect in DFT.

**5:18PM D64.00013: Tunable High-Temperature Superconductivity in Monolayer Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$**  
YIJUN YU (Presenter), LIGUO MA, PENG CAI, Fudan University, RUIDAN ZHONG, Brookhaven National Laboratory, CUN YE, JIAN SHEN, Fudan University, GENDA GU, Brookhaven National Laboratory, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — Atomically-thin layered van der Waals crystals represent ideal material systems in the ultimate two-dimensional (2D) limit. Among all layered materials, high-temperature superconductors stand out for their fundamental importance in material research and potential impact on future technology. Here, we developed a fabrication process that enabled us to produce intrinsic monolayer crystals of high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (Bi-2212; here monolayer refers to a half unit cell) and probe their transport properties. The lack of dimensionality effect on superconducting transition temperature $T_c$ defies expectations from Mermin-Wagner theorem; it also sharply contrasts with much reduced $T_c$ in conventional superconductors in 2D limit. Being atomically thin, monolayer Bi-2212 offers unprecedented tunability over its doping and disorder level across the superconductor-insulator transition (SIT). Finite size scaling analysis at SIT provides a unified picture for disparate observations in cuprate systems. Our results establish monolayer Bi-2212 as an ideal platform for studying high-temperature superconductivity and other strongly correlated phenomena in 2D.
Defect spin qubits in silicon carbide (SiC) combine near-telecom operation and long coherence with a host crystal amenable to wafer scale semiconductor device engineering[1]. In particular, the neutral divacancy ($VV^0$) in SiC has a spin-photon interface ideal for long distance quantum communications and repeater schemes[2]. Here, we isolate for the first time single $VV^0$ defects in functioning, doped semiconductor p-i-n diodes and use the device to control the charge states of these defects[3]. This integration of the single spin into the semiconductor junction not only allows for a drastic reduction in spectral diffusion of the emitter, but also a careful study of the defect's charge state under illumination. We focus on these photodynamics and demonstrate deterministic and optimized charge control of the defect, allowing for charge state stabilization and electrical gating of single photon emission. We discuss the outlook for electrical control, manipulation and readout of both the spin and charge degrees of freedom in these quantum emitters.

3:06PM D65.00002: Jahn-Teller Effects in Group IV Quantum Defects in Diamond*

CHRISTOPHER CICCARINO (Presenter), School of Engineering and Applied Sciences, Harvard University, JOHANNES FLICK, Center for Computational Quantum Physics, Simons Foundation, MATTHEW TRUSHEIM, PRINEHA NARANG, School of Engineering and Applied Sciences, Harvard University — Defects in diamond are leading solid-state candidates for a range of quantum technologies. Recent research has focused on identifying new color centers with properties that reach beyond the limitations of the well-known nitrogen-vacancy (NV\textsuperscript{−}) center. Group IV-vacancy centers have been a primary focus due to their symmetry-protected optical transitions and long-lived spin degree of freedom. A detailed understanding of the electronic structure of these emitters is paramount to their use in spin-photon systems. Here we detail the ground- and excited-state properties of the negative and neutral group IV color centers using first-principles methods. In particular, we outline the dynamic and product Jahn-Teller (pJT) effects expected in these defect systems, including their potential impact on zero phonon line energetics and spin-orbit coupling. We capture the interplay of spin-orbit and electron-phonon coupling in order to accurately describe the pJT-affected excited state manifold. These results provide a more accurate benchmark for comparison with experiment, especially for the group IV neutral centers, where many open questions remain.

3:18PM D65.00003: Group III Defects in Diamond for Quantum Information Applications

ISAAC HARRIS (Presenter), Massachusetts Institute of Technology, CHRISTOPHER CICCARINO, MATTHEW TRUSHEIM, Harvard University, JOHANNES FLICK, Flatiron Institute, DIRK R. ENGLUND, Massachusetts Institute of Technology, PRINEHA NARANG, Harvard University — Point defects in wide bandgap semiconductors have emerged as leading spin-photon interfaces for applications in quantum information science. In particular, several types of color centers in diamond have been characterised as promising candidates for spin-photon interfaces. However, no color center has yet demonstrated the required spin initialisation, spin coherence and optical stability required for easy integration into quantum devices. Here, we discuss theoretical and experimental results for a new class of color centers, the group III vacancy complexes in diamond, and in particular the negatively-charged gallium vacancy center. These group III color centers are predicted to be stable in an inversion-symmetric configuration, which makes their optical transition resilient to charge noise, and therefore well-suited to integration in nanostructures. Furthermore, they are thermodynamically stable in a spin-1 charge state, which gives them desirable level structures and spin coherence properties for quantum information applications. Based on these results, we comment on the suitability of these new color centers as spin-photon interfaces.
First-principles characterization of nitrogen-related spin-defects in 4H- and 6H-SiC

YIZHI ZHU (Presenter), GIULIA GALLI, University of Chicago — Optically active spin defects in wide-gap semiconductors are promising platforms for solid-state quantum technologies. For example, in the last few years several defect qubits with long coherence times have been realized in SiC, an attractive material due to its ease of growth and microfabrication, compared to diamond. Recent studies [1-3] have explored the possibility of realizing a nitrogen vacancy (NV) in SiC, in analogy with diamond. We used first-principles calculations based on density functional theory to identify fingerprints of nitrogen related spin-defects in SiC. We computed several properties of point-defects containing nitrogen impurities, including zero-fielding splitting, hyperfine tensors, and zero-phonon lines. In order to analyze the robustness of our results, we conducted sensitivity analysis to establish the effect of pseudopotentials, density functionals and optimized atomistic structures on the computed electronic and spectroscopic properties of the defects.

Vanadium spin qubits as telecom quantum emitters in silicon carbide

GARY WOLFOWICZ (Presenter), Center for Molecular Engineering, Materials Science Division, Argonne National Laboratory, CHRISTOPHER ANDERSON, BERK DILER, Pritzker School of Molecular Engineering, University of Chicago, OLEG G. POLUEKTOV, Chemical Sciences and Engineering Division, Argonne National Laboratory, JOSEPH P HEREMANS, Center for Molecular Engineering, Materials Science Division, Argonne National Laboratory, DAVID AWSCHALOM, Pritzker School of Molecular Engineering, University of Chicago — Solid state quantum emitters with addressable spin registers are promising platforms for quantum communication, yet few emit in the telecom band necessary for low-loss fiber networks. Here we create and isolate single vanadium dopants in silicon carbide (SiC) with emission in the O-band (~1300 nm) and with brightness allowing cavity-free detection, in a wafer scale CMOS-compatible material [1]. We demonstrate that their emission is stable and narrow near surfaces, enabling integration with nanoscale devices.

We characterize the complex $d^1$ orbital physics in vanadium ensembles in all five sites available in 4H- and 6H-SiC. The optical transitions are observed to be sensitive to mass shifts from the distribution of nearest neighbor silicon and carbon isotopes, enabling optically resolved nuclear spin registers. Optically detected magnetic resonance of ground and excited states’ spin transitions reveal diverse hyperfine interactions with the vanadium nuclear spin and offer clock transitions for use as quantum memories. Finally, we demonstrate coherent quantum control of the spin state at 3.3 K. These results provide a path for solid-state telecom emitters for quantum applications.

Finite-size and Surface effects: Deep Defects in Nanostructured SiC

TAMANNA JOSHI (Presenter), PRATIBHA DEV, Howard University — Spin-active deep defects in wide-bandgap semiconductors like silicon carbide (SiC) are being studied for application in quantum technologies, such as quantum computing, and nanoscale field sensing. Often these applications involve nanostructuring of the host semiconductor. In a nanostructure, the electronical and optical properties are expected to be affected by surface and quantum confinement effects. In our work, we investigate these finite size effects by studying the properties of silicon vacancies with different charge states in 2H-SiC (wurtzite) nanowires. Defect properties like formation energy, spin, and spin polarization energies are shown to be site-dependent in the nanostructured host. Our results indicate that a surface acts as a sink for the defects, and the migration of defects towards the surface may lead to the loss of the signal from a defect placed in a nanostructured host.

*This work is supported by NSF Grant number DMR-1738076 and the STC Center for Integrated Quantum Materials under NSF Grant number DMR-1231319. Computational support was provided by NSF's Extreme Science and Engineering Discovery Environment under project number PHY180014.

Formation and migration of vacancies in SiC

ELIZABETH LEE (Presenter), JUAN DE PABLO, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago — Divacancy spin defects in silicon carbide (SiC) are promising platforms for quantum information science applications. However, the formation mechanism and migration properties of point defects in SiC are poorly understood and hence difficult to control. Using advanced simulation techniques, we gain insight into the creation, interaction and migration of vacancies in SiC, aimed at deriving rules for the design of robust defects in scalable quantum materials. In particular, we used a combination of enhanced sampling methods (https://github.com/MICCoM/SSAGES-public) coupled with classical Molecular Dynamics, and Density Functional Theory to investigate the defect electronic properties. We compare our results with thermal annealing and photoluminescence experiments [1], and we discuss possible processing conditions for the formation of divacancy defects with favorable spin states.

*Supported by the Midwest Integrated Center for Computational Materials (MICCoM) as part of the Computational Materials Sciences Program funded by DOE/BES
Coherent control and high-fidelity readout of chromium ions in commercial silicon carbide

BERK DILER (Presenter), Pritzker School of Molecular Engineering, University of Chicago, SAMUEL J WHITELEY, CHRISTOPHER ANDERSON, Department of Physics, University of Chicago, GARY WOLFOWICZ, Center for Molecular Engineering and Materials Science Division, Argonne National Laboratory, MARIE WESSON, Department of Physics, University of Chicago, EDWARD S BIELEJEC, Sandia National Laboratories, JOSEPH P HEREMANS, Center for Molecular Engineering and Materials Science Division, Argonne National Laboratory, DAVID AWSCHALOM, Pritzker School of Molecular Engineering, University of Chicago — Transition metal ions provide a rich set of optically active defect spins in wide bandgap semiconductors. Their extrinsic nature promises easy device integration through nano implantation. Specifically, chromium in the 4+ charge state (Cr^{4+}) in silicon carbide (SiC) produces an S = 1 ground state and an S = 0 excited state with a strain insensitive near-telecom Λ-like optical-spin interface. In previous demonstrations the ground state spin control was limited by material quality. In this work [1], we study the formation Cr^{4+} in a commercial SiC substrate through implantation and annealing, enabling optical and coherent spin characterization. We measure an ensemble optical hole linewidth of 31 MHz, an order of magnitude narrower compared to as-grown samples. Through a detailed investigation of the Cr^{4+} governing transition dynamics, we optimize for high readout fidelities (79%). We report $T_1$ times greater than 1 s at T = 15 K with a $T_2^* = 317$ ns and a $T_2 = 81$ μs limited by the ensemble density. These results demonstrate Cr^{4+} in SiC to be an optically active spin-qubit for integration within hybrid quantum devices.

*DOE
4:30PM D65.00009: Decoherence of diamond NV ensembles with varying nitrogen spin concentration: a cluster expansion study  HUIJIN PARK (Presenter), Ajou Univ, JUNGHYUN LEE, SANG-YUN LEE, KIST Center for Quantum Information, HOSUNG SEO, Ajou Univ — Nitrogen-vacancy (NV) centers in diamond have been developed into essential hardware units to develop a wide range of solid-state quantum technologies. For such applications, the long coherence time of NV centers is crucial. Numerous previous studies identified that the NV's decoherence is often governed by the magnetic noise produced by the $^{13}$C nuclear spin bath and the nitrogen (P1) electron spin bath in a diamond. While the $^{13}$C-induced decoherence has been well understood, understanding of the P1-driven decoherence is still incomplete. In this study, we aim at the systematic theoretical investigation on the P1-driven decoherence of NV ensembles with varying P1 concentrations from 1ppm to 100ppm. We employ a cluster correlation expansion method. We discuss our results in comparison with recently published experimental data [1,2] and previous theoretical results [3,4]. Our results provide not only a microscopic understanding of the NV decoherence but also useful information to optimize the NV's performance in various quantum applications such as NV-based magnetometry and NV-based quantum registers.

4:42PM D65.00010: Dynamics of Silicon-Vacancy Color Center in Nanodiamonds  CHUNJING JIA (Presenter), YAN-KAI TZENG, YU LIN, THOMAS DEVEREAUX, STEVEN CHU, Stanford University — Diamond-based color centers have emerged for a variety of applications in quantum communication, quantum photonics, and biological sciences, etc. Optical color center of SiV formed by one silicon atom sited in the middle of two vacancies shows great promise as a single-photon source. Unlike the NV center, which can be improved sufficiently for quantum applications by high-temperature annealing to mobilize only vacancies, SiV center may become unstable in diamond lattice under annealing. Upon annealing to temperatures up to 800 ºC, both SiVs and vacancies would become mobile to the surface of diamond. It is unclear during the annealing process whether SiV or vacancy impurity migration dominates and the relative time-scale of the two processes. In this talk, we are going to present our studies to unravel this problem. An AOM-modulated laser heating and annealing in a diamond anvil cell has been used. The fluorescent intensities of SiV center before and after the annealing were measured using fluorescent spectroscopy. ab initio DFT calculations were used to quantify the dynamics of two impurities. Both experimental and theoretical results suggest that SiV centers can be stabilized associated with the crystalline quality during the production of artificial SiV photonic centers.
4:54PM D65.00011: Study of the Structure-property Relationship in Diamond (100), (110) and (111) Surfaces  HECTOR GOMEZ (Presenter), MICHAEL GROVES, Chemistry, California State University, Fullerton, MAHESH R NEUPANE, SEDD, US Army Rsch Lab - Adelphi — Understanding the electronic and physical properties of reconstructed diamond (100), (110), and (111) is important for meeting the increasing demand for high-powered control electronics in harsh environments. By determining the electronic and structural properties of reconstructed diamond (100), (110), and (111) surfaces, the effect reconstruction has on its electronic properties versus an ideal surface is revealed. Using GPAW, a density-functional theory (DFT) and the AutoNEB package, a stepwise surface reconstruction for diamond (111) and (100) was modeled. Diamond (100) reconstruction demonstrated an exothermic reaction with no observable intermediates or transition states. Following reconstruction in the (100) phase, -0.254 eV/atom energetic variance was observed from the bulk-like surface. In the (111) phase, a never before predicted intermediate state, with per atom energy difference of -0.011 eV from the bulk-like 2X1 surface, was observed between the bulk-like and Pandey-chain surfaces. Observed stable Pandey-chain reconstructed state resulted in an energy difference of -0.109 eV/atom from its bulk-like counterpart. Lastly, the favorability of the reconstruction suggests that 2x1 diamond (100) and (111) will follow this configuration instead of the bulk-like surface.

5:06PM D65.00012: The Spin-Flip Bethe-Salpeter Equation approach, and applications to molecular magnets and defects in solids for quantum information*  BRADFORD BARKER (Presenter), DAVID STRUBBE, University of California, Merced — Molecular magnets containing transition metals (e.g. Cr, Mn, Fe) are promising candidates for qubits due to their unpaired spins. Description of their ground- and excited-state energies is quite challenging for electronic structure methods, as these systems are poorly described by single-reference electronic-structure methods. The “spin flip” approach allows such methods to describe open-shell states as an excitation -- up or down in energy -- from a related single-reference high-spin state. Spin-flip time-dependent density-functional theory (TDDFT) has shown moderate successes in describing their energies, as well as their Heisenberg exchange coupling constants. The GW/Bethe-Salpeter equations have a similar form to TDDFT, but provide an ab initio kernel that overcomes many problems of standard TDDFT approximations. We have implemented spin-flip Bethe-Salpeter, allowing more accurate calculations on molecules, and enabling spin-flip for extended systems such as defects in solids for quantum information. We consider transition-metal dimers Mn_2 and Cr_2, and other molecular magnets, as well as the well-known diamond NV^ center.

5:18PM D65.00013: NV-color centers in nanodiamond as a photon emitter embedded in whispering-gallery-mode optical resonator*  SUNGWAN CHO (Presenter), ETRI, MUHAMMED KAAN YILDIZ, IN HWAN DO, DONG-IN JUNG, Department of Physics, KAIST, JUNG HYUN SHIM, KI SEOK HONG, HEE JIN LIM, JAE HOON LEE, HYUN GYU HONG, Korea Research Institute of Standards and Science, JUNG BAE YOON, DONG HUN LEE, Department of Physics, Korea University, HANSUEK LEE, Department of Physics, KAIST — Development of reliable and stable photon source is crucial for applications in quantum technology, as well as fundamental experiment and metrology. NV(Nitrogen-vacancy) color center in diamond, are among the promising candidate for photon source. Although coupling of color centers with an high-Q optical cavity has high potential, fabricating optical cavities embedding defect centers have been challenging tasks with recent initial demonstrations. Here, we present a novel approach to fabricate high-Q optical Whispering-Gallery-Mode resonator comprising NV-color center. Starting from disk resonator coated with nanodiamond particles, we also fabricate microtoroid optical resonator. Fabricated microtoroid resonator with NV-center shows Q-factor above $10^7$ at telecom wavelength. A scanning photoluminescence spectrum also confirms stable photoemission inside the microtoroid resonators. With further development of this hybrid UHQ resonator, we expect the realization of robust platform for cavity QED and quantum metrology

*This work is supported by Basic Science Research Program and Fundamental Technology Development Program through the National Research Foundation of Korea(NRF) (Grant No. 2017R1C1BB1012047, 2019M3E4A1080387).

Session D66 DCMP: Unconventional States and Excitations in the Fractional Quantum Hall Effect  Four Seasons 1 - Steven Kivelson, Stanford Univ - Tag(s): Invited
Precursors to Exciton Condensation in Quantum Hall Bilayers* [Invited]

JAMES EISENSTEIN (Presenter), physics, Caltech, LOREN PFEIFFER, KENNETH WEST, electrical engineering, Princeton — Bilayer two-dimensional electron systems at high magnetic field exhibit an interlayer coherent excitonic phase when the layer separation is sufficiently small, the temperature sufficiently low, and the total electron density in the bilayer equals the degeneracy of a single Landau level. This phase is well known to display exotic transport phenomena, notably Josephson-like interlayer tunneling and essentially dissipationless transport of excitons across the bulk of the 2D system. While first detected twenty years ago in GaAs-based double quantum wells, this and related interlayer correlated phases have recently been observed in graphene-based multilayer systems.

In spite of this long history, the nature of the quantum phase transition between the incoherent phase at large layer separation and the coherent excitonic phase at small separations remains poorly understood. In this talk I will report on recent experiments which shed new light on the transition. In particular, I will discuss tunneling spectroscopy measurements which reveal evidence for interlayer electron-hole correlations at layer separations near, but above, the transition to the exciton condensate at total Landau level filling $\nu_T = 1$. These correlations are manifested by a nonlinear suppression of the Coulomb pseudogap which inhibits low energy interlayer tunneling in weakly coupled bilayers. The pseudogap suppression is strongest at $\nu_T = 1$ and grows rapidly as the critical layer separation for exciton condensation is approached from above. These and other observations suggest that exciton-hole condensation fluctuations exist in the incoherent phase well above the critical layer separation, in a manner reminiscent of Cooper pair fluctuations above the superconducting critical temperature.

3:06PM D66.00002: Parton theory of the fractional quantum Hall effect: New developments* [Invited] JAINENDRA JAIN (Presenter), Pennsylvania State University — In the parton construction [1], one divides each electron into fictitious particles called partons, places each species of partons into an IQH state, and then fuses the partons back into physical electrons. This produces candidate FQHE states that are products of IQH states. Some of the states so produced are predicted to have non-Abelian excitations [2]. I will review recent work on the applicability of such wave functions to physically observed states at ν=5/2 [3], ν=2+6/13 [4], and ν=1/4 in wide quantum wells [5]. Theory suggests that a non-Abelian "221" state may appear at ν=1/2 in bilayer and trilayer graphene [6]. I will also discuss exact Hamiltonians for a subclass of such states [6,7].

*The work was supported by the U. S. Department of Energy, Oce of Basic Energy Sciences, under Grant no. DE-SC0005042.

3:42PM D66.00003: Duality in Quantum Hall Compressible States* [Invited] EDUARDO FRADKIN (Presenter), University of Illinois at Urbana-Champaign — It has long been known (at least since 1997) empirically that quantum Hall plateau transitions enjoy an apparent self-duality symmetry. The meaning of this statement is that the current-voltage (I-V) curves are non-linear and are symmetric around their linear behavior at the quantum phase transition. This behavior was first observed in dirtier samples and is now known to occur in the compressible states at filling fractions 1/2 and 1/4. This empirical result was interpreted by Shimshoni, Sondhi and Shahar (PRB 55, 13730 (1997)) as a manifestation of a particle-vortex duality. Yet, the origin of this symmetry has been mysterious and has remained unexplained until quite recently. In a very recent paper (Hart Goldman and Eduardo Fradkin, PRB 98, 165137 (2018)) Goldman and myself used the recently developed dualities of Dirac fermions (D. T. Son Phys. Rev X. 5, 031027 (2015); N. Seiberg, T. Senthil, C. Wang and E. Witten, Ann. Phys. 374, 3095 (2016)) to show that the mirror symmetry of the Jain sequences converging on 1/2n compressible states explain the observed self-duality as a property of the compressible states. Hart Goldman was the lead author of this work.

4:18PM D66.00004: New unconventional plasmons in the N=1 Landau level* [Invited]  LINGJIE DU (Presenter), School of Physics, Nanjing University — In the partially filled second Landau level (SLL) emergent exotic quantum fluids overlap and interplay with fractional quantum Hall (FQH) liquids. Collective modes of the exotic quantum fluids uncover underlying physical mechanisms responsible for emerging new ground states [1-3]. Resonant inelastic light scattering (RILS) spectra access unprecedented collective modes in the FQH regime of the SLL: intra-Landau-level plasmons[3]. The plasmons herald rotational-symmetry-breaking (nematic) phases in the SLL and reveal the nature of long-range translational invariance in these phases. The intricate dependence of plasmon features on filling factor provides new insights on complex interplay between topological quantum Hall order and nematic electronic liquid crystal phases. A marked intensity minimum in the plasmon spectrum at Landau level filling factor v = 5/2 strongly suggests that the paired state, which may support non-Abelian excitations, overwhelms competing phases, revealing the robustness of the 5/2 superfluid state for small tilt angles. In contrast, a sharp and intense plasmon peak in the state at v=7/3 reveals that the macroscopic coherence of the FQH liquid coexists with nematic order, supporting the proposed model of a FQH nematic at 7/3. Other interpretations of the new collective mode, such as chiral graviton [4], will be discussed.

Composite Fermions near Half-filled Landau Levels: Precise Experimental Tests of Luttinger Theorem, Particle-Hole Symmetry, and Fermi Sea Anisotropy

MANSOUR SHAYEGAN (Presenter), Princeton University — Composite fermions (CFs), exotic particles formed by pairing an even number of flux quanta to each electron, provide a fascinating description of phenomena exhibited by interacting two-dimensional electrons at high perpendicular magnetic fields and low temperatures. At and near Landau level half-fillings, CFs occupy a Fermi sea. In this talk, I will present our experimental results aimed at probing this Fermi sea directly and quantitatively. The probe consists of geometric resonance measurements, manifesting minima in the magneto-resistance when the CFs’ cyclotron orbit diameter becomes commensurate with the period of a periodic potential imposed in the plane. The data provide evidence that particle-hole symmetry and the Luttinger theorem are obeyed to very high precision for CFs, quasi-particles which themselves are a product of interaction. There are, however, quantitative differences from the predictions of the existing (Dirac and Halperin-Lee-Read) theories. We also report measurements of CF Fermi sea shape, tuned by the application of uniaxial strain. The strain-induced results reveal that the Fermi sea anisotropy for CFs ($\alpha_{CF}$) is less than the anisotropy of their low-field hole (fermion) counterparts ($\alpha_F$), and closely follows the relation $\alpha_{CF} = \alpha_F^{1/2}$.

Session D67 DCMP: Nematicity in Topological and Superconducting Materials Four Seasons 2-3 - Qimiao Si, Rice Univ - Tag(s): Invited
2:30PM D67.00001: Interacting multi-channel topological boundary modes in a quantum Hall valley system*  [Invited] MALLIKA RANDERIA (Presenter), Massachusetts Institute of Technology MIT — Two-dimensional quantum Hall systems offer a versatile platform to explore the interplay between topology and symmetry breaking facilitated by Coulomb interactions. Spontaneous valley ordering of bismuth surface states in a large magnetic field gives rise to the emergence of a nematic phase. We can directly visualize the rotational symmetry breaking of this nematic phase using a scanning tunneling microscope (STM) [1]. We further use an STM to image the formation of topological boundary modes in between nematic quantum Hall domains. By changing the valley flavor and number of modes at the domain wall, we realize strikingly different regimes where these boundary modes are either metallic or insulating. This behavior is a consequence of Coulomb interactions constrained by the valley flavor, making these channels a new class of interacting symmetry-protected Luttinger liquids [2,3].

3:06PM D67.00002: Odd-parity multipolar orders in the spin–orbit-coupled metal Cd$_2$Re$_2$O$_7$*  
[Invited] SATOSHI TAJIMA, DAIGOROU HIRAI, MASASHI TOKUNAGA, MASASHI TAKIGAWA, Univ of Tokyo, TATSUO C. KOBAYASHI, Okamaya University, TAKUMI HASEGAWA, Hiroshima University, ZENJI HIROI (Presenter), Univ of Tokyo — The pyrochlore oxide Cd$_2$Re$_2$O$_7$ is the only superconductor ($T_c = 1.0$ K) in the family of α-pyrochlore oxides [1]. Moreover, it exhibits two characteristic structural transitions losing the inversion symmetry below 200 K. Recently, it has attracted increasing attention as a candidate spin–orbit-coupled metal (SOCM), in which specific Fermi liquid instability can lead to odd-parity multipolar orders with spontaneous inversion-symmetry breaking [2] and parity-mixing superconductivity [3, 4]. More recent theoretical classifications based on the crystal symmetry reveal that the two parity-breaking phases are described by unconventional odd-parity multipoles, that are the electric toroidal quadrupoles (ETQs) with different components, $x^2−y^2$ and $3z^2−r^2$ [5]. These ETQs are unique as they are cluster multipoles defined on the tetrahedral unit of the pyrochlore lattice, distinguished from conventional atomic multipoles realized in f-electron systems [6]. Here we report our recent experimental progress and review the present understanding of the SOCM Cd$_2$Re$_2$O$_7$.

3:42PM D67.00003: Nematic Superconductivity [Invited] VLADYSLAV KOZII (Presenter), Physics, University of California, Berkeley, LIANG FU, Physics, Massachusetts Institute of Technology, JORN VENDERBOS, Physics, University of Pennsylvania, HIROKI ISOBE, Physics, Massachusetts Institute of Technology — Nematic superconductivity refers to the spontaneous breaking of rotational symmetry of a system in superconducting state. Nematic superconductivity in topological insulator Bi2Se3 doped with Cu, Nb, or Sr atoms was observed in numerous experiments, including Knight shift, upper critical field, specific heat, magnetic torque, and STM measurements. Remarkably, such a nematic state appears to be a clear signature of topological superconductivity. In this talk, I will discuss the theoretically predicted properties of these compounds and their relation to the existing experiments. Furthermore, the recent measurements of the upper critical field in twisted bilayer graphene revealed strong two-fold anisotropy of the superconducting state, indicating nematic superconductivity. Motivated by these experiments, I will also briefly describe some theoretical proposals aiming to explain such an exotic state.

4:18PM D67.00004: Nematicity in normal and superconducting states of twisted bilayer graphene [Invited] PABLO JARILLO-HERRERO (Presenter), Massachusetts Institute of Technology MIT — In this talk I will review our recent experiments on magic-angle twisted bilayer graphene which show normal state and superconducting state anisotropies in the resistivity and critical magnetic field, respectively. These represent evidence for nematicity in this novel correlated system.

4:54PM D67.00005: Spin-polarized correlated insulator and superconductor in twisted double bilayer graphene.* [Invited] XIAOMENG LIU (Presenter), ZEYU HAO, ESLAM KHALAF, JONG YEON LEE, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, ASHVIN VISHWANATH, PHILIP KIM, Harvard University — In flat electronic bands, the effect of interaction is elevated, which may lead to the emergence of correlated electronic states. Recently, the discoveries of correlated insulator and interaction-driven superconductivity in the magic-angle twisted bilayer graphene (MATBG) sparked the search of flat band materials enabled by moire superlattices. In this talk, I will present our experimental study of moire flat band in twisted double bilayer graphene (TDBG). In TDBG, the flatness of the band is tunable by perpendicular electric fields, adding another experimental knob and eliminating the requirement of a precise twist angle. Correlated insulators and superconductivity are discovered in TDBG with a much larger energy scale than in MATBG. Intriguingly, these emergent phases are found to be spin-polarized by in-plane magnetic field dependence. Since ferromagnetism and superconductivity typically compete with each other, the finding of spin-polarization in a superconductor carries an implication of exotic paring mechanism and pairing symmetry.

Session D68 DPOLY: Highly Loaded and Morphologically Enhanced Polymer Nanocomposites Four Seasons 4 - Zahra Fakhraai, University of Pennsylvania - Tag(s): Invited
Conventional methods of nanocomposite fabrication involve mixing and dispersing nanoparticles into a polymer matrix, making it challenging to produce composites with extremely high volume fractions (> 50 vol%) of nanoparticles. Recently our group has shown that such nanocomposites in the forms of films and membranes can be produced by capillary rise infiltration (CaRI) by thermally annealing a bilayer of polymer and nanoparticle. CaRI induces imbibition of polymer into the interstices of the nanoparticle packing via capillarity. This method has been further extended to induce polymer infiltration into nanoparticle packings through solvent annealing and leaching from a elastomer network. While these methods provide powerful ways to produce highly loaded nanocomposites, they also provide a rich platform to study the behavior of polymers under extreme nanoconfinement. The chain dimension of the polymer, which depends on its molecular weight, can be comparable to or greater than the average pore size of the nanoparticle packing. In this talk, I will share our current understanding of the transport phenomena of polymers under such nanoconfinement using a combination of experimental and computational approaches. I will show that the dynamics of CaRI depends strongly on the confinement ratio as well as the molecular weight of the polymer. In particular, the effective viscosity of the polymer can decrease or increase depending on the extent of confinement and the molecular weight of the polymer. We also show that the structure and properties of the resulting nanocomposites also depend strongly on the processing parameters and the molecular weight of the polymer.
Biomimetic nanocomposites exemplified by nanostructured nacre-like assemblies, provide a generalized approach to engineer materials. Continuing this research, we learn that the unique mechanics of tooth enamel can be replicated combining out-of-plane nanoscale columns with molecular precision of layer-by-layer (LBL) assembly. These composites reveal remarkably high vibrational damping thought to be impossible for stiff materials.

The novel type of biomimetic nanocomposites are those based on aramid nanofibers (ANFs). They spontaneously assemble into three-dimensional percolating networks reminiscent of cartilage. The nanoscale structure of ANF composites reveal nanoscale porosity that can be controlled by nanofiber branching. The latest results from multiple groups demonstrate that ANF composites resolve some of the essential property bottlenecks for ion-selective membranes, dendrite-resistant electrolytes, and structural batteries.

One of the emerging fields for biomimetic nanocomposites are optical devices. The high strain and strong polarization rotation make possible metaoptical devices with kirigami composites with wide-angle diffraction gratings for LIDARs and highly efficient quarter wave plates for THz scanners. Chiroplasmonic composites with mirror-asymmetrical 3D shapes of gold nanoparticles represent the first dynamically reconfigurable metaoptical composites for visible, near-IR and THz ranges of electromagnetic spectrum.

3:42PM D68.00003: Polymer Processing at Liquid Crystal-Air Interfaces* [Invited]  
XIAOSHUANG WEI, LAURA BRADLEY (Presenter), Univ of Mass - Amherst — Fluid interfaces are unique environments for materials processing because, as inherently open systems, they promote dynamic transport from adjoining phases and offer anisotropic structures that give rise to strong directional interactions during assembly. Liquid crystal interfaces add further prospects for producing materials with directional ordering or anisotropic morphology. For example, colloids assembled at liquid crystal-air and liquid crystal-water interfaces can form chains or hexagonal lattices. In this talk, we demonstrate liquid crystal-mediated synthesis and assembly of polymer colloids at liquid crystal-air interfaces. The polymer colloids are produced by polymerization of acrylic monomers in non-reactive liquid crystal mesogens. We examine mechanisms governing the simultaneous polymer growth and assembly as a function of reaction time, initial monomer concentration, and liquid crystal director orientation. Results outline design rules to control the nucleation and growth of morphologically enhanced polymer composites.

*This work is supported by an NSF CAREER Award (#1845631).

4:18PM D68.00004: Driving and manipulating polymer degradation in nanocomposites via photothermal heating of the particle* [Invited]  
LAURA CLARKE (Presenter), Physics, North Carolina State University, HONGLU HUANG, Wilson College of Textiles, North Carolina State University, GABRIEL FIRESTONE, DANIELA FONTECHA, Physics, North Carolina State University, RUSSELL GORGA, Wilson College of Textiles, North Carolina State University, JASON R BOCHINSKI, Physics, North Carolina State University — We are interested in thermally-driving chemical reactions in small volumes within a solid material, where diffusion of reactants and products are limited. Such experiments are achieved by photothermally heating metal nanoparticles incorporated within a polymer, which creates significant heat generation at the particle and an inhomogeneous steady state temperature distribution across the solid. Specifically, polymer far from any particle is cool while in contrast, local regions surrounding a particle experience temperatures up to few 100s deg. C. Utilizing polymer degradation as a test reaction creates a detectable product as a permanent record of the temperature profile and, if localized, forms defects which dramatically alter mechanical properties. In general, manipulating the connection between the fraction of chemical degradation and mechanical strength as an object deteriorates is important for plastic waste management where microfragmentation may either be harmful or beneficial depending on the remediation strategy. Polyethylcyanoacrylate (PECA) degrades by depolymerizing and in confinement the monomer will repolymerize to form oligomers. Photothermal heating of PECA exhibits heterogeneous degradation, including defect formation and synthesis of a carbonaceous by-product localized around each particle. Polyethylene (PE) degrades via thermo-oxidative processes that rely on the presence of oxygen and pre-existing defects in addition to heat; consequently, photothermal heating of PE demonstrates homogeneous degradation due to the distributed nature of the reaction pathway.

*National Science Foundation CMMI-1462966
There is an increasing need for the development of multifunctional lightweight materials that are strong, tough, and reconfigurable. Natural systems have evolved efficient strategies, exemplified in the biological tissues of numerous animal and plant species, to synthesize and construct composites from a limited selection of available starting materials that often exhibit exceptional mechanical properties that are similar, and frequently superior to, mechanical properties exhibited by many engineering materials. These biological systems have accomplished this feat by establishing controlled synthesis and hierarchical assembly of nano- to micro-scaled building blocks that are integrated into macroscale structures. However, Nature goes one step further, often producing materials with that display multi-functionality in order to provide organisms with a unique ecological advantage to ensure survival.

In this work, we investigate a variety of organisms that have taken advantage of hundreds of millions of years of evolutionary changes to derive structures, which are not only strong and tough, but also demonstrate the ability to articulate as well as display multifunctional features including damage sensing and self-cooling. We discuss the mechanical properties and functionality stemming from these hierarchical features as well as how they are formed. From the investigation of synthesis-structure-property relationships in these unique organisms, we are now developing and fabricating cost-effective and environmentally friendly multifunctional engineering composites.

Session D70 DPOLY DSOFT GSNP DBIO: Rheology and Dynamics of Polymer Liquids and Glasses 208 - Thomas O'Connor, Sandia National Laboratories - Tag(s): Focus
2:30PM D70.00001: Molecular Simulations of Poly[n]catenane Dynamics and Rheology*
PHILLIP RAUSCHER (Presenter), University of Chicago, KENNETH SCHWEIZER, University of Illinois, STUART J ROWAN, JUAN DE PABLO, University of Chicago — With the recent synthesis of poly[n]catenanes – polymers composed of interlocking ring molecules – the possibility of incorporating catenated moieties into functional materials continues to grow. However, catenated polymers have been only sparsely studied, as previous investigations have primarily focused on statistical, topological, or structural features, rather than the dynamics. To characterize these new systems, we conducted molecular dynamics simulations of model poly[n]catenanes in the melt. We observe unusual monomer diffusion and present a Rouse-like model that can qualitatively explain the results. We show that this model fails to account for topological interactions and that various measures of friction in the system are not self-consistent. We examine the stress relaxation and find that the viscosity exhibits a surprising non-monotonic dependence on ring size. We briefly outline how these results may be applied to material design and synthesis.

2:42PM D70.00002: Graft Polymers and Entanglements: From Linear Chains to Filaments*
ANDREY DOBRYNIN (Presenter), HEYI LIANG, Univ of Akron, GARY GREST, Sandia National Laboratories — Dynamics of melts and solutions of high molecular weight polymers is controlled by topological constraints (entanglements) imposing sliding chain motion along an effective confining tube. For linear chains, the tube size is determined by a universal packing number Pe, the number of polymer strands within a confining tube required for chains to entangle. Using coarse-grained molecular dynamics simulations, it is shown that in melts of graft polymers, the packing number is not universal and depends on the molecular architecture. The packing number of graft polymers is a nonmonotonic function of the degree of overlap between side chains belonging to the same molecule. Below side chain overlap, it decreases with increasing grafting density, then begins to increase as side chains start to interpenetrate, finally, in the limit of densely grafted side chains it approaches Pe for linear chains. This dependence reflects a crossover from chain-like entanglements in systems with loosely grafted side chains to entanglements between flexible filaments. This is in agreement with the experimental data for dependence of plateau modulus on the molecular architecture of graft poly(n-butyl acrylates) and poly(norbornene)-graft-poly(lactide) melts.

2:54PM D70.00003: Effect of Head-to-Head Association/Dissociation on Relaxation of Entangled Chains  
HIROSHI WATANABE (Presenter), YUMI MATSUMIYA, Kyoto Univ, YOUNGDON KWON, Sungkyunkwan Univ — For entangled high-cis polyisoprene (PI-COOH) undergoing monofunctional, head-to-head association/dissociation through hydrogen bonding of COOH groups attached at the chain head, viscoelastic and dielectric relaxation behavior was examined in bulk state. The relaxation was found to deviate significantly from that of a simple mixture (blend) of non-associative unimer PI and dimer (PI)₂ having the same composition as the associative PI-COOH (determined from FTIR spectroscopy for the COOH group). This deviation is attributed to an association/dissociation-induced motional coupling between the PI-COOH unimer and its dimer. Analysis based on the reptation eigenfunction expansion lends support to this conclusion.

3:06PM D70.00004: Unified analytic expressions for the entanglement length, tube diameter, and plateau modulus in polymer melts*  
ROBERT HOY (Presenter), Univ of South Florida, MARTIN KRÖGER, ETH Zurich — By postulating that the contributions to the dimensionless plateau modulus from flexible-, semiflexible-, and stiff-chain entanglement mechanisms combine additively (in parallel), and testing this postulate with molecular dynamics simulations and topological analyses of Kremer-Grest bead-spring polymer melts, we obtain analytic expressions that quantitatively predict the plateau modulus $G$, the entanglement length $N_e$, and the tube diameter $a$ in melts that span three orders of magnitude in $l_K/p$, where $l_K$ and $p$ are respectively the Kuhn and packing lengths. Our expressions resolve conflicts between previous scaling predictions for the loosely entangled [Lin-Noolandi: $Gl_K^3/k_BT \sim (l_K/p)^3$] and tightly-entangled [Morse: $Gl_K^3/k_BT \sim (l_K/p)^{7/5}$] regimes.

*Support from NSF Award No. DMR-1555242 is gratefully acknowledged.

3:18PM D70.00005: The Source of Strain Hardening in Glassy Polymers Investigated by Molecular Dynamics and Brownian Dynamics Simulations*  
RONALD LARSON (Presenter), Chemical Engineering, University of Michigan, ROBERT HOY, Physcs, University of South Florida, SOROUSH MOGHADAM, WEIZHONG ZOU, Chemical Engineering, University of Michigan — Using both fine-grained Molecular Dynamics (MD) simulations and coarse-grained simulations we show how strain hardening in polymeric glasses under uniaxial extension arises from highly stretched strands that form as the polymer chains deform subaffinely on increasing length scales as strain increases. We find that although the HBD model ignores entanglements, it accurately predicts how the MD chain configurations evolve during deformation. Both models shows similar strain hardening modulus $G_R$ that is much larger than the melt plateau modulus $G_N$ because chain segments become highly stretched at modest Hencky strain (<1 ). Both models also capture the increase in strain hardening with increasing chain length that saturates in the long chain limit. We improve upon HBD’s ability to accurately capture stress-strain curves at small strains through yielding and strain softening by extending the theory to multiple segmental relaxation modes, whose strain-dependent relaxation times are obtained from small-molecule probe relaxation experiments by Ediger and coworkers [Bending, B. & Ediger, M. D. J. Polym. Sci. B 2016, 54, 1957-1967].

*We acknowledge funding by the National Science Foundation DMR-1707640
3:30PM D70.00006: Predicting time-temperature-superposition breakdown near the glass transition with the Heterogeneous Rouse Model*  DAVID SIMMONS (Presenter), Chemical and Biomedical Engineering, University of South Florida — Since pioneering work by Plazek in the 1960’s, it has been known that time-temperature superposition breaks down in many polymers upon approach to the glass transition. Because TTS is fundamentally rooted in the Rouse model prediction of a shared temperature dependence for chain and segmental relaxation modes, this breakdown implies a significant gap in our understanding of polymer dynamics at low temperature. Here, we report on predictions of TTS breakdown by the Heterogeneous Rouse Model, which generalizes the Rouse model to incorporate dynamic heterogeneity – the emergence of a distribution of segmental relaxation times at low temperature. Predictions are in good agreement with simulations and with available experimentally observed relaxation spectra in the TTS-breakdown regime, suggesting that this theory provides a promising model for dynamics in the TTS breakdown regime.

3:42PM D70.00007: Relationship Between Large Amplitude Oscillatory Strain (LAOS) Experiments and Commercial Pressure Sensitive Adhesives Applications Testing  ALAN NAKATANI (Presenter), SIPEI ZHANG, Core R&D Analytical Science, The Dow Chemical Company, SEHBAN OZAIR, ASGHAR PEERA, DOW Adhesives, Collegeville, PA 19446, The Dow Chemical Company, OWEN YOUNG, Core R&D Analytical Science, The Dow Chemical Company, KYLIE MANNING, CACHAE PEARSON, HIMAL RAY, DOW Adhesives, Collegeville, PA 19446, The Dow Chemical Company — Historically, analytical test methods on pressure sensitive adhesives (PSA’s) have shown poor correlation to applications test results. Since applications tests such as peel and shear involve large deformations of the adhesive, large amplitude oscillatory strain (LAOS) experiments may correlate more strongly to the applications test results than typical linear viscoelastic measurements. Here we report the applications and characterization results on nine different commercial PSA films. The primary applications test results are 90° stainless steel peel and stainless steel shear. Based on these results, the adhesives were classified as “tape”, “label”, or “removable”, with three samples in each category. The adhesives were characterized analytically by large amplitude oscillatory strain (LAOS) tests. The various LAOS parameters appear correlated to the applications peel and shear results indicating LAOS may provide a better indication of applications performance in a more efficient way than existing applications test protocols.
3:54PM D70.00008: Polymer rheology predictions from first-principles using the slip-link model*  DIEGO BECERRA, ANDRES CORDOBA, Chemical Engineering, Universidad de Concepcion, MARIA KATZAROVA, Chemical Engineering, University of Delaware, MARAT ANDREEV, Chemical Engineering, MIT, DAVID CHRISTOPHER VENERUS, Chemical Engineering, New Jersey Institute of Technology, JAY SCHIEBER (Presenter), Physics, Applied Math, Chemical Engineering, Illinois Institute of Technology — The discrete slip-link theory a hierarchy of strongly connected models that have great success predicting the linear and nonlinear rheology of high-molecular weight polymers. Three of the four parameters of the most detailed model can be extracted from primitive path analysis, which give quantitative experimental agreement for all examined chemistries (PS, PI, PBd and PE). Here we show that the remaining friction parameter can also be extracted from atomistic simulations. In particular, an available quantum chemistry-based force field for polyethylene oxide (PEO) was used to perform molecular dynamics simulations of a 12kDa melt. Once the four parameters are determined for any chemistry, all parameters for all members of the slip-link hierarchy are determined. Then, using a coarser member of the hierarchy the dynamic modulus and nonlinear rheology of a 256kDa PEO melt was predicted. The predictions are compared to experimental measurements performed at the same temperature. Unfortunately, the extracted friction differs by a factor of two from experiment, which presumably arises from insufficient accuracy in the force field. Nonetheless, the work demonstrates that theory predictions without adjustable parameters should be possible.

4:06PM D70.00009: A priori Determination of the Extensional Viscosity of Polydisperse Linear Polymer Melts*  JOHN DORGAN, JOHN SZFRANSKI (Presenter), Michigan State Univ — Compared to coarse grained MD, the COMOFLO algorithm is 100,000 times faster. The steady-state extensional viscosity function is calculated in a parameter free completely a priori manner as previously done for shear (Parameter Free Prediction of Rheological Properties of Homopolymer Melts by Dynamic Monte Carlo Simulation, Dorgan et.al., Macromolecules, (2012) DOI: 10.1021/ma301307d). The algorithm captures molecular details of extensional flow in three dimensions for entangled polymer melts of arbitrary molecular weight distribution across multiple flow regimes from the correct low deformation limit, through the strain-hardening regime, to the high deformation rate strain softening region. Comprehensive a priori shear rheology of polydisperse systems was established earlier (Finding the Missing Physics: Mapping Polydispersity into Lattice-Based Simulations. Rorrer & Dorgan, Macromolecules, 2014, DOI: 10.1021/ma5001207 ). The ability to predict steady shear and elongational rheology for linear polymer melts of arbitrary molecular weight distribution can be considered a solved problem.

*Funding was provided by the Fluid Dynamics Program of the NSF under grant CBET-1067707 and by the David and Denise Lamp Endowment gift to the Michigan State University Foundation.
4:18PM D70.00010: Thinning and break up of freestanding polymer solutions* [Invited]  JAN VERMANT (Presenter), EMMANOUIL CHATZIGIANNAKIS, Materials, ETH Zürich — The stability and break-up of thin liquid polymer films is a fascinating subject and reflects a complex interplay between intermolecular forces, hydrodynamic and viscoleastic phenomena, osmotic pressure and the effects of confinement. We have studied the thinning dynamics of concentrated polymer-solutions liquid films experimentally using a modified thin film balance technique. The variation of the capillary pressure that is driving the thinning of the film allows us to control the ratio of the the competing timescales of drainage and rupture. It is shown that rupture occurs through the random evolution of thickness fluctuations, whereas the drainage dynamics are described well by continuum approaches, even down to length scales on the order of the radius of gyration of the films. Using time dependent positive, negative and oscillatory pressure jumps across the interface, a wide range of dynamical phenomena can be evidenced. The implications of these results on macroscopic stability of multiphase systems and modelling events such as coalescence will be discussed.

*We acknowledge funding of Shell, The Netherlands.

4:54PM D70.00011: Uniaxial Extensional Rheology of Associating Polymers: from Processing to Performance  ZACHARY HINTON (Presenter), NICOLAS ALVAREZ, Department of Chemical and Biological Engineering, Drexel University — Polymers which include associating groups show increased performance characteristics over the base backbone polymer. The tunable properties of associating polymers are desirable for a wide range of applications, including as self-healing materials. However, there is typically a loss of processability for strongly associating polymers. In this work, we use filament stretching uniaxial extension to probe the processing window of strongly associating polymers. We show that, processing is limited by melt fracture in a wide range of Weissenberg numbers. The presence of entanglements increases the level of processability both in terms of the maximum Hencky strain before failure and the minimum achievable strain at low temperatures. Furthermore, the mechanical performance of associating polymers is confirmed to depend strongly on the associating group strength. Both the processability and performance of associating polymers can be captured by a spectrum of relaxation timescales related to the polymer backbone and various states of the associating groups. By reducing the critical behaviors of associating polymers to key timescales, clear design and processing parameters can be addressed in terms of fundamental physics.
5:06PM D70.00012: Liquid to soft solid transition in block polymers via low strength magnetic fields*  KARTHIKA SURESH (Presenter), MICHELLE A CALABRESE, Chemical Engineering and Materials Science Department, University of Minnesota — Achieving magnetic field-induced orientation in block polymers (BCPs) has typically relied on large field strengths (B≥5 T), the addition of liquid-crystalline (LC) or rod-like blocks, substantial chain anisotropy, or combinations therein. BCP ordering upon application of low-strength fields (≤0.5 T) has only been reported in systems of over 60% wt LC mesogen by mass. Here, we identify substantial field-induced rheological and structural changes in several coil-coil BCP variants using magneto-rheology and small-angle neutron scattering (SANS). Linear viscoelastic temperature ramps combined with B≥0.1 T magnetic field show a liquid to gel transition where the increase by three-to-six orders of magnitude beyond a critical time (t_c). Here, t_c is a function of field strength, polymer concentration and molecular weight, temperature, and ionic strength. The resultant gel state is stable for several hours after field removal, where the structural relaxation time scales with the maximum achieved modulus. SANS detects distinct gelation mechanisms based on BCP variant. In addition to structure enhancement, this approach has the potential to discover new structures not accessible through traditional self-assembly routes with minimal input from external fields.

*Seed grant, UMN MRSEC

5:18PM D70.00013: Multiscale simulation of a well-entangled polymer melt flow in between two coaxial cylinders under non-isothermal condition*  YUJI HAMADA, TAKESHI SATO, TAKASHI TANIGUCHI (Presenter), Chemical Engineering, Kyoto University — We have successfully extended a multiscale simulation method to non-isothermal well-entangled polymer melt flows in between two coaxial cylinders. At the microscopic level, a dual slip-link model is employed as a model for well-entangled polymers. We found that the extended multiscale simulation method is quite effective to reveal the relation between non-isothermal polymeric flows and microscopic states of polymer chains expressed by primitive paths and slip-links. It is also found that the temperature-dependent reptation-time-based Weissenberg number is a suitable measure to understand how extent polymer chains are deformed in a range of the shear rate used in this study.

8:00AM F01.00001: Sensing and transduction with high-Q micromechanical membranes
[Invited] CINDY REGAL (Presenter), University of Colorado, Boulder —
I will present experiments probing micromechanical motion at quantum limits using SiN membranes. In particular I will discuss work in which we use ultra-high-Q patterned membranes in force sensing and in quantum transduction between microwave and optical signals.

8:36AM F01.00002: Improved optical cavity in microwave-mechanical-optical transducer*
MAXWELL URMEY (Presenter), BENJAMIN M BRUBAKER, SARANG MITTAL, PETER S BURNS, JONATHAN KINDEM, KONRAD LEHNERT, CINDY REGAL, JILA — Linking quantum computational nodes to form a long-distance network in an architecture based on superconducting qubits faces an inherent challenge: the low excitation energy of microwave photons precludes quantum signal propagation at room temperature. A quantum coherent transducer between microwave and optical frequencies would overcome this difficulty. By coupling both a superconducting LC resonator and an optical Fabry-Perot cavity to the same MHz-frequency mode of a SiN membrane micromechanical oscillator, we realize a converter with 47% efficiency \[1\]. The process adds 38 photons of noise which prevent its quantum operation, with a significant contribution associated with the optical pump mediating the optomechanical interaction. By redesigning the optical cavity, we have reduced misalignment-induced optical loss and enabled greater optomechanical coupling, allowing reduced pump powers.

8:48AM F01.00003: Toward on-chip microwave to optical transduction using erbium doped crystals

JAKE ROCHMAN (Presenter), TIAN XIE, JOHN G BARTHOLOMEW, IOANA CRAICIU, JONATHAN KINDEM, KEITH SCHWAB, ANDREI FARAON, Caltech — Future quantum networks based on superconducting circuits that operate at microwave frequencies will strongly benefit from optical interconnects between the distant nodes. One promising platform to achieve bidirectional conversion between microwave and optical photons are ensembles of rare-earth ions (REIs) strongly coupled simultaneously to an optical and a microwave resonator. The strong interactions between the REIs and photons are critical to minimize the optical power required to mediate the conversion process and for potential operation at temperatures below 100 mK. Here, we present our progress towards a REI-based transducer using superconducting microwave resonators and amorphous silicon photonic crystal resonators patterned on the surface of an erbium-doped yttrium orthovanadate crystal. Both resonators are designed to maintain high quality factors while preserving the mode overlap between the optical and microwave fields required for high conversion efficiency. We present initial results characterizing the device performance at cryogenic temperatures.

9:00AM F01.00004: Constructing Perfect Quantum Transducers Using Multi-Mode Imperfect Transducers

MENGZHEN ZHANG (Presenter), SHOUMIK CHOWDHURY, Yale University, LIANG JIANG, University of Chicago — Quantum transducers can transfer quantum information between different bosonic physical platforms, which are crucial for hybrid quantum devices and quantum networks. In practice, however, transduction devices are not perfect, as there are systematic deviations and coupling to other bosonic modes. Recently, Lau and Clerk showed that combining finite single-mode squeezing and imperfect transduction operations we can implement desired perfect quantum transduction, but only restricted to two-mode. In this work, we generalize the previous results and show how to transform generic multi-mode imperfect transducers into perfect transducers requiring only finite-squeezing resources, based on a general protocol of decoupling irrelevant bosonic modes from the original system.
9:12AM F01.00005: A compact trampoline-in-the-middle system for acoustic frequency quantum optomechanics
CHRISTIAN PLUCHAR (Presenter), AMAN AGRAWAL, EDWARD SCHENK, DALZIEL WILSON, College of Optical Sciences, University of Arizona — Strained nanomechanical resonators can have extremely low mechanical loss at acoustic frequencies, spurring recent proposals for ultra-sensitive force detection and quantum experiments at room temperature. We present a quasi-monolithic membrane-in-the-middle system that incorporates a 10 ng Si$_3$N$_4$ trampoline resonator with a fundamental frequency of 40 kHz into a 100 um Fabry-Perot cavity with a finesse of 30,000. Prior to cavity assembly, we record a mechanical loss rate of 0.8 mHz (a quality factor of 50 million) for the fundamental trampoline mode, corresponding to a force sensitivity of 30 aN/√Hz and a zero-point displacement spectral density of 0.3 pm/√Hz. Mounting results in significant added loss; however, the large optomechanical cooperativity still reveals itself as Brownian motion exceeding the cavity linewidth by an order of magnitude. We present a technique to “load” the resonator into the cavity by radiation pressure feedback cooling. Eliminating mounting loss would result in a vacuum cooperativity of $10^4$, accessing a regime currently targeted with levitated nanoparticles.

9:24AM F01.00006: Reducing added-noise in a micro-mechanically mediated electro-optic converter
SARANG MITTAL (Presenter), BENJAMIN M BRUBAKER, MAXWELL URMEY, PETER S BURNS, JONATHAN KINDEM, CINDY REGAL, KONRAD LEHNERT, JILA — Bidirectional transduction of microwave and optical fields would be a useful resource in the toolbox of quantum technology. We have demonstrated a mechanically mediated electro-optic converter by coupling a micromechanical oscillator to a microwave circuit and an optical cavity simultaneously. Operating this device at T < 100 mK, we recorded a conversion efficiency of 47% and added noise of 38 photons [1]. While we have realized high efficiency, the added noise is still an order of magnitude too large. Here, we present our efforts to lower the added noise by designing phononic shielding of the mechanics and replacing our superconducting metal with NbTiN.

9:36AM F01.00007: Towards quantum optomechanics using bulk acoustic wave resonators
HUGO DOELEMAN (Presenter), SILVAN VOLLENWEIDER, UWE VON LÜPKE, YIWEN CHU, ETH Zurich — Superconducting circuits are one of the most sophisticated architectures for quantum information processing to date. MW-to-optical conversion in the quantum regime could enhance their scalability and range of applications, since optical photons can be used as noise-free carriers of quantum information that connect circuits in different refrigerators. This requires conversion that is coherent, efficient, and with minimal added noise, which has not been demonstrated yet.

We present our advances in developing a cryogenic cavity optomechanical device based on a bulk-acoustic-wave (BAW) mechanical resonator, which can act as an essential part of a MW-to-optical transducer. Strong coupling to BAWs has been demonstrated both for microwave photons [1] and for optical photons [2]. Building on these works, we are developing an optomechanical system that is also compatible with coupling to superconducting circuits. We report on first experiments of BAW resonators cooled to millikelvin temperatures and coupled to optical cavity modes. As a first proof-of-principle, we discuss prospects for storage and retrieval of low-photon-number coherent optical states in the mechanical resonator.

9:48AM F01.00008: Towards entanglement and interconversion of single mm-wave and optical photons in a hybrid cavity-QED system with Rydberg atoms
AZIZA SULEYMANZADE (Presenter), MARK J STONE, LAVANYA TANEJA, ALEXANDER ANFEROV, JASMINE KALIA, DAVID I SCHUSTER, JONATHAN SIMON, University of Chicago — I will present our most recent progress towards entangling and interconverting single millimeter wave (mm-wave) and optical photons using Rydberg atoms as a transducer. Hybrid systems, which cross-couple optical and microwave regimes, can harness the unique strengths of optical systems for communication and microwave systems for quantum information processing, yielding a more powerful toolset for quantum information technology. The mm-wave band additionally offers access to single photon resolution at 1K, due to low thermal photon occupation at high frequencies. I will present our recent realization of a hybrid cavity with crossed mm-wave and optical modes, enabling smooth integration of cold atoms, laser beams and Rydberg excitations. The high-Q mm-wave cavity has a $Q_{tot} = 3 \times 10^7$ at 98GHz and mode volume of $V = 0.1 \lambda^3$, which allows strong coupling with cooperativity of $h=22000$ between single mm-wave photon and a single Rydberg atom on the 36S $\rightarrow$ 35P transition. I will report our first observations of intra-cavity vacuum Rabi Splitting, Rydberg Electromagnetically Induced Transparency (EIT) and outline our path towards creating strong interactions between single mm-wave and optical photons.
Large electromechanical coupling in inductively coupled electromechanics

PHILIP SCHMIDT, MOHAMMAD AMAWI, STEFAN WEICHSELBAUMER, DANIEL SCHWIENBACHER, STEFAN POGORZALEK, ACHIM MARX, RUDOLF O GROSS, HANS HUEBL (Presenter), Walther Meissner Inst — Light-matter interaction in optomechanical systems is the foundation for ultra-sensitive detection schemes measuring displacements, accelerations, and forces. In addition, this interaction enables the generation of mechanical quantum states and entangled states of photons and phonons. Electromechanical systems implement the field of optomechanics using microwave circuits. Most implementations realize the coupling using a mechanically compliant capacitance, demonstrating a maximum interaction rate of 280 Hz [1]. However, it was realized early on that inductive coupling schemes promise much higher interaction strengths even with the potential to reach the strong vacuum coupling regime. Here, we demonstrate electromechanical coupling based on a partly suspended SQUID combined with a coplanar microwave resonator exceeding a coupling rate of 1 kHz. This coupling enables force sensitivities on a sub-attonewton level using a single-photon ultra-low power readout. We discuss the performance of the concept including the tunability of this coupling with magnetic field.

This project is funded from the European Union’s Horizon 2020 programm (No 736943) and by the German Research Foundation (EXC-2111 – 390814868).

Laser cooling to the zero-point energy of a nanomechanical oscillator

LIU QIU (Presenter), ITAY SHOMRONI, Ecole Polytechnique Federale de Lausanne, PAUL SEIDLER, IBM Research -- Zurich, TOBIAS J. KIPPENBERG, Ecole Polytechnique Federale de Lausanne — Silicon optomechanical crystals enable coupling of photons at telecommunication wavelengths to GHz mechanical modes, giving rise to optomechanical dynamics that can extend well into the resolved-sideband regime. Despite these promising characteristics, high-fidelity ground state preparation has to date only been achieved using passive cooling in a dilution refrigerator. Moreover, heating due to optical absorption has limited measurement protocols to short, low-energy optical pulses. Here, we demonstrate continuous-wave laser sideband cooling of a silicon optomechanical crystal to the zero-point energy, reaching a mean thermal occupancy of $0.09^{+0.02}_{-0.01}$ quanta, or 92\% ground state occupation, self-calibrated via motional sideband asymmetry. Our results overcome previous limitations due to optical absorption heating and highlight optomechanical crystals for quantum-enhanced continuous displacement measurements, low-added-noise quantum transducers, and integration with superconducting qubit technology.

This work is supported by the Swiss National Science Foundation under grant No.~163387 and grant No.~51NF40-160591 (NCCR-QSIT), and the European Union's Horizon 2020 research and innovation programme under grant No.~732894 (FET Proactive HOT).
The possibility to operate mechanical systems close to the quantum regime has become central in both fundamental and applied science. A key parameter here is how strongly photons will impact the mechanics. The microwave regime offers the opportunity to achieve large couplings towards a regime where the coupling rate becomes the dominant time scale. In our ongoing experimental efforts to reach this single-photon strong coupling regime, we developed an approach based on a mechanical oscillator inductively coupled to a superconducting circuit. We place a NdFeB micromagnet on the tip of an AFM cantilever and align it on top of the SQUID of a tunable 3D microstrip resonator. When flux sensitive, the motion of the cantilever will result in a change in resonance frequency of the microstrip resonator, similar to typical cavity optomechanical setups. Varying the external flux allows us to tune the coupling strength from virtually zero to higher values, reaching single photon strong cooperativity, allowing for cooling with a single photon. Improving our current design, we hope to reach single photon strong coupling, allowing the quantum control of massive mechanical resonators.

8:00AM F02.00001: Vortices in Rotating Bose-Einstein Condensate Shells  KARMELA PADAVIC (Presenter), University of Illinois at Urbana-Champaign, KUEI SUN, The University of Texas at Dallas - Richardson, COURTNEY LANNERT, Smith College, University of Massachusetts - Amherst, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We present a study of superfluid vortices in rotating shell-shaped Bose-Einstein condensates (BECs). Hollow spherical BECs are of interest in connection to ongoing experimental efforts on the International Space Station and they naturally occur in optical lattice systems of ultracold bosons and interiors of neutron stars. Fundamentally, they have interesting geometry (non-zero curvature) and topology (hollow center). When BECs are rotated, discrete vortices are generated in pairs, as a consequence of the quantum coherence and the closed shape of the system. Using a mean-field approach, numerical solutions of the Gross-Pitaevskii equation and insights from classical fluid dynamics, we find that hollow condensates have a lower energy barrier to emergence of vortices than fully filled BECs. Further, we show that the rotation frequency at which nucleation of vortex lines is energetically favorable increases with BEC shell thickness. At this frequency the first vortex line is generated as straight and extends along the rotation axis. We consider the possibility of bent vortex lines (off-axis vortex pairs of opposite circulations in the two-dimensional shell limit) and determine that they are unstable except at fast rotation.

8:12AM F02.00002: Dynamics of Quantum Gas in Non-Abelian Gauge Field  MEHEDI HASAN (Presenter), CHETAN MADASU, CHANG CHI KWONG, Nanyang Tech Univ, FRÉDÉRIC CHEVY, Laboratoire Kastler Brossel, Ecole Normale Supérieure, DAVID WILKOWSKI, Nanyang Tech Univ — We experimentally realize SU(2)-symmetric artificial gauge field with the tripod laser scheme. First, the non-Abelian nature of the artificial gauge field is revealed by performing loop operations, at different orders, in the parameter space [1]. It was found that the dynamics of internal states leads to a new thermometric scheme that exploits the interferometric-displacement of atoms [1]. Afterwards, the coupling dynamics of internal(i.e., spin)- and external(i.e., momentum)-degrees of freedoms, in a two-dimensional non-Abelian gauge field, is shown to exhibit an asymmetric expansion of the atomic cloud [2]. This spin-orbit-coupled gas breaks the Galilean invariance and modifies the usual reflection-laws, owing to its inherent peculiar dispersion relation. The density distribution of external dynamics markedly carries the signature of the non-Abelian nature of the underlying gauge field.

8:24AM F02.00003: Quantum simulation of Dynamical gauge field for ultra-cold atoms in a cavity*  SANKALPA GHOSH (Presenter), POORNIMA SHAKYA, Indian Inst of Tech-New Delhi — Quantum simulation of synthetic gauge field in ultra-cold atoms provides opportunity to realize the analogues of Landau levels of electrons and Quantum Hall Physics, Hofstadter-Harper Hamiltonian, and topological phases in a much more controlled environment. Where the initial studies were mostly on synthetic gauge fields that do not have dynamics of their own, a number of current studies aimed to create dynamical gauge field for neutral ultra-cold atoms to extend the scope of such analogue quantum simulations for condensed matter and high-energy physics related phenomena. 

In this work, we propose that ultra cold atoms in high finesse ring cavity of suitable geometry to create a non-uniform dynamical gauge field for neutral ultracold atom. The resulting energy spectrum is similar to the energy dispersion for an electron in a similar magnetic modulation that can effectively create one dimensional flow of such ultra-cold atoms. Starting with single atoms dynamics in such synthetically created dynamical non-uniform gauge field we extend this idea to the ultra-cold atomic Bose-Einstein condensates and study the corresponding dynamics.

8:36AM F02.00004: Superfluidity and Bogoliubov excitations of a striped spin-orbit coupled BEC induced by a weak optical lattice*  GUANQIANG LI (Presenter), XIWANG LUO, JUNPENG HOU, CHUANWEI ZHANG, University of Texas at Dallas — We investigate the ground-state superfluidity and Bogoliubov excitations of a striped spin-orbit coupled Bose-Einstein condensate (BEC) with the momentum-space hopping induced by a weak optical lattice. The ground-state phase diagram and corresponding superfluid fraction are calculated for different system parameters. The Bogoliubov spectrum is studied and an exotic avoided band crossing between roton and Goldstone modes is revealed, which is very different from traditional spin-orbit coupled Bose-Einstein condensate with double-gapless Goldstone modes. We study the quantum depletion, which can be used to characterize the phase transitions.

8:48AM F02.00005: Optical Vortex Braiding in Composite Bessels* ANDREW VOITIV
(Presenter), JASMINE ANDERSEN, MARK SIEMENS, Univ of Denver, MARK T. LUSK, Department of Physics, Colorado School of Mines — We theoretically propose and experimentally demonstrate the braiding of optical vortices in a laser beam with more than 2π rotation by superposing Bessel modes with a plane wave. Laser beams containing a single, centered vortex with integer-valued orbital angular momentum (OAM) have been extensively studied and engineered, but beams with two or more optical vortices have received less attention. Optical vortex braiding refers to the periodic rotation of two or more vortices around the central axis of propagation in a laser beam. Braiding is a topological feature in knot theory, but no physically-realizable scheme for optical vortex braiding beyond a ¼ - rotation has been identified, much less experimentally demonstrated. In this work, we present a theoretical proposition for braiding optical vortices in Bessel beams, along with analytical expressions for the braiding trajectories and braiding period. We accompany this work with the experimental realization of vortex braiding in physical laser beams, using Bessel-Gaussian beams. We show two vortices braiding completely three times, the most observed to our knowledge.

9:00AM F02.00006: Spin Angular Momentum in Acoustic Field Theory LUCAS BURNS
(Presenter), Schmid College of Science and Technology, Chapman University, KONSTANTIN Y BLIOKH, Theoretical Quantum Physics Laboratory, RIKEN Cluster for Pioneering Research, JUSTIN DRESSEL, Institute for Quantum Studies, Chapman University — We construct a Lagrangian representation of acoustic field theory that accounts for the local radiation forces and torques experienced by subwavelength probe particles, analogous to those experienced by Rayleigh particles in optical fields. The traditional acoustic Lagrangian representation with a scalar potential is unable to reproduce these measured effects. By introducing a displacement vector potential, analogous to the electromagnetic vector potential, we derive the appropriate local momentum and spin densities directly as conserved Noether currents. The results agree with those proposed in recent analyses of intrinsic acoustic spin and are consistent with recent experiments.
Bose-Einstein condensation in effective Harper-Hofstadter bands: simulations of synthetic magnetic fields by optical lattice shaking

HAN FU (Presenter), FNU SETIAWAN, LOGAN W CLARK, University of Chicago, ANDREAS GLATZ, Argonne National Lab, KATHRYN LEVIN, University of Chicago — The cold atom field has been focused on generating topological and other exotic phases of quantum matter by, for example, creating strong synthetic magnetic fields. In the present work we use time-dependent Gross-Pitaevskii simulations to investigate the feasibility of these schemes. There are several key questions we numerically address: 1. Can one implement shaking so that a BEC will emerge, consistent with the effective energy minima of Bloch-Floquet bandstructure? 2. How realistic is it to experimentally enter the Harper-Hofstadter regime which involves extreme parameter values (such as for hopping and shaking frequency)? 3. An important attribute of applying these Bloch-Floquet recipes to cold atoms is that there are easily tunable many-body interactions present, which are necessary for equilibration. One can then be concerned that they undermine the single-particle Floquet bandstructure. In this talk we address these issues, and in the process provide advice for experimentalists in implementing these shaking recipes for arriving at a Hofstader BEC. Additionally, in our simulations we investigate what underlies “heating” and how it is affected by the strength of the interactions g.

Inhomogeneous mean-field approach for collective modes at the superfluid-Mott glass transition*

MARTIN PUSCHMANN (Presenter), Missouri Univ of Sci & Tech, JOSE A HOYOS, Universidade de São Paulo, THOMAS VOJTA, Missouri Univ of Sci & Tech — We employ an inhomogeneous mean-field approach plus Gaussian fluctuations to investigate disordered Bose-Hubbard models with particle-hole symmetry in two and three dimensions. Within this framework, the collective excitations, i.e., Goldstone mode and the Higgs (amplitude) mode, are described by two effective, decoupled, disordered single-particle Hamiltonians whose properties are determined by the underlying mean-field solution. Based on multifractal analysis, we investigate the localization properties of each mode separately as a function of energy and the distance from the superfluid-Mott glass transition. Furthermore, we calculate susceptibility functions and compare the results with Monte Carlo simulations and experiments.

*This work was supported by the NSF under Grant Nos. DMR-1506152, DMR-1828489, PHY-1125915 and PHY-1607611 as well as by the São Paulo Research Foundation (FAPESP) under Grant No. 2017/08631-0.
9:36AM F02.00009: Realizing $Z_2$ phases and Majorana Spectroscopy in extended Bose-Hubbard systems  SMITHA VISHVESHWARA (Presenter), University of Illinois at Urbana-Champaign, DAVID MINOT WELD, University of California, Santa Barbara — The connection between transverse XY spin chains and the fermionic Kitaev chain with nearest-neighbor hopping and pairing has been well known for decades, and has lately drawn attention for its rich phase diagram and relevance to realizations of Majorana fermions. Here, we study the novel system comprised of a Bose-Hubbard chain connected to a reservoir that can generate analogous pairing terms for bosons. We describe a cold-atom realization of such a system in a biased zig-zag optical lattice. We show that in certain limits, the Bosonic Kitaev chain maps on to the XY spin chain, resulting in an unusual $Z_2$ phase that has number fluctuation but no off-diagonal long range order associated with boson condensation. Noteworthy features include the possibility of a strongly correlated many-body qubit ground state and the potential for cold-atom measurements of the Kitaev chain energy spectrum, including zero-energy Majorana bound states.

9:48AM F02.00010: Dark states of multilevel fermionic atoms in doubly-filled optical lattices  ASIER PINEIRO ORIOLI (Presenter), ANA MARIA REY, JILA, NIST, University of Colorado — We propose to use fermionic atoms with degenerate ground and excited internal levels ($F_g \rightarrow F_e$), loaded into the motional ground state of an optical lattice with two atoms per lattice site, to realize dark states with no radiative decay. The physical mechanism behind the dark states is an interplay of Pauli blocking and multilevel dipolar interactions. The dark states are independent of lattice geometry, can support an extensive number of excitations and can be coherently prepared using a Raman scheme taking advantage of the quantum Zeno effect. These attributes make them appealing for atomic clocks, quantum memories, and quantum information on decoherence free subspaces.

10:00AM F02.00011: Numerical study of antiferromagnetic nearest-neighbor spin correlations of an SU(6) Fermi gas in an optical lattice*  EDUARDO IBARRA GARCIA PADILLA (Presenter), KADEN HAZZARD, Rice University, RICHARD THEODORE SCALETTAR, UC Davis, HAO-TIAN WEI, Fudan University, SHINTARO TAIE, NAOKI NISHIZAWA, YOSUKE TAKASU, YOSHIHITO KUNO, YOSHIRO TAKAHASHI, Kyoto University — Experimental progress with ultracold alkaline-earth-like atoms allows quantum simulation of novel phenomena and phases of matter. Many interesting SU($N$) phases are characterized by their magnetic correlations. Recently, the experiment at Kyoto has detected nearest-neighbor antiferromagnetic (AFM) spin-correlations in an SU(6)$^{173}$Yb Fermi gas loaded in 1D, 2D and 3D optical lattices. Such systems are effectively described by the SU($N$) Fermi Hubbard Model. We have developed and applied the Exact Diagonalization and Determinant Quantum Monte Carlo methods to solve such model in all of the relevant geometries. With these tools we calculate the density, double occupancy, entropy and magnetic correlations in a trapped gas under the local density approximation. We compare the calculated and measured nearest-neighbor AFM correlations, and we find they agree quantitatively. In 2D and 3D the experiments reach lower temperatures than is possible to accurately compute with theory, but in 1D, the temperature estimated from theory comparison is $k_B T/t = 0.08(2)$, being the lowest temperature ever reported for a Fermi gas in an optical lattice.

*RTS was supported by the Department of Energy, grant DE-SC0014671.
10:12AM F02.00012: Dynamics of an almost lattice gauge theory realized by an ultracold atom system  
DANIEL GONZALEZ CUADRA (Presenter), VALENTIN KASPER, ALEXANDRE DAUPHIN, ICFO, PHILIPP HAUKE, University of Trento, FRED JENDRZEJSKI, University of Heidelberg, MACiej LEWENSTEIN, ICFO — Recently carried out experiments with ultracold atoms have realized the first building blocks to simulate lattice gauge theories quantum. Despite the great progress, the influence of experimental imperfections on the phase structure or the non-equilibrium dynamics is unclear. In this thesis we study the effect of terms violating the local gauge invariance as they occur in a typical experimental setup. In particular, we focus on ultracold atom setups which exploit angular momentum conservation in order to realize local gauge invariance. We also study the influence of dissipation in these systems and compare the dynamics of a theory with exact and almost lattice gauge theory. Especially we determine the time scales and observables when the difference between the two theories becomes significant.

10:24AM F02.00013: $Z_2$ Lattice Gauge System and Dynamical Localization  
ZHIYUAN YAO (Presenter), CHANG LIU, PENGFEI ZHANG, HUI ZHAI, Tsinghua University — Gauge theory has been playing a fundamental role in our understanding of the deepest mysteries of physics. And recent advances in cold atom physics have also made the study of dynamical gauge systems a new frontier. Using Floquet approach, we propose to realize a one-dimensional $Z_2$ lattice gauge model, featuring extensive local constants of motions, using two specifies of Rb atoms. The resulting Floquet Hamiltonian turns out to be quite simple. Within a given symmetry sector of good quantum numbers, the system can be viewed as a 1D transverse quantum Ising model with a binary random longitudinal field. Therefore, the dynamics of the system is essentially controlled by disordered Hamiltonians, implying that the system can feature many body localization (MBL) as a result of dynamical localization. Numerical studies of energy level statistics and quench dynamics clearly demonstrate the existence of MBL phase in this system.

F02.00014: Unusual superfluid behavior of population imbalanced atomic Fermi gases in a two-dimensional optical lattice*  
LIN SUN (Presenter), Zhejiang university, QIJIN CHEN, University of Science and Technology of China — We study the superfluid behavior of population imbalanced ultracold atomic Fermi gases with a short range attractive interaction in a two-dimensional optical lattice (2DOL), using a pairing fluctuation theory, within the context of BCS-BEC crossover. We find that population imbalance now has highly unusual effects on the behavior of pairing and superfluidity, caused by the continuum-lattice mixing in 2DOL. We find that, in the presence of a finite population imbalance (p>0), the pair density at $T_c$ unexpectedly approaches zero towards to deep BEC regime and thus the transition $T_c$ is dramatically enhanced in the BEC regime and becomes proportional to the interaction strength $U$ in the BEC limit. This should be contrasted to the balanced case, for which $T_c$ decreases as $1/U$. And the system is an intermediate-temperature polarized superfluid state at unitarity and in the BCS regime. We perform stability analysis, and present complete phase diagrams along with the behavior of superfluid density. We show that a stable polarized superfluid emerges at relatively high temperature.

Tuesday, March 3, 2020 8:00 AM - 10:24 AM
Knowledge of the equation of state and chemical kinetics of materials under reactive conditions is needed for a wide number of research areas, including studies of planetary interiors, astrobiology, and high-pressure detonations of energetic materials. In this regard, we have developed a family of atomistic simulation models which yield similar accuracy to higher order quantum approaches (Kohn-Sham DFT) while yielding orders of magnitude increase in computational efficiency. This talk will focus on three different types of models in development in our research group: (1) semi-empirical quantum simulation approaches, (2) reactive force fields for molecular dynamics simulations, and (3) spin lattice models for solid phase reactivity. These efforts will be discussed in the context of corrosion on actinide and other metal surfaces, shock compression of organics and energetic materials, and prebiotic synthesis in impacting astrophysical ices. Our methods provide a straightforward way to conduct computationally efficient and highly accurate simulations over a broad range of conditions, where physical and chemical properties can be difficult to interrogate directly and there is historically a significant reliance on theoretical approaches for interpretation and validation of experimental results. Prepared by LLNL under Contract DE-AC52-07NA27344

Reactive molecular dynamics (MD) simulations can describe the complex physical and chemical processes in high energy density materials and ultimately contribute to a predictive understanding of their shock initiation under dynamical loading. However, computational intensity limits MD to the nanoscale, making it difficult to simulate hot spot formation and eventual shock to detonation transition. Thus, we developed a multiscale model that uses MD simulations to inform a continuum model capable of reaching the microstructural scales. We use dimensionality reduction via unsupervised learning to establish a two-step reduced-order chemistry model for the decomposition of RDX. From both homogeneous isothermal and adiabatic simulations, we extract chemical kinetics and heat of reaction parameters. The continuum model, capable of capturing chemistry, thermal transport and mechanics, is verified using homogeneous cook-off simulations and the multiscale approach validated from hot spot calculations. We find good agreement between the predicted critical temperatures from explicit MD simulations and the continuum model for nanoscale hot spots. Finally, we predict critical hot spot temperature as a function of size and quantify the effect of uncertainties for various materials’ parameters.
8:48AM F03.00003: Ultrafast Detonation of Hydrazoic Acid: Insights from Many-body Molecular Dynamics Force Fields*  HUY PHAM (Presenter), NIR GOLDMAN, LAURENCE FRIED, Lawrence Livermore Natl Lab — In this work, we present the development and application of the Chebyshev Interaction Model for Efficient Simulations (ChIMES) to the study of hydrazoic acid (HN₃) under detonation. Computational study of HN₃ is challenging due to its ultrafast detonation, i.e. the chemical decomposition to stable products is complete in less than 10 ps, and the system evolves through multiple thermodynamics (ambient and extreme conditions) and electronic (metal and insulator) states. We show that ChIMES, a generalized many-body reactive force field machine-learned to density functional theory (DFT) molecular dynamics trajectories, is able to retain the accuracy of DFT simulation in describing structural properties and chemistry for a wide range of thermodynamics states while increasing orders of magnitude in computational efficiency. Shock compression simulations show that the developed ChIMES model can capture the ultrafast chemical reactions of HN₃.

9:00AM F03.00004: Reaction rates in shocked nitromethane from density functional tight binding simulations*  ROMAIN PERRIOT (Presenter), MARC CAWKWELL, ENRIQUE MARTINEZ SAEZ, EDWARD KOBER, SHAWN DAVID MCGRANE, Los Alamos National Laboratory — The chemistry of energetic materials (EM) is characterized by rapid exothermic reactions that lead to dramatic increase of the pressure and temperature on the pico- to nanosecond timescales. Under these conditions, experiments have struggled to provide detailed insights into early and intermediate processes, and simulations have thus become a valuable tool to help interpret experiments and parameterize mesoscale models. We have performed molecular dynamics (MD) cook-off simulations of nitromethane under pressure with DFTB, a parameterized form of DFT that allows to simulate systems with hundreds of atoms, over hundreds of picoseconds, with explicit treatment of the electronic interactions and an accuracy close to that of DFT. We find drastically different times-to-explosion, even for the same initial T/P conditions, due to multiple complex and competitive chemical pathways. However, a simple effective reaction rate can be extracted, as long as multiple simulations are performed at each T/P to account for the stochastic component of detonation chemistry in EM. We built a two-step model for NM detonation that can be compared to experimental results and used in higher scale models.

9:12AM F03.00005: UQ-Driven Reactive Burn and EOS Parameterization, along with Particle Force Model Assessment for the Simulation of an Explosive Multiphase Experiment
JOSHUA GARNO (Presenter), SANGJUNE BAE, FREDERICK OUELLET, THOMAS L JACKSON, NAM-HO KIM, RAPHAEL HAFTKA, S BALACHANDAR, University of Florida — Recent results indicate that the Maxey-Riley-Gatignol (MRG) model is able to predict the force on a particle due to a passing air-shock and compressed flow. This work aims to assess the model’s predictive capability in the high-energy, post-detonation flow regime. Due to the tight coupling between the gas flow and particle motion, the evaluation of the particle force model necessitates high accuracy in the prediction of the gas flow. Therefore, modeling the detonation and rapid expansion of post-detonation product gases requires accurate models of reactive burn and the equation of state (EOS) for products of detonation. Using flow information extracted from experimental high-speed photographs as validation data, we make use of UQ methodologies to optimize the explosive-specific model parameters of the JWL EOS. With quantitative flow agreement between experiments and our finite-volume point-particle simulations, the MRG force model governing the motion of the particles is examined. Experimental X-ray data provides the trajectories of a few Tungsten particles for comparison with simulation results.

9:24AM F03.00006: Probing Intermediate Formation of Thin Film Explosives Through Ultrafast Broadband Infrared Spectroscopy
MICHAEL POWELL (Presenter), Purdue University/LANL, PAMELA BOWLAN, Los Alamos National Laboratory, STEVEN F. SON, Purdue University, CYNTHIA BOLME, KATHRYN E BROWN, DAVID STEVEN MOORE, MARC CAWKWELL, Los Alamos National Laboratory, ALEJANDRO H STRACHAN, Purdue University, SHAWN DAVID MCGRANE, Los Alamos National Laboratory — A first step to predicting explosive performance and safety is to understand the chemical pathways taken when high explosive materials are shocked. Unfortunately, there is insufficient data at relevant time and length scales to directly compare experiments to molecular level models. The intention of this work is to link experimental results to molecular dynamics models using ultrafast broadband mid-infrared and visible absorption spectroscopy to probe the chemical changes energetic materials undergo when shocked. PETN, a common HE, was shocked to the reactive regime and showed increased absorption near the anti-symmetric NO$_2$ stretch but not the symmetric NO$_2$ stretch. This change was attributed to absorbance from intermediate formation. These results were compared to molecular dynamics and accelerated chemistry models to interpret the shock chemistry. Comparing to gas phase calculations of the infrared absorption intensities, the intermediate was most likely HONO indicating H-ion and NO$_2$ elimination play an important role in early shock chemistry for PETN.
9:36AM F03.00007: Amorphous Explosives*  RAJEN PATEL (Presenter), VICTOR STEPANOV, Explosives Research Branch, US Army, CCDC-AC — Glassy amorphous organic energetics is a new field offering several novel areas for study. While practical application might be limited due to low density and propensity to crystallization of amorphous energetics, the scientific opportunities are fertile. For example, they allow an in depth view of crystallization in real time, even of novel systems such as cocryystals, and the in situ characterization of pores, cracks and other gross defects as they form. Amorphous energetic formulations with relatively low excipient (i.e. polymer used to inhibit crystallization) loadings offer a novel method of examining materials at extreme conditions. They can compared to their crystalline counterparts, and this could shed light on the processes of crystallization, shock induced phase transformations, and mechanically induced chemical reactions. While practical application will be limited for amorphous materials due to their low density, the scientific possibilities are quite exciting.

9:48AM F03.00008: Mechanical Stimulation of Gasless Reaction in Inorganic Systems: Overview*  ALEXANDER MUKASYAN (Presenter), University of Notre Dame — The phenomenon of a reaction, occurring in inorganic high energy density systems after it is stimulated by a shock wave, has been under investigation for a long time. The first experimental studies on the topic of chemical transformations in the inorganic substance under shock compression dated back to the late 1950s and a lot of work has been accomplished since. In this overview, we primarily consider reactive heterogeneous media that involves a powder mixture of the inorganic solid precursors, which, after mechanical stimulation, resulted in the synthesis of a new material. It is no doubt that such reactions can be initiated by sufficient mechanical impulse, but can they occur in the time scale of the high-pressure shock state? What mechanisms may be responsible for such rapid solid-state transformations? These and related questions are discussed based on the recent experimental findings.

10:00AM F03.00009: Dance of HMX molecule in conformational space by quasi-static heating: a combined Raman spectroscopy and theoretical study*  
YANGYANG ZENG  
(Presenter), National Key Laboratory of Shock Wave and Detonation Physics, Institute of Fluid Physics, China Academy of Engineering Physics, CHAN GAO, Department of Physics, University of Science and Technology of China, GUOYANG YU, National Key Laboratory of Shock Wave and Detonation Physics, Institute of Fluid Physics, China Academy of Engineering Physics, RUCHENG DAI, ZHONGPING WANG, The Centre for Physical Experiments, University of Science and Technology of China, ZENGMING ZHANG, Key Laboratory of Strongly-Coupled Quantum Matter Physics, Chinese Academy of Sciences, School of Physical Sciences, University of Science and Technology of China, XIANXU ZHENG, YANQIANG YANG, National Key Laboratory of Shock Wave and Detonation Physics, Institute of Fluid Physics, China Academy of Engineering Physics — The complexity of HMX polymorphs arises from conformers and molecular packing. In this study, HMX single crystal is heated at rates of 0.1 or 0.2 K/min during phase transitions. The sample is equilibrated at least 15 minutes at every step of increasing temperature to achieve the quasi-static condition. Raman spectroscopy is performed to monitor transitions between conformers by fitting position and full width at half maximum of the observed spectra. Conformers, transition states and IRC are verified at the level of DLPNO-CCSD(T)/cc-pVQZ//M062X-D3(0)/def2-TZVP for single HMX molecule. We attribute the response of spectra to ring puckering and nitro vibrations during phase transitions by analyzing Raman spectra and decomposition and identification of vibrational modes. Our results provide evidence of B-α and subsequent α-δ phase transition, which agree with recent thermodynamic model that α-HMX must be thermodynamically stable in phase diagram.

10:12AM F03.00010: DETONATION PROPERTIES OF PRESSED AND LIQUID HYDRAZINE NITRATE*  
ALEXANDER UTKIN (Presenter), VALENTINA MOCHALOVA, Institute of Problems of Chemical Physics RAS — In this work, the structure of the steady-state detonation waves, the critical diameter, detonation parameters and the dependence of detonation velocity on the charge diameter for pressed hydrazine nitrate (HN) and the HN/water solution were investigated by a VISAR laser interferometer. For pressed HN, it was found that the critical diameter drops with the initial density decrease. For pressed HN, the change of the detonation velocity with variation of the initial density is not monotonic, but has a characteristic s-shape. For the water solution of HN, the detonation velocity decreases linearly with increasing concentration of water. The limits of detonation propagation were found for HN/water solution. It doesn’t detonate at a water concentration exceeding 33 wt % at room temperature. Experiments on the determination of Hugoniot and initiation of detonation under shock wave action for pressed HN were carried out with samples of maximum density (1.68 g/cc). The results of the conducted experiments show the low shock wave sensitivity, which is much lower than that of TNT. A noticeable reaction rate behind the front of the initiating shock wave in charges of maximum density is observed only at a pressure above 20 GPa.

8:00AM F04.00001: Investigating graphene oxide-aqueous interfaces* [Invited] REVATI KUMAR (Presenter), ROLF DAVID, VISAL K. SUBASINGHEGE DON, Chemistry, Louisiana State University — Graphene oxides (GO) are nanosheets of graphene with oxygen bearing defects. The GO sheet is highly heterogeneous with the sp$^3$ carbons, connected to oxygen bearing functional groups, interspersed between the usual sp$^2$ carbons of graphene resulting in competition between aromatic regions and highly hydrophilic domains (from the oxygen containing functional groups, typically -OH and epoxy groups) at the GO-aqueous interface. GO materials are increasingly gaining traction for ion and molecule separations. The interfacial region between the GO material and aqueous solutions plays a key role in these applications. Our efforts are focused on gaining molecular level insight into the interfacial ordering using molecular simulations. Classical and Born-Oppenheimer molecular dynamics were performed to study the interfacial water structure, including hydrogen bonding environments, using different order parameters. The simulations were used to gain insight into the results from recent vibrational sum frequency generation experiments. The reactivity of the graphene oxide-neat water interface as well as in the presence of an acidic excess proton were also investigated. The results of this study will be presented and discussed.

8:36AM F04.00002: Viscoelasticity and dynamics of nanoconfined water by atomic force microscopy* PETER HOFFMANN (Presenter), EDWARD KRAMKOWSKI, Wayne State Univ, SHAH H KHAN, Physics, University of Peshawar — Our group has conducted extensive measurements of the viscoelastic properties of nanoconfined water in hydrophilic environments using a specialized high-resolution dynamic atomic force microscopy technique. Here we will present an overview of our findings, including the observation of dynamic solidification, the effect of ions on ordering and dynamics, and the recent observation of the compression rate dependence of the effective viscosity.

*We acknowledge generous funding from NSF DMR-0804283 and Wayne State University.
8:48AM F04.00003: Hydrogen bonding structure of confined water templated by a metal-organic framework with open metal sites*  KELLY HUNTER (Presenter), University of California, San Diego, ADAM J. RIETH, MIRCEA DINCA, Massachusetts Institute of Technology, FRANCESCO PAESANI, University of California, San Diego — While the properties of bulk water are difficult to understand, water in confinement is even more poorly understood. Metal-organic frameworks (MOFs) are unique a class of materials that display high adsorption properties. Recently, the MOF Co$_2$Cl$_2$BTDD has been shown to adsorb water at low relative humidity, attracting interest for applications in harvesting water from air. Here, we investigate structural and dynamical properties of water adsorbed in Co$_2$Cl$_2$BTDD as a function of relative humidity using many-body molecular dynamics simulations with the MB-pol model. Comparisons of the experimental and theoretical infrared spectra allow us to elucidate the mechanism of pore filling, with water initially binding to the open metal sites and forming one-dimensional chains along the interior of the framework. These chains nucleate pore filling, establishing a three-dimensional hydrogen-bond network. As the pore fills, the spectroscopic features and orientational dynamics indicate a gradual transition from “ice-like” to “liquid-like” properties modulated by the heterogeneous confinement, with individual water molecules exhibiting distinct behavior depending on their specific location inside the pores. Nat. Commun. 2019, 10, 1-7.

9:00AM F04.00004: Vibrational dynamics and quantum tunneling of water molecules in bassanite*  ALEXANDER KOLESNIKOV (Presenter), LAWRENCE {LARRY} M. ANOVITZ, STEPHAN IRLE, Oak Ridge National Lab — Using inelastic neutron scattering (INS) we studied dynamics of bassanite (CaSO$_4$*0.5H$_2$O), a structure of which has channels formed by CaO$_8$ and CaO$_9$ polyhedra with water molecules residing in the channels and occupying two different positions. The INS spectra showed that at low temperature ($T=5$ K) intramolecular O-H stretching modes of water are at high energy, around 445 meV (compared to 410 meV in ice-Ih), and the intermolecular librational band is at low energies, 35-90 meV (65-125 meV in ice-Ih), indicating weak hydrogen bonds acting on water molecules. At lower energies we observed a peak at about 1 meV, which shows the behaviour of tunneling mode: its intensity decreases with temperature increase and shows nonmagnetic momentum transfer dependence. In the talk we will discuss the observed INS results and attempt to explain the tunneling of water molecule, which was not observed before in other INS experiments involved confined water molecules in the presence of hydrogen bonds.

*This research used resources at the Spallation Neutron Source, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.
Carbon nanopores underpin a large array of materials systems and technological applications, including supercapacitors and water desalination. In these devices, understanding of the ion solvation and dynamics is essential for predicting and optimizing the performance; however, many mechanistic details remain enigmatic. Here, we employ first-principles simulations to unravel key features of the solvation structure of several common ions confined within graphene slit pores and carbon nanotubes (CNTs). We find that polarizable ions exhibit a stronger adsorption at the interfaces and these effects are found to be significantly enhanced under confinement. In addition, we find that confinement significantly influences ion selectivity and transport, i.e., ions with a small radius are found to yield a notably larger energy barrier to reach the pore entrance. Our study points to the complex interplay between confinement and specific ion effects, which has broad implications in optimizing nanopores for ion selectivity and energy storage.

This work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344. Financial support is from CENT, an EFRC funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0019112.
9:24AM F04.00006: One atom thick angstrom-scale capillaries: Water flow* [Invited] RADHA BOYA (Presenter), Univ of Manchester — It has been an ultimate but seemingly distant goal of nanofluidics to controllably fabricate capillaries with dimensions approaching the size of small ions and water molecules. But surface roughness makes it challenging to produce capillaries with precisely controlled dimensions. We have developed a method for fabrication of narrow and smooth angstrom (Å) scale capillaries through van der Waals assembly of 2D-materials, with atomically flat sheets at the top and bottom separated by spacers made of 2D-crystals with a precisely controlled number of layers. These capillaries can be envisaged as if individual atomic planes are removed from a bulk layered crystal leaving behind flat voids of a chosen height. Water transport through the channels, ranging in height from one to several dozen atomic planes, is characterized by unexpectedly fast flow (up to 1 metre per second) that we attribute to high capillary pressures of about 1000 bar and large slip lengths [1]. For channels that accommodate only a few layers of water, the flow exhibits a marked enhancement that we associate with an increased structural order. In this talk, I will also discuss about how ions reconfigure their hydration shell, becoming essentially “squashed” while flowing through these capillaries[2]. Water and ionic flows are coupled in such confinement, and the transport, driven by pressure and applied electric field, reveals a transistor-like electrohydrodynamic effect [3]. I will conclude the talk by showing our recent results where only one layer of water is confined in these channels, essentially leading to two-dimensional water [4]. Our results lay the basis for exploration of such Å-size channels in nanofluidics, molecular separation and other nanotechnologies.

10:00AM F04.00007: Nano-confined water and ions in cement pores ABHAY GOYAL (Presenter), Georgetown University, IVAN PALAIA, University Paris-Sud, KATERINA IOANNIDOU, University of Montpellier, EMMANUEL TRIZAC, University Paris-Sud, ROLAND JM PELLENQ, Massachussets Institute of Technology, EMANUELA DEL GADO, Georgetown University — We use numerical simulations to study the behavior of water confined by planar surfaces in the presence of divalent ions. The dynamics and mobility of the water are found to be strongly dependent on confinement. At large surface separations, most of the water behaves like in bulk conditions, but in high confinement the dynamics slow down and become coupled to the ions. This in turn increases the ion ordering and thus the overall attraction between two charged surfaces when the confinement is high. From these observations, we develop an analytical prediction of the attractive strength based on the formation of correlated ion-water structures. These results reveal a new mechanism for strong electrostatic cohesion of charged particles due to the restructuring of confined water. This effect is very relevant for the case of cement, where it explains the incredible strength of the material and could be the basis for intelligent design of cements.
**Microscopic study of proton kinetic energy anomaly for confined water**

MOHAMMAD MOID (Presenter), Indian Institute of Science - Dept of Physics, YACOV FINKESTEIN, Nuclear Research Center-Negev, Beer-Sheva, RAYMOND MOREH, Department of Physics, Ben-Gurion University of the Negev, Beer-Sheva, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — Several anomalies, related to structural and dynamical transition, have been reported for water at different thermodynamic conditions and environments. Of particular interest, the reported anomalies of the proton mean kinetic energy, $K_{e}(H)$, in nanoconfined water, as measured by deep inelastic neutron scattering (DINS), are a longstanding problem related to proton dynamics in hydrogen-bonded systems. We used classical MD method to deduce $K_{e}(H)$ by calculating the proton vibrational density of states, $H$-VDOS, for the case of water inside single wall carbon nanotubes (SWCNT) of varying diameters. The mean vibrational density of states (VDOS) of protons in water nanoconfined inside single wall carbon nanotubes (SWCNTs) is calculated as a function of temperature and SWCNT diameter, $D_{CNT}$. The calculated VDOS are utilized for deducing the mean kinetic energy of the water protons, $K_{e}(H)$, by treating each phonon state as a quantum harmonic oscillator. The calculation depicts a strong confinement effect as reflected in the drop of the value of $K_{e}(H)$ at 5K for $D_{CNT} < \sim 12\text{Å}$, while absent for larger diameters. The results also reveal a very significant blue and red shifts of the stretching and bending modes respectively compared to those in bulk ice, in agreement with experiment.

**Water dynamics in Evaporating Nanodroplets**

LUIS RUIZ PESTANA (Presenter), Civil, Architectural, and Environmental Engineering, University of Miami, TERESA HEAD-GORDON, Chemistry, University of California, Berkeley — The evaporation of droplets on heated substrates has been intensively studied in the last several decades. As such, well validated continuum theories have been developed that describe the modes of evaporation, evaporating profiles, and also predict the internal convective flows compatible with the evaporating modes. The evaporation of small nanoscale droplets plays a key role in a myriad of scientific and technological applications from atmospheric chemistry to the cooling of nanoelectronics to catalysis, where evaporating nanodroplets produced by electro spray ionization are increasingly being used to accelerate chemical reactions. At the nanoscale, however, where large surface to volume ratios govern the behavior, and fluctuations play a major role, it remains unclear whether the continuum theories can be applied to predict the the response. Here, we put that to the test and use classical molecular dynamics simulations of water nanodroplets of two different sizes both suspended under isothermal evaporation conditions and on heated substrates with different levels of hydrophobicity. We focus on mapping the convective flows that develop within water nanodroplets and the resulting evaporating profiles, with the aim of assessing the predictive power of the continuum theories.
A molecular view of glycerol-water hydrogen bonding patterns

CAMERON MACKIE, University of California, Berkeley, BO XU, OLEG KOSTKO, Lawrence Berkeley National Laboratory, NIKHIL CHARI, EMILY ZHANG, MARTIN P HEAD-GORDON, University of California, Berkeley, MUSAHID AHMED (Presenter), Lawrence Berkeley National Laboratory — Photoionization dynamics of micro-hydrated molecules in the gas phase when combined with theory can reveal information on the solution phase. Synchrotron based molecular beam mass spectrometry of water-glycerol clusters in the gas phase and terahertz time domain spectroscopy in solution coupled to calculations reveal the nature of hydrogen bonding in glycerol water solutions and provides a general picture of the interaction of polyols with water. A novel hydrogen bonding pattern is theoretically observed at specific glycerol to water concentrations. A significant shortening (and strengthening) of hydrogen bond lengths (~1.6 Å) are observed between H$_2$O molecules where one of the H$_2$O molecules is held in a “tweezed” fashion by the two hydroxyl groups of glycerol. This hydrogen bond shortening is also observed to reach beyond the first hydration shell. Experimental results show a clear preference for certain clusters to retain two water molecules due to the enhanced hydrogen bonding strengths. This shortening of hydrogen bonds is also proposed to explain the experimentally observed decrease of excess molar volumes with concentrations for various polyols.

Session F05 DCP DCMP DPOLY: The Chemical Physics of Molecular Polaritons III. Vibrational Strong Coupling 111 - Wei Xiong, University of California, San Diego - Tag(s): Focus
8:00AM F05.00001: Dynamics of Vibration-Cavity Polaritons* [Invited] JEFFREY OWRUTSKY (Presenter), ANDREA GRAFTON, ADAM DUNKELBERGER, BLAKE SIMPKINS, United States Naval Research Laboratory — Coupling vibrational modes to optical cavities results in vibration-cavity polaritons which can modify vibrational coherence and energy dynamics. Ultrafast infrared spectroscopy has been used to investigate vibration-cavity polaritons. We recently reported time resolved IR pump-probe studies on strongly-coupled vibration-cavity polaritons for tungsten hexacarbonyl (W(CO)$_6$) in hexane in a Fabry-Pérot cavity [1]. The results demonstrated that while much of the response is due to so-called reservoir or uncoupled excited state absorption as well as polariton contraction, a component of the observed signals is due to polariton state evolution. We observe saturable absorption as nearly complete polariton contraction not only in pump probe measurements but also in single pulse studies.[2] 2DIR spectroscopy was used to provide evidence of hybrid light-matter polariton evolution and clear indications of direct excitation of dark states.[3] We have further expanded the investigation of vibrational dynamics for strongly coupled vibration-cavity polaritons to W(CO)$_6$ in other solvents and to nitroprusside (Fe(CN)$_5$NO$_2$) in methanol. We explore salient features of the transient response, especially at short delay times, which show aspects of the response that are due to polaritons and are distinguished from uncoupled higher order excitations.

8:36AM F05.00002: Kinetic effects of vibrational polaritons in electron transfer.* JORGE CAMPOS GONZALEZ ANGULO (Presenter), RAPHAEL RIBEIRO, JOEL YUEN-ZHOU, University of California, San Diego — Chemical kinetics has been modified for thermally activated reactions with molecules under vibrational strong light-matter coupling (VSC). These experiments are counterintuitive since VSC can only be achieved when a collectivity of vibrational modes ($N \approx 10^{10}$) simultaneously couples to a single confined electromagnetic mode, and, as a result, the normal modes consist of two polaritonic modes and $N - 1$ dark modes that behave as uncoupled vibrations. In this work, we show how VSC can induce catalysis in electron transfer, as described by the Marcus-Levich-Jortner formalism, by providing low activation energy channels that dominate the kinetics even when they are largely outnumbered by channels with unmodified activation energy.

AFOSR award FA9550-18-1-0289
8:48AM F05.00003: Molecular dipole moment drives the dynamics of vibrational polaritons in the strong and ultrastrong coupling regimes  JOHAN TRIANA GALVIS (Presenter), FEDERICO J. HERNÁNDEZ, FELIPE HERRERA, Univ de Santiago de Chile — Molecular polaritonics is a growing research topic both theoretically and experimentally. However, the underlying microscopic mechanisms for the modification of chemical reactions observed in experiments has yet to be fully understood. To improve our theoretical understanding, models such as the Holstein-Tavis-Cummings or the multi-level quantum Rabi model have been proposed to describe light-matter interaction between quantized fields and molecular transitions. In the strong coupling regime, effects induced by the light-matter coupling may have implications in the modification of chemical reactions, which demands an analysis beyond the RWA. We study the dynamics of anharmonic vibrational polaritons for polar (e.g. R-CO) and non-polar (e.g. CO$_2$) molecules at equilibrium. We show that the electric dipole function strongly determines the dynamics of vibrational polaritons, and we describe such dependence in detail. Our results hint to a possible mechanism for cavity catalysis of chemical reactions under vibrational strong coupling and the spectroscopy of vibrational polaritons in liquid phase. In addition, our analysis could serve as a benchmark for future developments in the study of polariton chemistry in high-dimensional nuclear configuration spaces and multi-mode cavities.

9:00AM F05.00004: Strong Coupling of Terahertz Fields to Collective Intermolecular Vibrations*  RAN DAMARI, OMRI WEINBERG, DANIEL KROTKOV, NATALIA DEMINA, KATHERINE AKULOV, ADINA GOLOMBEK, SHARLY FLEISCHER, TAL SCHWARTZ (Presenter), Physical Chemistry, Tel Aviv University — Several years ago, strong coupling of intra-molecular vibrations to mid-infrared resonators was introduced as a new paradigm in the field of polariton chemistry [1]. Such vibrational strong coupling allows the manipulation of molecular processes occurring at the electronic ground-state, by targeting a specific bond within the molecules [2]. Here, we demonstrate for the first time strong coupling of collective vibrations in organic molecule crystallites, occurring at THz frequencies. In our experiments, we performed THz time-domain spectroscopy on a metallic cavity filled with α-lactose crystallites, which exhibit a sharp absorption peak at 0.53 THz. We observed a Rabi-splitting of ~70 GHz, and directly probe the Rabi-oscillations in the coupled system. Our results take strong coupling and polariton chemistry into a new class of material, including polymers, proteins and other organic materials, in which collective, spatially extended degrees of freedom participate in the dynamics.

9:12AM F05.00005: Polariton-mediated vibrational ladder climbing  RAPHAEL RIBEIRO
(Presenter), JOEL YUEN-ZHOU, University of California, San Diego — Vibrational ladder climbing (VLC) happens when a dipole-active molecular vibration is promoted to a highly excited-state by undergoing multiphoton absorption. Applications of this phenomenon include chemical reaction control via optical generation of non-equilibrium molecular excited-state populations with an increased probability of undergoing bond-breaking events. In this work, we present a theoretical treatment of VLC under strong infrared coupling, where the collective vibrational polarization efficiently exchanges energy reversibly with the electromagnetic field of an optical microcavity and hybrid light-matter excitations (polaritons) emerge. We focus on the basic principles of polariton-mediated VLC, including how its efficiency can be modulated by a proper choice of mesoscopic material, and conclude by discussing potential applications to reaction dynamics control, and spectroscopy of highly-excited states.

9:24AM F05.00006: Exploring Vibrational Polariton Dynamics with Ultrafast Two-Dimensional Infrared Spectroscopy* [Invited]  RONG DUAN, VIVIAN CRUM, KEVIN KUBARYCH
(Presenter), Univ of Michigan - Ann Arbor — Vibrational strong coupling (VSC) offers a new approach to manipulate reaction thermodynamics, vibrational energy flow, and intermolecular interactions. The complex energy relaxation, transfer, and dephasing processes in vibrational polaritons are ideally suited for study by ultrafast infrared spectroscopy, particularly two-dimensional infrared (2D-IR), which has become a major tool to unravel vibrational dynamics in general. This talk will introduce and review the key principles and molecular observables central to 2D-IR, while demonstrating its application to a vibrational polariton system. For our first implementations of VSC we have chosen a tripodal transition metal carbonyl complex, methyl cycopentadienyl manganese tricarbonyl (MeCMT), which has two strong CO stretching bands near 2000 cm$^{-1}$ separated by roughly 80 cm$^{-1}$. Using a cavity with a free spectral range that closely matches this energy splitting, we establish strong coupling between the molecule and two adjacent cavity modes. The 2D-IR spectra show significant coupling between the two branches of polaritons, as well as extensive coherences and signatures for coherence transfer.

*This work was supported by the National Science Foundation (CHE-1836529)
**10:00AM F05.00007: Controling quantum pathways in the vibrational polaritons system**

ZIMO YANG (Presenter), WEI XIONG, BO XIONG, University of California, San Diego — Molecular vibrational polaritons are hybrid quasi-particles between molecular vibrations and photons, through strong coherent light-matter coupling. It has attracted many attentions, because of its potential to alter photonic properties and also change the course of chemical reactions. Molecular vibrational polaritons have been studied by 2D infrared (2D IR) spectroscopy, which has advanced our understanding of the roles of dark states, hot excited state energy relaxation, and manipulation of nonlinear interactions in cavities. However, the coherent nature of polaritons imposes many quantum pathways contributing to the 2D IR signal, which complicates its interpretation and precision manipulation of quantum states. Using mid-IR pulse shaper, we report a way to selectively excite quantum pathways, to directly measure polariton nonlinear responses involving either coherence or population states. Because vibrational polariton forms a two-level system, it can serve a toy model to study the importance of coherence in energy transportation in energy materials. Thus, this work lays the foundation to prepare arbitrary quantum states in polaritons, for further exploration of the phenomena of nonlinear photonics, chemistry and quantum phenomena.

**10:12AM F05.00008: Remote of chemistry in optical cavities**

MATTHEW DU (Presenter), RAPHAEL RIBEIRO, JOEL YUEN-ZHOU, University of California, San Diego — Quantum states in different molecules can be hybridized by strong light-matter interaction. This phenomenon has been previously harnessed to realize long-range energy transfer between organic chromophores separated by optical length scales. Here, we propose a remote control of chemistry whereby photoexcitation of molecules in one optical microcavity influences the photochemical reactivity of molecules in another microcavity. For the infrared-induced \textit{cis}-to-\textit{trans} conformational isomerization of nitrous acid (HONO), we show that the proposed strategy leads to enhancement of the reaction efficiency by an order of magnitude.
10:24AM F05.00009: Cavity-Modified Chemical Reaction Kinetics and Electrochemical Modulation of Coupling Strength  BLAKE SIMPKINS (Presenter), United States Naval Research Laboratory, WONMI AHN, Excet, ADAM DUNKELBERGER, ANDREA GRAFTON, United States Naval Research Laboratory, JEREMY PIETRON, Lawrence Livermore National Laboratory, KENAN FEARS, JEFFREY OWRUTSKY, United States Naval Research Laboratory — Quantum emitters strongly coupled to optical cavities exchange energy inextricably, creating new hybrid polaritons. Recently, this half-light half-matter quasi-state has been demonstrated with molecular vibrations coherently coupled to optical modes. In this talk, we discuss (1) cavity-modified chemical reactivity and (2) modulation of the strong coupling phenomenon via electrochemical reaction. Specifically, we monitor transmission of a Fabry-Pérot microcavity filled with reactive species. Both reactants and products have strong molecular vibrations that couple to the optical cavity modes. We compare reaction rates in and out of the cavity to expose the influence of vibrational strong coupling on reaction kinetics. Secondly, we evaluate electrochemical switching of cavity coupling magnitude in both the visible and infrared regimes. Our results demonstrate full modulation of the Rabi splitting, a diffusion-limited redox process, and imaging of molecular adsorption/desorption processes on the metal surface. These results have important implications for chemical synthesis and catalysis.

10:36AM F05.00010: Ultrastrong coupling in hexagonal Boron Nitride microcavities*  UNAI MUNIAIN (Presenter), DIPC, MARIA BARRA-BURILLO, nanoGUNE, RUBEN ESTEBAN, DIPC and Ikerbasque, SARA CATALANO, MARTA AUTORE, nanoGUNE, LUIS HUESO, RAINER HILLENBRAND, nanoGUNE and Ikerbasque, JAVIER AIZPURUA, Centro de Física de Materiales-MPC (CSIC-UPV/EHU) — When the interaction between light and matter is very efficient, it is possible to attain the regime of ultrastrong coupling (USC), where a variety of quantum effects of considerable interest can be revealed [1]. In this contribution, we study an infrared Fabry-Perót microcavity formed by metallic mirrors, filled with hexagonal Boron Nitride (hBN) acting as a phononic material [2]. The optical response obtained within a transfer-matrix approximation can be interpreted with the use of a semi-classical model of coupled harmonic oscillators. As a consequence of the large Reststrahlen band of hBN, the Rabi splitting obtained is of the order of the frequencies of the bare cavity and the phonons. The system is thus in the USC regime. We also show that the calculations are in excellent agreement with experimental measurements, which suggests the interest of this configuration as a practical setup to explore USC.

Resonant Rayleigh Scattering from Collective Molecular Excitations

MUKUNDAKUMAR BALASUBRAHMANIYAM (Presenter), ADINA GOLOMBEK, MARIA KAEEK, KEREN HADAR, TAL SCHWARTZ, Physical Chemistry Department, Tel Aviv University — Resonant Rayleigh scattering (RRS) is the pronounced elastic scattering of photons present at the vicinity of the natural resonances of sub-wavelength physical objects such as molecules, which otherwise scatter negligibly. Here, we study RRS from molecular ensembles strongly coupled to an optical microcavity. Under these conditions, the coherent interaction between the molecules and the cavity mode produces collective molecular states known as cavity polaritons and which can drastically modify the properties of these molecules. Our spectroscopic measurements reveal that strong RRS occurs at the polaritonic energies, reaching ~25% efficiency. Interestingly, this resonant scattering corresponds to the collective scattering of each photon from a macroscopically-large ensemble of molecules, rather than the scattering by individual ones, as in the usual case. We show that the scattering from the polaritonic states exhibit non-trivial behaviors, specifically a linear dependence of the scattering strength on their photonic component. We believe that these observations, together with further investigation, may lead to a deeper understanding of these delocalized, collective molecular excitations, their non-equilibrium transport and the role of disorder in their dynamics.

Session F06 GMED FIAP DAMOP DSOFT: Optics in Soft Matter and Medicine 113 - Joshua Dijksman, Wageningen University - Tag(s): Focus, Undergrad Friendly

Novel biomedical applications of lasers: dermatology, gynecology, and stomatology [Invited] MATJAZ LUKAC (Presenter), Complex Matter, Institute Jozef Stefan, MATIJA MILANIC, Faculty of Mathematics and Physics, University of Ljubljana, MATIJA JEZERSEK, Faculty of Mechanics, University of Ljubljana — Water is an important constituent of all soft and hard human tissues. For this reason, the Er:YAG laser is of a particular interest for tissue ablation since its wavelength coincides with the major absorption peak of the water molecule. By controlling the temporal structure of Er:YAG pulses it is possible to control the laser-tissue interaction from “cold” to coagulative ablation, thus optimizing the laser either for skin resurfacing or for precise and painless cutting of teeth. The high absorption of the Er:YAG in irrigation fluids has been utilized also for photo-acoustically induced cleaning and disinfection of dental root canals. On the other hand, the wavelength of the Nd:YAG laser lies in the skin’s optical window and is thus suitable for transcutaneous delivery of laser energy deep into the adipose tissue. This characteristic has been explored for a novel “fat reduction” procedure offering a less invasive alternative to surgical liposuction. Recently, it was discovered that the extremely short absorption depth of the Er:YAG laser in soft tissues can be utilized also to create extremely short and intense heat shock pulses within the superficial tissue layer without causing irreversible thermal damage or ablation of the tissue. The discovery has led to the development of novel minimally invasive methods in various medical areas, including for treating vaginal atrophy, urinary incontinence or snoring, thus in many cases replacing much more aggressive and risky standard surgical procedures.
8:36AM F06.00002: Understanding coronary plaque biomechanical properties with intravascular imaging* [Invited] BRET BOUMA (Presenter), Massachusetts Institute of Technology
MIT — The biomechanical properties of coronary artery atherosclerosis are vital in understanding acute myocardial infarction and the factors that contribute to plaque instability. Intravascular cross-sectional imaging, with a resolution approaching that of histopathology and with high speed to avoid motion artifacts that arise from the dynamic cardiac cycle, can provide a basis for mechanical modeling and analysis to identify the primary compositional and structural factors in lesion vulnerability. We have recently developed a novel approach for real-time modeling that can be used during procedures in the cardiac catheterization laboratory.

9:12AM F06.00003: Optical properties of silicone rubber tissue phantoms for biomedical optics applications* MATIJA MILANIC (Presenter), Univ of Ljubljana, JURE NOVAK, Dia-vit, PETER NAGLIČ, YEVHEN ZELINSKYI, LUKA ROGELJ, Univ of Ljubljana, BORUT KUMPERŠČAK, Dia-vit, JOST STERGAR, MIRAN BÜRMMEN, Univ of Ljubljana — In medical physics, tissue phantoms play important role in characterization, validation, calibration and optimization of medical devices. A useful phantom must be well characterized, namely its physical properties must be accurately measured using standard techniques.

A set of silicon rubber tissue phantoms was prepared for applications in biomedical optics. A black pigment served as an absorber and hollow silica micro-spheres as scatterers. Nine samples with different absorber and scatterer concentrations were prepared. Refractive indices of the samples were measured in the 430 – 660 nm spectral range and did not vary significantly (<0.02 %). Optical properties (absorption and scattering coefficients, and similarity parameter γ) were estimated using spatially resolved reflectance spectroscopy in the subdiffusive regime (400 - 1000 nm). The determined optical properties covered the range characteristic for biological tissues.

Silicon rubber tissue phantoms feature many advantageous properties in comparison to other common phantoms in biomedical optics (e.g., intralipid, agar). They are stable, solid, reproducible, and their optical properties can be adjusted according to the application demands. Therefore, they are promising tools for biomedical optics.

*ARRS: P1-0389, J2-8171.
9:24AM F06.00004: Laser induced jets in needle free drug delivery*  
FNU PANKAJ (Presenter), JEREMY O MARSTON, Texas Tech Univ — Various actuation mechanisms have been used in the past for needle-free injection systems, predominantly springs and compressed gas. However, recent innovation has seen use of pulsed and continuous wave lasers for precise injection of ultra-low doses. Here, we have investigated the feasibility of laser-induced micro-jets as a needle-free injection technique. Effect of various parameters such as capillary diameter, laser pulse energy and distance of the laser focal point on jet dynamics were studied in the past, however, we also varied the fluid viscosity and orifice stand-off relative to the target. To quantify the penetration dynamics and dispersion of the liquid delivered, both gelatin gel (in-vitro) and porcine tissue (ex-vivo) were used as skin models. Lastly, we also discuss the possibility of using a spark-cavitation system to generate high-speed micro-jets instead of pulsed lasers.

9:36AM F06.00005: Fourier Transform Laser Speckle Imaging for art conservation  
JESSE BUIJS (Presenter), JASPER VAN DER GUCHT, JORIS SPRAKEL, Wageningen University — Laser speckle imaging is a powerful imaging technique that visualizes microscopic motion within turbid materials. At current two methods are widely used to analyze speckle data: one is fast but qualitative, the other quantitative but computationally expensive. We have developed a new processing algorithm based on the fast Fourier transform, which converts raw speckle patterns into maps of microscopic motion and is both fast and quantitative, providing a dynamic spectrum of the material over a frequency range spanning several decades. In this article we show how to apply this algorithm and how to measure a diffusion coefficient with it. We harness the potential of this new approach by constructing a portable laser speckle imaging setup that performs quantitative data processing in real-time on a tablet. We will show one of many possible applications of this method in the form of monitoring the cleanig process of artistic oil paintings.

9:48AM F06.00006: Doppler Functional Imaging of Cancer Drug Sensitivity in Living Tumor Biopsies  
ZHE LI (Presenter), Department of Physics and Astronomy, Purdue University, SHADIA I. JALAL, Department of Medicine, IU School of Medicine, JOHN TUREK, Department of Basic Medical Sciences, Purdue University, DAVID D NOLTE, Department of Physics and Astronomy, Purdue University — Biodynamic imaging is a deep-tissue digital holography imaging technique that captures the response of living tissue to applied therapeutics. Biodynamic metrics can predict patient clinical response with high accuracy. However, evaluating drug responses on a sample basis has high variance because of the underlying sample heterogeneity related to tissue features. We introduce a technique called tissue dynamics spectroscopic imaging (TDSI) to reveal drug response variations within small cubic millimeter biopsy samples. By performing tissue dynamics spectroscopy on a voxel basis and extracting biodynamic biomarkers, functional images are obtained of the heterogeneous spatial response of tumor tissue to anticancer drugs. Spatial maps of biodynamic biomarkers are created using a bivariate colormap to represent the spatial distribution of pairs of signed biomarkers. Time-lapse response maps provide further details into drug mechanisms.
**10:00AM F06.00007: Probing the interior dynamics of shear thickening colloidal suspensions using confocal line scans**  
JOIA MILLER (Presenter), DANIEL BLAIR, JEFFREY S URBACH, Georgetown University — Under high stresses, shear thickening suspensions transition from low viscosity to high viscosity or shear jammed states. While both the bulk rheology and the microscopic driving forces of such transitions are well-studied, the bridge between the microscopic and macroscopic scales is incomplete. Measurements at the boundaries indicate that dynamic high stress regions propagate through shear thickening suspensions of colloidal spheres, but the means of propagation within the suspension interior was inaccessible due to imaging limitations. Here we use line scans on a confocal microscope to visualize particle flows in a sheared suspension, increasing our temporal resolution by two orders of magnitude. These line scans reveal that high stress regions are correlated with significant changes in particle speed, density, and order that extend many particle diameters deep into the suspension.

*NSF Award DMR-1809890

**10:12AM F06.00008: Nanoscale Optical Imaging of Soft Matter Under Flow**  
ANISHA SHAKYA (Presenter), SEONG JUN PARK, JOHN KING, Center for Soft and Living Matter, Institute for Basic Science — Far-field fluorescence microscopy provides an enticing platform for spatially resolving equilibrium and nonequilibrium dynamics of soft matter systems, ranging from thin films to polymer solutions. However, several long-standing challenges, including limited spatial resolution and poor image contrast in densely labeled systems, have limited its application to such systems. Here, we develop a novel adaptation of super-resolution microscopy based on stimulated emission depletion (STED) coupled with fluorescence anisotropy detection to image concentration profiles of high molecular weight polyelectrolytes in semi-dilute solutions. We use this technique to study depletion layer formation and dynamics under Poiseuille flow, which remains an outstanding problem in fluid mechanics. While the inherently short length scales associated with depletion layer dynamics have traditionally prohibited direct imaging, STED-anisotropy imaging provides sufficient spatial resolution and contrast to measure small changes in polymer concentration over 10s of nanometers.

*Korean Institute for Basic Science, Project Code IBS-R020-D1.*
10:24AM F06.00009: Analyzing the Flow Drying Colloidal Suspensions Using Optical Coherence Tomography  LANFANG LI (Presenter), Physics Department and Emulsion Polymers Institute, Lehigh Univ, YONGYANG HUANG, Electrical&Computer Engineering, Lehigh Univ, ZHIYU JIANG, Physics, Lehigh Univ, CHAO ZHOU, Biomedical Engineering, Washington University in Saint Louis, HDANIEL OU-YANG, Physics Department and Emulsion Polymers Institute, Lehigh Univ — In this work, we present the visualization and analysis of flow in drying colloidal suspensions composed of colloidal polymer particles in water. The flow induced particle transport and deposition can influence the final structure of the polymer film deposited. Employing time-lapse, high-speed imaging, Optical Coherence Tomography was used to monitor the dynamic process of drying colloidal droplets. With the aid of high refractive index tracer particles, fluid flows were captured. The speckle contrast analysis differentiates the dynamics of particles, showing the packing process and particle transporting to the edge of droplet. In low particle concentration suspension, this resembles the coffee ring phenomenon. In high concentrations of particles, a situation in practical coatings or ink-jet applications, the viscosity plays an important role in the material flow and deposition, resulting in different flow pattern and final dry film structures, such as cracks, shear bands, and skin formation.

10:36AM F06.00010: Hyperspectral imaging as a technique to evaluate peritonitis in mouse models*  JOST STERGAR (Presenter), ROK DOLENEC, Univ of Ljubljana, KATJA LAKOTA, NEZA BREZOVEC, UMC Ljubljana, MARTINA PERSE, NIKA KOJC, Univ of Ljubljana, MATIJA TOMSIC, UMC Ljubljana, MATIJA MILANIC, Univ of Ljubljana — Hyperspectral imaging (HSI) is an optical technique that combines imaging and spectroscopy. Images can be processed spectroscopically, extracting information about tissue biochemistry and morphology that can be of importance to physicians. Peritonitis is an inflammation of the peritoneal cavity that can result in death. In animal model studies of the disease, golden standard is histology, while biomolecular techniques can also be used. These techniques only provide either good spatial resolution or area coverage. A technique with large area coverage and resolution is thus desired.

We present a classification method for determination of the state of peritonitis using HSI. The technique provides both good spatial resolution and coverage of the whole organ. Spectra are acquired in reflection geometry and processed using a custom model of light transport in thin samples. Tissue parameters including oxygenation and scattering properties are extracted from the images and used to assess disease state. Per subject scores are used to successfully separate control from model groups. HSI obtained scores are also compared with existing techniques (histology, PCR and Western blot) showing good concordance, meaning that HSI can be a useful tool for disease evaluation.

**8:00AM F07.00001: Variational Quantum Fidelity Estimation**

MARCO CEREZO DE LA ROCA (Presenter), Los Alamos National Laboratory, ALEXANDER POREMBA, Computing and Mathematical Sciences, California Institute of Technology, LUKASZ CINCIO, PATRICK COLES, Los Alamos National Laboratory — We present an efficient, near-term algorithm for estimating the well-known fidelity, which quantifies the closeness of quantum states. Our algorithm is an important tool for verifying and characterizing states on a quantum computer. This work is timely given the industrial rise of quantum computing. Prior to our work, there was no efficient algorithm to estimate the fidelity that could be refined to arbitrary tightness. We solve this outstanding problem by introducing novel bounds on the fidelity that can be estimated with hybrid quantum-classical computation. We show that our approach can detect quantum phase transitions and cannot be classical simulated efficiently.

*This work was supported by the Center for Nonlinear Studies at Los Alamos National Laboratory (LANL) and by the LDRD program at LANL.

**8:12AM F07.00002: Variational Quantum Algorithm for Markovian Open Quantum Systems**

NOBUYUKI YOSHIOKA, University of Tokyo, YUYA O. NAKAGAWA (Presenter), QunaSys Inc., KOSUKE MITARAI, KEISUKE FUJII, Osaka University — We propose a quantum-classical hybrid variational algorithm to simulate the non-equilibrium stationary states of Markovian open quantum systems, named the dissipative-system Variational Quantum Eigensolver (dVQE) [1]. In order to employ the variational optimization technique for a unitary quantum circuit, we first map a density matrix into a wavefunction with the doubled number of qubits, and then design the unitary quantum circuit so that the physical requirements for a mixed state are fulfilled. This allows us to define a cost function that consists of the time evolution generator of the Markovian quantum master equation. After the optimization, physical observables are evaluated by a quantum circuit with the original number of qubits. Our dVQE scheme is demonstrated by both numerical simulation on a classical computer and actual quantum simulation that makes use of the device provided in Rigetti Quantum Cloud Service.

**8:24AM F07.00003: Variational Generation of Thermofield Double States and Critical Ground States with a Quantum Computer**

ANNE MATSUURA (Presenter), SONIKA JOHRI, Intel Corp - Santa Clara, DAIWEI ZHU, NORBERT M LINKE, KEVIN LANDSMAN, NHUNG NGUYEN, CINTHIA ALDERETE, University of Maryland, TIMOTHY HSIEH, Perimeter Institute, CHRISTOPHER ROY MONROE, University of Maryland — Finite-temperature phases of many-body quantum systems are fundamental to phenomena ranging from condensed-matter physics to cosmology, yet they are generally difficult to simulate. Using an ion trap quantum computer and protocols motivated by the Quantum Approximate Optimization Algorithm (QAOA), we generate nontrivial thermal quantum states of the transverse-field Ising model (TFIM) by preparing thermofield double states at a variety of temperatures. We also prepare the critical state of the TFIM at zero temperature using quantum-classical hybrid optimization. The entanglement structure of thermofield double and critical states plays a key role in the study of black holes, and our work simulates such nontrivial structures on a quantum computer. Moreover, we find that the variational quantum circuits exhibit noise thresholds above which the lowest depth QAOA circuits provide the best results.

**8:36AM F07.00004: Exactly-solvable models as benchmarks for VQE**

KEN ROBBINS (Presenter), PETER LOVE, Tufts Univ — Perhaps the most promising application of Noisy Intermediate Scale Quantum (NISQ) computers is the Variational Quantum Eigensolver (VQE). Due to their namesake noise, NISQ computers performing VQE will need benchmarks to interpret their results. Exactly solvable models such as the Lipkin-Meshkov-Glick (LMG) model, a simple nuclear model of N fermions, can provide such benchmarks. We give circuits that produce low-N LMG eigenstates on a quantum computer with gate and qubit costs suited to the NISQ era. Further, we discuss how we might generalize the circuits for simulations of a higher number of particles.

*This project is supported in part by the Department of Energy under grant number DE-SC0019665.*
Variational Quantum Linear Solver: A Hybrid Algorithm for Linear Systems  
CARLOS BRAVO-PRIETO (Presenter), Barcelona Supercomputing Center, RYAN M LAROSE, Michigan State University, MARCO CEREZO, YIGIT SUBASI, LUKASZ CINCIO, PATRICK COLES, Los Alamos National Laboratory — Solving linear systems of equations is central to many engineering and scientific fields. Several quantum algorithms have been proposed for linear systems, where the goal is to prepare $|x\rangle$ such that $A|x\rangle \propto |b\rangle$. While these algorithms are promising, the time horizon for their implementation is long due to the required quantum circuit depth. In this work, we propose a variational hybrid quantum-classical algorithm for solving linear systems, with the aim of reducing the circuit depth and doing much of the computation classically. We propose a cost function based on the overlap between $|b\rangle$ and $A|x\rangle$, and we derive an operational meaning for this cost in terms of the solution precision. We also introduce a quantum circuit to estimate this cost, while showing that this cost cannot be efficiently estimated classically. Using Rigetti’s quantum computer, we successfully implement our algorithm up to a problem size of $32 \times 32$. Furthermore, we numerically find that the complexity of our algorithm scales efficiently in both $1/\kappa$ and $\kappa$, with $\kappa$ the condition number of $A$. Our algorithm provides a heuristic for quantum linear systems that could make this application more near term.

Variational Preparation of Quantum Hall States on a Lattice*  
ERIC JONES (Presenter), ELIOT KAPIT, Colorado Sch of Mines — Simulation of many-body quantum systems is one of the most promising applications of near-term quantum computers. The fractional quantum Hall states display fascinating many-body physics such as topological order and strong correlations and so are interesting candidates for quantum simulation experiments. We classically diagonalize for the low-energy spectrum of the Kapit-Mueller Hamiltonian for hardcore bosons on a lattice. The Laughlin state is an exact ground state of this long-range Hamiltonian for appropriate magnetic flux densities. In addition, we study the low-lying spectrum of a shorter-range proxy Hamiltonian and tune its hopping and interaction parameters in order to optimize the associated topological degeneracy and many-body gap. We then demonstrate a scheme for variational preparation of the Laughlin state on the lattice through a Trotterization of adiabatic state preparation with defect-pinned particles as the reference state. Such calculations suggest a way forward in the simulation of fractional quantum Hall states on quantum hardware.

9:12AM F07.00007: Variational quantum simulation of the Fermi-Hubbard model*
ALEXANDRE CHOQUETTE (Presenter), AGUSTIN DI PAOLO, Universite de Sherbrooke, PANAGIOTIS BARKOUTSOS, IBM Research Zürich, DAVID SENECHAL, Universite de Sherbrooke, IVANO TAVERNELLI, IBM Research Zürich, ALEXANDRE BLAIS, Universite de Sherbrooke — Noisy intermediate-scale quantum devices have the potential to be useful for quantum simulation of materials. A prominent approach for near-term quantum simulation is based on variational quantum algorithms (VQAs). In this talk, we propose a VQA to prepare the groundstate of the Fermi-Hubbard model. In particular, we investigate various state-preparation circuits and benchmark their performance in presence of realistic noise. We find that Hamiltonian-inspired variational forms perform better than a hardware-efficient approach. This work constitutes a first step towards the simulation of strongly correlated fermionic systems.

*This work was undertaken thanks in part to funding from NSERC, FRQNT and the Canada First Research Excellence Fund.

9:24AM F07.00008: A Non-Orthogonal Variational Quantum Eigensolver*
WILLIAM HUGGINS (Presenter), Chemistry, University of California, Berkeley, JOONHO LEE, Chemistry, Columbia University, UNPIL BAEK, Physics, University of California, Berkeley, BRYAN O’GORMAN, Electrical Engineering and Computer Sciences, University of California, Berkeley, BIRGITTA K WHALEY, Chemistry, University of California, Berkeley — We present an extension to the variational quantum eigensolver that approximates the ground state of a system by solving a generalized eigenvalue problem in a subspace spanned by a collection of parametrized quantum states. This allows for systematic improvement of a logical wavefunction ansatz without significant increase in circuit complexity. To minimize the circuit complexity, we propose a strategy for efficiently measuring the Hamiltonian and overlap matrix elements between states parametrized by circuits that commute with the total particle number operator. We propose a classical Monte Carlo scheme to estimate the uncertainty in the ground state energy caused by a finite number of measurements of matrix elements and to adaptively schedule the required measurements. We apply these ideas to two strongly correlated systems, a square configuration of H$_4$ and the π-system of Hexatriene (C$_6$H$_8$).

Variational quantum-classical algorithms (VQCAs) optimize the parameters of a quantum neural network, $V$, to minimize a cost function, $C$. Many researchers believe that VQCAs will enable the first practical applications of noisy quantum computers. However, VQCAs are heuristic methods with unproven scaling. Here, we rigorously prove two results related to the trainability of VQCAs. Our first result states that choosing $C$ to be a global function of $V$ leads to an exponentially vanishing gradient (i.e., a barren plateau) even when $V$ is shallow. This implies that many VQCAs proposed in the literature must revise their proposed cost functions. Our second results states that, under the same conditions, choosing $C$ to be a local function of $V$ leads to a non-vanishing gradient, i.e., with the gradient vanishing no worse than polynomially. This suggests that VQCAs have the potential to be trainable, if one chooses an appropriate cost function. We support these analytical results with numerics for large problem sizes.

We acknowledge funding from the Los Alamos National Laboratory (LANL) Laboratory Directed Research and Development (LDRD) program, and from the LANL Center for Nonlinear Studies (CNLS).

Scaling up variational quantum eigensolver (VQE) algorithms to practical applications utilizing quantum advantage with noisy intermediate-scale quantum (NISQ) devices is challenging. The expansive cost-function evaluation and demanding optimization quickly exhaust the precious quantum resource available on NISQ devices. In this work, we discuss the appropriate VQE strategy suitable for multi-site interacting boson systems, for example, the Holstein model and the Rabi lattice model. We investigate the cost-function setup and the optimization tactics to utilize the limited quantum resource efficiently. Our strategy illustrates that the scalable VQE algorithms of interacting bosons have a promising future.

10:00AM F07.00011: Efficient Variational Generation of Thermofield Double States on a Superconducting Quantum Processor: Theory (Part 1)  SHAVIDRRA PREMARATNE (Presenter), SONIKA JOHRI, XING CHRIE ZOU, Intel Labs, Intel Corporation, RAMIRO SAGASTIZBAL, MICHEL ADRIAAN ROL, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, BEREND KLAVER, MIGUEL MOREIRA, CARMINA ALMUDEVER, QuTech, Delft University of Technology, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, ANNE MATSUURA, Intel Labs, Intel Corporation — Thermofield double (TFD) states are entangled pure states between two systems which yield a thermal state when one of the systems is traced out [1]. TFD state generation on larger qubit systems is relevant for studying the finite-temperature phase diagram of condensed matter systems. We implement a quantum-classical hybrid variational optimization algorithm to efficiently generate TFD states of the tranverse-field Ising chain. Unlike Variational Quantum Eigensolvers with a cost function that is known a priori, the success of our optimization hinges on choosing the best cost function which can generate the desired TFD state. Here, we discuss the benefits and drawbacks of various cost functions that can be used for the optimization, and show how our constructed cost function yields excellent agreement across the full temperature range.

10:12AM F07.00012: Efficient Variational Generation of Thermofield Double States on a Superconducting Quantum Processor: Experiment (Part 2)  RAMIRO SAGASTIZBAL (Presenter), MICHEL ADRIAAN ROL, BEREND KLAVER, MIGUEL MOREIRA, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, SHAVIDRRA PREMARATNE, SONIKA JOHRI, XING CHRIE ZOU, Intel Labs, Intel Corporation, CARMINA ALMUDEVER, QuTech, Delft University of Technology, ANNE MATSUURA, Intel Labs, Intel Corporation, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Recent progress on Near Intermediate Small Quantum devices has allowed the field of quantum simulation to experimentally investigate many interesting systems such as spin lattices, Fermi-Hubbard models and electronic orbitals of molecules. Most of this work focuses on preparing low-energy eigenstates of a known target Hamiltonian. Here, we experimentally investigate finite-temperature effects on a transverse-field Ising chain using four qubits of a seven-transmon quantum processor. Specifically, we variationally approximate thermofield double (TFD) states through minimization of the constructed cost function described in Part 1. We extract various correlation functions over a range of simulated temperatures, showing good agreement to those of an exact TFD.

Efficient Symmetry-Preserving State Preparation Circuits for the Variational Quantum Eigensolver Algorithm

LINGHUA ZHU (Presenter), BRYAN T. GARD, GEORGE S. BARRON, Department of Physics, Virginia Tech, NICHOLAS J. MAYHALL, Department of Chemistry, Virginia Tech, SOPHIA E. ECONOMOU, EDWIN BARNES, Department of Physics, Virginia Tech

The variational quantum eigensolver (VQE) is one of the most promising approaches for performing chemistry simulations using noisy intermediate-scale quantum (NISQ) processors. The efficiency of this algorithm depends crucially on the ability to prepare multi-qubit trial states on the quantum processor that either include, or at least closely approximate, the actual energy eigenstates of the problem being simulated while avoiding states that have little overlap with them. Symmetries play a central role in determining the best trial states. Here, we present efficient state preparation circuits that respect particle number, total spin, spin projection, and time-reversal symmetries. These circuits contain the minimal number of variational parameters needed to fully span the appropriate symmetry subspace dictated by the chemistry problem while avoiding all irrelevant sectors of Hilbert space. We show how to construct these circuits for arbitrary numbers of orbitals, electrons, and spin quantum numbers, and we provide explicit decompositions and gate counts in terms of standard gate sets in each case.

Noncontextuality as classicality in variational quantum eigensolvers

WILLIAM KIRBY (Presenter), PETER LOVE, Tufts University

In this talk we show how to use contextuality, an indicator of non-classicality in quantum systems, to evaluate the variational quantum eigensolver (VQE), a promising tool for near-term quantum simulation. We present an efficiently computable test to determine whether or not the Hamiltonian in a VQE procedure is contextual. We then show that we may construct a simple, global unitary mapping that diagonalizes a noncontextual Hamiltonian. The diagonal Hamiltonian resulting from this mapping is efficiently classically calculable, which proves that the noncontextual Hamiltonian problem is NP-complete. We also give a quasi-quantized model for variational quantum eigensolvers whose Hamiltonians are noncontextual. This provides a second sense in which noncontextual Hamiltonians are essentially classical. These results support the notion of noncontextuality as classicality in quantum systems.

Variational hybrid quantum-classical algorithms (VHQCAs) seem likely to be the first useful algorithms in the era of near-term quantum computing. There is however a justified concern that the number of measurements needed for these algorithms to converge might become prohibitive when scaling up to non-trivial problem sizes. We address this issue by adapting results from classical optimization to the problem of shot-frugal optimization of VHQCAs. Specifically, we present new techniques and compare them with standard methods to demonstrate the potential for improvement both with noiseless and noisy quantum devices.

Session F08 DQI: Control and Modelling of Open Quantum Systems 104 - Sophia Economou

Experimental simulation of a two-level open system based on Trotter decomposition

Quantum simulation is one of the promising applications on a fully controlled quantum system. Such tasks can be solved with either high dimensional ancillary systems or deep feedback control network. We demonstrate a hardware-efficient repetitive Trotter scheme of open system simulation, which allows efficient simulation of arbitrary noisy environments for a two-level system. The scheme only requires an ancillary superconducting qubit, and real-time feedback control is not necessary. We verify that our implementation can be further strengthened in two ways: higher-order Trotter operation sequencing and error mitigation, which are straight forward with the controllability of our system. Our results show the feasibility to perform quantum simulation tasks on small systems and with restricted experimental resources.
**8:12AM F08.00002: Arbitrary quantum channel simulations of a superconducting qudit system**
WEIZHOU CAI (Presenter), JIA XIU HAN, LING HU, YU WEI MA, YUAN XU, XIANGHAO MU, YIPU SONG, Center for Quantum Information, Institute for Interdisciplinary Information Sciences, Tsinghua University, CHANG-LING ZOU, Key Laboratory of Quantum Information, CAS, University of Science and Technology of China, LUYAN SUN, Center for Quantum Information, Institute for Interdisciplinary Information Sciences, Tsinghua University — Unitary operations of closed quantum systems have been well studied. However, practical quantum systems are open and their evolution is described by quantum channels. So exploring arbitrary quantum channel simulation with minimum resources is of great importance for both fundamental understandings of open systems and mitigating of quantum noise. In this talk, we will introduce our recent experimental efforts on arbitrary quantum channel simulations of a high dimensional photonic qudit (cavity), with the assistance of a transmon qubit. First, continuous evolutions of an open quantum system are simulated by digitally and repetitively implementing Lindblad operators. Two interesting channels, odd parity stabilization channel and two-photon dissipation channel, have been demonstrated with this method. Then, the quantum channel that directly maps the input to output is simulated based on adaptive control. By using this method, preparation of arbitrarily mixed states and state tomography by symmetric informationally complete positive operator-valued measures are demonstrated.

**8:24AM F08.00003: Adiabaticity in non-Hermitian dynamics of a superconducting qubit**
WEIJIAN CHEN (Presenter), MARYAM ABBASI, Physics, Washington University, St. Louis, MAHDI NAGHILOO, Electrical engineering and computer science, Massachusetts Institute of Technology MIT, YOGESH JOGLEKAR, Physics, Indiana University - Purdue University Indianapolis, KATER MURCH, Physics, Washington University, St. Louis — In general, a quantum system subject to slow parameter variation will closely follow its instantaneous eigenstates. This well-known adiabatic theorem, however, has been shown to break down in recent studies of open systems with gain or loss. Such systems are effectively described by non-Hermitian Hamiltonians and thus possess complex eigenvalues and nonorthogonal eigenstates. In this talk, I will present our study of adiabaticity in non-Hermitian dynamics of a single dissipative superconducting qubit, where we tune the frequency and amplitude of microwave drives to vary the system Hamiltonian. The resulting dynamics is determined by the nonadiabatic coupling between eigenstates as well as their complex-eigenvalue-induced growth or decay. Our understanding of adiabaticity in the presence of complex eigenvalues will be important in harnessing non-Hermiticities for quantum sensing and control.

8:36AM F08.00004: Encircling exceptional points of a single dissipative qubit*  MARYAM ABBASI (Presenter), WEIJIAN CHEN, physics, Washington University, St. Louis, MAHDI NAGHILOO, Electrical engineering and computer science, Massachusetts Institute of Technology MIT, SCOTT HERSHBERGER, physics, Washington University, St. Louis, YOGESH JOGLEKAR, physics, Indiana University - Purdue University Indianapolis, KATER MURCH, physics, Washington University, St. Louis — We study the behavior of a single dissipative qubit which is described by a non-Hermitian Hamiltonian. This system exhibits a degeneracy known as an exceptional point (EP) where both eigenvalues and eigenstates coalesce. According to the adiabatic theorem, slow variation of the system parameters in a closed loop transports the system back to its initial state. Surprisingly, in a loop encircling an EP the eigenstates of the system will switch. Moreover, this behavior is chiral due to its dependence on the encircling direction and the initial state. We experimentally explore these phenomena by varying the drive parameters in a superconducting transmon circuit, creating closed loops in parameter space with one or two EPs. Our study shows how non-Hermiticities enable novel methods of quantum control.

*This work was supported by NSF PHY-1607156, NSF PHY-1752844 (CAREER)), and NSF grant DMR-1054020 (CAREER).

8:48AM F08.00005: Dissipative processs to generate entangled state in solid state system  WANG XIN (Presenter), Tsinghua University — When the target system interacts with the environment with some dissipative process, this process may be engineered to generate and protect the quantum state. Dissipation can be used to engineer some strongly correlated state, and also help one to understand the dynamics of the system and reservoir. Former work has been completed to design the dissipation in many experimental system, for example, ion trap, superconductor and atomic ensembles system. We demonstrate firstly that by utilizing a designed dissipative protocol one can generate a maximum entangled state in Nitrogen-vacancy solid spin system. Meanwhile, the fidelity of target state will stay steady and not change with the generation sequence number increasing.

9:00AM F08.00006: Shortcuts to adiabaticity in open systems: thermalization of an open quantum oscillator  AURELIA CHENU (Presenter), LEONCE DUPAYS, Donostia International Physics Center (DIPC), INIGO LOUIS EGUSQUIZA, Physics, Universidad del Pais Vasco (UPV), ADOLFO DEL CAMPO, Donostia International Physics Center (DIPC) — The dynamical control of quantum systems is a necessity to advance quantum sciences and technology. Techniques known as shortcuts to adiabaticity (STA) provide an alternative to adiabatic driving, and have proven useful in a wide diversity of applications. However, they are currently restricted to the control of closed systems. We introduce STA in open quantum systems, and develop a technique to control the thermalization of a driven open quantum oscillator. We provide the time modulation of the trap frequency and dephasing strength that allow for the preparation of an arbitrary thermal state in a finite time. Thereby, the super-adiabatic control of Gaussian states in non-unitary processes is demonstrated. Experimental implementation in the laboratory relies on stochastic parametric driving, which is readily accessible in a variety of platforms. The possibility to control cooling and heating of thermal states finds applications in finite-time thermodynamics.
9:12AM F08.00007: Modeling non-Markovian dynamics with augmented CPTP maps* KEVIN YOUNG (Presenter), ROBIN BLUME-KOHOUT, Sandia National Laboratories, STEPHEN D BARTLETT, University of Sydney — Markovian quantum processes on qubits can be perfectly described with completely-positive, trace-preserving (CPTP) maps. However, real physical systems are replete with non-Markovian effects. Trapped ions experience heating, microwave sources display power instabilities, and resonators take time to relax. Fluctuating magnetic fields display large spatial correlations, qubits experience leakage, and quantum gates that occur early in a circuit can impact the performance of those occurring later. CPTP maps on qubits capture none of these memory effects. In this talk, we propose a family of augmented CPTP maps that enable simple models of a wide variety of non-Markovian dynamics. We provide a number of numerical examples demonstrating that that these maps are easy to construct and interpret. Furthermore, we show that we can estimate the parameters of these maps from experimental data.

*This work funded in part by Sandia National Laboratories' Laboratory Directed Research and Development program.

9:24AM F08.00008: Learning the dynamics of open quantum systems from local measurements EYAL BAIREY (Presenter), Technion - Israel Institute of Technology, CHU GUO, Quantum Intelligence Lab (QI-Lab), Supremacy Future Technologies (SFT), DARIO POLETTI, Science and Mathematics Cluster and EPD Pillar, Singapore University of Technology and Design, NETANEL LINDNER, ITAI ARAD, Technion - Israel Institute of Technology — The increasing complexity of engineered quantum systems and devices raises the need for efficient methods to verify that these systems are indeed performing the desired quantum dynamics. Due to the inevitable coupling to external environments, these methods should obtain not only the unitary part of the dynamics, but also the dissipation and decoherence affecting the system's dynamics. Here, we propose a method for reconstructing the Lindbladian governing the Markovian dynamics of open many-body quantum systems, using data obtained from local measurements on their steady states. We show that the number of measurements and computational resources required by the method are polynomial in the system size. For systems with finite-range interactions, the method recovers the Lindbladian acting on each finite spatial domain using only observables within that domain. We numerically study the accuracy of the reconstruction as a function of the number of measurements, type of open-system dynamics and system size. Interestingly, we show that couplings to external environments can in fact facilitate the reconstruction of Hamiltonians composed of commuting terms.
9:36AM F08.00009: Noise Memory Kernel Reconstruction via the Post-Markovian Master Equation*  
HAIMENG ZHANG (Presenter), DANIEL A LIDAR, Univ of Southern California — Understanding and combating decoherence is one of the central topics in realizing quantum computation. Correlated, non-Markovian noise presents a particularly relevant challenge in superconducting qubit systems. This talk will present results on the construction of a bath memory kernel function from the experimentally measured state dynamics of a superconducting qubit. This phenomenological memory kernel arises in the post-Markovian master equation (PMME) [A. Shabani and D. A. Lidar, PRA 71, 020101 (2005)]. The memory kernel as constructed is of practical interest for quantum computation tasks as it provides insight into the noise origin and the characteristic timescales associated with bath memory effect. It also illuminates how the non-Markovian property of the noise can potentially be utilized to extend coherence timescales relative to the Markovian limit.

9:48AM F08.00010: Scalable Bayesian learning of local Hamiltonians and Lindbladian*  
TIMOTHY EVANS (Presenter), ROBIN HARPER, STEVEN FLAMMIA, Univ of Sydney — As the size of quantum devices continues to grow, the development of scalable methods to characterise and diagnose noisy devices is becoming an increasingly important problem. Recent results demonstrate how a local Hamiltonians and Lindbladians can be reconstructed from a single, arbitrary steady state with a number of measurements that scales efficiently in the size of the system. These methods, however, can only characterise the system up to scalar factor and lack sufficient robustness to noise, both of which are imperative to be of practical use. In this talk I will present a Bayesian method that addresses both of these issues by making use of any, or all, of the following: experimental control of Hamiltonian couplings, the preparation of multiple states and the availability of any prior information we may already have for the Hamiltonian couplings. Moreover we provide an adaptive measurement protocol that can be performed online, updating estimates and their corresponding uncertainties as experimental data becomes available.

*This work was supported by the Australian Research Council via EQuS project number CE170100009 and by the US Army Research Office grant numbers W911NF-14-1-0098 and W911NF-14-1-0103.
10:00AM F08.00011: Parametric Quantum Noise Spectroscopy Using SchWARMA
KEVIN SCHULTZ (Presenter), GREGORY QUIROZ, DAVID CLADER, Johns Hopkins University Applied Physics Lab — Markovian noise is a fundamental assumption in many characterization and analysis protocols for quantum circuits. However, this assumption is generally not valid in reality, which has led to considerable efforts to characterize and alleviate temporally correlated errors. Here, we adapt techniques from classical time series analysis to model, simulate, and estimate non-Markovian noise. We call this family of techniques Schrodinger Wave ARMA (SchWARMA), and show that it is not only a flexible method for representing noise spectra, but that it is a powerful statistical model that can be used for estimating noise and predicting the effects of non-Markovian noise on quantum circuits.

*Army Research Office, DOE Office of Science

10:12AM F08.00012: Experimental Realization of Noise Injection using SchWARMA
ANDREW MURPHY (Presenter), KEVIN SCHULTZ, JACOB EPSTEIN, KYLE P MCELROY, GREGORY QUIROZ, BRIAN S TIEN-STREET, JOAN AUDREY HOFFMANN, DAVID CLADER, TIMOTHY SWEENEY, Johns Hopkins University Applied Physics Laboratory — We develop a noise-injection scheme applied to an experimental qubit system in order to validate protocols that characterize and mitigate noise. We use a technique known as Schrodinger Wave Autoregressive Moving Average (SchWARMA) to mimic phase noise on a qubit. This is realized by imparting SchWARMA generated errors on the phase of the RF drive that is used to generate control pulses. The accumulation of phase errors mimics dephasing a qubit might experience relative to a perfect drive. We use quantum noise spectroscopy techniques to perform spectral estimation of the noise power spectrum and evaluate the efficacy of the noise injection approach. Our results show SchWARMA is a powerful tool for mimicking correlated phase noise processes in a superconducting qubit system. The power of SchWARMA can be shown to go beyond our initial experiments, extending to multi-axis noise models and arbitrary qubit systems.

10:24AM F08.00013: Continuous feedback of a controllable nonlinear cavity with Deep Reinforcement Learning
RICCARDO POROTTI (Presenter), MICHAEL ZWERGER, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light — Many tasks in quantum information processing require numerical methods to identify the best control sequence to achieve a specific goal. Deep Reinforcement Learning (DRL) has been applied with great success to many other fields, thanks to its ability to identify the best strategy in problems involving a competition between short and long-term rewards.
We focus on one of the simplest quantum systems highly relevant for quantum information processing, namely a controllable nonlinear cavity. We show how DRL can find the correct feedback control to stabilize a desired state (e.g. a particular Fock state), subject to dissipation and weak measurements.
The few existing DRL applications in physics rely mostly on discrete action spaces, but we show how continuous control sequences can be easily plugged in in such framework, which is the most natural way to handle feedback control sequences in physics. Finally, we exploit Long short-term memory (LSTM) networks to account for non-Markovianity in the master equation.
10:36AM F08.00014: Quantum Machine Learning using a Dissipative Quantum Reservoir*  
JOHN MILLER (Presenter), MARTHA VILLAGRAN, Univ of Houston — Recurrent neural networks (RNNs) are often slow learners, requiring extensive training of their hidden layers. In reservoir computing, the RNN's hidden layers are replaced by a reservoir, which can be a complex circuit (e.g., echo state network, or ESN) or physical system. The reservoir transforms recent temporal data into output patterns that can be read by a trainable single layer of neurons. The quantum reservoir, with just a few qubits and including dissipation, has recently been shown outperform a much larger classical ESN. Here we discuss the charge density wave (CDW) - a correlated electron-phonon system - as a candidate quantum reservoir. Some CDW materials (e.g., NbSe3) show learning, such as a pulse-duration memory effect, where 1-3 training pulses are needed experimentally vs. 100's to 1000's in classical simulations. This occurs in a highly dissipative environment with many normal electrons. Related materials (e.g., NbS3) have optimum CDW transport properties at room temperature, suggesting the possibility of certain types of quantum machine learning at high temperatures.

10:48AM F08.00015: Decoherence Properties of Qubits and Oscillators Coupled to Minimal Environments*  
KEVIN RANDLES (Presenter), Weber State University, DAVID DIAZ, Stony Brook University, JEAN-FRANCOIS VAN HUELE, TY BEUS, MANUEL BERRONDO, Brigham Young Univ - Provo — Decoherence refers to the loss of quantum coherence through contact with the environment. We are interested in characterizing this decoherence in models of simple quantum systems interacting with a minimal environment, following the work of Vidiella-Baranco [Physica A 402, 209 (2014) & Physica 459,78 (2016)]. We work out the full exact dynamics or approximations to the exact dynamics for coupled systems of qubits, oscillators, and mixed systems of qubits with oscillators. We then trace over the environment degrees of freedom and extract the decoherence of the reduced system as characterized by its linear entropy and visualize the results with Bloch spheres and Husimi functions. We relate decoherence rates to coupling strength. We also observe similarities and differences between solutions for couplings corresponding to the rotating and counter-rotating wave approximations. We notice in particular the disappearance of periodicity above a critical coupling strength in the counter rotating coupling in the oscillator case.

8:00AM F09.00001: Novel Trotter formulas for digital quantum simulation*  
YI-XIANG LIU  
(Presenter), Massachusetts Institute of Technology MIT, JORDAN H HINES, University of California, Berkeley, ZHI LI, University of Pittsburgh, ASHOK AJOY, University of California, Berkeley, PAOLA CAPPELLARO, Massachusetts Institute of Technology MIT — Quantum simulation promises to address many challenges in fields ranging from quantum chemistry to material science and high-energy physics, and could be implemented in noisy intermediate scale quantum devices. A challenge in building good digital quantum simulators is the fidelity of the engineered dynamics given a finite set of elementary operations. The goal of this work is to find a proper ordering of elementary operations so that they approximate as well as possible the desired evolution. However, when the quantum system is large, even calculating one elementary operation is computationally expensive. In this talk, I will introduce a geometric framework for optimizing the order of operations without considering the details of the operations themselves, thus achieving computational efficiency. Based on the geometric framework, I will present two alternative orderings. One has optimal fidelity at a short time scale, and the other one is robust at a long time scale. Thanks to the improved fidelity at different time scales, the two different orderings can form the basis for experimental-constrained digital quantum simulation.

*This work was supported in part by DARPA DRINQS, NSF grant EECS1702716, and PHY1734011.

8:12AM F09.00002: Quantum Simulation of Quantum Field Theory with Qubit Models*  
ALEX BUSER (Presenter), Caltech, TANMOY BHATTACHARYA, Los Alamos National Laboratory, SHAILESH CHANDRASEKHARAN, HERSHEYDEEP SINGH, Duke University, RAJAN GUPTA, Los Alamos National Laboratory — Quantum computers are expected to outperform classical methods in the simulation of strongly-coupled quantum field theories, as they permit the calculation of dynamic quantities in real-time and avoid the notorious sign-problem. We consider a class of qubit models which can be simulated efficiently on a fault-tolerant quantum computer, and present evidence that these models possess a rich phase diagram. One of the quantum critical points in the phase diagram may help define the traditional asymptotically free O(3) non-linear sigma model. We discuss implementation of these qubit models on both NISQ and fault-tolerant quantum computers, and provide numerical results on adiabatic ground state preparation for the O(3) sigma model. This work serves as a stepping stone towards simulating non-Abelian Kogut-Susskind type gauge theories with quantum devices.

8:24AM F09.00003: Quantum Simulation of Nonlinear Classical Dynamics*  ILON JOSEPH
(Presenter), ALESSANDRO ROBERTO CASTELLI, JONATHAN L. DUBOIS, VASILY GEYKO, FRANK R
GRAZIANI, STEPHEN BERNARD LIBBY, JEFFREY PARKER, YANIV J. ROSEN, YUAN SHI, Lawrence
Livermore Natl Lab — Nonlinear classical dynamics can be simulated by a quantum computer with
enough resources to approach the semiclassical limit. There is an exact embedding of a classical
system of $N$ ordinary differential equations (ODEs) within an enlarged quantum mechanical
system with $2N$ degrees of freedom. Any set of ODEs can be derived from a classical Hamiltonian
that is a sum over a set of $N$ constraints, thereby yielding $2N$ equations of motion. Quantizing the
constrained system leads to a Schrodinger equation that is equal to the classical Liouville
equation which ensures conservation of phase space density for the original set of ODEs.
Heisenberg’s uncertainty principle is satisfied by each variable and its canonically conjugate
momentum, the Lagrange multiplier, on the extended phase space. Hence, there is no
uncertainty in a simultaneous measurement of any of the variables of the original ODE. An
appropriate choice of Planck’s constant can be used to reduce the uncertainty in the degrees of
freedom of interest to a width on the order of the level spacing. Thus, excellent fidelity to the
classical system can be achieved.

8:36AM F09.00004: Predicting Features of Quantum Systems from Very Few Measurements
HSIN-YUAN HUANG (Presenter), RICHARD KUENG, JOHN PRESKILL, Caltech —
Predicting features of complex, large-scale quantum systems is essential to the characterization
and engineering of quantum architectures. We present an efficient approach for constructing an
approximate classical description, called the classical shadow, of a quantum system from very
few quantum measurements that can later be used to predict a large collection of features. This
approach is guaranteed to accurately predict $M$ observables with bounded Hilbert-Schmidt norm
from only order of $\log(M)$ measurements. This is completely independent of the system size and
saturates fundamental lower bounds from information theory. A distinct realization of the
concept can also be used to predict $M$ few-body observables using classical descriptions
constructed from single-qubit measurements on $\log(M)$ copies of the system. These protocols
have applications in variational quantum algorithms, estimating quantum fidelity, or inferring
entanglement properties of the quantum system. We support our theoretical findings with
numerical experiments over a wide range of problem sizes (2 to 162 qubits). These highlight
advantages compared to existing machine learning approaches.
8:48AM F09.00005: Characterizing quantum phase transitions by the entanglement of high symmetric points: A quantum computational investigation*  XIAO XIAO (Presenter), ALEXANDER F KEMPER, North Carolina State University — Quantum phase transitions play fundamental roles in our understanding of various properties of quantum materials. Therefore, how to characterize quantum phase transitions efficiently is pursued, especially for topological quantum phase transitions, which have no well-defined order parameters. Here we demonstrate that the entanglement of a small subset of a product state can be used as an indicator for quantum phase transitions. Moreover, this strategy can be easily applied with the near-term quantum computers, in which the number of qubits is highly limited. As examples, we demonstrate with IBM quantum computers for the transverse Ising and Kitaev spin model that the entanglement of product states formed by the states at the high-symmetric points of the Brillouin zone, which are subsets of the real ground state, can be used to determine different ground state phases.

9:00AM F09.00006: CnNOT gates for implementing random quantum walks*  SELIM SOUFARGI, IYED BEN SLIMEN, SysCom Lab, National Engineering School of Tunis, ENIT, University of EL Manar, 1002 Le Belvédère, Tunis, Tunisia, AMOR GUEDDANA (Presenter), Green & Smart Communication Systems Lab, Gres’Com, Engineering School of Communication of Tunis, Sup’Com, University of Carthage, Ghazela Technopark, 2083, Ariana, Tunisia, VASUDEVAN LAKSHMINARAYANAN, University of Waterloo — Quantum walks have been investigated for traversing graphs with certain oracles. This is important for building quantum routers on future quantum computers. Building quantum walk circuits benefit from the exponential increase in speed when compared to classical random walks. Here we investigated CnNOT based implementation of quantum walks along different length cycles and 2-D hypercycle. We decomposed the circuits into a set of series and parallel combinations of elementary CNOT and single qubit gates and simulated them theoretically taking into consideration the deterministic functioning of the gates. In addition, we ran a Python code simulating the same circuits on an IBM-Q supercomputer implemented with superconducting qubits. Based on the outputs, we highlight the physical constraints behind the real backend results and give numerical approximations for the errors for higher qubit number systems.

9:12AM F09.00007: Isolated Vertices in Continuous-Time Quantum Walks on Dynamic Graphs* THOMAS WONG (Presenter), Creighton University — It was recently shown that continuous-time quantum walks on dynamic graphs, i.e., sequences of static graphs whose edges change at specific times, can implement a universal set of quantum gates. This result treated all isolated vertices as having self-loops, so they all evolved by a phase under the quantum walk. In this paper, we permit isolated vertices to be loopless or looped, and loopless isolated vertices do not evolve at all under the quantum walk. Using this distinction, we construct simpler dynamic graphs that implement the Pauli gates and a set of universal quantum gates consisting of the Hadamard, $T$, and CNOT gates, and these gates are easily extended to multi-qubit systems. For example, the $T$ gate is simplified from a sequence of six graphs to a single graph, and the number of vertices is reduced by a factor of four. We also construct a generalized phase gate, of which $Z$, $S$, and $T$ are specific instances. Finally, we validate our implementations by numerically simulating a quantum circuit consisting of layers of one- and two-qubit gates, similar to those in recent quantum supremacy experiments, using a quantum walk.

*This work was supported by startup funds from Creighton University.

9:24AM F09.00008: Enhancing Quantum Linear System Algorithm by Richardson Extrapolation ALMUDENA CARRERA VAZQUEZ (Presenter), IBM Research - Zurich, ALBERT FRISCH, DOMINIK STEENKEN, HARRY BAROWSKI, IBM Systems - Germany, RALF HIPTMAIR, ETH Zurich, STEFAN WOERNER, IBM Research - Zurich — We present a complete implementation of the HHL algorithm to solve tridiagonal Toeplitz systems of linear equations of size $N$ with $O(\log(N)\log^3(1/\varepsilon) + \log(\kappa)\lambda_{\text{min}}/\varepsilon)$ gates, where $\varepsilon$ is the accuracy, $\kappa$ the condition number and $\lambda_{\text{min}}$ the smallest eigenvalue, an exponential improvement in the size of the system over classical methods. In particular, we present efficient oracles for preparing a quantum state where amplitudes are specified by a given function, Hamiltonian simulation and solution observables, and we show that the Euclidean norm of the solution can be obtained deterministically.

The main result is the use of Richardson extrapolation for general product formulae Hamiltonian simulation, resulting in an implementation of the quantum phase estimation part at $\text{polylog}(1/\varepsilon)$ complexity instead of $\text{poly}(1/\varepsilon)$.

For each result we provide detailed mathematical analysis that do not restrict to tridiagonal matrices, and analyze whether it is possible to obtain a quantum advantage taking into account different classes of right hand sides and quantum algorithms.

All the procedures presented are implemented with Qiskit and tested on a quantum simulator. We demonstrate our algorithm for a small illustrative problem and two different observables on real hardware of the IBM Quantum Computing Center.
9:36AM F09.00009: Universality and conformal invariance in hybrid quantum circuits

YAODONG LI (Presenter), University of California, Santa Barbara, XIAO CHEN, Kavli Institute for Theoretical Physics, ANDREAS W LUDWIG, MATTHEW P A FISHER, University of California, Santa Barbara — We establish the emergence of conformal field theories (CFT) in (1+1)-dimensional hybrid quantum circuits right at the measurement-driven entanglement transition, by revealing the remarkable space-time conformal covariance of entanglement entropies and mutual information, computed numerically for various subregions at all time steps within Clifford circuits of up to \( L = 512 \) qubits and \( T = 1024 \) time steps. Though the evolution takes place in real-time, the time dimension of the circuit becomes “imaginary” or “space-like” – to be consistent with conformal invariance – as a result of measurements that break unitarity. Throughout the paper we investigate Clifford circuits with several different boundary conditions by injecting physical qubits at the spatial and/or temporal boundaries, all giving consistent characterizations of the “Clifford CFT”. We emphasize universal results that are consequences solely of the conformal invariance and do not depend crucially on the precise nature of the CFT. Among these are the infinite “entangling speed” as a manifestation of “many-body entanglement swapping”, and the critical decaying behavior of the thermal entropy of a mixed state at the recently discovered “purification transition”.

9:48AM F09.00010: Time Complexity Reduction for Gate-Model Quantum Computers

LASZLO GYONGYOSI (Presenter), Univ of Southampton, SANDOR IMRE, Budapest University of Technology and Economics — A method is defined for the time complexity reduction of near-term gate-model quantum computers. The proposed solution evaluates the reduced time complexity equivalent of a reference quantum circuit and recovers the reference output quantum system of the reference quantum circuit via quantum operations on the output of the reduced time complexity quantum circuit. We prove the complexity of the proposed quantum algorithm and the achievable reduction in time complexity. We define the auxiliary cost of the proposed quantum algorithm and show that it is significantly lower than the gainable reduction in time complexity. The algorithm provides a tractable solution to reduce both time complexity and the economic cost of implementing the physical-layer quantum computer by reducing quantum hardware elements. The results are useful for experimental gate-model quantum computations and the near-term quantum devices of the quantum Internet.

*The research has been supported by the National Research, Development and Innovation Fund (TUDFO/51757/2019-ITM), by the National Research Development and Innovation Office of Hungary (2017-1.2.1-NKP-2017-00001), by the Hungarian Scientific Research Fund - OTKA K-112125 and in part by the BME Artificial Intelligence FIKP grant of EMMI (BME FIKP-MI/SC).
10:00AM F09.00011: Green's functions of molecules using a quantum computer  
TAICHI KOSUGI (Presenter), YUICHIRO MATSUSHITA, Tokyo Institute of Technology — Given the recent rapid development of techniques for quantum computation of electronic structures[1], we propose an algorithm for the construction of one-particle Green's function (GF) of an interacting electronic system via statistical sampling on a quantum computer for quantum chemistry.[2] By avoiding the difficulty coming from the non-unitarity of creation and annihilation operators for the electronic spin orbitals, we provide quantum circuits equipped with at most two ancillary qubits for obtaining all the components of GF. We perform simulations of such construction of GFs for LiH and H2O molecules based on the unitary coupled-cluster (UCC) method and compare the quasiparticle and satellite spectra exact within UCC and those from full configuration interaction calculation.

10:12AM F09.00012: Quantum Phase Estimation with Time-Frequency Qudits in a Single Photon*  
ZIXUAN HU, HSUAN-HAO LU, MOHAMMED S ALSHAYKH, ALEXANDRIA J. MOORE, YUCHEN WANG (Presenter), POOLAD IMANY, ANDREW M WEINER, SABRE K AIS, Purdue Univ — In this work, we report an experimental realization of a qudit-based PEA on a photonic platform, utilizing the high dimensionality in time and frequency degrees of freedom (DoFs) in a single photon. The controlled-unitary gates can be realized in a deterministic fashion, as the control and target registers are now represented by two DoFs in a single photon. We also proposed a systematic scheme to decompose an arbitrary unitary matrix into smaller d-level unitary matrices. Representing and connecting these d-level unitary matrices with photonic qudit gates is our plan for future research.

*This work was supported in part by the National Science Foundation under award number 1839191-ECCS.

10:24AM F09.00013: Implementing single-qubit POVMs on a circuit-based quantum computer  
YORDAN YORDANOV (Presenter), Univ of Cambridge — We present a deterministic protocol to implement general single-qubit POVMs on near-term circuit-based quantum computers. The protocol has a modular structure, such that an n-element POVM is implemented as a sequence of (n-1) circuit modules. Each module performs a 2-element POVM. Two variations of the protocol are suggested, one optimal in terms of number of ancilla qubits, the other optimal in terms of number of qubit gate operations and quantum circuit depth. We use the protocol to implement 2- and 3-element POVMs on two publicly available quantum computing devices. The results we obtain are positive, and suggest that implementing non-trivial POVMs could be within the reach of current noisy intermediate scale quantum computing devices.
OLEG OLENSKI (Presenter), Department of Applied Physics and Astronomy, University of Sharjah — One-parameter functionals of the Renyi $R_{\rho,\gamma}(\alpha)$ and Tsallis $T_{\rho,\gamma}(\alpha)$ types are calculated in the position (subscript $\rho$) and momentum (subscript $\gamma$) spaces for the 2D nanoring placed into the combination of the uniform magnetic field $B$ and the AB flux $\Phi_{AB}$. Ring potential is modelled by the superposition of the quadratic and inverse quadratic dependencies on the radius $r$.

Position (momentum) Renyi entropy depends on $B$ as a negative (positive) logarithm of $\omega_{\text{eff}} = (\omega_0^2 + \omega_c^2/4)^{1/2}$, where $\omega_0$ determines the quadratic steepness of the confining potential and $\omega_c$ is a cyclotron frequency. This makes the sum $R_{\rho nm}(\alpha)+R_{\gamma nm}(\alpha/(2\alpha-1))$ a field-independent quantity that increases with the principal $n$ and azimuthal $m$ quantum numbers and satisfies corresponding uncertainty relation. In the limit $\alpha\to1$ both entropies in either space tend to their Shannon counterparts along, however, different paths. Analytic expression for the lower boundary of the semi-infinite range of the dimensionless coefficient $\alpha$ where the momentum entropies exist reveals that it depends on the ring geometry, $\Phi_{AB}$ and $m$. There is the only orbital for which both uncertainty relations turn into the identity at $\alpha=1/2$ and which is not necessarily the lowest-energy level. At any coefficient $\alpha$, the $R_{\rho}\cdot\Phi_{AB}$ curve mimics the energy variation with $\Phi_{AB}$.

Session F10 GIMS: Advances in Scanned Probe Microscopy 3: Scanning Probes Spectroscopic Techniques 108 - Stephen Jesse, University of Tennessee - Tag(s): Focus
Direct and converse flexoelectricity: the effect of strain and electric field gradients on nanoscale electromechanical responses

NEUS DOMINGO (Presenter), Institut Català de Nanociència i Nanotecnologia (ICN2), AMIR ABDOLLAHI, Universitat Politècnica de Catalunya (UPC), KUMARA CORDERO EDUARDS, DQMP, Université de Geneve, JORDI SORT, Universitat Autònoma de Barcelona (UAB), IRENE ARIAS, Universitat Politècnica de Catalunya (UPC), GUSTAU CATALAN, Institut Català de Nanociència i Nanotecnologia (ICN2) — Surface electromechanics at the nanoscale are typically studied by Piezoresponse Force Microscopy (PFM), based on the inverse piezoelectric effect. As a first approach, generally only homogeneous responses are taken into account, but it has been realized that the effect of gradients in electro-mechanical phenomena at the nanoscale can become dominating: the generation of electrical signals after the application of mechanical strain gradients with an AFM tip has been proved, and it has been shown that it is possible to write ferroelectric domains [1] or to move oxygen vacancies and charges.

In this talk, I will review how gradient-based electro-mechanical effects couples and affects the quantification of PFM measurements. I will start by showing the asymmetry in mechanical properties induced by the coupling of flexoelectricity to ferroelectricity leading to ferroelectrics as smart mechanical materials [2], and opening new opportunities to mechanically read ferroelectric polarization states in both, thin films and single crystals, on the base of Contact Resonance Frequency AFM mode. Then, I will show how converse flexoelectric effect [3] due to the presence of strong local electric field gradients at the tip end can induce a mechanical strain of the sample in dielectric centrosymmetric materials with magnitudes comparable to piezoelectric $d_{33}$ coefficient.

New modalities for cryogenic nano-imaging and spectroscopy

Sven A. Doenges (Presenter), Kyung-Duck Park, Tao Jiang, Fabian Menges, Markus B. Raschke, Department of Physics, Department of Chemistry, and JILA, University of Colorado, Boulder — Scanning nano-optical imaging and spectroscopy have emerged as powerful tools in investigating and understanding heterogeneities and underlying physics in a wide range of organic, layered van der Waals, and correlated electron materials. However, the extension to variable and low temperatures has remained a major experimental challenge, yet highly desirable with many fundamental properties and phase transitions only emerging far below room temperature. Here, we present the development of cryogen-free variable temperature infrared nano-imaging and spectroscopy, as well as variable temperature tip-enhanced photoluminescence and nano-Raman spectroscopy in different instruments based on closed cycle cryocoolers with an exchange gas cooled low vibration interface. At the example of surface plasmon polariton nano-imaging in graphene, we establish infrared scattering scanning near-field optical microscopy (s-SNOM) at temperatures as low as 15 K with spatial resolution of 10 nm. Further, we demonstrate tip-enhanced photo-luminescence (TEPL) and tip-enhanced Raman spectroscopy (TERS) of different excitonic systems based on 2D transition metal dichalcogenide (TMD) heterostructures.

Bulk ferromagnetic tips for spin-polarized scanning tunneling microscopy

Masahiro Haze (Presenter), Hung-Hsiang Yang, Kanta Asakawa, Ryosuke Yamamoto, Nobuyuki Watanabe, Yasuo Yoshida, Yukio Hasegawa, Univ of Tokyo-Kashiwanoha — To develop nano-controlled magnetic materials for condensed matter physics and device applications, it has been required to investigate magnetic structures in atomic scales. While spin-polarized scanning tunneling microscopy (SP-STM) is one of the powerful tools, the usage is still hampered because of the issue on its probe. Tips coated with magnetic thin films are often used, but fabricating stable and reliable ones is not easy unless well equipped. Among the bulk magnetic probes, which can be prepared rather easily, chemically etched antiferromagnetic Cr tips are most commonly used. However, antiferromagnetic probes have disadvantages that the magnetization direction cannot be controlled and defined. On the other hand, bulk ferromagnetic probes are good choices if target materials are robust against stray fields such as antiferromagnetic materials.

In this study, we demonstrate that chemically etched bulk ferromagnetic Ni and Fe tips are ones of the best choices for reliable SP-STM probes using an antiferromagnetic spin-spiral sample; Mn double layers formed on W(110). We also demonstrated that their magnetization direction can be easily controlled by external magnetic fields. This work provides new options for the magnetic probes, opening up versatility of SP-STM.
9:00AM F10.00004: Fourier transform infrared scanning tunneling microscopy: Measuring vibrational modes at the nanoscale  KRISTOPHER BARR (Presenter), NAIHAO CHIANG, ANDREW IRA GUTTENTAG, PAUL S WEISS, University of California, Los Angeles — Scanning probe microscopy has enabled unprecedented surface imaging capability down to atomic resolution. Recent advances in photon technologies has led to successful integration of optical spectroscopy with various scanning probe microscopy. In this work, we use the scanning tunneling microscope tip as a nano antenna and a multiplexed signal from a bench-top Fourier-transform interferometer to discover vibrational modes at the nanoscale. By back illuminating our gold on sapphire samples, we are able to excite molecular self-assembled monolayers into vibrationally excited states evanescently, thus creating a perturbation in the conductance of the STM junction. We use cyanide on gold as a proof-of-concept system because of its distinct vibrational spectra, its stability under ambient conditions, and our control of the molecules interactions. In previous work, we have demonstrated direct control of the gold cyanide molecular packing structures – cubic or hexagonal close packed – and can contribute a vibrational mode from Raman and infrared spectroscopy to each phase. This custom-built instrument performs operates at ambient temperature and pressure, enabling us to image chemical structure with single-molecule resolution on a variety of systems.

9:12AM F10.00005: Role of steps on Pb atomic-layer superconductivity  YUDAI SATO (Presenter), FUMIKAZU OGURO, KANTA ASAKAWA, Institute for Solid State Physics, The University of Tokyo, TAKASHI UCHIHASHI, International Center for Materials Nanoarchitectonics, National Institute for Material Science, YUKIO HASEGAWA, Institute for Solid State Physics, The University of Tokyo — Atomic-layer superconductors [1] exhibit various unique characteristics. One of the features is the enhancement of the in-plane critical magnetic field. The presence of steps, which work as a Josephson barrier [2], is inevitable. It is thus expected that the weakened coupling between terraces confines cooper pairs within the terraces and modifies superconductivity depending on the terrace width. Pb monolayers on a Si(111) substrate is known to form various superconducting phases. Using scanning tunneling microscopy (STM), we found a√3×√43 superconductivity phase still remains on narrow terraces (< 150 nm) even under out-of-plane magnetic fields above its critical magnetic field (190 mT). In addition, on a striped incommensurate (SIC) phase formed on a 1.1 degrees tilted vicinal Si(111) substrate, where 15 nm-narrow terraces covers the whole surface, we observed suppression of the superconductivity breaking against out-of-plane magnetic field. Our results open up the possibility of creating superconducting materials whose the critical magnetic fields of all directions are enhanced in a macroscopic level.

9:24AM F10.00006: GHz-THz near-field imaging of extreme subwavelength metal structures

XINZHONG CHEN (Presenter), State Univ of NY - Stony Brook, XIAO LIU, University of Shanghai for Science and Technology, XIANGDONG GUO, National Center for Nanoscience and Technology, SHUCHEN, CIC nanoGUNE, HAI HU, National Center for Nanoscience and Technology, ELIZAVETA NIKULINA, CIC nanoGUNE, ZIHENG YAO, State Univ of NY - Stony Brook, HANS BECHTEL, MICHAEL MARTIN, Lawrence Berkeley National Laboratory, G CARR, Brookhaven National Laboratory, QING DAI, National Center for Nanoscience and Technology, SONGLIN ZHUANG, University of Shanghai for Science and Technology, QING HU, Massachusetts Institute of Technology, YIMING ZHU, University of Shanghai for Science and Technology, RAINER HILLENBRAND, CIC nanoGUNE, MENGKUN LIU, State Univ of NY - Stony Brook, GUANJUN YOU, University of Shanghai for Science and Technology — Modern scattering-type scanning near-field optical microscopy (s-SNOM) has become an indispensable tool in material research. In this talk we present a home-built GHz-THz s-SNOM using Schottky diodes as both light source and detector, achieving unprecedented spatial resolution at long wavelength (~2 mm). We systematically investigated a series of extreme subwavelength metallic nanostructures at the micrometer scale. The near-field material contrast is found to be greatly impacted by the lateral size and connectivity of the nanostructures, which is drastically different from the cases at shorter wavelengths (e.g. IR s-SNOM). The observed phenomena can be explained by a quasi-static analysis and full-wave electromagnetic simulations. Our results reveal that s-SNOM with long wavelength excitation is an ideal candidate for investigating the electrostatic behavior of metallic devices.

9:36AM F10.00007: Ultrafast infrared nano-spectroscopic imaging of heterogeneous photoinduced dynamical processes

JUN NISHIDA (Presenter), SAMUEL C. JOHNSON, SVEN A. DOENGES, Department of Physics, Department of Chemistry and JILA, University of Colorado, Boulder, AMANI H ALFAIFI, National Renewable Energy Laboratory, SEAN SHAHEEN, Renewable and Sustainable Energy Institute, University of Colorado, Boulder, MARKUS B. RASCHKE, Department of Physics, Department of Chemistry and JILA, University of Colorado, Boulder — Low-energy responses and interactions at mid-infrared frequencies often play central roles in photoinduced dynamical phenomena, ranging from phase transitions in quantum materials to polaron formations in photovoltaic materials. However, the spatial heterogeneities and temporal evolution associated with such low-energy processes in the photoinduced transient state has remained elusive. Here, we develop and apply ultrafast infrared scattering scanning near-field optical microscopy (IR s-SNOM) to characterize photoinduced dynamics with far-from-equilibrium excitation and ultrahigh spatio-temporal-spectral resolution. For unambiguous determination of nano-scale phase and spectral responses, we develop optical pump - infrared probe nano-imaging with heterodyne detection. We demonstrate the performance of ultrafast IR s-SNOM to probe transient quantum states of the photoinduced heterogeneous metallic phase in vanadium oxide microrods, as well as spatially varying polaron-molecule coupling in lead halide perovskite films. The approach of ultrafast heterodyne IR s-SNOM with strong pump excitation is generally applicable to a wide range of strong transient field phenomena, providing for fundamental insight into heterogeneous electronic, structural, and dynamical properties of materials.
9:48AM F10.00008: Calibrating atomic force microscope detectors on soft surfaces  DANIEL FORCHHEIMER (Presenter), KTH Royal Inst of Tech, DANIEL PLATZ, MST, TU Wien, RICCARDO BORGANI, DAVID HAVILAND, KTH Royal Inst of Tech — Quantitative force microscopy requires independant means of calibrating both cantilever stiffness and detector responsivity (i.e. the factor mapping cantilever deflection in nanometers to photo-detector signal in Volts). The conventional methods slowly approach the surface while observing either static bending or change in oscillation amplitude. Detector responsivity is then obtained under the assumption that the surface does not deform during the region of approach used for calibration. This assumption may be satisfied for large force and stiff sample, both of which risk damaging the tip. Here we present a new method for detector calibration based on Intermodulation AFM where the tip-surface force versus cantilever deflection is continuously monitored during the slow approach. This method allows us to calibrate the detector without the previously mentioned assumptions. We can therefore calibrate on any surface, hard or soft, or directly on the sample with the same magnitude of force used for quantitative imaging. We present the theory of this method and its experimental implementation on a variety of different surfaces.

10:00AM F10.00009: The influence of time and temperature on viscoelastic properties of nanoscale domains within polymer composites  BEDE PITTENGER (Presenter), SERGEY OSECHINSKIY, JOHN THORNTON, SOPHIE LOIRE, THOMAS MUELLER, AFM Unit, Bruker Nano Surfaces — The behavior of polymer composites is controlled by the properties of the components as well as the microstructure of the material. Because confinement effects and interphase formation can alter properties of the microphases, only measurements performed directly on the composite can provide the needed local property distribution. Mechanical properties of polymers are generally time dependent, so a full understanding requires measurements over a range of frequencies and temperatures. Ideally, one would like to observe the mechanical behavior of these microscopic domains while they pass through their glass transitions to appreciate the influence of size effects and confinement on time dependent mechanical properties.

Recently, Atomic Force Microscopy based nano-Dynamic Mechanical Analysis (AFM-nDMA) was introduced. Like bulk DMA, this mode provides spectra of storage and loss modulus across frequency and temperature, allowing construction of master curves through Time Temperature Superposition (TTS). In addition, it allows high resolution measurements localized to the microscopic structures within heterogeneous samples. This presentation will examine the capabilities of this new mode with examples in a wide range of polymers and composites.
F10.00010: Cryogenic Scattering-type Scanning Near-field Optical Microscopy (s-SNOM) has become an important branch of modern optical techniques in the past decade, which allows nanoscale imaging over a broad spectral range. This informative technique is feasible to study the electrodynamics of correlated quantum materials with a spatial resolution down to 10 nm. As a powerful scanning probe microscopy, although the importance of cryo-SNOM has been universally recognized, the realization remains to be a challenging task. Based on the experience of cryo-AFM, we built a set of s-SNOM operating with variable sample temperature down to 10 K. The scanning probe is located in ultra high vacuum chamber with He-bath cryostat maintaining low temperature and combined with a molecule beam epitaxy (MBE) system. The nine home-made positioners of the scanning system function well at low temperature. The system is equipped with CO\(_2\) laser which can provide long-time stable light source. Our cryo-SNOM has been tested at liquid nitrogen temperature, which shows good performance and is promising to work well below 10K.

Session F11 APS/SPS: Undergraduate Research VI

8:00AM F11.00001: Measuring the Glass Transition in Dense 2D Colloidal Fluids* WILLIAM MOORE (Presenter), ORRIN SHINDELL, Trinity University — We use Total Internal Reflection Fluorescence Microscopy (TIRF) to analyze dense colloidal fluids fully restricted to two dimensions near their glass transition. Our experiments use 40-100 nm diameter phospholipid vesicles (nanospheres) produced in the lab and commercially manufactured 500 nm and 1000 nm diameter fluorescent polystyrene spheres (microspheres). The microspheres are individually resolvable under TIRF, which allows us to measure their instantaneous positions in both a fluid and a glass state. For both the nanospheres and the microspheres, the position of the colloidal particles is tracked as a function of time, which allows us to measure the viscosity of the colloidal fluid at a range of particle densities. We are thus able to obtain both structural and dynamical information about two-dimensional dense fluids near their glass transition.

*Murchison Fellowship and Mach Fellowship from Trinity University
8:12AM F11.00002: Minimum flow rate in electro-coflow* BENJAMIN OVERLIE (Presenter), JOSEFA GUERRERO MILLAN, Augusta University — Controlled generation of micron and sub-micron sized drops continues to be of strong interest for the scientific community due to the variety of applications in many different fields. Emulsion drops can be generated by flowing two immiscible liquids inside a glass-based microfluidic device. Their minimum size will be of the order of the tip size. To create smaller drops, an external electric field can be used, similarly to what it is done in the classical electrospray. In electrospray, a liquid is issued into air from an electrified needle. When the flow rate of the liquid is controlled, there is a minimum flow rate below which a cone-jet cannot be formed regardless of the applied voltage. This minimum flow rate gives you the minimum drop size that can be generated, usually one or two orders of magnitude smaller than the tip size. We explore this lower limit in electro-coflow using pressure control instead, and we have found a different result than in electrospray, with a more complex behavior. The use of pressure control and the presence of an outer moving fluid, enrich the dynamics in the minimum flow rate limit.

*Acknowledgment is made to the donors of the American Chemical Society Petroleum Research Fund for support (or partial support) of this research (60302-UR9).

8:24AM F11.00003: Energy spectra for turbulent Rayleigh-Bénard convection MICHAEL KWAN (Presenter), JANET D SCHEEL, Occidental Coll — We investigated the scaling behaviors for numerically simulated, turbulent Rayleigh-Bénard convection by determining the kinetic and thermal energy spectra. The systems have aspect ratio 1, Prandtl numbers 0.7, 0.021 and 0.005, and various Rayleigh numbers ranging from $10^5$ to $10^{10}$. Whereas in previous studies the frequency spectra from a time series were considered, we calculated the energy spectra from spatial fields. In particular, we performed Fourier analysis on two-dimensional cross sections of the temperature and velocity fields. We also computed the velocity and temperature structure functions on the same cross sections to verify our findings. Lastly, we tested whether Kolmogorov's 1941 (K41) scaling law or the Bolgiano-Obukhov (BO) scaling law applied to both the kinetic and thermal energy spectra for the various systems.

8:36AM F11.00004: The Effect of Short Range Attractions on Sequence Defined Polyelectrolyte Coacervation NATALIA MARKIEWICZ (Presenter), TYLER LYTLE, CHARLES SING, University of Illinois at Urbana-Champaign — Complex coacervation is the liquid-liquid phase separation of polyelectrolytes in aqueous salt solution into a polymer-dense phase, the coacervate, and a polymer-dilute phase, the supernatant. Previous work using Monte Carlo simulations demonstrated that changing the sequence of charged and neutral monomers on polyelectrolytes while keeping the charge fraction constant alters the extent of phase separation. However, previous data does not account for the hydrophobicity of different neutral monomers. To understand the coacervation of polymers with various chemical structures, van der Waals interactions at various strengths are included in Monte Carlo simulations to show hydrophobic effects in the system. Comparisons are made to existing Monte Carlo simulations and experimental data. Understanding these patterning effects will enhance the knowledge of biomacromolecule phase separation, as well as expand the understanding of sequence-dependent polymer physics.
8:48AM F11.00005: Measurement of Low Temperature Strain in 3D Printed Materials
JOESEPH MOORE (Presenter), MICHAEL RAY, California State University, Sacramento — The versatility and ease of use of 3D printing provides access for custom built parts to be quickly manufactured for experimental applications. However, not much is currently known about the behavior of these materials at low temperatures. In this project we measured the thermal properties of a 3D printed material in a cryogenic environment in order to determine its suitability for use in low temperature applications. Specifically, we used a strain gauge to measure the thermal contraction of Polylactic Acid, which is a common material used in 3D printing. We will present our results and discuss the implications for its use in low temperature experiments.

*This work is supported by the National Science Foundation under grant DMR-1807476

9:00AM F11.00006: Measurement of the Low Temperature Porosity of 3D Printed Materials
KEVIN COAN (Presenter), MICHAEL RAY, California State University, Sacramento — Over the past decade, 3D printing has become popular due to its ease of manufacturing and low cost. This work will explore the possibility of using 3D printers to design custom components for use in low temperature experiments. Specifically, we designed an experiment to test the low temperature porosity of Polylactic Acid, a common 3D printed material. We will present the methods used in this experiment, the results obtained, and then discuss its implications for low temperature use.

*This work is supported by the National Science Foundation under grant DMR-1807476

JOHN REVELLE (Presenter), ANKIT KUMAR, ALEXANDER F KEMPER, Department of Physics, North Carolina State University — Time-resolved optical conductivity is an oft-used tool to interrogate quantum materials driven out of equilibrium. Theoretically calculating this observable is a complex topic with several approaches discussed in the literature. Using a non-equilibrium Keldysh formalism and a functional derivative approach to the conductivity, we present a comparison of two particular approaches to the calculation of the optical conductivity, and their distinguishing features, as applied to a pumped superconductor. The two methods are distinguished by the relative motion of the probe and gate times; either the probe or gate time is kept fixed while the other is swept. We find that both the methods result in same qualitative features of the time-resolved conductivity after pump is over. However, calculating the conductivity by keeping the gate fixed removes artifacts inherent to the other method. We provide software that, based on data for the first method, is able to construct the second approach.

*This material is based upon work supported by the National Science Foundation under Grant DMR-1752713.
9:24AM F11.00008: Superconductor-based light detection*  KYRIL KAVETSKY (Presenter),
Department of Physics & Astronomy, Rowan University, HARISH KRISHNAMOORTHY, CESARE SOCI,
Division of Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Department of
Physics & Astronomy, Rowan University — The ability to detect a single photon could have powerful
applications in high-precision object location and quantum information encryption. A
superconducting nanowire single-photon detector (SNSPD) is a promising solution that is smaller
than the period at the end of this sentence. While they are commercially available now, there is
still some room for improvement of efficiency, particularly when a wider operational bandwidth
is required, which could be achieved by improving the light absorption. This research presents
finite-element-method-based simulations to enhance the absorption in superconducting thin
films by utilizing plasmonic nanostructures with broadband absorption response.

*The authors acknowledge support from NSF-IRES 1559410.

9:36AM F11.00009: Phenomenological description of excitonic complexes in tip-enhanced
photoluminescence of 2D materials  ZACHARY WITHERS (Presenter), DMITRI VORONINE,
Department of Physics, University of South Florida — Two dimensional materials exhibit different
electronic and optical properties than the corresponding bulk materials. Transition metal
dichalcogenides (TMDs) are semiconducting 2D crystals that exhibit unusually strong
photoluminescence (PL) signals due to the stability of excitons at room temperature. However,
many factors can effect the measured intensity of PL signals including charge doping or the
presence of a plasmonic AFM tip. Here we present a set of phenomenological rate equations in
order to model the intensity of PL in tip-enhanced experiments involving tip-sample distance
dependent measurements and near field imaging. Furthering the understanding of exciton
dynamics around heterojunctions of TMDs may lead to the engineering of new optoelectronic
devices such as optical transistors, novel optomechanics, and controllable signaling on the
nanoscale.
Double Resonant Local Fields Appreciably Enhance Third Harmonic Generation in Core-shell Nano-cavity  

WENBO ZANG, ZHUO CHEN, ZHONGWEI WANG  
(Presenter), Physics Department, Nanjing University — We simulate the intensity of third harmonic generation (THG) in a metallic core-shell nanostructure in double resonant conditions, where the corresponding wavelength of two cavity modes are tuned in to couple with the wavelength of the pump light and the THG signal simultaneously by adjusting the refractive index of the dielectric. It turns out that the double resonant condition is crucial to our discovery.

Numerical simulations show that if the fundamental wavelength of the pump light is adjusted to 1390nm, which is the corresponding eigen wavelength of TM$\text{2}_{1}$ mode, and the frequency of a higher-order cavity mode, say, TE$\text{3}_{2}$ mode was also adjusted to the frequency of THG, the THG signal was more intensified than the single resonant condition on which only TM$\text{2}_{1}$ mode was tuned in to the fundamental frequency. What's more, when the two cavity modes involved, e.g., TM$\text{2}_{1}$ and TM$\text{2}_{3}$ mode, have the same multipolar moment (as indicated by the first number), the final THG efficiency will be enhanced up to 3 magnitudes, much more than the enhancement in situations where two cavity modes have different multipolar moment, for instance, TM$\text{2}_{1}$ and TM$\text{1}_{3}$ mode. It can be believed that this phenomenon is important and will open new opportunities in nonlinear optics.

Developing and controlling single-photon emitters by tip-enhanced photoluminescence nanospectroscopy and nano-localized force control  

JUN YAN  
(Presenter), CHUANLIN LI, MOLLY A. MAY, TAO JJANG, MARKUS B. RASCHKE, Department of Physics, Department of Chemistry, and JILA, University of Colorado - Boulder — Strain-induced single-photon emitters in two-dimensional (2D) materials associated with deterministically located quantum wells could pave the way for quantum state transfer in solid state qubits. However, far-field optical techniques can neither spatially resolve these highly localized emitters nor allow for deterministic control of the light-matter interaction. Here, we develop plasmonic tip-induced, nano-localized force control to generate, tune, and control nano-localized quantum states in monolayer WSe$_2$ by tuning the strain gradients and the plastic deformation depth with sub-nanometer precision. We investigate exciton funnelling behavior and strain-induced bandgap modification from spectral peak shift and intensity of the indented nanostructures, which could possibly help to reveal the deterministic formation of single-photon quantum emitter. In addition, we provide a perspective on this tip-based nanocavity approach, which has been used to probe in photoluminescence bright and dark exciton emissions, localized states, and interlayer excitons in 2D heterostructures.
10:12AM F11.00012: *Velocity, Release and Attack Angle and Distance of an Ultimate Frisbee Disc* ANDREW POLCARI (Presenter), Ithaca Coll — This study is exploring how an ultimate frisbee disc rotates and acts while in flight using high-speed video. The relationship between angular speed and flight stability and optimal release angle and flight distance will be explored. The methods used will all be physical methods as opposed to a re-creation of a computer program. By attaching a disc to a motor and spin it at varying speeds, we will be able to determine the optimal angular velocity and relate those measurements to flight stability. To measure the distance, this project will use a high-speed camera to measure the angle of release and then correlate those data to the distance travelled by that specific throw. The results explore pitch, roll, and velocity. This project will show that physics can be related to any topic and discipline. It relates a sport, hobby and past time all together and shows how physics affects the classic piece of plastic we toss between us.

*Ithaca College Physics and Astronomy Department*

10:24AM F11.00013: Study on the Apparent Weight of Hourglass Caused by Sand Flow CHUNZHEN LI (Presenter), Nankai University — Due to the acceleration of the sand centroid, the hourglass's apparent weight will change slightly with time in the process of sand flow, which is the sum of the effects of each part of the sand in the hourglass. By establishing an hourglass model, in this paper we can get the relationship between the centroid position vector of each part of the sand and the time, and then get the time-dependent acceleration of the overall centroid of the sand. According to the shape of the hourglass itself and the parameters of each part, the process of sand flow can be divided into five stages. Then the mismatch between theoretical and experimental values is analyzed, and the imperfect elastic collision between sand and the bottom of the hourglass is used to explain and further revise the previous theory.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F12 APS/SPS: Undergraduate Research VII 112 - Matthew Wright, Adelphi University - Tag(s): Undergrad Friendly
8:00AM F12.00001: netQuil: A quantum playground for distributed quantum computing simulations*  MATTHEW RADZIHOVSKY (Presenter), ZACHARY ESPINOSA, Stanford Univ — NetQuil is an open-source Python framework for quantum networking simulations built on the quantum computing framework pyQuil, by Rigetti Computing. NetQuil is built for testing ideas in quantum network topology and distributed quantum protocol. This platform allows users to create multi-agent networks, connect parties through classical and quantum channels, and introduce realistic noise and device models. NetQuil also makes running multiple trials for non-deterministic experiments, reviewing traffic in real-time, and synchronizing agents based on local and master clocks simple and easy. We provide an overview of the state of distributed quantum protocol, as well as a basic introduction to netQuil's framework. We present several demonstrations of canonical quantum information protocol built using netQuil's distributed quantum gates and pyQuil. We hope netQuil allows users to explore the quantum playground and the possibilities of distributed quantum computing.

*We wish to thank Yewon Gim, the entire team at AT&T Foundry for providing support and helpful feedback throughout development.

8:12AM F12.00002: Hardware and Software for Qubit Control*  GREGORY PENN (Presenter), Department of Physics, Temple University, ALESSANDRO LANDRA, Centre for Quantum Technologies, National University of Singapore, RAINER DUMKE, Division of Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Department of Physics & Astronomy, Rowan University — Quantum computers have the potential to exponentially increase the speed of certain algorithms. Such a quantum information processor is currently under construction at the Centre for Quantum Technology, Singapore. It is based on Josephson-junction qubits, the basic unit of quantum information. A crucial part of this system is the control of the individual qubits and their interaction. We describe the experimental setup for qubit spectroscopy to measure the excitation energy of each qubit. Modular hardware was realized to initialize and read out qubit states using a phase measurement technique.

*The authors acknowledge support from NSF-IRES 1559410.
8:24AM F12.00003: Nonlinear Optical Properties of Janus 2D Materials: A First Principles Study*  ALEX STRASSER (Presenter), HUA WANG, XIAOFENG QIAN, Texas A&M Univ — Two-dimensional (2D) transition metal dichalcogenides (TMDCs) have provided a unique materials platform with a variety of interesting optoelectronic properties and great potential for device applications. Janus 2D TMDCs is a new class of 2D materials with lower symmetry. Here we present our first-principles study of nonlinear optical properties in Janus 2D TMDCs. Electronic structures such as linear and nonlinear optical properties were calculated using first-principles density functional theory and analyzed in combination with group theory. The microscopic origin of these nonlinear optical properties of Janus TMDs is elaborated by k-point resolved absorption, shift current, and shift vector. We found that the absence of horizontal mirror plane enables the out-of-plane second harmonic generation (SHG) and other nonlinear optical phenomena, such as shift photocurrent and circular photocurrent. Janus 2D materials, therefore, offer a unique platform for exploring nonlinear optical phenomena and designing configurable layered nonlinear optical materials.

*This work was supported by the National Science Foundation (NSF) under award no. DMR-1753054. First-principles calculations were conducted with advanced computing resources provided by Texas A&M High Performance Research Computing.

8:36AM F12.00004: Reflectance of Graphene Coated Metals: Copper & Nickel*  MATTHEW CRITCHLEY (Presenter), DANIEL FINKENSTADT, STEVEN MONTGOMERY, RAJRATAN BASU, US Naval Academy — Accelerator technology often requires the presence of a photocathode electron source. Unfortunately, these materials are often very volatile. In order to improve the lifetime of materials without compromising their quantum efficiency, we look at the optical effects of monolayer graphene coatings on known substances. This project looks at the optical effects a monolayer coating of graphene has on copper and nickel surfaces. We analyze the optical effects via theory by developing an effective dielectric medium model, computation by using Density Functional Theory, and experiment with graphene coated copper samples. In addition, we plan to conduct specular reflection for graphene off nickel. These methods allow us to compare the reflectivity and dielectric constant between pure and graphene coated metals over the visible light spectrum.

8:48AM F12.00005: Modeling the Progression of Women in STEM Fields  JESSICA JENSEN (Presenter), Engineering, Roger Williams University, DARRELL VALENTI, Mathematics, Roger Williams University, JULIETTE M CAFFREY, Engineering, Roger Williams University, JENNIFER PEARCE, Physics, Roger Williams University — Creating a mathematical model to predict participation in STEM fields would allow social scientists to quantitatively examine their theories, as well as provide a multitude of simulated populations to explore. Furthermore, these models can be used to predict the result of interactions between populations. One model that simulates the progression of women through male-dominated academic fields explores the idea of homophily between women as the driving force for their advancement. We propose an alternate model that simulates the progression of women in these male-dominated fields as a predator-prey type system. We believe that such a model more effectively describes the population dynamics.

9:00AM F12.00006: Deep Learning for Engineering Problems  ANANYANANDA DASARI (Presenter), Mechanical Engineering, INDIAN INST. OF TECH MADRAS, DEEPAK SOMASUNDARAM, Mechanical Engineering, College of Engineering, Guindy, VISHAL V.R. NANDIGANA, Mechanical Engineering, INDIAN INST. OF TECH MADRAS — In this paper, we propose a data driven deep learning model to solve transport phenomenon without incorporating physics based PDEs. Here, a deep Recurrent Neural Network (RNN) with Long Short Term Memory (LSTM) is used to solve a general 2D heat conduction phenomenon. The problem is solved for square and circular geometries. The model is trained on 1670 cases for square domain and 3000 cases for circular domain. The cases include both Dirichlet boundary conditions and Neumann boundary conditions. The model was then tested on 610 cases for square geometry and 1000 cases for circular geometry. Our proposed RNN-LSTM model shows a 3-order speed up in computational time compared to conventional finite difference method. Moreover, the predicted solution shows 99.9% accuracy. Also, our proposed model can easily be generalized and extended for other transport phenomenon problems, both linear and nonlinear. We test this by considering a simple nonlinear advection-conduction phenomenon. We believe the RNN-LSTM deep learning method has the ability to predict transport phenomenon in applications like aerospace, automobile, semiconductor and thermal management domains like electronic cooling applications, without incorporating physics based PDEs.

9:12AM F12.00007: The phenomenon of nonlinear coupling in an asymmetric pendulum  QIUHAN JIA (Presenter), YAO LUO, Nanjing Univ — We investigate the nonlinear effect of a pendulum with the upper end fixed to an elastic rod which is only allowed to vibrate horizontally. The pendulum will start rotating while oscillating without initial angular momentum. We explain it as amplitude and phase modulation due to nonlinear coupling between the two dimensions. We build the theoretical model and obtain the pendulum's equations of motion. The pendulum's motion patterns are solved numerically and analytically using the method of multiple scales. In the analytical solution, the conversion period not only depends on the dynamical parameters, but also on the pendulum's initial releasing positions, which is a typical nonlinear behavior. The analytical approximate solutions are consistent with numerical solutions with good accuracy.
9:24AM F12.00008: Individual and Collective Transient Behavior near Daido's Aging Transition  AUSTIN HOWARD (Presenter), DAVID MERTENS, Physics, Eckerd College — We report on individual and collective behavior of an ensemble of electronic oscillators near the Daido aging transition. Work by Diado and others indicate that the collective response in an aging transition of identical oscillators should possess dynamics that are nearly identical to that of the individuals. Theoretical calculations for our oscillators predict a Hopf transition, which we have confirmed with measurements of individual transient behavior. However, it was previously reported that the collective behavior of these oscillators near the aging transition exhibited an intriguing discontinuity, seemingly contradicting the above conjecture. It turns out that this seeming contradiction arose from a high sensitivity to the system bifurcation value. We will explore the boundaries of Daido's hypothesis and examine how variation in non-bifurcation parameters across the population lead to collective behavior that differs from that of an individual oscillator.

9:36AM F12.00009: A Theoretical Study of Chaos in Higher Dimensions*  JOSE PACHECO (Presenter), AJIT HIRA, DAVID NUNN, ARRICK GONZALES, RAMKRISHNA KHALSA, RUBEN RIVERA, Northern New Mexico College — We use the computational tools available to us to explore the possibility of creating chaos in four dimensions and in higher dimensions. Even basic physics leads to unexpected results, when we go beyond 3-dimensional space. In four dimensions, we can create Klein bottles, can tape the edges of two Möbius strips together, and can invent sailing knots of stunning complexities: all of the knots that work in 3 dimensions will fall apart in higher dimensions. Our calculations for gravitational force reveal that the force drops as $1/(R^D - 1)$, where $D$ is the dimension and $R$ is the distance between the interacting objects. We first review generalizations of the Li and Yorke definition of chaos to difference equations in $\mathbb{R}^n$, and the higher dimensional conditions leading to the existence of chaos. Then we consider many 3-D, 4-D, 5-D, and 6-D Generalized Henon Maps (GHMs). We look for fixed points that are locally stable. We find that for many values of the parameter $\alpha$, chaotic behavior exists in dimensions $D = 4, 5$ and 6. We also discuss the possibility of uncovering the existence of some of the higher dimensions, by delineating the 3-D projections of chaotic behavior from higher dimensions.

*New Mexico AMP program, funded by NSF, provided some financial support for this research.
9:48AM F12.00010: Fractional derivative of composite functions: exact results and physical applications*  GAVRIL SHCHEDRIN, NATHAN C SMITH, ANASTASIA GLADKINA, JOSHUA LEWIS (Presenter), JOEL BEEN, LINCOLN CARR, Physics, Colorado School of Mines — We examine the fractional derivative of composite functions and present a generalization of the product and chain rules for the Caputo fractional derivative. We derive the product rule with the expression of the Caputo fractional derivative as an infinite expansion of integer order derivatives and the chain rule as a generalization of di Bruno's formula. Unlike the Leibniz and di Bruno formulae that characterize an integer-order derivative of a product of functions and composite functions, respectively, and which result in a finite series of lower order derivatives, the fractional analogs of these formulae produce an infinite series of fractional derivatives of the constituent functions. These results are important for a comprehensive description of transport phenomena through multiscale physical systems and biological structures, e.g., porous materials, disordered media, and neuron clusters. We demonstrate the utility of these results by the evaluation of the Caputo fractional derivative of hyperbolic tangent and suggest that the application of the derived chain and product rules to elementary functions, whose Caputo fractional derivative is expressible as a generalized hypergeometric function, leads to an infinite series of generalized hypergeometric functions.

10:00AM F12.00011: Why Polygons are Mostly Pointless  JOHN CHRISTENSEN (Presenter), JEREMY JORGENSEN, GUS HART, Brigham Young Univ - Provo — When performing materials calculations, one of the most computationally expensive calculations is performing an integral of the electronic band structure of a material. For reasons explained in the talk, integration techniques that rely on non-uniform sampling cannot utilize the full symmetry of the system. To ensure optimal symmetry reduction, calculations should be performed in the symmetrically irreducible Brillouin zone (IBZ). We present an algorithm for finding the IBZ for an arbitrary lattice.

10:12AM F12.00012: Transform as a vector? Tying functional parity with rotation angle of coordinate axes  SAYAK BHATTACHARJEE (Presenter), Department of Physics, Indian Institute of Technology Kanpur — A vector is defined as a quantity which remains unchanged under a rotation of coordinate axes. This definition is associated with the phrase 'transform as a vector'; however, students are frequently confused about the meaning of the phrase and seldom realize its significance. To remedy this, an exposition to this definition is pursued. As a central notion, quantities (triplets) of the form \( C = (\Phi(x), \Phi(y), \Phi(z)) \) (where \( x, y \) and \( z \) are coordinate points and \( \Phi \) is a real valued function) are investigated using the definition. This novel approach employs elementary mathematics to determine possible value(s) of rotation of axes angle \( \theta \) at which \( C \) may transform as a vector, even if it does not for all \( \theta \). A notable correspondence between the parity of function and rotation angle(s) is observed. The analysis, initially carried out in an orthogonal coordinate system, is subsequently generalized for skew coordinate systems. This work was accepted for publication in the European Journal of Physics in October 2019 [1].

Expansion of fractional derivatives in terms of an integer derivative series: physical and numerical applications*  
ANASTASIA GLADKINA, GAVRIL SHCHEDRIN, Colorado School of Mines, U. AL KHAWAJA, Physics, United Arab Emirates University, JOEL BEEN (Presenter), JOSHUA LEWIS, LINCOLN CARR, Colorado School of Mines — We use the displacement operator to derive an infinite series of integer derivatives for the Grünwald-Letnikov fractional derivative and demonstrate that the infinite series of integer order derivatives is the same for Grünwald-Letnikov, Riemann-Liouville, and Caputo fractional derivatives. With the first few terms of the infinite series, we find that for functions with a finite radius of convergence of their Taylor series, the corresponding integer derivative expansion has by an infinite radius of convergence. Specifically, we demonstrate a robust convergence of integer derivative expansion for the hyperbolic secant and tangent functions, characterized by a finite radius of convergence of the Taylor series R=pi/2. Moreover, for a plane wave with an infinite radius of convergence, we show the truncation error decreases as the number of terms in the expansion increases. We find that our numerical results closely approximates the exact solutions given by the Mittag-Leffler and Fox-Wright functions. Thus, we demonstrate that the truncated expansion is a powerful method for solving linear fractional differential equations.

Nonlinear tuning curves of a tuning fork  
LINTAO XIAO (Presenter), QIUHAN JIA, CHENYU BAO, Nanjing Univ — Cantilever beams of a tuning fork have both hardening and softening oscillation modes. Yet, teaching experiments concerning tuning forks usually only demonstrate their linear resonance. In this work, we introduce a simple experiment that can be used to measure the nonlinear tuning curve of a regular tuning fork. Using double-grating Doppler interferometry, our measurement accuracy reaches tens of micron. With this experimental setup, we observed typical nonlinear phenomena of the tuning fork such as the bent tuning curve and "jump phenomena". Our experiment is inexpensive and easy to operate, so it can readily be used as a lecture demonstration for undergraduate students.
10:48AM F12.00015: Anti-Cancer targeting and treatment using nanocarriers based drug delivery system  PRAGATI GUPTA (Presenter), Indian Inst of Technology Roorkee — Cancer is the second leading cause of death globally and recurring disease. Main problems associated with anti-cancer drugs is that it targets healthy cells along with cancer cells. Others include multidrug resistance, poor water solubility. Even small drug molecules get eliminated by the liver and kidneys. Cancer drugs need to have higher activity and selectivity and be non-toxic to healthy cells. Nanotechnology has the potential to revolutionize cancer diagnosis and therapy and they provide a great alternative for the classical drug delivery techniques. The reasons being improved drug tolerability, efficacy, decreased toxicities, enhanced solubility, stability and controlled release. Advances in protein engineering and material science have contributed to novel nanoscale targeting approaches that bring new hope to cancer patients. However, to date, there are only a few clinically approved nanocarriers that incorporate molecules to selectively bind and target cancer cells. This review examines some of the advanced formulations and discusses the challenges in translating basic research to the clinic and emphasizing the challenges in cancer treatment

Session F15 DFD DBIO: Swimming, Motility, & Locomotion 210/212 - Alison Patteson, Syracuse University

8:00AM F15.00001: Scattering of a fast-swimming bacterium off of a surface  ALEXANDER PETROFF (Presenter), SCHUYLER MCDONOUGH, BENJAMIN ROQUE, Clark University — The sediment bacterium Thiovulum majus is one of the fastest known bacteria. Each bacterium is spherical and covered in approximately 200 flagella, which propel cell at a speed of 600 micron/sec. When a cell collides with a surface, it often becomes hydrodynamically trapped. A bound cell exerts a force normal to the surface and rotates. These cells self-organize into active two-dimensional crystals of rotating cells. Here we present the first experimental observations of the scattering of a fast-swimming bacterium off of a flat surface. We show that the probability that a cell becomes bound decays exponentially with the angle at which the cell approaches the surface; cells colliding head on with the surface are most likely to become trapped. We examine the stability of bound cell and measure the timescale over which the cell orients normal to the surface. Finally we show that when a cell escapes, it leaves the surface at a fixed angle. These results give insight into the the ecology of fast-swimming sediment microbes as they navigate the water saturated pore spaces in which they live.
8:36AM F15.00002: Optically-Powered Microscopic Bubble Rockets*  SAMANTHA NORRIS (Presenter), MICHAEL REYNOLDS, ALEJANDRO CORTESE, PAUL L MCEUEN, Cornell University — Artificial microswimmers have attracted great interest recently, especially for applications in sensing and biology. In particular, micro-propulsion by producing bubbles using decomposition of a chemical fuel is an attractive method, but it requires a fuel source. In this talk, we demonstrate a new optically-powered approach to catalyst-free bubble self-propulsion that works in a broad range of fluids, including deionized water. These devices, approximately 100 microns in size, consist of encapsulated silicon photodiodes connected in series with two external electrodes. Under standard illumination conditions in a microscope, the photovoltaics drive water splitting at the electrodes and eject the resulting bubbles preferentially in one direction, propelling the device through fluid. These devices are fabricated and released in parallel using standard semiconductor technologies. We discuss the fabrication and characterization of these devices, demonstrate working bubble rockets, and discuss their efficiency and potential applications.

8:48AM F15.00003: Antagonism in multiple-cue chemotaxis in breast cancer cells*  SOUTICK SAHA (Presenter), Department of Physics and Astronomy, Purdue University, HYE-RAN MOON, BUMSOO HAN, School of Mechanical Engineering, Purdue University, ANDREW MUGLER, Department of Physics and Astronomy, Purdue University — Chemotaxis is defined as biased cell motion towards an external chemical gradient. It is a pivotal step in cancer metastasis where cancer cells move towards chemical cues and spread to different parts of the body. We used triple-negative breast cancer cells to study chemotaxis towards cues formed by multiple growth factors and found, surprisingly, that the bias in the movement was less pronounced when we combine two attractant gradients compared to when we have individual gradients. We study this antagonism using stochastic simulations and a simple analytic model.

9:00AM F15.00004: A universal mechanism for chiral swimming at low Reynolds number
DARIO CORTESE (Presenter), KIRSTY WAN, Living Systems Institute, University of Exeter — Eukaryotes evolved radically new ways to sense and respond to a constantly changing environment. Even single-celled microorganisms display near-deterministic navigation towards sensory cues. Helical alignment towards gradients is a ubiquitous mechanism by which ciliated and flagellated organisms achieve reorientation in three-dimensional space. This navigational strategy usually requires the presence of a specialised organelle which detects stimulus direction and an about-axis rotation of the organism. Here, we consider the biflagellate green alga *Chlamydomonas reinhardtii* which has an eyespot photosensor and rotates steadily at 2Hz in the absence of stimuli. We combine theory and experiment to reveal how *Chlamydomonas* actively modulates asymmetries in flagellar beating to produce axial rotation and steering. In previous models, helical swimming is usually assumed rather than derived. In contrast, in our model chiral axial rotation emerges naturally from the 3D flagellar dynamics. We perform high-speed imaging to measure key simulation parameters, which successfully reproduce the experimentally observed dynamics. Finally, we demonstrate how this coupling between signal detection and motor output constitutes a universal strategy for responding to an arbitrary, vectorial stimulus.

9:12AM F15.00005: Bacterial swarming: Motion under extreme forces?  IRAKLI GUDAVADZE (Presenter), JANELLE KORF, ERNST-LUDWIG FLORIN, University of Texas at Austin — Bacterial swarming is a rapid, collective movement of bacteria over a surface powered by rotating flagella [1]. Unlike swimming, swarming takes place in thin liquid films, constraining bacteria to two dimensions. So far, it always has been assumed that the film is thicker than the diameter of a bacterium, but its exact thickness has never been measured. Here we present a novel method for measuring film thickness with tens of nanometer precision. For *Bacillus subtilis* colonies grown on agar gels, we find film thicknesses as thin or even thinner than the diameter of a single bacterium. For thicknesses thinner than a single bacterium, surface tension forces are expected to be on the order of tens of nanonewtons. These forces are about 4 orders of magnitudes greater than forces bacteria experience during swimming [2]. It remains unclear how flagella driven motility can be achieved under such strong confinement.

9:24AM F15.00006: Analysis of run-reverse-reorient motility of Helicobacter pylori and its ΔChePep mutant

WENTIAN LIAO, Boston Univ, MAIRA A CONSTANTINO, National Institutes of Health, MANUEL RICARDO AMIEVA, Stanford University School of Medicine, RAMA BANSIL (Presenter), Boston Univ — The gastric disease causing bacteria, Helicobacter pylori utilize flagella driven motility and chemotaxis to detect external signals as they swim away from acid to cross the mucus layer and colonize the epithelial surface of the stomach. The lack of the chemotaxis regulator protein ChePep leads to increased reversal frequency (Howitt et al2). We analyze translational and cell body rotational motility data obtained by phase contrast microscopy to compare the speed and turn angle distribution of the wild type (WT) with the ΔChePep mutant and compare with run-reversal-reorient model and Resistive Force Theory calculations of torque. We observe higher reversal frequency of ΔChePep in agreement with previous observation, however the cell body rotational rate and torque are not influenced by the lack of protein ChePep. Interestingly, both WT and ΔChePep are most likely to maintain their initial run speed after a reorientation or a reversal event, although the distribution of the change in speed indicates that large speed changes by factor of two and beyond are possible.

9:36AM F15.00007: Force and torque on a rotating helical flagellum near a boundary

BRUCE RODENBORN (Presenter), CESAR ROMERO, JIN LEE, Centre College, HOA NGUYEN, ORRIN SHINDELL, Trinity University — As a free swimming bacterium approaches a boundary, both the propulsive force and torque on its helical flagellum increase rapidly. Though a constrained helical swimmer pumps the fluid, a similar increase in force and torque occur near a boundary (Das et al. 2018). We use scaled macroscopic experiments to measure this functional dependence of the force and torque as a constrained rotating helical flagellum approaches a boundary. We keep the Reynolds number in the experiments much less than unity to model bacterial fluid dynamics. These Reynolds-number-scaled experiments are compared with numerical simulations that use the method of images for regularized Stokeslets (Ainley et al. 2008). The computations find a similar functional dependence of force and torque on boundary distance. We also compare the results to biological measurements that use total internal reflection fluorescence microscopy to simultaneously measure the distance to the boundary and the dynamics of the bacteria. We show that all of the data can be collapsed onto a single curve by non-dimensionalizing the force, torque and boundary distance appropriately.

10:00AM F15.00009: Swimmers at low Reynolds number driven by Quincke rotation  ENDAO HAN (Presenter), LAILAI ZHU, JOSHUA SHAEVITZ, HOWARD A STONE, Princeton University — In biological systems, the rotation and oscillation of flagella and cilia play important roles in realizing certain functions, such as self-propulsion and fluid mixing. Most previous attempts to build artificial small swimmers use an oscillatory drive. Here we present an artificial swimmer at low Reynolds number driven by an elasto-electro-hydrodynamic instability [1] based on Quincke rotation: a sphere in oil rotates in the presence of a high DC electric field. In our experiments, by attaching thin elastic fibers to a solid plastic sphere, we created swimmers that exhibit diverse behaviors when varying different control parameters. We demonstrate that the flexibility of the fibers leads to multiple stable states, where the swimmer can have unidirectional rotation or oscillatory motion controlled by the applied field. Furthermore, we relate these modes of motion to the kinematic properties of the swimmer such as the rotational speed and the ability to generate locomotion.

10:12AM F15.00010: Aerotaxis in Sinorhizobium meliloti, a soil bacterium* JULIEN BOUVARD (Presenter), FREDERIC MOISY, HAROLD AURADOU, University of Paris Sud — The legume family needs the help of soil bacteria to fix the atmospheric nitrogen they need to grow. In order to do so, such bacteria, called rhizobia, are swimming towards the plants by following the chemical gradient created by their roots. One of the most common member of the rhizobia family, Sinorhizobium meliloti, is displaying this chemotactic behaviour as well as an aerotactic one. To study and compare this not yet referenced aerotaxis to the already found chemotaxis, we made a few experimental set-ups. The first one consists of a sealed chamber containing S. meliloti, in which we insert an air bubble. The second one is a capillary filled with bacteria, sealed at one end and closed with PDMS at the other. In these experiments, we notice the formation of a profile of motile bacteria peaked at the interface with the air bubble or the PDMS. We also uses microfluidic devices to control the oxygen gradient in which the bacteria are swimming. The characterization of the swimming behaviour in presence of oxygen will help us understand the motility of S. meliloti in situ, and thus could lead us to some culture optimizations.

10:24AM F15.00011: Pairwise and Collective Interactions of a Model Swimmer at Intermediate Reynolds Numbers* THOMAS DOMBROWSKI (Presenter), Univ of NC - Chapel Hill, AMNEET PAL SINGH BHALLA, San Diego State University, BOYCE E. GRIFFITH, DAPHNE KLOTSA, Univ of NC - Chapel Hill — In between the two extremes of Stokes flow, home to microorganisms, and inviscid flow, home to human swimmers and large fish, resides the less studied intermediate Reynolds regime where millimeter to centimeter sized organisms thrive. Here, both viscosity and inertia play a role in an organism’s movement, and few models have been developed which relate movement to general underlying physical mechanisms. In this presentation, we investigate pairwise interactions between reciprocal, asymmetric dumb-bell swimmers at intermediate Reynolds numbers (Re). Even for a single swimmer we find interesting behavior: a transition in the swimming direction from a small-sphere-leading to a large-sphere-leading regime. Their pairwise interactions are just as surprising. We computationally vary a broad range of parameters and find a wealth of states: steady pairs that cooperatively swim differently from individual swimmers under identical conditions, bi-stable pairs, orbits, and diverging paths. Averaged flow fields are analyzed to further understand these configurations. We continue by studying the collective behavior of large numbers of swimmers (up to a hundred) in order to identify pairwise versus many-body emergent behaviors.

10:36AM F15.00012: Hydrodynamics of biomimetic propulsion using externally and internally actuated fins*  ERSAN DEMIRER (Presenter), ALEXANDER ALEXEEV, Georgia Institute of Technology — We combine experiments and computer simulations to examine the hydrodynamics of two different actuation types that can be used to actuate an elastic plate to serve as a biomimetic propulsor in robotic fish. In the first case the elastic palate is actuated to perform sinusoidal plunging at the root, whereas in the second case the actuation is due to a distributed internal bending moment that represents piezoelectric actuation of smart materials such as macro fiber composites. The Morison equation is often used to characterize the forces acting on oscillating submerged bodies in terms of two parameters: the inertia and drag coefficients. We evaluate these parameters using our simulations and experiments. We find close agreement between the experiments and simulations for both actuation types. We find that the inertia coefficient depends strongly on the actuation type and the magnitude of the trailing edge displacement. We rationalize this dependency by analyzing the differences in the kinematics of the plates with different actuation types. Our results are useful for developing efficient propulsors for biomimetic underwater locomotion.

Session F16 DQI: Superconducting Qubit Materials, Fabrication, and Coherence I

8:00AM F16.00001: T1 of transmons with electrodes that have different gaps.*  KUNGANG LI (Presenter), FREDERICK C WELLSTOOD, CHRISTOPHER J LOBB, SUDEEP DUTTA, RUI ZHANG, SHAHRIRI KESHVARI, DYLAN POPPERT, University of Maryland, College Park — Using double-angle evaporation we fabricated a transmon which had one electrode formed by deposition of nominally pure aluminum and the counter-electrode formed by deposition of oxygen-doped aluminum. On the same sapphire chip, during the same pump-down of the evaporator we deposited a second transmon with both electrodes made from nominally pure aluminum. The energy gaps of the electrodes depend on the film thickness and the grain size, which is affected by the oxygen doping. Measurements of the relaxation time $T_1$ of the first device at 10 mK revealed a typical lifetime of about 200 microseconds while the second device had a typical $T_1$ of about 90 microseconds. When $T_1$ was measured as a function of temperature up to 300 mK, the two devices showed significantly different onset temperatures for the appearance of thermal quasiparticles. We compared our $T_1$ vs T results to a model based on the behavior of nonequilibrium quasiparticles residing in the electrodes and extracted the energy gap and the density of the non-equilibrium quasiparticles.

8:12AM F16.00002: Power and temperature dependence of High Q superconducting resonators
ASHISH ALEXANDER (Presenter), CHRISTOPHER WEDDLE, CHRISTOPHER RICHARDSON, Laboratory of Physical Sciences, University of Maryland, College Park — An integrated power and temperature dependent model of resonator quality factor predicts loss contributions from two-level systems and quasiparticles simultaneously. At millikelvin temperatures, in the presence of external power, the weak electron-phonon coupling between the phonons and quasiparticles may lead to quasiparticles thermalizing at a different temperature than phonons. Here we propose a two temperature power and temperature dependent model to evaluate resonator losses that considers quasiparticle and phonon temperatures to be different. Resonators fabricated from epitaxial molecular beam epitaxy grown aluminum and titanium nitride on float-zone refined silicon are evaluated to have quality factors above 1M. These results are analyzed with the proposed model and the contribution of various loss mechanisms will also be explored.

8:24AM F16.00003: Integration of InAs-Al Heterostructures into Microwave Circuit
JOSEPH YUAN (Presenter), MATTHIEU DARTIAILH, WILLIAM MAYER, NOAH GOSS, TRI D NGUYEN, KAUSHINI S WICKRAMASINGHE, KASRA SARDASHTI, JAVAD SHABANI, New York Univ NYU — Semiconductor-based Josephson junctions provide a platform to study the proximity effect and for the realization of topological superconductivity. Recently our group has demonstrated the possibility of having highly transparent contact between a superconductor and a semiconductor by combining high mobility Indium Arsenide (InAs) surface two dimensional electron gases (2DEGs) with epitaxially grown aluminum (Al) [1]. This allows for gate-tunable superconducting Josephson Junctions and consequently gate-tunable Transmons [2]. Here we present the integration of these InAs-Al heterostructures into microwave circuits such as Gatemon Qubits. The steps needed to fabricate on III-V material platform while mitigating microwave losses and microwave response will be discussed.

*We acknowledge support from the US Army Office of Research and the ARO/LPS QuaCGR fellowship.
**8:36AM F16.00004: Preprocessing Method for Microwave Resonator Fitting**  
KEEGAN MULLINS (Presenter), University of Colorado Boulder, COREY RAE MCRAE, DAVID PAPPAS, National Institute of Standards and Technology Boulder, JOSH Y MUTUS, Google Inc., HAOZHI WANG, National Institute of Standards and Technology Boulder, DAVID FORK, Google Inc. — We present a preprocessing method for S21 data from superconducting microwave resonators. In the field of quantum computing, it is becoming increasingly necessary to characterize loss in superconducting circuits to a higher degree of accuracy. The goal of the code implemented is to provide a rigorous standard for characterizing this loss. The method is implemented in python where the Diameter Correction Method, Inverse S21 method and Closest Pole and Zero method are all used in conjunction with the preprocessing. Accuracy of the preprocessing method is tested by comparing results from computer simulated resonator data from circuit elements to calculated values from the circuit elements of the simulated data. The preprocessing method entails a removal of the S21 data background by linear fit of the end points for both magnitude and phase, as well as the option to remove background from a user background file (a dataset of the same format without resonator behavior to establish a baseline). Testing the preprocessing method across varying parameters of circuit elements allows us to view correlation between preprocessing and error in determination of parameters.

*We acknowledge support from NIST Boulder, JILA labs CU Boulder and Google Quantum Computing.*

**8:48AM F16.00005: Materials Engineering in Superconducting Qubits**  
ALEXANDER PLACE (Presenter), BASIL M SMITHAM, LILA RODGERS, PRANAV MUNDADA, MATTIAS V FITZPATRICK, SARA SUSSMAN, ANJALI PREMKUMAR, JACOB BRYON, BERTHOLD JAECK, GUANGMING CHENG, HARSHVARDHAN BABLA, TRISHA MADHAVAN, AUSTIN FERRENTI, ANDRAS GYENIS, ROBERT J. CAVA, NAN YAO, NATHALIE DE LEON, ANDREW HOUCK, Princeton University — During the early days of superconducting qubits, increases in coherence times were frequently driven by improvements in materials and fabrication techniques. More recent advances have focused on manipulating capacitive, inductive, and Josephson energy scales, as well as engineering favorable qubit environments. In this talk we again focus on materials engineering of qubits. We explore how new materials and surface treatments can improve coherence times. Furthermore, we correlate the results of materials spectroscopy and time domain measurements to provide insight into relaxation mechanisms.

9:00AM F16.00006: Observation of individual two-level defects at material surfaces using circuit QED  
TIMOTHY KOHLER (Presenter), CHIH-CHIAO HUNG, University of Maryland, College Park, KEVIN OSBORN, NEDA FOROUZANI, Laboratory of Physical Science —  
The coherence of superconducting qubits have grown exponentially over the last decade. However, the coplanar electrodes used to shunt the JJ capacitance contain ubiquitous two-level system (TLS) defects on its surfaces. These defects are a major source of loss and decoherence in general, and the characteristics of the surface TLS are largely unknown. In an aluminum thin film on sapphire substrate we observe individual surface TLS using a DC electric-field bias in an interdigitated shunting capacitor with a submicron linewidth and line spacing. We use an electrical bridge of capacitors to apply the dc bias to manipulate the TLS energies allowing us to observe a hyperbolic dependence as well as splittings with the resonator. This technique allows us to capture the TLS average dipole moment as well as coherence time.

9:12AM F16.00007: TBD [Invited]

9:48AM F16.00008: The dielectric dipper: a differential technique to measure dielectric loss tangents with high sensitivity*  
ALEXANDER P READ (Presenter), KAICHENG LI, BENJAMIN J. CHAPMAN, CHAN U LEI, VIJAY JAIN, Yale University, CHRISTOPHER AXLINEN, ETH Zurich, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Dielectric loss is suspected to limit superconducting qubit lifetimes. This could be tested by a measurement capable of detecting bulk dielectric loss smaller than the bound inferred from recent experiments (i.e., loss tangent less than $10^{-7}$). We have devised a method for characterizing bulk dielectric loss with a sensitivity on the order of $10^{-8}$. The method is compatible with cryogenic temperatures and single-photon powers and does not require lithographic processes. This allows for rapid comparison of isolated substrates, processing techniques, and their statistical variations. Such comparisons will inform designs and practices to better minimize dielectric loss. We present experimental comparisons of common dielectric substrates measured using this method.

*This research is supported by US Army Research Office modular grant W911NF-18-1-0212.
10:00AM F16.00009: Transmon qubit in a magnetic field: Evolution of coherence and transition frequency

MARTIN WEIDES (Presenter), University of Glasgow, ANDRE SCHNEIDER, TIM WOLZ, MARCO PFIRRMANN, MARTIN SPIEKER, HANNES ROTZINGER, ALEXEY V. USTINOV, Karlsruhe Institute of Technology — We report on spectroscopic and time-domain measurements on a fixed-frequency concentric transmon qubit in an applied in-plane magnetic field to explore its limits of magnetic field compatibility. We demonstrate quantum coherence of the qubit up to field values of $B=40mT$, even without an optimized chip design or material combination of the qubit. The dephasing rate $\Gamma_\phi$ is shown to be unaffected by the magnetic field in a broad range of the qubit transition frequency. For the evolution of the qubit transition frequency, we find the unintended second junction created in the shadow angle evaporation process to be non-negligible and deduce an analytic formula for the field-dependent qubit energies. We discuss the relevant field-dependent loss channels, which cannot be distinguished by our measurements, inviting further theoretical and experimental investigation. Using well-known and well-studied standard components of the superconducting quantum architecture, we are able to reach a field regime relevant for quantum sensing and hybrid applications of magnetic spins and spin systems.

10:12AM F16.00010: Design of The Merged Element Transmon Qubit

SUNGOH PARK (Presenter), University of Colorado Boulder, RUICHEN ZHAO, COREY RAE MCRAE, National Institute of Standard and Technology Boulder, JUNLING LONG, TONGYU ZHAO, University of Colorado Boulder, RUSSELL LAKE, Bluefors, MUSTAFA BAL, HAOZHI WANG, DAVID PAPPAS, National Institute of Standard and Technology Boulder — Transmon qubits are one of the most promising candidates for building a universal quantum processor. They consist of two discrete elements: a nanoscale Josephson junction (JJ) and a coplanar capacitor. In conventional transmon designs, the plates of the shunt capacitor have to be very large to achieve low participation ratio of the lossy interfaces. To circumvent this issue, we propose to engineer the device so that the electric field distribution is confined to junction dielectric by merging the capacitor and JJ into a single superconductor/dielectric/superconductor trilayer structure such that the frequency, anharmonicity, and $E_J/E_C$ parameters are in the transmon regime. We refer to this architecture a mergemon to distinguish it from conventional designs. We explore different low-loss dielectrics such that the trilayer itself would provide not only the nonlinear inductance but also most of the capacitance of the transmon qubit. By FEM based simulation, we design the mergemon qubit-readout resonator to be in the strong dispersive regime. We also verify that this design can be realized with standard optical lithography process. Finally, we also discuss possibility of leveraging the state-of-the-art molecular-beam epitaxy technology to enhance the coherence of the mergemon.
10:24AM F16.00011: Improving the performance of superconducting coplanar waveguide resonators using interface engineering*  ARCHAN BANERJEE (Presenter), Lawrence Berkeley National Laboratory, MOHAMMED ALGHADEER, AHEMD HAJIR, King Fahd University of Petroleum and Minerals, JOHN MARK KREIKEBAUM, University of California, Berkeley, FRANK OGLETREE, VIRGINIA ALTOE, Lawrence Berkeley National Laboratory, SALEEM RAO, King Fahd University of Petroleum and Minerals, IRFAN SIDDIQI, University of California, Berkeley — Superconducting resonators are a key component in quantum circuits. While extensive research has explored techniques to improve the quality factor of such devices, the precise structure of amorphous dielectric layers on surfaces and interfaces and their associated loss mechanism remains a topic of active discussion. In this study, we explore the characterization and the fabrication of niobium coplanar waveguide resonators with more than $10^6$ internal quality factor at single-photon-excitation power (measured at 100 mK) for a variety of different surface treatments. Following electrical measurements, resonator samples have been probed using a suite of structural characterization tools (XPS, TEM and AFM) in order to correlate the efficacy of surface treatment with resonator quality factor. We also compare our measurement results with numerical simulations.

*This work was funded by U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05-CH11231 within the QISLBNL program.

10:36AM F16.00012: Reliable Growth of TaN Superconducting Film with Atomic Layer Deposition for Quantum Circuit Applications*  WONHO SONG (Presenter), Ulsan Natl Inst of Sci & Tech, SUNGCHUL JUNG, SK Hynix, JUNHYUNG KIM, Ulsan Natl Inst of Sci & Tech, GAHYUN CHOI, JOONYOUNG LEE, YONUK CHONG, Korea Research Institute of Standards and Science, KIBOG PARK, Ulsan Natl Inst of Sci & Tech — Atomic layer deposition (ALD) is a well-known method to grow a thin film which can ensure the uniformity and conformality of the grown film. In this work, several different thicknesses of TaN thin films are grown on SiO$_2$/Si or Si substrates with plasma enhanced ALD process using the Tris(diethylamido)(tert-butylimido)tantalum(TBTDET) precursor reacted with H$_2$ gas. The grown TaN films show superconductivity reproducibly and their transition temperatures vary in the range of 3-5 K depending on the film thickness. The superconducting transition temperature and microwave transmission properties of TaN films will be analyzed in terms of their correlation with DC transport parameters including carrier type, carrier density, and carrier mobility obtained from Hall effect measurements.

10:48AM F16.00013: Microwave Loss in High-Q Titanium Nitride Resonators  RUI ZHANG (Presenter), ASHISH ALEXANDER, University of Maryland, College Park, CHRISTOPHER RICHARDSON, Laboratory of Physical Sciences, FREDERICK C WELLSTOOD, University of Maryland, College Park, BENJAMIN PALMER, Laboratory of Physical Sciences — We have measured the loss in a superconducting thin film titanium nitride microwave resonator from 20 mK to 1 K and at different stored microwave powers. The titanium nitride film had a superconducting transition temperature of $T_c = 5.5$ K and was grown in an MBE by reactively reacting evaporated titanium in a nitrogen plasma. The measured internal loss of the resonator is found to decrease by approximately a factor of 10 from $Q^{-1} = 2.5 \times 10^{-6}$ at low applied microwave powers and low temperatures to $Q^{-1} = 2.5 \times 10^{-7}$ at large applied powers and a temperature of 600 mK. We compare the measured $Q$ data to a model based on loss from the interaction of the superconducting resonator with lossy two-level systems and separately to a model we have developed based on non-equilibrium quasiparticles accumulating in regions of the TiNx film with a lower superconducting gap ($D$). To distinguish between these competing models, we will also discuss results where we apply superconducting pair-breaking infrared light directly to the resonator device and measure the loss.

Session F17 DQI: Focus Semiconductor Spin Qubit Readout 203 - Jason Petta, Princeton University - Tag(s): Focus

8:00AM F17.00001: Readout of small-scale semiconductor spin-qubit arrays [Invited]  ANASUA CHATTERJEE (Presenter), Niels Bohr Institute, University of Copenhagen — The engineering of readout methods becomes crucial as single qubits are scaled up in linear and two-dimensional arrays to form NISQ processors. In particular, fast, high-fidelity and simultaneous measurements across these small arrays are essential. I will present our work on readout techniques and scaling efforts, in particular involving RF-reflectometry, in small two-dimensional arrays of quantum dots in GaAs and silicon. In these systems we utilize techniques such as crosstalk mitigation, multi-qubit DC and pulse calibration, sensor compensation, virtual gates, and adaptive searching in high-dimensional spaces. First, I will discuss simultaneous, single-shot, and interlaced measurements for singlet-triplet spin qubits, performed via four independent sensors spaced across a GaAs chip. I will also show single-shot reflectometry measurements via compact gate-based dispersive sensing, carried out in a two-dimensional CMOS silicon array. These methods, combined with pulsed-gate techniques, enable deterministic single-electron shuttling within the array, and may be beneficial for many other quantum-dot devices or spin- and charge-based hybrid systems.

*In collaboration with Fabio Ansaloni, Federico Fedele, Heorhii Bohuslavskyi, Saeed Fallahi, Geoffrey C. Gardner, Michael J. Manfra, Louis Hutin, Maud Vinet, Yann-Michel Niquet, Silvano De Franceschi, and Ferdinand Kuemmeth.
Cascade-Based Fast, High-Fidelity and Scalable Spin Readout

CORNELIS VAN DIEPEN (Presenter), TZU-KAN HSIAO, UDITENDU MUKHOPADHYAY, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zürich, LIEVEN M VANDERSYPEN, Delft University of Technology — Spin-qubits based on gate-defined semiconductor quantum dots are a promising platform for quantum computation and simulation. An important advantage of quantum dots is their small footprint. The dot pitch is about 100 nm, hence 100 million dots fit on 1 mm². A problem is that qubit readout with charge sensing based on capacitive coupling only enables to sense nearby quantum dots and placing charge sensors within the quantum dot array hosting the qubits is detrimental for connectivity. Here, we report on cascade-based fast, high-fidelity and scalable spin readout. The cascade consists of an initial charge transition, far away from the sensor, and subsequent charge transitions induced by Coulomb repulsion, with the final transition nearby the sensor. Combined with spin-to-charge conversion a cascade enables the readout of charge and spin occupation of quantum dots remote from the charge sensor. We demonstrate fast and high-fidelity spin readout by performing Pauli spin blockade with a cascade implemented in a quadruple dot with a sensing dot. The cascade-based readout is a promising alternative for readout of large quantum dot arrays compared to gate-dispersive readout or state transfer via either shuttling or logical operations.

*The work is supported by NWO, ERC and SNF.

Fast charge sensing in undoped silicon quantum dots with radio-frequency reflectometry

AKITO NOIRI (Presenter), KENTA TAKEDA, JUN YONEDA, TAKASHI NAKAJIMA, Center for Emergent Matter Science (CEMS), RIKEN, TETSUO KODERA, Department of Electrical and Electronic Engineering, Tokyo Institute of Technology, SEIGO TARUCHA, Center for Emergent Matter Science (CEMS), RIKEN — Fast and sensitive charge sensing is an essential ingredient in quantum dot (QD) based spin qubit experiments. A performance of the charge sensing can be drastically improved by embedding the sensor in a radio-frequency (rf) tank circuit [1]. While the technique is commonly used in depletion-mode devices, applying it to accumulation-mode devices is a challenge due to a large parasitic capacitance by accumulation gates [2]. In this presentation, we report how to reduce this capacitance and realize charge sensing by the rf reflectometry in undoped Si/SiGe QDs. To this end, we introduce a specially designed device geometry comprising a small accumulation gate area [3]. We observe that the reflected rf power changes more than 30 dB by modulating the sensor conductance, which allows sensitive charge sensing. We achieve single-shot singlet-triplet readout with a SNR of 6 in an integration time of 0.8 μs.

9:00AM F17.00004: Rapid high-fidelity spin state readout in Si/SiGe quantum dots via radio-frequency reflectometry*  
JJ NELSON (Presenter), ELLIOT CONNORS, JOHN NICHOL, University of Rochester — Radio-frequency (rf) reflectometry, while enabling rapid high-fidelity readout of GaAs spin qubits, is challenging to implement in accumulation-mode Si quantum dot devices. The difficulty arises when a large parasitic gate capacitance is distributed along a relatively large resistance two-dimensional electron gas (2DEG). Here we will present minor design changes that when implemented in a Si/SiGe quantum dot device enable charge readout fidelity above 99.9% in 300ns using rf reflectometry. The rf compatible Si design can perform single-shot readout of spin states via spin-selective tunneling in microsecond integration times. We will also show high fidelity singlet and triplet readout of a double quantum dot via Pauli spin blockade. With the use of a charge latching mechanism we achieve a maximum fidelity of 99.0%.

9:12AM F17.00005: Repetitive Quantum Nondemolition Measurement of a Silicon Spin Qubit Using Different Decodings  
XIAO XUE (Presenter), Delft University of Technology, BENJAMIN D’ANJOU, McGill University and University of Konstanz, THOMAS F WATSON, Delft University of Technology, DAN R. WARD, DONALD E SAVAGE, MAX G LAGALLY, MARK G FRIESEN, SUSAN NAN COPPERSMITH, MARK ALAN ERIKSSON, University of Wisconsin-Madison, WILLIAM COISH, McGill University, LIEVEN M VANDERSYPEN, Delft University of Technology — Silicon spin qubits show great promise for fault-tolerant quantum computing. As an essential step towards practical quantum error correction, quantum nondemolition (QND) measurements are needed to efficiently detect the state of a logical qubit without totally losing track of its state. Here we implement QND measurements in a Si/SiGe two-qubit system [1], with one qubit as the logical qubit and the other as the ancilla. Making use of a two-qubit controlled-rotation gate, the state of the logical qubit is mapped onto the ancilla, followed by a destructive readout of the ancilla. In contrast, QND measurement does not destroy the logical qubit but keeps it at the same state after the collapse caused by the first measurement, which allows us to enhance the readout fidelity by multiple QND measurements. Moreover, we also make use of a new analysis method called soft decoding to extract additional information on the state of the logical qubit [2]. We compare the two methods and discuss the conditions for which soft decoding provides an advantage.

Single-shot single-electron spin readout with a single-lead quantum dot charge sensor

MARK R HOGG, ANDREY V TIMOFEEV, PRASANNA PAKKIAM, SAMUEL KEITH GORMAN, MATTHEW HOUSE (Presenter), MICHELLE Y SIMMONS, Univ of New South Wales — “Gate-based”, or dispersive, charge sensors for the readout of semiconductor spin qubits have been growing in popularity because these compact sensors integrate readout capability into electrical control structures. However, dispersive readout can only directly measure a spin state in a double quantum dot, either by Pauli blockade or with a large magnetic field gradient. Here we demonstrate a dispersively-probed single-lead quantum dot (SLQD) charge sensor which senses the charges on four quantum dots, each defined with P atoms in Si using scanning tunnelling microscope lithography. With this charge sensor we demonstrate single-shot, single-spin readout via energy-selective tunnelling. We achieve a voltage signal-to-noise ratio of 8 for charge detection with a measurement bandwidth of 15 kHz and demonstrate spin readout with high fidelities of up to 97.4% at 2.5 Tesla. The capacitive coupling between all four quantum dots and the charge sensor is strong enough that there is no loss of sensitivity for detecting the more distant quantum dots, up to about 100 nm away from the sensor. Good sensitivity, compact geometry, and long-range sensing makes the SLQD a promising choice of sensor for scaling up future atomic-precision single-spin qubit devices to larger numbers of qubits.

Theory of Pulsed Spectroscopy in Quantum Dots: Interdot Dynamics

ANDREW PAN (Presenter), HRL Laboratories, LLC — Understanding the energy structure and dynamics of excited states in quantum-dot qubits is critical for device design and operation. Incoherent methods for probing these quantities typically call for loading from neighboring baths or applying large external magnetic or RF fields. These methods may be problematic if they require operating conditions far from the intended qubit environment. We have developed a technique to characterize these quantities using typical tune-up conditions, relying on the incoherent dynamics of interdot charge transitions. In the first half of this two-part talk, we examine theoretically how tunneling, dephasing, and detuning-dependent relaxation affect the time-dependent populations near charge transition points and allow excited states to be resolved. We compare these expectations to experimental results in Si/SiGe quantum dots. Potential connections to the dynamics relevant for spin qubit readout are considered.

Pulsed Spectroscopy of Si/SiGe Quantum Dots: One- and Two-Electron Valley-Orbit Excited States

KATE RAACH (Presenter), HRL Laboratories, LLC — The one- and two-electron energy spectra of silicon quantum dots can be complicated due to the interplay of valley and orbital degrees of freedom, affecting all aspects of spin qubit operation. For instance, in exchange-only qubits, low-lying single electron excitations are relevant during coherent evolution, while the two-electron singlet-triplet splitting limits the initialization and readout fidelity. In the second half of this two-part talk, we present experimental data and analysis of this energy structure using pulsed techniques to simultaneously probe multiple valley and orbital states of double quantum dots. We discuss the variations in one- and two-electron structure across dots and as a function of bias and how they compare with theoretical expectations.
10:00AM F17.00009: Developing Monolithic Superconducting Resonators for Gate-Based Quantum Dot Readout  ZAC BARCIKOWSKI (Presenter), University of Maryland, College Park, MICHAEL DAVID STEWART, MUSTAFA BAL, National Institute of Standards and Technology, CHRISTOPHER RICHARDSON, Laboratory for Physical Sciences, DAVID PAPPAS, JOSHUA POMEROY, National Institute of Standards and Technology — Gate-based sensing using resonant circuitry has been identified as a promising path towards high fidelity, fast, and compact readout for semiconductor quantum computing architectures. By coupling a quantum dot (QD) system to an LC resonator, the state is inferred via the reflected phase response. The resistive loss in the discrete inductors and loss associated with wirebonds often limit measurement sensitivity. In contrast to oft used surface mount components, we have fabricated Nb superconducting resonators to reduce resistive loss and will explore additional high kinetic inductance materials. The resonators are intended for monolithic integration with QD gates to reduce resonator-gate loss. We present transmission and reflection data used to assess our ability to deterministically fabricate resonators with designed inductance and capacitance values. Efforts to optimize resonance quality factor and integrate resonators with QDs are discussed.

10:12AM F17.00010: Non-Markovian qubit spectroscopy in cavity QED  ZOÉ MCINTYRE (Presenter), WILLIAM COISH, McGill Univ — The strong-coupling regime of cavity quantum electrodynamics (QED) can be identified spectroscopically from a peak splitting (~qubit-cavity coupling) that is large compared to the qubit decoherence and cavity decay rates. This interpretation normally relies on a Markovian model of qubit dynamics together with input-output theory. A Markovian description may however break down for charge qubits (coupling to ~1/f noise) or spin qubits (coupling to a slow nuclear-spin bath). Motivated by very recent work showing strong coupling of spin/charge qubits coupled to superconducting microwave resonators, we use a generalized input-output theory to account for a generic non-Markovian environment. This allows us to calculate a spectroscopic lineshape that fully accounts for non-Markovian features and which may be relevant to recent experiments.
10:24AM F17.00011: Low-magnetic field single-spin qubit operation in isotopically enriched silicon* RUICHEN ZHAO (Presenter), TUOMO TANTTU, University of New South Wales, KUAN YEN TAN, Aalto University, BAS HENSEN, KOK WAI CHAN, JASON HWANG, ROSS LEON, CHIH-HWAN YANG, WILL GILBERT, FAY E. HUDSON, University of New South Wales, KOHEI M ITOH, Keio University, ANDREY KISELEV, THADDEUS D LADD, HRL Laboratories, ANDREA MORELLO, ARNE LAUCHT, ANDREW STEVEN DZURAK, University of New South Wales — Single-spin qubit readout traditionally relies on selective tunneling to a neighboring reservoir. It requires sophisticated microwave engineering to deliver high-frequency qubit drives to the quantum chip from room-temperature electronics, which will be a challenge for scaling of a silicon-based quantum processor. Here we present an alternative scheme where we use high-fidelity Pauli spin blockade readout to enable single-spin qubit operation in a magnetic field as low as 150mT. We discover the qubits decohere faster in low magnetic fields due to the background (800 ppm) $^{29}$Si nuclear spins in the isotopically enriched substrate. A simulation modeling the nuclear spin induced qubit frequency fluctuation produced results consistent with our experimental data. This work indicates that further isotopic enrichment may be needed to achieve the high fidelities required for a scalable quantum processor.

*This research is funded by the Australian Research Council (CE170100012), the US Army Research Office (W911NF-17-10198), and, in part, by Silicon Quantum Computing Proprietary Limited.

10:36AM F17.00012: Adiabatic conversion for qubit readout: Optimal pulse shapes and dephasing FELIX FEHSE (Presenter), Physics, McGill University, Montreal, Canada, MICHEL PIORO-LADRIERE, Physics, Université de Sherbrooke, Sherbrooke, Canada, WILLIAM COISH, Physics, McGill University, Montreal, Canada — Adiabatic conversion schemes are commonly used to measure quantum states. These schemes may include, e.g., spin-to-charge conversion for spins in quantum dots or parity-to-charge conversion for qubits based on Majorana zero modes. In all of these schemes, a common element is that dephasing is minimized at an "operating point" (e.g., for the 'spin' or 'parity' quantum number), but measurement-induced dephasing is maximized at the "measurement point". The balance between 'adiabaticity' and dephasing can be optimized to improve performance of these readout schemes. We give an explicit construction that allows for optimal state conversion in qubit readouts. Applying this scheme to the specific case of spin qubits in quantum dots, we show that a high-fidelity (better than 99.9%) single-shot all-electrical readout is possible.
Recent advances towards employing quantum dots (QD) as a platform for quantum computation and simulation have shown promising results [1]. However, as the control parameters space grows significantly with increasing number of QDs, working with large QD arrays is challenging. Thus, finding a scalable and non-heuristic control approach to tune the electronic configuration in QDs is necessary. Due to high-dimensional patterns defining dot states, machine learning (ML) algorithms present a natural solution.

In this project, we extend a recent proposal [3,4] of employing a ML-based auto-tuner to linear QD devices to the more general case of 2D arrays. We use a Thomas-Fermi solver to establish an ensemble of simulated measurements for 2x2 QD arrays. This data set allows us to train and evaluate an image-based classifier that maps the charge stability diagrams showing the electronic configuration of the QD device into classes defining the number of dots formed in the system. This work will set foundations for research on machine learning-based control of 2D QD devices.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F18 DSOFT: Non-Equilibrium Bioinspired Modes of Assembling Materials 205 - Cecilia Leal, University of Illinois at Urbana-Champaign - Tag(s): Invited
Bioinspired liquid crystal patterns to command living matter*
OLEG D LAVRENTOVICH (Presenter), Department of Physics, Chemical Physics Interdisciplinary Program, and Advanced Materials and Liquid Crystal Institute, Kent State University — Microscale biological systems such as swarms of swimming bacteria and cell tissues demonstrate fascinating out-of-equilibrium dynamics. This dynamics is difficult to control by factors other than transient gradients, such as gradients of nutrients; visual, acoustic and tactile communication channels that humans use to control large animals are not effective. To establish communication with microscale biological systems, we propose to use special class of nontoxic lyotropic chromonic liquid crystal with a long-range orientational order. The anisotropy axis of the liquid crystal can be designed as uniform or be pre-patterned into various structures. We describe how the patterned liquid crystals can be designed to command dynamics of two systems, (i) swimming bacteria; (ii) tissues formed by human dermal fibroblast cells. Topological defects in liquid crystals are demonstrated to impact the biological microstructures most strongly, causing spatial variation of bacterial concentration and cell phenotype. The control of active matter by patterned liquid crystals might result in new approaches to harness the energy of collective motion for micro-robotic, biomechanical, and sensing devices.

*The work is supported by DOE DE-SC0019105, NSF DMS-1729509, CMMI-1663394 grants.

Reaction-Diffusion Driven Pattern Formation in Soft Materials*
NANCY SOTTOS (Presenter), EVAN M LLOYD, LEON DEAN, JEFFREY MOORE, Beckman Institute, University of Illinois at Urbana-Champaign — Reaction-diffusion processes are versatile, yet underexplored methods for manufacturing that provide unique opportunities to control the spatial properties of materials, achieving order through broken symmetry. The mathematical formalism and derivation of equations coupling reaction and diffusion were presented in the seminal paper by Alan Turing [Phil. Trans. R. Soc. Lond. B 237, 37, 1952], which describes how random fluctuations can drive the emergence of pattern and structure from initial uniformity. Inspired by reaction-diffusion systems in nature, this talk will describe a new processing strategy predicated on the exploitation of an advancing polymerization front sustained through coupled reaction and thermal diffusion. The system uses the exothermic release of energy to provide a positive feedback to the reaction. In turn, this stimulates further exothermic energy release and a self-propagating reaction “front” that rapidly moves through the material – a process called frontal polymerization. We recently reported the frontal ring-opening metathesis polymerization (FROMP) of dicyclopentadiene (DCPD) that exhibits the high energy density, high reactivity, relatively long pot life, and low viscosity required for the synthesis of high-performance thermosetting polymers and composites [Robertson et al., Nature, 557 (2018)]. This talk will describe several novel methods to control thermal transport in this system, giving rise to symmetry breaking events that enable complex, emergent pattern formation and control over growth, topology, and shape.

Silvia Vignolini Invited Talk

Jay Groves Invited Talk
Programming dynamic pathways to colloidal self-assembly using DNA nanotechnology* [invited]  WILLIAM ROGERS (Presenter), ALEXANDER HENSLEY, Brandeis Univ — DNA is not just the stuff of our genetic code; it is also a means to build new materials. For instance, grafting DNA onto small particles can, in principle, 'program' the particles with information that tells them exactly how to put themselves together--they 'self-assemble.' Recent advances in our understanding of how this information is compiled into specific interparticle forces have enabled the assembly of crystalline phases. However, programmable assembly of other user-prescribed structures, such as aperiodic solids, liquids, or other mesophases remains elusive. Furthermore, the dynamic pathways by which DNA-based materials self-assemble are largely unknown. In this talk, I will present experiments showing that: (1) combining DNA-grafted particles with free DNA oligomers dispersed in solution can create suspensions with new types of assembly pathways; and (2) we can quantify the dynamic pathways to self-assembly, such as nucleation and growth, using a combination of microfluidics, video microscopy, and image analysis. Whenever possible, I will describe attempts to understand and model our observations using simple physical arguments. In the future, this work could prove especially useful in nanomaterials research, where a central goal is to manufacture functional materials by growing them directly from solution.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F19 GMAG: Correlated and Magnetic Topological Materials

8:00AM F19.00001: Three-dimensional correlated topological semimetals* [Invited]  JOHANNES GOOTH (Presenter), Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — The physics of topological materials is typically well described by the band theory of non-interacting fermions. In contrast, some of the most fascinating effects in condensed matter physics merely emerge from electron correlations. Here, we will present two recent examples of phases of matter, arising from the interplay of interaction and non-trivial topology: an axionic charge density wave and three-dimensional quantum Hall states. Our electrical transport measurements reveal a positive longitudinal magnetoconductance in the sliding mode of the quasi-one-dimensional CDW–Weyl semimetal (TaSe₄)₂I, a signature that is linked to the presence of an axionic phason. In addition, we report the observation of integer and fractional quantum Hall plateaus in the bulk semimetal HfTe₅.

*European Union’s Horizon 2020 research and innovation program under Grant Agreement ID 829044 “SCHINES”.
The advent of Topological Quantum Chemistry (TQC) and Magnetic Topological Quantum Chemistry (MTQC) provides a straightforward approach to look at the topological properties of a material through ab-initio calculations. Combined with the non-magnetic material database from the Inorganic Crystal Structure Database and the Bilbao Magnetic Material Database, this allows for a systematic search of topological materials. In this talk, we will present the two databases of topological materials that we now provide to the community. Overall more than 37000 non-magnetic and 470 magnetic unique materials are available with a full topological characterization.
Weyl semimetals are gapless topological materials, breaking either spatial inversion or time reversal symmetry, that host Weyl fermions in the bulk and topological Fermi arc states on their surface. The time reversal symmetry broken Weyl semimetals are particularly attractive since they enable to study the interplay between magnetism, electron correlations, and topology. While several inversion symmetry broken Weyl semimetals have been verified experimentally, showing unambiguous evidence for a time reversal symmetry breaking Weyl semimetal is quite challenging. We used scanning tunneling spectroscopy to study the ferromagnetic semimetal $\text{Co}_3\text{Sn}_2\text{S}_2$ and verified spectroscopically its classification as a time-reversal symmetry-broken Weyl semimetal [1]. In my talk I will describe how we visualize the topological “Fermi arc” states using quasiparticle interference measurements and show that the measured band structure of $\text{Co}_3\text{Sn}_2\text{S}_2$ exhibits direct signature of time reversal symmetry breaking, induced by the magnetic order of the Co atoms. By investigating three distinct surface terminations of the sample we examined complementary aspects of the surface and bulk band structure. I will describe the various surface and bulk electronic properties we extracted from each of the terminations. In particular I will demonstrate that the three different terminations of $\text{Co}_3\text{Sn}_2\text{S}_2$ exhibit not only distinct Fermi-arc contours, but also distinct connectivity between the Weyl nodes. The observed Weyl node connectivity changes from intra Brillouin zone connectivity on the Sn termination to a cross Brillouin-zones on the Co termination. This has significant implication on the magneto-transport properties of the Weyl electrons. Finally, the S termination allowed us to extract the extent of the Weyl gap by following the surface state dispersion. This provides a clear demonstration of the surface bulk correspondence in Weyl semimetals.

Chiral and magnetic topological semimetals

(NIELS SCHRÖTER)
(Invited)

Paul Scherrer Institute — Chiral topological semimetals (which possess neither mirror nor inversion symmetries) are expected to host numerous novel phenomena, such as multifold fermions with large topological charge, long Fermi-arc surface states, unusual magnetotransport and lattice dynamics, and a quantized response to circularly polarized light. Until recently, all experimentally confirmed topological semimetals crystallized in space groups that contain mirror operations, which means that the aforementioned phenomena vanish [1].

Here, I will present evidence from angle-resolved photoelectron spectroscopy that a family of intermetallic catalysts, including PtAl and PdGa [1,2], are chiral topological semimetals. We directly visualize the exotic multifold fermions in these materials and show that they carry the largest possible Chern number that is available in any material. We also show experimentally that there is a direct relationship between the handedness of the crystal structure and the electronic chirality (i.e. the Chern number sign) of the multifold fermions. This finding demonstrates that structural chirality can be used as a tuning knob to control the direction of topological photocurrents, which is sensitive to the Chern number sign.

Furthermore, I present evidence for multifold fermions in structurally chiral magnetic materials and show that CoS$_2$ - a putative half-metal - is in fact not-half metallic, but may host topological surface states that could affect its performance as a spin-injector.

Chiral spin textures: anti-skyrmions, elliptical skyrmions and Néel skyrmions

(STUART PARKIN)
(Invited)

Max Planck Inst Microstructure — Magnetic non-collinear spin textures that are chiral are of great current interest. We discuss various spin textures that range from chiral domain walls in synthetic antiferromagnetic racetracks to anti-skyrmions and elliptical skyrmions in inverse tetragonal Heusler compounds to Néel skyrmions in a non-centro-symmetric hexagonal ternary compound. We compare the properties of these distinct spin textures to skyrmions and to magnetic bubbles. We show that the symmetry of the Dzyaloshinskii-Moriya exchange that stabilizes many of these spin textures strongly influences the properties of the spin textures including especially their size, which in some cases, strongly depends on the thickness of the lamella in which they are observed. Using a combination of Lorentz transmission electron microscopy and magnetic force microscopy we show that for anti-skyrmions, which we have observed in several inverse tetragonal Heusler compounds, the diameter of the anti-skyrmion can be varied by more than an order of magnitude from <100 nm to more than 1 micron. This tunability is related to the important role of magnetic dipole-dipole interactions.

Information extraction, analysis and feedback for directing matter by design [Invited] BOBBY SUMPTER (Presenter), Oak Ridge National Laboratory — Recent technical advances in the area of nanoscale imaging, spectroscopy and scattering/diffraction have provided tremendous capabilities for investigating materials structural, dynamical and functional characteristics. At the same time, advances in computational algorithms, including deep learning approaches, and computer capacities that are orders of magnitude larger and faster, have enabled extreme-scale simulations and deep data analytics of materials properties and processes starting with nothing but the identity of the atomic species and the basic principles of quantum and statistical mechanics and thermodynamics. This powerful confluence of capabilities/advances and the information bound in large volumes of high-quality data, offers new opportunities for advancing materials and chemical sciences. In this talk I will discuss how we are probing in-situ, chemical reactions and materials transformations, including hierarchical assembly, as a modality for direct feedback to an experiment in order to precisely impart directed energy (electrons, ions, photons, thermal) that manipulates a material at the nanoscale. This approach is enabled via the dual capability of high-resolution imaging and focused energy in-situ, with data rates, quality and volumes that allow for a deep learning framework to efficiently identify structures and dynamics across broad length and time scales. We have found that the approach can provide efficient mapping of solid-state reactions and transformations and overall allows a major step toward directing matter by design.

This research was conducted at the Center for Nanophase Materials Sciences, which is a US Department of Energy Office of Science User Facility.
8:36 AM F20.00002: High throughput search for plasmonic semiconductors using DFT databases*  ETHAN SHAPERA (Presenter), Physics, University of Illinois at Urbana-Champaign, ANDRE SCHLEIFE, Materials Science and Engineering, University of Illinois at Urbana-Champaign — The field of plasmonics aims to manipulate light via choice of materials and nanoscale structuring. Finding materials which exhibit low-loss responses to applied optical fields while remaining feasible for widespread use is an outstanding challenge. Online databases have compiled structural and electronic data for of tens of thousands of materials, but lack the expensive optical response calculations needed for selection of plasmonic materials. Understanding the optical response of semiconductors within DFT is complicated due to the DFT bandgap error and the influence of carrier doping density. We describe, validate, and demonstrate an approach which rapidly screens existing online databases to identify high quality factor plasmonic semiconductors. Using DFT bandstructures, we tabulate material bandgaps, optical transition energies, and effective masses. From correlations between bandstructure features and quality factor computed for a restricted set of semiconductors we predict CaMg$_2$N$_2$, InGaO$_3$, and LiInO$_2$ as candidate high quality factor plasmonic semiconductors. Quality factors are verified with DFT to describe optical absorption and the Drude model for intraband transitions.

8:48 AM F20.00003: Combined High-Throughput and Machine Learning Approach for Prediction of Lattice Thermal Conductivity  RINKLE JUNEJA, GEORGE YUMNAM, SWANTI SATSANGI, ABHISHEK SINGH (Presenter), Indian Institute of Science — Search for materials via explicit evaluation of thermal conductivity ($\kappa_l$) either experimentally or computationally is very challenging. We carried out high-throughput screening on a dataset containing total of 2691 binary, ternary, and quaternary compounds. The $\kappa_l$ values of 120 dynamically stable and nonmetallic compounds are calculated. Among these, 11 ultrahigh and 15 ultralow $\kappa_l$ materials are identified. For the machine learning prediction models, the descriptor set is usually tuned via conventional algorithms such as least absolute selection and shrinkage operator (LASSO). However, we generated an extensive property map from high-throughput calculations to design a minimal set of descriptors directly related to the physics of $\kappa_l$. These simple descriptors are maximum phonon frequency, integrated Grüneisen parameter up to 3 THz, average atomic mass, and volume of the unit cell. Using these descriptors, a Gaussian process regression-based machine learning (ML) model is developed. The model predicts room temperature log-scaled $\kappa_l$ with a very small root mean square error. The superior performance of the ML model can ensure a reliable and accelerated search for a multitude of low and high $\kappa_l$ materials.

9:00AM F20.00004: Machine Learning-Assisted Design and Discovery of Next Generation 2D Materials  VICTOR VENTURI (Presenter), HOLDEN LOW PARKS, ZEESHAN AHMAD, VENKAT VISWANATHAN, Carnegie Mellon Univ — Atomically thin two-dimensional materials have attracted interest in the fields of electrochemistry, catalysis, and photonics due to the ease with which their properties may be tuned. First-principles calculations have proven an essential tool in the quest for new 2D materials with tailored properties. However, an exhaustive exploration of the parameter space is infeasible even in the monolayer case. In this work, we use a novel machine learning technique – Crystal Graph Convolutional Neural Networks (CGCNN) [1] – to train accurate models that can predict monolayer 2D material properties more efficiently than density functional theory simulations. Previously, CGCNN architectures have been demonstrated to successfully predict properties of solid electrolytes [2]. Here, we leverage their power to find design principles for 2D materials in light-absorbing and water-splitting applications.

9:12AM F20.00005: Revealing the Spectrum of Unknown Layered Materials with Super-Human Predictive Abilities  GOWOON CHEON (Presenter), Applied Physics, Stanford University, EKIN DOGUS CUBUK, Google Brain, EVAN ANTONIUK, Chemistry, Stanford University, JOSHUA GOLDBERGER, Chemistry, The Ohio State University, EVAN J. REED, Materials Science and Engineering, Stanford University — We use semi-supervised learning to discover over 1000 new two-dimensional layered materials that have yet to be discovered or synthesized. We accomplish this by combining physics with machine learning on experimentally obtained data and verify a subset of candidates using density functional theory. Our model accelerates the discovery of layered materials by 13 times compared to random trial-and-error approaches. Even compared to expert scientists working in the field of two-dimensional materials, it is five times better than practitioners in the field at identifying layered materials and is comparable or better than professional solid-state chemists. We also find that our model is orders of magnitude faster than any human.

To achieve super-human performance, we employ semi-supervised learning techniques for the first time in materials discovery. Semi-supervised learning utilizes unlabeled data in addition to labeled data, which is powerful in cases where labels are expensive to obtain or are noisy. We find that semi-supervised learning provides benefits over supervised learning in identifying layered materials, and it may be applicable to a wide range of problems in materials science.
9:24AM F20.00006: Probing the microscopic origin of magnetism in two-dimensional materials using machine learning*  TREVOR DAVID RHONE (Presenter), Physics, Rensselaer Polytechnic Institute, EFTHIMIOS KAXIRAS, Physics, Harvard University — Magnetic ordering in two-dimensions is at the forefront of research since the discovery of magnetism in monolayer CrI$_3$ in 2017. We study two-dimensional (2D) materials with intrinsic magnetic order and explore the microscopic origins of magnetism in these novel materials. The Mermin-Wagner theorem asserts that magnetic ordering cannot occur in 2D without the presence of magnetocrystalline anisotropy (MCA), which arises due to spin-orbit coupling. 2D materials with magnetic order provide a platform with which to study magnetism in low dimensions – the positions of all the atoms are known in theoretical studies and some experimental studies. This contrasts studies of magnetism in thin films. We use data analytics to study the magnetic and thermodynamic properties of 2D materials. Crystal structures based on monolayer CrI$_3$, are studied using density functional theory (DFT) calculations and machine learning. Magnetic properties, such as MCA and the magnetic moment are determined. We show that machine learning, combined with DFT, provides a means to learn patterns in 2D magnetic materials data, thereby providing insights into the microscopic origins of magnetic ordering in 2D. This approach to materials research also facilitates the rapid discovery of 2D magnets.

*DOE DE-AC02-06CH11357

9:36AM F20.00007: Topological data analysis for magnetic domain structure characterization*  MASATO KOTSUGI (Presenter), Tokyo Univ of Science, Katsushika — Analysis of the magnetic domain structure is an important process in the development of advanced magnetic materials. A number of successful studies have been carried out by high-resolution magnetic imaging or LLG simulations. However, the treatment of the information of the whole image, especially the shape of the magnetic domain structure, has not been sufficiently discussed.

We here executed the topological data analysis (TDA) to extract the feature of the shape in a magnetic domain structure [1, 2]. Maze magnetic domain structure was analyzed by TDA to visualize the pinning site during the magnetization reversal process. We utilized persistent homology to extract the topological feature of the magnetic domain structure, and principal component analysis was used to construct the correlation between persistence diagram and a magnetic hysteresis loop. As a result, we could automatically visualize the pinning site as a topological defect in the original magnetic domain structure for the first time.

*A part of this research was supported by MI2I-NIMS, KAKENHI-MEXT, Hitachi Metals Materials Science Foundation.
9:48AM F20.00008: Extracting Interpretable Physical Parameters from Spatiotemporal Systems using Unsupervised Learning* PETER LU (Presenter), Department of Physics, Massachusetts Institute of Technology, SAMUEL KIM, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, MARIN SOLJACIC, Department of Physics, Massachusetts Institute of Technology — Real-world data from spatiotemporal systems is often difficult to analyze and interpret due to complex dynamics as well as uncontrolled experimental variables. We demonstrate an unsupervised machine learning technique for extracting interpretable physical parameters from noisy spatiotemporal data and for building a transferable predictive model of the system. This is accomplished without prior knowledge of the underlying dynamics or the governing partial differential equation (PDE). Numerical experiments using simulated data governed by PDEs show that our method accurately identifies and extracts relevant parameters that characterize independent variations in the system dynamics. Our method for discovering interpretable latent parameters in spatiotemporal systems will allow us to better understand real-world phenomena by analyzing datasets with varying dynamical behaviors that are difficult to disentangle.

*This work is supported in part by the U.S. Department of Defense through the National Defense Science & Engineering Graduate Fellowship (NDSEG) Program, the MIT-SenseTime Alliance on Artificial Intelligence, the Army Research Office under Cooperative Agreement Number W911NF-18-2-0048, and the Defense Advanced Research Projects Agency (DARPA) under Agreement No. HR00111890042.

10:00AM F20.00009: Prediction of Seismic Wave Arrivals Using a Convolutional Neural Network* JORGE GARCIA (Presenter), LAUREN WASZEK, Department of Physics, New Mexico State University — Seismology uses energy from earthquakes to image the deep interior of Earth. Large amounts of seismic data are required in order to obtain detailed observations of the its internal structure; typical datasets comprise over 100,000 seismic records. With the exception of some basic processing methods, compilation of the data is performed by hand using simple visualization software. The most significant and time-consuming task is the identification and picking of seismic phases. Previous attempts at automating this procedure involve algorithms that generally underperform compared to a human expert. However, even among human-compiled datasets, consistency of phase arrival across and within datasets is a problem. The variation in decisions results in disagreement between obtained images, and subsequent interpretation of Earth's structure and processes. We employ a Convolutional Neural Network (CNN) to predict the arrival time of the mantle shear-wave phases in a seismogram in an effort to accelerate and make consistent the task of data processing. We approach strategies to ensure correct prediction of arrival time and polarity of the seismic phase, as well as applying the model for identification of precursor signals of the same phase.

10:12AM F20.00010: Using Reinforcement Learning to Optimize Crystal Structure Determination*  WILLIAM RATCLIFF (Presenter), National Institute of Standards and Technology, KATE MEUSE, Montgomery Blair High School, JESSICA OPSAHL-ONG, Mclean High School, JOSEPH RATH, Rowan University, PAUL KIENZLE, National Institute of Standards and Technology, TELON YAN, RYAN CHO, Montgomery Blair High School, ABIGAIL WILSON, Tufts University — The first step to understanding the microscopic origins of the properties of a material is to determine the crystal structure. This can be accomplished with neutron diffraction. However, there are a small number of neutron sources in the world and thus it is critical to perform measurements as optimally as possible. We use reinforcement learning to address this problem. We compare several approaches within this framework including epsilon-greedy, Q-learning, and actor-critic. We find that in toy models, it is possible to measure a significantly smaller fraction of measurements than would commonly be performed to determine structural properties with the same accuracy.

*Support for Abigail Wilson, Joseph Rath, Kate Meuse, Jessica Opsahl-Ong, Ryan Cho, and Telon Yan was provided by the Center for High Resolution Neutron Scattering, a partnership between the National Institute of Standards and Technology and the National Science Foundation under Agreement No. DMR-1508249.

10:24AM F20.00011: Active Learning for Quantum Experimental Controiling  YADONG WU (Presenter), HUI ZHAI, Tsinghua University — Experimental control problems are popular task for experimental physicists in quantum experiments. Generally human tune the experimental parameters step by step, hand by hand to fine the suitable experimental parameters to set up the experimental system. While this way of tuning parameters is not efficient and may miss the ‘global minimum’. Here we apply one semi-supervised machine learning method, active learning, to this parameters tuning task to find the suitable parameters automatically. We will show the advantage of this machine learning method by two simulated examples. First we set the Efimovian expansion as a benchmark. Putting the unitary fermi gases into a harmonic trap with time dependent trapping frequency $\omega(t)$, active learning told us the most efficient way to release the trap is $\omega(t) \propto 1/t$ which is assistant with the theory. Then we apply this active learning to evaporative cooling issue. Comparing to the simulated result, this active learning can give us a better cooling trajectory which can reach to a lower temperature during less time.
International Radiological Information Exchange (IRIX) Standards for Emergency Radiation Monitoring Data Reporting

SANJOY MUKHOPADHYAY (Presenter), International Atomic Energy Agency — The Incident and Emergency Centre (IEC) of the International Atomic Energy Agency (IAEA) has developed a web application, the International Radiation Monitoring Information System (IRMIS). IAEA Member States (MS) can share and visualize large quantities of radiation monitoring data (viz. gamma dose rate, isotope specific ground depositions and air concentrations) using IRMIS. The radiation monitoring data may be uploaded into IRMIS in the International Radiological Information Exchange (IRIX) format. IRIX is a technical standard developed by the IAEA, in cooperation with the MSs and the European Commission (EC). IRIX enables the development of interoperable systems and solutions for exchanging emergency information and data between organisations at both national and international level during a nuclear or radiological emergency. IRIX is an open format based on the Extensible Markup Language (XML), which makes it both machine and human readable. The system interface specification (or web-service specification) enables organizations to interconnect their emergency information systems to automate information exchange. The XML provides a software- and hardware-independent way of storing, transporting, and sharing data. The article will discuss applications of IRIX in IRMIS.

Session F21 GERA: Towards Realizing the Energy Future

Undergrad Friendly
Three terminal tandem (3TT) solar cells can overcome some of the limitations of two terminal (current matched) and four terminal (independently operated) solar cell designs. This design is a compelling platform for tandem cell integration because 3TTs based on Si bottom cells with interdigitated back contacts enable the same robust performance of four terminal tandems but do not require lateral current extraction between the cells, which can become challenging when scaling devices to large areas. However, the coupled nature of 3TT devices adds a degree of complexity to the devices themselves and the ways that their performance can be measured and reported. While many different configurations of 3TT devices have been proposed, there is no standard taxonomy to discuss the device structure or loading topology. I will discuss a proposed taxonomy for classifying 3TT devices and explaining how to rigorously measure their performance. I will show how TCAD models agree with simple physical models and experimental results to explain the trends in the behavior of 3T tandems.

Tremendous progress has been made in wide-bandgap (WBG) power electronic devices. Most WBG devices today are based on silicon carbide (SiC) or gallium nitride (GaN). However, the most mature GaN-based power device, the high electron mobility transistor (HEMT), falls short of the full potential of GaN for several reasons: (1) internal stress due to the growth of thick buffer layers on non-native substrates; (2) the lateral architecture of the HEMT produces a non-ideal internal electric field distribution; and (3) avalanche ruggedness is lacking. GaN-based HEMTs are thus unacceptable for higher-voltage applications such as the electric grid and vehicle drivetrain electrification. In contrast to GaN HEMTs, vertical GaN power devices grown on native GaN substrates do not suffer from these shortcomings. However, materials challenges exist for vertical GaN, such as the quality of native substrates and the epitaxial growth of thick (tens of microns or more), low-doped (< 10^16 cm^-3 n-type) drift layers required for high breakdown voltage. Processing challenges also exist, such as the ability to selectively dope GaN and to activate buried p-layers. This talk will present progress in the design, fabrication, and evaluation of vertical GaN power devices. The fundamental material properties relevant for such devices will be discussed, including how they enable devices superior to those fabricated from other semiconductors. Challenges and progress associated with substrates and epitaxial growth will be covered, as will design trade-offs and processing challenges (including yield and reliability) for various types of diodes and transistors.

9:12AM F21.00003: Advancements in soft magnetic materials for future energy needs*

[Invited]  TODD MONSON (Presenter), Sandia National Laboratories — Power electronics and motor drives are now transitioning to wide band gap semiconductors, operating at higher frequencies, and enabling faster rotational speeds in electrical machines. This is creating a need for improved soft magnetic materials that can sustain higher flux densities with lower losses. Many different materials and strategies are being pursued and it is almost certain that a mix of soft magnetic materials will be required to meet all current and emerging applications. I will provide a brief overview of the history of soft magnetic materials and discuss some of the most promising approaches to meet the needs of future power electronics and rotating machines.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

9:48AM F21.00004: Data-Driven Discovery of Materials for Photocatalytic Energy Conversion

[Invited]  ARUNIMA SINGH (Presenter), Department of Physics, Arizona State University — Photocatalytic fuel production, e.g. generation of hydrogen from water splitting or the conversion of the greenhouse gas carbon dioxide to chemical fuels, promises us alternative energy sources that are clean, environmentally friendly and renewable. Advancements have been made in improving the efficiencies and product selectiveness of currently known photocatalysts, but the attempts for finding new photocatalytic materials have been few and based largely on trial and error.

In this talk, I will show how we can design first-principles simulations based descriptors for synthesizability, corrosion resistance, visible-light absorption, and compatibility of the electronic structure for the catalytic reaction and use them for a rational photocatalytic materials screening. I will present two examples here, first where we have performed the largest CO$_2$ photocathode search to date, starting with 68,860 candidate materials and found that only 52 materials meet the stringent requirements for CO$_2$ reduction photocatalysts.\textsuperscript{1} The photocathode materials identified include 9 materials previously reported as CO$_2$ photocathodes, as well as the discovery of a set of 43 new candidate photocathodes. In the other example, I will show how we discovered five manganese-based ternary metal-oxides for oxygen evolution through a joint computational and experimental photocatalyst screening.\textsuperscript{2}

Solvent-in-salt (SIS) electrolytes differ substantially from the traditional electrolytes: in such systems amounts of the dissolved salt is equivalent or more by weight/volume of that of the solvent. As a result, SIS systems feature a number of unique properties and provide electrochemical performance advantages that could not be attained by usage of the traditional electrolytes. One of the notable examples of SIS electrolytes are highly concentrated “water-in-salt”, WIS, systems which were demonstrated to be highly attractive electrolytes for aqueous batteries since they can offer significantly extended stability window, improved coulombic efficiency and cycling stability.\textsuperscript{1,2,3,4} Yet, while it is clear that such an extreme increase in salt concentration would result in highly modified interactions of the ionic and molecular components of the electrolyte a detailed our understanding is still lacking.

Here we present on multi-technique study of the two distinct WIS systems based on i) lithium salts of organic imides and ii) potassium acetate. Using a combination of the X-Ray Absorption Spectroscopy, wide angle X-Ray scattering and molecular dynamics simulations we reveal effects of the solution concentration and introduction of the multivalent cations such as Zn\textsuperscript{2+} on the solvation structure of the ionic species, local order within electrolytes and nano-heterogeneity within the studied WIS systems.

8:00AM F22.00001: The avian eggshell: evolution and engineering of a tough, lightweight biological material [Invited]  MARY CASWELL STODDARD (Presenter), Princeton University, ZHIFEI DENG, ZI'AN JIA, LING LI, Virginia Tech, JAMES WEAVER, Harvard University — The eggs laid by modern birds are the products of more than 150 million years of evolution, resulting in a sophisticated package designed to balance a range of competing demands. The egg must be tough enough to prevent external damage but weak enough to permit a chick to hatch. It must resist bacterial contamination but allow gas exchange between the chick and the outside environment. The egg satisfies these requirements, which is remarkable given that it forms in under 24 hours. From an evolutionary perspective, bird eggs are fascinating because they come in a great variety of shapes, sizes, colors, and structures despite the fact that they serve the same essential function: to nourish and protect a chick until it hatches. What selective pressures influence the diversity of egg phenotypes? From an engineering perspective, eggshell is impressive because it is a strong, lightweight material, yet we understand relatively little about eggshell biomechanical properties outside of those from domestic chickens. What is the relationship between the structure and function of eggshell? In addition, how do eggs form in the avian oviduct? Here, we explore these questions through the lenses of evolutionary biology, biophysics and mechanical engineering, which together provide an integrative picture of the form and function of avian eggs.

8:36AM F22.00002: Misorientation and enhanced hardness in tooth enamel* CAYLA STIFLER (Presenter), CHANG-YU SUN, University of Wisconsin - Madison, ELIA BENIASH, University of Pittsburg, PUPA GILBERT, University of Wisconsin - Madison — Teeth are subjected to extreme, repetitive forces on a daily basis. Human enamel exerts forces up to 770 Newtons, hundreds of times per day, and must remain functional for decades\(^1\). By comparison, great white shark enameloid exerts 7400 Newtons of force when biting, but they shed their teeth regularly\(^2\). The mechanical stress the teeth undergo suggests there are structural features in enamel that prevent catastrophic failure. We used PIC (polarization-dependent imaging contrast)\(^3,4\) mapping at the calcium L-edge\(^5\) to reveal the crystal orientations within rods in mammalian enamel and in bundles in fish enameloid. Analysis of PIC maps from the enamel(oid)\(^6\) of diverse animals indicates that c-axis orientations of adjacent crystals are slightly misoriented by small angles. The observed misorientation is positively correlated with the hardness and elastic modulus, suggesting that crystal misorientation is related to, and possibly causes, these enhanced properties.

8:48AM F22.00003: Crystallographic Parameters Of Rod And Interrod Enamel Crystallites Differ Systematically*  
ROBERT FREE, KAREN DEROCHER, STUART STOCK, DERK JOESTER  
(Presenter), Northwestern University — Dental enamel has evolved to bear large masticatory forces, resist mechanical fatigue, and withstand wear over decades of use. Functional impairment or loss, as a consequence of developmental defects or tooth decay, has a dramatic impact on health and quality of life. Enamel formation and its degradation remain incompletely understood. This is in part due to its hierarchical architecture. Our objective was to test the hypothesis that crystallographic features of two microstructural features of enamel, rod and interrod enamel, differ as a consequence of their developmental origin. Towards this goal, we mapped crystallographic order/disorder by azimuthal autocorrelation of WAXS patterns recorded at 500 nm spot size and correlated this information with crystallite size, lattice parameters, and microstrain at each point. We find that there are systematic variations in these parameters for rod and interrod crystallite populations that suggest differences in composition and imply that there are distinct crystallization environments during amelogenesis.

9:00AM F22.00004: Characterization of a Novel Antimicrobial Agent for Endodontic Applications*  
ARIS ZHU (Presenter), JEFFREY WOLBERG, FARZAD KOOSHA, Dentistry, Stony Brook University, KARENA ETWARU, MIRIAM RAFAILOVICH, Materials Science, Stony Brook University — Recurrent endodontic infections are primarily caused by persistent bacteria Enterococcus faecalis and are more challenging to treat, compared to primary infection of the root canal system. Current treatment, calcium hydroxide (CaOH), is used despite its inefficacy against E faecalis and other common endodontic pathogens, so we developed a more effective composite material named “CASA”. This study characterizes the antimicrobial properties, cytotoxicity, and differentiation potential of CASA for dental pulp stem cells (DPSCs). To determine antimicrobial properties, agar plates were inoculated with common endodontic pathogens. Then, CASA or CaOH was inserted into wells in the agar plate with a diameter of 6 mm. They were incubated for 24 hrs, and then zones of inhibition were measured. CASA produced larger zones of inhibition than CaOH for all species tested. Cytotoxicity studies indicated a high tolerance for DPSCs for CASA, with a measured IC50 of 1.0 mg/ml, a far higher dose than tissue would be exposed to during standard treatment. Addition of 0.25 mg/ml of CASA to DPSCs in osteogenic culture, in the absence of dexamethasone, was observed to hinder differentiation and preserve stemness of the culture.

Evolutionary patterns in skeletal biomineralization* [Invited] SUSANNAH PORTER (Presenter), JOHN MOORE, LEIGH ANNE RIEDMAN, Earth Science, University of California at Santa Barbara — Mineralized skeletons evolved many times within eukaryotes, providing multiple independent data points for testing hypotheses about skeletal evolution. We have identified >80 acquisitions of mineralized skeletons in eukaryotes along with their time of first appearance and their mineralogy, and have found several interesting patterns. First, the distribution of skeletal mineralogies tends to be non-uniform: most animals and archaeplastidans, for example, chose carbonate, whereas most rhizarians and stramenopiles chose silica. Whether this reflects functional constraints, e.g. related to uni- vs. multicellularity, or phylogenetic constraints, e.g. related to homologous genes involved in nucleation/inhibition of these minerals, is unclear. Second, acquisitions of phosphatic skeletons are clustered in the Cambrian, perhaps due to high PO$_4^{3-}$ in the oceans at this time. Finally, more than 60% of animal acquisitions occurred in the early Cambrian, whereas those of other eukaryotes are distributed more uniformly in time, supporting the view that factors affecting only animals, e.g., the appearance of carnivores, rather than factors affecting all marine organisms, e.g., increased Ca$^{2+}$, drove widespread biomineralization in the early Cambrian.

Biomineralization by particle attachment in early animals* PUPA GILBERT (Presenter), Physics, University of Wisconsin - Madison, SUSANNAH M PORTER, Geosciences, University of California - Santa Barbara, CHANG-YU SUN, Physics, University of Wisconsin - Madison, SHUHAI XIAO, Geosciences, VA Tech, BRANDT M GIBSON, Geosciences, Vanderbilt University, NOA SHENKAR, Life Sciences, Tel-Aviv University, ANDREW H KNOLL, Organismic and Evolutionary Biology, Harvard University — Crystallization by particle attachment (CPA$^1$ of amorphous calcium carbonate (ACC) was demonstrated in modern biominerals from diverse animals. Precisely the same precursors, hydrated and anhydrous ACC, have been observed spectromicroscopically in echinoderms$^{2-4}$, molluscs$^5$, cnidarians$^6$. This is surprising, as these three phyla have no common ancestor that formed biominerals, and have, therefore, evolved carbonate biomineralization independently ~100 million years after diverging from one another$^7$. Here we correlate the occurrence of CPA of ACC precursor particles with nanoparticulate fabric and then use the latter to investigate the antiquity of the former. SEM images of the oldest known animal biominerals show that these animals used attachment of ACC particles to form their biominerals. The convergent evolution of biomineral CPA may have been dictated by the same thermodynamics and kinetics as we observe today.

10:00AM F22.00007: Applications of molecular taphonomy to the invertebrate fossil record  
[Invited] CORINNE MYERS (Presenter), Earth and Planetary Sciences, University of New Mexico, KRISTIN BERGMANN, Earth, Atmospheric, and Planetary Sciences, MIT, PUPA GILBERT, Physics, University of Wisconsin-Madison — Recently several studies have demonstrated the utility of PhotoEmission Electron spectroMicroscopy (PEEM) to observe exceptional preservation of organic matrix components and shell microstructure in fossil mollusks. Comparisons to modern representatives suggests very strong similarity and potential links to paleoenvironmental conditions (e.g., temperature). Current work must focus on replicating these results across additional time periods and types of biomineralizing species. Future work on the utility of hyperspectral imaging, the geography of preservation, and complementary analyses (e.g., Raman spectroscopy), will provide additional clues into the molecular and structural preservation of biominerals, as well as their evolution through geologic time.

Tuesday, March 3, 2020 8:00 AM - 11:00 AM

Session F23 DBIO GSNP: Physics of Microbiomes and Bacterial Communities 304 - Raghuveer Parthasarathy, Univ of Oregon

8:00AM F23.00001: A statistical-mechanics approach to microbiome data analysis* ROBERT MARSLAND (Presenter), PANKAJ MEHTA, Boston Univ — Next-generation sequencing, high-throughput metabolomics and other measurement technologies have opened vast new horizons for collecting data on the structure and function of microbial communities. But it remains unclear how to leverage this data for effective intervention in medical and agricultural applications. We do not know which quantities can be reliably predicted, which are hopelessly contingent, and what the predictors are for the former. In this talk, I will draw on conceptual tools from statistical physics, which were designed to answer precisely these sorts of questions. In particular, I will argue that the key features of community structure are encoded in a susceptibility matrix, which contain the response of species population sizes to small changes in growth rates. I will show how to estimate this matrix in different scenarios from existing data sets, and then explain how it can be used to cluster species into functionally redundant groups for enhanced predictability of community composition.

8:12AM F23.00002: Quantifying multi-species bacterial interactions in larval zebrafish
DEEPIKA SUNDARRAMAN (Presenter), EDOUARD HAY, DYLAN MARTINS, DREW SHIELDS, NOAH PETTINARI, KAREN GUILLEMIN, RAGHUVEER PARTHASARATHY, Univ of Oregon — The microbial communities resident in animal intestines are composed of many species and play an important role in host development, health and disease. The complex nature of these diverse communities makes it challenging to determine the driving forces behind microbial composition. Further, it is unclear for many multi-species consortia whether species-level makeup can be predicted solely on pairwise inter-species interactions, or whether higher-order interactions are needed to explain the composition of these communities.
To address this, we consider commensal intestinal microbes in larval zebrafish, initially raised germ-free to allow introduction of controlled combinations of bacterial species. Using dissection and plating assays we demonstrate the construction of communities of 1 to 5 bacterial species and show that the outcomes from the 2-species competitions do not contain enough information to predict the abundances in more complex communities. Furthermore, we observe a dampening of strong negative interactions as the microbial composition of the gut becomes more diverse. Our data suggests higher order interactions are important in the zebrafish gut, possibly due to changes in spatial organization that ongoing live imaging experiments are illuminating.

8:24AM F23.00003: Species covariance in *C. elegans* microbiome demonstrates existence of bacteria-bacteria and host-bacteria interactions*  
K. MICHAEL MARTINI (Presenter), MEGAN TAYLOR, ILYA M NEMENMAN, NICOLE MARIE VEGA, Emory University — The structure and internal dynamics of complex microbial communities in the guts of organisms is poorly understood. Here we analyze a simplified community of bacteria in the gut of *Caenorhabditis elegans*, a roundworm. Initially germ-free adult *C. elegans* are introduced into an environment with equal concentrations of eight bacterial species from a native worm microbiome. After four days, we examine individual worm gut communities and calculate the covariance structure of the bacterial abundances. We find statistically significant off-diagonal covariances. We demonstrate that a simple model only considering migration, birth, death, and competition for space among the bacteria can capture the mean values of bacterial abundances and their variances. However, it is incapable of explaining the off-diagonal covariances. We also show that the positive off-diagonal covariances can be partially explained by variation of the birth rate and other bacterial parameters among the worm hosts. However, to explain the off-diagonal negative covariances observed in the experiment requires interactions between bacteria beyond competition for space. We thus show that the structure of the microbiome is affected by both bacteria-bacteria and bacteria-host interactions.

Evidence for a multi-level trophic organization of the human gut microbiome  

TONG WANG (Presenter), University of Illinois at Urbana-Champaign, AKSHIT GOYAL, Physics of Living Systems, Massachusetts Institute of Technology, VERONIKA DUBINKINA, SERGEI MASLOV, University of Illinois at Urbana-Champaign — The human gut microbiome is a complex ecosystem, in which hundreds of microbial species and metabolites coexist, in part due to an extensive network of cross-feeding interactions. However, both the large-scale trophic organization of this ecosystem and its effects on the underlying metabolic flow, remain unexplored. Here, using a simplified model, we provide quantitative support for a multi-level trophic organization of the human gut microbiome, where microbes consume and secrete metabolites in multiple iterative steps. Using a manually-curated set of metabolic interactions between microbes, our model suggests about four trophic levels, each characterized by a high level-to-level metabolic transfer of byproducts. It also quantitatively predicts the typical metabolic environment of the gut (fecal metabolome) in approximate agreement with the real data. To understand the consequences of this trophic organization, we quantify the metabolic flow and biomass distribution and explore patterns of microbial and metabolic diversity at different levels. The hierarchical trophic organization suggested by our model can help mechanistically establish causal links between the abundances of microbes and metabolites in the human gut.

Regime shifts in a phage-bacterial ecosystem and strategies for its control*  

SERGEI MASLOV (Presenter), University of Illinois at Urbana-Champaign, KIM SNEPPEN, Niels Bohr Institute — We show [1] that phage-bacterial ecosystems can have several alternative species compositions separated by abrupt regime shifts. In one of these states the fast-growing bacteria competitively exclude the slow-growing species by depleting common nutrient. In the other state the slow-growing bacteria with a large burst size make so many phages that the other species cannot survive. This scenario can be realized e.g. if two bacterial strains are protected from the same phage by, respectively, abortive infection or CRISPR, and partial resistance defence mechanisms. Alternative stable states and regime shifts greatly complicate the task of manipulation of microbial communities. We propose and study a successful control strategy via short population pulses aimed at inducing the desired regime shifts. In particular, we predict that a fast-growing pathogen could be eliminated by a combination of its phage and a slower-growing susceptible host.

9:00AM F23.00006: Biophysical consequences of sublethal antibiotics on gut bacterial persistence and transmission*  BRANDON SCHLOMANN, TRAVIS J WILES, ELENA S WALL, KAREN GUILLEMIN, RAGHUVEER PARTHASARATHY (Presenter), Univ of Oregon — Antibiotics induce large changes in the composition of the gut microbiome even at sublethal concentrations, by mechanisms that have remained elusive. Using larval zebrafish, which allow controlled studies of microbial dynamics, we found that sublethal doses of the common antibiotic ciprofloxacin cause severe drops in bacterial abundance. Contrary to conventional expectations, disruption was more pronounced for slow-growing, aggregated bacteria than for fast-growing, motile species. Three-dimensional live imaging revealed that antibiotic treatment promoted physical aggregation of bacteria in both planktonic and cohesive species and increased susceptibility to intestinal expulsion. Intestinal mechanics therefore amplify antibiotics effects on resident bacteria. A biophysical model, reminiscent of models of polymer growth and gelation, describes microbial dynamics and makes testable predictions of aggregation properties. The antibiotic-induced expulsion of live bacteria from the host influences the transmission of microbes to new hosts, which we suggest may contribute to the spread of antibiotic resistance.

9:12AM F23.00007: Delayed antibiotic exposure induces population collapse in enterococcal communities with drug-resistant subpopulations  KELSEY HALLINEN (Presenter), JASON KARSLAKE, KEVIN WOOD, Biophysics, University of Michigan — The molecular and genetic causes of bacterial antibiotic resistance are increasingly understood, while less is known how these molecular events influence population dynamics. In this work, we show the dynamics of E. faecalis communities exposed to antibiotics can be surprisingly rich, as increasing population size or delaying drug exposure can promote population collapse. We combine experiments in computer-controlled bioreactors with simple mathematical models to reveal density-dependent feedback loops, coupling growth and antibiotic efficacy of populations with drug-resistant (β-lactamase) subpopulations. With a wide range of behavior—population survival, collapse, or one of two qualitatively distinct bistable behaviors where either small or large populations survive—competing density-dependent effects arise: drug-sensitive cell growth increases while drug-resistant cell growth decreases drug efficacy. We experimentally show how populations receiving immediate drug influx may thrive, while identical populations exposed to delayed drug influx (and lower average drug concentrations) collapse. These results illustrate the spread of drug resistant determinants—even in single-species communities—may be governed by counterintuitive dynamics driven by population-level interactions.
9:24AM F23.00008: Predicting microbial community metabolic function from genomic structure* KARNA GOWDA (Presenter), DEREK J PING, LAURA B TROYER, Physics, University of Illinois at Urbana-Champaign, MADHAV MANI, Engineering Sciences and Applied Mathematics, Northwestern University, SEPPE KUEHN, Physics, University of Illinois at Urbana-Champaign — The genes and organisms present in microbial communities determine metabolic flows that drive global nutrient cycles. A primary objective of microbial ecology is therefore to predict the metabolic function of a community from its genomic structure. We approach this prediction problem using denitrification as a model metabolic process. Denitrification is mediated by bacterial consortia that convert nitrate to dinitrogen gas. Using metabolite measurements and sequencing of denitrifying bacteria isolated from local soils, we develop a statistical-empirical approach to predicting community function from genomic structure. We show that for each strain in monoculture, the dynamics of denitrification are parameterized by a consumer-resource model. With some well-defined exceptions, we then find that the metabolite dynamics of simple communities are predictable from monoculture dynamics. This means we need only predict single-strain metabolite flows from genomes to successfully predict community-level metabolism. We solve this by predicting consumer-resource parameters via regression onto the presence/absence of each strain's denitrification genes, thereby providing a complete map from community genomic structure to metabolic function.

9:36AM F23.00009: Cross-feeding is not necessarily evolutionarily stable BO LIU (Presenter), Harvard University, ZHIYUAN LI, Peking University, NED WINGGREEN, Princeton University — Cross-feeding is widely observed in microbial communities. Intuitively, cross-feeding provides mutual benefits: one species exports metabolic waste which can be taken up and utilized by another species. However, it remains unclear whether mutually beneficial cross-feeding is evolutionarily stable in the face of mutations, invasion by other species, and the cost of transporting metabolites. To address this question, we constructed a minimum metabolic model of cross-feeding, with trade-offs in enzyme allocation and reversible energy-producing reactions. The population dynamics of this system in a chemostat reveal that cross-feeding is evolutionarily unstable. Instead, we find stable coexistence between a species that exports an intermediate and a species that consumes the same nutrient but processes the intermediate. We show why cross-feeding is unstable for this system, and generalize our results for the coexistence of different consumption strategies to multi-step reactions. Further, we identify a scaling relation for the population ratios of coexisting species at large nutrient supply. In summary, our model reveals that cross-feeding is not necessarily evolutionarily stable, and identifies a mechanism for coexistence based on species polluting their own metabolic environment.
Percolation transition of pusher-type microswimmers*  
FABIAN JAN SCHWARZENDAHL (Presenter), School of Natural Sciences, University of California, Merced, MARCO G. MAZZA, Interdisciplinary Centre for Mathematical Modelling, Loughborough University — In this talk I will present the presence of a continuum percolation transition in model suspensions of pusher-type microswimmers. The clusters dynamically aggregate and disaggregate resulting from a competition of attractive and repulsive hydrodynamic and steric interactions. As the microswimmers' filling fraction increases, the cluster size distribution approaches a scale-free form and there emerge large clusters spanning the entire system. We characterize this microswimmer percolation transition via the critical exponents, analytical arguments, and scaling relations known from percolation theory. This finding opens new vistas on microswimmers' congregative processes.

Biphasic Chemotaxis of E. coli to the Microbiota Metabolite Indole*  
JINGYUN YANG, RAVI CHAWLA, KATHY RHEE, RACHIT GUPTA, MICHAEL MANSON, ARUL JAYARAMAN, PUSHKAR LELE (Presenter), Texas A&M Univ — Bacterial chemotaxis to microbiota metabolites in the GI tract is important in the development of microbial communities. A prominent metabolite is indole, which has received wide attention for its role in regulating a broad range of bacterial phenotypes including virulence. The basis of chemotaxis to indole however, remains poorly understood. With a combination of flagellar motor and FRET assays, we have discovered a time-dependent inversion from a chemorepellent to chemoattractant response to indole. Such an inversion caused a bipartite response – wild-type cells were attracted to regions of high indole concentration if they had previously adapted to indole but were otherwise repelled. Interestingly, the flagellar motor itself mediated a repellent response independent of the chemoreceptors. I will discuss analytical models to explain these and other physiological responses to indole. The spatial filtering of cells by indole is likely important in repelling invaders while recruiting beneficial resident bacteria to growing microbial communities within the GI tract.

Dynamic motility selection drives population segregation in a bacterial swarm*  

YILIN WU (Presenter), WENLONG ZUO, Chinese Univ of Hong Kong — Ecological models usually take growth rate fitness as the essential driver of population dynamics. However, as a widespread natural phenomenon, population expansion in space (or range expansion) is often governed by both motility and growth. Microbial communities offer unique systems to study how individual’s motility contributes to space competition among heterogeneous microbial populations during range expansion. Here we show that motility heterogeneity can promote the spatial segregation of sub-populations in structured microbial communities via a dynamic motility selection mechanism. Our findings are relevant to microbial stress response and microbial ecology. The results may also provide new insight to range expansion in other biological systems, such as tumor invasion and collective stress tolerance of cancer cells in densely packed environments.

Continuum modeling of bacterial biofilm development*  

CHENYI FEI (Presenter), RICARD ALERT, BOYANG QIN, ANDREW BRIDGES, BONNIE BASSLER, NED WINGREEN, Princeton University — Biofilms are surface-associated bacterial communities embedded in an extracellular matrix. *Vibrio cholerae*, a rod-shaped bacterium, forms biofilms starting from a single cell and growing into a three-dimensional structure. Recent advances in single-cell imaging reveal the kinematics of this developmental process with single-cell resolution. To understand the role of mechanics in shaping the biofilm, we develop a multiphase continuum model of biofilm development. We find that the kinetic friction between the growing biofilm and the surface leads to a universal “fountain-like” flow of material within the biofilm, in good agreement with experimental data. Using a phase-field approach, we study how cell-cell and cell-matrix mechanical interactions affect the internal organization of cells in the growing biofilm.

*This work was supported by NIH Grants R01 GM082938 and 1R21AI146223-01, and by the National Science Foundation, through the Center for the Physics of Biological Function (PHY-1734030).

E. coli Bacteria near "Black Hole"*  

TRUNG PHAN (Presenter), Princeton University, RYAN MORRIS, University of Edinburgh, MATTHEW BLACK, KE-CHIH LIN, Princeton University, JULIA BOS, Pasteur Institute, ROBERT AUSTIN, Princeton University — In microfluidic environment, we create hydrodynamic horizon from which no E. coli bacteria can escape ("black hole") to study the collective behaviors of those organisms under the influence of such background, probing for their strategy to avoid potentially harmful region where part of the population disappears.

*This work was supported by NSF PHY-1659940.
10:48AM F23.00015: Microbial communities governed by interplay of bacterial interaction and biofilm mechanics*  GABI STEINBACH (Presenter), MICHAEL NG SIULUNG, CRISTIAN CRISAN, BRIAN K. HAMMER, PETER YUNKER, Georgia Inst of Tech — Biofilms are highly structured, densely packed bacterial consortia. Their structures are often explained as the result of social interactions between bacteria, e.g. cooperation and competition. Others concentrate on the role of local mechanics in biofilm formation. These two lines of argumentation are typically treated separately. Here, we show that mechanics and social interactions can be strongly interrelated and their combination can crucially impact biofilm formation and dynamics. Using Vibrio cholerae strains that kill each other on contact, we examine how bacterial antagonism impacts biofilm mechanics, and vice versa. We find that this interplay leads to counterintuitive results. For example, killing produces dead cells, which can prevent subsequent killing, and, thus, stabilizes coexistence.

Session F24 GSNP DBIO: Noise-Driven Dynamics in Far-From-Equilibrium Systems I  401 - Stephen Teitsworth, Duke University - Tag(s): Focus

8:00AM F24.00001: Climate variability: a manifestation of fluctuations in a nonequilibrium steady state* [Invited]  JEFFREY B. WEISS (Presenter), University of Colorado, Boulder, BAYLOR FOX-KEMPER, Brown University, DIBYENDU MANDAL, University of California, Berkeley, ARIN D. NELSON, University of Michigan, Ann Arbor, ROYCE ZIA, Virginia Polytechnic Institute and State University — The climate system is forced by incoming solar radiation, is damped by outgoing long-wave radiation, and is, apart from time-dependent natural and anthropogenic forcing, approximately in a nonequilibrium steady state. The natural variability about the time-mean climate state takes the form of coherent, preferred, spatio-temporal patterns with names such as the El-Niño Southern Oscillation, the Madden-Julien Oscillation, the Atlantic Multidecadal Oscillation, and the Pacific Decadal Oscillation. These climate oscillations have large human impacts and their response to anthropogenic climate change is uncertain. Nonequilibrium steady states can be characterized by persistent currents in phase space and we interpret climate oscillations as the physical space manifestation of those phase space currents. We describe a new diagnostic for phase space currents, the phase space angular momentum, which describes the rotational flow of trajectories in phase space by analogy to the mass angular momentum of a fluid rotating in physical space. One advantage of the phase space angular momentum is that it can be readily calculated from an observed time series with no assumptions about an underlying model. We find that the phase space angular momenta in simple stochastic models of the El-Niño Southern Oscillation and the Madden-Julien Oscillation agree surprisingly well with that seen in observations of the climate system. We propose that the phase space angular momentum might be a useful general metric to describe fluctuations in nonequilibrium steady states.

8:36AM F24.00002: Critical Dynamics of Anisotropic Antiferromagnets in an External Field*
UWE CLAUS TAUBER (Presenter), RIYA NANDI, Department of Physics & Center for Soft Matter and Biological Physics, Virginia Tech — We numerically investigate the non-equilibrium critical dynamics in three-dimensional anisotropic antiferromagnets in the presence of an external magnetic field. The phase space of this system exhibits two critical lines which meet at a bicritical point. In this system, the non-conserved components of staggered magnetization order parameter couple dynamically to the conserved component of the magnetization density along the direction of the external field. By employing a hybrid computational algorithm that combines reversible spin precession with relaxational Monte Carlo updates, we study the aging scaling dynamics for the model C critical line, identifying the critical initial slip, decay and aging collapse exponents, thus also verifying the dynamic critical exponent. We also probe the dynamic exponent of the model F critical line by investigating the system-size dependence of the characteristic spin wave frequencies near criticality. Furthermore, we investigate the aging scaling behavior of the slow order parameter and conserved field near the bicritical point.

*Research was sponsored by the U.S. Army Research Office and was accomplished under Grant Number W911NF1710156.

8:48AM F24.00003: Current fluctuations in presence of time-periodic metabolic conditions*
DANILO FORASTIERE (Presenter), GIANMARIA FALASCO, MASSIMILIANO ESPOSITO, University of Luxembourg Limpertsberg — We address the current response to periodic driving of a crucial biochemical reaction network, namely, substrate inhibition. We focus on the conversion rate of substrate into product under time-varying metabolic conditions, modelled by a periodic modulation of the product concentration. Coarse-graining the original model to a minimal solvable one by means of a projection technique, we study the leading behavior of the time averaged current and its fluctuations using a large deviations approach. We show that there exist different regimes, depending on the kinetic rates, in which positive and negative amplitude resonant effects take place, and we provide interpretations for the role that these nonequilibrium effects can play in the metabolic network.

*This work was funded by the European Research Council project NanoThermo (ERC-2015-CoG Agreement No. 681456).
While the biochemistry of metabolism in many organisms is well studied, details of the metabolic dynamics are yet fully explored.

Unless the parameters of a vast number of enzyme-catalyzed reactions happened to fall into very special ranges, a kinetic model on a large metabolic network would fail to reach a steady state.

Acquiring adequate in vivo kinetic parameters experimentally has always been an obstacle.

Approach:
A stable metabolic network can be systematically established via a biologically/evolutionally motivated regulatory process.

May be understood via a landscape description of metabolism as a stochastic system, which draws enzymatic parameters towards stable phase spaces.

Allows explicit thermodynamics constraints on concentrations and optimal balance of efficiency vs viability (i.e. stability/fitness/robustness).

The strategy was applied successfully to the central metabolism of Methylobacterium extorquens AM1 and the secondary metabolism and metabolic switches in Streptomyces xiamenensis 318.

*The work was partially supported by the Natural Science Foundation of China No. 91329301 and No. 91529306 (PA), No. 81273404 and No. 81473105 (MJX).
9:12AM F24.00005: Temperature interfaces in the Katz-Lebowitz-Spohn driven lattice gas* 
RUSLAN MUKHAMADIAROV (Presenter), PRIYANKA ., UWE CLAUS TAUBER, Virginia Tech — We explore the intriguing spatial patterns that emerge in a two-temperature Katz-Lebowitz-Spohn (KLS) model in two dimensions, a driven lattice gas with attractive nearest-neighbor interactions and periodic boundary conditions. The domain is split into two regions with hopping rates governed by different temperatures $T > T_c$ and $T_c$, respectively, where $T_c$ indicates the critical temperature for phase ordering. When the temperature boundaries are oriented transverse to the drive, the hotter region experiences an unexpected phase separation caused by the lower sustained current in the cooler region. The resulting density profiles in both hot and cold subsystems are similar to the well-characterized coexistence and maximal-current phases in (T)ASEP models with open boundary conditions, yet display marked fluctuation corrections. In contrast, when the temperature boundaries are oriented along the drive, the KLS dynamics is crucially determined by the choice of hopping rates across the temperature interfaces. In particular, when the latter break particle-hole symmetry, we observe particle influx from the cooler into the hotter region.

*Research was sponsored by the Army Research Office and was accomplished under Grant Number W911NF-17-1-0156.

9:24AM F24.00006: Anomalous heating in a colloidal system: Observation of the inverse Mpemba effect* 
AVINASH KUMAR (Presenter), JOHN BECHHOEFER, Simon Fraser Univ — We present the first experimental observation of anomalous heating in colloidal systems, a phenomenon known as the inverse Mpemba effect. In particular, under certain conditions, we observe that an initially cold system heats up faster than an identical warm system when coupled to the same thermal bath. We study the effect in a system consisting of a Brownian particle in a tilted double-well potential set in an asymmetric domain. We also study the forward Mpemba effect, where an initially hot system cools faster than an identical warm system. We observe the forward effect for a wide range of temperatures and domain sizes (region in space explored by the particle). By controlling the relative sizes of the basins of attraction of the stable and metastable potential wells, we can provide a direct kinetic path between the hot initial state and the cold equilibrium. We then observe exponentially faster cooling. This is the first experimental evidence for the strong Mpemba effect.

*This research work has been supported by Discovery and RTI Grants from the National Sciences and Engineering Research Council of Canada (NSERC).
9:36AM F24.00007: Decomposition of anomalous diffusion in generalized Lévy walks into its constitutive effects*  VIDUSHI ADLAKHA (Presenter), Department of Physics and TcSUH, Univ of Houston, PHILIPP G. MEYER, EREZ AGHION, HOLGER KANTZ, Max Planck Institute for the Physics of Complex Systems, KEVIN E. BASSLER, Department of Physics and TcSUH, Univ of Houston — Anomalous diffusion is observed in a variety of physical and social systems, including blinking quantum dots, animal locomotion, intra-day trades in financial markets and cold atoms in dissipative optical lattices. Generalized Lévy walks can be used to model their dynamics. We show that the anomalous diffusive behavior found in these systems can be decomposed into three fundamental constitutive causes. These causes, or effects, are related to ways that the Central Limit Theorem fails. The increments generated through the stochastic process can have either long-time correlations, infinite variance, or be non-stationary. Each of these properties can cause anomalous diffusion and is characterized by what is known as the Joseph, Noah and Moses effects, respectively. In generalized Lévy walks, a complex combination of these effects leads to the observed sub- and super-diffusive behaviors. We analytically calculate the scaling exponents determining each of the three constitutive effects and confirm the results with numerical simulations. The results satisfy a fundamental scaling relation between the exponents.

*This work was supported by the NSF through grant DMR-1507371.

9:48AM F24.00008: A coupled two-species model for the pair contact process with diffusion*  SHENGFENG DENG (Presenter), UWE CLAUS TAUBER, Department of Physics, Virginia Tech — The contact process with diffusion (PCPD) defined by the pair reactions $2B \rightarrow 3B$, $2B \rightarrow 0$ and diffusive particle spreading exhibits an unusual active to absorbing phase transition whose universality class has long been disputed. Multiple studies indicated that further coarse-graining of the model may be needed for its effective long-time, large-scale description. We introduce a coarse-grained two-species representation for the PCPD in which single particles $B$ and particle pairs $A$ are coupled according to the processes $2B \rightarrow A$, $A \rightarrow A+B$, $A \rightarrow 0$, $A \rightarrow 2B$, with each type of particles diffusing independently. We employ Monte Carlo simulations in one, two, and three dimensions to demonstrate that this model consistently captures the pertinent features of the PCPD. In the inactive phase, $A$ particles die out rapidly, effectively leaving the $B$ species to undergo pure pair annihilation kinetics. At criticality, both $A$ and $B$ densities decay with similar exponents to those measured for the PCPD and display mean-field scaling above the critical dimension $d_c=2$. In one dimension, exponents for the $B$ species obtained from seed simulations also agree well with previously reported ranges.

*Research was sponsored by the Army Research Office under Grant No. W911NF-17-1-0156 and CSC fellowship (No. 201806770029).
10:00AM F24.00009: Anomalous Diffusion with an Absorbing Wall*  ALEX WARHOVER
(Presenter), THOMAS VOJTA, Missouri Univ of Sci & Tech — Fractional Brownian Motion and the Fractional Langevin Equation, random processes characterized by long-time power law correlations in the noise, are prototypical models for anomalous diffusion. We employ large scale Monte Carlo simulations to investigate these models in the presence of an absorbing wall. In the limit of vanishing correlations, our findings reproduce the well-known results for normal diffusion. In contrast, the interplay between the absorbing wall and the long-range power correlations leads to a singular probability density close to the wall. We compare our results to those of Fractional Brownian Motion [1] as well as the Fractional Langevin Equation [2] in the presence of a reflecting wall, and we discuss implications of our results.

*This work was supported in part by the NSF under Grant No. DMR-1506152 and DMR-1828489.

10:12AM F24.00010: Diffusion in dynamic crowded spaces  DAVID YLLANES (Presenter), HARRY BENDEKGEY, GREG HUBER, LE YAN, Chan Zuckerberg Biohub — Brownian motion in disordered media is now well understood in the case of immobile hard obstacles. In many practical applications, however, the space itself can be dynamic. An important example is transport inside the cell, a very crowded environment with obstacles of varying sizes and complicated shapes that are constantly being rearranged. This situation has received comparatively little attention. With the ever-increasing quality of microscopy techniques, allowing for the tracking of particles inside living cells, the need for a quantitative model is clear.

Here we propose an extension of commonly used "Swiss-cheese" models to include moving obstacles and study it with numerical simulations in one, two and three dimensions. The motion of our tracer particles is anomalous over many decades in time, before reaching a diffusive steady state with an effective diffusion constant that depends on the obstacle density and diffusivity. Moreover, we find that the scaling behaviour of the effective diffusivity, above and below a critical regime at the percolation point for void space, can be characterised by two critical exponents: the conductivity $\mu$, also found in models with frozen obstacles, and a new exponent $\psi$ that quantifies the effect of the obstacle diffusivity.
10:24AM F24.00011: Trajectories and transport characteristics of a Brownian particle in a 1D potential subject to bias.*  TREV JIRON (Presenter), JARROD SCHIFFBAUER, Physical and Environmental Sciences, Colorado Mesa University — We investigate one-dimensional driven, diffusive motion of a single Brownian particle moving through a periodic lattice potential and subject to a constant, uniform bias using a Langevin equation of motion. The model yields explicit trajectories with bias-dependent trapping, hopping, and linear response regimes at sufficiently low temperatures and the statistical behavior generated by an ensemble of trajectories are essentially those of an asymmetric simple exclusion process. Moreover, we find that, at low bias, the system exhibits a negative differential mobility, decreasing with applied bias, to a distinct local minimum in the hopping transport regime. In the context of the dynamical model, we argue the non-monotonic behavior of the transport coefficient can be explained by the role of friction as the particle passes through the minima in each well. Such a model may be employed to describe a wide variety of intriguing transport behaviors. As an example, we show that experimental data on the transition from static to kinetic friction through a plastic regime can be described by such a model.

10:36AM F24.00012: Fluctuation theorem for geometric pumping processes*  HISAO HAYAKAWA (Presenter), Yukawa Institute for Theoretical Physics, Kyoto University — We derive an extended fluctuation theorem for an open quantum system coupled with two reservoirs under one-cycle modulation. We confirm that the geometric phase caused by the Berry-Sinitsyn-Nemenman curvature in the parameter space generates non-Gaussian fluctuations. This non-Gaussianity is enhanced for the instantaneous fluctuation relation when the bias between the two reservoirs disappears.

*This work is partially supported by a Grant-in-Aid of MEXT for Scientific Research (Grant No. 16H04025).
**Stochastic Line Integrals as Metrics of Irreversibility and Heat Transfer**

STEPHEN TEITSWORTH (Presenter), Physics, Duke University, JOHN NEU, Math, UC Berkeley —

Stochastic line integrals provide a powerful tool for quantitatively characterizing irreversibility and detailed balance violation in noise-driven dynamical systems. A particular realization of such integrals, the stochastic area, was recently introduced for linear systems and has been tested experimentally in coupled linear electrical circuits [1,2]. In this talk, we provide a framework for understanding general properties of stochastic line integrals and clarify their implementation for experiments and simulations as well as their utility as metrics for quantifying non-equilibrium behavior. Theoretical results are supported by numerical studies of an overdamped, two-dimensional mass-spring system driven out of equilibrium. In this case, the stochastic area can be concisely expressed in terms of a streamfunction the sign of which determines the orientation of probability current loops. Furthermore, the stream function allows one to analytically understand the dependence of stochastic area on key parameters such as the noise strength (equivalently temperature) for both nonlinear and linear springs.

**Session F25 GSNP: Mechanical Metamaterials II**

**Tuesday, March 3, 2020 8:00 AM - 11:00 AM**

**8:00AM F25.00001: On the design of multi-stable metastructures with rotational degrees of freedom**

YONG ZHANG (Presenter), MARCEL TICHEM, FRED VAN KEULEN, Department of Precision and Microsystems Engineering, Delft Univ of Tech —

Buckling-induced multi-stable metastructures are rationally designed structures whose unit cells exhibit bi-stable or multi-stable configurations. Apart from achieving transitions between two stable states at the unit cell level, metastructures composed of bi-stable beams are also able to realize rotations due to the spatial arrangement of beams. In this work, the design space of the geometric parameters for metastructures exhibiting both rotational and translational motions is explored on the basis of both theoretical and experimental studies. First, numerical results demonstrate that beam thickness, height and length play key roles in determining the rotational snapping. To quantify the effects of these structural parameters, we analytically model the rotational snapping behavior of a representative element that consists of two beam units. Furthermore, we conduct a comprehensive parametric survey based on the proposed model. This study reveals that the rotational stability is highly dependent on the ratio between beam thickness and height. In order to allow for rotational stable states, this ratio should be constrained within a specific range. Finally, we validate these effects by measuring the mechanical response of 3D-printed specimens with different geometric parameters.
8:12AM F25.00002: Prediction of Elastic Wave Propagation Characteristics of Composites via Strong-Contrast Expansions*  JAEUK KIM (Presenter), SALVATORE TORQUATO, Princeton University — The preponderance of previous treatments to predict the effective elastic properties of composites assume the purely static limit. Here we derive exact expressions for effective elastodynamic properties of two-phase composites at intermediate wavelengths by extending the "strong-contrast" expansion approach previously applied to the static problem. The resulting series expansion explicitly incorporates complete microstructural information about the composite via \( n \)-point correlation functions and is endowed with excellent convergence properties, even for high contrast ratios of phase moduli. The fast convergence of this series enables us to extract an accurate approximation that depends on the microstructure via the two-point correlation function or its Fourier counterpart, which we call the "spectral density." Our formula thus extends previous "mean-field" treatments that typically do not account for nontrivial microstructural information and/or are limited to small phase contrasts. We apply our spectral-density formula to a variety of models of disordered composites and discuss how to engineer composites with prescribed attenuation properties for elastic waves.

8:24AM F25.00003: What is the bending rigidity of a book? Stacked plates as a dissipative structured beam  SAMUEL POINCLoux (Presenter), TIAN CHEN, FlexLab, Ecole Polytechnique Federale de Lausanne, BASILE AUDOLY, Laboratoire de mécanique des solides, CNRS, Institut Polytechnique de Paris, PEDRO REIS, FlexLab, Ecole Polytechnique Federale de Lausanne — Multi-layered structures have long been exploited in engineering to design stiff and lightweight structural elements. For example, sandwich-structured composites involve an interplay between the mechanical properties of the individual layers and the inter-layer interactions through the matrix. In the absence of a matrix, when the layers are free to slide with respect to one another, energy is dissipated by frictional interactions. Here, in the context of designing high-performing metamaterial dampers, we focus on providing a quantitative description of the mechanical response of stacks composed of a large number (\( n \sim 50 \)) of elastic plates interacting through friction. In essence, we ask: “What is the bending rigidity of a book?” The mechanical response of our stacks is assessed experimentally through precision nonlinear bending tests. Naturally, our findings deviate from the purely linear elastic case, exhibiting surprising stiffening effects and hysteretic behavior. Taking friction as a perturbation, we develop a predictive model involving the coupling between the geometric nonlinearities, elasticity and friction that is in excellent agreement with experiments.
8:36AM F25.00004: The effect of dualities on elastic moduli
MICHEL FRUCHART (Presenter), VINCENZO VITELLI, University of Chicago — Elasticity describes how a rigid object like a rubber duck goes back to its original form when slightly deformed. Microscopic symmetries impose strong constraints on the elasticity of a crystalline solid. For instance, the elasticity of a 2D crystal with triangular symmetry is isotropic, and hence has only two independent elastic moduli (instead of six without any symmetry). This is because the elastic tensor relating stress and deformation transforms as a tensor under spatial transformations. Hence, it is surprising to encounter a family of anisotropic microscopic crystals devoid of any symmetry that however exhibits isotropic elasticity. We will show that a duality lies at the root of this riddle.

In addition to usual spatial symmetries, non-spatial symmetries can occur microscopically, that are not captured in the tensorial character of the elastic tensor. Such additional symmetries can emerge in families of microscopic systems where a duality transformation relates pairs of different systems: in self-dual systems (mapped to themselves by the duality), the duality can become an new symmetry different from spatial operations. These relations can constrain the elastic tensor, reducing the number of independent moduli both in self-dual systems and away from the self-dual point.

8:48AM F25.00005: Emergent plasticity and hysteresis in disordered packings of filaments.*
NICHALAS WEINER (Presenter), HUNTER KING, University of Akron, YASHRAJ R BHOSALE, MATTIA GAZZOLA, University of Illinois at Urbana-Champaign — A bird's cup-nest can be viewed as a disordered packing of slender grains, defined by average quantities -- coordination number and packing fraction; and dependent on grain properties -- flexibility, friction, and aspect ratio. Experimental data from packings of varying aspect ratio grains, subject to cyclic, quasi-static, oedometric compression reveal two distinctly meta-mechanical responses: plasticity associated with rearrangement without damage; and hysteresis associated with static friction rather than viscoelasticity. These qualitative behaviors appear to be common across systems of round grains to extremely fine fibers. One-to-one numerical simulations allow us to relate otherwise inaccessible micromechanical quantities such as contact distributions to bulk behaviors, confirming underlying assumptions regarding their origin.

*NSF CMMI #1825924
9:00AM F25.00006: Viscoelasticity and plasticity in the formation of creases in thin sheets
BUWANETH DHARMADASA (Presenter), University of Colorado, Boulder, CHINTHAKA H.M.Y. MALLIKARACHCHI, University of Moratuwa, FRANCISCO LOPEZ JIMENEZ, University of Colorado, Boulder — Origami inspired folding, which enables the transformation of a flat sheet into different geometries, has recently become a topic of interest among the engineering community as it helps solving problems ranging from deployable structures for space engineering to micro scale grippers for bio-medical applications. However, the mechanics of a folded sheet are not only governed by the sheet properties and the folding pattern, but also by the properties of the creases. We study them by performing experiments exploring the influence of different control parameters, such as the applied force and the time the film was pressed. We rationalize the experimental results with numerical simulations: a 1D elastica beam model and a high-fidelity finite element analysis, both accounting for elasto-plastic behavior and non-linear geometry. By considering the curvature localization, we can define a crease length that depends on the properties of the film and the fold control parameters. We found that non-dimensionalized results provide a robust scaling that enables to extend the results to other geometries and material properties. We also explore the effect of viscoelasticity of the sheet material.

9:12AM F25.00007: Viscoelastic Metamaterials
DAVID DYKSTRA (Presenter), JORIS BUSINK, Institute of Physics, University of Amsterdam, ALEKSI BOSSART, School of Engineering, École polytechnique fédérale de Lausanne, JOP VAN DER LAAN, Institute of Physics, University of Amsterdam, BERNARD ENNIS, Materials Design Department, Tata Steel Europe R&D, CORENTIN COULAIS, Institute of Physics, University of Amsterdam — We show how viscoelasticity can be harnessed to increase functionality in mechanical metamaterials. First, we explore experimentally the mechanical snap-through response of metamaterials that are made of constituents that exhibit large viscoelastic relaxation effects, encountered in the majority of rubbers [1]. Second, we demonstrate that we can rationally design multimode mechanical metamaterials, featuring viscoelastic and elastic elements. By altering the loading rate, we can switch between the two modes of deformation. Our findings bring a novel understanding of metamaterials in the dynamical regime and opens up avenues for the rational design of multifunctional viscoelastic metamaterials.

9:24AM F25.00008: Memory of a mechanical metamaterial
HADRIEN BENSE (Presenter), MARTIN VAN HECKE, FOM Inst - Amsterdam — Many disordered systems – granular suspensions, spin-glasses, crumpled paper – present history dependent features. However, their complex geometry makes observing, understanding and controlling such memory effects challenging. We introduce a class of patterned thin sheets that, when forced, exhibit controlled crumpling via elastic snap-through instabilities. Individual snap-through events act as `hysterons' that can be observed directly, and that lead to complex yet fully observable deformation pathways. We explore a variety of memory effects in these system, and connect memory to pathways.
**9:36AM F25.00009: Amplitude-dependent input to reprogram static and dynamic properties of multistable structures**

HIROMI YASUDA (Presenter), LUCIA KORPAS, JORDAN R. RANEY, University of Pennsylvania — Phase transformations can be observed from the nanometer scale of crystalline order to macroscale mechanical structures. These transformations are often associated with dramatic reconfigurations and changes to properties. Here, we study a tunable mechanical structure composed of a 1D chain of rotating squares and embedded magnets, with each cell along the chain capable of being in any of three possible stable phases, defined by the angular orientation of the square. We demonstrate the ability to change the static and dynamic responses, particularly linear/nonlinear wave dynamics, by reversibly reconfiguring the structure via controlled use of transition waves. We numerically and experimentally demonstrate the propagation of transition waves in a 1D chain. We then analyze the dynamic properties of the chain, including the opening/closing of a frequency band gap, and the coupling behavior between rotational and translational motion as a function of the phase. We demonstrate that transition waves with opposite rotational directions can be generated, and that a collision between such waves results in the formation of a phase boundary.

**9:48AM F25.00010: Porous Inclined Auxetic Structural Material**

MATHEUS C FERNANDES (Presenter), John A. Paulson School of Engineering and Applied Sciences, Harvard University, SAURABH MHATRE, OLGA MESA, Graduate School of Design, Harvard University, KATIA BERTOLDI, John A. Paulson School of Engineering and Applied Sciences, Harvard University, MARTIN BECHTHOLD, Graduate School of Design, Harvard University — Porous structural materials with well-defined periodicity are ubiquitous not only in nature but also in synthetic structures and devices. These types of materials have been proven to offer various types of auxetic behavior, ranging from negative Poisson's ratio to high energy absorption and excellent acoustic damping. Yet, here we present a novel auxetic behavior harnessed by introducing angled cuts into a periodic porous material. Using this approach, we utilize out-of-plane behavior with the potential to control friction, light emission and reflection, as well as fluid flow properties. Using a combination of physical experiments and non-linear finite element analysis, we study the effects of geometry on creating and propagating this out-of-plane auxetic behavior.

*NSF-GRFP Fellowship Grant DGE-1144152 (for M. C. F.)
10:00AM F25.00011: Engineering auxetic geometry design for flexible and stretchable devices  YU-KI LEE (Presenter), Department of Materials Science and Engineering, Seoul National University, YOUNG-JOO LEE, Department of materials science and engineering, University of pennsylvania, YOUNG-CHANG JOO, IN-SUK CHOI, Department of Materials Science and Engineering, Seoul National University — In this talk, we present how the auxetic design can be used to flexible and stretchable electronic devices. An auxetic structure called 'fractal cut', which means that the basic rotating units can be subdivided into a self-similar hierarchy, enables us to develop extremely and omni-directionally deformable batteries. During stretching or crumpling, deformation occurs only at hinges between two adjacent units while the units did not undergo distortion. In addition, a re-entrant auxetic elastomer used for capacitive-type stretchable strain sensor can overcome the theoretical limit of the conventional capacitive-type strain sensor. We believe that our auxetic geometry design can provide a strategy to apply mechanical metamaterials for fabricating flexible and stretchable electronic devices.

10:12AM F25.00012: Auxetic foam revisited: understanding the origin of negative Poisson's ratio using micro-CT and pore structure analysis*  LAMEI DU, SIDA LUO, YE XU (Presenter), BeiHang University — Porous foam with negative Poisson's ratio, namely auxetic foam, is a typical mechanical metamaterial. One of the commonly used approach in producing auxetic foam is the thermomechanical compression of porous thermoplastic materials such as Polyurethane (PU) foams. While qualitatively it is well understood that the negative Poisson's ratio arises from the reentrant cell shape, quantitative relation between the auxetic behavior and pore structure is still lacking. Using micro-CT, we systematically quantify the pore structures of a series of auxetic PU foams prepared with various degrees of thermomechanical compression, and correlate with their mechanical behaviors measured from tensile tests. We find that the fraction of bucked ribs of the pore structure is related to the initial value of Poisson's ratio upon stretching while the extent of buckling is related to the maximum tensile strain for negative Poisson's ratio. Our findings can shed light in designing mechanical metamaterials with targeted auxetic behaviors.

*This work is supported by National Natural Science Foundation of China (Grant No. 11674019)
10:24AM F25.00013: Dynamics and Topology of Non-Hermitian Elastic Lattices with Non-Local Feedback Interactions* MATHEUS NORA ROSA (Presenter), Georgia Inst of Tech, MASSIMO RUZZENE, Department of Mechanical Engineering, University Of Colorado Boulder — We investigate a family of non-Hermitian 1D elastic lattices whereby feedback control is used to establish non-local, non-reciprocal strain based interactions. We demonstrate that wave propagation is largely non-reciprocal for all frequencies within the dispersion bands, manifesting as either gain or loss for opposite propagation directions. The non-reciprocal bands are tunable based on the non-local interactions, which can define multiple frequency bands with opposite non-reciprocal behavior. The large non-reciprocity also manifests in finite lattices whereby all the bulk eigenmodes are localized at a boundary, which is known as the non-Hermitian skin effect. In analogy to recent work in quantum lattices, we show that the winding numbers of the dispersion bands on the complex plane predict the localization edge of the skin modes of finite lattices, which can be interpreted as a bulk-bulk correspondence principle. Finally, we investigate wave propagation in 2D lattices where directional non-reciprocity is demonstrated, and show preliminary results that suggest a 2D manifestation of the non-Hermitian skin effect in the form of corner modes for finite lattices.

10:36AM F25.00014: Non-Commuting Mechanical Metamaterials AMITESH SINGH (Presenter), Leiden University, MATTHIEU LABOUSSE, ESPCI Paris, MARTIN VAN HECKE, Leiden University — Strategies for programmable metamaterial design need to be sensitive to the order of input signals. Here, we introduce a non-commuting mechanical metamaterial that consists of a quasi-1D chain of weakly symmetry-broken beams. We demonstrate, via simulations and experiments, that its response depends on the order of external actuation. Our work opens a new route to mechanical memory and reprogrammable metamaterials.

10:48AM F25.00015: Bounds on resonant bandgap limits in a branched 1D lattice modeled by Bloch’s theorem MARY BASTAWROUS (Presenter), MAHMOUD I. HUSSEIN, Ann and H.J. Smead Department of Aerospace Engineering Sciences, University of Colorado Boulder — Elastic metamaterials exhibit unique properties associated with local resonance band gaps. A 1D lattice unit cell comprising a monatomic chain connected to a branch is examined leading to mathematical relations relating the vibration behavior of the independent branch to the dispersion of the entire unit cell. This perspective is distinct from studying the resonances of the full system and relating them to the local-resonance band gaps. The closed-form relation, based on Bloch’s theorem, determines the dependence of the upper and lower band-gap limits on the resonances and antiresonances of the frequency response of the separate branch. This offers a formal approach for identifying bounds for the location of band-gap edges. Moreover, it demonstrates that local resonance band gaps form as a result of a balance between the inertia and restoring forces of the main chain and the branch effective restoring force. This framework is further employed to study a special case where the branch is constructed out of a finite number of repeating diatomic units where the periodic branch's Bragg band gaps are exploited. Conditions are derived for a global unit-cell dispersion exhibiting super-wide local resonance band gaps or pass bands, super narrow pass bands, and tailored fano-resonances.
8:00AM F26.00001: **Vimentin intermediate filament biomechanics in 3D cell motility** [invited]

ALISON PATTESON (Presenter), Physics, Syracuse University — The migration of cells through confining spaces in tissues is important for many biological processes and depends on the mechanical properties of a cytoskeleton made up of three different filaments: F-actin, microtubules, and intermediate filaments. The signaling pathways and cytoskeletal structures that control cell motility on 2D are often very different from those that control motility in 3D. Previous studies have shown that intermediate filaments can promote actin-driven protrusions at the cell edge, but have little effect on overall motility of cells on flat surfaces. They are however important for cells to maintain resistance to repeated compressive stresses that are expected to occur *in vivo*. Using mouse embryonic fibroblasts derived from wild-type and vimentin-null mice, we find that loss of vimentin increases motility in 3D micro-channels even though on flat surfaces it has the opposite effect. Atomic force microscopy and traction force microscopy experiments reveal that vimentin enhances perinuclear cell stiffness while maintaining the same level of acto-myosin contractility in cells. We propose a minimal model in which a perinuclear vimentin cage constricts along with the nucleus during motility through confining spaces, providing mechanical resistance against large strains that can damage the structural integrity of cells and their nuclei.

8:36AM F26.00002: **Confined cell migration - a dynamical systems perspective**

DAVID BRÜCKNER (Presenter), ALEXANDRA FINK, MATTHEW SCHMITT, NICOLAS ARLT, JOACHIM O RÄDLER, CHASE BROEDERSZ, Faculty of Physics and Center for NanoScience, Ludwig Maximilian University Munich — In many biological phenomena, cells migrate through confining environments. However, a quantitative conceptual framework for confined migration has remained elusive. To provide such a framework, we employ a data-driven approach to infer the dynamics of cell movement, morphology and interactions of cells confined in two-state micropatterns. In this confinement, cells stochastically migrate back and forth between two square adhesion sites connected by a thin bridge. By inferring a stochastic equation of motion directly from the experimentally determined short time-scale dynamics, we show that cells exhibit intricate non-linear deterministic dynamics that adapt to the geometry of confinement. This approach reveals that different cell lines exhibit distinct classes of dynamical systems, ranging from bistable to limit cycle behavior. To connect these findings to underlying migratory mechanisms, we track the evolution of cell shape and develop a framework for the dynamics of cell morphology in confinement. Our approach yields a conceptual framework for the motility and morphology of confined cells which can be generalized to more complex environments including multiple interacting confined cells.
Finite element simulation of a cell entering a pipette: Effects of large deformation and frictional contact

XIAOHAO SUN (Presenter), Mechanical Engineering, University of Colorado, Boulder, KE WANG, Institute of Electronics, Chinese Academy of Sciences, HENGAN WU, Modern Mechanics, University of Science and Technology of China, JIAN CHEN, Institute of Electronics, Chinese Academy of Sciences, RONG LONG, Mechanical Engineering, University of Colorado, Boulder — The process of single cells entering a confined channel under pressure is widely seen in cell mechanics experiments (e.g., micropipette aspiration) and biological process (e.g., tumor cell migration in capillaries). Finite element method that models the cell as a continuum solid has been extensively used to study this process. However, most previous modeling studies suffered from limitations including inaccurate pressure and frictional boundary conditions, therefore making it challenging to simulate the complete entry process involving large deformation of the cell. Here we present a simulation approach that can continuously update the boundary condition according to the contact status as the cell enters the channel, thus enabling more accurate description of the pressure and frictional conditions. Using a quasi-linear viscoelastic solid model for the cell, we show that the detailed pressure boundary condition and interface friction coefficients can significantly affect the cell entry process.

Modeling the effect of vimentin on confined cell motility.

SARTHAK GUPTA (Presenter), ALISON PATTESON, JENNIFER SCHWARZ, Physics, Syracuse University — As a cell moves in a strongly confined geometry, its cytoskeleton undergoes changes as does the peri-nuclear cage. How do these changes affect cell motility? The cytoskeleton is made up of three different semi-flexible polymers: actin, microtubules, and intermediate filaments, such as vimentin. Recent studies demonstrate that the loss of vimentin enhances cell motility through micro-channels and confining spaces, though it has the opposite effect in 2D. We are, therefore, modeling the effects of intermediate filaments on cell motility in confinement to understand these latest experiments. We have developed a biophysical model for a cell moving through various confined geometries based on Brownian dynamics. It includes an intracellular network along with a peri-nuclear cage, both of which involve vimentin. We explore a possible mechanism behind the enhanced motility of vimentin-null cells, irrespective of channel width, in comparison to wild-type. We also characterize the increased speed of vimentin-null cells with increasing confinement and the minimal effect on the speed of wild-type cells under the same conditions. We also investigate the effects of flexible confinement walls on cell motility to better mimic the physiological conditions.

NSF-DMR-1832002
9:12AM F26.00005: Regulation of nuclear architecture, mechanics, and nucleocytoplasmic shuttling of epigenetic factors by cell geometric constraints* [Invited] FARID ALISAFAEI, University of Pennsylvania, DOORGESH SHARMA JOKHUN, GV SHIVASHANKAR, National University of Singapore, VIVEK SHENOY (Presenter), University of Pennsylvania — Cells sense mechanical signals from their microenvironment and transduce them to the nucleus to regulate gene expression programs. To elucidate the physical mechanisms involved in this regulation, we developed an active 3D chemomechanical model to describe the three-way feedback between the adhesions, the cytoskeleton, and the nucleus. The model shows local tensile stresses generated at the interface of the cell and the extracellular matrix regulate the properties of the nucleus, including nuclear morphology, levels of lamin A,C, and histone deacetylation, as these tensile stresses 1) are transmitted to the nucleus through cytoskeletal physical links and 2) trigger an actomyosin-dependent shuttling of epigenetic factors. We then show how cell geometric constraints affect the local tensile stresses and subsequently the three-way feedback and induce cytoskeleton-mediated alterations in the properties of the nucleus such as nuclear lamina softening, chromatin stiffening, nuclear lamina invaginations, increase in nuclear height, and shrinkage of nuclear volume. We predict a phase diagram that describes how the disruption of cytoskeletal components impacts the feedback and subsequently induce contractility-dependent alterations in the properties of the nucleus. Our simulations show that these changes in contractility levels can be also used as predictors of nucleocytoplasmic shuttling of transcription factors and the level of chromatin condensation. The predictions are experimentally validated by studying the properties of nuclei of fibroblasts on micropatterned substrates with different shapes and areas.

9:48AM F26.00006: Effective pressure in a dense cell monolayer and collective cell migration EVGENIY KHAIN (Presenter), Physics, Oakland University — A system of dividing and growing cells provides an intriguing example of active matter far from equilibrium. Living cells in a dense system are all in contact with each other. The common assumption is that such cells stop dividing due to a lack of space. Recent experimental observations have shown, however, that cells continue dividing for some time, even after a dense cell monolayer is formed. Effective pressure is introduced in order to model the experimentally observed phenomenon in which the average cell size dramatically decreases over time, and cell area distribution becomes narrower. For a non-uniform system, I will consider the cell shift due to the gradient of the effective pressure and examine its effect on the average cell area profiles. Then I will discuss collective cell migration where cells maintain contact with their neighbors. This migration can be described in terms of a novel front propagation phenomenon; the front speed and effective pressure profile are found both numerically and analytically.
10:00AM F26.00007: Effects of cell-cell adhesion on collective migration of multicellular clusters*  USHASI ROY (Presenter), ANDREW MUGLER, Physics and Astronomy, Purdue University — Collections of cells exhibit directional coherent migration during morphogenesis, cancer-metastasis, and wound healing. Often during migration, bigger clusters split, smaller sub-clusters collide and reassemble, and gaps continually emerge. This leads to the formation of protrusions by some inner cells which eventually act as “leaders”, along with the cells at the leading edge, pulling the cluster towards the favorable direction. Large populations like neural crest cells are known to exhibit such phenomena. We hypothesize that the cells may have an optimal adhesion among themselves, rather than very strong or weak, to favor the formation of gaps and achieve an effective faster migration. We test this hypothesis for one- and two-dimensional cell clusters that collectively track chemical gradients using a mechanism based on contact inhibition of locomotion. We develop both a minimal framework based on the lattice gas model of statistical physics, as well as a more realistic framework based on the cellular Potts model. Results from both frameworks support our hypothesis, suggesting that intermediate adhesion leads to optimal migration. We discuss the mechanisms behind this optimum and relate our results to specific cellular systems.

10:12AM F26.00008: Plasticity of cell migration resulting from mechanochemical coupling*  ELISABETH GHABACHE (Presenter), YUANSHENG CAO, WOUTER-JAN RAPPEL, University of California, San Diego — Eukaryotic cells can migrate using different modes, ranging from amoeboid-like, during which actin filled protrusions come and go, to keratocyte-like, characterized by a stable actin wave at the front of the cell and persistent motion. How cells can switch between these modes is not well understood but waves of signaling events that lead to actin waves propagation are thought to play an important role in these transitions. Our experiments, performed with Dictyostelium discoideum, show that systematically reducing the protrusion force of the actin network using a drug, latrunculin B, leads to different migration modes including amoeboid-like and keratocyte-like. We find that a sufficient decrease of the protrusion force can destabilize keratocyte-like cells, resulting in cells that employ amoeboid-like migration. We then present a simple two-component biochemical reaction-diffusion model based on relaxation oscillators and couple this to a model for the mechanics of cell deformations. Predictions of the model are in good agreement with the experiments. Our results indicate the importance of coupling signaling events to cell mechanics and morphology and may be applicable in a wide variety of cell motility systems.

10:24AM F26.00009: Collective Cell Migration in Wound Healing  KELLY VAZQUEZ (Presenter), JACOB NOTBOHM, University of Wisconsin - Madison — Following a wound, epithelial cells migrate collectively to heal. During healing, “leader cells” begin to form at the free edge and migrate as finger-like, multi-cellular protrusions into the wound boundary. While the presence of leader cells is well documented, factors contributing to their formation is not well understood. Standard wound healing assays often culture cells against a physical barrier, and cells migrate to the free space once the barrier is removed. However, the role of time in culture against a barrier in leader cell formation has not been studied. To address this, a monolayer of Human Keratinocytes (HaCaTs) is seeded against PDMS barriers. The time in culture is varied to study its effect on cell force, motion, wound closure, distribution of actin, and the presence of leader cells following barrier removal by using traction force microscopy and fluorescent imaging. With increased time against a barrier, the number of leader cells increased, a multi-cellular actin cable was formed at the leading edge, and cell migration speeds decreased. The resulting data point to the importance of time in culture in altering cellular mechanics to affect wound healing and add new understanding of factors affecting formation of leader cells in collective cell migration.

10:36AM F26.00010: Traction dynamics in collective cell migration  AASHRITH SARASWATHIBHATLA (Presenter), University of Wisconsin - Madison — Recent theoretical models have emphasized cell motility force as a key driver of collective cell migration. In experiments, the equivalent to the motility force is traction applied by each cell to the substrate, which can be measured by traction force microscopy. Previous experiments have measured tractions in groups of cells but have not tracked tractions applied by individual cells. As a result, there is a lack of information on single-cell tractions over time, which makes it difficult to bridge the gap between single cell and collective cell dynamics. Here, we designed experiments to follow cells in a Lagrangian frame of reference, tracking each cell using fluorescent imaging of its nucleus. To investigate the evolution of traction of each cell over time, we built a Voronoi tessellation based on the centroids of cell nuclei and mapped tractions obtained from traction force microscopy onto each cell's Voronoi-based polygon. The resulting data can be used to compute different metrics of traction dynamics of each cell such as the persistence of both direction and magnitude of traction. This new approach helps to investigate theoretical predictions of cell motility force on collective cell migration, thus bridging the gap between single cell and collective cell dynamics.

Session F27 FIAP: Electronic Structure: Theory & Spectra  404 - Maicol Ochoa, National Institute of Standards and Technology
8:00AM F27.00001: Extracting Electron Densities in n-Type GaAs from Raman Spectra.
MAICOL OCHOA (Presenter), IREAP, University of Maryland College Park, JAMES E MASLAR, HERBERT S. BENNETT, National Institute of Standards and Technology — Raman measurements can be utilized as a non-destructive method for determining carrier density in compound semiconductors. Rigorous determination of carrier density involves comparing measured and simulated coupled phonon-plasmon Raman spectra. Theories of varying degrees of complexity have been employed for simulating spectra in which spectra are generated as a function of Fermi energy (or carrier density in the degenerate limit). In general, previously utilized spectral models are strictly valid only for a temperature near 0 K and either for the classical or degenerate doping limit. However, such models cannot necessarily capture all spectral information. To overcome this limitation, we have developed a model that is valid at any temperature, any doping level, and for arbitrary values of the ratio $Q^2/\alpha$ (where $Q$ is the magnitude of the normalized wavevector, and $\alpha$ is the normalized frequency used in the Raman measurements). We compare measured n-type GaAs spectra, obtained from epilayers with different carrier concentrations, with simulated spectra obtained with this new spectral model employing different descriptions of the band structure as a function of Fermi energy.

8:12AM F27.00002: Microscopic perspective on the magnetoelectric response of an insulator*
PERRY MAHON (Presenter), JOHN EDWARD SIPE, University of Toronto — We implement a microscopic theory of polarization and magnetization to calculate the magnetoelectric response of an insulator at zero temperature. To first order in the applied fields the free charge and current densities vanish, and as a consequence the response of the system is characterized by the first-order corrections to the microscopic polarization and magnetization fields arising from the applied electric and magnetic fields. Associated with the dipole moment of the microscopic polarization (magnetization) field is a macroscopic polarization (magnetization), for which we extract various response tensors. The magnetoelectric tensor is composed of two distinct parts: the Chern-Simons and cross-gap contributions. We compare our results for these with those of earlier work. We analyze the origin of both the Chern-Simons and cross-gap terms from the perspective of our microscopic theory, and find the former to arise from more “localized” contributions to the response, while the latter to arise from more “extended” contributions.

8:24AM F27.00003: Accurate, Ground State Electronic and Transport Properties of h- BN
YURIY MALOZOVSKY (Presenter), CHEIK BAMBA, ANTHONY STEWART, LASHOUNDA T FRANKLIN, DIOLA BAGAYOKO, Southern Univ & A&M Coll — We present an ab-initio, density functional theory (DFT) description of ground state electronic and related properties of hexagonal boron nitride (h-BN). We used a local density approximation (LDA) potential and the linear combination of atomic orbitals (LCAO) formalism. We implemented the Bagayoko, Zhao, and Williams method, as enhanced by Ekuma and Franklin (BZW-EF). The method leads to the ground state of the material, in verifiable manner, without employing over-complete basis sets. Consequently, our results possess the full, physical content of DFT, as per the second DFT theorem [AIP Advances, 4, 127104 (2014)]. We report the ground state band structure, band gap, total and partial densities of states, and electron and holes effective masses. Our calculated, indirect band gap of 4.3 eV is in excellent agreement with the measured value. The valence band maximum is slightly to the left of the K point, while the conduction band minimum is at the M point. Our calculated total width of the valence, total and partial densities of states are in agreement with corresponding, experimental findings.

8:36AM F27.00004: Electronic structure of p-type transparent conducting oxide CuAlO₂
MOHAMED SALAH (Presenter), ALS, Lawrence Berkeley National Laboratory, JOONSEOK YOON, Department of Physics, Yonsei University, XIAOSONG LIU, WANLI YANG, ALS, Lawrence Berkeley National Laboratory, BONGJIN SIMON MUN, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, MOHAMED MAHMOUD EL-DESOKY, Physics Department, Suez University, ZAHID HUSSAIN, ALS, Lawrence Berkeley National Laboratory, HONGLYOUL JU, Department of Physics, Yonsei University, SUNG-KWAN MO, ALS, Lawrence Berkeley National Laboratory — Transparent Conducting Oxides (TCOs) are generally considered to be very distinctive material because of their combining of electrical conductivity with the visible light transmission in a single material. The delafossite oxide CuAlO₂ is a p-type TCO which can be used to fabricate transparent p-n junction from TCO materials. In this work, we combine angle-resolved photoemission spectroscopy (ARPES) and X-ray emission and absorption spectroscopies (XES & XAS), to visualize the low-energy electronic structure. Fermi surface topology, detailed band structure, the effective mass of valence electrons, and the band gap size of the single crystal CuAlO₂ were examined experimentally. The electronic structure obtained from ARPES measurements are compared with theoretical calculations. These results indicate that CuAlO₂ is a good p-type TCO that may serve as a platform for optoelectronic applications.
A higher-dimensional electronic superstructure in a misfit chalcogenide (PbSe)_{1.16}(TiSe_2)_2

YUHKO KOHSAKA (Presenter), RIKEN, TEPPEI UENO, Okayama University, TADASHI MACHIDA, TETSUO HANAGURI, RIKEN, JUN AKIMITSU, KAYA KOBAYASHI, Okayama University — Aperiodic crystals, despite lack of translational invariance, are characterized by the primitive vectors as periodic crystals. A characteristic of aperiodic ones is number of the primitive vectors, which is larger than the physical dimension. This represents higher-dimensional nature of aperiodic crystals, resulting in exotic phenomena in atomic quasicrystals, light, and ultracold atom. However, no higher-dimensional phenomena have been found in electronic matters, where inner degrees of freedom and strong correlation are involved to yield rich phenomena. Here we show a higher-dimensional electronic modulation in a misfit chalcogenide (PbSe)_{1.16}(TiSe_2)_2 with spectroscopic imaging scanning tunneling microscopy. We find that the local density-of-states exhibits an aperiodic superstructure while the periodic charge density wave of 1T-TiSe_2 is completely suppressed. Our finding demonstrates that the interplay between hexagonal and tetragonal sublattices provides the electronic matters with extra degrees of freedom from higher dimensions and higher-dimensional electronic properties can be explored in a wider range of materials including artificial heterostructures.
