Session 1A DPOLY: DPOLY Short Course: Machine Learning for Polymer Physicists I 201

1:00PM 1A.00001: DPOLY Short Course: Machine Learning for Polymer Physicists I — Recent developments in machine learning and related data-driven approaches have created a new paradigm for approaching scientific research. The field of polymer physics has seen important applications in the design of experiments, analysis of scattering data, prediction of molecular properties, and identification of important structural and dynamic patterns. Additionally, the use of high throughput computational and experimental techniques promises to increase the amount of data available to polymer physicists and presents new opportunities for discovery. This day and a half short course will provide an essential introduction to machine learning and data analytics as relevant to polymer physicists, while also showcasing recent advances by leaders in the field. Topics covered will include data capture, design of experiments, varying levels of data quality, model building, optimization and general analysis of both experimental and computational data. Attendees will leave with a sound basis in key algorithmic concepts including when those algorithms are appropriate, an understanding of the state-of-the-art applications, and a foundational understanding of how to incorporate machine learning and data science into their current research.

Session 1B GDS: GDS Short Course: Deep Learning for Image Processing Applications 212
Artificial Intelligence (AI) is a collection of advanced technologies and mathematical methodologies that allows machines to think and act through sensing, comprehending, acting, and learning. This half-century-old field of research has recently garnered renewed attention, partly by several breakthroughs in the design of new AI algorithms, in particular, for image analysis, but also because of the new computing technologies that make the calibration of AI models feasible on personal computers, thus allowing their wide-spread usage by individual researchers in diverse fields of science and engineering. This hands-on workshop will be investigating how deep learning techniques for image analysis can be adapted or developed to address topics and challenges in image analysis and material science. Some of these topics are hyperspectral data analysis in imaging, deep learning applications in active imaging (denoising, drift correction, and deep-learning-based feature extraction), materials discovery, and learning physics from imaging data of mesoscopic and stochastic systems.

Sunday, March 1, 2020 8:00 AM - 4:30 PM

Session 1C GSNP: GSNP Short Course: Machine Learning in Statistical and Nonlinear Physics

Machine learning tools play a growing role in progress in many fields of science. The complex systems addressed by statistical and nonlinear physics are often well suited to exploration with machine learning. In turn, the physics approaches for studying these systems has lead to improvements in machine learning in a new area called the "Physics of Artificial Intelligence." This workshop will include pedagogical talks by experts in our field as well as hands-on computational activities.

Sunday, March 1, 2020 8:15 AM - 4:30 PM

Session 1D DPOLY: DPOLY Short Course: Machine Learning for Polymer Physicists II
Recent developments in machine learning and related data-driven approaches have created a new paradigm for approaching scientific research. The field of polymer physics has seen important applications in the design of experiments, analysis of scattering data, prediction of molecular properties, and identification of important structural and dynamic patterns. Additionally, the use of high throughput computational and experimental techniques promises to increase the amount of data available to polymer physicists and presents new opportunities for discovery. This day and a half short course will provide an essential introduction to machine learning and data analytics as relevant to polymer physicists, while also showcasing recent advances by leaders in the field. Topics covered will include data capture, design of experiments, varying levels of data quality, model building, optimization and general analysis of both experimental and computational data. Attendees will leave with a sound basis in key algorithmic concepts including when those algorithms are appropriate, an understanding of the state-of-the-art applications, and a foundational understanding of how to incorporate machine learning and data science into their current research.

Sunday, March 1, 2020 8:30 AM - 12:30 PM

Session 1E APS: Tutorial 1: Density Functional Theory 607

Density Functional Theory (DFT) provides a practical route for calculating the electronic structure of matter at all levels of aggregation. Five decades after its inception, it is now routinely used in many fields of research, from materials engineering to drug design. Time-dependent Density Functional Theory (TDDFT) has extended the success of DFT to time-dependent phenomena and excitations. Most applications are carried out in the linear-response regime to describe excitation and emission spectra, but the theory is applicable to a much broader class of problems, including strong-field phenomena, attosecond control of electron dynamics, nanoscale transport, and non-adiabatic dynamics of coupled electron-nuclear systems. The tutorial will provide an introduction to the basic formalism of DFT and TDDFT, an overview of state-of-the-art functionals and applications, and a discussion of the most pressing and challenging open questions.

Sunday, March 1, 2020 8:30 AM - 12:30 PM

Session 1F APS: Tutorial 2: Active Learning and AI for Computational and Autonomous Experiments 605
**8:30AM 1F.00001: Tutorial 2: Active Learning and AI for Computational and Autonomous Experiments** — During the course of research, we are often faced with the question of which experimental or computational measurement to perform next. When these measurements are expensive or time-consuming to perform, this question becomes critical. Active learning is a technique in machine learning that provides a framework to systematically answer that question by finding an optimal set of measurements to maximize knowledge gained (given the results already in hand), thus controlling the cost. Machine Learning can then be placed in control of materials synthesis and characterization in a closed-loop system, with active learning providing experiment design on every iteration. Recent examples of autonomous systems include mapping out phase diagrams as well as choosing which computational experiments to perform. In this tutorial, we will introduce the theory of Gaussian processes and active learning using open source python libraries. Here, Gaussian processes are used to learn from prior data and make predictions for the results of future experiments, with associated uncertainty. Active learning then utilizes these predictions to determine the next best experiment to perform. Hands-on exercises will be provided based on actual use cases.

**Sunday, March 1, 2020 8:30 AM - 12:30 PM**

**Session 1G APS: Tutorial 3: Noisy Quantum Devices 601-603**

**8:30AM 1G.00001: Tutorial 3: Noisy Quantum Devices** — The last few years have seen impressive progress in the construction of multi-qubit quantum devices towards the ultimate goal of a fault-tolerant universal quantum computer. However, until we achieve this final goal, we must learn to take advantage of large, but rather noisy devices. Since there are multiple technologies being explored, such as superconducting circuit, ions and spins, we must also learn how to devise tools that are agnostic to the underlying implementation. In this regime there are two main challenges. One challenge is how to characterize and (hopefully) improve errors due to this noise. The other challenge is how to harness the quantum behavior available despite this noisy environment. There are many proposals and some demonstrations for how to obtain a quantum advantage in such systems. These lectures will give an introduction to the types of noise on these devices, typical characterization methods, and applications.

**Sunday, March 1, 2020 9:00 AM - 6:00 PM**

**Session 1H DSOFT: DSOFT Short Course: DNA Nanotechnology Meets Soft Matter 205**
DNA Nanotechnology is a rapidly growing technology impacting many sectors of science and technology, and in particular it is increasingly being harnessed to tackle new and frontier challenges in soft matter science. This course aims to introduce junior researchers in the soft matter field about the elements of DNA Nanotechnology and the state-of-the-art in how it is being applied to address problems in soft matter science and engineering. The course will cover topics outlining the physical chemistry of DNA, the design and assembly of DNA based nanostructures such as DNA tiles and DNA origami, the programming of assembly using DNA, DNA based hydrogels, and DNA-functionalized colloids.

Sunday, March 1, 2020 1:30 PM - 5:30 PM

Session 1J APS: Tutorial 4: Data Analysis and Modern Visualization 607

1:30PM 1J.00001: Tutorial 4: Data Analysis and Modern Visualization — Visualization is an integral part of the scientific process. As an excellent communication tool used by researchers, it is crucial to make complicated scientific data and relations accessible and understandable. This tutorial will train attendees to expand and develop their visualization skills by providing a "from the ground up" understanding of visualization and its utility in error diagnostic and exploration of data for scientific insight. When used effectively, visualization can provide a complementary and effective toolset for data analysis, which is one of the most challenging problems in many scientific domains. We plan to bridge these gaps by providing attendees with fundamental visualization concepts, execution tools, customization, and usage examples. The tutorial will cover different viewpoints, including (1) a rapid introduction to fundamental visualization concepts, (2) an assay of visualization techniques available accompanied by example application scenarios centered around the VisIt software, (3) scientific data visualization using the Blender software, and (4) combination of visualization of data into advanced animations and videos using a full programming language such as Matlab or Python.

Sunday, March 1, 2020 1:30 PM - 5:30 PM

Session 1K APS: Tutorial 5: Medical Metrology 605
1:30PM 1K.00001: Tutorial 5: Medical Metrology — Medicine is becoming increasingly quantitative. Continuing innovation in medical sensors has greatly expanded the range of physical variables that can be accurately measured to probe various aspects of the structure, function, and composition of human body. The analysis of the resulting rich streams of information is enabled by the rapidly developing data science techniques, yielding sophisticated quantitative descriptors of disease and therapeutic response ("quantitative biomarkers"). The trend towards measurement-driven medicine opens exciting opportunities for physicists to contribute their expertise in metrology. This tutorial will cover (i) recent advances in medical sensor technologies (How and what do we measure?), (ii) the discovery and validation of quantitative biomarkers (How do we establish whether a given physical measurement is a biomarker?), and (iii) data analysis techniques that enable clinical decision support based on complex, multi-dimensional biomedical measurements (How do we combine multiple biomarkers into a statistical inference framework?).

**Sunday, March 1, 2020 1:30 PM - 5:30 PM**

**Session 1L APS: Tutorial 6: Quantum Metrology 601-603**

1:30PM 1L.00001: Tutorial 6: Quantum Metrology — Quantum sensing and metrology encompasses a class of techniques and devices that exploit quantum properties such as coherent superposition, wave-particle duality, and entanglement to detect weak or nanoscale signals arising, e.g., from electromagnetic fields, temperature, gravitational gradients, and pressure. As their behavior is tied to physical constants and symmetries, quantum sensors can achieve accuracy, repeatability, and precision approaching fundamental limits. As a result, these devices have shown utility in a wide range of applications spanning across the physical and life sciences —leading to a new generation of real-world technologies with exciting potential. Example quantum sensing platforms to be discussed include atom interferometers; optically-active quantum defects in solids, which have electronic and nuclear spin and can be deployed both for nanoscale sensing with single defects and for bulk sensing with dense ensembles of defects; and atomic vapors constrained in micro-machined ("chip-scale") chambers. (Go to https://march.aps.org/program/tutorial-quantum-metrology/ to view the rest of the tutorial description.)

**Sunday, March 1, 2020 5:00 PM - 6:00 PM**

**Session 1M APS: First-Time Attendee Orientation** Hyatt Mineral B/C - Tag(s): Undergrad Friendly
**5:00PM 1M.00001: First-Time Attendee Orientation** — Join APS staff and leadership to learn how to easily navigate the APS March Meeting. You'll get a crash course on how to use the meeting program to locate sessions you want to see, find out how to use the mobile app to access the meeting program and schedule your events, and find out about interesting and fun events happening throughout the week. You'll also learn about the services APS provides at meetings. Refreshments will be served.

**Sunday, March 1, 2020 6:15 PM - 7:15 PM**

**Session 1Q APS: Future of Physics Days Undergraduate Student Meet-Up** Hyatt Mineral B/C - Tag(s): Undergrad Friendly

**6:15PM 1Q.00001: Future of Physics Days Undergraduate Student Meet Up** — If you would like to informally meet with other undergraduate students from all over to chat about school, professors, science, life, food, ... please check out the undergraduate meet up at the APS March meeting and make some great connections! This is an unstructured meet up with Society of Physics Student leaders and elected leaders of SPS. Once you have assembled we'll grab some snacks and get to know one another.

**Monday, March 2, 2020 8:00 AM - 11:00 AM**

**Session A02 DQI DAMOP: Advances in Atomic Systems** 105 - Daniel Slichter, National Institute of Standards and Technology Boulder - Tag(s): Focus

**8:00AM A02.00001: Trapped Ion Quantum Computing at Honeywell** RUSSELL STUTZ (Presenter), Honeywell Quantum Solutions, Honeywell Intl — Honeywell Quantum Solutions is pursuing a scalable quantum computing architecture based on trapped atomic ions. To this end, Honeywell is developing a broad array of enabling technologies and capabilities, including demonstrations of high-fidelity quantum gate and measurement operations, fast ion transport and re-order, and integration of parallel multi-zone processing of trapped ion qubits to form NISQ devices. We will report recent progress on these and other fronts.
**8:12AM A02.00002: Sandia’s Quantum Scientific Computing Open User Testbed (QSCOUT)**

CHRISTOPHER YALE (Presenter), SUSAN M. CLARK, DANIEL LOBSER, JESSICA M. PEHR, MELISSA C REVELLE, PETER MAUNZ, Sandia National Laboratories — Trapped ions are a leading candidate for quantum computation due to their high-fidelity gate operations, indistinguishability, qubit connectivity, and routes to scalability. Harnessing these advantages, we are developing the Quantum Scientific Computing Open User Testbed (QSCOUT) based on a trapped-ion quantum register at Sandia, using our microfabricated surface electrode traps to host chains of ions with all-to-all connectivity adaptable to diverse algorithms. Here, we present the experimental development of QSCOUT, the current and anticipated capabilities of the testbed, as well as opportunities for use of this platform. As an open testbed, it will feature fully specified operations and hardware allowing users to modify quantum gates and pulse sequences for desired control.

*Sandia National Laboratories is managed and operated by NTESS, LLC, a subsidiary of Honeywell International, Inc., for the US DOE NNSA under contract DE-NA0003525. This work is funded by the US DOE Office of Science ASCR Quantum Testbed Program. The views expressed here do not necessarily represent the views of the DOE or the US Government.

**8:24AM A02.00003: Building a Logical Qubit-sized Ion Trap Quantum Information Processor**

ANDREW RISINGER (Presenter), MICHAEL L GOLDMAN, LAIRD EGAN, CRYSTAL NOEL, DAIWEI ZHU, DEBOPRIYO BISWAS, MARKO CETINA, CHRISTOPHER ROY MONROE, Department of Physics & Joint Quantum Institute, University of Maryland, College Park — We present the system design and architecture of a trapped ion universal quantum processor with high-fidelity quantum gates and addressing of up to 32 qubits. Our approach takes advantage of individual optical addressing to achieve simultaneous high-fidelity operations on a long chain of 171Yb+ ions, resulting in one of the largest academic general-purpose quantum computers. This framework enables long gate-depth, general-purpose algorithms, with the goal of demonstrating an error-corrected logical qubit. We will also cover advances we have made in the control system, specifically in canceling crosstalk and running long experiments.

*This work is supported by the ARO with funding from the IARPA LogiQ program, the NSF Practical Fully-Connected Quantum Computer program, the DOE program on Quantum Computing in Chemical and Material Sciences, the AFOSR MURI on Quantum Measurement and Verification, and the AFOSR MURI on Interactive Quantum Computation and Communication Protocols.

**8:36AM A02.00004: Constructing Trapped Ion Quantum Computers** [Invited]

KENNETH BROWN (Presenter), Duke University — Atomic ion qubits are a promising system for quantum computation with high-fidelity state preparation, measurement, and gates. These systems have already demonstrated complex quantum algorithms from hidden shift problems to quantum simulations. In this talk, I will discuss our experimental work at Duke towards constructing larger ion trap quantum systems. I will also describe the prospects for quantum error correction with trapped atomic ions.

*This work was support by the NSF, IARPA, ARO, and DOE*
A compact room temperature trapped ion system

YUHI AIKYO (Presenter), GEERT VRIJSEN, Department of Electrical and Computer Engineering, Duke University, TOM NOEL, ColdQuanta, JUNGSANG KIM, Department of Electrical and Computer Engineering, Duke University

A trapped ion system is a leading platform for a practical quantum computer. The current gate fidelity is dominated by systematic errors in the control systems delivering the laser beams that drive the gates. The main sources of these errors - mechanical instability and temperature fluctuation - are most effectively addressed by designing compact and robust optical systems. In this work, we present a collaborative work between Duke University and ColdQuanta, where a compact ultra-high vacuum (UHV) chamber operating at room temperature was developed for a trapped ion system. The internal volume of the UHV chamber is only a few cubic centimeters and its vacuum is maintained by a miniaturized ion pump. We demonstrate chain loading of Ytterbium (Yb) ions into a surface trap by ablating a metallic Yb target with a Q-switched Nd:YAG laser. We characterized the vacuum level of this small package by monitoring the hopping rate of an ion in a double well potential, driven by the collision events with background molecules. We also monitored the rate of collision events that cause reordering of the ions in a 6-ion chain containing two isotopes of Yb, one of which appears dark when it is monitored.

*NSF ACQUIRE program, the IARPA LogiQ program and the ARO VISIT STTR program.

A trapped ion system with integrated optics for logical quantum operations

CHRISTOPHER AXLINE (Presenter), KARAN K MEHTA, ROLAND MATT, ROBIN OSWALD, CHIARA DECAROLI, LEON STOLPMANN, JONATHAN P HOME, ETH Zurich

Implementing algorithms using quantum error correction in a quantum computer may require on the order of one million physical qubits. Trapped ion systems have shown long lifetimes and exceptional single- and multi-qubit gate fidelities. It will be critical to preserve these high fidelities while creating a scalable trapping and manipulation scheme. With integrated, independent control of trapped ions within a chain, we can limit noise and simplify the sequence of operations required to realize an error-corrected logical qubit. We are implementing two approaches for individual addressing of $^{40}\text{Ca}^+$ ions in a cryogenic ion trap system; the first involves a fiber array imaged onto an ion string, while the second integrates optical waveguides directly within the ion trap chip. In the same setup, we characterize self-stabilized superconducting magnetic field coils for long-lived coherence. We present designs for operation of multiple trapping zones that could be implemented and interfaced as logical qubits. With such a noise-resilient, configurable system, we aim to demonstrate multi-qubit stabilizer readout towards a powerful ion trap quantum processor.

*We acknowledge support from the Swiss NSF, ETH Zurich Postdoctoral Fellowship, IARPA, and EU Horizon 2020/FET-Open (PIEDMONS).
9:36AM A02.00007: Individual control of an array of neutral atom qubits for quantum computing  
Brian Lester (Presenter), Sabrina Hong, Jonathan King, Stanimir Kondov, Krish Kotru, Mickey McDonald, Remy P.M.J.W. Notermans, Alexander Papageorge, Robin Coxe, Prasahn Sivarajah, Benjamin Bloom, Atom Computing, Inc — Ultracold neutral atoms have emerged as a promising platform for scalable quantum computation. Universal single-qubit control requires high quality state preparation, spatially resolved manipulation, and projective readout of each qubit. For state preparation and readout, neutral atom platforms can apply techniques commonly used in quantum gas microscopes and single atom trapping machines. Furthermore, the ability to isolate the internal spin states of individual neutral atoms from both external fields and neighboring atoms allows for fundamental coherence times exceeding 10 seconds, as demonstrated in recent optical lattice clock experiments. Here, we present initial results on the universal single-qubit control of an array of atomic qubits comprised of neutral strontium atoms. Importantly, the utilized gate scheme enables individual qubit control without relying on global operations that would need to be serialized as the number of qubits is increased.

9:48AM A02.00008: Integrated optical implementation of multi-ion quantum logic*  
Karan Mehta (Presenter), Chi Zhang, Maciej Malinowski, Thanh-Long Nguyen, Martin Stadler, Jonathan P Home, ETH Zurich — Practical and useful quantum information processing will require improvements in operation fidelity and robustness, and simultaneously in scale and integration. Ion qubits’ fundamental qualities are promising for long-term systems, but the optics used to precisely control and measure their quantum states are a challenge to scaling. Previous work with single ions has suggested that trap-integrated optics may make this control more robust, and simultaneously parallelizable [1]. We have designed and implemented planar traps with integrated waveguides and grating couplers, for controlling multiple 40Ca+ ions. We measure 1.5 dB direct fiber-to-chip coupling losses, eliminating the need for beam alignment into vacuum systems/cryostats. Using these photonics, we have realized two-qubit entangling gates with fidelities over 97%, with understood errors suggesting significant possible improvement. The experimental realization of high-fidelity quantum logic in this platform suggests it can enable larger systems in multiple zones connected by transport [2].

*We acknowledge support from the Swiss National Fund, NCCR QSIT, ETH, the EU Flagship, and an ETH postdoctoral fellowship.
10:00AM A02.00009: Efficient Arbitrary Simultaneously Entangling Gates on a trapped-ion quantum computer
NIKODEM GRZESIAK (Presenter), REINHOLD BLUMEL, KRISTIN BECK, KENNETH WRIGHT, VANDIVER CHAPLIN, JASON AMINI, NEAL PISENTI, SHANTANU DEBNATH, JWOSY CHEN, YUNSEONG NAM, IonQ, Inc — Entanglement is a key ingredient in quantum computing. On a trapped ion quantum computer, parallel entangling operations have traditionally been implemented with the help of nonlinear solvers. In this talk, I will present an exact, linear protocol that entangles multiple arbitrary pairs of trapped-ion qubits. The protocol is efficient and can leverage the all-to-all connectivity available on trapped-ion quantum computers to implement up to quadratically many two-qubit gates at the same time. [arXiv:1905.09294]

10:12AM A02.00010: Teleported CNOT Gate in a Mixed-Species Trapped-Ion System
STEPHEN ERICKSON (Presenter), YONG WAN, DANIEL KIENZLER, KARL MAYER, TING REI TAN, JENNY WU, HILMA VASCONCELOS, SCOTT GLANCY, EMANUEL H KNILL, DAVID J WINELAND, ANDREW C WILSON, DIETRICH LEIBFRIED, National Institute of Standards and Technology — Scaling up quantum information processing (QIP) can be aided by distributing qubits across multiple processing zones. Universal quantum computation across such an architecture will require entangling gates between qubits in separate zones. Quantum gate teleportation achieves this, requiring only local operations within each zone, a single entangled ancilla pair split between the two zones, and classical communication. Using this protocol, we demonstrate a teleported CNOT gate between two spatially separated $^9$Be$^+$ ions by means of a split entangled pair of $^{25}$Mg$^+$ ions and measure an entanglement fidelity in the interval $(0.845, 0.872)$ at the 95% confidence level. Our demonstration combines many important tools for scaling trapped-ion QIP, including ion separation and shuttling, individually addressed single qubit rotations and detections, same- and mixed-species entangling gates, and real-time conditional feedforward operations.

*This work was supported by the Office of the Director of National Intelligence (ODNI) Intelligence Advanced Research Projects Activity (IARPA), ONR, the NIST Quantum Information Program, and the National Science Foundation Graduate Research Fellowship Program.
10:24AM A02.00011: Laser-free trapped-ion entangling gates with an oscillating magnetic-field gradient at radio frequency*  
RAGHAVENDRA SRINIVAS (Presenter), SHAUN BURD, University of Colorado, Boulder, ROBERT TYLER SUTHERLAND, Lawrence Livermore National Laboratory, HANNAH M KNAACK, University of Colorado, Boulder, DIETRICH LEIBFRIED, National Institute of Standards and Technology, Boulder, DAVID J WINELAND, University of Oregon, Eugene, ANDREW C WILSON, National Institute of Standards and Technology, Boulder, DAVID THOMAS CHARLES ALLCOCK, University of Oregon, Eugene, DANIEL H SLICHTER, National Institute of Standards and Technology, Boulder — We demonstrate a recently proposed method for trapped-ion entangling gates implemented using an oscillating magnetic-field gradient at radio frequency in addition to two microwave magnetic fields symmetrically detuned about the qubit frequency [1]. This technique enables laser-free entangling gates with reduced sensitivity to qubit frequency errors. The experiment is performed in a surface-electrode trap that incorporates current-carrying electrodes to generate the microwave fields and the oscillating magnetic field gradient. Currently, we achieve a Bell-state fidelity of 0.996(2) with ground-state-cooled ions and 0.991(3) for ions cooled to the Doppler limit (nbar=2). The radio-frequency currents used to generate the gradient also give rise to a tunable differential ac Zeeman shift on the two ions which can be turned on and off. While the gate is insensitive to this shift, it can be used independently to perform single ion addressing. This method of addressing does not require additional control fields or rotation of the ion crystal. We can combine this addressing with an entangling gate to create any Bell state from a given initial state.

*We acknowledge support from the NIST Quantum Information Program.

10:36AM A02.00012: Quantum hopping of frequency-bin entangled photon pairs*  
POOLAD IMANY (Presenter), NAVIN B LINGARAJU, MOHAMMED S ALSHAYKH, DANIEL E LEAIRD, ANDREW M WEINER, Purdue University — Quantum walks of entangled particles have promising applications in simulating many-body physics, as well as in implementing quantum search algorithms. Here, we report continuous quantum walks of a two-photon quantum frequency comb using electro-optic phase modulation to tune the evolution of the state through the quantum circuit. By manipulating the spectral phase of the initial entangled state, we demonstrate either enhanced ballistic energy transport or energy bound states, which are signatures of bosonic and fermionic frequency hopping, respectively. In addition, applying quadratic spectral phase on the initial state creates different subspaces featuring bosonic or fermionic character. We also explore the effect of increasing entanglement dimensionality in frequency domain quantum hopping; our results suggest the potential of our circuit for certifying high-dimensional entanglement.

*National Science Foundation no 1839191-ECCS.
10:48AM A02.00013: Improved Light-Matter Interaction in a Thulium Cavity Memory for Quantum Light Storage  JACOB DAVIDSON (Presenter), Qutech, Delft University of Technology, PASCAL LEFEBVRE, JUN ZHANG, DANIEL OBLAK, Physics, University of Calgary, WOLFGANG TITTEL, Qutech, Delft University of Technology — We design and implement an atomic frequency comb quantum memory using a thulium-doped crystal in an impedance matched optical cavity to create absorption of more than 90% of input signal, resulting in a memory efficiency of 27%. This low finesse optical cavity design enables efficient storage over the conventionally large frequency bandwidths ($\geq$ 500 MHz) present for single photons and high communication rates. We store one member of a photon pair created through spontaneous parametric down-conversion and, by measuring a value of $g(2) = 9.3 \pm 1.2 > 2$ for the cross-correlation function of the photons, verify that the non-classical nature of the light persists after storage in the cavity memory. Using quantum process tomography to measure time-bin qubits after storage in this high-bandwidth memory, we characterize the qubit storage fidelity to be as high as $F = 95.0 \pm 0.1\%$, confirming non-classical qubit storage. These results demonstrate progress toward efficient, faithful, and high bandwidth storage of single photon qubits for quantum networking.

Monday, March 2, 2020 8:00 AM - 10:36 AM

8:00AM A03.00001: Time resolving the loss of crystallinity during detonation in a secondary solid explosive [Invited]  PAMELA BOWLAN (Presenter), LAURA SMILOWITZ, BRYAN HENSON, DENNIS REMELIUS, NATALYA SUVOROVA, DAVID M OSCHWALD, Los Alamos National Laboratory — There are still significant uncertainties in our ability to predict and control detonation in secondary solid explosives which has serious implications for the safety and performance of explosives. One reason is for this uncertainty is that while chemical kinetics are well understood in gases and liquids, much less is known about how chemistry proceeds within a crystalline lattice. Secondly, events like detonation, where a bulk material can go from ambient conditions to pressures of Gigapascals (GPa) and temperatures of about 4000 kelvin (K) within nanoseconds (ns), are extremely difficult to directly observe. To better understand the role of the loss of crystallinity and how this affects temperature and chemical kinetics during a detonation, we developed a technique using visible laser scattering to probe morphology changes on a nanosecond time scale before and during a detonation. We will present our results applying this to several common secondary solid explosives, PETN, HMX and TATB, and considering steady detonation, initiation of detonation, and failure scenarios. These measurements reveal when during a detonation wave, and how fast that the initial crystals change into a less scattering dense product fluid giving new insight into the microscopic mechanism of a detonation in solid explosives.
8:36AM A03.00002: A Hotspot’s Better Half: A Characterization of the Local Potential Energy Rise in Mechanically Induced Hotspots  
BRENDEN HAMILTON (Presenter), Purdue Univ, MATTHEW P KROONBLAWD, Lawrence Livermore National Laboratory, CHUNYU LI, ALEJANDRO H STRACHAN, Purdue Univ — Shock loading of high explosives leads to energy localization into hotspots, which are thought to govern the initiation of detonation. Hotspots are typically characterized in terms of their size and temperature. Criticality of a hotspot depends on a competition between thermal diffusivity and endothermic reactions that tend to quench the hotspot against exothermic reactions that can transform the hotspot into a deflagration wave. However, this view ignores the role of potential energy (PE) as a descriptor of energy localization and criticality. We show through large-scale molecular dynamics simulations of TATB pore collapse that more energy is localized in PE than in kinetic energy (KE). Furthermore, the spatial extent and diffusivity of the PE and KE hotspots are significantly different, and far from expectations based on equipartition. An analysis of the MD trajectories reveals the molecular origin of this puzzling observation. Prepared by LLNL under Contract DE-AC52-07NA27344. Approved for unlimited release, LLNL-ABS-794457.

8:48AM A03.00003: Void collapse in shocked β-HMX single crystals across scales*  
CAMILO DUARTE (Presenter), CHUNYU LI, MARISOL KOSLOWSKI, ALEJANDRO H STRACHAN, Purdue Univ — Heat generation in the vicinity of a void during shock compression plays a critical role on the initiation of detonation in high explosives (HE). Atomistic simulations of under shock compression have shown that the void collapse regime transitions from visco-plastic to hydrodynamic jetting as the shock strength increases in many energetic materials. However, atomistic simulations are limited to nanometer size voids. On the other hand, void collapse experiments have been performed in micron size samples. Here, we present a mesoscale model informed from atomistic simulations to study the anisotropic response of shocked β-HMX single crystals that bridges nanometer to micrometer scales. The shock response of an β-HMX single crystal containing a void is studied with finite element simulations that include plasticity and heat transport. The effect of crystal orientation over a range of impact velocities are discussed. The continuum model is calibrated with non-reactive molecular dynamics simulations of planar socks. The simulations are compared with both atomistic simulations and gas gun experimental results of β-HMX containing a single void.

*US Department of Defense, Office of Naval Research, MURI contract number N00014-16-1-2557, program managers: Chad Stoltz and Kenny Lipkowitz.
9:00AM A03.00004: Mechanisms and Size Effects of Hotspot Formation due to Shock-Induced Collapse of Pores and Cracks  CHUNYU LI (Presenter), BRENDEN HAMILTON, ALEJANDRO H STRACHAN, Purdue Univ — The shock to detonation transition in heterogeneous high energy density materials starts with the spatial localization of mechanical energy into hotspots due to the interaction of the mechanical wave with microstructural features and defects. We present large-scale molecular dynamics simulations of hotspot formation in HMX crystals following the collapse of pores of various shapes and sizes for impact velocities ranging from 0.5 to 2.5 km/s. Hotspots resulting from cracks elongated along the shock direction show significantly higher sensitivity to both shock strength and defect size. Elongated cracks 80 nm in length result in temperatures almost three times higher that voids 80 nm diameter and reach values corresponding to the ideal case of isentropic recompression of a gas. The MD trajectories reveal the atomic origin of this contrasting behavior. While circular voids undergo a transition from viscoelastic pore collapse to a hydrodynamic regime with increasing shock strength, shock focusing in elongated cracks results in jetting and vaporization, which upon recompression leads to increased heating.

9:12AM A03.00005: Time-resolved x-ray imaging of void collapse at micron length scales*  MICHAEL ARMSTRONG (Presenter), RYAN AUSTIN, Lawrence Livermore Natl Lab, PAUL CHOW, YUMING XIAO, Advanced Photon Source, PAULIUS GRIVICKAS, BATIKAN KOROGLU, ERIC V BUKOVSKY, WILLIAM L SHAW, JOSHUA A HAMMONS, TREVOR M WILLEY, ANDREW K ROBINSON, Lawrence Livermore Natl Lab — Pulsed x-ray imaging can provide substantial insight into a wide range of initiation-related phenomena, particularly the in situ imaging of dynamically compressed voids, which are thought to play a fundamental role in explosive initiation. Current models of the dynamic compression behavior of inhomogeneous materials are empirically calibrated to bulk, aggregate experimental data. The development of more fundamental models depends on detailed measurements and corresponding simulations which resolve single void collapse events. Further, since material strength depends on scale, experiments at the scale of actual voids (10 μm) are preferred. Since the field of view for these experiments is relatively small (~100s μm) and void collapse occurs at low pressure, these experiments can be performed with a small scale (100 mJ) laser in a portable experimental setup. Here we present the results of x-ray imaging experiments at the Advanced Photon Source on voids embedded in TNT and silicon using both explosive and laser-driven shocks, which approach the spatial scale of void collapse in actual explosives, 1-10 μm.

Evaluation of the roles of crystal plasticity and hydrodynamic jetting in hot-spot formation in heterogeneous energetic materials under shocks

OISHIK SEN (Presenter), NIRMAL KUMAR RAI, Univ of Iowa, CAMILO DUARTE, MARISOL KOSLOWSKI, Purdue University, H.S. UDAYKUMAR, Univ of Iowa — Heterogeneous energetic materials are crucial components in munitions and energy-delivery systems. Under shocks, localized hot-spots are formed near voids and microstructural defects in these materials. Hydrodynamic jetting due to void collapse and strain localization due to plastic work are two important mechanisms for hot-spot formation in the material. This work evaluates the relative contribution of these two mechanisms in the formation of hot-spots under shocks in energetic materials. To this end, an Eulerian computational framework is used to study the response of HMXs comprising a single void under shock loading. To study the role of hydrodynamic jetting, the voids are resolved sharply using level-sets and the hot-spot temperatures are tracked at different stages of void collapse. To model heating due to plastic work, an anisotropic crystal plasticity model based on a power-law slip-rate with hardening and thermal softening is used; the localized temperatures in the slip/shear bands formed in the material under shocks are also tracked. Computations are performed for different crystal orientations and shock strength. The presentation will discuss the combined roles of jetting and plastic heating in hot-spot formation in HMXs.

Measurements of State Variables During Exploding Bridgewire Detonator Function

LAURA SMILOWITZ (Presenter), BRYAN HENSON, PAMELA BOWLAN, DENNIS REMELIUS, NATALYA SUVOROVA, Los Alamos Natl Lab — We have studied the behavior of exploding bridgewire detonators using a variety of observables for measuring temperature and density during detonator function. Continuous density movies have been collected using either proton or x-ray radiography and continuous light emission videos simultaneously measured using ultra-high speed video cameras. Spectrally resolved and single broadband pyrometric measures of temperature are also measured. We attempt to provide a description of the mechanism of function for EBW detonators based on the full suite of observations made and comparisons to studies in the literature. In this talk, we will show the results of measurements on PETN and HMX based detonators run in a variety of conditions.

Internal shock structure and thermal response in the function of Exploding Bridgewire Detonators

BRYAN HENSON (Presenter), LAURA SMILOWITZ, PAMELA BOWLAN, NATALYA SUVOROVA, DENNIS REMELIUS, Los Alamos Natl Lab — We have recently shown that the input shock, subsequent initiation and detonation propagation in an Exploding Bridgewire (EBW) detonator exhibits complex internal structure and temporal behavior. Using flash radiography we have observed the prompt emanation of a relatively weak shock wave (3000 m/s) from the region of the bridgewire at the time of vaporization. Abel inversion of the images reveals a highly symmetric, hemispherical structure in the density that propagates through the initial pressing. Visible imaging of the cylindrical surface of the detonator reveals a luminous wavelike structure that appears radially symmetric but lacking the exact symmetry of the density feature. In this talk these structures will be directly compared spatially and temporally for a number of EBW detonators of different sizes and materials. The relationship between shock and detonation like features will be discussed in the context of the mechanism of function of EBW detonators and recent progress in modeling the chemistry of energy release in these applications.
10:00AM A03.00009: Comparing small-scale detonation simulation to experimental data and multi-dimensional initiation sensitivity study  RACHEL MORNEAU (Presenter), MICHAEL J MURPHY, JAMES QUIRK, Los Alamos National Laboratory — We are interested in modeling exploding foil initiator (EFI) detonators to help with design timelines and understanding the fundamental science of detonators. We will discuss efforts to model small-scale detonations in the absence of calibration data that take into account the ignition and growth in PETN sub-centimeter pellets. Several reaction rate models along with parameter studies were performed to show variation in the breakout time and wave shape at the end of the pellet using the hydrocode FLAG. Since 1D initiation does not wholly describe the initiation in these small-scale detonations of interest, we will explore the effect of multi-dimensional ignition on the outcome. We will show several comparisons of simulation data to experimental data and discuss the results.

10:12AM A03.00010: (U) Introducing HEDONIST- A Low Explosive Mass Experiment That Attains Very High Pressures*  CARL JOHNSON (Presenter), JOHN GIBSON, Los Alamos National Laboratory — The proton radiography facility at LANL offers unique experimental capabilities, particularly the planned Pu@pRad line. Pu@pRad limitations however preclude the usage of large quantities of high explosives. We present the hydrocode analysis of a small-scale system (under 30g TNT equivalent) capable of reaching pressures in excess of 2 Mbar. This system utilizes a novel multipoint initiation system to establish converging detonation waves which deliver a strong shock wave onto a sample cell. HEDONIST has been designed to present a low areal density to the pRad beam thereby providing ample signal-to-noise ratio to discern shock waves in sample cell materials from other shocks present. Results from the first two pRad experiments and the comparison to hydrocode simulations will be discussed.

10:24AM A03.00011: Modeling and Experimental Analysis of Shaped Charge Jet Characteristics  KEVIN MIERS (Presenter), DANIEL PUDLAK, Detonation Physics and Experimental Research Branch, U.S. Army CCDC Armaments Center — The U.S. Army CCDC Armaments Center at Picatinny Arsenal, NJ uses a variety of computational and analytical tools to predict and validate shaped charge warhead performance. In this work, an 81mm copper lined conical shaped charge loaded with the HMX-based explosive LX-14 is modeled in the hydrocode ALE3D and tested using flash radiography. Jet characterization x-ray films are digitized and analyzed using a series of computer programs developed by Miers and Pham. Experimentally determined jet parameters such as velocity profile and accumulated length/mass/energy are compared with hydrocode predictions. Additionally, the Walsh theory for plastic instability and particulation in stretching metal jets is utilized to predict jet breakup time from hydrocode models, and results are compared with experiment. The resulting effects on armor penetration performance predictions are discussed.

Monday, March 2, 2020 8:00 AM - 10:36 AM
8:00AM A04.00001: Electric Fields, Reorientation, and Water at the Air-water Interface of Iron and other Salt Solutions* [Invited]  HEATHER ALLEN (Presenter), Ohio State Univ - Columbus — Water at the air-water interface organizes and facilitates the accommodation of ion complexes and that of surface active species. The hydration shells of these surface active components are evident by their spectroscopic signatures mostly in the OH stretching regions using both vibrational sum frequency generation and infrared reflection absorption spectroscopies. In addition, surface potential measurements reveal information on the interfacial electric field strength and thus ordering of molecular and ion complexation dipoles in the interfacial region. We report evidence of interfacial iron (III) speciation and other ions and their interfacial hydration effects. We also report on the resistance to dipole reorientation of ion and molecular species at the air-aqueous interface of iron(III) sulfate and nitrate versus iron(III) chloride.

*DOE-BES CPIMS

8:36AM A04.00002: The structure and polarization of the water-graphene interface from molecular dynamics simulations and X-ray reflectivity experiments*  FELIPE JIMENEZ-ANGELES (Presenter), KATHERINE HARMON, TRUNG NGUYEN, Northwestern University, PAUL FENTER, Chemical Sciences and Engineering Division, Argonne National Laboratory, MONICA OLVERA DE LA CRUZ, Northwestern University — Nanconfined water is found in numerous applications across natural and technological systems where water mediates chemical reactions, adsorption, diffusion, ion transport, among other processes. Water affects the interactions among ions, molecules, and surfaces. The electrostatic forces in the systems and processes are modified through polarization which is the collective orientation of the molecules' dipole moment. The polarization of water is different in bulk, in confinement, and at interfaces. Here we study the water structure and polarization next to uncharged graphene surfaces by means of molecular dynamics simulations and X-ray reflectivity experiments. Despite graphene being hydrophobic, our simulations and experiments show an adsorbed water layer on graphene. Even in the absence of an external electric field this adsorbed water layer has a persistent polarization and an induced electrostatic potential. In addition, the adsorbed water molecules form a hydrogen bond network and make the graphene surface repulsive to ions.

8:48AM A04.00003: Polarizable Potentials For Metals: The Density Readjusting Embedded Atom Method (DR-EAM)*  
HEMANTA BHATTARAI (Presenter), Department of Physics, University of Notre Dame, J. DANIEL GEZELTER, Department of Chemistry and Biochemistry, University of Notre Dame, KATHIE ELAINE NEWMAN, Department of Physics, University of Notre Dame — In simulations of metallic interfaces, a critical aspect of metallic behavior is missing from the some of the most widely used classical molecular dynamics force fields. We present a modification of the embedded atom method (EAM) which allows for electronic polarization of the metal by treating the valence density around each atom as a fluctuating dynamical quantity. The densities are represented by a set of additional fluctuating variables (and their conjugate momenta) which are propagated along with the nuclear coordinates. This “density readjusting EAM” (DR-EAM) preserves nearly all of the useful qualities of traditional EAM. We show that DR-EAM can successfully model polarization in response to external charges, capturing the image charge effect in atomistic simulations. DR-EAM also captures behaviors of metals in the presence of uniform electric fields, predicting surface charging and shielding internal to the metal. Our additional studies of DR-EAM used to model a metal-water interface show local surface ordering of water dipoles due to the polarizability of the metal. We also discuss the interfacial thermal conductivity of the metal-water interface calculated using both polarizable and non-polarizable models for the metal and for water.

9:00AM A04.00004: Orientational Dynamics of the Hydrogen-bonded OH of Interfacial Water*  
JOHN MCGUIRE (Presenter), School of Physical Science and Technology, ShanghaiTech University, FLORIAN FIGGE, Department of Physics and Astronomy, Michigan State University — We report on the orientational dynamics of the bonded OH (bOH) of interfacial water, i.e., the OH groups in which the H atom participates in a hydrogen bond (HB). A vibrationally resonant infrared-visible sum-frequency signal provides a surface sensitive probe of the dynamics following excitation by a vibrationally resonant infrared pump. Using p-polarized probe beams, we measure the evolution of the pump-induced orientational anisotropy following p- and s-polarized pump excitation. Previous work showed that the dangling OH (dOH) groups (i.e., OH groups in which the H atom does not participate in a HB) reorient much faster than do bulk bOH[1,2]. Measuring the dynamics of interfacial bOH is challenging, though, on account of strong intermolecular resonant vibrational energy transfer (RVET). Using isotopic dilutions down to 1 part H₂O in 19 parts D₂O, we minimize RVET and show that interfacial bOH reorient on the same timescale as do bulk bOH. These dynamics are robust to interfacial ion concentrations and suggest that the interfacial hydrogen bond network becomes bulk-like within a single molecular distance from the surface.

Why are Water-Hydrophobe Interfaces Electrically Charged? JAMILYA NAURUZBAYEVA (Presenter), Water Desalination and Reuse Center, King Abdullah University of Science and Technology, ZHONGHAO SUN, Ali i. Al-Naimi Petroleum Engineering Research Center, King Abdullah University of Science and Technology, ADAIR GALLO JUNIOR, MAHMOUD IBRAHIM, Water Desalination and Reuse Center, King Abdullah University of Science and Technology, J. CARLOS SANTAMARINA, Ali i. Al-Naimi Petroleum Engineering Research Center, King Abdullah University of Science and Technology, HIMANSHU MISHRA, Water Desalination and Reuse Center, King Abdullah University of Science and Technology — Mechanisms underlying the electrification of water-hydrophobe interfaces are of much interest in chemical science, but are not entirely clear. In response, a systematic investigation of excess electrical charges carried by water droplets dispensed from capillaries was performed by: (i) studying the deflections of pendant droplets under uniform electric fields, and (ii) the direct measurement of electrical charges of the dispensed droplets using an ultrasensitive electrometer coupled with a Faraday cup. Thus, the effects of the following crucial factors were unraveled: hydrophobicity/hydrophilicity of the capillary, the presence/absence of a water reservoir inside the capillary, water pH, ionic strength, dielectric constant, the dissolved CO₂ content, and the relative humidity. The emerging picture is that the electrification at interfaces of common hydrophobic materials, e.g., polytetrafluoroethylene and polypropylene, is not limited to interfaces with water alone; nor is this phenomenon entirely dependent on the specific adsorption of OH⁻ or H₃O⁺ ions, as commonly believed. Our exhaustive study also draws together an extensive body of literature on this subject.

Free Energy of Water Dissociation at the Water - TiO₂ Interface from Ab Initio Deep Potential Molecular Dynamics* [Invited] ANNABELLA SELLONI (Presenter), Princeton University — TiO₂ is a widely used photocatalyst in science and technology and its interface with water is important in fields ranging from geochemistry to biomedicine. Yet, it is still unclear whether water adsorbs in molecular or dissociated form on TiO₂ even for the case of well-defined crystalline surfaces. To address this issue, we simulated the TiO₂-water interface using molecular dynamics with an ab initio-based deep neural network potential. Our simulations show a 6% equilibrium fraction of water dissociation at room temperature, in agreement with enhanced sampling estimates of the dissociation free energy [1]. Due to the relevance of surface hydroxyl groups to the surface chemistry of TiO₂, our model might be key to understanding phenomena ranging from surface functionalization to photocatalytic mechanisms. Refs: [1] Marcos F. Calegari Andrade, Hsin-Yu Ko, Linfeng Zhang, Roberto Car and Annabella Selloni, submitted.

10:00AM A04.00007: Laser-Assisted Dissolution of Geological Samples Submerged in Water: Evidence of Hydrothermal Processing*  CHAD DURRANT (Presenter), RAYMOND MARIELLA, JORDAN COMBITSIS, DAVID WEISZ, LLNL — We investigate the use of a 240 ns pulse Nd:YLF (3 kHz, 0.33 mJ/pulse) laser to rapidly break down and dissolve an obsidian sample submerged in water. We propose a mechanism, a hydrothermal surface interaction, by which this laser-assisted dissolution process occurs. The laser fluence is below the ablation thresholds, 0.4-7 J/cm$^2$ vs 10 J/cm$^2$ and is directed onto the submerged sample causing an increase in temperature and pressure at the water-sample interface. Our results indicate that this process is highly efficient at removing, and potentially dissolving, amorphous glassy substrates (i.e. an obsidian sample) at the water-sample interface. This is further shown by the formation of purified SiO$_2$ structures that reform on the surface post-pulse. We additionally show how various parameters (e.g. dwell time, power, repetition rate, and focal length) affect the efficiency of this process.

10:12AM A04.00008: Intrinsic pH of water/vapor interface revealed by ion-induced water alignment*  KUO-YANG CHIANG, LAETITIA DALSTEIN, YU-CHIEH WEN (Presenter), Academia Sinica — Protons at the water/vapor interface are relevant for atmospheric and environmental processes, yet to characterize their surface affinity on the quantitative level is still challenging. Here we utilize phase-sensitive sum-frequency vibrational spectroscopy to quantify the surface density of protons (or their hydronium form) at the intrinsic water/vapor interface, through inspecting the surface-field-induced alignment of water molecules in the electrical double layer of ions. With hydrogen halides in water, the surface adsorption of protons is found to be independent of specific proton-halide anion interactions and to follow a constant adsorption free energy, $\Delta G \sim -3.74 (\pm 0.56) \text{ kJ/mol}$, corresponding to a reduction of the surface pH with respect to the bulk value by 0.66 (±0.10), for bulk ion concentrations up to 0.3 M. Our spectroscopic study is not only of importance in atmospheric chemistry, but also offers a microscopic-level basis to develop advanced quantum-mechanical models for molecular simulations.

10:24AM A04.00009: The behavior of water confined between two hydrophobic surfaces with grafted polymeric segments studied using molecular simulations  RAMIN MEHRANI (Presenter), Mechanical engineering, Ohio University, SUMIT SHARMA, Chemical and Biomolecular engineering, Ohio University — We have performed Indirect Umbrella Sampling (INDUS) molecular simulations to calculate the free energy barrier of evaporation of water confined between two hydrophobic surfaces grafted with polymeric segments. Dependence of the free energy barrier on grafting density and segment flexibility will be discussed. We have calculated the potential of mean force between the two surfaces as a function of the distance between them. The implications of the presence of flexible grafted segments on the hydrophobic collapse of the surfaces will be illustrated.
The control of the photophysical and photochemical properties of molecules through truly quantum mechanisms remains an outstanding goal for the chemical physics community. The strong coupling of spatially confined photons to the electrons of molecules appears among the most promising quantum mechanisms test for molecular control. The formation of cavity polaritons through this strong coupling mechanism has been proposed to amend the excited state structure of molecules embedded in electromagnetic resonantors. Despite these proposals, definite experimental evidence of changes to the dynamics and structure of molecular cavity polaritons remain elusive. In this talk I present experimental results demonstrating the ways in which polariton formation amends the dynamics and structure of strongly cavity-coupled metalloporphyrin molecules. First, I examine how the strong coupling of photons in a nanoscale cavity to the Soret resonance of zinc tetraphenylporphyrin (ZnTPP) affects the competition between excited state absorption and fluorescence processes. I show polariton formation incerases the cross section of excited state absorption relative to stimulated emission. Second, I highlight ultrafast spectroscopic results demonstrating the control of energy gap laws via deterministic polariton formation. In particular, these results show the time scale of populating of an excited singlet state of ZnTPP can be controlled through changes to the Rabi splitting. Third, I propose nonlinear optical spectroscopic methods capable of directly assessing the ways the structure of a molecular excited state change in response to polariton formation. These results demonstrate the power of vibrational light scattering spectroscopies to not only assess structural changes central to the proposed control available through polariton formation, but also novel quantum optical phenomena polaritons may enable.
Optical activity from exciton Aharonov-Bohm effect: a Floquet engineering approach*  
KAI SCHWENNIECKE (Presenter), University of California, San Diego — We theoretically demonstrate that an originally achiral molecular system can exhibit nonzero circular dichroism (CD), through Floquet engineering, when it is driven with elliptically polarized light. More specifically, we consider an isotropic ensemble of small cyclic molecular aggregates in solution whose local low-frequency vibrational modes are driven by a continuous-wave infrared pump. We attribute the origin of the nonzero CD to time-reversal symmetry breaking due to an excitonic Aharonov-Bohm (AB) phase arising from laser-driving and coherent interchromophoric exciton hopping. The obtained Floquet-engineered excitonic AB phases are far more tunable than their analogous electronic AB phases in the nanoscale, highlighting a virtually unexplored potential that excitonic AB phases have in the coherent control of molecular processes and simultaneously introducing new analogues of magneto-optical effects in molecular systems which bypass the use of strong magnetic fields.

*We acknowledge support from the Air Force Office of Scientific Research award FA9550-18-1-0289 for the excitonic design of AB phases and the Defense Advanced Research Projects Agency under Award No. D19AC00011 for the calculation of pseudo-MO effects.

Controlling Coherent Light-Matter Interactions in Semiconductors*  
HUI DENG (Presenter), Univ of Michigan - Ann Arbor — Light-matter interactions are at the heart of quantum electrodynamics and underpin modern photonic technologies. As we develop means to control the properties of light, matter and their interactions, intriguing new phenomena emerge. Using the mature, III-Arsenide semiconductor system, we build a designer cavity platform of polaritons 1. With it, we demonstrate a shot-noise limited polariton lasers with strong nonlinearities 2 and a Bardeen-Cooper-Schrieffer like polariton condensate 3. Coupling two trapped polariton condensates through both coherent tunneling and incoherent dissipation, we form a model system of rich nonlinear dynamics where new, equidistant frequency lines emerge due to limit cycle self-oscillations 4. Extension to larger arrays together with the flexibility to engineer fundamental properties of the polaritons may enable the discovery and understanding of new quantum many-body states. Using two-dimensional van der Waals semiconductors, we establish coherent light-matter coupling in a variety of photonic structures with unprecedented freedom to engineer both the optical modes and excitonic properties 5-7, which may enable new many-body phenomena and novel photonic device concepts.

9:24AM A05.00004: Topological polaritons and magneto-optical materials  SINDHANA SELVI PANNIR SIVA THI (Presenter), JOEL YUEN-ZHOU, University of California, San Diego — In recent years topological polaritons have been theoretically proposed and also observed in experiment. Our work aims to understand the fundamental features for a system to exhibit topological polaritons. We find that topological polaritonic states emerge in magneto-optical materials strongly coupled to surface plasmons in the presence of a magnetic field. In this particular system, we numerically demonstrate unidirectional edge modes.

9:36AM A05.00005: Quantum optics with molecules  CLAUDIU GENES (Presenter), Max Planck Inst for Sci Light —
Recent experimental progress in the collective strong coupling regime of organic molecules with optical cavity or plasmonic modes has shown light-induced modifications of material properties. Experimental and theoretical endeavors go in the direction of charge and energy transport, Förster resonance energy transfer (FRET) enhancement, modified chemical reactivity etc. Oftentimes experiments rely on theoretical models developed for standard cavity quantum electrodynamics with two-level quantum emitters. Molecular systems however have an increased complexity as molecular vibrations and level disorder play a crucial role. We provide a theoretical formalism to tackle the light-electronic-vibrations dynamics modeled via the Holstein-Tavis-Cummings Hamiltonian [1]. We analytically describe aspects such as: polariton asymmetry, molecular branching ratio modification in the Purcell regime and cavity-mediated donor-acceptor FRET processes.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A06 GMED FIAP: Physics of Medical Devices 113 - Stephen Russek, National Institute of Standards and Technology Boulder - Tag(s): Focus

8:00AM A06.00001: The Physics of System Integration: Merging Radiotherapy and Magnetic Resonance Imaging to Improve Patient Outcomes* [Invited]  MICHAEL THOMPSON (Presenter), Innovation, ViewRay — The integration of imaging into radiotherapy presents an opportunity to improve the precision and accuracy of radiation delivery to the therapy target. More precise delivery is expected, and has been shown in some cases, to reduce treatment times, radiation toxicity, and improve outcomes. However, to achieve these goals two systems that rely on very accurate electromagnetic fields must be integrated without compromising the performance of either system. In this talk the advantages of integrating low field MRI with radiotherapy will be briefly reviewed. The challenges involved with integrating an MRI system and a linear accelerator to effect superior image guided, and intensity modulated, radiotherapy will be covered in some detail with specific examples.

*The author of this work, and presenter, are employees of ViewRay Inc.
8:36AM A06.00002: Proteomic Assay to Predict Health, Wellness, and Disease [Invited]  JASON CLEVELAND (Presenter), SomaLogic — The ever-changing state of the proteins in your body is arguably one of the most important indicators of health and disease, but, to date, measurements have only been possible on individual proteins or small multiplexes. SomaLogic has commercialized a rapid proteomic scanning platform (SOMAScan) that quantifies over 5000 proteins in blood or urine spanning 7 orders of magnitude in concentration, with sub-pM limits of detection. The assay relies on SOMAmers (Slow-Offrate-Modified AptaMERs), short pieces of DNA with additional chemical diversity that are selected to bind tightly to a specific protein. Rather than directly measure the proteins themselves, the fundamental principle underlying the assay is to turn a protein counting problem into a DNA counting problem. DNA has a few important differences relative to proteins that make the DNA counting problem much more tractable, including that a chemical complement exists, and that DNA can be amplified and sequenced inexpensively. To date, we have measured over 100,000 human samples. Applying machine learning to the large resulting databases has led to a rapidly growing number of health measures, including diabetes and cardiovascular risk, with the ultimate goal of providing hundreds of results from a single liquid sample. I will briefly review the physics underlying the current assay and highlight a few of the health measurements. I will also briefly address some thoughts on future device physics to move the assay from the lab to the home.

9:12AM A06.00003: Light-induced pathogenic bacterial deactivation by using graphene quantum dot and methylene blue*  ERMEK BELEKOV (Presenter), LAUREN COOPER, KHOMIDKHODZA KHOLIKOV, ALI O ER, Western Kentucky Univ — Graphene quantum dots (GQD) is one of the most promising antimicrobial agents with promising potential in photodynamic therapy. GQD was obtained from benzene by focusing high power nanosecond laser pulses. Detailed characterization was performed with transmission electron microscopy (TEM), scanning electron microscopy (SEM), Fourier-transform infrared (FTIR), UV-Visible (UV-Vis), and photoluminescence (PL) spectra. Later, we have attached Methylene Blue (MB), a standard photosensitizer, to graphene quantum dots. The effectiveness of the MB/GQD compound was evaluated on different strains of bacteria such as Escherichia coli and Micrococcus luteus. In addition, MTT assay was used to study human cellular side-effects, cancer and noncancer cellular viability under dark conditions.Combining MB with GQDs caused enhanced singlet oxygen generation and a higher deactivation rate compared to MB and GQD only. These results suggest that the MB/GQD combination is a promising form of photodynamic therapy. Further, ongoing experiments on the germicidal effects of different nanoparticles such as silver (Ag), and aluminum (Al) with MB will be presented.

*Kentucky Biomedical Research Infrastructure Network (KBRIN)
9:24AM A06.00004: Analysis of experimental acoustic waves induced by high energy pulsed X-ray beams*  Farnoush Forghani (Presenter), Adam Mahl, Bernard Jones, University of Colorado, Denver, Mark Borden, University of Colorado, Boulder, Moyed Miften, David Thomas, University of Colorado, Denver — X-ray induced acoustic tomography has recently gained attention for its potential use for 3D dose distribution imaging in radiation therapy and for low dose high resolution 3D imaging in diagnostic therapy. X-ray acoustic waves are produced by the temperature rise following the energy absorption from a pulsed photon beam. While the theory for X-ray acoustics is well established, there is little known about how the X-ray source properties affect the acoustic signal strength and frequency. Here, we present current experimental results of the X-ray acoustic signals obtained by two types of X-ray sources; megavoltage energy with a long pulse width (4 us) and kilovoltage energy with short pulse width (10 ns). The effect of the pulse length and the X-ray source energy on the acoustic signals are investigated. Experimental acoustic signals with high signal to noise ratio are generated when the X-rays strike thin sheets (between 0.1-3 mm) of a high Z material in a water tank. The experimental signals are compared to simulated acoustic waves using Monte Carlo modeling combined with a numerical solver for time domain acoustic wave propagation (kWave).

*This work is supported by American Cancer Society, Colorado Clinical and Translational Sciences Institute, and Cancer League of Colorado.

9:36AM A06.00005: Optimizing coded aperture imaging techniques to allow for online tracking of fiducial markers using high energy scattered radiation from clinical treatment beam.*  Adam Mahl (Presenter), Brian Miller, Moyed Miften, Bernard Jones, University of Colorado, Denver — Real time visualization of fiducial markers and their movement as surrogates for tumor motion during radiotherapy treatment allows for more accurate dose delivery. This project aims to optimize techniques for online tracking by detecting the scattered radiation from clinical treatment beams through a coded aperture (CA).

MCNP6 was used to model radiotherapy beams through phantoms containing gold fiducials. Orthogonal scatter radiographs were collected through a CA geometry. After decoding the simulated radiograph data, the centroid location and FWHM/SNR of the fiducial signals were analyzed. The method was able to accurately localize the markers to within <1mm. The effects of the CA/detector parameters (rank, pattern, and physical dimensions), and the incident beam energy were characterized. Fourier filtering was used to reduce the effects of phantom scatter and decoding artifacts.

Current results will present a proof of concept for a novel real-time imaging method which can be used to further optimize the CA imaging parameter space and guide design and testing of a clinical device.

9:48AM A06.00006: Imaging Surgical Devices with Reduced Metal Artifact*  
PENGWEI WU, NIRAL SHETH, ALEJANDRO SISNIEGA, ALI UNERI, RUNZE HAN, ROHAN VIJAYAN, PRASAD VAGDARGI, Johns Hopkins University, BJOERN KREHER, HOLGER KUNZE, GERHARD KLEINSZIG, SEBASTIAN VOGT, Siemens Healthineers, JEFFREY H SIEWERDSEN (Presenter), Johns Hopkins University  
— Imaging in OR is essential to high-precision, minimally invasive spine surgery, but artifacts arising from surgical devices (e.g., implanted screws) present a major challenge to image quality. Such metal objects cause spectral shift (beam-hardening), photon starvation, and scatter, which confound visualization in regions near surgical devices – e.g. to assess the accuracy of screw placement. We present a method to predict patient and device specific orbits of C-arm cone-beam CT system that avoid metal artifacts by acquiring projection data with minimal influence from metal-related polyenergetic bias (spectral shift). The method localizes devices via neural network segmentation in a few low-dose scout views (commonly acquired for patient positioning), and all C-arm rotation and tilt angles are analyzed to identify the orbit with minimal polyenergetic bias. The method was evaluated in simulation, phantoms, and a cadaver with multiple pedicle screws, demonstrating accurate prediction of orbits that optimally avoided metal artifacts. The results yielded ~200-500 HU reduction of shading artifacts, and ~30-45% reduction in blooming artifacts about the screw shaft. Such method can improve the safety and precision of spine surgery.

*Academic-industry partnership with Siemens Healthineers.

10:00AM A06.00007: Personalized radiation attenuating materials for mucosal protection*  
JAMES DONALD BYRNE, Harvard Radiation Oncology Program, JENNIFER PURSLEY (Presenter), KYLA REMILLARD, SAMANTHA EDGINGTON, Department of Radiation Oncology, Massachusetts General Hospital, JONATHAN D SCHOENFELD, Department of Radiation Oncology, Dana-Farber Cancer Institute/Brigham and Women's Hospital, GIOVANNI TRAVERSO, Department of Mechanical Engineering, Massachusetts Institute of Technology — Patients receiving radiation therapy will develop normal tissue injury as a result of treatment. If a radiation attenuating material is placed in normal tissues, it may reduce the radiation received by that tissue. In this study, we measured the radiation attenuating properties of different materials. We investigated the dosimetric impact of three patient-specific radioprotective devices: a 3D-printed intra-oral device for oral cavity cancer patients, and balloon catheters with radioprotective liquids in the esophagus and rectum for lung and prostate cancer patients respectively. The oral cavity and rectum devices demonstrated protective properties in retrospective treatment plans, so in vivo application of these devices was tested in a rat model. Rats treated with the protective devices in place showed decreased ulcerations and erythema of the oral and rectal mucosa compared to control animals. Use of radioprotective devices in patients has the potential to reduce the morbidity of radiation treatments for cancer.

10:12AM A06.00008: Fast, Small Volume Blood Diagnostics using Homogeneous Thin Solid Films of µL-sized Drops on Super-Hydrophilic Coatings - Impact of Film Properties on Test Accuracy*  
NIKHIL SURESH (Presenter), SHAURYA KHANNA, AMBER A. CHOW, AASHI R GURIJALA, MOHAMMED SAHAL, Department of Physics, Arizona State University, SUKESH RAM, Yale University, SAAKETH R NARAYAN, University of Pennsylvania, NICOLE HERBOTS, THILINA BALASOORIYA, WESLEY PENG, Department of Physics, Arizona State University, ERIC J. CULBERTSON, MicroDrop Diagnostics, LLC, ROBERT J CULBERTSON, Department of Physics, Arizona State University — Blood diagnostic tests require ~7 mL of blood, taking hours for results. Repeated testing can cause Hospital-Acquired Anemia. Accurate blood testing methods with smaller blood volumes and shorter analysis time are needed.

µL-sized blood drops can be rapidly solidified via Super- and Hyper-Hydrophilic HemaDrop™ coatings to yield reproducible Homogeneous Thin Solid Films (HTSFs). HTSFs are investigated for accuracy in measuring electrolytes and heavy metals. Calibration using Balanced Saline Solution allows for conversion of atomic % into concentration in mg/dL, the main metric in blood diagnostics.

Compositions from Ion Beam Analysis, X-ray Photoelectron Spectroscopy, and X-ray Fluorescence are compared at different depths and establish a minimum film homogeneity, volume and surface area to measure blood composition reproducibly and accurately. Relative error analysis shows that reproducibility to <10% can be attained. The damage curve method extracts elemental composition while accounting for possible IBA damage, which is found to be negligible.

Blood HTSFs formed via HemaDrop™ coatings can make accurate solid state analysis of µl blood composition possible.

*We would like to acknowledge SiO2 Innovates and MicroDrop Diagnostics, LLC for providing funding for experimentation.

10:24AM A06.00009: Selection of High Quality Sperm with Lower DNA Fragmentation  
AFROUZ ATAEI (Presenter), ANDY W.C. LAU, THEODORA LEVENTOURI, WASEEM ASGHAR, Florida Atlantic University — The first step of in-vitro fertilization is to sort out the motile sperm from the non-motile. Centrifugation based sperm swim-up and density gradient separation are common methods to sort sperm. However, these methods reduce sperm quality during the repetitive centrifugation steps and isolate sperm with high DNA fragmentation. In this work, we construct a microfluidic device based on the observation that motile sperm can swim against the flow within a specific range of flow rates. This sperm-sorting device consists of two chambers, top and bottom separated by a filter. After 45 minutes the sorted motile sperm is collected from the top retrieval chamber and placed on a glass slide for visual inspection with a light microscopy and data collection. The process is repeated for various flow rates. We find that 1) the most motile and functional sperm pass selectively through the micropores against the flow; 2) the optimum flow rate is the one that gives the highest concentration of motile sperm, the lowest DNA fragmentation and higher percentage of morphologically normal sperm. Our device provides an efficient, inexpensive way to sort sperm-out without the disadvantages of centrifugation.
10:36AM A06.00010: Characterization of neuroblastoma SH-SY5Y cell lines using dielectrophoresis  
SAMANEH RIKHTEHGARAN (Presenter), LUC T WILLE, THEODORA LEVENTOURI, JIANNING WEI, E DU, Florida Atlantic University — Dielectrophoresis (DEP) is a frequency-selective translation of polarized particles under the spatially nonuniform electric field. Particles can move toward the high-field region by positive DEP (pDEP) or away from high-field region by negative DEP (nDEP). This method is label-free, fast and noninvasive characterizing the electrical properties of neuroblastoma SH-SY5Y cell lines. This cell line has been used as an in vitro cell model for the study of Parkinson’s disease or neuronal function and differentiation. We constructed a microdevice that consists of two parts: the interdigitated ITO electrodes to generate AC electric field and a Polydimethylsiloxane (PDMS) with two wells to inject the cells and the media. Then the measured DEP frequency spectra fitted using the spherical shell model to compute electrical properties of the cells.

10:48AM A06.00011: Optimize The Blood Flow In Blood Vessels By Magnet Field To Cure Hypertension*  
RONGJIA TAO (Presenter), Physics, Temple Univ — Sever hypertension comes with headaches, chest pain, shortness of breath, flushing, and visual changes etc. Without timely medical treatment, sever hypertension will lead to heart attack and strokes. Here we report our discovery: the blood flow in blood vessels can be optimized by application of a strong magnetic field along its flow direction. The red blood cells are polarized and aggregated into short chains. The blood viscosity along the flow direction is significantly reduced, turbulence is suppressed, and the flow becomes stable laminar. Hence the blood pressure is lowered down to the normal range. Our clinical trials have more than 250 people tested. The technology is effective for everyone. On average, in 15 minutes the magnetic treatment lowers the blood pressure by 21.4%. The effect lasts more than 24 hours and can be kept continuously if the magnetic treatment is repeated everyday. Our placebo tests have also confirmed that without application of magnetic field, the blood pressure cannot be lowered. The effect is truly produced by improvement of blood flow with magnetic field. We expect that this technology will help people to cure hypertension, preventing cardiovascular diseases.

**8:00AM A07.00001: Bifurcating entanglement-renormalization group flows of fracton stabilizer models**  
ARPIT DUA (Presenter), PRATYUSH SARKAR, DOMINIC WILLIAMSON, MENG CHENG, Yale University — We investigate the entanglement-renormalization group flows of translation-invariant topological stabilizer models in three dimensions. Fracton models are observed to bifurcate under entanglement renormalization, generically returning at least one copy of the original model. Based on this behavior we formulate the notion of bifurcated equivalence for fracton phases, generalizing foliated fracton equivalence. The notion of quotient superselection sectors is also generalized accordingly. We calculate bifurcating entanglement-renormalization group flows for a wide range of examples and, based on those results, propose conjectures regarding the classification of translation-invariant topological stabilizer models in three dimensions.

**8:12AM A07.00002: Quantum electrodynamics in a topological metamaterial: Part 1**  
EUN JONG KIM (Presenter), XUEYUE ZHANG, ALP SIPAHIGIL, VINICIUS S FERREIRA, JASH BANKER, MOHAMMAD MIRHOSSEINI, OSKAR PAINTER, Caltech — The rich quantum electrodynamical properties arising from topological photonics open new possibilities for studying novel many-body states and implementing topologically protected quantum information processing protocols. It has been recently suggested that a topological waveguide, which realizes a photonic analog of the Su-Schrieffer-Heeger (SSH) model, can host unconventional quantum optical phenomena [Sci. Adv. 5, eaaw0297 (2019)]. We discuss the implementation of the topological waveguide with superconducting metamaterials. We explore the exotic properties of qubit-photon bound states and topological edge states emergent in this system.

**8:24AM A07.00003: Quantum electrodynamics in a topological metamaterial: Part 2**  
XUEYUE ZHANG (Presenter), EUN JONG KIM, ALP SIPAHIGIL, VINICIUS S FERREIRA, JASH BANKER, MOHAMMAD MIRHOSSEINI, OSKAR PAINTER, Caltech — Topological concepts in photonics give rise to novel ways of controlling light or microwaves. By coupling quantum emitters to topological photonic structures, photon-mediated interaction between the emitters inherits the topological properties, which can lead to novel radiative phenomena. Here, we study superconducting qubits coupled to a microwave metamaterial waveguide which is a photonic analog of the Su-Schrieffer-Heeger (SSH) model [Sci. Adv. 5, eaaw0297 (2019)]. We report the observation of novel interaction profiles and scattering properties of the qubits induced by the topological photonic bath.
8:36AM A07.00004: Transition from 2D to 1D topological superconductivity in a triangular island of p-wave superconductor  
AIDAN WINBLAD (Presenter), HUA CHEN, Colorado State University —

We study the connection between 0D and 1D Majorana modes in a triangular island of a model topological superconductor, with the motivation of designing a flexible platform for performing braiding operations on Majorana zero modes for topological quantum computation. Using the mean-field Bogoliubov-de Gennes theory, we solve a tight-binding model with Rashba spin-orbit coupling, out-of-plane Zeeman field, and s-wave pairing on an equilateral triangle, which hosts chiral Majorana edge modes. Using an eigen-value solver we were able to show breaking of the three-fold rotation symmetry of the model by applying an additional in-plane Zeeman field, which is expected to result in an effectively 1D topological superconductor. To further understand the evolution of the pseudo-Majorana states at the corners we treat the corner as a wedge with open boundary conditions and solve the BdG equation analytically.

8:48AM A07.00005: Time-resolved electrical detection of chiral edge vortex braiding*  
INANC ADAGIDELI (Presenter), Sabanci University, FABIAN HASSLER, JARA-Institute for Quantum Information, RWTH Aachen University, AURELIEN GRABSCH, MICHAL PACHOLSKI, CARLO W J BEENAKKER, Physics, Leiden University —  

$2\pi$ phase shift across a Josephson junction in a topological superconductor injects vortices into the chiral edge modes at opposite ends of the junction. When two vortices are fused they transfer charge into a metal contact. We calculate the time dependent current profile for the fusion process, which consists of $\pm e/2$ charge pulses that flip sign if the world lines of the vortices are braided prior to the fusion. This is an electrical signature of the non-Abelian exchange of Majorana zero-modes.

*This research was supported by the Netherlands Organization for Scientific Research (NWO/OCW) and by the European Research Council (ERC).
9:00AM A07.00006: Braiding of Majorana Fermions in a Cavity  MIRCEA TRIF (Presenter), Institute of Physics, Polish Academy of Sciences, PASCAL SIMON, LPS Orsay, University of Paris-Saclay — We study the dynamical process of braiding Majorana bound states (MBS) in the presence of the coupling to photons in a microwave cavity. We show theoretically that the $\pi/4$ phase associated with the braiding of MBS, as well as the parity of the ground state are imprinted into the photonic field of the cavity, which can be detected by dispersive readout techniques [1]. We use a density matrix description for the dynamics of the low energy states in order to account for various relaxation channels both in the adiabatic regime, as well as within the Floquet formalism in the case of periodic driving. We evaluate the average photon number and the second order photon coherence function $g^{(2)}(0)$, and show they are affected by the non Abelian Berry phase accumulated during the braiding process [2]. These manifestations are purely dynamical, they occur in the absence of any splitting of the MBS that are exchanged, and they disappear in the static setups studied previously. Conversely, the cavity can affect the braiding phase, which in turn should allow for cavity controlled braiding.

9:12AM A07.00007: Braiding Majorana Fermions and Creating Quantum Logic Gates with Vortices on a Periodic Pinning Structure*  XIAOYU MA (Presenter), University of Notre Dame, CYNTHIA REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — We show how vortices that support Majorana fermions when placed on a periodic pinning array can be used for vortex exchange and independent braiding by performing a series of specific moves with a probe tip. Using these braiding operations, we demonstrate realizations of a Hadamard and a CNOT gate. We specifically consider the first matching field at which there is one vortex per pinning site, and we show that there are two basic dynamic operations, move and exchange, from which basic braiding operations can be constructed in order to create specific logic gates. The periodic pinning array permits both control of the world lines of the vortices and freedom for vortex manipulation using a set of specific moves of the probe during which the probe tip strength and height remain unchanged. We measure the robustness of the different moves against thermal effects and show that the three different operations produce distinct force signatures on the moving tip.

Towards practical self-correction with augmented Majorana stabilizer codes

STEPHAN PLUGGE (Presenter), MARCEL FRANZ, ROBERT RAUSSENDORF, IAN AFFLECK, University of British Columbia — We present design ideas for an augmented Majorana surface code (MSC) that allows improved error-correcting behavior on practically relevant time-scales. The underlying mechanism resembles that of interacting anyon models, and facilitates the protected Hamiltonian-level generation of stabilizer operators in MSCs together with coupling to auxiliary bosonic degrees of freedom. In this talk, I will discuss MSCs and their extensions affording improved error-correction, towards the goal of thermally stable quantum memories in 2D.

We acknowledge funding by NSERC, CIFAR, and the Stewart Blusson Quantum Matter Institute at UBC Vancouver. Further we acknowledge computational resources provided by UBC ARC Sockeye and the Compute Canada network.

Optimizing Clifford gate generation for measurement-only topological quantum computation with Majorana zero modes

ALAN TRAN (Presenter), Physics, University of California, Santa Barbara, ALEX BOCHAROV, BELA BAUER, PARSA BONDESON, Microsoft — One of the main challenges for quantum computation is that while the number of gates required to perform a non-trivial computation may be very large, decoherence and errors in realistic architectures limits the number of physical gate operations that can be performed coherently. Therefore, an optimal mapping of the quantum algorithm into the physically available set of operations is of crucial importance. We examine this problem for a measurement-only topological quantum computer based on Majorana zero modes (MZMs), where gates are performed through sequences of measurements. Such a scheme has been proposed as a practical, scalable approach to process quantum information in an array of topological MZM qubits. Building on previous work that has shown that multi-qubit Clifford gates can be enacted in a topologically protected fashion in such qubit networks, we discuss methods to obtain the optimal measurement sequence for a given Clifford gate under the constraints imposed by the physical architecture, such as layout and the relative difficulty of implementing different measurements. Our methods also provide tools for comparative analysis of different architectures and strategies, given experimental characterizations of particular aspects of the systems under consideration.
9:48AM A07.00010: Computational universality of symmetry-protected topologically ordered cluster phases on 2D Archimedean lattices*  AUSTIN DANIEL (Presenter), RAFAEL ALEXANDER, AKIMASA MIYAKE, University of New Mexico — Which symmetry-protected topologically ordered (SPTO) ground states can be used for universal measurement-based quantum computation in a similar fashion to the 2D cluster state? 2D SPTO states are classified not only by global on-site symmetries but also by subsystem symmetries, which are fine-grained symmetries dependent on the lattice geometry. Recently, all states within so-called SPTO cluster phases on the square and hexagonal lattices have been shown to be universal, based on the presence of subsystem symmetry and associated structures of quantum cellular automata. Motivated by this, we analyze the computational capability of SPTO cluster phases on all vertex-translative 2D Archimedean lattices. There are four subsystem symmetries here called ribbon, cone, fractal, and 1-form symmetries, and the former three are fundamentally in one-to-one correspondence with three classes of Clifford quantum cellular automata. We conclude that nine out of the eleven Archimedean lattices support universal cluster phases protected by one of the former three symmetries, while the remaining lattices possess 1-form symmetry and have a different capability related to error correction.

10:00AM A07.00011: Parafermions and $Z_3$ Charge-Flux attachment  PENG RAO (Presenter), Max Planck Institute for the Physics of Complex Systems, VIJAY SHENOY, Indian Institute of Science, INTI SODEMANN, Max Planck Institute for the Physics of Complex Systems — A recent construction (Ann. Phys. 393, 234 (2018)) has introduced an interesting route to bosonization of fermions in two spatial dimensions by implementing a precise lattice version of flux-charge binding. The idea is to modify Kitaev’s Toric code so that the electric charge ($e$) and magnetic flux ($m$) are always created in a tight "dipolar" pair $\varepsilon (=e \times m)$ which is a fermion, providing a way to represent any local fermionic Hamiltonian as a local Hamiltonian of spins. We discuss an extension of these ideas to the case of a $Z_N$ toric which allows a bosonization of anyons with more general statistitical angles. We have focused particularly in the case of $N=3$. We will prove that ground states in the torus in this case are at least three-fold degenerate, and, discuss a model featuring a topological phase transition between a 3-fold degenerate state and a 9-fold degenerate ground state featuring parafermionic excitations.

10:12AM A07.00012: Fun with fractons [Invited]  DOMINIC WILLIAMSON (Presenter), Stanford Univ — Interest in fracton topological order has grown explosively over the past several years, leading to a plethora of models that exhibit exotic topological physics tied to mobility constrained superselection sectors. At the same time a classification of even the simplest class of stabilizer fracton Hamiltonians remains elusive. I will describe some recent efforts to tame the vast array of models with the goal of a systematic construction and classification of all topological phases of matter in three spatial dimensions.

Monday, March 2, 2020 8:00 AM - 11:00 AM
8:00AM A09.00001: Finding Navier-Stokes fluid flows through quantum computing  FRANK GAITAN (Presenter), Laboratory for Physical Sciences; College Park, MD — We present a quantum algorithm that solves an arbitrary set of coupled non-linear partial differential equations and show how it can be used to solve the governing equations for a Navier-Stokes fluid. To test the algorithm we examine the problem of inviscid, compressible flow through a convergent-divergent nozzle. We numerically simulate application of the algorithm to find the steady-state flow when a shockwave is and is not present in the divergent part of the nozzle. In each case excellent agreement is found between the output of the quantum simulation and the exact analytical solution, with the simulation successfully capturing the shockwave when present. We compare the computational cost of the quantum algorithm to that of deterministic and random classical algorithms; discuss future applications as well as the potential long-term significance of quantum computing for the fluid dynamics community.

8:12AM A09.00002: Quantum eigenvalue estimation via time series analysis*  ROLANDO SOMMA (Presenter), Los Alamos National Laboratory — We present an efficient method for estimating the eigenvalues of a Hamiltonian $H$ from the expectation values of the evolution operator for various times. For a given quantum state $\rho$, our method outputs a list of eigenvalue estimates and approximate probabilities. Each probability depends on the support of $\rho$ in those eigenstates of $H$ associated with eigenvalues within an arbitrarily small range. The complexity of our method is polynomial in the inverse of a given precision parameter. Unlike the well-known quantum phase estimation algorithm that uses the quantum Fourier transform, our method does not require large ancillary systems, large sequences of controlled operations, or preserving coherence between experiments, and is therefore more attractive for near-term applications. The output of our method can be used to compute spectral properties of $H$ and other expectation values efficiently.

*This work was supported in part by the Laboratory Directed Research and Development program of Los Alamos National Laboratory and by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, Quantum Algorithms Teams program.
**8:24AM A09.00003: A robust algorithm for finding phase factors in quantum signal processing**

YULONG DONG (Presenter), LIN LIN, University of California, Berkeley, XIANG MENG, Peking University, BIRGITTA K WHALEY, University of California, Berkeley — Quantum Signal Processing (QSP) provides a general way to implement matrix functions on quantum computers. The algorithm can be efficiently used to solve quantum linear systems, to perform Hamiltonian simulation, and to prepare Gibbs ensembles, among other applications. QSP can exactly encode a degree-d polynomial transformation of a matrix using d+1 phase factors. However, the current strategies for solving for the phase factors of a given function can be numerically unstable. We present an efficient method to find the phase factors for a general real function, and demonstrate the performance for solving linear systems and eigenvalue problems.

*This work was supported by a Quantum Research Award from Google LLC and also by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, Quantum Algorithm Teams Program, under contract number DE-AC02-05CH11231.

**8:36AM A09.00004: Finding symmetry-broken ground states with variational quantum algorithms**

NICOLAS VOGT (Presenter), SEBASTIAN ZANKER, JAN-MICHAEL REINER, HQS Quantum Simulations GmbH, THOMAS ECKL, ANIKA MARUSCZYK, Robert Bosch GmbH, MICHAEL MARTHALER, HQS Quantum Simulations GmbH — One of the most promising applications for near-term intermediate scale quantum computers (NISQ) is the preparation of the true ground state of strongly correlated electron systems. Besides the ground-state energy the properties of interest of the ground state are its broken symmetries and the corresponding phases of the system.

We study the preparation of broken symmetry ground states on a gate based quantum computer with different variational algorithms, including the variational Hamiltonian ansatz (VHA) with initial state preparation and extensions to the standard VHA. The two-dimensional Hubbard model is used as a toy model, to compare the variational algorithms to each other and to exact diagonalisation. To this end, we simulate the full algorithm including initialization and read-out running on a gate-based quantum computer. We use a hardware model based on the gates available in currently available quantum computers.

---

**8:48AM A09.00005: Strategies for digital quantum simulation of bosons**

NICOLAS SAWAYA (Presenter), Intel Labs, TIM MENKE, Physics, MIT, THI HA KYAW, Computer Science, U Toronto, SONIKA JOHRI, Intel Labs, ALAN ASPURU-GUZIK, Computer Science, U Toronto, GIAN GIACOMO GUERRESCHI, Intel Labs — Many prominent bosonic simulation problems are thought to be intractable on a classical computer, including the Bose-Hubbard model, quantum photonics, and molecular vibronics. The behavior of such systems would be efficiently studied on a quantum computer. Before such a simulation is performed, one must choose how to encode the bosonic degrees of freedom into a set of qubits. We present a general methodology for encoding truncated bosons into arrays of qubits, and consider several encoding types. We study the quantum operations and qubit counts for local and composite operators. Importantly, we also consider the utility of interconverting between mappings in the middle of a simulation. These methods lower the quantum resource requirements compared to previous encoding strategies, which may allow for larger problems to be simulated on near-term quantum devices.
**9:00AM A09.00006: A Method of Determining Excited-States for Quantum Computation**

PEJMAN JOUZDANI (Presenter), STEFAN A BRINGUIER, MARK KOSTUK, General Atomics - San Diego — The calculation of molecular ground-state and excited-state energies, or more generally the energy spectra of chemical and material systems, is an application of great interest in a gate-based quantum computational model. In this contribution, we propose a phenomenological approach to the calculation of low-lying excited-states of a given problem Hamiltonian. Specifically, a method is presented in which the ground-state subspace is projected out of a Hamiltonian representation. As a result of this projection, an effective Hamiltonian is constructed where its ground-state coincides with an excited-state of the original problem. Thus, low-lying excited-state energies can be calculated using existing hybrid quantum-classical techniques and variational algorithm(s) for determining ground-state. The method is shown to be fully valid for the H2 molecule. In addition, conditions for the method’s success are discussed in terms of classes of Hamiltonians. A discussion on the broad impact of this method in the era of NISQ devices will also be presented.

*This material is based upon work supported by General Atomics internal R&D funding.

**9:12AM A09.00007: Quantum simulation by qubitization without Toffoli gates**

MARK STEUDTNER (Presenter), Lorentz Institute, STEPHANIE WEHNER, Delft University of Technology — Qubitization is a modern approach to estimate Hamiltonian eigenvalues without simulating its time evolution. While in this way approximation errors are avoided, its resource and gate requirements are more extensive: qubitization requires additional qubits to store information about the Hamiltonian, and Toffoli gates to probe them throughout the routine. Recently, it was shown that storing the Hamiltonian in a unary representation can alleviate the need for such gates in one of the qubitization subroutines. Building on that principle, we develop an entirely new decomposition of the entire algorithm: without Toffoli gates, we can encode the Hamiltonian into qubits within logarithmic depth.

**9:24AM A09.00008: Emulation of fractional quantum Hall states with existing quantum hardware**

ARMIN RAHMANI (Presenter), Western Washington University, POUYAN GHAEMI, City College of the City University of New York, ZHANG JIANG, Google Research, Venice, CA, PEDRAM ROUSHAN, Google Inc., Santa Barbara, CA, KEVIN J SUNG, Google Research and the University of Michigan — Emulating strongly correlated phases of matter with existing or near-term quantum hardware is of considerable interest. Here we present quantum circuits to generate both the ground and quasiparticle states corresponding to the Laughlin’s \( \nu = 1/3 \) fractional quantum Hall state in the second-quantized representation. Our circuit depth is linear in the number of qubits. We identify experimentally accessible correlation functions as signatures of this state and discuss the quantum hardware implementation.

*Google Quantum Innovation Award
9:36AM A09.00009: Computing partition functions in the one clean qubit model*  ANIRBAN NARAYAN CHOWDHURY, Physique, Universite de Sherbrooke, ROLANDO SOMMA, YIGIT SUBASI (Presenter), Los Alamos National Laboratory — In this talk we will present a method to approximate partition functions of quantum systems using mixed-state quantum computation. For non-negative Hamiltonians, our method runs on average in time almost linear in \((M/(\varepsilon_{\text{rel}} Z))^2\), where \(M\) is the dimension of the quantum system, \(Z\) is the partition function, and \(\varepsilon_{\text{rel}}\) is the relative precision. It is based on approximations of the exponential operator as linear combinations of certain operations related to block-encoding of Hamiltonians or Hamiltonian evolutions. The trace of each operation is estimated using a standard algorithm in the one clean qubit model. For large values of \(Z\), our method may run faster than exact classical methods, whose complexities are polynomial in \(M\). Using this method we will demonstrate that a version of the partition function estimation problem within additive error is complete for the so-called DQC1 complexity class, suggesting that our method provides an exponential speedup.

9:48AM A09.00010: Reaction dynamics on a quantum computer*  ANDREW TRANTER (Presenter), PETER LOVE, Tufts Univ — The study of quantum chemistry is expected to be a principal use of emergent quantum computing devices. The ability of quantum computers to efficiently provide highly accurate electronic structure data could have major consequences where such accuracy is required, such as in the prediction of the kinetics and dynamics of chemical reactions. However, such simulations often require vast numbers of electronic structure calculations, potentially exacerbating resource limitations of small-scale quantum devices.

In this talk, we present theoretical results characterising the quantum resources required for the simulation of reactions involving small numbers of light atoms through semi-classical trajectory simulation. We consider how this process can be aided by recent optimisations to variational quantum algorithms. Finally, we report simulation results and discuss experimental progress to this end.

*The authors acknowledge Lincoln Labs for financial support.
10:00AM A09.00011: A size-extensive scheme for variational quantum ansatzes without Trotter approximation*  
YAROSLAV HERASYMENKO (Presenter), THOMAS O'BRIEN, Leiden University — One of the most promising applications for quantum computers is simulating the low-energy states of complex quantum systems. In the near-term, this can be done with variational ansatzes. Such ansatzes should follow physical principles to ensure high performance, one of the key principles being size-extensivity. Unfortunately, digitizing such ansatzes into standard operations generally requires the use of the inexact Trotter expansion, which constrains the expected accuracy of the ansatz.

In this work, we resolve this conflict by developing a framework for physically motivated ansatzes, which is fundamentally digital and thereby involves no Trotter errors. Using the stabilizer formalism, we construct a family of digital ansatzes that provably cover the entire Hilbert space with a minimal number of parameters. We show how to compress such parent ansatzes into practical child ansatzes that target specific systems, following the principle of size-extensivity. For this purpose, we develop a convenient diagrammatic approach. We apply our method numerically to the quantum Ising chain, with good convergence outside the critical regime.

*This work was funded by the Netherlands Organization for Scientific Research (NWO/OCW), an ERC Synergy Grant, and Shell Global Solutions BV.

10:12AM A09.00012: Finding the ground state of the Hubbard model by variational methods on a quantum computer with gate errors  
JAN-MICHAEL REINER (Presenter), HQS Quantum Simulations, FRANK WILHELMI, Theoretical Physics, Saarland University, GERD SCHÖN, Institut für Theoretische Festkörperphysik, Karlsruhe Institute of Technology (KIT), MICHAEL MARTHALER, HQS Quantum Simulations — A key goal of digital quantum computing is the simulation of fermionic systems such as molecules or the Hubbard model. Unfortunately, for present and near-future quantum computers the use of quantum error correction schemes is still out of reach. Hence, the finite error rate limits the use of quantum computers to algorithms with a low number of gates.

The variational Hamiltonian ansatz (VHA) has been shown to produce the ground state in good approximation in a manageable number of steps. Here we study explicitly the effect of gate errors on its performance. The VHA is inspired by the adiabatic quantum evolution under the influence of a time-dependent Hamiltonian, where the -- ideally short -- fixed Trotter time steps are replaced by variational parameters. The method profits substantially from quantum variational error suppression, e.g., unitary quasi-static errors are mitigated within the algorithm. We test the performance of the VHA when applied to the Hubbard model in the presence of unitary control errors on quantum computers with realistic gate fidelities.
10:24AM A09.00013: Quantum algorithm for spectral projection by measuring an ancilla iteratively*

TZU-CHIEH WEI (Presenter), YANZHU CHEN, State Univ of NY - Stony Brook — We propose a quantum algorithm for projecting a quantum system to eigenstates of any Hermitian operator, provided one can access the associated control-unitary evolution for the ancilla and the system. The procedure is iterative by preparing a fresh ancilla state, applying the controlled unitary, and then measuring the ancilla. There are some freedoms in the ancilla state parameter and the control unitary. We give examples to illustrate that the algorithm works. Simulations of the procedure also show that the distribution of the projected eigenstates obeys the Born rule. This algorithm can be used as a subroutine in the quantum annealing procedure by measurement to drive the system to the ground state, and we also simulate this for a quantum spin chain.

*This work was supported by National Science Foundation under grants No. PHY 1620252 and No. PHY 1915165.

10:36AM A09.00014: Quantum Simulation of Quantum Z2 Gauge Theory demonstrated in a GPU Simulator*

YU SHI (Presenter), Fudan Univ — We outline a quantum simulation scheme of quantum Z2 gauge theory using quantum adiabatic algorithm implemented in terms of quantum circuit, and then demonstrate it in the classical simulator QuEST using a CUDA enabled GPU server. In particular, we obtained useful results in (3+1)-dimensional and (2+1)-dimensional theories. It is identified that the quantum phase transition is topological in both dimensions, and is first-order in (3+1) dimensions but second-order in (2+1) dimensions. High-performance classical simulation of quantum simulation, which may be dubbed pseudoquantum simulation, is not only a platform of developing quantum software, but also represents a new practical mode of computation.

10:48AM A09.00015: Term Grouping Techniques for VQE and Quantum Dynamics Circuits

KAIWEN GUI (Presenter), PRANAV GOKHALE, University of Chicago, TEAGUE TOMESH, Princeton University, YONGSHAN DING, University of Chicago, OLIVIA ANGIULI, University of California, Berkeley, MARTIN SUCHARA, Argonne National Laboratory, MARGARET MARTONOSI, Princeton University, FRED CHONG, University of Chicago — Digital quantum simulations are among the most promising near-term applications of quantum computation. Variational Quantum Eigensolver and time evolution of quantum dynamics are two examples of such algorithms. However, the amount of required quantum resources typically do not scale favorably as the desired accuracy of the calculations increases. Both VQE and quantum dynamics circuits are represented by tensor products of Pauli matrices that are obtained from the second quantization form using transformation methods such as Jordan-Wigner or Bravyi-Kitaev. We demonstrate various grouping techniques that optimize the order of these tensor products, with the goal of optimizing the total quantum resource cost. For VQE circuits, we minimize the number of required measurement operations. For quantum dynamics circuits, we minimize the circuit depth and maximize its fidelity.

Monday, March 2, 2020 8:00 AM - 10:12 AM
8:00AM A10.00001: Scanning Probe Microscope in an Ultra-High Vacuum Cryogen-free Environment*  
ANGELA COE (Presenter), GUOHONG LI, EVA ANDREI, Rutgers University, New Brunswick — Our new design concepts expand the use of scanning probe microscopy (SPM) into an ultra-high vacuum cryogen-free system. Typical cryogen-free systems are too noisy to effectively operate SPM, which require a low noise environment. We have created an internal vibration isolation unit that is able to connect to existing cryogen-free cryostats making their noise level low enough to operate SPMs. Our SPM is a modular design that can accommodate interchangeable probes, including STM, AFM, and MFM. The instrument is equipped with stages for sputtering, e-beam film deposition, and exfoliation for in-situ sample preparation and tip conditioning. The SPM is assembled at room temperature in ultra-high vacuum and a novel low-profile vertical transfer mechanism makes it possible to transfer the SPM, without breaking vacuum, to a variable temperature cryogen-free cryostat and magnet. The integration of all these capabilities into one instrument enables in-situ nano-scale characterization of low dimensional systems.

8:12AM A10.00002: Graphene-based Hall probe magnetic imaging*  
DAVID COLLOMB (Presenter), PENGLEI LI, SIMON J BENDING, Univ of Bath — Hall probe microscopy is a powerful tool for mapping magnetic fields across a sample surface, and can be used to investigate key properties of magnetic and superconducting materials. However, to date the technique has not been widely used under ambient conditions because the figures-of-merit of available GaAs-based Hall probes degrade substantially at room temperature. To address this we have recently demonstrated sub-100nm CVD graphene Hall devices with room temperature field resolutions in the μT/√Hz range, greatly exceeding the performance of GaAs-based Hall probes.¹ Additionally, we have demonstrated improved stability and increased mobility in graphene devices encapsulated in HSQ.² We build upon these developments to optimise CVD graphene Hall probes for high resolution ambient magnetic imaging. We also report progress made in extending the technique to include local susceptometry mapping for, e.g., characterisation of ferromagnetic data storage media.

Absorption of ground-borne vibrations by aggregate of particulate is investigated to determine attenuation versus frequency and material properties. The goal is to mitigate transmission of vibrations from the ground into the building structures. Attenuation depends on mechanical properties of the particulates medium, such as; elastic moduli, contact areas, aggregate size-distribution, and degree of compactness. Experimental findings show that aggregate material behaves as a band-pass filter for vibrations transmitted through them. Some aggregate materials have a frequency band-gap where frequencies in a certain range are strongly attenuated. Media of uniform size particulates are subjected to mechanical vibrations at different frequencies and amplitudes. Vibration attenuation versus frequency is measured as a function of material thickness, aggregate size, and compactness. The results can provide the characteristics of optimal dampers for external vibrations transmitted into the building structures.

The ability to measure and manipulate electrons at the nanoscale gives insight into nanoscale physics and paves way for its applications in electronics and photonics. We present a design and implementation of a scanning probe microscope that is cooled to liquid nitrogen temperature, to image electrons at the nanoscale. The imaging technique relies on a conductive scanning tip that acts as a local, movable electrostatic gate. The tip creates a local change in density of electrons in the material directly underneath it deflecting the electrons away from their original path. This changes the conductance of the device. The conductance is measured as a function of tip position while the tip moves across the material. The conductance change vs. tip position gives the map of the electron flow in the material. To align the tip within a micron of the sample at liquid nitrogen temperature, we use a home-built coarse positioning system. By applying high voltages to a piezo tube, the tip is raster scanned over the sample. With this method, we plan to image the viscous flow of electrons in graphene at liquid nitrogen temperature. Our design also allows us to image electronic flow in other nanoscale materials such as 2D semiconductors and topological insulators.
8:48AM A10.00005: Our software eliminates up to 80% of vibrational noise in a scanning tunneling microscope*  JONATHAN GOETTSCH (Presenter), School of Engineering and Applied Sciences, Harvard University, HARRIS PIRIE, BRYCE PRIMAVERA, Department of Physics, Harvard University, ALBERT CHIEN, School of Engineering and Applied Sciences, Harvard University, JENNIFER E. HOFFMAN, Department of Physics, Harvard University — Scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) are globally employed techniques to measure the electronic structure of condensed matter systems with atomic precision. They require extremely stable environments to operate: modern microscopes typically use a combination of pneumatic isolators and massive inertial blocks to reduce ambient vibrations to the picometer scale. However, improvements beyond this benchmark are challenging and even the best microscopes are still limited by residual vibrations. Here we demonstrate a software algorithm that cancels up to 80% of vibrational noise over a 300 Hz bandwidth, even in modern ultra-low-vibration laboratories. Our scheme relies on a precisely calibrated transfer function to accurately propagate geophone-recorded vibrations to the STM tip. These vibrations are then subtracted from spectroscopic and topographic measurements by post processing. Our algorithm mitigates STM vibrational noise in a wide range of experimental environments, including those with high-amplitude noise.

9:00AM A10.00006: Progress on the Scanning Majorana Microscope*  ERIC GOODWIN (Presenter), MICHAEL GOTTSCHALK, Michigan State University, ALEX LEVCHENKO, University of Wisconsin - Madison, STUART TESSMER, Michigan State University — Quantum dots have proven to be powerful probes for studying a variety of mesoscopic effects. In general, lithographically-defined surface quantum dots and scanning single-electron-transistor (SET) quantum dot microscopes fulfill different niches, in part due to the inability to bring the scanning SET close enough to the surface to provide strong coupling. We show significant progress on a new type of scanning quantum dot microscope which we call the Scanning Majorana Microscope (SMM). This novel probe is capable of resolving single electrons entering a quantum dot situated at the tip’s apex; and importantly, we are able to position the quantum dot within tunneling range (~1nm) of the surface of a sample. With the ability to strongly couple surface states to the quantum dot and study how the single-electron signal evolves as a function of coupling strength, this probe represents a new tool to study mesoscopic systems, including candidate Majorana states.

*This work is supported by the U.S. Department of Energy, Basic Energy Sciences under Award DE-SC0017888.
CHRISTOPHER LUTZ (Presenter), IBM Research – Almaden — We use a low-temperature scanning tunneling microscope (STM) to perform electron spin resonance (ESR) of individual magnetic atoms on a surface, and employ these atoms as atomic-scale magnetic sensors. This technique combines the single-atom control of STM with the high energy resolution of ESR. We drive spin resonance by using the large electric field available in the tunnel junction, and sense the spin by means of magnetoresistance, using a spin-polarized STM tip. Magnetic coupling between two iron atoms placed a few nanometers apart on an MgO film shows inverse-cube distance dependence, indicating magnetic dipolar interaction. This yields a precise measure of the magnetic moment of the iron atom, which is then used to probe other atoms, such as the bistable magnetic bits formed by individual holmium atoms. We also use STM to drive ESR of titanium and copper atoms, which show free spin-1/2 behavior, in contrast to the high spin and large magnetic anisotropy of iron. Assembled arrays of low-spin atoms show exchange coupling that results in highly entangled magnetic states for quantum simulation of many-body states. ESR also reveals hyperfine coupling between the nucleus and the electrons of each atom. Furthermore, pulsed ESR allows us to perform coherent manipulation of atomic spins in order to observe Rabi oscillation, Ramsey fringes, and spin echoes. The combination of STM with ESR thus provides a versatile tool for exploring nano-scale quantum magnetism.

*We acknowledge funding from the Office of Naval Research.
9:48AM A10.00008: Sputtered Mo-Re SQUID-on-Tip for High-Field Magnetic and Thermal Nanoimaging  KOUSIK BAGANI (Presenter), JAYANTA SARKAR, AVIRAM URI, Department of Condensed Matter Physics, Weizmann Institute of Science, MICHAEL RAPPAPORT, Physics Core Facilities, Weizmann Institute of Science, MARTIN E HUBER, Departments of Physics and Electrical Engineering, University of Colorado Denver, ELI ZELDOV, YURI MYASOEDOV, Department of Condensed Matter Physics, Weizmann Institute of Science — Scanning nanoscale superconducting quantum interference devices (SQUIDs) have attracted attention as highly sensitive microscopic magnetic and thermal characterization tools of quantum and topological states of matter and devices. We present here a technique of collimated differential-pressure magnetron sputtering for the versatile self-aligned fabrication of SQUID-on-tip (SOT), which cannot be produced by conventional sputtering methods due to their diffusive, rather than the required directional point source, deposition. The technique provides access to a broad range of high $H_{c2}$ superconducting materials, alloys and possibly even high-Tc superconductors. This advancement is crucial for expanding the ranges of operating temperatures and magnetic fields essential of SOTs for the study of magnetic phenomena and dissipation mechanisms in a wide variety of quantum systems, unconventional superconductors, and topological materials. As a first example, we have fabricated Mo-Re SOTs with sub-50-nm diameter, that operates up to an unprecedentedly high magnetic field of 5 T with spin sensitivity better than 1.2 $\mu_0$/Hz$^{1/2}$ up to 3 T at 4.2 K, and thermal sensitivity better than 4 $\mu$K/Hz$^{1/2}$ up to 5 T—about five times higher than any previous report [1].

10:00AM A10.00009: Spin-polarized Seebeck effect at the nanoscale measured with scanning tunneling thermovoltage microscopy*  JEWOOK PARK (Presenter), Institute for Basic Science, Pohang, Republic of Korea, FELIX LUEPKE, Oak Ridge National Lab, JUN JIANG, XIAOGUANG ZHANG, University of Florida, AN-PING LI, Oak Ridge National Lab — Spin caloritronic effects have gained recent interest due to, e.g., potential low-power applications of magnetic tunnel junctions in which a temperature gradient-driven tunneling of electrons gives rise to a spin-dependent thermovoltage due to the Seebeck effect. Here, we report spatial mapping of the spin-resolved thermovoltage in a tunneling junction formed by ferromagnetic Co islands on a Cu(111) substrate and the magnetic tip of a scanning tunneling microscope. Our measurements reveal variations of the thermovoltage as function of spin polarization, island size, and stacking orientation of the islands with respect to the substrate. This method allows to reveal nanoscopic heterogeneities of both, the magnetic structures and the spin-dependent thermoelectric power.

*This research was performed at the Center for Nanophase Materials Sciences which is a DOE Office of Science User Facility.

Computational and experimental study of the doping of Bi$_2$Fe$_{4-x}$M$_x$O$_9$ (M=Ga, Al, or Ge)*

JOSEPH LANIER (Presenter), DAVID JONATHAN PRYCE MORRIS, Physics, Xavier University, Cincinnati, OH — Transition metal oxides have attracted interest due to the range of physical properties which are of scientific interest and of interest due to their potential applications. Here we report a study into the doping of Bi$_2$Fe$_{4-x}$M$_x$O$_9$. Doping the system with M=Ga, Al, or Ge, allows us to modified the magnetic moment on the iron site and alter the ionic and magnetic order of the material. The structure itself consists of metal oxide polyhedron that are seen throughout the entire crystal. Two edge sharing octahedron are connected to a tetrahedron in all locations, where the bismuth sits outside of these polyhedrons. Monte-Carlo simulations have been performed using the Metropolis algorithm to reduce the Coulomb energy - taking into account ionic radii and charge - to determine whether the M sit on the tetrahedron sites, or the octahedron. As well as using the Heisenberg Model to model the overall magnetic moment of the crystal. Crystals of the material with the three options for M have been grown, and we also report results from magnetization and x-ray measurements that test the simulations.

Surface Plasmon Resonance Dispersion Relation of Gold-Aluminum Thin Films Using the Kretschmann Configuration*

ROBERT KENT (Presenter), ABDUL QADEER REHAN, MARIAMA REBELLO SOUSA DIAS, Physics, University of Richmond — The prevalence of gold (Au) in the excitation of surface plasmon resonance (SPR) has been widely explored, due to these elements' pronounced dip in reflected intensity in the visible and near-IR spectrum, and their integrity in sensors owing to their resistance to oxidization. Other metals such as aluminum also exhibit SPR, but it remains a challenge to work with because of its propensity to form a surface oxide layer which can inhibit the response. Our research explores SPR in gold-aluminum (AuAl) alloyed thin films. We fabricate the thin films using the co-sputtering technique, with some concentrations (Au$_{0.85}$Al$_{0.15}$) showing a higher SPR quality factor than pure gold. The mixture of these elements should reduce the possibility of oxidization of Al, and therefore exhibit a better response. Numerous works have explored SPR using AuAl thin films, but few have done so with such high angular and spectral resolution, over such a wide range, using this many alloys. This is a result of the precision, equipment, and time necessary to take such measurements. We were able to produce high-resolution, homogenous images of SPR for various concentrations of AuAl alloys, that strongly agree with calculations.

8:24AM A11.00003: Simulating Spin Relaxation in Organic Semiconductors*  RICHARD GERST (Presenter), NICHOLAS HARMON, Univ of Evansville — Understanding spin lifetimes in organic semiconductors is important for spin-based applications as well as for devices like organic solar cells and OLEDs. Spin relaxation and diffusion in disordered organic semiconductors is explored with numerical simulations. Previous theories and simulations examined the role of nuclear and spin-orbit interactions in relaxing spin [1, 2]. This work extends and explores in more detail the influence of spin-orbit interactions. Spin relaxation is studied in two regimes: one in which hops are uncorrelated with each other (multiple trapping) and the other where hops are correlated (multiple hopping). For multiple trapping we find agreement with analytic solutions [1]. For multiple hopping we find the simulation gives a smaller spin relaxation rate (a factor of 2/3). Both models are studied in either the semi-classical approximation where the carrier spin is a classical vector or in a quantum model where the carrier spin is a quantum object. We find interesting differences emerge between the two approaches when the hopping rates depends on orbital alignment.

*This work was funded by a UExplore grant from the University of Evansville.

8:36AM A11.00004: Electrically conductive gels of single wall carbon nanotubes and PEDOT:PSS*  ANGELO PORCU (Presenter), LUIS D. RIVAS BAGUER, ANAMARIS MELENDEZ, IDALIA RAMOS, Physics and Electronics, University of Puerto Rico at Humacao, ARJUN G YODH, Physics, University of Pennsylvania, MOHAMMAD F ISLAM, Materials Science and Engineering, Carnegie Mellon University — The development of lightweight, flexible, and electrically conductive carbon aerogels has important technological applications. Their high surface area to volume ratio and electrical conductivity make them suitable for energy storage and chemical sensing. Here, we report on preparation and characterization of highly porous (void volume ~0.9) gels with a range of shapes and sizes and composed of co-networks of single wall carbon nanotubes (SWCNTs) and the conducting polymer poly(3,4-ethylenedioxythiophene)-poly(styrene sulfonate) (PEDOT:PSS), at ratios ranging from 1:5 to 1:9 using concentration dependent sol-gel method. We validated the porous, filamentous microstructure of these gels by imaging their cross-sections using scanning electron microscopy. The aerogels exhibited good electrical conductivity of ~100 S/cm, determined from four-point I-V measurements. We will also present how to enhance the electrical conductivity of the co-gels by the addition of dopants and to fabricate mechanically robust, highly electrically conducting fibers.

Applying uniaxial strain to graphene devices fabricated on flexible substrates*

JUSTIN OH (Presenter), BRIAN T SCHAEFER, Cornell University, VERONIKA SUNKO, Max Planck Institute for Chemical Physics of Solids, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CLIFFORD W. HICKS, ANDREW P. MACKENZIE, Max Planck Institute for Chemical Physics of Solids, KATJA NOWACK, Cornell University — Strain engineering is a promising avenue for tuning the band structure and electronic properties of two-dimensional materials. We report progress toward applying uniaxial strain to bilayer graphene devices with the ultimate goal of studying their magnetic properties using scanning superconducting quantum interference device (SQUID) microscopy. We fabricate graphene devices on flexible polyimide substrates and use a spring-based strain apparatus [1] to apply uniaxial strain by compressing or stretching the substrate, achieving a planar geometry compatible with scanning probe microscopy. We use Raman microscopy to monitor changes in the Raman peaks of graphene in response to uniaxial strain. Finally, we discuss the effects of strain on the band structure of bilayer graphene and outline our plans for studying this system using scanning SQUID microscopy.

*This work was primarily supported by the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875) and performed in part at the Cornell NanoScale Facility, (NSF NNCI, Grant ECCS-1542081).

Novel Technique for Inducing Large Area Uniaxial Strain in Graphene*

LUCAS HANSON (Presenter), ANGELA COE, GUOHONG LI, EVA ANDREI, Rutgers University, New Brunswick — The effect of uniaxial strain on the electronic band structure of graphene is an exciting topic of inquiry, for both studies into the fundamental physics of 2D electron systems as well as applicative investigations in the design of “straintronics”. Tight binding calculations of the effect of strain in graphene have shown that strain on the order of 20 percent causes the Dirac points to merge, resulting in the formation of a band gap. However, experimental realization of this prediction has yet to be achieved, as current techniques for inducing strain in graphene cannot generate strain exceeding a few percent. We have devised a novel technique for inducing large uniaxial strain in graphene using a piezoelectric mechanism. The mechanism allows for controllable and continuously variable strain, with an expected upper limit on the inducible strain set only by the tearing of graphene at 26 percent. Device functionality and performance are discussed, and strained graphene samples are characterized by Raman spectroscopy. Results are compared with existing Raman spectra of strained graphene.

9:12AM A11.00007: Quantum Transport in a Graphene-Superconductor Hybrid Device*
ELIZABETH ZHOU (Presenter), University of Southern California, VIVEK MANU KAKANI, JIAN LIAO, XURUI ZHANG, XIAOYAN SHI, University of Texas at Dallas — The interplay of superconductivity and the two-dimensional (2D) quantum Hall edge states is of great current interest for both fundamental science and applications. It could be an ideal platform to realize the non-Abelian zero modes, which is crucial for topological quantum computation. Here we fabricated an encapsulated few-layer graphene flake, which is in proximity to s-wave superconducting leads to form a Josephson-junction-like structure. At temperatures down to 20 mK, we have studied the magnetotransport properties of the device in a wide range of magnetic fields (both parallel and perpendicular orientations). In addition, the differential resistance has been measured as well. Experiments show multiple peaks at low fields, which may indicate the existence of Andreev reflections.

*This work was supported by the Research Experience for Undergraduates program funded by the National Science Foundation and hosted by the University of Texas at Dallas.

9:24AM A11.00008: Growth of ZnO on Nanosphere templates by Glancing Angle Vapor Deposition and Growth Modeling  DERICK DETELLEM (Presenter), PRITISH MUKHERJEE, SARATH WITANACHCHI, Univ of South Florida — Growth of coatings on a curved surface at steep angles enables the formation of pillar structures. In this research glancing angle laser deposition method was used to deposit Zinc Oxide (ZnO) nanostructures on silica nanoparticle templates in the size range of 3.5um to 250 nm. Self-assembled silica nanosphere templates were prepared by the Langmuir-Blodgett technique. It was observed that the diameter of the pillars and the number of pillars on each nano sphere decreased with decreasing sphere size. A simple model based on the nucleation theory that is adopted for nucleation and growth on a curved surface was developed to predict the evolution of the nanopillar structures. Results pertaining to the morphology, structure, and composition investigated for varying template sphere sizes by SEM, EDS, AFM, and XRD will also be presented.

9:36AM A11.00009: First order reversal curves simulation for core-shell nanoparticles via 3D-Ising model*  NICOLÁS VERGARA (Presenter), EDWIN ER RAMOS, JUAN RAMIREZ, University of the Andes — We studied the magnetic properties of the 3D-Ising model employing Montecarlo simulations. The system is built with a cubic unit cell compound of spherical nanoparticles with a core-shell structure. We have recovered the dynamical magnetic properties such as the susceptibility, energy, heat capacity and equilibrium magnetization for Ferro and Anti-Ferro magnetic couplings. All these properties were studied as a function of nanoparticle size. We found a nanoparticle critical-size limit below which the magnetic properties depart from those of the bulk. In addition, in simulating first order reversal curves (FORC) of the core-shell structures, we found that we were able to identify features on the FORC diagram that allowed us to decouple individual magnetic reversal mechanisms of the core, shell and the interface. Our results suggest that nano-confinement modify bulk properties and that FORC is able to separate individual magnetic contributions to the magnetism that are otherwise hidden in the isothermal hysteresis loops.

9:48AM A11.00010: Plasmonic interactions of gold nanoparticles with MoS$_2$-WS$_2$ Heterostructures

MUMTAZ HASSAN (Presenter), Mechanical Engineering, University of South Florida, HANA HRIM, SHARAD AMBARDAR, DMITRI V VORONINE, Physics, University of South Florida — Scanning probe force microscopic techniques and optical spectroscopy have been widely used for sensing applications. Raman scattering and photoluminescence (PL) signals provide vital spectroscopic information about low vibrational modes and electronic properties of two-dimensional transition metal dichalcogenides (2D TMD). Since Raman signals are generally weak, chemical and electromagnetic mechanisms can enhance these signals using plasmonic materials such as gold nanoparticles (NPs) leading to surface-enhanced Raman scattering (SERS). The effects of the gold NPs deposited on lateral MoS$_2$-WS$_2$ heterostructures has been investigated using a combination of optical spectroscopic techniques. Changes in surface topography have been observed using atomic force microscopy (AFM), Kelvin probe force microscopy (KPFM), Tip-enhanced PL (TEPL) and Raman (TERS) spectroscopy. Contact potential difference obtained through KPFM has decreased as a result of high accumulation of gold NPs. Raman spectroscopy peak intensities have decreased, and PL peaks have been observed to become sharper and narrower which could be a result of the formation of surface cavities on TMD's after the deposition of gold nanoparticles. This information can be applied to nano-optoelectronics and biosensing.

10:00AM A11.00011: Atomistic and Coarse-Grained MD Simulation Studies of the Energetics and Interactions of Regulatory Dib1 Protein Inside a Highly Dynamic Pre-Catalytic Spliceosomal Macromolecular Complex Preceding Pre-Messenger RNA Splicing in Eukaryotic Cells*

RACHEL GOLDSTEIN (Presenter), Trinity University, SARA CHENG, University of Texas at Austin, GABRIELLE ORR, CHRISTIAN SCHREIB, CORINA MAEDER, KWAN CHENG, Trinity University — The spliceosome is a complex RNA/protein macromolecular machine responsible for catalyzing the removal of introns from pre-messenger RNA in eukaryotic cells. As part of the highly dynamic spliceosome assembly pathway, the key protein Dib1 must depart the pre-catalytic B complex prior to pre-mRNA splicing. Experimentally, we have identified several Dib1 temperature-sensitive mutants that disrupt splicing activity and spliceosome assembly. However, the molecular mechanisms underlying how these mutations perturb protein-protein and protein-RNA interactions in the B complex are not known. Using 200ns of atomistic and 2µs of coarse-grained MD simulations, the interactions between Dib1 and its neighboring molecules were determined for spliceosomal B complexes containing wild-type and mutant Dib1 at conditions similar to biochemical experiments. We observed specific changes in the interaction energy, residue-contact, and hydrogen-bonding propensity at the interfacial region between Dib1 and neighboring RNAs and proteins. Our results offer an explanation for the experimental finding that the Dib1 mutations disrupt the transition from B to B$^{act}$ complexes in the splicing pathway.

Electrodepositing switchable photovoltaic window electron and hole transport layers*  
RACHEL THAM (Presenter), University of Illinois at Urbana-Champaign, KEVIN PRINCE, ANICA NEUMANN, Colorado School of Mines, CALEB BOYD, Stanford University, LANCE WHEELER, National Renewable Energy Laboratory — Vertical glass facade buildings, such as skyscrapers, have significant potential for generating electricity using solar window technologies, such as SwitchGlaze, a switchable photovoltaic window, containing a perovskite layer that absorbs visible and UV light. To commercialize these perovksite solar cells, it is essential to optimize electrodeposition, a scalably and controllably fabricate stable transport layers. This technique can then be used to fabricate back contact solar devices to decrease delamination occurrence and allow for more sunlight to directly interact with the perovskite and increase device efficiency. Nickel oxide and tin oxide, are promising transport layers due to higher stability and electron mobility, respectively. A three-electrode system was used to determine, in a range of 0.03 M to 0.1 M electrolyte concentrations, the electrodeposition times, current densities, and annealing times would electrodeposit that produced most uniform, least surface roughness, and thinnest transport layers. Initial results have produced solar cell devices up to about 12% efficiency.

Manipulating Generation and Spatial Distribution of Plasmon-Generated Hot Electrons via Oxygen Vacancies on Au/TiO$_2$ Heterostructures for Photochemistry*  
GRACE ROHALEY (Presenter), Allegheny College, JIAWEI HUANG, APRIL LO, W. DAVID WEI, Chemistry, University of Florida — Utilizing hot electrons on plasmonic metal/oxide heterostructures offers unique opportunities for solar photocatalysis. However, the role that surface oxygen vacancies (OVs) play in governing plasmon-driven photochemical reactions is poorly understood. Here, we demonstrate that surface OVs on Au/TiO$_2$ heterostructures manipulate plasmon-generated hot electrons in the generation process and spatial distribution for visible-light methylene blue (MB) degradation. Hot electrons originating from the plasmon-mediated electron transfer (PMET) pathway (i.e. the electron transfer from Au to TiO$_2$) and the plasmon-induced energy transfer (PIRET) pathway (i.e. the generation of electrons in TiO$_2$) accumulate under $\lambda > 435$ nm excitations, occupying surface OVs. Together, they result in ca. 5x enhancement in MB degradation than that under $\lambda > 495$ nm excitations, in which hot electrons only originate from the PMET pathway. Taken together, our study demonstrates an essential role played by surface OVs in plasmon-driven photochemistry and reveals two distinct mechanisms clarifying visible-light photocatalytic activity under different excitation conditions.

Molecular Dynamics Simulations of the Anorthite-Water System Under Extreme Conditions  
DEVEN ROMINE (Presenter), ROBERT MAYANOVIC, Missouri State Univ — Incorporation of water plays an important role in modifying the physical and chemical properties of silicate melts. Water reacts with the melt constituents causing depolymerization and reduces the viscosity of the melt which directly impacts the eruptive power of magmas and the transfer of mass in magmatic processes. Anorthite is a Ca-bearing aluminosilicate having the chemical formula CaAl$_2$Si$_2$O$_8$. It is an end member of the feldspar series and an important constituent of the rocks comprising the Earth's crust. We have made large simulation-cell molecular dynamics calculations in order to develop a detailed quantitative structural analysis of an hydrous anorthite melt system. ReaxFF reactive force fields are utilized to simulate the reaction between an anorthite melt and water at extreme temperatures. An analysis of bond lengths, pair correlations and bond angles within the hydrous melt is being made in order to determine how the structural properties of the system change under the extremes of pressure and temperature. The extent of depolymerization of the hydrous aluminosilicate melt, as determined from the transformation of Si – O – Si, Si – O – Al, and Al – O – Al bonds into terminating, non-bridging Si – OH and Al – OH bonds, will be discussed.

Simulating Noise in Superconducting Qubits Using Qiskit* 
EVA GURRA (Presenter), ERIC BERG, ELIZABETH DOSS, MATTHIEU DARTIAILH, KASRA SARDASHTI, JAVAD SHABANI, Center for Quantum Phenomena, NYU — Qubits are quantum systems analogous to classical bits. Classically, errors in bits arise from environmental factors like external magnetic fields, and intrinsic factors like dissipation in resistors. To correct for these errors, bits are copied for detection and corrected. In qubits, errors can result from internal factors such as improper state preparation from inaccurate gates, or coupling with the environment, which leads to energy relaxation and decoherence. Error correction in qubits requires a new approach as qubits cannot be copied, and because they exist in superposition, phase information must also be preserved. Through IBM Qiskit, we simulated different noise models such as bit and phase flips, energy relaxation, and decoherence errors to analyze their effect on a singlet state. We generated $T_1$ and $T_2$ times, which denote when the system exponentially decays to 63% of its initial state through energy relaxation. Then, we compared the impact of these models on the singlet state and the preparation process. Lastly, we analyzed the extent to which these models cause a complete loss of information in the qubit state and whether this can be detected and partially reversed.

Noise Temperature Measurements of Josephson Parametric Amplifiers for the Axion Search at IBS/CAPP

ALLISON SCHROEDER (Presenter), Regis University, ÇAĞLAR KUTLU, Center for Axion and Precision Physics — Josephson parametric amplifiers (JPAs) are promising devices for amplifying the weak signal of the axion in haloscopes due to their low noise amplification and tunable resonant frequency. For the axion experiment, the noise temperature of the JPA needs to be determined at various frequencies, which requires altering the noise source temperature. Optimizing the time required to collect this data is crucial for this experiment. Two methods were used to estimate the noise temperature of the JPA and calculate the standard deviation of the fitted data. First, a modified Y-factor method was developed to calculate the noise temperature using only two noise source temperatures. Then, a method using curve fitting to estimate the noise temperature was applied, utilizing all fifty-three noise source temperature spectra, and the standard deviation was calculated. The fitting method provided much more accurate results, but the measurement time was significantly longer than what would be required for the Y-factor method.

Integrating Molecular Rectifiers in AC Circuits

ROBERT BRADFORD (Presenter), ZACHARY LAMPORT, RYAN SULLIVAN, Physics, Wake Forest University, SURYA BANKS, MARK WELKER, Chemistry, Wake Forest University, OANA D. JURCHESCU, Physics, Wake Forest University — The field of molecular electronics exploits single molecules as basic components. Envisioned to provide a route to the continued satisfaction of Moore's Law, these nano-scale components exploit quantum effects to provide functionality at a length scale impossible with current technologies. This presentation focuses on molecular rectifiers based on single molecular layers sandwiched between two electrodes, operating similarly to solid-state diodes. We have developed a new molecule, (E)-1-(4-cyanophenyl)-N-(3-(triethoxysilyl)propyl)methanimine, that allows current rectification with rectification ratios greater than 2500. We further tested the functionality of molecular rectifiers made from this molecule in a standard AC circuit to create a DC rectifier. A test circuit was built where molecular diodes were connected in series with a 1 MΩ resistor and 100 nF smoothing capacitor, using a specially designed 3D-printed low-noise integration system. The rectification ratio of each diode was tested before circuit integration to associate this value with circuit performance. DC voltages measured for a variety of input frequencies show low ripple voltage, the mark of a quality DC rectifier, indicating that the experimental molecular layer acts as a stable diode in AC circuitry.
8:36AM A12.00004: Gating dynamics in ionic-liquid-gated FeS$_2$ single crystals* KEI HELTEMES (Presenter), Department of Physics, Augsburg University, BRYAN VOIGT, Department of Chemical Engineering and Materials Science, University of Minnesota, JEFF WALTER, Department of Physics, Augsburg University, CHRIS LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota — Ionic liquid (IL) gating has proven remarkably effective in voltage control of superconductivity, insulator-metal transitions, and magnetism. This is in large part due to its high electric fields, and thus large accumulated surface charge densities (> $10^{14}$ cm$^{-2}$). Recent studies, however, emphasize the importance of distinguishing electrostatic from electrochemical gating mechanisms in such devices. Here, we present a detailed study of the transport dynamics of IL-gated FeS$_2$ single crystals, where a positive gate voltage is observed to induce a remarkable insulator-metal and diamagnetic-ferromagnetic transition. This transition is found to be highly reversible in transport, which, given the delicate nature of surface conduction in FeS$_2$ [1], strongly evidences an electrostatic gating mechanism. Hysteretic gate voltage sweeps suggest the electrostatic electron accumulation and depletion to be spatially non-uniform, with a sweep-direction-dependent percolation transition. The observation of reversible electrostatic response is discussed in terms of the formation enthalpy and diffusivity of S vacancies in FeS$_2$.

*Work supported by the NSF MRSEC under DMR-1420013 (UMN) and by a Margaret A. Cargill Philanthropies grant (Augsburg).

8:48AM A12.00005: Electrical characterization of a tungsten diselenide/silicon heterostructure* AHMAD MATAR ABED (Presenter), ANAMARIS MELENDEZ, NICHOLAS PINTO, Department of Physics and Electronics, University of Puerto Rico - Humacao, JOSÉ O. SOTERO-ESTEVA, Department of Mathematics, University of Puerto Rico - Humacao, IDALIA RAMOS, Department of Physics and Electronics, University of Puerto Rico - Humacao — A pn diode was fabricated by using a simple method of transferring a p-type two-dimensional WSe$_2$ film onto a cleaved n-Si/SiO$_2$ wafer. The current-voltage characteristics of the device were measured, and the conduction mechanisms analyzed over a temperature range of 80 K–300 K. At high temperatures, the current-voltage characteristics of the diode show that thermionic emission transport dominates. However, tunneling also contributes at low temperatures. To explain the transport behavior of the heterojunction, a model that takes into consideration both thermionic emission and tunneling will be presented. Furthermore, the device was tested as a half-wave rectifier at room temperature at low frequencies. The rectification ratio and low turn-on voltages of the diode make it suitable for optoelectronic applications.

*The WSe$_2$ films were provided by the PSU 2DCC-MIP, which is supported by NSF cooperative agreement DMR-1539916. Research at UPRH was supported by NSF under grant NSF-DMR-1523463 (PENN-UPRH Partnership for Research and Education in Materials).
9:00AM A12.00006: Measuring the Dielectric Constants of Perovskite Nanoparticles in a Polymer Matrix  JOSHUA MORGAN (Presenter), JACKSON BAKER, DANIEL BRITO, GUADALUPE QUIRARTE, ELEANOR RACKOFF, ALBERT DATO, Harvey Mudd College, TODD MONSON, Sandia National Laboratories — Barium titanate (BTO) is a perovskite material used in energy storage applications due to its high dielectric constant [1, 2]. Interestingly, Wada et al. found that BTO nanoparticles ranging from 17 to 500nm exhibited a dependence of their dielectric constant on particle size [2]. Particles with sizes over 300 nm exhibited a dielectric constant of 4000, but a sharp increase in dielectric constant to over 15,000 was observed at a BTO size of 70 nm [2]. To investigate the relationship between the particle size and dielectric constant of BTO, we developed an injection molding process to fabricate polymer-matrix nanocomposites containing BTO powders. Here we present our novel fabrication method and the results of our investigation, which was focused on determining the dielectric constants of nanocomposites containing BTO nanoparticles with sizes ranging from 50 to 500 nm. We will discuss our methods of (1) measuring the dielectric constants of nanocomposites and (2) extracting the dielectric constants of the BTO nanoparticles from those measurements and relating them to particle size and volume loading.

9:12AM A12.00007: Electronic Properties in Strained and Suspended Sheet of MoS\textsubscript{2} on Anodized Aluminum Oxide.*  TAN DAO (Presenter), SHAWNA HOLLEN, Univ of New Hampshire — Two-dimensional materials are as thin as physically possible and have tunable electronic properties that can be useful for the development of faster and smaller electronic devices. One way to tune the electronic properties of 2-D materials is to induce strain by deforming the lattice. In addition to strain impact on the electronic properties, a suspended sheet of 2-D material exhibits higher electrical conductivity. In this project, I induce strain by deforming a semiconductor, MoS\textsubscript{2}, lattice with a nanopatterned substrate, and characterize the strain by atomic force microscopy (AFM) and Raman spectroscopy. Here I present the results of patterning strain and suspension into MoS\textsubscript{2}, and their impact on the electronic properties of MoS\textsubscript{2}. Single layer MoS\textsubscript{2} is isolated via mechanical exfoliation and transferred onto anodized aluminum oxide (AAO) - a substrate with nanoscale valleys and hills. The average strain in the MoS\textsubscript{2} sheet is 0.23% and 0.29%, which obtained from the Raman spectroscopy and AFM data, respectively. AFM techniques such as KPFM, C-AFM, and TERS are used in this project to characterize the electronic properties in the strain-textured MoS\textsubscript{2}.

*This project was supported by the Hamel Undergraduate Reseaarch Center and the McNair Scholars Program.
Understanding the Effects of Controlled Strain on Low Dimensional Material Properties

MICHAEL O'CONNOR (Presenter), MANOJ K SINGH, MICHAEL BOYER, Clark University — A material is typically considered low dimensional if electron movement within the material is limited, for example, to within a particular ionic plane or along an axis. When strain is introduced to an ideal material, lattice deformations may cause substantial changes in structural and electronic properties. Studying the effects strain have on a material can lead to basic insights into the physics governing the material as well as an understanding of how a material's properties can be manipulated for use in applications. Strain can be introduced to a low dimensional material through processes such as sample cleaving, elemental doping, chemical pressure, and external mechanical application. First, we detail our efforts in characterizing the expected strain delivered to the sample from our external application as a function of temperature. We then present resistivity measurements showing the effects strain has on the bulk phase transition temperature of a charge density wave compound. We will discuss how this system can be used in further studies that characterize strain on the nanoscale.

Studying the Crystallization of ALD-Deposited Doped Nb$_2$O$_5$ into NbO$_2$ for Next Generation Electronics Applications

NICOLE ZHE (Presenter), ANDREW H ROWLEY, NICHOLAS MORABITO, ZACHARY ROBINSON, SUNY Brockport, ALEXANDER KOZEN, University at Maryland, LAURA RUPPALT, Naval Research Laboratory — Phase change materials have a variety of applications across many disciplines. They can be used in homes to produce more energy-efficient refrigerators and freezers, or in clothes to help regulate body temperature in varying climates. NbO$_2$ is one such material, and can be used in a variety of electronic applications. In this project, we studied the conversion of amorphous Nb$_2$O$_5$ thin-films doped with either Al$_2$O$_3$ or ZnO (supplied by our collaborators at the Naval Research Laboratory) to crystalline NbO$_2$. Previous studies show Nb$_2$O$_5$ can be converted into NbO$_2$ by annealing to temperatures around 800 C. Systematic anneals in a tube furnace showed how the dopants affect the conversion of Nb$_2$O$_5$ into NbO$_2$. Our results indicate that samples of Nb$_2$O$_5$ doped with Al$_2$O$_3$ convert much slower than pure Nb$_2$O$_5$, and those with ZnO appear to convert faster.
9:48AM A12.00010: A Graphene Encapsulated Growth Method to form Ultra-thin Magnesium Diboride (MgB₂)*

PATRICK RONDONANSKI (Presenter), Department of Physics, Pennsylvania State University, JOAN M REDWING, Department of Materials Science and Engineering and 2D Crystal Consortium - Materials Innovation Platform, Pennsylvania State University, ANUSHKA BANSAL, AZIMKHAN KOZHAKHMETOV, JOSHUA ROBINSON, Department of Materials Science and Engineering, Pennsylvania State University, KE WANG, Materials Research Institute, Pennsylvania State University, ZAKARIA AL BALUSHI, Department of Materials Science and Engineering, University of California - Berkeley — There is interest in coupling 3D topological insulators (TI) with s-wave superconductors (SC) for realizing topological superconductivity (TSC) for quantum computing applications. MgB₂ is an intriguing superconductor for this application as it has $T_c = 39K$ and a hexagonal crystal structure, compatible with common Bi-based TIs. However, MgB₂ oxidizes in air making it difficult to form high quality TI/SC interfaces. Here, we propose a novel approach to synthesize ultra-thin MgB₂ via intercalation between epitaxial graphene (EG) and SiC. EG is used to protect the MgB₂ surface while enabling epitaxial growth of the TI on top. Initial studies investigated Mg intercalation between EG and SiC using a tube furnace. X-ray photoelectron spectroscopy (XPS) and cross section transmission electron microscopy-energy dispersive spectroscopy (TEM-EDS) confirmed Mg intercalation between EG and SiC. Current studies are being performed to optimize process conditions to intercalate Mg. The results of planned investigations to convert Mg to MgB₂ via annealing in B₂H₆ will also be discussed.

10:00AM A12.00011: Temperature Dependent Switching Dynamics in BaTiO₃ at ns Speeds*

ALEXANDER QUALLS (Presenter), ERIC PARSONNET, YIZHE JIANG, WENBO ZHAO, University of California, Berkeley, CHIA-CHING LIN, TANAY GOSAVI, Intel Corp, LANE WYATT MARTIN, RAMAMOORTHY RAMESH, University of California, Berkeley — BaTiO₃ (BTO) is a model ferroelectric, which has been studied extensively, both in bulk crystals and thin films. We have made significant progress, achieving ultra-low coercive fields in thin film BTO samples that hold promise for low-power microelectronics. While there has been extensive work studying switching kinetics in BTO, relatively few studies have performed time-domain experiments on timescales in the low ns regime, since they are typically limited with instrumental constraints (e.g., rise time of oscilloscope or the voltage source). We are able to access this regime by using ultra-low coercive field BTO as a model system and measuring the response to voltage pulses with ~100ps rise time. We present data revealing switching speeds faster than previous reports for BTO, on the order of 1ns. Further, with this setup we study switching dynamics as a function of temperature as we approach the ferroelectric phase transition. The data reveals a decrease in switching time with increasing temperature, which we analyze in the context of classical ferroelectric switching theory.

*Intel Corporation
10:12AM A12.00012: Detection of Phase Transitions in Phase Separated \((La_{1-y}Pr_y)_{1-x}Ca_xMnO_3\) Thin Films*  JONATHAN DESTEFANO (Presenter), A. BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Phase separated manganites have competing phases that each have unique electronic, magnetic, and structural properties. The similar free energies these phases possess allow for the manipulation of phase transitions with the application of external stimuli. Here we report the role of an external magnetic field and a change in chemical doping ratios on the phase transitions in \((La_{1-y}Pr_y)_{1-x}Ca_xMnO_3\) thin films grown on NdGaO_3. These thin films showed that the nucleation and growth of ferromagnetic metallic regions in an anti-ferromagnetic charge ordered insulating background occurs at a higher temperature when an external magnetic field is applied. At a high enough field strength, these ferromagnetic metallic regions hinder the phase transition from paramagnetic insulating to anti-ferromagnetic charge ordered insulating phase which occurs at a relatively high temperature (close to 200 K). The value of the activation energy for the anti-ferromagnetic charge ordered insulating phase calculated by fitting the resistance vs. temperature data to the Arrhenius equation agrees with direct measurements taken using scanning tunneling spectroscopy.

*NSF DMR-1410237, NSF DMR-1852138

10:24AM A12.00013: Doublons Instability in the Presence of Impurities*  MIRIAM BAITNER (Presenter), LEA SANTOS, Yeshiva Univ — In the presence of strong interactions, particles can bind in pairs forming what became known as doublons. A doublon moves together as a single particle, but contrary to it, doublons move slowly. They emerge in common models of condensed matter physics, such as the anisotropic Heisenberg model and the Bose-Hubbard model. We show that doublons are very stable and do not split up even when this would not violate energy conservation. We illustrate our results using one- and two-dimensional spin models in the presence of impurities.

*We are supported by the NSF Grant No. DMR-1603418

10:36AM A12.00014: Localization in two-dimensional trivial and Chern insulators  SPENSER TALKINGTON (Presenter), RAHUL ROY, University of California, Los Angeles — We investigate the localization properties of two-dimensional tight-binding models using transfer matrix methods. In particular, we numerically determine the localization length for cylindrical lattices with single-particle hamiltonians that have nearest-neighbor and next-nearest-neighbor hopping terms, both in the trivial and Chern insulator phases. We consider the role of disorder strength and particle energy on localization, and construct phase diagrams of conductivity properties. In addition, we use these results to guide an exploration of the critical behavior of localization-delocalization transitions in these models.

Session A15 DFD DSOFT: Flow of Complex Fluids: Rheology, Structure, and Instabilities I 210/212 - Larry Galloway, University of Pennsylvania
8:00AM A15.00001: Bistability in the Flow of Polymer Solutions in Porous Media
CHRISTOPHER BROWNE, AUDREY SHIH, SUJIT DATTA (Presenter), Princeton University — Polymer solutions are often injected in porous media to improve oil recovery or groundwater remediation, but applications are limited by an incomplete understanding of the underlying physics. In a tortuous pore space, the flow becomes unstable at sufficiently large injection rates. However, how the spatio-temporal characteristics of this flow state depend on pore geometry is poorly understood. We shed light on this question by systematically varying the spacing between pores. We find that when the pore spacing is large, unstable eddies form upstream of each pore, similar to the case of an isolated pore. By contrast, when the pore spacing is sufficiently small, the flow exhibits a surprising bistability, stochastically switching between two distinct flow states. We hypothesize that this unusual behavior arises from the interplay between the retention of polymer strain between pores, hysteresis in polymer conformations, and fluctuations in the flow. Moreover, we find that while flow state is correlated between neighboring pores, these correlations do not persist long-range. Our results thus help to elucidate the rich array of flow behaviors that can arise in polymer solution flow through porous media.

8:36AM A15.00002: Shear melting and recovery of cellulose nanocrystal-polymer gels*
ABHINAV RAO, Mechanical Engineering, Massachusetts Institute of Technology, THIBAUT DIVOUX (Presenter), Civil and Environmental Engineering, CNRS / Massachusetts Institute of Technology, GARETH H MCKINLEY, JOHN HART, Mechanical Engineering, Massachusetts Institute of Technology — Cellulose nanocrystals (CNC) are naturally-derived nanostructures of growing importance for the production of composites of attractive mechanical properties. Their fabrication involves extrusion of CNC suspensions and gels in organic solvents, in the presence of additives such as polymers and curing agents. Here, we study the rheological behavior of composite polymer-CNC gels in dimethylformamide, which include additives for both UV and thermal crosslinking. Using rheometry coupled with in-situ infrared spectroscopy, we show that under external shear, CNC-polymer gels display progressive and irreversible failure of the hydrogen bond network that is responsible for their pronounced elastic properties. In the absence of cross-linking additives, polymer-CNC gels show an instantaneous but partial recovery of their viscoelasticity upon cessation of flow, whereas, the presence of additives allows the gels to recover over much longer timescale via van der Waals interactions. By exploring a broad range of shear history and CNC concentrations, we construct master curves for the temporal evolution of the viscoelastic properties of the polymer–CNC gels, illustrating the universality of the observed dynamics with respect to gel composition and flow conditions.

*Procter & Gamble Company
8:48AM A15.00003: Observing phase separation in colloid-polymer mixtures with a custom light-sheet rheoscope*  JING WANG (Presenter), RYAN J. MCGORTY, Univ of San Diego — We study liquid-liquid phase separation (LLPS) with a colloid-polymer system subjected to shear. Our colloid-polymer mixture consists of temperature-responsive PNIPAM microgel particles and polymers acting as a depletant. This mixture separates into two phases: a colloid-poor, or “gas” phase, and a colloid-rich, or “liquid” phase. We observe the process of phase separation using a custom-built light-sheet microscope, which allows for simultaneously acquiring optically-sectioned images of our sample and shearing the sample in a Couette geometry. We measure the size and shape of elongated liquid domains that have been deformed due to flow as a function of shear rate. The temperature-responsive feature of our colloidal particles allows us to further explore the kinetics of phase separation under shear flow. We hope our study of phase separation under shear can provide fundamental insights into hydrodynamics and thermodynamics and provide novel strategies for structuring soft materials.

9:00AM A15.00004: Understanding and predicting flow instabilities in self-assembled polymers  PATRICK J MCCAULEY, SATISH KUMAR, MICHELLE CALABRESE (Presenter), University of Minnesota — Shear banding flow instabilities are common in wormlike micelles (WLMs). Despite reported shear banding in polymer WLMs (pWLMs), current research has focused on surfactant WLMs (sWLMs) or linear polymers. Shear banding in linear polymers is typically transient, unstable, or an artifact of slip, fracture, or geometry; conversely, sWLMs dynamically rearrange and break, enabling steady state shear banding. As breakage in pWLMs is limited, the shear banding characteristics likely fall between these limiting cases, though this behavior remains largely unexplored. Here, we use nonlinear rheology and small angle neutron scattering (SANS) to systematically evaluate pWLM shear banding in commercial triblock poloxamers, where the molecular weight, block length, and block ratios are well-controlled. Poloxamer characteristics and micelle features identified via linear rheology and SANS are then used to develop guidelines to predict shear banding a priori, where important parameters include micelle dimensions, solvent penetration, and entanglement degree, among others. Understanding the fundamental role of poloxamer subunit and self-assembled structure provides insight into shear banding mechanisms absent significant breakage, which can be widely used to predict instability formation.
9:12AM A15.00005: Depletion Layer Dynamics of Polyelectrolyte Solutions under Poiseuille Flow*  
JOHN KING (Presenter), SEONG JUN PARK, ANISHA SHAKYA, Center for Soft and Living Matter, 
Institute for Basic Science — The flow of complex fluids over solid surfaces remains an outstanding 
problem in fluid mechanics that is relevant for fields ranging from lubrication to nanofluidics. 
Direct experimental access to depletion layer dimension and composition has been prohibited 
due to the inherently short length scales associated with depletion layers. Here, we develop 
a novel adaptation of super-resolution microscopy based on stimulated emission depletion (STED) 
to directly measure depletion layer composition in real-space with 10s of nanometer resolution. 
The composition and dimension of depletion layers formed in solutions of high molecular weight 
poly(styrene sulfonate) at solid, non-adsorbing walls is measured at equilibrium and under 
Poiseuille flow. Using this novel approach, we 1) confirm concentration profile consistent with 
entropically driven depletion at the interface, 2) observe depletion layer narrowing at low to 
intermediate shear rates, and 3) observe depletion layer composition that approaches pure 
solvent at unexpectedly low shear rates.

*Korean Institute for Basic Science, Project Code IBS-R020-D1

9:24AM A15.00006: Honey bees transport pollen particles of varying shape and size by 
forming them into a permanent granule*  
MARGUERITE MATHERNE (Presenter), SUARJ 
PUVVADA, Georgia Institute of Technology, BEN GUY, Corning, Inc., WILSON POON, The University of 
Edinburgh, DAVID HU, Georgia Institute of Technology — Honey bees (Apis mellifera) carry pollen back 
to their hive by mixing it with nectar and forming it into a pellet, which they carry in the corbcula, 
or pollen basket, on their hind legs. We show that most pellets do not fluidize when subjected to 
vibrations or when brought into contact with a similar suspension of lower volume fraction, 
suggesting that it is a permanent granule. We also explore the behavior of pellets made from 
different size and shaped pollen particles. The bees form the pellet by squeezing small amounts 
of pollen and nectar through the joint of their hind leg, called the pollen press, into the pollen 
basket. Through many repetitions, they form a pellet of up to 2 mm$^3$. This method allows honey 
bees to collect pollen of various sizes and shapes.

Research Fellowship under Grant No. DGE-1650044.

9:36AM A15.00007: Shear thickening of dense suspensions in the limit of jamming*  
YASAMAN MADRAKI (Presenter), Department of Mechanical Engineering, Ohio University, GUILLAUME 
OVARLEZ, University of Bordeaux, SARAH HORMOZI, Department of Mechanical Engineering, Ohio 
University — In shear thickening suspensions, viscosity appears to increase when the shear rate 
increases. In this work, we focus on the shear thickening phenomenon that occurs in the limit of 
jamming. We have designed a model non-Brownian suspension to experimentally study this 
phenomenon. We have developed a series of comprehensive rheometry tests to provide a 
physical understanding of the problem. We provide a closure for shear stresses in the limit of 
jamming and we test this closure by studying boundary driven flows of dense suspensions.

*NSF Grant No. CBET-1554044-CAREER
9:48AM A15.00008: A new dimensionless number governing dethickening in orthogonally perturbed shear thickened suspensions*  MEERA RAMASWAMY (Presenter), ITAY GRINIASTY, ABHISHEK SHETTY, JAMES PATARASP SETHNA, ITAI COHEN, Cornell University — When concentrated colloidal suspensions are under stress, their viscosity can increase by over an order of magnitude. Previous work has shown that this shear thickened viscosity can be tuned by applying fast oscillatory perturbations orthogonal to the primary shear flows in the system. In this talk, I show that dethickening in the regime where the primary shear flow has fully thickened the suspension, is governed by a single dimensionless parameter – the ratio of the orthogonal shear rate amplitude to that of the primary shear rate. In contrast, a second parameter is required to describe the data in the primary shear flow regime where the suspension is thickening. Understanding these parameters will enable better strategies to tune the properties of shear thickening suspensions for applications ranging from 3D printing to the processing of cement.

*This work is supported by NSF CBET award numbers 1804963 and 1509308.

10:00AM A15.00009: Connecting microscale stresses to macromolecular motion in entangled ring-linear DNA blends*  KARTHIK REDDY PEDDIREDDY (Presenter), MEGAN C LEE, JONATHAN GARAMELLA, RYAN J. MCGORTY, RAE M ROBERTSON-ANDERSON, Univ of San Diego — Ring polymers, as well as mixtures of ring and linear polymers, are ubiquitous in nature yet still poorly understood. Due to the lack of free ends in ring polymers, the motion and dynamics of entangled rings is complex and distinctly different than their linear chain counterparts. As such, the dynamics of entangled blends of ring and linear polymers remain a topic of fervent debate. Here, we use DNA - which occurs naturally in rings and linear forms - as a model system to investigate highly entangled ring-linear blends. To elucidate the dynamics of these blends, we demonstrate a novel technique that combines optical tweezers microrheology with fluorescence imaging and differential dynamic microscopy. This technique enables us to directly image single polymers while performing active microrheology. As a result, we show that it is possible to unambiguously connect the stresses induced by both linear and nonlinear strains to the corresponding macromolecular deformations and network rearrangement in ring-linear polymer blends.

8:00AM A16.00001: Coherent control of a hybrid superconducting circuit made with van der Waals heterostructures* [Invited] WILLIAM OLIVER (Presenter), Massachusetts Institute of Technology MIT —
In this talk, we present the demonstration of a superconducting transmon qubit realized using a graphene-based weak-link junction. The graphene is encapsulated by hexagonal Boron Nitride (hBN), forming a van der Waals heterostructure. Applying a voltage to a backgate in proximity to the weak-link junction enables voltage tunability of the qubit frequency. We present the coherent control of this qubit, and discuss the promise and the challenges if building superconducting qubits with such van der Waals heterostructures.

*ARO grant no. W911NF-17-S-0001, NSF QII-TAQS, ASDR&E via Lincoln Laboratory under AF contract FA8721-05-C-0002.

8:36AM A16.00002: On-chip microwave spectroscopy of Andreev and Majorana bound states in semiconductor nanowires* [Invited] ATTILA GERESDI (Presenter), Department of Microtechnology and Nanoscience, Chalmers University of Technology — The microscopic picture of the Josephson effect, describing the flow of supercurrent through a weak link, is based on the formation of Andreev bound states, localized at the weak link. In narrow gap semiconductors, such as InAs and InSb, the interplay of induced superconductivity with spin-orbit coupling and magnetic field can give rise to 4π-periodic Andreev levels, signifying the presence of topological superconductivity and Majorana end modes.

In this talk, I will summarize our efforts to understand the Andreev level spectra in proximitized semiconductor nanowires by exploiting the AC Josephson effect and using on-chip microwave detection techniques based on superconducting tunnel junctions. With this technique, we investigate gate-tunable Andreev bound states in ballistic semiconductor nanowire channels [1] and the microwave spectrum of nanowire-based Cooper-pair transistors [2]. I will also showcase our measurements of the 4π-periodic Josephson effect above a threshold magnetic field [3], which is consistent with the topological phase transition and the emergence of Majorana bound states.

*We acknowledge the Netherlands Organization for Scientific Research (NWO) and the European Union’s Horizon 2020 research and innovation programme.
9:12AM A16.00003: Magnetic-field-compatible hybrid superconducting circuits* [Invited]
ANGELA KOU (Presenter), Microsoft Corp, MARTA PITA-VIDAL, ARNO BARGEBOS, Delft University of Technology, CHUNG-KAI YANG, DAVID J. VAN WOERKOM, WOLFGANG PFAFF, Microsoft Corp, NADIA HAIDER, Netherlands Organization for Applied Scientific Research, PETER KROGSTRUP, LEO P KOUWENHOVEN, GIJS DE LANGE, Microsoft Corp — Hybrid circuits that incorporate semiconducting elements into superconducting circuits have recently provided new insights into mesoscopic superconductivity. Extending the capabilities of hybrid circuits to work in large magnetic fields would enable the investigation and control of spin-polarized and topological phenomena. In this talk, I will discuss our work building a magnetic-field-compatible nanowire-based fluxonium. We in-situ tune the Josephson energy of the fluxonium with an electrostatic gate and demonstrate operation of the fluxonium in magnetic fields up to 1T. We use the fluxonium spectrum to map out the dependence of the Josephson energy of the junction on magnetic field and also use it to observe the $\phi_0$-junction effect. Our work demonstrates the utility of hybrid superconducting circuits for exploring mesoscopic physics and paves the way for manipulating Majorana zero modes in these circuits.

*This research was co-funded by the allowance for Topconsortia for Knowledge and Innovation (TKI's) from the Dutch Ministry of Economic Affairs and the Microsoft Quantum initiative.

9:48AM A16.00004: A ballistic graphene superconducting microwave circuit* [Invited] GARY STEELE (Presenter), FELIX SCHMIDT, MARK JENKINS, Quantum Nanoscience, Delft University of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba — Josephson junctions are a fundamental component of microwave quantum circuits, such as tunable cavities, qubits and parametric amplifiers. Recently developed encapsulated graphene JJs, with supercurrents extending over micron distance scales, have exciting potential applications as a new building block for quantum circuits. In this talk, I will present our demonstration of a superconducting microwave circuit based on a ballistic graphene Josephson junction. We directly observe a gate-tunable Josephson inductance through the resonance frequency of the device and, using a detailed RF model, we extract this inductance quantitatively. We also observe the microwave losses of the device, and translate this into sub-gap resistances of the junction at $\mu$eV energy scales, not accessible in DC measurements. The microwave performance we observe here suggests that graphene Josephson junctions are a feasible platform for implementing coherent quantum circuits.

*This project has received funding from the European Union’s Horizon 2020 research and innovation programme under grant agreement nr. 785219 – GrapheneCore2
10:24AM A16.00005: Coherent Semiconductor-Based Superconducting Quantum Circuits*

[Invited] KARL PETERSSON (Presenter), Microsoft Quantum Lab Copenhagen and Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark — The recent development of semiconductors with epitaxial superconducting Al contacts offers new approaches to realizing coherent superconducting quantum devices. In particular, we have demonstrated superconducting transmon qubits with Josephson junctions based on hybrid superconductor-semiconductor nanowire materials [1-2]. These gate tunable transmons (gatemons) have the potential advantage that they can be readily controlled through local electrostatic gating of the junction element. I will discuss progress in improving coherence times and scalability of gatemon qubits. I will also discuss how these hybrid circuits might be used to realize novel qubits that are intrinsically protected against sources of decoherence.

*Research is supported by Microsoft and the Danish National Research Foundation.

Session A17 DQI: Quantum Machine Learning I

8:00AM A17.00001: Challenges and opportunities for hybrid quantum-classical machine learning and optimization

[Invited] MASOUD MOHSENI (Presenter), Google Inc. — We present an overview of our progress on quantum-inspired and quantum-assisted algorithms for optimization and machine learning at Quantum AI Lab at Google. We develop an end-to-end quantum-inspired discrete optimization platform that uses an interplay of local and non-local thermal updates to sample from inaccessible low-energy states of spin-glass systems that encode high-quality solutions of certain hard combinatorial optimization. We introduce several new techniques for quantum circuit learning on Noisy Intermediate-Scale Quantum (NISQ) processors. We show how we can learn to learn on parameterized quantum circuits via classical recurrent neural networks. We apply this metalearning approach for efficient initialization of Quantum Approximate Optimization Algorithm for Sherrington-Kirkpatrick model and variational Quantum Eigensolver for the Hubbard model. Moreover, we introduce two different layerwise learning for quantum neural networks. In the first method we train layer-wise POVMs to perform variational quantum unsampling of unknown noisy quantum operations. In the second method, we are training varying subsets of the quantum circuit's parameters iteratively while increasing the circuit depth to have sufficient representation of classical or quantum data. In our approach the problem of vanishing gradients or barren plateaus of training landscape can be avoided to a large extent. We provide several applications of such quantum models for characterization of NISQ devices and classification of quantum data.
**8:36AM A17.00002: Variational Quantum Unsampling on an Photonic Quantum Processor**

JACQUES CAROLAN (Presenter), Massachusetts Institute of Technology MIT, MASoud MOHSEni, Google Quantum AI Laboratory, JONATHAN P OLSON, Zapata Computing Inc., MIHIKA PRABHU, CHANGCHEN CHEN, DARIUS BUNANDAR, Massachusetts Institute of Technology MIT, MURPHY YUEZHEN NIu, Google Quantum AI Laboratory, NICHOLAS C HARRIS, Lightmatter, FRANCO N. C. WONG, Massachusetts Institute of Technology MIT, MICHAEL HOCHBERG, Elenion Technologies, SETH LLOYD, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — Quantum algorithms for Noisy Intermediate-Scale Quantum (NISQ) processors have emerged as promising routes towards demonstrating practical advantage over classical machines. In these systems samples are typically drawn from probability distributions which — under plausible complexity-theoretic conjectures — cannot be efficiently generated classically. Rather than first define a physical system and then determine computational features of the output state, we ask the converse question: given direct access to the quantum state, what features of the generating system can we efficiently learn? Here, we introduce the Variational Quantum Unsampling (VQU) protocol, a nonlinear quantum neural network approach for verification and inference of near-term quantum circuits outputs. We experimentally demonstrate this protocol on a quantum photonic processor. Alongside quantum verification, our protocol has broad applications; including optimal quantum measurement and tomography, quantum sensing and imaging, and ansatz validation.

**8:48AM A17.00003: Quantum Hamiltonian-Based Models and the Variational Quantum Thermalizer Algorithm**

GUILLAUME VERDON (Presenter), JACOB MARKS, SASHA NANDA, STEFAN LEICHENAUER, JACK HIDARY, Quantum, X - The Moonshot Factory — We introduce a new class of generative quantum-neural-network-based models called Quantum Hamiltonian-Based Models (QHBMs). In doing so, we establish a paradigmatic approach for quantum-probabilistic hybrid variational learning, where we efficiently decompose the tasks of learning classical and quantum correlations in a way which maximizes the utility of both classical and quantum processors. In addition, we introduce the Variational Quantum Thermalizer (VQT) for generating the thermal state of a given Hamiltonian and target temperature, a task for which QHBMs are naturally well-suited. The VQT can be seen as a generalization of the Variational Quantum Eigensolver (VQE) to thermal states: we show that the VQT converges to the VQE in the zero temperature limit. We provide numerical results demonstrating the efficacy of these techniques in illustrative examples. We use QHBMs and the VQT on Heisenberg spin systems, we apply QHBMs to learn entanglement Hamiltonians and compression codes in simulated free Bosonic systems, and finally we use the VQT to prepare thermal Fermionic Gaussian states for quantum simulation.
9:00AM A17.00004: Variational Fast Forwarding for Quantum Simulation Beyond the Coherence Time*  
ANDREW SORNBORGER (Presenter), Los Alamos National Laboratory, CRISTINA CIRSTOIU, Computer Science, Oxford University, ZOE HOLMES, Controlled Quantum Dynamics Theory Group, Imperial College, JOSEPH IOSUE, QC Ware, LUKASZ CINCIO, PATRICK COLES, Los Alamos National Laboratory — Trotterization-based, iterative approaches to quantum simulation are restricted to simulation times less than the coherence time of the quantum computer, which limits their utility in the near term. Here, we present a hybrid quantum-classical algorithm, called Variational Fast Forwarding (VFF), for decreasing the quantum circuit depth of quantum simulations. VFF seeks an approximate diagonalization of a short-time simulation to enable longer-time simulations using a constant number of gates. Our error analysis provides two results: (1) the simulation error of VFF scales at worst linearly in the fast-forwarded simulation time, and (2) our cost function's operational meaning as an upper bound on average-case simulation error provides a natural termination condition for VFF. We implement VFF for the Hubbard, Ising, and Heisenberg models on a simulator. Finally, we implement VFF on Rigetti's quantum computer to show simulation beyond the coherence time. See full paper at: https://arxiv.org/abs/1910.04292

9:12AM A17.00005: Stochastic Gradient Descent for Hybrid Quantum-Classical Optimization*  
FREDERIK WILDE (Presenter), RYAN SWEKE, JOHANNES JAKOB MEYER, Freie Universität Berlin, MARIA SCHULD, University of KwaZulu-Natal, PAUL K. FÄHRMANN, Freie Universität Berlin, BARTHÉLÉMY MEYNARD-PIGANEAU, Ecole Polytechnique, JENS EISERT, Freie Universität Berlin — Gradient-based methods for hybrid quantum-classical optimization typically rely on expectation values with respect to the outcome of parameterized quantum circuits. In this work, we investigate the fact that the estimation of these quantities on quantum hardware leads to a form of stochastic gradient descent. In many relevant cases estimating expectation values with \( k \) measurements results in optimization algorithms whose convergence properties can be rigorously understood, for any value of \( k \geq 1 \). Moreover, in many settings the required gradients can be expressed as linear combinations of expectation values and we show that in these cases \( k \)-shot expectation value estimation can be combined with sampling over terms of the linear combination, to obtain doubly stochastic gradient descent. For all algorithms we prove convergence guarantees. Additionally, we explore numerically these methods on benchmark VQE, QAOA and quantum-enhanced machine learning tasks and show that treating the stochastic settings as hyper-parameters allows for significantly fewer circuit executions.

9:24 AM A17.00006: Robust and efficient algorithms for high-dimensional black-box quantum optimization* ZHAOQI LENG (Presenter), Physics, Princeton University, PRANAV MUNDADA, Electrical Engineering, Princeton University, SAEED GHADIMI, Operations Research and Financial Engineering, Princeton University, ANDREW HOUCK, Electrical Engineering, Princeton University — Hybrid quantum-classical optimization using near-term quantum technology is an emerging direction for exploring quantum advantage in high-dimensional systems. However, precise characterization of all experimental parameters is often impractical and challenging. A viable approach is to use algorithms that rely only on black-box inference rather than analytical gradients. Here, we combine randomized perturbation gradient estimation with adaptive momentum gradient updates to create the AdamSPSA and AdamRSGF algorithms. We prove the asymptotic convergence of our algorithms in a convex setting, and we benchmark them against other gradient-based optimization algorithms on non-convex optimal control tasks. Our results show that these new algorithms accelerate the convergence rate, decrease the variance of loss trajectories, and efficiently tune up high-fidelity (above 99.9%) Hann-window single-qubit gates from trivial initial conditions with twenty variables.

9:36 AM A17.00007: A Hybrid Quantum-Classical Algorithm for Training Quantum Boltzmann Machines CHRISTA ZOUFAL (Presenter), IBM Research - Zurich, AURÉLIEN LUCCHI, ETH Zurich, STEFAN WOERNER, IBM Research - Zurich — A Boltzmann Machine is a Machine Learning algorithm based on a measure from statistical mechanics, i.e. the Boltzmann distribution. The respective concepts can also be used with quantum computers which leads to Quantum Boltzmann Machines. These have the potential to outperform classical algorithms in a variety of learning problems and to enable classically intractable tasks, such as discriminative learning with quantum data and generative modeling of classically inaccessible structures. Several implementations have been suggested, but they all face practical difficulties. Firstly, it is often challenging to generate the quantum Gibbs state representing the Boltzmann distribution. Secondly, the training performance is usually impaired as the problem formulation requires that the system must be trained with an upper bound instead of the actual loss function. In this work, we use variational quantum Gibbs state preparation to enable gate-based Quantum Boltzmann Machines which can be trained with the true loss function. Moreover, the algorithm relies on a hybrid quantum-classical optimization algorithm and is, thus, compatible with near-term quantum computers. The applicability of this approach is demonstrated on illustrative examples.
9:48AM A17.00008: Quantum classifier with tailored quantum kernel*  KYUNGDEOCK PARK
(Presenter), KAIST, CARSTEN BLANK, Data Cybernetics, JUNE-KOO(KEVIN) RHEE, KAIST, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal — Kernel methods have broad applications in machine learning. Recently, a link between quantum computing and kernel theory has been formally established, opening up opportunities for quantum enhancements in various machine learning methods. We present a distance-based quantum binary classifier whose kernel is based on the quantum state fidelity between training and test data. The quantum kernel can be tailored systematically with a quantum circuit to assign an exponent to the kernel and assign weights to training data. Our classifier calculates the weighted power sum of fidelities of quantum data in parallel via a swap-test circuit and two single-qubit measurements, requiring only a constant number of repetitions regardless of the number of data. Furthermore, our classifier is equivalent to measuring the expectation value of a Helstrom operator, from which the optimal quantum state discrimination can be derived. We demonstrate the proof-of-principle via classical simulations with a realistic noise model and experiments using an IBM quantum computer.

10:00AM A17.00009: Machine learning with solid-state NMR using quantum kernel*  TAKERU KUSUMOTO (Presenter), KOSUKE MITARAI, MAKOTO NEGORO, KEISUKE FUJII, MASAHIRO KITAGAWA, Osaka Univ — We employ so-called quantum kernel estimation to exploit complex quantum dynamics of solid-state NMR for machine learning. Kernel method is a popular branch in machine learning algorithms where only the inner products among feature vectors each representing an input datum are required to construct a prediction model. We propose to map an input to a feature space by input-dependent Hamiltonian evolution, and the kernel is estimated by the interference of the evolution. Simple machine learning tasks, namely one-dimensional fitting tasks and two-dimensional classification tasks, are performed as demonstrations. The performance of the trained model tends to increase with the longer evolution time, or equivalently, with a larger number of spins involved in the dynamics. This work can be regarded as one of the baselines for this emerging field.

**10:12AM A17.00010: Hybrid quantum-classical algorithms for generative models**

TENG BIAN (Presenter), SABRE KAIS, Department of Physics, Department of Chemistry, and the Birck Nanotechnology Center, Purdue Univ — Quantum machine learning is a field that combines machine learning techniques and quantum computation together. It has the potential of enjoying impressive data analysis power while improving the time efficiency greatly. We propose a new hybrid quantum-classical circuit design for one major problem from machine learning aspect: generative models. We will discuss different ways to construct generative models using quantum algorithms. We will also apply this new design in example datasets and compare the complexity and the results. This work might help to find hidden patterns behind data and offer applications for near-term quantum devices.

*This material is based upon work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Award Number DE-SC0019215.*

**10:24AM A17.00011: Quantum-tailored machine-learning architectures**

ELIE GENOIS (Presenter), AGUSTIN DI PAOLO, ALEXANDRE BLAIS, JONATHAN GROSS, Institut quantique and Département de Physique, Université de Sherbrooke — Future quantum technologies are expected to be fundamentally challenging to characterize and calibrate. For this reason, a heuristic will most likely be required for this task, and machine learning provides an attractive framework for developing such a heuristic. To this end, we introduce a machine-learning architecture for inferring the dynamics of a quantum device from time-series measurement data. Our architecture is recurrent in nature and leverages quantum-mechanical structure in its design to interpret measurement data from complex quantum devices more efficiently. We investigate how the architectural structure influences the way we learn from data generated by quantum experiments and address applications of our techniques to the calibration and characterization of superconducting quantum devices.

*This work was undertaken thanks in part to funding from NSERC and the Canada First Research Excellence Fund.*
10:36AM A17.00012: Scalable Quantum State Tomography with Attention Network*  
PETER CHA (Presenter), Cornell University, JUAN CARRASQUILLA, Vector Institute for Artificial Intelligence, PAUL GINSPARG, EUN-AH KIM, Cornell University — The problem of many-body wavefunction reconstruction, which suffers from exponential scaling in system size as well as noisy state preparation and measurement, remains a major obstacle to the study of intermediate-scale quantum systems. Recent works found success by recasting the problem of reconstruction to learning the probability distribution of quantum state measurement vectors, a natural task for generative neural network models. Networks based on the attention mechanism, designed to learn long-range correlations in natural language sentences, appear especially well-suited to the task of learning highly entangled wavefunctions. In this work, we demonstrate that an attention mechanism-based generative network, based on the model proposed in "Attention is all you need" by Vishwani et al (2017), can outperform previous neural network based approaches to quantum state tomography. Specifically, in addition to working with state-of-the-art system sizes, the attention mechanism is able to accommodate noise by directly reconstructing the density matrix of mixed states. This work represents an important step forward in the applicability of machine learning to the study of noisy intermediate-scale quantum systems.

*This work was supported by NSF grant 1934714

10:48AM A17.00013: Implementing perceptron models with qubits*  
ROELAND WIERSEMA (Presenter), HILBERT JOHAN KAPPEN, Radboud Univ Nijmegen — We propose a method for learning a quantum probabilistic model of a perceptron. By considering a cross entropy between two density matrices we can learn a model that takes noisy output labels into account while learning. Although some work has been done that aims to utilize the curious properties of quantum systems to build a quantum perceptron, these proposals rely on the ad hoc introduction of a classical cost function for the optimization procedure. We demonstrate the usage of a quantum probabilistic model by considering a quantum equivalent of the classical log-likelihood, which allows for both a quantum model and training procedure. We show that this allows us to better capture noisyness in data compared to a classical perceptron. By considering entangled qubits we can learn nonlinear separation boundaries, such as XOR.

Session A18 FED: Challenges and Best Practices for Preparing Future Physics Teachers  
205 - Monica Plisch, American Physical Society - Tag(s): Careers, Education, Invited, Undergrad Friendly
8:00AM A18.00001: Addressing the Critical Physics Teacher Shortage Through Advocacy
[Invited]  BRIAN PYPER (Presenter), Brigham Young University - Idaho — There is a documented critical shortage of qualified physics teachers in the US today. Data from several sources are confirming this need. Some well-intentioned regulatory demands are exacerbating the problem, but have solutions that you can help with by knowing what they are and wisely advocating for improved policies and processes.

8:36AM A18.00002: Preparing Physics Teachers by Building Bridges Between High Schools and Colleges* [Invited]  THOMAS NOVIELLO (Presenter), Worcester Polytechnic Institute — Physics Education Research has made substantial advancements towards understanding how to offer best practices to ensure equity amongst all learners. However, this has not translated into an increased graduation rate of physics teachers within the United States. PhysTEC aims to address this crisis through granting the funds for universities to hire a Teacher-in-Residence. In this position, the Teacher-in-Residence has a goal of promoting the field of teaching and preparing prospective teachers through direct experience and fieldwork. At Worcester Polytechnic Institute (WPI), a bridge is being built between the university and local high schools through various pathways. One of these pathways is the creation of a science fair course, which is structured project-based learning. A partnership between WPI and Leominster High School affords WPI students the opportunity to engage in curriculum development, and for the high school students to become familiar with research-based approaches to problem solving. Aspirant teachers will not only become familiar with how to engage students throughout a lesson, but will also understand how to apply the elements of backward design to create effective curriculum. It is believed that this will create thoughtful and engaged physics teachers.

*PhysTEC

9:12AM A18.00003: Getting the Facts Out About the STEM Teaching Profession* [Invited]  WENDY ADAMS (Presenter), Physics, Colorado School of Mines — The Get the Facts Out (GFO) project is a joint effort between four national societies and the Colorado School of Mines to change the conversation around grade 7-12 physics, chemistry, and math teaching careers. We have developed a toolkit of recruitment materials which are designed to be customizable and adaptable to the local situation. To develop these materials and better understand best practices around recruiting math and science teachers, GFO has a rigorous research arm. Our research includes the study of both student, faculty, and the general public’s perceptions of the teaching profession including development of instruments to measure these. We also have embarked on a study to identify emotionally engaging ways to share facts about the profession. Finally, to measure the effectiveness of the project, we have an aggressive research design that includes annual collection of qualitative data from eighteen departments and quantitative data from another ~50 departments.

*This work is supported by NSF Grant No's 1821710 & 1821462.
9:48AM A18.00004: Departmental support for future physics teachers: Creating community, nurturing identity* [Invited] ELEANOR W CLOSE (Presenter), HUNTER G CLOSE, JESSICA CONN, DAVID DONNELLY, Texas State University — The physics department at Texas State University has recently experienced a dramatic increase in pre-service physics teachers. We attribute this primarily to students’ experiences in our Physics Learning Assistant (LA) program and to the financial and mentoring support available through our NSF Noyce teacher scholarship program. Our LA program serves all sections of the calculus-based introductory physics sequence, and has a particular focus on supporting LAs’ sense of belonging. LA Program structures are informed by the theory of Communities of Practice. The majority of our majors now serve as LAs for at least one semester. Those who pursue K-12 teacher certification are eligible for Noyce scholarships of $10-15K. Noyce Scholars receive mentoring and professional development through monthly Saturday STEM Seminars, which also serve as a catalyst for community among the Scholars. Together, these programs positively impact students’ identity as physics learners and teachers, and their recruitment into teaching careers.

*This work has been supported in part by NSF grants DUE-1557405, DUE-1557276, DUE-1431578, and PHY-0808790 (PhysTEC).

10:24AM A18.00005: A Research-Based Rubric for Driving Improvement in Physics Teacher Preparation.* [Invited] STEPHANIE CHASTEEN (Presenter), University of Colorado, Boulder, RACHEL E SCHERR, University of Washington Bothell, MONICA J PLISCH, American Physical Society — Given the insufficient number of well-qualified future physics teachers, physics programs often seek guidance for how to address this national need. But, as the saying goes, “if you can’t measure it, you can’t improve it.” Measurement tools can provide useful guidance, both by defining excellence and providing a means to measure progress towards excellence. This talk describes the development of such a measurement tool – the Physics Teacher Education Program Analysis (PTEPA) Rubric. The rubric defines levels of success in several areas that are important for physics teacher education, such as strength of program leadership, or the content of licensure courses, based on observed practices at 8 “thriving” U.S. physics teacher education programs. Initial findings suggest that thriving programs are strong in multiple areas (especially institutional commitment, leadership, and collaboration among partners in education and physics), and that several areas of strength align with those indicated by the existing physics teacher education literature. However, thriving programs are not necessarily strong in all areas, instead reflecting local conditions at the institutional and state level. The rubric and its’ associated supporting materials are intended to shed light on critical practices in physics teacher education, supporting research and hypothesis testing. The rubric is also intended to help program leaders in using a process of continuous improvement to strengthen local programs. We will briefly describe development of the rubric, insights gained from it, and how physics programs can use it to drive improvements.

*We acknowledge funding from NSF-0808790, NSF-1707990 and APS’s 21st Century Campaign for this work.

Monday, March 2, 2020 8:00 AM - 11:00 AM
8:00AM A19.00001: Kang-Kuen Ni Invited Talk [Invited] —

8:36AM A19.00002: Atom arrays of ultracold strontium: new tools for many-body physics and metrology* [Invited] ADAM KAUFMAN (Presenter), Physics, JILA/CU/NIST — The development of microscopic detection of ensembles of neutral atoms has transformed our ability to study complex many-body systems. Techniques like quantum gas microscopy and optical tweezer arrays grant a unique single-particle-resolved perspective on solid-state analogs and idealized quantum spin models, as well as detection capabilities of quantities like entanglement. In this talk, I will describe our group’s progress towards developing these tools for a new atomic species, strontium. In doing so, we establish new prospects enabled by the rich internal degrees-of-freedom associated with alkaline-earth atoms. I will report on our recent results in which we apply our platform to optical atomic clocks, a new application of optical tweezer arrays which indicates a number of strengths for metrology. I will then describe our progress towards engineering entanglement on an optical clock transition, as well as new strategies to coherently control samples with 100s of atoms.

*ARO, AFOSR, NSF-PFC, NIST

9:12AM A19.00003: Rydberg mediated entanglement in a two-dimensional neutral atom qubit array* [Invited] MARK SAFFMAN (Presenter), Physics, University of Wisconsin - Madison — We demonstrate high fidelity two-qubit Rydberg blockade and entanglement in a two-dimensional qubit array. The qubit array is defined by a grid of blue detuned lines of light with 121 sites for trapping atomic qubits. Improved experimental methods have increased the observed Bell state fidelity to FBell = 0.86(2). Accounting for errors in state preparation and measurement (SPAM) and single qubit operations we infer that a Bell state created with the Rydberg mediated CZ gate has a fidelity of 0.89. Comparison with a detailed error model based on quantum process matrices indicates that finite atom temperature and laser noise are the dominant error sources contributing to the observed gate infidelity.

*We acknowledge support from NSF PHY-1720220, the ARL-CDQI, DOE award DE-SC0019465, and ColdQuanta, Inc. .
9:48AM A19.00004: Quantum Science with Ytterbium Rydberg Atoms in Optical Tweezer Arrays* [Invited]  ALEX BURGERS (Presenter), Princeton University — Engineering Rydberg-mediated interactions in arrays of neutral atom qubits is a leading platform for quantum computing and quantum simulation architectures. The advantages of this experimental platform are derived from the strong nature of Rydberg interactions coupled with highly controllable optical tweezer arrays. To date, most neutral atom array experiments utilize alkali atoms, however alkaline-earth-like atoms offer many advantages including extremely long coherence times for nuclear spins in the \( j = 0 \) electronic ground state and narrow optical transitions for use in efficient laser-cooling, metrology and precision measurement. Our experimental approach is to utilize laser-cooled neutral ytterbium (Yb) atoms trapped in optical tweezer arrays. We use the narrow intercombination line, \( ^1S_0 - ^3P_1 \), for cooling and imaging atoms in magic-wavelength (532 nm) optical tweezers and achieve very high atom detection fidelity [1]. An additional advantage of Yb is the ability to stably trap Rydberg states of the atom by leveraging the Yb\(^+\) ion core polarizability for trapping in the optical tweezer. Here we maintain trapping of the Rydberg atom at high \( n \) states thus extending the lifetime for interactions. The expanded interaction time has important implications for quantum computing and simulation with strongly interacting Rydberg atoms. These attributes make Yb atoms in optical tweezers an attractive platform for a wide variety of applications in quantum information science.

*ARO contract W911NF-18-1-0215 and the Sloan Foundation.

10:24AM A19.00005: Quantum Science with Tweezer Arrays [Invited] MANUEL ENDRES (Presenter), Caltech — Recently cold atoms in optical tweezer arrays have emerged as a versatile platform for quantum science experiments. I will review some of these developments, specifically, atom-by-atom assembly [1] as a fast and simple method to generate defect-free atomic arrays and Rydberg-based quantum simulation of spin models. While already reaching competitive results, these systems are still in their infancy and limitations in coherence, detection fidelity, and scalability remain. I will outline how we can improve on these issues and at the same time open new avenues in quantum metrology by using alkaline earth atoms, followed by an overview of recent results: 1) A record in imaging-fidelity for neutral atoms and demonstration of narrow-line cooling in tweezers [2,3]. 2) High-fidelity Rydberg excitation from a clock state, including a record in entanglement-fidelity for two neutral atoms [4]. 3) Demonstration of an optical clock with single-atom detection in tweezer arrays [5].

8:00AM A20.00001: Lessons from Designing Optogenetic Tools* [Invited] ANDREW WOOLLEY (Presenter), Chemistry, University of Toronto — In the course of trying to engineer proteins to have a particular function, unexpected behaviours sometimes arise. I will describe how following up on some odd behaviour observed while trying to engineer photoactive yellow protein as a light-controlled switch, led to interesting, perhaps, general new insights into the behavior of these remarkable molecules

*NSERC (Canada)

8:36AM A20.00002: Engineering and application of a biosensor with focused ligand specificity* DENNIS DELLA CORTE (Presenter), Brigham Young Univ - Provo — Microbial cell factories efficiently converting bio-based precursors to chemicals represent an attractive avenue to a more sustainable economy. Yet screening of genetically diverse strain libraries to identify the best-performing whole-cell biocatalysts is a low throughput endeavor. For this reason, transcriptional biosensors attracted attention as they allow screening of vast libraries in combination with fluorescence-activated cell sorting. However, a broad ligand specificity of many transcriptional regulators often prohibits the development of such ultra-high-throughput screens. We here solved the structure of the transcriptional regulator LysG of Corynebacterium glutamicum detecting all three basic amino acids. Semi-rational engineering of LysG using a FACS-based screening/counterscreening approach yielded a new biosensor bearing a regulator insensitive to l-lysine. Molecular dynamics simulations uncovered the underlying structure-function relationships of a crucial amino acid substitution. As proof of principle, we applied the new biosensor and isolated several l-histidine producing strains by FACS.

*This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation program (grant agreement No 638718).
8:48AM A20.00003: Spontaneous Rupture and Entanglement of Human Neuronal Tau Protein Induced by Piconewton Compressive Force* SUSOVAN ROY CHOWDHURY (Presenter), H PETER LU, Bowling Green State University —
Mechanical force vector fluctuations in the living cells can have a significant impact on protein behavior and functions. We have observed abrupt and spontaneous tau protein ruptures under a compressive force ranging from \( \sim 5 \) to \( \sim 125 \) pN, at a biologically available force amplitude range in living cells, using a home-modified atomic force microscopy single-molecule manipulation. The rupture behavior is dependent on the physiological level of the presence of ions, such as K\(^+\) and Mg\(^{2+}\). We observed rupture events in the presence of K\(^+\) but not in the presence of Mg\(^{2+}\) ions. We have also explored the entangled protein state formed following the events of the multiple and simultaneous protein ruptures under crowding. Crowded proteins simultaneously rupture and then spontaneously refold to an entangled folding state, different from either folded or unfolded states of the tau protein, which can be a plausible pathway for the tau protein aggregation that is related to several neurodegenerative diseases, such as the Alzheimer's and Parkinson's Diseases.

*We acknowledge the support of this work from the Ohio Eminent Scholar Endowment fund.

9:00AM A20.00004: Allosteric communications via substrate and linker between domains modulate protein function SUSANTA SARKAR (Presenter), Colorado School of Mines — The relation between structure and dynamics of biomolecules is important for their functions. Intra-domain dynamics occurring at pico- to milli-second timescales have been shown to correlate with activity. However, the correlation of allosteric communications between domains with biomolecular function is poorly understood. Here we show that inter-domain dynamics of matrix metalloprotease-1 (MMP1) on collagen fibrils are correlated with activity. Using single-molecule FRET, we identified the functionally relevant conformations where the two MMP1 domains are far apart, which were significantly absent for inactive MMP1 and could be modulated by inhibitor and enhancer of activity. All-atom and coarse-grained simulations reproduced the experimental features and revealed that dynamics are similar at pico- and milli-second timescales and substrate-dependent. Functional conformations are accompanied by larger catalytic pocket openings, which are increased by the communications mediated by collagen even if the domain linker is absent. Inter-domain communications are likely important for multidomain proteins in general.
9:12AM A20.00005: Disordered Protein Folding and Solubility as a Determinant of Human Disease* [Invited] ZACHARY LEVINE (Presenter), Department of Pathology, Yale University — A longstanding principle in protein biophysics is that a protein’s sequence dictates its threedimensional fold, and that structure is inherently linked to function. However, nearly a third of the human proteome contains intrinsically disordered regions that lack a discernible tertiary structure. Many of these proteins, referred to as intrinsically disordered proteins (IDPs), adopt transient conformations in order to carry out a wide-variety of functions, challenging the classical structure-function paradigm. Dysregulation of IDPs can also lead to the pathological accumulation of proteinaceous plaques and fibrils, which are observed in over 22 degenerative diseases and even in many types of cancers. In this talk, I will summarize our efforts to leverage molecular models of IDPs that populate vast free energy landscapes, reconciling how disordered and often soluble protein intermediates contribute to human disease. I will also discuss how these observations can supplement experiments, where transient protein conformations are often extraordinarily difficult to extract.

*We acknowledge funding from the National Institutes of Health (R01AG057912-01) and XSEDE (MCB170142, MCB180088, MCB190047).

9:48AM A20.00006: Is the Protein Dynamical Transition Useful?* AKANSHA SHARMA (Presenter), DEEPU K GEORGE, ANDREA G MARKELZ, State Univ of NY - Buffalo — Terahertz Time Domain spectroscopy (THz TDS) has been used to characterize the protein dynamical transition [1, 2]. Typically the THz measurements are performed using solutions, however there is some question as to whether the freezing of the solution effects protein structure or dynamics. To address these questions we performed terahertz dynamical transition measurements in the 100-270 K range and between 0.15 – 2.00 THz on buffered solutions, dry glycerol solutions and minimally hydrated glycerol solutions. Buffer solution measurements using chicken egg white lysozyme and myoglobin protein with concentrations between 2 – 30 mM follow Beer’s law concentration dependence below 15 mM from which terahertz molar absorptivity of the hydrated protein can be extracted. For dry glycerol-protein solutions, the dynamical transition is absent, although it is present for 0.5 g water/g protein indicating that freezing of bulk water does not effect the measurements.

10:00AM A20.00007: Anti-cancer drug containing apolipoprotein B refolding through first-order-like phase transition process*  CHIA HSIN CHENG (Presenter), WEI-PING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Taiwan, PO YEN LIN, Division of Core Facilities Imaging, Institute of Cellular and Organismic Biology, Academia Sinica, Taiwan, YU CHUAN LIANG, Agricultural Biotechnology Research Center, Academia Sinica, Taiwan, CALEB G. CHEN, Department of Hematology-Oncology, Mackay Memorial Hospital, Taiwan 5Institute of Physics, Academia Sinica, Taiwan, CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Taiwan — First-order-like phase transition process is a promising approach for protein refolding into functional state. However, lipid binding protein, apolipoprotein B (apoB), reconstitution is challenging until our previous study. At the same time, the reconstituted apoB lipoparticle (rABL) may be an idea vehicle for drug delivery. In this study, we refolded apoB with anti-cancer drug from denatured state to functional state follow a first-order-like state transition model. By characterizing the reconstituted drug loaded rABL (drug@rABL) with circular dichroism (CD), dynamic light scattering (DLS), zeta potential and transmission electron microscope(TEM), we found drug@rABL is similar to rABL and native LDL. Moreover, cell viability assay indicated drug@rABL demonstrated highly anti-cancer efficacy in low concentration. Futhermore, the anti-cancer mechanism of the drug can be revealed, too.

10:12AM A20.00008: Integrative structural biology: insights from photoactive yellow protein  YICHAO WU, Nanjing University, MASATO KUMAUCHI, Oklahoma State University-Stillwater, WENFEI LI, Nanjing University, AIHUA XIE, WOUTER HOFF (Presenter), Oklahoma State University-Stillwater — The integration of computational approaches with multiple different experimental techniques offers an exciting avenue to address open questions in protein science. We report such an integrative structural biology approach using a bacterial photoreceptor (photoactive yellow protein) as an accessible model system. A coarse-grained model of PYP in its initial pG state and its light-activate pB intermediate was calibrated based on a range of experimental techniques and was used to obtain mechanistic and molecular insights into the structure and energetics of the pB intermediate. Engineered disulfide bonds were used to limit specific molecular motions in PYP. This approach revealed that the pB state is highly glassy, with multiple substates in which the N-terminal region of PYP adopts quite distinct conformations, which in turn greatly alter the lifetime of the pB intermediate. These results reconcile apparent contradictions in published literature regarding the structure of pB, demonstrate that the N-terminal region undergoes Functionally Important Motions (FIMs) during the PYP photocycle, and explains the classic observation that the N-terminal region of PYP modulates pB lifetime.
10:24AM A20.00009: Decoupling between translation al and rotation al motions of water in the proximity of a protein molecule*  PAN TAN (Presenter), LIANG HONG, Shanghai Jiao Tong Univ — The interaction between water and bio macromolecules is of fundamental interest in biophysics and biochemistry. By performing neutron scattering on a perdeuterated protein at various hydration levels, we characterized the dynamics of water in each molecular layer surrounding the biomolecule. We found that the translation al motion of the interfacial water is slowed down more significantly by protein than its rotation, and the retardation effect extends to the second hydration layer for translation while being limited in the first layer for rotation. Molecular dynamics simulation revealed that the observed translation rotation decoupling in hydration water results from that the translation of water is more correlated over space and highly restrained by the spatial confinement on protein. More importantly, water molecules around the structurally most stable protein residues exhibit the most retarded translation while maintaining their rotational freedom. Restraining translation of water around these residues protect the protein stability while maintaining the rotational mobility renders local flexibility to the biomolecule.

10:36AM A20.00010: Probing Temperature-Dependent Dynamics of Hemoglobin and Water Molecules in the Hydration Shells Using High Sensitivity Dielectric Spectroscopy*  LUAN C. DOAN (Presenter), ABHISHEK SINGH, CHENGYUAN WEN, SHENGFENG CHENG, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Hemoglobin, an iron-containing protein in red blood cells, has diverse biological functions including oxygen/carbon-dioxide transport and storage. The functions and behaviors of hemoglobin proteins strongly depend on environmental conditions and temperatures. The complicated quaternary structure of hemoglobin and the hydrogen-bond network in aqueous environments make it a challenge of identifying the conformational dynamics. Employing high-sensitivity dielectric megahertz-to-terahertz frequency-domain spectroscopy, we have systematically examined the dynamics of hemoglobin and the water molecules in their hydration shells as a function of temperature at the molecular level. Combining experiments with molecular dynamics simulations, we have determined the conformational dynamics of hemoglobin and water in aqueous solutions. The results help us identify hemoglobin dynamics and hemoglobin-water interactions that determine the biochemical functions and reactivity of hemoglobin proteins.

10:48AM A20.00011: Single Molecule Studies of DNA-Histone Interactions  SANTOSH GAIRE (Presenter), Physics, The Catholic University of America — Mechanically-induced unfolding of protein-compactified-DNA molecules is a powerful tool for studying protein-DNA interactions at the single-molecule level. We perform single molecule experiments using horizontal magnetic tweezers on histones complexed with tethered DNA under tension. Native or hyperacetylated histones purified from cultured cells were used. Our experiments allowed us to characterize the step-length distribution for nucleosomes reconstituted from native histones allowing for a comparison to data from hyperacetylated histones. Here we present preliminary data characterizing the mechanical properties of DNA molecules bound to native and post-translationally modified histones.

Monday, March 2, 2020 8:00 AM - 10:48 AM

Session A21 GERA: Energy Storage - Electrode Physics 302

8:00AM A21.00001: Anion charge dependent lithium ion diffusion in solids  ZHENMING XU (Presenter), HONG ZHU, Shanghai Jiao Tong Univ — Our recent studies of the chalcopyrite-structured sulfides and non-spinel-structured halides show that the lithium-ion migration energy barrier can be effectively reduced by comprehensively regulating the anion charge and lithium-ion coordination environments. For example, for lithium ion diffusion between two adjacent lithium-anion octahedrons through a tetrahedral transition state, the greater the anionic charge is, the lower the lithium ion diffusion energy barrier will be. While for lithium ion diffusion between two adjacent lithium-anion tetrahedrons through an octahedral transition state, the smaller the anion charge is, the lower the lithium ion diffusion barrier will be. This new understanding of comprehensively regulating the anion charge and lithium-ion coordination environments to enhance lithium ion transport can be applied for the design and optimization of new superionic conductors.
8:12AM A21.00002: Stable Ionic Conductive Layer on Si Nanoparticles inside Si/C Composite for High-Performance Lithium-Ion Battery Anode  YONG SU KIM (Presenter), Analytical Engineering Group, Samsung Advanced Institute of Technology, HEECHUL JUNG, Energy Laboratory, Samsung Advanced Institute of Technology, JUCHEOL PARK, Business Support Department, Gumi Electronics & Information Technology Research Institute, SEONG HEON KIM, Department of Physics, Myongji University — In this study, we developed a simple and effectual method to form the stable Li ionic conductive layers for Si-based LIB anode materials. (1) For the purpose of maintaining a Li ionic conductive solid electrolyte interphase (SEI) during operation, the protective oxide coating for Si/C composite is practical, which can be simply applied by mixing a poly(vinyl alcohol)-PO₄ with the Si/C composite. The in-depth analysis revealed that the oxide coating reduces the loss of high ionic conductive SEI (Li₂O), resulting in the formation of a stable SEI [1-2]. (2) In the manufacturing step, stable Li ionic conductive layer (Li₂SiO₃) can be successfully fabricated on the Si nanoparticles inside Si/C composite by simply mixing the Li₂O nanoparticles with coal tar pitch. From the electrochemical measurements applied to various cells, it was demonstrated that the Si/C composite with stable Li₂SiO₃ layers show a considerably high performance in stability [3]. The design of this study and analysis provides the direction to enhance the stability of Si-based anode materials at low cost for developing high performance LIB.

8:24AM A21.00003: Creating a Chevrel Hybrid Mo6S₈₋ₓSeₓ to Improve the Performance of Beyond Li-Ion Batteries  TAYLOR JURAN (Presenter), MANUEL SMEU, Binghamton University — Attempting to solve the energy crisis, we consider the use of beyond Li-ion batteries. We are especially interested in the use of Ca and Al metals, due to their abundance within Earth’s crust. Ca and Al are more cost-effective, and environmentally friendly than Li. Additionally, the increased valency increases the energy density. We consider the Chevrel phase (CP), Mo₆X₈ where X= S, Se, Te, as a cathode for Ca-ion batteries. The CP cathode has widely been studied as a cathode for multivalent ion batteries. Several studies have shown that changing the chalcogen X, impacts the potential and diffusion kinetics. Literature shows that the S-rich CP yields a high voltage, with sluggish ion mobility; compared to the Se-rich CP which exhibits a lower voltage and improved ion mobility. We evaluate several S/Se chalcogen concentrations, testing 256 unique configurations, to tune both the potential and diffusion kinetics. Density functional theory is used to investigate the electronic properties, stability, diffusion kinetics, and voltage properties of CaMo6S₈₋ₓSeₓ, where y = 0-8. We implement the SCAN functional, a meta-GGA for an improved level of theory.
**8:36AM A21.00004: An in situ Study of Solid Electrolyte Interface (SEI) Formation on Tungsten Thin Film Electrodes by Neutron Reflectometry with Contrast Variation**  
JOSEPH DURA (Presenter), ERIC D. RUS, National Institute of Standards and Technology — Solid-electrolyte interphase (SEI) formation in LiPF$_6$ in mixed DEC/EC electrolytes was studied in situ by neutron reflectometry (NR) with scattering length density (SLD) contrast variation of the solvent. Tungsten, a non-Li-intercalating material, was used as the working electrode to greatly improve sensitivity to the SEI vs earlier studies.\(^1\) A two-layer SEI was formed upon polarization to +0.25 V vs. Li/Li$^+$. Insensitivity of the inner SEI layer to solvent deuteration at this potential suggested limited incorporation of hydrogen atoms from the solvent molecules. Its low SLD indicated Li$_2$O could be a major constituent. The outer SEI layer SLD scaled with that of the solution, indicating it either had solution filled-porosity or incorporated hydrogen from the solvent, or both. Returning the electrode to +2.65 V removed lithium from both SEI layers, though the effect was more pronounced for the inner SEI layer. Potential cycling increased the solution-derived species content in the inner SEI and decreased the contrast between the outer and inner layers, possibly indicating intermixing of the layers.

**8:48AM A21.00005: Aqueous Solutions at Graphitic Interfaces: Effects of Charge Transfer, Ion Hydration, and Confinement on Interfacial Structure and Capacitance**  
CHENG ZHAN (Presenter), MAIRA R CERON, STEVEN A HAWKS, Lawrence Livermore National Laboratory, MINORU OTANI, National Institute of Advanced Industrial Science and Technology (AIST), Japan, BRANDON WOOD, MICHAEL STADERMANN, PATRICK G CAMPBELL, TUAN ANH PHAM, Lawrence Livermore National Laboratory — Improved understanding of aqueous solutions at charged graphitic interfaces is critical for designing new carbon-based materials for energy storage. However, many mechanistic details remain unclear, including how interfacial structure and response are dictated by intrinsic properties of solvated ions under applied voltage. Here, we combine first-principles simulations with electrochemical measurements to investigate adsorption of several alkali-metal cations at the interface with charged graphene and within graphene slit-pores. We confirm that adsorption energy increases with ionic radius, while being highly dependent on pore size under confinement conditions. In addition, in contrast with conventional electrochemical models, we find that interfacial charge transfer contributes non-negligibly to this interaction and can be further enhanced by confinement. Overall, the measured interfacial capacitance trends result from a complex interplay between voltage, confinement, and specific ion effects—including ion hydration and degree of charge transfer.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
9:00AM A21.00006: Stone-Wales type defect induced performance enhancement in BC$_3$ monolayer for Lithium-ion battery anode applications  SIBY THOMAS (Presenter), MOHSEN ASLE ZAEEM, Department of Mechanical Engineering, Colorado School of Mines, Golden, CO-80401, United States, Colorado School of Mines — Based on first-principles density functional theory (DFT) simulations, we systematically explored the possibility of pristine and defective two-dimensional boron carbide (BC$_3$) monolayer for designing high-performance Li-ion battery (LIB) anodes. Our calculations show that the BC$_3$ monolayer possesses significant structural and electronic stability and also noticed that after adsorbing Li atom, the semiconducting characteristic of both pristine and defective BC$_3$ monolayer is transformed into a metallic state, becoming an electrical conductor, which provided enhanced conductivity for LIB application. Our results reveal the Li adsorption in these structures are exothermic and the Stone-Wales type defect filled BC$_3$ shows a higher theoretical specific capacity of 1287 mAhg$^{-1}$ for Li atoms compared to pristine BC$_3$ (1144 mAhg$^{-1}$) and conventional graphite anode (372 mAhg$^{-1}$). We also found that both the pristine and defect filled BC$_3$ possess fast Li mobility with a low diffusion barrier (~ 0.33 eV) as well as a low average open-circuit voltage (< 0.48 V). Because of these excellent properties, our work predicts that the experimentally synthesized BC$_3$ monolayer, especially the one with Stone-Wales defect can be a promising anode material for the development of future LIBs.

9:12AM A21.00007: Structures Properties of Li-S Redox Solid Products* KAH CHUN LAU (Presenter), Physics and Astronomy, California State University, Northridge, QING GUO, RAVINDRA PANDEY, Physics, Michigan Technological University — Among the candidates for high gravimetric energy storage beyond Li-ion battery technology, Lithium-Sulfur (Li-S) battery is considered one of the promising candidates owing to its high gravimetric capacity, and earth-abundant reactant materials (i.e. sulfur). However, despite these attractive attributes, successful commercialization of Li–S batteries is currently hindered by poor cycling performance and capacity retention that is primarily caused by our limited understanding of the Li-S redox products at the level of the nanoscale and atomistic scale. To help us to understand the related materials properties, the state-of-the-art atomistic simulation can be a timely solution. In this talk, I will share with you some of our recent theoretical studies in Li-S redox solid products (e.g. Li$_2$S$_2$, Li$_2$S$_3$) structures properties using first-principles calculations that focus on the fundamental structure-property (e.g. thermodynamic stability, vibrational, mechanical and electronic properties) prediction of these new Li-S solid compounds. The underlying materials properties related design rules and the implications to Li-S battery cycling performance will be discussed.

9:24AM A21.00008: Insights into the electrochemical behavior of layered oxides intercalated with Na or K  JONAS KAUFMAN (Presenter), University of California, Santa Barbara, MICHAEL TORIYAMA, Northwestern University, ANTON VAN DER VEN, University of California, Santa Barbara — Layered transition-metal oxides, like those used in Li-ion batteries, remain popular candidate electrode materials for the emerging, low-cost Na- and K-ion battery technologies. However, shuttling the larger Na/K ions into and out of these compounds leads to two effects less commonly seen with Li: phase transitions between different stackings of the oxide layers and strong ion-vacancy orderings. Both phenomena are often detrimental, as they can result in mechanical degradation and sluggish ionic transport. To understand this behavior, we have performed first-principles studies of the layered Na$_x$CoO$_2$ and K$_x$CoO$_2$ cathode materials using configurational cluster expansions trained on density functional theory energies. We obtain excellent agreement with the experimentally observed voltage profiles and phase transitions upon cycling. In both systems, we predict several families of stable hierarchical orderings made up of antiphase boundaries between similar ordered regions. We find that K stabilizes unusual distorted phases at high concentrations due to strong K-K repulsion. Our results have important implications for diffusion and may be extended to other layered intercalation compounds.

9:36AM A21.00009: Computational modelling studies on discharge of nanoporous spinel LiMn2O4*  PHUTI NGOEPE (Presenter), Materials Modelling Centre, University of Limpopo — Porosity plays an important role in the performance of Li-ion batteries. Simulated amorphisation recrystallisation methods [1], based on molecular dynamics methods, were used to generate nanoporous LixMn2O4 spinels of approximately 25000 atoms, with different pore sizes. The resulting structures were discharged by lithiation in the concentration range x=1 to 2, and were characterised from XRDs, microstructures and mechanical properties. Generally a transition from the cubic to tetragonal spinel was observed in the range of x=1.5 to 2. In particular, at x=1.75 a broadening of XRD peaks, multiple grain boundarys and a reduction in the yield stress were noted. A pore size that minimises such effects was identified together with associated heterostructures.

9:48AM A21.00010: Influence of Structural Defects on the Electrochemical Properties of MnO$_2$ in Rechargeable Zn/MnO$_2$ Alkaline Batteries: An Ab Initio Study* NIRAJAN PAUDEL (Presenter), BIRENDRA ALE MAGAR, New Mexico State Univ, TIMOTHY N. LAMBERT, Department of Materials, Devices, and Energy Technologies, Sandia National Laboratories, IGOR VASILIEV, New Mexico State Univ — Electrical energy storage is essential for seamless integration of intermittent renewable energy sources into the power grid. Rechargeable alkaline Zn/MnO$_2$ batteries are attractive for large-scale electrical energy storage due to their high energy density, non-toxicity and low cost. The performance of MnO$_2$ electrodes in Zn/MnO$_2$ batteries can be enhanced by nanostructuring and by introducing defects into the crystal structure of MnO$_2$. However, the mechanism of this enhancement is not fully understood. We apply first-principles computational methods based on density functional theory to study the mechanism of hydrogen ion insertion into the crystal structures of pyrolusite ($\beta$), ramsdellite ($R$), and nsutite ($\gamma$) MnO$_2$ polymorphs containing oxygen and cation vacancies. Our calculations show that the presence of oxygen and cation vacancies significantly changes the binding energies of hydrogen ions inserted into the structures of MnO$_2$ polymorphs. The results of our study could explain the influence of structural defects on the electrochemical properties of MnO$_2$ in rechargeable Zn/MnO$_2$ batteries.

*This work was supported by the U.S. Department of Energy, Office of Electricity.

10:00AM A21.00011: Novel states in transition metal oxides: a view based on high-efficiency RIXS of battery electrodes* WANLI YANG (Presenter), Lawrence Berkeley National Laboratory — To meet today’s energy storage requirements for sustainable energy applications, battery electrodes based on transition-metal oxides have been pushed towards very high voltages to achieve a high-energy and high-capacity battery. Such an approach drives the system into a highly oxidized states, which fundamentally leads to stability issues of the battery device. On the other hand, this unconventional state provides a unique playground for studying atypical states in transition metal oxides.

In this presentation, we will discuss spectroscopic studies of battery electrodes, with the focus on ultra-high efficiency mapping of resonant inelastic X-ray scattering (mRIXS). We show that the high voltage operation could trigger redox activities of oxygen (oxygen redox) that could be detected reliably by mRIXS. The spectroscopic results provide striking evidences that oxygen redox, if constrained in the lattice and under control, is not necessarily a detrimental activity as conventionally believed. Understanding and improving energy storage devices are therefore in keen need of collaborating efforts in both materials and fundamental physics.

Energy Biosciences Institute through EBI-Shell program
10:12AM A21.00012: Computational modeling of two-dimensional materials for sustainable energy storage*  
DIBAKAR DATTA, VIDUSHI SHARMA (Presenter), New Jersey Inst of Tech — Two-dimensional materials (2DM) such as graphene, transition metal dichalcogenides (TMD), MXenes, and their heterostructures are among the most promising electrode candidates for radically advanced batteries. In this talk, two important computational aspects of 2DM-based batteries are addressed – (i) 2DM-based anode materials, and (ii) 2DM as van der Waals (vdW) slippery interface. The conventional anode materials have several problems, such as low gravimetric capacity and high volume expansion. We demonstrate that topologically modified 2DM can be utilized as high-capacity anode materials for Li-, Na-, and Ca-ion batteries with a capacity of 1675, 1450, and 2900 mAh/g. Moreover, by building heterostructures made by the stacking of different 2DMs, it is possible to combine the advantage and eliminate the disadvantages of the individual materials. The second part of the talk discusses the interface of anode and current-collector. To combat the issue of high-stress generations at anode-current collector interface during intercalation and deintercalation, we propose the usage of the graphene layer over the current collector as a vdW slippery interface. The computational results are in good agreement with the experimental findings.

*National Science Foundation, CMMI-1911900

10:24AM A21.00013: Crosslinkable Nitroxide Radical Polymer for Energy Storage Applications  
SHAOYANG WANG (Presenter), ALEXANDRA D EASLEY, FEI LI, JODIE LUTKENHAUS, Texas A&M University — Due to the amount of waste generated by lithium-ion batteries disposal, a more environmentally friendly option such as organic batteries is desired to fulfill the need of this large market. Redox-active radical polymers such as poly(2,2,6,6-tetramethylpiperidinyloxy-4-yl methacrylate) (PTMA) are popularly studied as electrode materials for organic batteries. However, linear PTMA may dissolve in the electrolyte and thus degrade the battery's capacity over time. Therefore, crosslinked PTMA is gaining interest as one solution to this challenge.

Here, we present a simple, post-synthetic route to crosslink PTMA while maintaining a relatively high discharge capacity. PTMA monomer is randomly copolymerized with glycidyl methacrylate (GMA). Upon thermal treatment or UV radiation, PTMA is immobilized in a network. The swelling ratio of the crosslinked electrode is calculated from the dry and swelled thickness measured by electrochemical quartz crystal microbalance with dissipation (EQCM-D). The electrochemical properties of the P(TMA-co-GMA) electrodes are obtained using cyclic voltammetry and galvanostatic cycling to evaluate whether crosslinking improves cell performance. Our general finding is that PTMA dissolution was prevented by this crosslinking approach.
10:36AM A21.00014: Highly Mesoporous Carbon Aerogel as Catalyst Support in Proton Exchange Membrane Fuel Cells  ERIC KIM (Presenter), Stuyvesant High School, KEVIN GU, Deerfield Academy, SUNIL SHARMA, STOYAN BLIZNAKOV, MIRIAM RAFAILOVICH, Stony Brook University — Carbon aerogel possesses unique structural and electrical properties, such as high mesopore volume, large specific surface area, and high electrical conductivity, which make it suitable for use as catalyst support in Proton Exchange Membrane Fuel Cell (PEMFC). In this study, we present a novel synthesis of highly mesoporous carbon aerogel via freeze-drying approach and investigate its application in the fuel cell. The structural effects of activation on carbon aerogel will also be discussed. The TEM and XRF, NLDFT and BJH analysis were carried out to observe the morphology and pore structure. Pt on carbon aerogel and activated carbon aerogel show efficient activity in both ORR and HOR reactions compared to Pt on Vulcan XC-72, with increases up to 721% and 194% in specific power density, respectively. The enhanced performance of carbon aerogel is attributed to its large specific surface area, high mesopore to micropore ratio, and even dispersion of catalyst particles. Accelerated stress tests show that carbon aerogel has comparable durability with Vulcan XC-72, while activated carbon aerogel is less durable than both materials. Thus, this mesoporous carbon aerogel provides an efficient, cost-reduced alternative to existing microporous carbon material as catalyst support in PEMFC.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A22 DBIO: Animal Behavior 303 - Gordon Berman, Emory University

8:00AM A22.00001: Uncovering the dynamical structure of behavioral repertoires*  ITAI PINKOVIEZKY, GORDON BERMAN (Presenter), Emory University — Animal behavior consists of an intricate hierarchy of dynamics, from brief muscle twitches to stereotyped behaviors to longer-lived states like hunger, aggression, and parenting. How does an animal bridge these timescales to create complex sequences of actions? The approach that most researchers take when studying sequences of behaviors tends to be probabilistic, observing how discrete states transition in a largely memoryless fashion. In this talk, we take a different approach, fitting dynamical models to long behavioral sequences from fruit flies and other species. We show that these models replicate many summary statistics of the underlying behavioral sequence data and that their fixed points have a geometry that mirrors the geometry of the animals' behavioral repertoires. In addition, we show that the long timescales generated by this model are best explained by a hierarchy of interacting dynamical subsystems that is comparable to the hierarchical structure of behavior. These results suggest a new framework for uncovering the hidden states that modulate the behaviors that an animal performs and predicting how physiology may be linked to behavior.

8:12AM A22.00002: Collective bumblebee foraging in a controlled stochastic environment
DAVID HOFMANN (Presenter), AHMED HEMDAN ROMAN, Physics, Emory University, DONNA ROSA MCDERMOTT, BERRY J BROSI, Environmental Science, Emory University, ILYA M NEMENMAN, Physics, Emory University — We study bumblebees in a flight chamber with 10 artificial flowers to explore and accurately quantify foraging behavior. An RFID system is employed to identify the individual foragers and detect their presence in flowers as well as entry and exit of the hive. Flowers release rewards upon bee's visit with a predefined probability and are divided into two groups of separate reward probabilities and color. Furthermore, we impose a reward refractory period, that is a time span that a bee needs to stay away from a recently triggered flower before it is able to trigger it again.

In this study, an entire colony of tagged bees is kept in the foraging chamber for 4-6 days. We study 7 colonies with 40-70 bees each. We analyze and quantify the operant learning of the relation between flower color and reward probability: bees are able to identify the more rewarding flower type, effectively matching the reward probability ratios. However, the number of bees who are able to do so strongly depends on the length of the imposed refractory period. We conclude that a combined setting of refractory time and reward probability is too challenging for most bumblebees to learn in the given time span and thus leads to suboptimal foraging choices whereas they quickly learn to adapt to Bernoulli trials alone.

8:24AM A22.00003: A Low-Cost Modular Camera System for 3D Pose Estimation in the Field
SCOTT WOLF (Presenter), JULIEN AYROLES, JOSHUA SHAEVITZ, Princeton University — The individual behavior of animals determines the outcome of ecological interactions and drives group organization and community dynamics. Considerable attention has been given to understanding these types of interactions by way of automated tracking of individuals and bio-logging; however, these methods rarely investigate the behaviors performed by animals. Recent developments in deep learning for pose estimation provide a promising avenue for understanding individual behavior at resolutions previously not possible. However, systems for generating datasets appropriate for these methods in the field are lacking. To fill this gap, we developed a low-cost, modular camera platform to generate 3D imaging data compatible with contemporary pose estimation techniques. We use a connected network of solar-powered cameras that supports synchronous capture, triggering, and the integration of multisensory metadata. We initially generated datasets from three camera modules that allow for 3D pose estimation in a large outdoor area of over 600m² and demonstrate its use in an open field experiment at the Mpala Research Centre and Wildlife Foundation in Nanyuki, Kenya. Our system is designed to be modular and extensible, facilitating the use of many camera modules in very large open areas.
8:36AM A22.00004: Bridging time scales in *C. elegans* behavior through transfer operators*
ANTONIO COSTA (Presenter), Vrije Univ (Free Univ), DAVID JORDAN, Department of Genetics, University of Cambridge, GREG STEPHENS, Vrije Univ (Free Univ) — Animal behavior is modulated over multiple timescales: from fast control by neural activity to slower variation due to starvation or aging. Can we extract these hidden processes from the movement dynamics alone? We introduce a principled method to simultaneously reconstruct and partition the dynamical state-space, which we use to approximate the Perron-Frobenius operator. Our operator approximation is built to be maximally predictive and Markovian and its spectral decomposition provides a hierarchy of modes, which evolve over multiple time-scales. Applied to *C. elegans* locomotion, we find coherent structures which represent behavioral motifs, while the dynamics of the long-lived modes capture slower changes in behavioral “strategies”, e.g. the worm’s exploratory propensity. By subsuming the nonlinear dynamics into the process of partitioning and state space reconstruction, we obtain a model of the dynamics which is simple yet still able to faithfully reproduce the complexity of worm behavior from milliseconds to hours.

*Project funding was provided by OIST Graduate University and VU Amsterdam. AC is supported through a program grant from the Netherlands Organization for Scientific Research and DJ is supported by a Herchel Smith postdoctoral fellowship.

8:48AM A22.00005: Inferring behavioral homologies from dynamical models*
KATHERINE OVERMAN (Presenter), ITAI PINKOVIEZKY, GORDON BERMANN, Emory University — Linking the evolution of animal behavior to the genes underlying it has proven challenging, largely due to our inability to find representations of behavior that allow for inter-species comparisons. Animals exhibit variability in many different traits across species, but certain traits are relatively conserved. These traits are known as homologies or homologous structures, and quantitatively identifying these homologies in behavior could provide a new approach for understanding the evolution of behavior. Here, we measure the behavioral repertoires of six fruit fly species, finding both the frequency of behavioral performance, as well as their temporal dynamics. By fitting dynamical models to these transitions, we can reproduce the summary statistics of our dataset, including long timescale dynamics and hierarchical structure. We show that features of these models can be used to define such homologies, providing future avenues for exploring the genetic basis of behavioral evolution.

Long timescale dynamics in freely behaving rats

KANISHK JAIN (Presenter), Department of Physics, Emory University, Atlanta, GA, ELENA MENICHINI, TOMASO MUZZU, Institute of Behavioural Neuroscience, Department of Experimental Psychology, University College London, London, United Kingdom, JAKOB MACKE, Departments of Computational Neuroengineering and Electrical and Computer Engineering, Technical University of Munich, Munich, Germany, AMAN SALEEM, Institute of Behavioural Neuroscience, Department of Experimental Psychology, University College London, London, United Kingdom, GORDON BERMAN, Departments of Physics and Biology, Emory University, Atlanta, GA — Natural behavior is composed of rich postural dynamics that contain stereotyped movements performed by the animal. These behaviors span multiple timescales and are performed in a structured manner during spontaneous behavior. Thus, a quantitative understanding of behavioral dynamics is crucial to help unravel the latent physiological states driving behavior. Here, we extract postural information from videos of freely moving rats in an arena using markerless tracking tools. Using these postural time series’ we create a low-dimensional behavioral state space using unsupervised methods that characterizes stereotypic behavioral bouts. We find long, non-Markovian timescales of predictability across novel and familiar trials of light and dark conditions in the arena. These behavioral sequences are found to be arranged in hierarchical clusters, similar to previous results in fruit flies. These results support hierarchical organization of behavior as a general principle across species for generating long timescale dynamics.

Supported by HSFP RGY0076/2018.

Measuring and modeling the dynamics of the thermal memory of C. elegans

AHMED ROMAN (Presenter), Physics, Emory University, KONSTANTINE PALANSKI, ANTIBODY Healthcare Communications, ILYA M NEMENMAN, Physics, Emory University, WILLIAM RYU, Physics, University of Toronto — The roundworm C. elegans learns from its experiences. When placed on a thermal gradient, worms perform thermotaxis to or away from the conditioned temperature, depending on food abundance during the conditioning phase. To quantify this behavior, we developed a novel assay that tracks single worms—each experiencing a Spatio-temporal thermal gradient with thermal precision ±0.01C—in a small (2.8ul) droplets of buffer, arrayed on hydrophobic-printed microscope slides. CCD cameras monitor many worms simultaneously in many droplets, each droplet at 20C midpoint with a thermal gradient of 0.5C/cm. A worm’s thermal preference is summarized as a thermotaxis index, and the index dynamics are tracked at a high temporal resolution for many hours. Initially, worms reared at 15C and 25C exhibit cryophilic or thermophilic tendencies, respectively, and starvation during conditioning or in the droplet reverses these tendencies. This reversal is non-monotonic indicating multiple dynamic processes for learning that operate on different time scales. We build a predictive model with multiple time scales and utilize mutants to detangle the various learning processes. The model predicts the behavior under various conditions.

Multi-animal pose tracking using deep neural networks*  
TALMO PEREIRA (Presenter), SHRUTHI RAVINDRANATH, NATHANIEL TABRIS, JUNYU LI, MALA MURTHY, Princeton Neuroscience Institute, Princeton University, JOSHUA SHAEVITZ, Physics, Princeton University — Dissecting behavior in freely moving animals at the fast timescales requires rich representations of their motor dynamics. Recently, we developed a method to automate the estimation of animal pose from videos using deep neural networks (Pereira et al., 2019). This method, termed LEAP, detects body part positions in single animal videos. Extending these techniques to a multi-animal context presents technical challenges, such as assigning body part positions to the correct animal. Here we present a new framework we term SLEAP (Social LEAP Estimates Animal Poses) that can explicitly model the relationship between body parts, enabling accurate multi-animal pose estimation. The framework implements multiple neural network meta-architectures which we empirically evaluate on tracking sub-tasks. We demonstrate the generalizability of this framework by applying this technique to videos of a variety of animals, including a high-resolution dataset of freely interacting fruit flies to construct a map of postural dynamics during courtship.

Phenotype to Function: Predicting drug mode of action from behavioural fingerprints  
ADAM MCDERMOTT-ROUSE, ELENI MINGA, ANDRE BROWN (Presenter), Imperial College London — Pesticides and anthelmintics (nematode-killing drugs) are discovered through phenotypic screens in target species. This means that their efficacy is often known early in the development pipeline, but their mode of action is not. Therefore, an important problem in developing new compounds to combat the rise of anthelmintic resistance is determining their mode of action. We record multiple worms from 96-well plates using a multi-camera imaging system and extract behavioural features from tracked animals to define a quantitative phenotype for each well in response to a library of ~80 drugs from 10 known mode of action classes. Because drug dose can have a strong effect on behavioural response, we record worms' response to a range of doses. We combine information across doses using multiple-instance learning to predict a compound's mode of action on unseen data.
Mammals are generalists, capable of flexibly deploying movements across a range of behavioral contexts. However, existing paradigms for studying the genesis of movement in the brain often probe only a narrow range of highly trained behaviors, leaving the neural mechanisms that support this flexibility unclear. To extend the range of behaviors and contexts that can be studied, we developed a new behavioral monitoring system, CAPTURE, that combines motion capture and deep learning to track the 3D movements of twenty points on a freely behaving rat’s trunk and appendages, continuously over week-long timescales. We combined CAPTURE with continuous neural recordings in the dorsolateral striatum, a brain region with a known, if debated, role in controlling diverse aspects of movement and behavior. Within individual behavioral states, striatal neurons displayed tuning to kinematic and behavioral variables. However across states, these tuning properties changed, in a manner that improved the within-state behavioral decodability. This suggests that context-specific coding may be a means to efficiently represent behavioral variables that are flexibly deployed across states, and that representational findings observed in tasks may fail to generalize.

10:00AM A22.00011: Speed selection and sampling strategies for terrestrial trail tracking*
GAUTAM REDDY (Presenter), Harvard University, MASSIMO VERGASSOLA, University of California, San Diego, BORIS I SHRAIMAN, University of California, Santa Barbara — Terrestrial animals such as ants, mice and dogs use surface-borne odor trails to establish navigation routes or to find food and mates by following adsorbed chemical traces. Trail-tracking behavior is commonly observed, yet the strategies animals use to track trails are largely unknown. We examine generic features of trail-tracking by posing the problem as a search task of finding the trail after each loss of contact. We show that trail geometry imposes strong constraints on tracking speed; the maximal speed scales as the square-root of the typical radius of trail curvature with a strategy-dependent prefactor. By posing the problem in the reinforcement learning framework, we obtain optimal sampling strategies under various movement constraints and sensor configurations. An exactly solvable model in the Hamilton-Jacobi-Bellman framework recapitulates features of sampling strategies obtained via learning and quantifies the trade-off between movement cost, speed and sampling efficiency. Our work provides a general framework for trail tracking and testable hypotheses on the algorithms that animals use to follow trails.

10:12AM A22.00012: Specialization of control strategies in terrestrial slithering snakes.*
PERRIN E SCHIEBEL (Presenter), Physics, Georgia Institute of Technology, BO LIN, Mathematics, Georgia Institute of Technology, ALEX M HUBBARD, BioE, Georgia Institute of Technology, LILLIAN CHEN, Biology, Georgia Institute of Technology, GREG BLEKHERMAN, Mathematics, Georgia Institute of Technology, DANIEL I GOLDMAN, Physics, Georgia Institute of Technology — Limbless locomotors like snakes use environmental heterogeneities for propulsion. We tested two snake species adapted to different habitats, the desert specialist *C. occipitalis* and the multi-terrain generalist *P. guttatus*, in a model terrestrial terrain—rigid arrays of posts on a low-friction whiteboard substrate. Principal component analysis (PCA) revealed the specialist maintained its stereotyped sand-swimming wave in the arrays, while results for the generalist were inconclusive, indicating either a periodic gait was higher dimensional, or the motion was aperiodic. Persistent homology, a mathematical technique which can identify cycles without reducing dimension, suggested the generalist used aperiodic kinematics. We hypothesized that the generalists instead controlled reaction forces and tested this using a simplified terrain, a single force-sensitive post on whiteboard. The generalist was more effective at using the post, maintaining longer contacts and more consistent force vectors. Our study suggests control specialization; the specialist targets beneficial sand swimming kinematics while the generalist controls for advantageous force generation in accord with early studies of generalist snakes in lattices [e.g. Gray 1955].

10:24AM A22.00013: Proceed with caution: dynamics of novelty-directed risk assessment behavior in mice* YORIKO YAMAMURA (Presenter), JEFFERY R WICKENS, Okinawa Inst of Sci & Tech — Mice encountering a novel object initially display a distinctive set of behaviors that have been described as "risk assessment," including slow extensions of their snout toward the object followed by rapid retractions. These behaviors have also been observed in mouse models of anxiety, such as during elevated plus maze tasks, and are proposed to reflect a conflict between exploration and risk avoidance. However, a simple conflict does not explain the asymmetry in the speeds of approach and retreat: why do mice spend more time approaching the object than retreating from it, when spending less time near the object overall could reduce their exposure to risk? Analyzing the snout trajectories of mice exploring a novel object, we test the hypothesis that these behaviors reflect an internal evidence accumulation process, in which mice integrate a subjective "risk" while approaching and retreat when the cumulative "risk" crosses a threshold. We ask whether 1) a feed-forward model can predict retreat timings from preceding trajectories of approach, and 2) including feedback from risk to snout velocity explains the asymmetrical dynamics of "risk assessment".

10:36AM A22.00014: Transitions between stochastic and oscillatory active sensing in pulse-type electric fish  ALEXANDRE MELANSON (Presenter), Département de physique et d'astronomie, Université de Moncton, ANDRE LONGTIN, Department of Physics, University of Ottawa — Rather than wait passively for signals to be detected by their sensors, animals actively move in order to gather information from their environment. Furthermore, when sensing is performed by means of rhythmic movements, reafferent sensory streams are also rhythmic, which is advantageous for sensory processing. Here, we report on and characterize an hitherto unknown behavioural state of pulse-type weakly electric fish during which electrosensory acquisition becomes rhythmic and is coupled to low-frequency movement. The oscillatory nature of this sensory sampling strategy is in stark contrast to that exhibited during other behavioural states, which we show to be well-modelled by jump-diffusion stochastic processes.

To characterize the oscillatory dynamics of these rhythmic behavioural states, we identify and extract them from long-term observations of freely-moving fish. To achieve this, we apply a wavelet transform to the inter-pulse interval time series and use the resulting spectra as input for t-distributed Stochastic Neighbor Embedding. This creates a 2D clustered representation of the data from which we successfully classify different sensory acquisition strategies. This approach reveals that rhythmic sampling in fact occurs over a range of frequencies between 0.5 and 1 Hz.

10:48AM A22.00015: Steering and turning control of C. elegans  KELIMAR DIAZ (Presenter), BAXI CHONG, Georgia Tech, TIANYU WANG, Carnegie Mellon University, KATHLEEN BATES, JIMMY L DING, Georgia Tech, GUILLAUME SARTORETTI, Carnegie Mellon University, HANG LU, Georgia Tech, HOWIE CHOSET, Carnegie Mellon University, DANIEL I GOLDMAN, Georgia Tech — Elongate animals (e.g., snakes, nematodes) propagate waves of body curvature to generate propulsion in dissipative environments. In particular, the nematode worm C. elegans lives in environments (e.g., rotting fruit) where maneuverability is crucial to overcome heterogeneities and post-interaction deformations. To search for steering control principles in undulatory locomotion, we studied C. elegans traversing both agar and liquid buffer. These worms generate a time-dependent omega-like shape for reorientation to achieve body rotation of 150±26° on agar and 84±39° in liquid buffer. Principal component analysis (PCA) revealed the worms use four principal components during turning, superimposing two body traveling waves with two spatial frequencies. A geometric mechanics framework rationalized the observed turning dynamics by properly coupling the amplitude and the phase of the two body traveling waves. Theory predicted omega turns can achieve rotation of 153° on agar and 89° in liquid buffer, in agreement with worm experiments. These results and robophysical experiments implementing the behavior suggest that omega turns are a robust strategy for turning in diverse environments.

Mechanics and Elasticity of dynamic cellular monolayers - How *Volvox* embryos turn inside-out

[Invited] STEPHANIE HOEHN (Presenter), PIERRE A HAAS, RAYMOND E GOLDSTEIN, Applied Mathematics and Theoretical Physics, University of Cambridge — Living tissues are intelligent materials that can change their mechanical properties while they develop. In spite of extensive studies in multiple model organisms we are only just beginning to understand these dynamic properties and their role in tissue development. Although many tissues are known to exhibit visco-elastic properties, it is unclear which properties dominate three-dimensional shape changes of cellular monolayers, such as epithelia.

The embryonic *inversion* process in the micro-algal order Volvocales is uniquely suited for studies on epithelial morphogenesis. Volvocalean embryos consist of cup-shaped or spherical cellular monolayers which invert their curvature in order to expose their flagella. *Volvox globator* exhibits one of the most striking processes of cell sheet folding: Through inwards folding at the equator of the initially spherical cell sheet adopts a mushroom shape and eventually turns itself entirely inside-out through an anterior opening [1]. These global deformations are driven by several waves of active cell shape changes [2, 3]. A combination of advanced imaging and computational analyses is used to explore the role of tissue contractility during invagination. The associated internal stresses as well as the elastic properties of the dynamic cell sheet are determined through laser ablation experiments.

A bilayer model of the non-linear elastodynamics of Hydra mouth opening*  TAPAN GOEL (Presenter), CASSIDY TRAN, University of California, San Diego, ELLEN ADAMS, Swarthmore College, PATRICK HENRY DIAMOND, University of California, San Diego, EVA-MARIA COLLINS, Swarthmore College — Mouth opening in *Hydra* involves extreme deformations, with radial cell strains of up to 30%. *Hydra* consists of two neuronally excitable, mechanically coupled epithelia-muscular cell layers, an outer ectoderm and an inner endoderm. The layers are coupled basally by a viscoelastic extracellular matrix, into which the cells extend contractile fibers (myonemes). In the head, ectodermal myonemes are arranged radially and endodermal myonemes in concentric rings. Experiments show that mouth opening proceeds through a series of radial ‘tugs’ – local myoneme contractions that must synchronize to produce a symmetric opening. We investigate if a bilayer model of viscoelastic sheets containing networks of radial and circular non-linear springs with Poisson distributed compressive forcing can capture mouth opening. Constraining the model using *in vivo* data, we test its ability to reproduce the time history of the mouth area during opening. We compare the kinematics generated by radially travelling contraction pulses with that for simultaneous contractions at all radii. Further, we explore the conditions required for space-time synchronization of ‘tugs’ into a quasi-symmetric opening and the dependence on the ratio of firing rate and the relaxation timescale of the viscoelastic sheet.

Investigation of Rice Root Tip Circumnutation Functions in Heterogeneous Environments  ERIN MCCASKEY (Presenter), Georgia Inst of Tech, ISAIAH TAYLOR, KEVIN LEHNER, PHILIP N BENFEY, Duke University, DANIEL I GOLDMAN, Georgia Inst of Tech — Circumnutation is the pattern of oscillatory growth widespread among plants. Little is known about the function of circumnutation, particularly in root-heterogeneity interactions. Traits that allow for exploration may be advantageous, as roots can encounter heterogeneities in their environment that prevent productive growth. In this work we used a clear gel-based media to create a growth environment of two gel layers with varying stiffness, which can model soil horizons with varying compaction. A high-throughput automatic imaging system acquired images to visualize the root growth. Roots were grown in either a soft gel upper layer to a stiffer gel bottom layer, or the opposite. Our results show interesting differences in the ability of wild-type and non-circumnutating roots to penetrate the lower gel layer. These differences provide insights into the function of circumnutation.
Mechanics of behavior: Comprehensive search behavior encoded in cytoskeletal dynamics of single cell *Lacrymaria olor*  

ELIOTT FLAUM (Presenter), Program in Biophysics, Stanford University, DEEPAK KRISHNAMURTHY, Mechanical Engineering, Stanford University, SCOTT COYLE, Biochemistry, University of Wisconsin, MANU PRAKASH, Bioengineering, Stanford University — Complex animal behavior arises from interplay between actuators and sensors. Surprisingly, single eukaryotic cells such as protists are also capable of complex behavior, but how an algorithm such as search might be encoded in intrinsic dynamics of a single cell remains unknown. Here we elucidate the mechanics of search behavior in the predatory ciliate *Lacrymaria olor*, which has the ability to extend and contract its “neck” seven body lengths in a second while efficiently searching the space around it for prey in minutes. Our recent work establishes that *L. olor*’s search strategy is encoded in antagonistic active systems: subcellular structures that use surface cilia and the cortical cytoskeleton (Coyle et al, 2019). Here we reveal the underlying geometrical features of the cytoskeleton, and membrane and volume constraints, that together program extension and contraction dynamics of this active filament. Through force spectroscopy and membrane tension experiments in live cells, we reveal the role of this dynamic force landscape and how it shapes the search phase space. Our work combines theoretical active filament models with experimental data to unravel how active mechanics leads to emergent behavior in single cells.

Functional consequences of microscopic skin features on snake locomotion  

JENNIFER RIESER (Presenter), Georgia Inst of Tech, TAI-DE LI, CUNY, DANIEL I GOLDSMAN, Georgia Inst of Tech, JOSEPH MENDELSON, Zoo Atlanta — Interactions between limbless animals and their natural environments, which are essential for movement, are mediated solely through skin contact. We used atomic force microscopy to investigate how surface textures on shed skins vary across snakes and environments. While most snakes have microfibrils oriented longitudinally, a few distantly-related snake species have convergently lost these features in favor of a more isotropic structure. We hypothesize that these microstructures affect the frictional interaction with the substrate and we use resistive force theory to model the effects of frictional anisotropy on snake locomotion. For lateral undulation, we predict that an anisotropic frictional interaction in movement along the body is favored over transverse movement, improving performance (measured in distance traveled per cycle), and that larger anisotropies produce larger displacements. In sidewinding locomotion, however, we predict the opposite trend: decreased frictional anisotropy improves performance. These predictions are consistent with our AFM measurements of small-scale features on snake skins and suggest a functional benefit for the convergent loss of structure shared by sidewinding vipers.
Bioelectrical signaling via domain wall migration*  HAROLD MCNAMARA
(Presenter), RAJATH SALEGAME, ZIAD AL TANOURY, HAITAN XU, SHAHINOOR BEGUM, Harvard University, GLORIA ORTIZ, Chemistry, University of California Berkeley, OLIVIER POURQUIE, ADAM COHEN, Harvard University — Electrical signaling in biology is typically associated with action potentials, transient spikes in membrane voltage that return to baseline. The Hodgkin-Huxley equations of electrophysiology belong to a more general class of reaction-diffusion equations which could, in principle, support patterns of membrane voltage which are stable in time but structured in space. Here we show theoretically and experimentally that homogeneous or nearly homogeneous tissues can undergo spontaneous spatial symmetry breaking into domains with different resting potentials, separated by stable bioelectrical domain walls. Transitions from one resting potential to another can occur through long-range migration of these domain walls. We map bioelectrical domain wall motion using all-optical electrophysiology in an engineered cell line and in human iPSC-derived myoblasts. Bioelectrical domain wall migration may occur during embryonic development and during physiological signaling processes in polarized tissues. These results demonstrate a novel form of bioelectrical pattern formation and long-range signaling.

Modeling the Mechanosensitivity of Crawling Cells*  JOHN MOLINA
(Presenter), RYOICHI YAMAMOTO, Chemical Engineering, Kyoto University — In this work, we study the ability of cells to probe and dynamically adapt to the mechanical properties of their surroundings, i.e., their mechanosensitivity. Experimentally, this can be studied by observing the reorientation of crawling cells over cyclically stretched substrates. To understand the observed cell-specific reorientation, we have introduced a computational model that couples the cyclically stretched substrate to the sub-cellular elements responsible for cell shape and motility: cell membrane, actin cytoskeleton, and focal adhesions. Depending on which sub-cellular process is being probed, and the type of coupling with the substrate, our simulations predict either no reorientation, a bi-stability in the parallel and perpendicular directions, or a complete reorientation. In particular, we show that an asymmetry in the adhesion dynamics during the loading and unloading phases of the stretching can be used to selectively align the cells. Our results provide further evidence for the importance of focal adhesion dynamics in determining the mechanosensitive response of cells.

9:48AM A23.00008: Geometry, Elasticity, Growth: The Connection Between Cowrie Growth Dynamics and Shell Form  
MICHAEL GABRIEL LEVY (Presenter), Biophysics Graduate Group, University of California, Berkeley, MICHAEL ROBERT DEWEESE, Physics and Neuroscience, University of California, Berkeley — Thin elastic sheets are currently a hot topic in soft matter physics. We propose a new model illustrating how the physics of bending and wrinkling sheets could underlie the geometry of Cowrie Seashells, offering both qualitative and quantitative insights. This work suggests generally new approaches to the mechanics underlying biological development. Despite both the cowry's import -- in monetary history and as a collector's item -- and a rich history of seashell modeling, we are the first to mechanistically consider cowrie form at all, let alone couple growth, elasticity, and form to recapitulate the shape of the central spiral, the thickening of the shell base, and the ridge-like teeth which form at the shell opening. By connecting elasticity with the biological processes of shell repair and body growth, we suggest that most aspects of form are emergent from the developmental decision to extend the mantle and extrude it over the shell instead of standard volumetric growth. In addition to our theoretical results, we test our model against both published and reported data, suggest previously unreported scaling relations, and demonstrate methods for extracting geometrical information from both three-dimensional scans and two dimensional images.

10:00AM A23.00009: Theoretical tool bridging cell polarities with development of robust morphologies*  
SILAS BOYE NISSEN (Presenter), STEVEN RØNHILD, ALA TRUSINA, KIM SNEPPEN, Niels Bohr Institute, University of Copenhagen — Despite continual renewal and damages, a multicellular organism is able to maintain its complex morphology. How is this stability compatible with the complexity and diversity of living forms? Looking for answers at protein level may be limiting as diverging protein sequences can result in similar morphologies. Inspired by the progressive role of apical-basal and planar cell polarity in development, we propose that stability, complexity, and diversity are emergent properties in populations of proliferating polarized cells. We support our hypothesis by a theoretical approach, developed to effectively capture both types of polar cell adhesions. When applied to specific cases of development – gastrulation and the origins of folds and tubes – our theoretical tool suggests experimentally testable predictions pointing to the strength of polar adhesion, restricted directions of cell polarities, and the rate of cell proliferation to be major determinants of morphological diversity and stability.

Session A24 GSNP: GSNP Dissertation, Graduate Student, and Post-doctoral Speaker Awards  
401 - Daniel Lathrop, University of Maryland, College Park - Tag(s): Prize/Award
8:00AM A24.00001: Geometry and Topology in Motion* [Invited] SURAJ SHANKAR (Presenter), Physics, Harvard University — Topological and geometric ideas are now a mainstay of condensed matter physics, underlying much of our understanding of conventional materials in terms of defects and geometric frustration in ordered media, and protected edge states in topological insulators. In this talk, I will argue that such an approach successfully identifies the relevant physics in metamatials and active matter as well, even when traditional techniques fail. Novel topological phenomena acquire unique realizations in active fluids that pose a particular challenge to conventional statistical mechanics, by virtue of being far from equilibrium. I will present some recent results to illustrate this and show how spontaneous flow on complex substrates can mimic synthetic gauge fields allowing them to be fruitfully viewed using topological ideas and analogies with superconductors.

*This work was supported partly by NSF Grant DMR-1609208.

8:36AM A24.00002: Minimal Model for Intermittent Dynamics and "Turbulence" in Many-Body Systems* GURAM GOGIA (Presenter), Emory University — Complex systems are known to exhibit emergent properties that are missing on the constituent level. One particular property shared by many seemingly unrelated complex systems is intermittent switching between distinct dynamical states. Inspired by our previous experimental findings [1], here we present computational results for a particle-based system that exhibits intermittent switching between two distinct phases. The emergent dynamics are a direct consequence of coupling between structural disorder arising from particle polydispersity, inertial dynamics, and external forcing. Modelling the orthogonal mechanical energies of the system using ODEs with both noise and coupling terms based on kinetic arguments surprisingly results into predator-prey-like interactions. Such equations have recently been employed to describe intermittent turbulence in a pipe flow [2]. The only non-dimensional number derived from our equations resembles the Reynolds number in fluid flow and accurately predicts where intermittent dynamics are manifested.

*NSF, DMR-1455086
8:48AM A24.00003: Vortices, space-time braids and loops in the membrane of a living cell
JINGHUI LIU (Presenter), MIT — Topological defects determine the structure and function of matter over a wide range of scales. Many advances have been made in understanding and controlling the defect dynamics in active and passive non-equilibrium fluids. Yet, it remains unknown whether the statistical laws which govern the dynamics of defects in classical or quantum fluids extend to active living matter. Here, we show a defect-mediated turbulence underlies the complex wave propagation patterns of Rho-GTP signaling proteins on the membrane of starfish oocytes. Our experiments reveal that the phase-velocity field extracted from Rho-GTP concentration patterns exhibits vortical defect motions and annihilation dynamics reminiscent of those seen in quantum systems. Space-time analyses of defect trajectories reveal the existence of two characteristic types of braids: loops braided by multiple pairwise creation and annihilation events, and long-lived defect pairs that wiggle and form braid groups. Several key statistics and scaling laws of the defect dynamics, braids and loops can be captured by a generic complex Landau-Ginzburg continuum theory, suggesting space-time braids and loops are useful topological measures for unraveling information scrambling and transmission in dissipative living systems.

9:00AM A24.00004: A mechanical model for supervised learning* MENACHEM STERN (Presenter), University of Chicago — A broad goal of engineering is to make functional machines with specific, programmed input-output responses. When inputs are specified in advance and few in number, this goal is sought through rational design, changing the system elements to obtain desired responses. In the supervised learning framework of computer science, system parameters (synapses) are modified in response to observed examples of the correct input-output mapping (classification).

In this work, we apply the supervised learning framework to self-folding sheets, using a physically motivated learning rule. The trained sheet classifies labeled forces by folding into discrete folded states. These sheets succeed in classifying real-world data like Iris flowers, and also generalize, similar to other learning algorithms. As learning provides a straightforward framework to programming complex input-output relationships, we hope that implementing these ideas in engineering could usher in new classes of machines, that have so far eluded design.

*We acknowledge NSF-MRSEC 1420709 for funding and the University of Chicago Research Computing Center for computing resources.
9:12AM A24.00005: Ecological mechanisms of direct and indirect bacteriotherapies in generalized Lotka-Volterra systems* ERIC JONES (Presenter), University of California, Santa Barbara — Over the last two decades, an association between microbiome composition and some human diseases has been unambiguously established. The correlation between gut microbe composition and these diseases has prompted medical interest into bacteriotherapies, which seek to modify the gut microbiome composition in the hopes of treating the correlated disease. In this work we use generalized Lotka-Volterra (gLV) models to probe the ecological mechanisms through which these bacteriotherapies function. We first describe direct bacteriotherapies, which drive a microbiome to a target state via an instantaneous influx of foreign microbes (e.g. probiotics or fecal microbiota transplantation). Then, we present a novel control framework for indirect bacteriotherapies, which drive a microbiome to a target state by deliberately modifying its environment (e.g. diet, acidity, or nutrients). These dual control methods for gLV systems, interpreted as bacteriotherapies, could eventually inform personalized medicine for the microbiome.

9:24AM A24.00006: Noisy driven oscillators: Adaptive drives break the fluctuation-dissipation theorem JANAKI SHETH (Presenter), UCLA — The steady-state dynamics of complex nonlinear systems include limit cycles in which the dynamic variables trace a closed path in phase space. Biological systems are replete with examples of such driven oscillators in a diverse range of systems including circadian rhythms, neuronal central pattern generators, and the active mechanics of hearing. These biological systems are inherently noisy, and they are typically controlled by active feedback. We explore the fluctuations and response functions of intrinsically noisy limit-cycle oscillators starting with models of stereocilium dynamics in the inner ear. We show that one can obtain a generalized fluctuations-dissipation theorem (GFDT) for the system in a reference frame comoving with the mean dynamical state moving about the limit cycle. However, in the presence of adaptive drives where there is feedback so that the energy input driving the oscillator depends on the state of the system, as in the driven stereocilium, even these generalized fluctuation theorems fail. We further explore the essential role of these feedback mechanisms in breaking GFDTs in noisy driven systems using a combination of simple computational models, analytical calculations, and stereocilium dynamics data.

9:36AM A24.00007: Diffusive behavior in walking droplets AMINUR RAHMAN (Presenter), Texas Tech University — Fluid droplets walking on a vibrating fluid bath have been observed to display deterministic diffusion. We present an experimental and theoretical investigation of such droplets. In our experiments a droplet is placed into an annular region on a vibrating fluid bath. The droplet motion becomes increasingly diffusive as the bath vibration is intensified above the Faraday wave threshold. This is also captured in our hydrodynamic – kinematic models, which shows close agreement between theory and experiments. Since the model can be studied at a much higher spatio-temporal resolutions than experiments, we use the model to numerically investigate bifurcations and chaotic dynamics suggested by experiments. Finally, we briefly discuss the possibility of model reduction to mitigate computational costs.
9:48AM A24.00008: Exotic Soft Modes in 2D Mechanical Metamaterials Yield Powerful New Analytic Prediction Methods  MICHAEL CZAJKOWSKI (Presenter), Georgia Inst of Tech — Maximally Auxetic behavior, where Poisson’s ratio is the most negative, has been explored and identified in 2D perforated elastic sheets in which rigid square elements are connected at the corners by comparatively flexible elastic “hinges”. While these metamaterials are designed to emulate a uniform zero-energy motion of the free hinge material (mechanism), experiments have revealed qualitatively different non-uniform mechanical response. To understand this, we utilize a coarse graining approach, combined with highly detailed finite element simulations and experiments, to reveal that the perforated elastic sheet mechanics is controlled by a novel set of soft modes that correspond precisely to the well-studied planar Conformal Maps. We exploit this very convenient result to demonstrate new and highly accurate methods of analytically solving for linear and non-linear deformations of real materials. This includes a powerful holographic approach, in which large non-linear deformations may be predictably controlled by simple actuation at the boundary. Finally, we introduce a more general methodology for identifying and controlling the soft modes associated with a broad class of 2D mechanisms including the Miura and Eggbox origami patterns.

10:00AM A24.00009: Low frequency vibrations of deformable particles  DONG WANG (Presenter), Yale University — Disk packings at jamming onset exhibit an excess of low-frequency vibrational modes compared to the number predicted by Debye scaling. The excess number of modes, which controls the mechanical response of packings, decreases as the packings are compressed above jamming onset. In this work, we calculate the spectrum of vibrational modes from the eigenvalues of the dynamical matrix for truly deformable particles at jamming onset as a function of the shape parameter $A = \frac{p^2}{4\pi a}$, where $p$ is the perimeter and $a$ is the area of the particle. We show that there is an excess number of low frequency, collective modes in the density of vibrational modes for jammed packings of deformable particles over a wide range of particle shape both above and below the characteristic value $A \approx 1.15$ at which the system is confluent.
10:12AM A24.00010: Hydrodynamic memory and driven microparticle transport: hedging against fluctuating sources of energy*  
SEAN SEYLER (Presenter), Arizona State University — In a viscous fluid, the motion of an accelerating particle is retained as an imprint on the vorticity field, giving rise to the famous $t^{-3/2}$ decay of the velocity autocorrelation. For nonuniform particle motion at low Reynolds number, this hydrodynamic memory effect is captured by the Basset-Boussinesq-Oseen (BBO) equation, which can be derived from various physical perspectives, including (fluctuating) hydrodynamics and kinetic theory. Moreover, finite-temperature dynamics can be modeled by using fluctuation-dissipation to reincorporate (correlated) thermal noise, turning BBO into a generalized Langevin equation. In this work, we numerically solve the BBO equation to simulate driven microparticles and show that hydrodynamic memory generally reduces transport friction, particularly when driving forces do not vary smoothly. Remarkably, this enables coasting over uneven potentials that otherwise trap particles modeled by pure Stokes drag. Our results are germane to questions surrounding intracellular transport efficiency and, more generally, provide direct physical insight into the role of particle-fluid coupling in microparticle transport.

10:24AM A24.00011: Landscapes, nonlinearity, and optimality of ion transport in sub-nanoscale pores*  
SUBIN SAHU (Presenter), University of Maryland, College Park — Biological ion channels evolved to have high transport rates and high selectivity, among other functional characteristics. Synthetic nanoscale pores aim to mimic these properties for applications such as desalination and osmotic power generation.¹ In these systems, ion-ion and ion-channel interactions occur at sub-nanometer distances which entails large electrostatic and dehydration energies.² The balance of these energies determines selectivity and permeation rates. Importantly, the susceptibility of transport and selectivity to minute changes in distances—changes on the order of picometers—is enormous resulting in highly-nonlinear behavior. Biological systems can exploit this susceptibility via variations in protein structure that steer the local electrostatic and structural conditions. We demonstrate how this works in a synthetic selectivity filter and discuss how to probe this system, which will help to experimentally quantify optimal transport conditions and will give the foundation for a robust understanding of more complex biological pores.

8:36AM A25.00002: Universal thermodynamic bounds on nonequilibrium response with biochemical applications JEREMY OWEN (Presenter), Massachusetts Institute of Technology, TODD R GINGRICH, Northwestern University, JORDAN HOROWITZ, University of Michigan — Diverse physical systems are characterized by their response to small perturbations. Near thermodynamic equilibrium, the fluctuation-dissipation theorem provides a powerful theoretical and experimental tool to determine the nature of response by observing spontaneous equilibrium fluctuations. In this spirit, we derive a collection of equalities and inequalities valid arbitrarily far from equilibrium that constrain the response of nonequilibrium steady states in terms of the strength of nonequilibrium driving. Our work opens new avenues for characterizing nonequilibrium response. As illustrations, we show how our results rationalize the energetic requirements of common motifs in biochemical networks, with implications for the thermodynamics of information processing in biological systems.
8:48AM A25.00003: Trade-Offs between Error, Speed, Noise and Energy Dissipation in Biological Processes with Proofreading* JOEL MALLORY (Presenter), ANATOLY BORIS KOLOMEISKY, OLEG A IGOSHIN, Rice Univ —
Fundamental biological processes are highly accurate because the enzymes select the correct substrate out of a pool of chemically similar substrates by activating the so-called proofreading mechanisms. Enzymes with such proofreading ability have remarkably low error rates, e.g., on the order of ~10^{-8}-10^{-10}. While the importance of such proofreading mechanisms is widely accepted, it is still not well understood if enzymes are optimized with respect to certain characteristic properties. We theoretically investigate the trade-offs between four characteristic properties for optimization, i.e., error, speed, noise and energy dissipation, using a discrete-state stochastic framework with a first-passage analysis. Two crucial biological processes are analyzed: DNA replication by T7 DNA polymerase and tRNA selection during protein translation by *Escherichia Coli* ribosome. We developed a quantitative method to rank the importance of the properties. It was determined that the overall reaction speed is the main optimization criterion in both systems, and the energy dissipation comes in second. I will also discuss features of the free energy landscapes that affect the characteristic properties, e.g., error rate and energy dissipation.

9:00AM A25.00004: Observation of Stochastic Resonance in Transport of the DNA between Entropic Traps* SHAYAN LAME (Presenter), Brown University — We describe a nanofluidic system in which stochastic resonance (SR) could be observed in the motion of single DNA molecules. SR is a nonlinear dynamical phenomenon occurring in bistable systems where a weak signal that is below a sensor’s threshold for detection can be boosted and made detectable with addition of white noise. We fabricated nanofluidic devices with embedded pits that give rise to a bistable landscape for confined DNA molecules. An applied periodic pressure generates a weak periodic force on the DNA that represents a sub-threshold signal. We also developed a technique to control the noise inside a nano-fluidic device using electrokinetic forces. By computing the correlation between the periodic driving signal and the measured hoping of molecules between adjacent wells, the occurrence of SR can be revealed by a peak in that quantity as a function of noise level.

9:12AM A25.00005: Over-damped Brownian dynamics in piecewise-defined energy landscapes*  
EE HOU YONG (Presenter), Nanyang Technological University, THOMAS GRAY, University of Cambridge — We study the over-damped Brownian dynamics of particles moving in piecewise-defined potential energy landscapes $U(x)$, where the height $Q$ of each section is obtained from the exponential distribution $p(Q) = a \beta \exp(-a \beta Q)$, where $\beta$ is the reciprocal thermal energy, and $a > 0$. The averaged effective diffusion coefficient $D_{\text{eff}}$ is introduced to characterise the diffusive motion: $\langle x^2 \rangle = 2 D_{\text{eff}} t$. A general expression for $D_{\text{eff}}$ in terms of $U(x)$ and $p(Q)$ is derived, and then applied to three types of energy landscape: flat sections, smooth maxima, and sharp maxima. All three cases display a transition between sub-diffusive and diffusive behaviour at $a = 1$, and a reduction to free diffusion as $a \to \infty$. The behaviour of $D_{\text{eff}}$ around the transition is investigated and found to depend heavily upon the shape of the maxima: energy landscapes made up of flat sections or smooth maxima display power-law behaviour, whilst for landscapes with sharp maxima, strongly divergent behaviour is observed. Two aspects of the sub-diffusive regime are studied: the growth of the mean squared displacement with time, and the distribution of mean first-passage times.

9:24AM A25.00006: An Energy-Accuracy Tradeoff for Nonequilibrium Receptors*  
SARAH HARVEY (Presenter), SUBHANEIL LAHIRI, SURYA GANGULI, Applied Physics, Stanford University — Living systems constantly collect and process information about their surroundings in order to respond to changes in the environment. In particular, single cells are capable of remarkably sensitive chemical concentration sensing using membrane-bound receptors. The physical limit of this sensing capability has been studied since the Berg-Purcell limit in 1977; however, thermodynamic constraints on the design of these sensors have remained theoretically elusive. Here we discuss two novel analytical bounds on signal estimation uncertainty in different limits of the observability of the sensing system. First, we consider estimating a signal based on a fully observable system trajectory, and second we study estimation based only on the coarse-grained occupation time of a subset of states. In the second, more biophysically plausible limit, we derive an energy-accuracy tradeoff for nonequilibrium processes using stochastic thermodynamics and large deviation theory. These lower bounds, supported by numerical simulations, reveal a theoretical limit on the estimation accuracy in terms of the energy consumption of the system and the observation time.

9:36AM A25.00007: Functional Thermodynamics for Arbitrary Maxwellian Ratchets
ALEXANDRA JURGENS (Presenter), JAMES P CRUTCHFIELD, University of California, Davis —
Autonomous Maxwellian demons use structured environments as a resource to generate work
by randomizing ordered inputs and leveraging the increased Shannon entropy to transfer energy
from a thermal reservoir to a work reservoir. To date, determining their functional
thermodynamic operating regimes was restricted to information engines for which correlations
among information-bearing degrees of freedom can be calculated exactly via compact analytical
forms - a highly restricted set of engines. Although information engines may be represented as
finite hidden Markov chains, (i) no finite expression for their Shannon entropy rate exists, (ii) the
set of their predictive features is generically uncountably infinite, and (iii) their statistical
complexity diverges. To solve the problems these pose, we adapt recent results from dynamical
systems theory to efficiently and accurately calculate the entropy rates and the rate of statistical
complexity divergence of general hidden Markov chains. The results allow for precise
determination of the thermodynamic functionality of previously-studied Maxwellian demons, as
well as greatly expand the class of analyzable information engines.

9:48AM A25.00008: Trajectory-Class Fluctuation Theorems: Work Decomposition in
Metastable Information Processing  GREG WIMSATT (Presenter), University of California, Davis,
OLLI SAIRA, California Institute of Technology, ALEC BOYD, University of California, Davis, MATTHEW
MATHENY, California Institute of Technology, SIYUAN HAN, University of Kansas, MICHAEL ROUKES,
California Institute of Technology, JAMES P CRUTCHFIELD, University of California, Davis — Information
processing is physical. It requires particular and precise control of the underlying thermodynamic
system. While system parameters in a cyclic control protocol begin and end in the same
configuration, their intermediate paths determine the evolution of the system's informational
states.
The full work distribution generated during thermodynamic computing is surprisingly complex.
Even if simple, efficient, and accurate, the effective information processing may exhibit
thermodynamically-distinct temporal substages. For example, a bit erasure protocol similar to
that of Jun et. al. (2014 PRL 113.190601) consists of four substages, each linearly changing a
single protocol parameter. Combining substage decomposition with partitioning the microscopic
state-space into thermodynamically-metastable regions, a symbolic dynamics emerges that
naturally decomposes the work distribution into canonical components, with each substage
obeying its own fluctuation theorems. Practically, through describing macroscopic observables,
such as net work, these components can be used to diagnose the predominance of specific
microscopic informational failure and success modes. In this way, the trajectory-class fluctuation
theorems can be used to guide optimal protocol design.
10:00AM A25.00009: Quantifying scale-dependent irreversibility using persistent homology
LERON PEREZ (Presenter), KABIR HUSAIN, University of Chicago, SAMIR CHOWDHURY, Stanford University, BENJAMIN SCHWEINHART, Mathematics, Ohio State University, VAHE GALSTYAN, California Institute of Technology, PANKAJ MEHTA, Stanford University, SAMIR CHOWDHURY, Stanford University, BENJAMIN SCHWEINHART, Mathematics, Ohio State University, VAHE GALSTYAN, California Institute of Technology, PANKAJ MEHTA, Stanford University, SAMIR CHOWDHURY, Stanford University, BENJAMIN SCHWEINHART, Mathematics, Ohio State University, VAHE GALSTYAN, California Institute of Technology, PANKAJ MEHTA, Stanford University — Irreversibility is a measure of whether an observer can distinguish a process from its time reversed version. For physical systems, irreversibility is a fundamental property related to dissipation, breaking of detailed balance and non-equilibrium phenomena. But in any real non-equilibrium system, such as in vivo studies of oocytes or in vitro reconstituted actomyosin, irreversibility is associated with the specific timescales of the system's non-equilibrium dynamics: an observer can be fooled into believing a process is reversible if they watch on the wrong timescales. Here, we generalize persistence homology, a scale-dependent topological characterization method, to quantify irreversibility on different scales. While persistence homology is usually used to detect undirected loops, we define a similarity score inspired by statistical physics that captures information about directed circular fluxes. The resulting persistence barcode quantifies irreversibility on different timescales without any prior knowledge of what the relevant variables are.

Session A26 DBIO GSNP DSOFT DPOLY: Mechanics of Cells and Tissues Across Scales I 403 - Kandice Tanner, National Institutes of Health - NIH - Tag(s): Focus

8:00AM A26.00001: The nematic feedback between cancer cells and the extracellular matrix* [Invited] BO SUN (Presenter), Oregon State Univ — The reciprocal mechanical interaction between cancer cells and their extracellular matrix (ECM) has been shown to play important roles in tumor growth, survival and metastasis. Previous studies have primarily focused on the cell-induced stiffness change of the ECM, which is often characterized using bulk measurement. On the cellular scale, however, ECM produce anisotropic mechanical microenvironment to the cells. Cell generated forces align ECM fibers, and the aligned fiber direct cell polarization and migration through contact guidance. These interactions create a nematic feedback between cancer cells and their local ECM. In this talk I will first discuss quantitative measurements of cellular response to 3D contact guidance cues, which are inevitably noisy and spatially heterogeneous. I will then discuss how cell-induced ECM alignment can be controlled by tumor geometry, and regulate the long-term invasive potential of tumor cells. Together, these results highlight the rich biomechanical functions and powerful control mechanisms of the nematic feedback between cancer cells and extracellular matrix.

*The work is partially supported by the National Science Foundation grant PHY-1844627, as well as SciRIS-II grant from Oregon State University.
8:36AM A26.00002: Mechanical regulation of shape deformation by matrix viscoelasticity in breast tissues  
ALBERTO ELOSEGUI-ARTOLA, ANUPAM GUPTA (Presenter), L MAHADEVAN, DAVID MOONEY, Harvard University — The shape change is one of the phenomena seen in cancerous tissue and the physical mechanism that allows this process to take place has not been clear. The synthetic extracellular matrix (ECM) are typically almost purely elastic. In contrast, the physiological ECM in various tissues, such as brain, liver, adipose tissue, and coagulated bone marrow, etc. are all viscoelastic. Most of the studies to date have focussed largely on elastic properties of ECM. Recently synthetic ECMs have been developed which closely mimic the natural viscoelastic ECMs. In this study, we are further looking into the role of such mechanical properties in inducing the malignant phenotype in normal mammary epithelium MCF10A cell line. Based on these experimental findings we have proposed a mathematical model to capture the qualitative results. This is the first mechanical model to capture this epithelial to mesenchymal transition by changing the viscoelastic properties of ECM. We observe that as you increase the fluidic nature of the ECM, the cell proliferation rate increases, loses its spherical shape, the interface becomes rough and for small viscosities leads to the formation of fingers. We show it in the model that this finger formation can be arrested either by increasing the viscosity or elasticity.

8:48AM A26.00003: Why do rigid tumors contain soft cancer cells?*  
THOMAS FUHS (Presenter), FRANZISKA WETZEL, ANATOL W FRITSCH, Soft Matter Physics Division, University of Leipzig, DAPENG BI, Department of Physics, Northeastern University, ROLAND STANG, STEVE PAWLIZAK, TOBIAS KIESSLING, ERIK MORAWETZ, STEFFEN GROSSER, FRANK SAUER, JÜRGEN LIPPOLDT, FRED RENNER, SABRINA FRIEBE, MAREIKE ZINK, Soft Matter Physics Division, University of Leipzig, LARS-CHRISTIAN HORN, Division of Gynecologic, Breast and Perinatal Pathology, University Hospital Leipzig, BAHRIYE AKTAS, Department of Gynecology, University Hospital Leipzig, KLAUS BENDRAT, Pathology Hamburg-West, MAJA OKTAY, Montefiore Medical Center, AXEL NIENDORF, Pathology Hamburg-West, JOHN S CONDEELIS, Albert Einstein College of Medicine, MICHAEL HÖCKEL, Department of Gynecology, University Hospital Leipzig, M CRISTINA MARCHETTI, M. LISA MANNING, Department of Physics, Syracuse University, JOSEF ALFONS KAES, Soft Matter Physics Division, University of Leipzig — As early as 50 AD, the Roman medical encyclopaedist Celsus recognized that solid tumors are stiffer than surrounding tissue. However, cancer cell lines are softer, which facilitates invasion. This paradox raises several questions: Does softness emerge from adaptation to mechanical and chemical cues in the external microenvironment? Or are soft cells already present inside a rigid primary tumor? We investigate primary samples from patients with mammary and cervical carcinomas on multiple length scales from tissue level down to single cells. We show that primary tumors a highly heterogeneous in their mechanical properties on the tissue level as well as cells do exhibit a broad distribution of rigidities, with a higher fraction of softer and more elongated cells compared to normal tissue. Mechanical modelling based on patient data reveals that tumors remain solid containing a significant fraction of very soft cells. Moreover, it predicts that in such tissues, softer cells spontaneously self-organize into multicellular streams, which we observe experimentally.

9:00AM A26.00004: A tug of war between cell-cell and cell-ECM interaction during tumor invasion* YU LING HUANG (Presenter), SUMIT K DEY, CARINA SHIAU, CINDY WU, YUJIE MA, Cornell University, JEFFREY SEGALL, Albert Einstein College of Medicine, MINGMING WU, Cornell University — Tumor invasion within the interstitial space is critically regulated by the force balance between the cell-cell and cell-ECM adhesion. In this talk, we will present a newly developed 3D tumor model in which tumor spheroids were embedded within collagen matrix, and tumor cell dynamics are subsequently imaged and analyzed. We varied cell-cell and cell-ECM adhesion by using three epithelial cell lines with increasing expression levels of E-cadherin (responsible for cell-cell adhesion) and decreasing expression of integrin (responsible for cell-ECM adhesion). Interestingly, our results demonstrated that the tumor cells at the peripheral of the tumor spheroid underwent a tug of war between the cell-ECM and the cell-cell adhesion. Integrin dependent cell-ECM adhesion promoted tumor invasion, while E-cadhesion mediated cell-cell adhesion inhibited tumor invasion.

9:12AM A26.00005: Understanding the crosstalk between mechanical and chemical guidance in 3D cell migration* PEDRAM ESFAHANI (Presenter), CHRISTOPHER EDDY, JIHAN KIM, RYAN WONG, BO SUN, Physics, Oregon State University — Critical to many physiological and pathological processes, human cells exhibit motility responses to a variety of chemical and mechanical environmental factors. This includes both contact guidance, where cells migrate along the ECM fibers axes; and chemotaxis, in which cells move against the gradient of a chemoattractant. Both cases had been studied extensively. However, there are some synergistic effects that are not fully characterized in 3D cell migration. To reveal the combined effects of mechanical and chemical guidance, and their possible crosstalk, we develop a magneto-microfluidics device to individually control the chemoattractant gradient as well as contact guidance cues. To objectively characterize the cell migration and morphologies, we developed a deep learning based cell tracking method. This novel experimental platform enables us to observe how cells respond to chemotaxis and contact guidance cues in both parallel and perpendicular orientations with respect to each other, as well as in varying strengths. In our continuing work, we will develop a mathematical model to recapitulate our experimental observations and fully characterize the cell response to coupled chemical and mechanical cues.

**9:24AM A26.00006: The role of tissue biophysics in organ selectivity in metastasis** [Invited]
KANDICE TANNER (Presenter), National Institutes of Health - NIH — In the event of metastatic disease, emergence of a lesion can occur at varying intervals from diagnosis and in some cases following successful treatment of the primary tumor. Is there a difference in strategy to facilitate outgrowth? Why is there a difference in latency? Genetic factors that drive metastatic progression have been identified, such as those involved in cell adhesion, signaling, extravasation and metabolism. However, organ specific biophysical cues may be a potent contributor to the establishment of these secondary lesions. Here I discuss using optical tweezer based active microrheology to measure the mechanical cues that may influence disseminated tumor cells in different organ microenvironments. I further discuss in vitro and in vivo preclinical models such as 3D culture systems and zebrafish in efforts of understanding the role of the biophysical properties of the stromal architecture on the earliest stage of organ colonization.

**10:00AM A26.00007: Distinct Roles of Tumor-Associated Mutations in Collective Cell Migration**
RACHEL M. LEE (Presenter), MICHELE I. VITOLO, University of Maryland School of Medicine, WOLFGANG LOSERT, University of Maryland, College Park, STUART S. MARTIN, University of Maryland School of Medicine — Recent evidence suggests that groups of cells are more likely to form clinically dangerous metastatic tumors, emphasizing the importance of understanding mechanisms underlying collective behavior. The emergent collective behavior of migrating cell sheets *in vitro* has been shown to be disrupted in tumorigenic cells but the connection between this behavior and *in vivo* tumorigenicity is unclear. Here we use particle image velocimetry to measure a multi-dimensional collective migration phenotype for genetically defined cell types that range in their *in vivo* behavior from non-tumorigenic to aggressively malignant. By using cells with controlled mutations, we show that Ras activation and PTEN deletion lead to opposing effects on collective migration, despite both mutations being frequently found in patient tumors.

*This research was supported by NIH grants T32-CA154274 and R01-CA154624 as well as AFOSR grant number FA9550-16-1-0052 and the American Cancer Society Research Scholar Grant RSG-18-028-01-CSM.

**10:12AM A26.00008: Precision of flow sensing by self-communicating cells**
MICHAEL VENNETTIILLI (Presenter), Physics and Astronomy, Purdue University, SEAN FANCHER, Physics and Astronomy, University of Pennsylvania, NICHOLAS HILGERT, ANDREW MUGLER, Physics and Astronomy, Purdue University — Metastatic cancer cells have been observed to detect the direction of lymphatic flow by “self-communication”: they secrete a chemical which, due to the flow, does not return to the cell surface isotropically. The secretion rate is low, meaning detection noise may play an important role, but the sensory precision of this mechanism has not been explored. Here we derive the precision of flow sensing for two ubiquitous mechanisms: absorption of the chemical and binding/unbinding to surface receptors. We find that the latter mechanism is significantly more precise due to the fact that absorption distorts the signal that the cell aims to detect. Comparing to experiments, our results suggest that the cancer cells operate remarkably close to the physical detection limit. Furthermore, we predict that they should bind the chemical reversibly, not absorb it, a prediction that is supported by endocytosis data for these cells.

*This work was supported by the Simons Foundation.
10:24AM A26.00009: Classification of healthy and cancerous cells using optical rheology and machine learning*  ERIK MORAWETZ (Presenter), DIMITRIJ TSCHODU, JOSEF ALFONS KAES, Univ Leipzig — The optical stretcher (OS) probes single suspended cells with forces around 100 pN. It has been shown, that in the physiological regime of the OS carcinoma cells tend to be softer than their healthy counterparts. Yet, a clear characterization based on rheological data could not be achieved, even though its correlation with cancerous traits is strongly suggested. We use the high throughput of the OS to perform machine learning based discrimination of individual cells with a breast cancer model. We performed around 30,000 single cell stretching experiments on epithelial cells (MCF-10A), carcinoma cells (MDA-MB 436) and fibroblasts (NIH 3T3), and extracted 33 morphological and rheological parameters to use them for classification with random forest and support vector machine algorithms. Our approach allows us to distinguish among the three cell types with an average sensitivity of 71%. These intial results do not only elevate the importance of the mechanics of cells during tumor progression, but also promise live cell sorting for scientific and medical applications.

*European Research Council (ERC-741350/HoldCancerBack), European Union and the European Social Fond in Saxony (ESF-100234741).

10:36AM A26.00010: Modeling biophysical tumor-stroma interactions in 3D co-cultures of pancreatic cancer cells and pancreatic stellate cells  ERIC STRUTH (Presenter), JONATHAN P CELLI, Univ of Mass - Boston — Mechanical interactions between tumor cells and stromal components impact cancer progression and therapeutic response. Tumors of the pancreas in particular are associated with stiff fibrous stroma impacting growth and drug delivery. Here we use time lapse imaging to study contractile force mediated by adhesions between pancreatic ductal adenocarcinoma (PDAC) cells and pancreatic stellate cells (PSCs), a fibroblastic stromal signaling partner, in 3D culture on laminin rich extracellular matrix (ECM). PDAC cells overlaid on ECM form compact multicellular 3D nodules. When PSCs are introduced there is a profound change in growth behavior culminating in the formation of large connected structures mediated by contractile force of activated PSCs. We analyze this behavior using particle image velocimetry, as well as analysis of nodule size distribution. We use immunofluorescence to characterize the E-cadherin/N-cadherin adhesion in these co-cultures and show that E-cadherin deficient PDAC cells are unable to form adhesions with stromal cells and exhibit decreased contractility as a result. Going forward, we are leveraging this system to model and study drug delivery through fibrotic PDAC stroma and evaluate stromal depletion therapies.
AUSTIN NAYLOR (Presenter), DAVID H MCINTYRE, BO SUN, Oregon State Univ — Tumors are known to remodel the local extracellular matrix (ECM) in which they live. This remodeling causes the stiffness of the ECM to change, and is a major footprint in diagnosing tumors, specifically metastatic solid tumors such as breast or brain tumors. However, most studies up to date conduct bulk rheology or macroscopic rigidity experiments on the remodeled ECM. By using optical tweezers based assays, we are able to probe the local remodeling of the ECM and measure the local micromechanics as the tumor continuously expands and invades into the surrounding ECM. We find that the tumor can introduce strong mechanical anisotropy as well as stiffen the ECM. We find that these remodelings are spatially and temporally dependent on the tumor invasion dynamics. We hypothesize that the found remodelings are dominated by two factors, the volume preservation of cells and the traction force generated by cells. We also test our results by using different geometries of tumors.

Monday, March 2, 2020 8:00 AM - 10:48 AM

Session A27 FIAP: Atomic Structure, Lattice Properties, and Phase Transitions 404 - Nihar Pradhan
8:00AM A27.00001: Electric Field-Induced Metal-to-Insulator Phase Transition in Few-Layered MoSe$_2$* NIHAR PRADHAN (Presenter), Department of Chemistry, Physics and Atmospheric Science, Jackson State University, Jackson, MS-39217, USA, CARLOS GARCIA, Florida State University, Tallahassee, FL 32310, USA, National High Magnetic Field Lab, BHASWAR CHAKRABARTI, Center for Nanoscale Materials, 9700 S-Cass Avenue, Lemont, IL-60439, USA, Argonne National Lab, JAWNAYE NASH, Department of Chemistry, Physics and Atmospheric Science, Jackson State University, Jackson, MS-39217, USA, CHRISTINA S MILLER, Center for Nanoscale Materials, 9700 S-Cass Avenue, Lemont, IL-60439, USA, Argonne National Lab, DHARMARAJ RAGHAVAN, 6525 College Street, NW, Department of Chemistry, Washington DC 20059, Howard University, ALAMGIR KARIM, Department of Chemical & Biomolecular Engineering, S333 Engineering Bldg 1, 4726 Calhoun Rd, Houston, TX 77204, University of Houston, LILIANA STAN, RALU DIVAN, DANIEL ROSENMANN, ANIRUDHA SUMANT, Center for Nanoscale Materials, 9700 S-Cass Avenue, Lemont, IL-60439, USA, Argonne National Lab, STEPHEN A MCGILL, Florida State University, Tallahassee, FL 32310, USA, National High Magnetic Field Lab — The Metal-Insulator phase transition (MIT) is one of the most interesting phenomena to study particularly in two-dimensional transition-metal dichalcogenides (TMDCs). A few recent studies$^{1,2}$ have indicated a possible MIT on MoS$_2$ and ReS$_2$, but the nature of the MIT is still enigmatic due to the interplay between charge carriers and disorder in 2D systems. We will present a potential MIT in few-layered MoSe$_2$ FETs based on four-terminal conductivity measurements. Conductivities measured in multiple samples strongly demonstrate the insulating-to-metallic-like phase transition when the charge carrier density increased above a critical threshold. The nature of the phase transition will be discussed with an existing theoretical model.

8:12AM A27.00002: Partial Switching in Phase Change Material Sb$_2$Te$_3$ Nanowires to an Intermediate Resistance State by Microwave injection POK LAM TSE (Presenter), Univ of Southern California — Microwave (MW) induced resistance responses on Sb$_2$Te$_3$ nanowire (NW) samples were observed at about 3GHz in the MW frequency sweeps from 0 to 4GHz. The step-wise shifts in resistance occurred for varies samples with Ti/Au or Nb electrodes. The magnitude of electrical resistance change depended on the initial resistance of the NW samples and it appeared to be a crystalline transition into an intermediate state before changed to amorphous. Temperature dependences of NW samples at saturated resistance state of $10^8\Omega$ - $10^9\Omega$ exhibited semiconductor property while pristine NW sample at 500 Ω range had metallic property.
Understanding the Phase Behaviour of Pyrochlore Bi$_2$Sn$_2$O$_7$  

WARDA RAHIM (Presenter), University College London, JONATHAN M. SKELTON, University of Manchester, ARON WALSH, Imperial College London, DAVID SCANLON, University College London — Bi$_2$Sn$_2$O$_7$ exists in a number of polymorphic forms, with an α to β transition occurring at ≈400 K and β to γ transition occurring above 900 K.$^1$ The structural model for γ is undisputed (Fd-3m) but there has been a controversy over the structural models of α and β, with two models existing for α, one with 352 atoms per cell (P1C1)$^2$ and other with 88 atoms per cell (C1c1),$^3$ and recently β belonging to space group Aba2 has been reported.$^3$ We perform DFT lattice dynamics calculations using Phonopy$^4$ starting from γ, and map out the potential energy surfaces$^5$ spanned by imaginary mode eigenvectors, with the aim of elucidating the lowest energy structure. This approach successfully takes us from γ to the new structural model suggested for α, and also shows that β is a thermal average of a lower symmetry structure. The success of the method highlights the strength of ab-intio lattice dynamics in predicting the dynamically stable structural model of a compound and can speed up the exploration of different structures for solid-state applications.

Electron Transfer in Contact Electrification*  

BENJAMIN J KULBAGO (Presenter), JAMES CHEN, JUN LIU, THOMAS G THUNDAT, State Univ of NY - Buffalo — Contact causes a weak interaction at the interface of two materials. This interaction transforms the surface of the lattice into a perturbed state. This perturbed surface is modeled as a series of dipoles. These dipoles change the surface state of both materials and contribute to a modified work function. The surface dipoles also induce a potential field at the interface, which drives electron transfer across the gap between the materials. A tribopair of Si and SiO2 is used to demonstrate how the modified work function and potential field drive electron transfer, as described by Schrodinger’s equation. The results will also be compared to experimental data.

*This study is supported by U.S. National Science Foundation (grant number 1662879).
8:48AM A27.00005: Density Functional Investigation of Phase Transition in Silicon Nanomembranes  JOEL AMBRIZ PONCE (Presenter), University of Wisconsin - Parkside, EVAN M MACINTOSH, University of Wisconsin - Milwaukee, WILLIAM D PARKER, University of Wisconsin - Parkside — Silicon is an important material at the center of the microelectronic systems industry, and nanomembranes of silicon have a wide range of material, mechanical, optical, and device applications. Recent experimental advances have achieved nanometer-scale flatness, and membrane properties have been found to depend directly on thickness. Using an atomistic slab model, we simulate the electrons with density functional theory in order to investigate the pressure phase transition of silicon in the membrane from semiconducting diamond phase to metallic beta-tin phase. We vary exchange-correlation approximation, comparing to bulk values in each approximation, and we calculate the electronic and vibrational properties of the membranes.

9:00AM A27.00006: Ultra-High Mechanical Flexibility of 2D Silicon Telluride*  ROMAKANTA BHATTARAI (Presenter), XIAO SHEN, Univ of Memphis — Silicon telluride (Si$_2$Te$_3$) is a two-dimensional material with a unique variable structure where the silicon atoms form Si-Si dimers to fill the “metal” sites between the Te layers. The Si-Si dimers have four possible orientations: three in-plane and one out-of-the plane directions. The structural variability of Si$_2$Te$_3$ allows unusual properties, especially mechanical properties. First-principles density functional theory calculations are performed to determine the critical strain of monolayer Si$_2$Te$_3$. The results show that Si$_2$Te$_3$ can sustain a critical uniaxial tensile strain up to 38% with a breaking stress of 8.63 N/m along the direction of Si dimer, making Si$_2$Te$_3$ the most flexible 2D material reported. Because of the high flexibility, a large strain can be used to tune the band structure, and the bandgap can be reduced by up to 1.5 eV. With increasing strain, the bandgap undergoes an unusual indirect-direct-indirect-direct transition. We also find that the uniaxial strain can effectively control the orientation of Si dimers, which may be beneficial for certain applications.

9:12AM A27.00007: Entanglement entropy of skeletal regions  ALEX VIGEANT (Presenter), Universite de Montreal — Entanglement entropy (EE) provides deep insights about quantum matter. For most groundstates and spatial regions, the EE is dominated by the celebrated area law. However, much less is known about the EE of skeletal regions, i.e. regions without volume such as a line embedded in 2D. When the boundary and volume coincide, there is little understanding about what is encoded in the EE. Here, we study this question using a 2D harmonic lattice model that leads to a relativistic massless scalar (conformal field theory) at low energy. We find new universal contributions to the EE as a function of the geometry of the skeletal region. We also discuss the field theory interpretation, and outline general open questions.
9:24AM A27.00008: Origin of unexpectedly low thermal conductivity in AMg$_2$X$_2$ ($A = \text{Mg, Ca, Yb}, \ X = \text{Sb, Bi}$) * JINGXUAN DING (Presenter), TYSON LANIGAN-ATKINS, Mechanical Engineering and Materials Science, Duke University, MARIO CALDERON CUEVA, ALEXANDRA ZEVALKINK, Chemical Engineering and Materials Science, Michigan State University, ARNAB BANERJEE, Neutron Scattering Division, Oak Ridge National Laboratory, OLIVIER DELAIRE, Mechanical Engineering and Materials Science, Physics, Duke University — Thermoelectric (TE) materials enable direct conversion of heat into electrical energy. The conversion efficiency is inversely proportional to the thermal conductivity, which is dominated by phonons in semiconductors. Zintl compounds AMg$_2$X$_2$ constitute a class of new TE with excellent performance in n-type Mg$_3$(Sb,Bi)$_2$ alloys, with $zT$ up to 1.6 reported so far. Mg$_3$X$_2$ exhibits very low lattice thermal conductivity (~1 W/m/K at 300K), comparable with PbTe and Bi$_2$Te$_3$, despite a much lighter average ionic mass. We report on inelastic neutron scattering (INS) and first-principles studies of the lattice dynamics of AMg$_2$X$_2$. INS provided the temperature dependent phonon density of states. Extra peaks were found at low frequency in Mg$_3$X$_2$ compared to CaMg$_2$X$_2$ or YbMg$_2$X$_2$, possibly originating from softer low-frequency TA phonons. Considerably stronger softening with temperature is also observed in Mg$_3$X$_2$. The anharmonic effects were examined with first-principles simulations, including ab initio molecular dynamics. We present our analysis of the thermal conductivity based on INS and simulations.

*Neutron scattering and first-principles simulation were supported by the US DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Award No. DE-SC0019299.

9:36AM A27.00009: Anharmonic Effects on Phonon Eigenvectors and $S(Q,E)$ in Quantum Paraelectric SrTiO$_3$ * XING HE (Presenter), Duke University, DIPANSHU BANSAL, Indian Institute of Technology Bombay, BARRY WINN, SONGXUE CHI, LYNN A BOATNER, Oak Ridge National Laboratory, OLIVIER DELAIRE, Duke University — The quantum paraelectric behavior and strongly anharmonic lattice dynamics of SrTiO$_3$ have attracted interest for decades. Inelastic neutron scattering (INS) measurements of SrTiO$_3$ reveal an anomalous evolution of transverse acoustic (TA) phonon intensity with temperature as the transverse optic (TO) mode softens. This reflects the incipient ferroelectric (FE) instability near the quantum critical point and couplings between TA and TO phonons. The experimental trends are confirmed and rationalized using DFT simulations including anharmonic renormalization. By analyzing the temperature-dependent force constants (FC) and eigenvectors, it is found that the structure factors of phonon modes change dramatically with temperature, as a direct consequence of the anharmonicity in this system. We identify that changing Ti and O eigenvectors, originating from FC changes in the Ti-O bonds, are responsible for these striking observations. These results establish how temperature-dependent phonon intensities from INS can provide direct insights into the behavior of phonon eigenvectors, and show how first-principles simulations can rationalize such anharmonic effects.

9:48AM A27.00010: Covalency-driven Structural Evolution in the Polar Pyrochlore Series
\( \text{Cd}_2\text{Nb}_2\text{O}_{7-x}\text{S}_x \) *  
DANIEL HICKOX-YOUNG (Presenter), Northwestern University, GENEVA LAURITA, SAMRA HUSREMOVIC, Bates College, JAMES RONDINELLI, Northwestern University — Pyrochlores have attracted considerable interest lately due to their ability to host a variety of interesting phenomena, often derived from their geometrically frustrated interpenetrating sublattices. The triangular arrangement of cations tends to disfavor the coordinated displacements necessary to realize polar structures, but there are a few materials which overcome this frustration and exhibit ferroelectricity. Here we examine the origin and nature of the distortion mechanisms in the oxysulfide series \( \text{Cd}_2\text{Nb}_2\text{O}_{7-x}\text{S}_x \). Using density functional theory, group theoretical methods, and diffraction techniques, we characterize changes in the phase transition under sulfur substitution. We ultimately identify the role of covalent bonding on the Cd-X’ sublattice in shifting the ferroelectric phase transition from proper (x=0) to improper (x=0.25) and eventual elimination (x=0.7). This work sheds light on the origin of polar distortion mechanisms in the pyrochlore structure family, in addition to providing insight into the off-centering mechanisms of complex oxides in general.

10:00AM A27.00011: Relationship between multiple degrees of freedom and oxygen interstitial ordering in rare earth ferrites*  
YANG ZHANG (Presenter), Tsinghua University, WENBING WANG, Fudan University, WANDONG XING, RONG YU, JING ZHU, Tsinghua University — Oxygen interstitials and vacancies, as two kinds of common defects in oxide system, usually play an important role in tuning the microstructure and properties of materials. To understand the tuning mechanism resulting from oxygen doping, the precise positions of these point defects and interaction between them and with other degrees of freedom need to be solved. Here, we report how such information can, for the first time, be obtained from the rare earth ferrite \( \text{LuFe}_2\text{O}_{4+x} \) by high-resolution electron microscopy, atomic-resolution spectroscopy and DFT calculations. The oxygen interstitial ordering and related lattice, charge, spin ordering form a new modulation structure, described by the same modulation vector. Meanwhile, we prove the modulation structure can be affected by changing the oxygen interstitial ordering. The interaction between oxygen interstitials and multiple degrees of freedom presented here provide a direct insight into tuning mechanism of oxygen doping in non-stoichiometric oxide systems.

First Principle Study of Phase Change Properties of Ag- and In-doped Sb-Te compound as Phase Change Material  

HANJIN PARK (Presenter), YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee Univ - Seoul, DASOL KIM, MANN-HO CHO, Department of Physics and Applied Physics, Yonsei University — Ag- and In- doped Sb-Te binary compounds (AIST) are widely attracted as base material of phase change random access memory (PCRAM) with its fast recrystallization time (ps scale) and less energy consumption in the phase transition than GeTe-Sb$_2$Te$_3$ pseudo-binary compounds (group 1) which are most famous as phase change material (PCM). Although AIST has better phase change behavior than group 1, it has much less investigated such as local structural environments or roles of Ag and In atoms. To reveal phase change properties and local atomic behavior in AIST, we performed molecular dynamics (MD) simulations using \textit{ab initio} density functional theory. AgInSb$_{18}$Te$_4$ is selected as an exemplary model configuration. We identify its crystalline phase with various atomic configurations and evaluating their total energy. Amorphous phase, a representative expanded structure to be a 2×2×2 supercell, is constructed with MD simulation which mimics the melt-quenching experiment process. We explore the phase change mechanism by evaluating the radial distribution function, angle distribution function, solid angle distribution, and order parameter, and find that the In atom plays an important role not only in the phase transition process but also in retaining or stabilizing amorphous phase.

Structural order-by-disorder in framework materials*  

GIAN GUZMAN-VERRI (Presenter), Univ de Costa Rica, PETER B LITTLEWOOD, Materials Science Division, Argonne National Laboratory — Systems which do not order at absolute zero due to a large ground state degeneracy can generate new correlations through thermal or quantum fluctuations and attain long-range order. Here, the internal energy of different ground states is the same, but their free energy can differ because the fluctuations around them give a different entropic weighting to each ground state. This is known as order-by-disorder (ObD) and has proven useful in understanding a wide variety of observed ordering phenomena in magnetic systems such as spin ices and frustrated anti-ferromagnets. Outside magnetism, however, the ramifications of ObD physics remain largely unexplored. In this talk, we propose an ObD mechanism is at play in the observed structural transitions in a class of framework materials (MF$_3$ metal triflourides), which display soft manifold lattice dynamics with an inability to go through a symmetry breaking distortion, providing the required ground state degeneracy analogous to that of frustrated magnetism.

*Work supported by the Vice-rectory for Research at the University of Costa Rica and the DOE Office of Basic Energy Sciences, (Materials Science and Engineering Division).
Electrical properties of ferroelectric 1,4-diaminobutane zinc formate crystals under high hydrostatic pressure.*

ANNA SZEREMETA (Presenter), ANDRZEJ NOWOK, Institute of Physics, University of Silesia in Katowice, ADAM SIERADZKI, Department of Experimental Physics, Wroclaw University of Technology, MIROSLAW MACZKA, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, SEBASTIAN PAWLUS, Institute of Physics, University of Silesia in Katowice — 1,4-diaminobutane zinc formate is an example of metal organic frameworks, MOF, which possesses a nicolite-type structure. This compound is characterized by ordered pore structure, formed by a specific arrangement of atoms formed by coordinating bonds between zinc atoms and formate ligands. Due to its multiferroic properties this compound as well as other MOFs can be applied in memory components.

The electric impedance was measured by means of broadband dielectric spectroscopy (BDS). In the studied crystal one relaxation process was observed. At ambient pressure the phase transition was registered at T = 243 K. The application of Havriliak-Negami model in the description of the relaxation process allowed us to determine relaxation time and consequently activation energy as E_a = 0.48 eV.

The hydrostatic pressure affected both the temperature of phase transition and the relaxation process times. After the sample being pressurized up to 1.7 GPa the phase transition temperature increased by ~ 12 K. Simultaneously the relaxation times got longer which was accompanied by the increase of energy barrier.

*The authors are grateful for the financial support provided by the National Science Centre within the framework of the Opus13 project (Grant No. DEC-2017/25/B/ST3/02321).

Cubic and Tetragonal Perovskites from the Random Phase Approximation*

FANHAO JIA (Presenter), Shanghai University, GEORG KRESSE, CESARE FRANCHINI, PEITAO LIU, Faculty of Physics and Center for Computational Materials Sciences, Vienna University, JIAN WANG, Department of Physics, University of Hong Kong, ALESSANDRO STROPPA, CNR-SPIN, Università degli Studi dell'Aquila, WEI REN, Shanghai University — Evaluating many body correlation effects beyond the commonly applied local or semi-local density functionals has received tremendous attention over the past few years. Using the random phase approximation (RPA) to describe the correlation energy combined with the exact exchange energy, we have investigated twenty cubic ABO_3-type perovskites and three prototypical ferroelectric (tetragonal) perovskites. A quantitative analysis and comparison of the performance of various local and semi-local exchange-correlation functionals (XCFs) shows that the inclusion of dynamical correlation effects allows for an excellent account of the structure and energetics of complex ABO_3-type oxides.

8:00AM A28.00001: Electrical actuation of DNA-based nanorobotic structures* [Invited]
FRIEDRICH SIMMEL (Presenter), TU Munich — DNA nanotechnology provides efficient methods for the sequence-programmable construction of mechanical devices with nanoscale dimensions. The resulting nanomachines could serve as tools for the manipulation of macromolecules with similar functionalities as mechanical tools and machinery in the macroscopic world. In order to drive and control these machines and to perform specific tasks, fast, reliable and repeatable actuation are required. In this context, we recently developed an effective method for actuating DNA nanostructures using externally applied electric fields. Electrical control allows us to dynamically drive DNA-based nano-robotic systems, which allows us to move and position molecules on a molecular platform with high speed and accuracy.
In this talk we will focus on the physical characterization of this nanorobotic system using single molecule fluorescence techniques as well as a discussion of the physical mechanisms underlying the motion of the robotic arm. We will also touch upon potential applications of such systems in single molecule biosensing and nanoplasmonics

*DFG SFB 1032 TPA2

8:36AM A28.00002: Real-time magnetic actuation of DNA nanodevices* [Invited]
RATNASINGHAM SOORYAKUMAR (Presenter), Department of Physics, The Ohio State University — Recent advances in biomolecular nanotechnology, in particular DNA nanotechnology, have led to molecular devices with precisely designed motion, mechanical properties, and triggered conformational changes. This talk will report an advancement in this field that opens the door to manipulate molecules and nanomaterials with programmed or user-driven magnetic control in real-time.
The magnetic approach to control DNA nano devices that has been developed allow direct manipulation over the device conformation in real-time up to frequencies of several Hertz with tunable applied forces.[1] The technique relies on coupling the motion of micron-sized magnetic beads, which can be easily manipulated using a low-cost platform, to the nanoscale DNA devices via stiff lever arms. The mechanical lever arm has a high aspect ratio, where its cross-sectional dimensions are on the scale of the nanomachines (~25 nm), but the length is on the scale of the actuator (~ 1 µm). While actuation of nano-hinges and nano-rotors is demonstrated, the robust assembly methods can be translated to a variety of molecular devices.
These results thus establish many key advances over several existing methods to actuate molecular devices including sub-second temporal control, the ability to actuate into many different conformations, and capability to manipulate devices with tunable forces.

*This work was supported by the Army Research Office under contract W911NF-14-1-0289 and the National Science Foundation grant ECCS-1916740.
DNA nanotechnology is one of the most powerful methods for constructing nano-mechanical devices. The ability to actuate these devices on-demand would provide a powerful method for creating dynamic nanomachines that can reconfigure nanostructures, apply precisely defined forces, or spatiotemporally control self-assembly. Typically, DNA nanostructures have been temporally modulated by either 1) introducing external toehold-mediated displacement strands, or 2) incorporating photoswitchable azobenzene nucleotides that can reversibly break hybridization. However, these approaches suffer from drawbacks like 1) the need to introduce an exogenous strand (which is not feasible for many applications, especially in biology), and 2) slow kinetics or undesired reversibility. To circumvent these limitations, we have photo-caged the displacement strands within an existing nanostructure, preventing their action until illuminated. These “spring-loaded” nanostructures are in a metastable state until activated by light, whereupon the high local concentration of the displacement strand will drive irreversible nanostructure reconfiguration. To demonstrate this concept, we designed a nano-mechanical tweezer that switches between the closed and open state with UV light. In effect, this device can apply a nano-mechanical force within a few seconds of illumination, paving the way for dynamic nanomachines that can exert controlled motion. The tweezer was analyzed using AFM, FRET, and computational simulations. Our results demonstrate that the photocaged mechanism is efficient and fast, surpassing externally added strand displacement by almost two orders of magnitude. We envision that this approach will allow for light-activated nanomachines in the future for biophysical studies with cells.

Rapid Reconfiguration and Tunable Control of DNA-based Mechanisms

ALEXANDER E. MARRAS (Presenter), Pritzker School of Molecular Engineering, University of Chicago, LIFENG ZHOU, The RNA Institute, University at Albany, State University of New York, ZE SHI, Department of NanoEngineering, University of California, San Diego, GAURAV ARYA, Department of Mechanical Engineering and Materials Science, Duke University, HAI-JUN SU, CARLOS E CASTRO, Department of Mechanical and Aerospace Engineering, Ohio State University — Precise robotic motion is ever-present within our cells with proteins like ATP synthase and kinesin, functioning much like macroscopic machines using multiple components and defined motion paths. Structural DNA nanotechnology enables researchers to construct mechanisms with similar functionality exhibiting nanoscale spatial and dynamic control by employing its vast physical design space and directed self-assembly methods. Our early work contributed to a library of DNA devices with controllable motion, primarily using strand invasion to bind or displace reconfigurable components with timescales of minutes or longer. Here, we present a strategy for tunable actuation in near real time. We demonstrate an approach using a simple modification to existing devices that adds weak binding sites on complementary components. A network of short DNA handles is activated by increasing cation concentration, raising the avidity of the network to join components. Likewise, reconfiguration is quickly reversible in decreased salt conditions. Actuation kinetics are measured via single molecule FRET using buffer exchange through a simple microfluidic system. This level of temporal control over DNA devices serves as a foundation for real-time manipulation of molecular systems.

Session A29 DSOFT DBIO GSNP DFD: Active Matter in Complex Environments I

Clogging and Depinning of Active Matter Systems in Disordered Media

CYNTHIA REICHHARDT (Presenter), Los Alamos Natl Lab — We numerically examine the transport of active run-and-tumble particles with steric particle-particle interactions driven with a drift force over random disordered landscapes comprised of fixed obstacles. For increasing run lengths, the net particle transport initially increases before reaching a maximum and decreasing at larger run lengths. The transport reduction is associated with the formation of cluster states that become locally jammed or clogged by the obstacles. We also find that the system dynamically jams at lower particle densities when the run length is increased. Our results indicate that there is an optimal activity level for transport of run-and-tumble type active matter through quenched disorder, and could be important for understanding biological transport in complex environments or for applications of active matter particles in random media.
8:36AM A29.00002: Flocking through disorder  AMÉLIE CHARDAC (Presenter), Laboratoire de Physique, Ecole Normale Supérieure de Lyon, SURAJ SHANKAR, Physics department, Harvard University, M CRISTINA MARCHETTI, Department of Physics, University of California Santa Barbara, DENIS BARTOLO, Laboratoire de Physique, Ecole Normale Supérieure de Lyon — We address the robustness of flocking motion to challenging environments.

The emergence of collective motion in groups of motile bodies arises from the competition between rotational diffusion and polar interactions in ensemble of active particles. This minimal picture was successfully employed to account for the large scale dynamics of systems as diverse as starling flocks and self-propelled colloids.

Building on model experiments based on Quincke rollers, I will show how colloidal flocks lose their orientational order when cruising through disordered lattices. I will present a series of quantitative experiments that elucidate the existence of a novel state of active matter that supports orientational order (through a sparse rivers network) but no net transport. In particular, I will show that this state can be seen as a glass of topological defects.

8:48AM A29.00003: Enhanced bacterial motility in colloidal media*  SHASHANK KAMDAR (Presenter), LORRAINE F. FRANCIS, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota-twin cities — The study of the locomotion of biological and artificial microswimmers in Newtonian and non-Newtonian fluids is gaining rapid momentum with applications in many areas such as pathogenicity, bioremediation, and drug delivery. Here, we experimentally investigate the motility of Escherichia coli, a flagellated bacterium, in colloidal media. We systematically vary the size of passive colloidal particles in the mixture from 20 nm to 1 μm and the volume fraction up to 20%. Using confocal microscopy, we image the motion of fluorescent-labeled bacteria and implement an in-house tracking algorithm to obtain the speeds of bacteria. We observe a substantial increase in bacterial speeds (up to 74%) as the colloid volume fraction increases to 3%, followed by a decrease at higher volume fractions. Additionally, we find that increasing the size of colloidal particles results in larger speed enhancement. We construct a model that qualitatively explains our experiments. Our study highlights the unusual locomotion of swimming microorganisms in colloidal suspensions and illustrates the rich dynamics that arises from swimmers’ interactions with their environment.

*This research is supported by the UMN IPRIIME program.
9:00AM A29.00004: Theoretical Framework to Describe Traveling Waves of Bacteria in Porous Media  DANIEL AMCHIN (Presenter), TAPOMOY BHATTACHARJEE, FELIX S KRATZ, JENNA A OTT, SUJIT DATTA, Princeton University — How bacteria move in porous media like tissues and soil underlies processes like infection and bioremediation. However, existing models of how bacteria coordinate their motion at the population scale cannot fully explain collective migration inside porous media. To address this gap in knowledge, we use confocal microscopy to directly track bacteria deep inside transparent porous media. Similar to the case of free liquid, we find that the cells move together in directed, traveling waves following self-generated nutrient gradients. However, unlike the case of free liquid, the wave speed and shape are also regulated by the structure of the porous medium itself. By analyzing the single cell tracks, we characterize how biased “hopping and trapping” of the individual cells generates traveling waves; surprisingly, in stark contrast to the case of chemotaxis in free liquid, we find that hop length bias is not the dominant contributor to this mode of collective migration. Further, we show how the statistical features of single cell motion can be used to develop a continuum model that can describe collective migration in a porous medium over large length and time scales. Together, our work provides new principles to predict and possibly control bacterial migration in complex environments.

9:12AM A29.00005: The role of diversity for collective bacterial migration through diverse environments*  HENRY MATTINGLY, THIERRY EMONET (Presenter), MCDB & Physics, Yale University — Chemotactic bacteria form expanding wave fronts that allow populations to achieve directed expansion towards new territory (Adler J. Science 1966), which can enhance total population growth. But even isogenic populations exhibit phenotypic heterogeneity in their chemotactic properties, and it has been unclear how this affects their directed expansion with growth. We recently showed that diverse cells can travel together in the expanding front by sorting themselves by chemotactic ability, which compensates for their differences by matching ability to the local chemotactic signal (Fu, Kato et al. Nature Communications 2018). However, this places the lowest-performing cells at the back of the wave and at highest risk of falling behind. Here, through a combination of simulations and theory, we demonstrate the conditions in which diversity is valuable (or not) for collectively-migrating populations that grow and encounter varying environments during travel.

Light-Sensing Microbes in Complex Geometries: Surface Adhesion, Gliding Motility and Self-Organization

ALEXANDROS FRAGKOPOULOS, SEBASTIAN TILL, SEBASTIAN RAUM, RODRIGO CATALAN, OLIVER BAEUMCHEN (Presenter), Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Göttingen, Germany — Life on Earth has evolved under the exposure of sunlight and many microbes are equipped with photoreceptors enabling them to perceive light. The microhabitats of such light-sensing microbes include liquid-infused soil, porous rocks and microdroplets, featuring complex geometric architectures that induce strong spatial and temporal fluctuations of light exposure. In these confined environments the cells frequently encounter and interact with interfaces. We discovered that Chlamydomonas reinhardtii, a soil-dwelling photoactive microorganism and biological model system, can reversibly switch its adhesion to surfaces on and off by light (Kreis et al., Nature Physics, 2018). The adhesiveness is regulated by a blue-light photoreceptor and mediated by their two flagella. Once they are attached to a surface, gliding motility sets in and enables the microbes to maneuver on the surface. Based on cell tracking and statistical analysis, we study the surface adsorption and gliding motility of light-sensing microbes and demonstrate how surface gliding, in conjunction with cell-cell interactions, may control the emergence of microbial self-organization in confinement.

Active Brownian filaments: deviations from blob scaling theory and dynamics inside cavities

SHIBANANDA DAS (Presenter), ANGELO CACCIUTO, Columbia University — Active filaments have become the subject of intense scrutiny in recent years because of their biological implications, and their role as a minimal model where the competition between thermal, elastic and active forces can be systematically studied.

Scaling arguments used to predict the radius of gyration of passive self-avoiding flexible polymers have been shown to hold even under the influence of active fluctuations. Via a numerical study we establish how the standard blob scaling theory representations of a polymer breaks down when dealing with active polymers under confinement. We find that the predicted exponents hold only whenever the persistence length generated on the polymer by the active forces is much smaller than the size of the characteristic blob in the scaling theory. Further, when the activity is directed along the backbone of a semi-flexible filament, while confined in a spherical cavity, a highly dynamic scenario emerges. The filament is capable of escaping local and global energy minima and sample, in a quasi-periodic fashion, an ensemble of conformations usually associated to higher bending energies, and previously observed for passive filaments only under very different degrees of confinement or identified as glassy metastable states.

*NSF Grant No. DMR-1703873
9:48 AM A29.00008: Fitness of cell colonies to navigate obstacles*  BO LI (Presenter), Center for Soft and Living Matter, Institute for Basic Science, SUN-MIN YU, YOON-KYOUNG CHO, School of Biomedical Engineering, Ulsan National Institute of Science & Technology, STEVE GRANICK, Center for Soft and Living Matter, Institute for Basic Science — We confront confluent epithelial cells with the need to adapt from wide-channel to narrow-channel growth. Upconversion from single cell, the colony self-organizes to facilitate migration with greater efficiency than that would be accomplished by fluid hydrodynamics. This is traced to long-range mechanical signaling. Stretched leader cells trigger acceleration of the whole group; the resulting velocity difference, in turn, reinforces stretching of the leaders and establishes positive feedback between cell morphology and mechanical strength, as we confirm by direct visualization of F-actin expression, cadherin localization, and the shapes of cells and their nuclei. The relevance is to show how mechanical signaling promotes a 'smart' group navigation strategy in which adaptations of individual cells to the local environment propagate over long distances to benefit the whole colony.

*IBS-R020-D1

10:00 AM A29.00009: Anomalous size-dependence of bacterial diffusion in a micropillar array  POOJA CHOPRA (Presenter), DAVID A. QUINT, AJAY GOPINATHAN, BIN LIU, University of California, Merced — Microorganisms are endowed with phenotypic variations, including diversities in sizes within the same species, which are crucial to their adaptation to living habitats. Here, we investigate how such size variations affect the transport of bacteria in a structured medium, using an array of microscale pillars and a smooth-swimming mutant of Escherichia coli. In contrast to the common belief that a smaller object can navigate solid obstacles more efficiently, we find that the long-time diffusion of individual E. coli actually decreases with decreasing cell size. By varying the pillar geometries, we determine that such anomalous diffusion is governed by the cell size relative to the pillar curvature: cells with smaller sizes relative to the pillar radius are more easily attracted to the pillar surface and are thus effectively “trapped.” We show that such an attractiveness can be well characterized by a size-dependent residency time that the bacterium spends near the pillar surfaces. We develop an agent-based model that purely relies on the geometry of the micropillars, bacteria and residency time. The numerical model agrees reasonably well with our experimental observations, suggesting that solid structures can affect bacterial transport by purely geometric mechanisms.
HAMID REZA KARANI (Presenter), GAŠPER KOKOT, PETIA M. VLAHOVSKA, Northwestern University — The natural habitat of many microorganisms is not a simple homogeneous environment. A ubiquitous observation is that diffusion becomes anomalous with nonlinear scaling between mean-squared displacement and time. A major challenge in biological sciences and condensed matter physics is to uncover these links to gain insight paramount for design of efficient filter membranes, medical diagnostics and drug delivery, and micro-robots operated in heterogeneous environments.

Building on our recently developed tunable colloidal random walker, we combine microfluidics experiments with theory to characterize and quantify the degree of anomalous diffusion. We define high-order measurable microstructural descriptors which carry information on connectivity and clustering of the designed obstacles that offer a convenient platform to test the theoretical predictions. Results reveal a complex nature of interactions between the colloidal random walker and obstacles which goes beyond a simple correlation between the diffusive behavior and obstacle volume fraction. Using scaling analysis, we provide new quantitative measures for predicting how anomalous diffusion emerges in a heterogeneous micro-environment with known morphological information.

OLEKSANDR CHEPIZHKO (Presenter), THOMAS FRANOSCH, Institute for Theoretical Physics, University of Innsbruck — Microswimmers are exposed in nature to crowded media and their transport properties depend in a subtle way on the interaction with obstacles. Here, we investigate a model for a single circle swimmer exploring a two-dimensional disordered array of impenetrable obstacles. The microswimmer follows the surface of an obstacle for a certain time upon collision. An ideal microswimmer [1] can display long-range transport or be localized in a finite region depending on the obstacle density and the radius of circular orbits. Close to the transition lines from two localized states to a diffusive state the transport becomes subdiffusive, which is rationalized as a dynamic critical phenomenon. We determine the non-equilibrium state diagram and evaluate the diffusivities. For the microswimmer subjected to angular noise [2] increasing the noise tends to amplify diffusion, yet large randomness leads to a strong suppression of transport. We rationalize the suppression and amplification of transport by comparing the relevant time scales of the free motion to the mean-free path time between collisions with obstacles.

10:36AM A29.00012: Escape of a Nanoparticle from Cavities in a Porous Matrix  HAICHAO WU (Presenter), BENJAMIN GREYDANUS, DANIEL K SCHWARTZ, University of Colorado, Boulder — Translocation from one cavity to another through a narrow constriction (i.e. a “hole”) represents the fundamental elementary process underlying hindered mass transport of nanoparticles and macromolecules within many natural and synthetic porous materials, including intracellular environments. This process is complex, and may be influenced by long-range (e.g. electrostatic) particle-wall interactions, transient adsorption/desorption, surface diffusion, and hydrodynamic effects. Here, we used a three-dimensional (3D) tracking method to explicitly visualize the process of passive Brownian nanoparticle and self-propelled Janus particle diffusion within periodic porous nanostructures. Specifically, we quantified the spatial dependence of particle motion and the residence times of individual particles in the interconnected confined cavities, allowing us to test hypotheses regarding the effects of self-propulsion on mass transport in confined porous environments.

Session A30 DSOFT GSNP: Morphing Matter: From Soft Robotics to 4D Printing I 502 - Pierre-Thomas Brun, Princeton University - Tag(s): Focus

8:00AM A30.00001: Robotic Morphing Matter as Materialized AI [Invited]  LINING YAO (Presenter), Carnegie Mellon Univ — Morphing Matter are physical materials that are transformable, adaptive and autonomous. They are programmable or pre-programmable with inherent sensing, actuating and computational behaviors across scales from the nano to macro. Situating Morphing Matter in the present, it is materialized AI that makes conventional computers disappear and computation weaves itself into the fabric of everyday life - the ultimate dream of ubiquitous computing envisioned by Mark Weiser. These material systems can be leveraged to design soft robots, self-assembling furniture, adaptive fabrics, and self-folding foods. In this talk, Lining presents the recent works in the Morphing Matter Lab, Human-Computer Interaction Institute of School of Computer Science at Carnegie Mellon University and highlights several robotic morphing materials that weave advanced manufacturing, computational tools, and design thinking. Her team believes that the term “robotics” does not only refer to conventional robotic forms and controls but also connects to the artifacts’ abilities to make decisions, adapt, move, and respond to different stimuli. More information from the lab site:

8:36AM A30.00002: Spider-morphs: Designing 3D shapes from multiple tapered \textit{elasticae}.
MINGCHAO LIU (Presenter), LUCIE DOMINO, DOMINIC VELLA, Mathematical Institute, University of Oxford — Foldable three-dimensional (3D) structures are important in a wide range of engineering applications. Transforming flat two-dimensional sheets with cuts into 3D structures, or kirigami, has emerged as an exciting manufacturing paradigm. However, achieving a particular 3D shape usually requires multiple materials and/or the application of external stimuli. Here we introduce a design framework for forming approximately axisymmetric 3D structures by harnessing the buckling of multiple tapered elastic sheets (the legs) connected in a central portion (the body). Together this creates a spider-like structure that morphs in 3D: a spider-morph. We design spider-morphs that deform into axisymmetric 3D structures with positive, negative, and variable Gaussian curvature. We conduct both numerical simulations and physical experiments to verify our theoretical approach.

8:48AM A30.00003: Reshapable groovy sheets  ANNE MEEUSSEN (Presenter), Designer Matter, AMOLF, MARTIN VAN HECKE, Leiden University — Most mechanical metamaterials are designed for a single function. But multifunctional metamaterials need to respond distinctly to different kinds of mechanical input. We show that groovy sheets---thin sheets with parallel corrugations---form patterns of snap-through defects and shift into different shapes, depending on how they are actuated. We show that geometric nonlinearities and frustration lie at the heart of the reversible yet multistable behaviour of groovy sheets.

9:00AM A30.00004: Under pressure: Mechanics of swelling hydrogels under confinement
JEAN-FRANCOIS LOUF (Presenter), NANCY LU, MARGARET O'CONNELL, Princeton University, H. JEREMY CHO, Mechanical Engineering, University of Nevada Las Vegas, SUJIT DATTA, Princeton University — Hydrogels are polymer networks that can absorb considerable amounts of water. They are thus promising additives to soil in arid conditions, increasing water retention and decreasing the need for plant irrigation. However, field measurements indicate that confinement in soil alters both the ability of hydrogels to hold water, as well as the properties of the soil itself—and the underlying physical reasons remain unknown. We have developed the ability to directly visualize hydrogel swelling within a three-dimensional porous medium that mimics soil. Using this platform, we quantify how the presence of the solid grains around a hydrogel hinders its ability to swell. By testing different applied loads and sizes of porous media, we show that the deformations of the hydrogel and the medium can be described by a balance between the osmotic swelling pressure of the hydrogel, the local elastic strain energy needed for the hydrogel to swell into the pores, and the frictional interactions holding grains together. Our results thereby provide a general framework by which hydrogel swelling can be understood, potentially improving their ability to help plants survive drought, and informing applications in new settings like oil fields and lab-on-a-chip devices.
9:12AM A30.00005: Delicate and Precise Grasping using Kirigami*  DOUGLAS HOLMES
(Presenter), YI YANG, KATHERINE VELLA, Boston Univ — The ability to precisely and delicately handle deformable, fragile, slippery, or microscale objects remains a significant challenge for robotic grippers. In this work, through a combination of experiments and modeling, we demonstrate how the mechanical actuation of kirigami shells enables both delicate and precise grasping of a wide variety of objects. The design is geometric, so it can be adapted to many material systems, and the geometry was optimized to produce a structure with a high carrying capacity and a low actuation force. We combined individual kirigami grippers in series and in parallel to form gripper arrays capable of grasping slender rods, and simultaneously grasping multiple objects and moving them without changing their relative orientation and position. The kirigami gripper is scalable, lightweight, and can be incorporated with commercially available robotic system to perform delicate and high precision grasping.

*We gratefully acknowledge the financial support from NSF through CMMI-1824882.

9:24AM A30.00006: Design and mechanics of complex inflatable networks  TREVOR J JONES, ETIENNE JAMBON-PUILLET, PIERRE-THOMAS BRUN (Presenter), Princeton University — The use of compliant materials to accomplish complex movements, made difficult or impossible by rigid materials, has inspired a wide array of soft robots. We have recently introduced “bubble casting”, a novel assembly method that leverages the fluidity of curing silicone elastomers to easily fabricate soft actuators with complex shapes. While liquid, an elastomer is first injected in a tube or tubular mold. An inner void is subsequently sculpted by injecting an elongated bubble into the channels, leaving elastomer only on the channels walls. As the elastomer cures into an elastic solid, gravity passively drains the top part of the channel and lifts the bubble to form the final actuator whose cross-section consists of a thin upper membrane attached to a thick lower beam. Here we explore the mechanical response of our soft actuators: while linear actuators are found to curl when inflated owing the asymmetry of their cross section, the deformation of closed shapes, such as loops, or that of connected networks is more intricate. We will discuss the experimental results we obtained with these programmable robots, and the models we have derived to rationalize our observations.

9:36AM A30.00007: Buckling and Metastability in 2D Impurity Arrays  ABIGAIL PLUMMER (Presenter), DAVID R. NELSON, Harvard University — We study a periodic array of impurities that produce local dilations, embedded in a two-dimensional crystalline solid that can buckle out of the plane. These arrays provide a simple elastic model of shape memory. As the size of each impurity increases (or the relative cost of bending to stretching decreases), it becomes energetically favorable for the impurities to buckle either up or down, allowing for a vast number of metastable states. Using discrete simulations and continuum theory, we consider the buckling of isolated impurities as well as impurity arrays, guided by an analogy to the Ising antiferromagnet. We characterize the buckling transition and conjecture ground states for systems with triangular and square lattice microstructures.
4D printing of mechanically programmable shape-shifting liquid crystal elastomers  

MORGAN BARNES (Presenter), RAFAEL VERDUZCO, Rice Univ — 4D printing is a promising method to develop actuators for applications in soft-robotics and biomedical devices where complex structures are required that might be difficult to create using traditional fabrication methods. However, most 4D printing relies on shear alignment upon printing to align liquid crystal or composite fibers that undergo anisotropic expansions/contraction when actuated. This limits the types of shape changes available to researchers as determining the print path required to induce a desired shape change is not trivial. Here, we use a new reactive printing method that enables the printing of a dual network liquid crystal elastomer (LCE) which can be mechanically programmed into the desired shape change. First, a thiol-acrylate Michael addition is completed upon printing an LCE oligomer solution into a catalyst bath. Next, the printed structure is dried, deformed to a desired shape change, and UV cured to crosslink excess acrylates in the network. The resulting LCE transforms between the printed and mechanically deformed shape when heated and cooled, respectively, and is capable reversible strains up to 100%. We demonstrate the versatility of this method by printing a variety of LCE actuators which could not be printed using conventional 4D printing methods.

Versatile and controllable shape morphing using twisted-and-coiled actuators  

JIEFENG SUN (Presenter), JIANGUO ZHAO, Colorado State University — Various shape morphing strategies have been investigated in recent years. Even though existing work has demonstrated complicated shape morphing (e.g., a human face), they can only deform along with a predefined pattern. We propose a different strategy: strategically embedding soft actuators into a soft body to enable versatile shape morphing by actively controlling the deformation of each soft actuator. We utilize a soft actuator, twisted-and-coiled actuators (TCAs), which can be easily fabricated from low-cost sewing threads to generate large force and displacement. We also leverage a jamming-based method to change the stiffness of soft bodies. With these two elements, we realize a shape morphing module that can quickly transform to and hold versatile shapes to adapt to various environments. Different modules can also be combined to generate more complicated shapes. We demonstrate a fast grasping and holding process, which consumes no energy, with a gripper with two shape morphing fingers. We also demonstrate a morphing surface that can hold different 3D configurations. We envision that the concept can be applied to soft robots, medical robots, morphing structures, etc.

10:12AM A30.00010: Controlled Shape-morphing of Elastic Sheets by Chemically-driven Fluid Flow*  RAJ KUMAR MANNA (Presenter), OLEG SHKLYAEV, 1Department of Chemical Engineering, University of Pittsburgh, HOWARD A STONE, Department of Mechanical and Aerospace Engineering, Princeton University, ANNA BALAZS, 1Department of Chemical Engineering, University of Pittsburgh — Shape-morphing of two-dimensional (2D) materials into complex three-dimensional (3D) structures provides a wide range of applications from wearable electronics to soft robotics. Convective flows generated by the appropriate chemical reactions provide a mechanism for shape transformation of elastic 2D materials submerged in a flow environment. Here, using a computational model that incorporates interrelated chemical, hydrodynamic and mechanical interactions, we demonstrate how a (2D) enzyme-coated elastic sheet can spontaneously morph into 3D structures in response to specific chemical stimuli introduced in the fluid-filled microchamber. We outline design principles for creating a multi-responsive elastic sheet that self-morphs into different 3D structures. We further develop a theoretical model based on lubrication theory for thin liquid films coupled to the deformations of an elastic sheet that rationalizes our simulation observations and provides insights into the initial dynamics of the transformation of elastic sheets within the microfluidic system.

*The work was supported by NSF Grant 1740630, Centers for Chemical Innovation Phase I, Center for Chemo-mechanical Assembly and computational facilities at the Center for Research Computing at the University of Pittsburgh.

10:24AM A30.00011: Morphing Surfaces formed by Liquid Crystal Elastomer Coatings: Design and Modeling*  ROBIN SELINGER (Presenter), YOUSSEF MOSADDEGHIAN GOLESTANI, JONATHAN SELINGER, SAJEDEH AFGHAH, MICHAEL P VARGA, Kent State Univ - Kent — The suction cups on the arms of an octopus are morphing structures that can actuate to adhere to a non-porous surface, and then release on command. To mimic this functionality in an engineered material, we design and model dynamically morphing surface coatings composed of stimuli-responsive liquid crystal elastomers (LCE). In these programmable materials, patterned molecular orientation gives rise to complex shape transformations, driven by change of temperature. Using a combination of Finite Element Modeling (FEM) and analytical calculations, we design and characterize director patterns that create a variety of surface topographies: a lattice of spikes and/or indentations, an array of parallel microchannels or ridges, and patterned zones of positive and negative Gaussian curvature. To drive a thin film coating to morph into a lattice of suction cup-like indentations, we design an LCE with an array of topological defects, where the orientation of the director near each defect core follows a sigmoid function. By tuning adjustable parameters that define the structure of the defect core, we control the resulting surface topography.

10:36AM A30.0001: Active rapid morphing mechanism of the Venus flytrap  JEONGEUN RYU (Presenter), YOËL FORTERRE, IUSTI, CNRS, Aix-Marseille University, Marseille, France — The Venus flytrap (*Dionaea muscipula*) exhibits rapid snapping in about 100 ms, which has long fascinated scientists as one of the fastest botanical movements. Its motion is mechanically initiated by stimulating the trigger hairs, and accelerated by using the snap buckling instability of the poroelastic curved shell geometry of the leaves. At a macroscopic level, its kinematics and dynamics are well understood. However, the mechanism to actively change its natural curvature remains unknown. Here we first characterise the ‘active’ dynamics of the Venus flytrap by removing the buckling instability. We probe the change of its mechanical properties before and after triggering the closure and investigate the key components driving this rapid motion at a microscopic level. Then we elucidate the physical mechanisms underlying the rapid morphing of the Venus flytrap. A better understanding of active movements in plants could allow us to design new rapid and programmable morphing structures.

Session A31 DSOFT DFD GSNP: Microflows Meet Soft Matter I: Crystals, Colloids, & Particles 503 - Ivan Christov, Purdue Univ - Tag(s): Focus

8:00AM A31.00001: Wetting and dewetting of nanoscale films of nematic liquid crystal*

[Invited]  LINDA CUMMINGS (Presenter), LOU KONDIC, New Jersey Inst of Tech, MICHAEL LAM, Coastal Hydraulics Laboratory, ENSELA MEMA, Mathematics, West Point Military Academy — The evolution of ultra-thin films (tens of nm) of nematic liquid crystals (NLCs) is considered. Such free-surface films can undergo complex dewetting behavior, as observed in experiments. We present a simplified thin-film model for the free surface evolution that includes strong spatially-varying planar anchoring at the substrate, and weak antagonistic anchoring at the free surface. A number of large-scale simulations are presented, showing good qualitative agreement with experiments. Ongoing work including the effect of spatially-varying electric fields on film evolution is briefly highlighted.

*NSF DMS 1815613
8:36AM A31.00002: A phase-field model for a modulated-disordered interface with varying density* EDUARDO VITRAL (Presenter), PERRY H. LEO, JORGE VINALS, University of Minnesota — Soft modulated phases have been shown to undergo complex morphological transitions at high temperatures, in which the orientation of their layers and the Gaussian curvature play a major role. This is the case of smectic films under thermal treatment, where focal conics can be reshaped into conical pyramids and concentric ring structures. While evaporation-condensation mechanisms have been theoretically and numerically studied for a smectic-isotropic interface, hydrodynamic stresses at the interface and their resulting flows are yet to be analyzed. This is particularly challenging in the case of a smectic-air boundary, due to the large density ratio between the phases. We derive a phase-field model that accounts for a varying density field and represents the smectic layering by an order parameter. The resulting equations govern the evolution of an interface between a modulated and a disordered phase with distinct densities, being able to account for compressibility effects at the interface and accommodate topological transitions. By integrating the equations in time, we investigate the interfacial flow on a disturbed smectic, and verify the implementation based on the derived dispersion relation.

*We thank the support from UMN MSI and XSEDE. EV has been supported by UMN DDF.

8:48AM A31.00003: Non-reciprocal motion in superparamagnetic magnetoelastic membrane patches* CHASE BRISBOIS (Presenter), Northwestern University, MYKOLA TASINKEVYCH, Department of Physics, University of Lisbon, MONICA OLVERA DE LA CRUZ, Northwestern University — Magnetic fields allow for the remote manipulation of bio-orthogonal microscale robots that have applications in drug delivery or microsurgery. We develop a theoretical approach for autonomous locomotion of superparamagnetic membranes through viscous media. Oscillations in triaxial magnetic fields induce non-reciprocal, wave-like motions on circular membrane patches. We show how the strength, angle and frequency of rotating magnetic fields affects circumferential and radial membrane wave propagation. Using the lattice Boltzmann method, we implement hydrodynamic interactions that reveal the flow field of the surrounding fluid and show how truncated circular patches swim at low Reynolds numbers.

*This work is funded by the Center for Bio-Inspired Energy Science (CBES), and Energy Frontier Research Center funded by the Department of energy. DE-SC0000989.

9:00AM A31.00004: Particle motion nearby rough surfaces CHRISTINA KURZTHALER (Presenter), AMIR PAHLAVAN, LAILAI ZHU, HOWARD A STONE, Department of Mechanical and Aerospace Engineering, Princeton University — Interactions between particles and boundaries are ubiquitous in nature and play a pivotal role in microfluidic applications. Here, we study the hydrodynamic couplings between particles and solid, rough boundaries that are characterized by periodic and random surface shapes. Using the Lorentz reciprocal theorem, we derive analytical expressions for the mobility tensor of a spherical particle and investigate its gravity driven sedimentation near a random rough wall. Our theory and experiments show that the particle exhibits translation perpendicular to the gravitation force, in striking contrast to its motion near a planar wall, and follows the surface shape in close proximity to the boundary. Overall, our results should lay the foundation to study microswimmer motion close to random, heterogeneous boundaries.
Growth of clogs in parallel microchannels

EMILIE DRESSAIRE (Presenter), Department of Mechanical Engineering, UCSB, EMMANUEL VILLERMAUX, Universite Aix Marseille, ALBAN SAURET, Department of Mechanical Engineering, UCSB — During the transport of colloidal suspensions in microchannels, the deposition of particles can lead to the formation of clogs. Once a clog is formed in a microchannel, advected particles form an aggregate upstream from the site of the blockage. This aggregate called filter cake grows over time, which leads to a dramatic reduction of the flow rate. We present an analytical description that captures the time evolution of the volume of the aggregates. The results are compared with experiments performed using a pressure-driven suspension flow in an array of parallel microchannels. The coupled dynamics of the aggregates is key to bridge clogging at the pore scale with macroscopic observations of the flow rate evolution at the filter scale.

Flow and Fouling in Elastic Membrane Filters with Complex Pore Morphology

PEJMAN SANAEI (Presenter), Mathematics, New York Institute of Technology, SHI YUE LIU, ZHENGYI CHEN, Mathematics, New York University, Shanghai — Filtration technology has been increasingly used for industrial purposes and the study of membrane science is beneficial for filtration efficacy prediction and performance analysis. Real membranes have complex geometry, with pores inside the membrane branch and interconnected with each other. Membrane fouling, as an indispensable consequence for removing particles, occurs in course of filtration process and deteriorates the membrane permeability. In this work, we consider standard blocking as a fouling mechanism, which decreases membrane porosity. However, for membranes with elastic materials, the pressure within the membrane results in membrane pore radius expansion and further influences the filtration performance. We present a mathematical model with multi-layer bifurcating interior morphology, where two pervasive filtration forcing mechanisms are considered: (i) constant pressure drop; and (2) constant flux through membrane.

9:36AM A31.00007: Hydrodynamic shock and instability in sedimenting colloidal suspensions along a surface*

SHAKE KARAPETYAN (Presenter), SAM WILKEN, MICHIO TANAKA, BRENNA SPRINKLE, ALEKSANDAR DONEV, PAUL M CHAIKIN, New York Univ NYU — We combine experiments, large-scale simulations, and a continuum model to study the emergence of a coherent density profile in a suspension of passive particles sedimenting near an inclined plane. Sedimenting colloids form a shock when there are sharp density gradients in the suspension and agree well with a solution to a modified Burger's equation. We also observe the formation of an instability at the front of the shock that is different from the case of driven microrollers¹ and other fluid-like instabilities in that the amplitude does not grow exponentially. The instability is characterized by a wavelength controlled by the gravitational height, the typical height of the particles above the inclined plane.

*This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-1420073.

9:48AM A31.00008: Unsteady Sedimentation of a Colloidal Sphere in a Horizontal Channel*

LAUREN ALTMAN (Presenter), DAVID G GRIER, New York Univ NYU — The elementary system of a sphere sedimenting through a viscous fluid under gravity becomes remarkably difficult to treat analytically when the host fluid is bounded by parallel horizontal walls. The simplest treatment, due to Oseen, involves linear superposition of Faxén's classic single-wall correction to the mobility. We investigate the limits of the Oseen superposition approximation in this canonical system by measuring the trajectories of colloidal spheres sedimenting through water in slit pores. Measurements are performed by lifting solid or liquid droplets to the top glass-water interface with holographic optical tweezers and tracking their descent with nanometer precision by interpreting holographic video microscopy data with the Lorenz-Mie theory of light scattering. This analysis also yields precise measurements of the particles' refractive indexes that can be interpreted with Maxwell Garnett effective medium theory to estimate the particles' buoyant masses. Agreement between the hydrodynamic theory and these measurements establishes the limits of validity of the measurement technique and the hydrodynamic model.

*This work was supported by the MRSEC program of the NSF under Award Number DMR-1420073, as well as by the SBIR program of the NIH under Award Number R44TR001590.
Stresslet of colloidal suspensions in a spherical cavity

EMMA DEL CARMEN GONZALEZ GONZALEZ (Presenter), ROSEANNA ZIA, Chemical Engineering, Stanford University — Early studies of force and torque hydrodynamic functions for a colloid in a spherical cavity\(^1\text{-}^3\) paved the way to more sophisticated computational methods, such as the Confined Stokesian dynamics algorithm\(^4\text{-}^5\). However, these studies are restricted to equilibrium situations owing to the lack of stresslet coupling. Currently, the study of confined colloids is gaining traction given its direct application to intracellular transport. In cells, the dynamics are driven out-of-equilibrium by active transport, concentration gradients, and metabolic responses. Furthermore, a predictive model for intracellular transport needs to characterize rheological parameters (\(\eta, OP, \ldots\)), this is only possible by accurately incorporating the stresslet coupling. Here we present the exact solution for stresslet hydrodynamic functions of a colloid in a spherical cavity, and its application to more concentrated suspensions via the Confined Stokesian dynamics algorithm. With this algorithm, we predict high-frequency dynamic viscosities that show non-monotonic behavior throughout the confined domain.

Shape induced segregation and anomalous diffusion of particles under confinement

JIYUAN LI (Presenter), ABHINENDRA SINGH, XIKAI JIANG, University of Chicago, JUAN P. HERNANDEZ-ORTIZ, Colombia/Wisconsin One-Health Consortium, Universidad Nacional de Colombia-Medellin, JUAN DE PABLO, HEINRICH M. JAEGGER, University of Chicago — Diffusive behaviors in a confined environment is a fundamental problem that finds applications in various areas of science and engineering, including cells, supercooled liquids, and mesoporous materials, etc. These behaviors should intuitively be affected by particle shapes and concentrations. However, these effects remain poorly understood due to the computational difficulties in solving hydrodynamic interactions (HIs) between arbitrarily shaped particles in confined space. Here, an immersed boundary–General geometry Ewald-like method (IB-GgEm) is adopted to simulate the dynamics of a mixture of particles of different shapes and relative concentrations with the consideration of both short- and long-range fluctuating HIs. We find that increasing the fraction of cylinders induces particle segregation, where the spherical particles are pushed towards the wall, while the cylinders prefer to be near the center of the cavity. In addition, increasing the fraction of cylinders also affects the diffusive-to-anomalous transition and the degree of anomaly. We believe that our results offer a pathway to understanding fundamental questions in biology, e.g., anomalous macromolecular diffusion in cells, and serve as a route to design and optimize drug-delivering platforms.
10:24AM A31.00011: Equilibrium diffusion, thermodynamics, and rheology of confined Brownian suspensions*  ALP SUNOL (Presenter), ROSEANNA ZIA, Department of Chemical Engineering, Stanford University — Computational modeling of spherically confined, hydrodynamically interacting colloids has led to a new framework for modeling biological cells. While modeling of cellular behavior is robust in atomistic-scale structural biology, with little time evolution, and kinetics-based systems-biology, which abstracts away space, many cellular processes operate over colloidal length scales, where interparticle interactions and particle motion play central and nontrivial roles in whole-cell behavior. Here, we present the results of our dynamic simulation studies using both Confined Stokesian Dynamics and Confined Brownian Dynamics algorithms. We compare the role of thermodynamic structure induced by confinement on the short- and long-time transport properties with and without hydrodynamic interactions. Additionally, we find relations between the variables of particle size and volume fraction within the confinement to rheological properties, such as osmotic pressure and viscosity, and highlight how these findings can play an important role in understanding how prokaryotic cells regulate their function.

*This work was supported in part by a National Science Foundation DGE grant No. 1656518 as well as a J. Hewes Crispin and Marjorie Holmes Crispin Stanford Graduate Fellowship.

10:36AM A31.00012: Auto-phoretic nanorods driven up the wall by gravity  QUENTIN BROSSEAU (Presenter), University of Pennsylvania, FLORENCIO BALBOA USABIAGA, Simons Foundation, ENKELEIDA LUSHI, Applied Mathematics, New Jersey Institute of Technology, YANG WU, Department of Chemistry, New York University, LEIF RISTROPH, CIMS, New York University, MICHAEL WARD, Department of Chemistry, New York University, MICHAEL JOHN SHELLEY, JUN ZHANG, CIMS, New York University — Gravitaxis is the directed upward motion of micro-organisms against gravity, and is observed for a few ciliated organisms like Chlamydomonas, Euglenas or Paramecium. Lacking a dedicated sensor, their gravitactic response relies on bottom-heaviness or shape anisotropy to induce a bias in their swimming direction.

Here we study the gravitaxis of heavy self-electrophoretic Janus nanorods that move upwards on a steeply inclined substrate. Comparisons in experiments and simulations between homogeneous and bottom-heavy nanorods reveals two mechanisms contributing to the gravitactic response of the latter: a buoyancy torque and hydrodynamic interactions with the wall. We show that lubrication forces induce an effective fore-aft asymmetry on nanorods that reinforces the orientation bias to move up the steep wall against gravity.
When microrollers meet anisotropy

ERNEST VAN DER WEE (Presenter), Northwestern University, RAMAKRISHNA KOTNI, ALFONS VAN BLAADEREN, Utrecht University, MICHELLE R DRISCOLL, Northwestern University — Driven colloidal particles can display an array of collective effects. Here we study a system in which these collective interactions are largely driven by hydrodynamics: microrollers. Microrollers can be experimentally realized by driving (weakly) magnetic colloidal particles suspended in a liquid above a wall with a rotating magnetic field. Using fluorescence microscopy and particle tracking we can study their response to the field, as well as their collective interactions. Here, we study how anisotropy in the shape of the rollers alters their dynamics. We explore the collective response of rod-shaped hematite-silica microrollers and how this response is modified by adjusting their concentration and shape. Additionally, we study the role of the alignment of the magnetic moment of the rollers with respect to the anisotropic axis of the rollers themselves. Finally, we will show how these microrollers interact with passive obstacles.

Mechanophore with analogue force readout in a polymer network

KAIKAI ZHENG (Presenter), YIFAN ZHANG, Institute for Basic Science, LINGXIANG JIANG, Jinan University, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, STEVE GRANICK, Institute for Basic Science — Polymer networks are fundamental from materials science to cellular biology, however their intrinsic properties are normally characterized using common ensemble-averaged methods. In this work, we introduce a synthetic mechanophore to read out the local force, and to show the proof of concept we covalently link it into a PMA (polymethylacrylate) network as crosslink. We observe differing local intensities of different mechanophores as well as their differing evolution during stretch, and from this quantify locally non-affine responses. Interestingly, it seems to be the single-molecule response yet with analogue force readout inaccessible using conventional mechanophores based on irreversible bond scission mechanisms.

Extending the Real Elastic Network Theory to Account for Cooperative Effect of Cyclic Defects

TZYY-SHYANG LIN (Presenter), Massachusetts Institute of Technology MIT, RUI WANG, University of California, Berkeley, JEREMIAH JOHNSON, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — The real elastic network theory, or RENT, has provided insights into how cyclic defects within a phantom network lead to significant lowering of the modulus of polymer networks. However, RENT is a linear theory derived under the ideal loop gas assumption, which is strictly true only in the limit of infinite dilution of defects, rendering RENT inapplicable for networks with nonnegligible loop fraction. To go beyond the linear regime, the cooperative effects of multiple loops are investigated. First, the multi-defect effect is studied through the Virial expansion, in which the behavior of adjacent loops is compared to isolated loops. In most cases, it was found that the Virial coefficients vanish identically except for the first order terms, indicating that the results for the linear approximation are exact. Next, a nonperturbative probability-based theory was developed to capture the nonlinear behaviors. As expected, the nonlinear theory gave predictions almost identical to that of the linear theory in the small loop fraction regime. However, as loop fraction is increased, the nonlinear theory predicts a significant negative deviation from the linear theory, qualitatively matching the behavior observed in experiments.

WITHDRAWN ABSTRACT

Reactivity-property relationships in photocontrolled polymer networks

JULIA KALOW (Presenter), Chemistry, Northwestern University — In polymer networks based on dynamic covalent bonds, changes in reactivity can be translated into macroscopic responses. Light offers precise, tunable, and noninvasive spatiotemporal control over molecular reactivity. In polymer networks based on dynamic covalent bonds, these changes in reactivity can be translated into macroscopic responses. The Kalow lab has designed crosslinks that allow us to tune the thermodynamics and kinetics of dynamic covalent bonds with light, including visible light, based on the conformation of an adjacent photoswitch. When incorporated into polymer networks, the stability or lifetime of these dynamic covalent bonds can be tuned with light. I will discuss our efforts to elucidate the molecular mechanism underlying these macroscopic changes, as well as rational optimization of the photoswitch to enable applications in 3D cell cultures and recyclable elastomers.

Belousov Zhabotinsky reaction systems: How “far” is far from equilibrium?

VANDANA RAJPUT (Presenter), PRATYUSH DAYAL, Indian Inst of Tech Gandhinagar — Understanding the behaviour of dynamical systems that are far from equilibrium has been a challenge for science and engineering. Belousov Zhabotinsky (BZ) reaction is a system that exhibits chemical oscillations due to periodic oxidation/reduction of the metal ion catalyst. In essence, the oxidized catalyst concentration varies with time crossing its steady state (SS) concentration with each oscillation. Mathematically, the Limit Cycles (LC), which represent self-sustained oscillations occur when the equilibrium (or SS) loses its stability via Hopf bifurcation. The LC resulting from HB, typically, surrounds the equilibrium, which is analogous to variation of oxidized catalyst concentration around SS. Using the Oregonator model, however, we demonstrate that the equilibrium point can be outside the LC under special conditions. Further, we use the nonlinear stability analyses and calculate Lyapunov coefficients to quantify how “far” the LCs are from the corresponding “equilibrium”. In addition, we predict the amplitude and frequency of oscillations, which are in good agreement with our simulation results. These findings can not only be used to characterise behaviours of nonlinear dynamical systems but can also be used to design smart functional materials.

General Approach to Photo-Crosslink Bottlebrush Polymers

RENXUAN XIE (Presenter), SANJOY MUKHERJEE, VERONICA REYNOLDS, CHRISTOPHER BATES, MICHAEL L. CHABINYC, University of California, Santa Barbara — Entanglement-free bottlebrush polymers can form exceptionally soft networks that are compelling in applications ranging from mimics of biological tissue to sensor skins. Controlled polymerizations provide a route to synthesize precisely defined bottlebrush polymers, but require crosslinking to form networks. We have developed a general strategy to photo-crosslink bottlebrush precursors with miscible bis-benzophenone-based additives in ambient conditions without solvent. We demonstrate that this approach is effective with a wide variety of different side-chain chemistries including acrylates, esters, and siloxanes. Current bottlebrush network models assume all crosslinks are elastically effective, which is inadequate for our randomly crosslinked networks formed with benzophenone-based additives. We present a modified Phantom network model that is capable of distinguishing elastically effective crosslinks from the ineffective ones. This model is validated by examining the moduli of networks formed from bottlebrush polymers with different molar masses and side-chain chemistries. We also experimentally verified the minimal amount of crosslinkers predicted to achieve the lowest network modulus and high gel fraction.

9:36AM A32.00007: Gel Formation in Urethane Liquid Oligomers  PRAVEEN AGARWAL
(Presenter), BOB SAMMLER, LUIGI PELLACANI, ASJAD SHAFI, PRAVEENKUMAR
BOOPALACHANDRAN, DAVID REUSCHLE, Dow — The phenomenon of gel formation is ubiquitous for various materials including polymer solutions, ionomers, biomaterials, and consumer household products. Developing a physical understanding of the interactions that lead to gel formation is essential for rational material design, and controlling the gel formation characteristics is a topic of significant interest. We have investigated a physical gel formed in a urethane oligomer system dispersed in an organic solvent. The mechanism of gel formation was investigated by rheology, polarized optical microscopy and FTIR. We find evidence of hydrogen bonding and ordered structure formation in the gel. Additionally, a rheology-based technique was developed to predict the gel formation characteristics.

9:48AM A32.00008: Modelling Intermolecular Cross-Linking in Collagen Fibrils  MATTHEW LEIGHTON (Presenter), LAURENT KREPLAK, ANDREW RUTENBERG, Dalhousie Univ — Collagen fibrils are microscopic molecular ropes that are structural components in many animal tissues. We present an equilibrium coarse-grained model for the structural and mechanical properties of these cross-linked fibrils. We model enzymatic cross-links as anisotropic Gaussian chains, which allows us to approximate their free-energy contributions. We add additional terms in the free energy for the Frank elastic energy due to the orientation of collagen molecules within the fibril, for the surface tension, and phase-field crystal terms which account for the D-band density modulations observed along the length of collagen fibrils. We computationally minimize the sum of these free-energy terms with respect to imposed strain fields acting on the fibril to obtain equilibrium structures. Using this framework we investigate the effect of strain on various important structural and mechanical properties of the fibril, such as the molecular director field and the stress-strain curve.

10:00AM A32.00009: From Gels to 3-D Networks: Creating Multifunctional Polymer-silica Nanofiber based Aerogels  TAHIRA PIRZADA (Presenter), ZAHRA ASHRAFI, WENYI XIE, SAAD KHAN, North Carolina State University — Gels containing water or solvents abound in applications with considerable efforts being made to fabricate new ones with enhanced functionalities. An area that remains less explored is the creation of aerogels by replacing the liquid matrix of gels with air. Can we preserve the structure of these systems on liquid removal and can we create materials that are just as versatile by doing so? We present a facile and sustainable solid templating approach to fabricate highly porous, flexible aerogels of hybride nanofibers of cellulose acetate and silica which are produced via sol gel electrospinning. SEM micrographs demonstrate a hierarchical architecture consisting of large secondary pores (30-50 μm) interconnected by a network of entangled nanofibers with 2-5 μm primary pores. XPS and in-situ FTIR studies provide evidence that thermal treatment of as-prepared aerogels results in crosslinking the silica-CDA network therefore enhancing their mechanical stability and hydrophobicity without compromising their low bulk density (~10 mg.cm⁻³) and porosity (>98%). Thermal studies demonstrate highly enhanced thermal stability and flame retardancy. These functional features together with ease of processing make these aerogels just as promising, if not more, than their liquid-based analogs!
10:12AM A32.00010: Probing the distribution of localization lengths in amorphous solids via wavelength-dependent elasticity  BOLI ZHOU (Presenter), RAFAEL HIPOLITO, PAUL GOLDBART, University of Texas at Austin — The amorphous solid state exhibited, for example, by randomly crosslinked macromolecular systems has two distinguishing features: (i) it arises via a continuous transition controlled by the crosslink density; and (ii) as a result of the intrinsic randomness, the state is described by a distribution of single-particle localization lengths. Owing to the continuity of the transition, in its vicinity the localization-length distribution is concentrated predominantly at intermediate lengthscales, i.e., lengthscales larger than microscopic but not truly macroscopic. We report on the development of an elasticity theory for the amorphous solid state that is valid not only in the limit of long-wavelength strains but also for strains at wavelengths corresponding to intermediate lengthscales. The corresponding wavelength-dependent shear modulus is sensitive to the distribution of localization lengths, diminishing monotonically with decreasing lengthscale -- a physical reflection of the idea that elasticity at a given lengthscale is primarily supported by particles localized on that or shorter lengthscales. The dependence of the shear modulus on wavelength therefore provides an experimental pathway to probing the distribution of localization lengths.

10:24AM A32.00011: Asynchronous Dynamics in Crosslinked Polymer Networks*  KETAN S KHARE, FREDERICK PHELAN (Presenter), National Institute of Standards and Technology — Recently, we successfully applied time-temperature superposition to obtain master curves of the mean squared displacement (MSD) of atoms in a cross-linked epoxy using atomistic simulations. The resulting curves extend to a macroscopic time-scale \(10^9\) s and can be quantitatively compared with creep compliance obtained from experiments. Here, we show that the MSD trends of the center of mass of molecular units can also be superposed using identical shift factors. Comparison of the master curves and time-scaling exponents of different molecular moieties shows that units which differ in their topological constraints exhibit asynchronous dynamics. We call this feature topology-induced asynchronous (TIA) dynamics and define it as the temporal difference in the dynamics of atoms in a network that vary in their topological constraints. TIA dynamics arise due to the interplay between the chemistry of the epoxy monomer and the crosslinker. We discuss the role of asynchronous dynamics in the thermomechanical behavior of polymer networks composed of non-Gaussian monomers, and how chemistry-specific topological details are important for controlling the polymer dynamics.

**10:36AM A32.00012: Probing rheology and mechanics of compressed microgel suspensions**

SVETOSLAV NIKOLOV (Presenter), ALBERTO FERNANDEZ-NIEVES, ALEXANDER ALEXEEV, Georgia Inst of Tech —

The unusual and adjustable mechanical properties of compressed microgel suspensions arise from the high deformability and responsiveness to external stimuli, such as temperature and pH, of the constituent microgel particles. Compressed microgel suspensions exhibit a three order of magnitude difference between the bulk and shear moduli that can be further altered by applying an external stimulus which drives the swelling transition in microgels. These properties make compressed microgel suspensions ideal for the development of new materials able to autonomously recover their internal structure after mechanical damage. We use mesoscale simulations to understand the mechanical and rheological response of compressed microgel suspensions and to establish how this response depends on the properties of individual microgels. Our findings show that at high packing fractions deformation occurs mainly as a result of particles shrinking, indicating particle interpenetration is relatively small. We further show that rheological and mechanical responses of the suspensions are directly related to the single particle modulus that sets the scale for particle shrinking.

**10:48AM A32.00013: Energy Renormalization Approach to Coarse-Grained Epoxy Resins**

ANDREA GIUNTOLI (Presenter), Northwestern University, ZHAOXU MENG, Clemson University, NITIN HANSOGE, SINAN KETEN, Northwestern University —

Cross-linked networks of epoxy resins are ubiquitous materials with a broad range of applications, thanks to the flexibility in their chemical composition that can be fine tuned to obtain the desired properties. The huge parameter space makes it challenging to optimize the material, and modeling efforts can greatly contribute to their development. In particular, many properties of epoxy resins stem from fundamental features like cross-linking density, dynamical heterogeneity and relaxation phenomena that do not depend on the fine atomistic structure of the system.

We developed a new coarse-grained molecular dynamics model for epoxy resins. Thanks to a novel energy renormalization technique, the model parameters can be tuned to match the dynamics and mechanical properties of atomistic simulations over a wide range of temperatures. The coarse-grained nature of the model allows for increased computational efficiency and focus on fundamental physical properties of the resin. We show how tuning these properties affects the dynamical and mechanical behavior of the network.

By highlighting the role of relevant features, the results obtained with this model can guide and accelerate the molecular design and optimization of epoxy resins.

8:00AM A33.00001: Nanoparticle Structure and Dynamics in Polymer Nanocomposites*  
[Invited]  MICHAEL HORE (Presenter), Case Western Reserve University — The physical properties of polymers can be significantly altered both by embedding nanoparticles within them and by grafting them to nanoparticle surfaces. The ability to predict and measure the structure, dynamics, and thermodynamics of grafted polymers is central to purposefully creating new nanocomposite materials. In particular, one powerful technique for studying these aspects of nanocomposites is neutron scattering. This talk will review recent work we have performed to study the behavior of nanoparticles in nanocomposite materials, with a focus on nanorods and nanospheres. Small-angle neutron scattering measurements of poly(ethylene oxide)-grafted Au nanorods, poly(methyl acrylate)-grafted SiO$_2$ nanospheres, and poly(methyl methacrylate)-grafted Fe$_3$O$_4$ nanospheres will be discussed, along with approaches to interpret the scattering results. The conformation of the grafted polymers will be compared between solution and nanocomposite states. Neutron spin echo measurements of the relaxation dynamics of grafted chain will be discussed, along with opportunities for future research and measurements.

*A portion of this research was funded by the NSF Polymers program (DMR-1651002).

8:36AM A33.00002: Hybrid nanoparticles with continuously tunable scattering length density for the analysis of phase separation in mixed colloidal systems*  
YUE ZHAI, JIN HAN, Carnegie Mellon Univ, WENJIE WU, Chemical and Biomolecular Engineering, University of Houston, KRZYSZTOF MATYJASZEWSKI, Carnegie Mellon Univ, ALAMGIR KARIM, Chemical and Biomolecular Engineering, University of Houston, MICHAEL BOCKSTALLER (Presenter), Carnegie Mellon Univ — The modification of nanoparticle surfaces with polymeric chains has emerged as an effective tool to control the interactions and assembly behavior of colloidal systems. Recent results have shown that interactions between chemically distinct polymeric ligands can drive the phase separation of mixed particle systems. This provides opportunities for the fabrication of microstructured hybrid materials that derive functionality from the organization of nanoparticle constituents into microscopic domains.
We will present recent results on the phase separation behavior of polymer tethered particles in thin films. In the thin film state, phase separation resembles the corresponding linear polymer blends provided the length of polymer ligands exceeds a threshold value. However, domain growth kinetics differs from the prediction for diffusion-controlled systems. To elucidate the origin of this deviatory behavior, small angle neutron scattering is performed in the bulk state. A method enabling the continuous variation of the scattering length density of nanoparticles will be presented and its application to the SANS analysis of phase separation in mixed brush particle systems will be demonstrated.

**8:48AM A33.00003: Fast solvent induced switchable phase-states of binary polymer-grafted nanoparticle blends**

WENJIE WU (Presenter), MANINDERJEET SINGH, Department of Chemical and Biomolecular Engineering, University of Houston, XIAOTENG WANG, Department of Polymer Engineering, University of Akron, YUE ZHAL, Department of Materials Science and Engineering, Carnegie Mellon University, ZONGYU WANG, Department of Chemistry, Carnegie Mellon University, TANGUY TERLIER, Shared Equipment Authority, SIMS laboratory, Rice University, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, MICHAEL BOCKSTALLER, Department of Materials Science and Engineering, Carnegie Mellon University, ALAMGIR KARIM, Department of Chemical and Biomolecular Engineering, University of Houston — Polymer-grafted nanoparticles (PGNPs) have potential applications in nanoelectronics, photonic devices, and as tough materials with tunable enhanced mechanical properties. However, these applications require the particles to form well-controlled structures. We hypothesize that these can be achieved through liquid-enabled phase-separation as a facile approach. To this end, we developed a method to switch the state of phase-separated structures in a binary blend film of PGNPs, poly (methyl methacrylate) silica (PMMA-SiO\(_2\)) and poly(styrene) silica (PS-SiO\(_2\)), by using a direct solvent immersion annealing (DIA) method. Our results show that by varying the solvents in the DIA solution, interchangeable phase-separated and homogeneous morphologies are formed in the PMMA-SiO\(_2\)/PS-SiO\(_2\) blends within 1 minute. Such homopolymer matrix free PGNP only blend systems are novel, and these switchable transitions are not readily obtainable by thermal annealing due to the large masses and the athermal property of PGNPs involved.

**9:00AM A33.00004: PEO / SiO\(_2\) nanocomposites: Correlating Polymer Morphology to Rheological Properties**

KIRIAKI CHRISSOPOULOU (Presenter), SOKRATIS KOGCHYLAKIS, SPIROS H. ANASTASIADIS, FORTH-IESL and Univ. of Crete — Polymer nanocomposites, comprised of a polymer matrix and inorganic additives, possess improved and often innovative physicochemical properties compared to conventionally filled systems. In this work we report on the rheological behavior of a series of poly(ethylene oxide) / silica, PEO/SiO\(_2\), nanocomposites through oscillatory shear rheology measurements. The nanohybrids were synthesized by dispersing spherical SiO\(_2\) nanoparticles of two different radii within high molecular weight (Mw) PEO at different compositions in order to investigate the effect of the additive on the material rheological properties. PEO crystallinity was found to depend on the degree of spatial confinement that the nanoparticles impose as well as their adsorption capacity. Dynamic time and strain sweep tests verify the material thermal stability and linear viscoelastic behavior whereas dynamic frequency sweeps probe its dynamic response. The effect of nanoparticle size and concentration on the behavior is examined to correlate the morphological changes to the rheological response of the materials in an attempt to better understand the structure-properties relationship.

**9:12AM A33.00005: Decoupling the polymer dynamics and the nanoparticle network dynamics of polymer nanocomposites through dielectric spectroscopy and rheology**

SHIWANG CHENG (Presenter), JIE YANG, Michigan State Univ, WEI YANG, Sichuan University — The dynamics of polymer nanocomposites (PNCs) are dictated by two intertwining components, the polymer matrix and the nanoparticle network, whose characteristics have not been clearly elucidated. Here, we unravel the salient features of the polymer matrix dynamics and the nanoparticle network dynamics through dielectric spectroscopy and rheology. Dielectric measurements show that the dynamics of the polymer matrix of PNCs are almost identical to the neat polymer. In contrast, rheological measurements exhibit a strong deviation in the dynamics of PNCs from that of the neat polymer. Detailed analyses show that the rheology captures both the contributions of the polymer matrix and the nanoparticle network while dielectric measurements are only sensitive to polymer matrix dynamics. Moreover, the dynamics of the polymer matrix and the nanoparticle network have very different temperature dependences, leading to a dynamic decoupling phenomenon and the breakdown of the time-temperature superposition principle in PNCs.

**9:24AM A33.00006: Segmental dynamics in matrix-free polymer grafted nanoparticles**

MAYANK JHALARIA (Presenter), Columbia Univ, ERIC RUZICKA, University of South Carolina, MADHUSUDAN TYAGI, NIST Center for Neutron Research, VICTORIA GARCIA-SAKAI, Rutherford Appleton Laboratories, BRIAN C BENICEWICZ, University of South Carolina, SANAT KUMAR, Columbia Univ — Polymer grafted nanoparticle based composite materials display a rich spectrum of complex chain and nanoparticle dynamics. Specifically, composite materials constructed using only polymer grafted nanoparticles display several dynamic anomalies—spanning a large range of time and length scales. We focus on the segmental and local dynamics of polymer chains using spatial and temporally sensitive probes with the view of identifying the primary dynamic driving force for penetrant transport in polymers. The composite materials used in the study exhibit enhanced light gas diffusivities highly dependent on the graft chain length and the grafting density, providing a chemically homogenous platform for identification of the relevant dynamics. We find that the segmental motions are highly accelerated in the composites; these speeded up dynamics appear to correlate with the diffusivities observed for these materials, in contrast to localized side group dynamics which are less affected by grafting and do not seem to affect transport. In fact, side group motion is invariant in the presence of high pressures of CO$_2$ further supporting this assertion.

**9:36AM A33.00007: Modeling the Entanglement Distribution in Polymer-grafted Nanoparticle Systems**

ROBERT J TANNENBAUM (Presenter), Columbia University, TAIJI MIKAMI, GAETAN MAUREL, MARC COUTY, Michelin, SANAT KUMAR, Columbia University — Polymer nanocomposites have become increasingly useful materials due in part to their ability to provide improved strength and mechanical reinforcement over pure polymer systems. Difficulty controlling nanoparticle dispersion in these nanocomposites has lead researchers to use polymer grafted nanoparticles embedded in matrices of free polymer chains. We believe the nature of the improved mechanical properties in grafted systems is the result of graft chains on different filler particles forming an entanglement network. A computational modeling technique was developed that utilizes slipsprings to model the mobility constraints that physical entanglements impose on individual polymer chains. Focusing on the distribution of entanglements, we found that graft chains appear to be more highly entangled than free chains, irrespective of filler particle loading. The amount of inter-particle graft interactions is also always higher than we would expect if the entanglement pairs were randomly distributed based solely on their probability of occurrence.

**9:48AM A33.00008: Disentangling the role of chain conformation on the mechanics of polymer grafted nanoparticle materials**

JIARUL MIDYA (Presenter), Institute of Physics, Johannes Gutenberg University Mainz, YU CANG, Max Planck Institute for Polymer Research, SERGEI A. EGOROV, Department of Chemistry, University of Virginia, KRZYSZTOF MATYJASZEWSKI, MICHAEL R. BOCKSTALLER, Department of Materials Science and Engineering, Carnegie Mellon University, ARASH NIKOUBASHMAN, Institute of Physics, Johannes Gutenberg University Mainz, GEORGE FYTAS, Max Planck Institute for Polymer Research — The linear elastic properties of isotropic materials of polymer tethered nanoparticles (NPs) are evaluated using noncontact Brillouin light spectroscopy. While the mechanical properties of dense brush materials follow predicted trends with NP composition, a surprising increase in elastic moduli is observed in the case of sparsely grafted particle systems at approximately equal NP filling ratio. Complementary molecular dynamics simulations reveal that the stiffening is caused by the coil-like conformations of the grafted chains, which lead to stronger polymer–polymer interactions compared to densely grafted NPs with short chains. Our results point to novel opportunities to enhance the physical properties of composite materials by the strategic design of the “molecular architecture” of constituents to benefit from synergistic effects relating to the organization of the polymer component.

*German Research Foundation (DFG) through project NI 1487/2. Further, J. Midya received funding by the Impulsfund of Rhineland Palatinate (Germany).
10:00AM A33.00009: Suppression of Creep in Model Polymer Nanocomposites  ENTAO YANG (Presenter), JAMES PRESSLY, ERIC BAILEY, University of Pennsylvania, BHARATH NATARAJAN, ARUNA MOHAN, ExxonMobil Chemical, KAREN WINEY, ROBERT RIGGLEMAN, University of Pennsylvania — While the elastic properties of polymer nanocomposites (PNCs) have been widely studied, the ability of nanoparticles (NPs) to suppress creep in a polymer matrix has received comparatively less attention, and creep suppression is essential for the use of composites in structural applications. It is believed that the primary mechanism of reinforcement in PNCs is the presence of a layer near the NPs' surfaces where the polymer monomers have modified mobility. Thus, understanding how the dynamics in this layer changes as a function of stress, NP size, and polymer-nanoparticle interaction is critical. In this work, we use molecular dynamics simulation to investigate the PNC's creep response with different NP sizes and polymer-nanoparticle interactions. Our results indicate that the small NPs with strong polymer-nanoparticle interaction can best suppress materials' creep response and stiffen the material. A recently developed, machine-learning field called softness is applied to describe the local structures in our composites. We find that the softness is modified near the NP surfaces and largely reduced for attractive polymer-particle interactions, though the range over which softness is modified differs from the range over which the relaxation time is different from the bulk.

10:12AM A33.00010: Nanoparticles with controllable dispersion and localization in immiscible polymer blends  HUSAM ALKHODAIRI (Presenter), SEBASTIAN T RUSSELL, Columbia University, JULIA PRIBYL, BRIAN C BENICEWICZ, University of South Carolina, SANAT KUMAR, Columbia University — Polymer blending is a versatile route to the development of new polymeric materials with enhanced properties and hence applications. However, the unfavorable interaction between most polymer pairs leads to phase-separated systems with unstable morphologies, weak interfaces and poor properties. The use of nanoparticles (NPs) as interfacial stabilizers has gained momentum recently due to their high surface area and strong adsorption at interfaces, but controlling their dispersion and localization in immiscible polymer blends is a major challenge. Recent work has demonstrated that polymer-grafted NPs, which exhibit surfactant-like properties, can self-assemble into a variety of superstructures that depend on the polymer grafting density (σ) and the graft chain length (N). Here, we will show that the location of polystyrene-grafted NPs within an immiscible blend of polymethyl methacrylate (PMMA)/polystyrene (PS) can be determined using $\sigma N^{0.5}$, the brush crowding parameter, and, $1/\alpha$, which describes the entropic effects associated with a mismatch in brush/matrix polymer chain lengths. Using these parameters, the spatial control over NP segregation in immiscible polymer blends is probed and understood.
10:24AM A33.00011: Polymer/Star-Polymer composites: structure and dynamics of bulk and confined materials*  
JINPENG FAN (Presenter), Department of Physics, Wesleyan University, JACK DOUGLAS, Materials Science and Engineering Division, National Institute of Standards and Technology, FRANCIS STARR, Department of Physics, Wesleyan University — Polymer-grafted nanoparticles (NP) are versatile building blocks to create tunable particle superstructures and polymer nanocomposites with customizable properties. Polymer grafted NP are topologically very similar to star polymers. While nanocomposites with polymer-grafted NP have been explored recently, comparatively little is known about composites consisting of star polymers and chain polymers, or star polymers in polymer thin films. We investigate how both the number of arms and molecular weight affect the morphology of self-assembled structures in both a bulk polymer material and an ultra-thin polymer film. Additionally, we study how star polymers affect the glass transition of these composites and films. In doing so, we also examine how star polymers affect the nature of cooperative molecular motions in the matrix and film, and how this potentially relates to changes in the mechanical and rheological properties of the material.

*This work was supported in part by National Institute of Standards and Technology (NIST) Award 70NANB15H282.

10:36AM A33.00012: Tuning structure and dynamics of segmented ionenes with added spherical nanoparticles  
NICHOLAS LIESEN (Presenter), LISA HALL, Ohio State Univ - Columbus — Segmented ionenes can be synthesized such that short ion-containing segments alternate with uncharged segments. By changing the ratio of relatively soft and hard uncharged segment types, material properties can be easily tuned. Incorporating nanoparticles may allow for further manipulation of structure and mechanical behavior. However, the multiple length/time scales involved, the large parameter space, and the nanoparticles’ tendency to aggregate complicates material design. Using efficient coarse-grained molecular dynamics simulations, we aim to establish architecture-structure-property relationships to guide synthetic efforts. Inspired by experimental ammonium ionenes with short polyethylene segments and long, soft segments (such as polyethylene oxide), we study segmented ionenes and spherical nanoparticles using a simple bead-spring model. Soft segment length, the ratio of the two polymer types, and nanoparticle surface chemistry is tuned and structure and dynamics analyzed. We find weight fraction dependent local microphase segregation of soft and hard polymer segments. We also determine the nanoparticle’s impact on the local structure as a function of weight fraction and chemistry.
Polyelectrolyte-Grafted Nanoparticles in Solution

KOTESWARARAO MEDIDHI (Presenter),
Tennessee Tech Univ, PINAR AKCORA, Stevens Institute of Technology, VENKAT PADMANABHAN,
Tennessee Tech Univ — Polyelectrolytes have found applications in fuel cells, solar cells,
membranes, etc. Here, we investigate the structural and flow properties of polyelectrolyte grafted
nanoparticles (PENP) in a solution using coarse-grained molecular dynamics simulations. The
degree of ionization (pH) and the concentration of PENP in solution are systematically varied. For
low pH, the flow properties are dominated by grafted chain entanglements, while at high pH, the
strong electrostatic repulsions between the ionized groups are the major factor. At intermediate
pH, the hydrogen bonding between the ionized and non-ionized groups along with the
concentration of PENP plays a significant role in dictating the solution viscosity. At low PENP
concentrations, intra-particle hydrogen bonds are formed that lowers the viscosity, while at
higher concentrations, inter-particle hydrogen bonds are formed enhancing the viscosity of the
solution.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A34 DPOLY DSOFT: Confinement, Dynamics, and Ion
Interactions in Ion-Containing Polymers I

8:00AM A34.00001: Ion Transport Mechanisms in Ionomers* AMALIE FRISCHKNECHT
(Presenter), BRYCE THURSTON, JONATHAN BOLLINGER, MARK STEVENS, Sandia National
Laboratories, BENJAMIN PAREN, KAREN WINEY, University of Pennsylvania — An understanding of
dynamics in single-ion conducting polymers, such as ionomers with ionic groups covalently
bonded to the polymer backbone, is needed to design these polymers for use as electrolytes. In
melt ionomers, the ions tend to self-assemble into nanoscale ionic aggregates, and the
morphology of these aggregates affects both the ion and chain dynamics. I will describe the ionic
aggregate and ion dynamics in atomistic molecular dynamics (MD) simulations of precise
polyethylene-based ionomers. In particular, the mechanisms for ion transport are the same as
those found in previous coarse-grained MD simulations. In systems with isolated ionic
aggregates, ions move through a process of aggregates merging, rearranging, and breaking up. In
systems with percolated ionic aggregates, ions "shuttle" along the ionic aggregate. From new CG
simulations, we find that the diffusion constant for ions in systems with percolated ionic
aggregates is inversely proportional to an ion "stepping" time scale, which quantifies the cation-
anion association lifetime.

8:12AM A34.00002: Confined polyelectrolyte solution driven by an external electric field
DEBARSHEE BAGCHI (Presenter), MONICA OLVERA DE LA CRUZ, Northwestern University — The transport properties of a dilute polyelectrolyte solution, confined inside a charged cylinder and driven by a constant external electric field, are studied using coarse-grained molecular dynamics simulations. The polyelectrolyte is negatively charged and modeled as linear bead-spring chains with explicit monovalent counterions and implicit solvent. We find that, when the confinement walls are negatively charged, the polyelectrolyte mobility is independent of the confinement charge density, whereas, when they are positively charged, the counterion mobility exhibits an intriguing non-monotonic dependence on the surface charge density. We study the dependence of the transport features on the diameter of the confinement, the presence of polarization effects, and on multivalent salts. We also study the mobility of the polyelectrolyte solution when the counterions of the charged surface are placed outside the confinement. In this case, the mobilities remain practically unaffected by the surface charge density, unless excluded volume effects become important.

*This work has been funded by NSF DMR Award No.1611076.

8:24AM A34.00003: Ion Correlations and Transference Number in Model Polymer Electrolytes: Effects of Ion Size and Dielectric Strength
KUAN-HSUAN SHEN (Presenter), LISA HALL, Ohio State Univ - Columbus — Salt-doped polymers have potential as safe electrolytes for batteries but suffer from low ion conductivity. Using bulky anions with delocalized charge may reduce ion agglomeration and increase conduction. However, size asymmetry between ions may increase preferential solvation of cations versus the larger anions, lowering the transference number $t^+$ (fraction of conductivity contributed by the cation). Here, we use coarse-grained molecular dynamics simulations, including a $1/r^4$ potential to capture size-dependent solvation effects, to relate polymer and ion chemistry to $t^+$ and overall conductivity. We calculate conductivity from ion mobilities in an external electric field, which improves accuracy versus the typical use of fluctuation dissipation relationships. We find that there is a discrepancy in $t^+$ estimated from ion diffusion constants and $t^+$ calculated from ion mobilities, especially at large ion size asymmetry or when ion-polymer interactions are strong. By understanding the impact of ion size, polarizability, and polymer dielectric strength on ion correlations, diffusion, and transference number, we aim to help guide design of future materials with improved conduction.

*This work is supported by the National Science Foundation under Grant 1454343.
**8:36AM A34.00004: Influence of Water Content and Morphology on Proton Transport in Biocompatible Conductive Polymer Membranes**

GLORIA BAZARGAN (Presenter), SEAN A FISCHER, DANIEL GUNLYCKE, United States Naval Research Laboratory — Proton transport plays a critical role in many biological processes, including chemical signaling to cells within the human body. Devices that control the flow of protons to biological systems for medicinal and therapeutic purposes are known as bioprotonic devices, and they depend on conductive polymer membranes to facilitate proton transport. The development of bioprotonic devices demands proton-conducting polymers with suitable transport properties and biocompatibility. Herein, the results of theoretical investigations on the transport properties of candidate polymer membranes for bioprotonic devices are described. The effects of water content and morphology on proton transport in these candidate polymer systems are established. This provides a theoretical basis for the design optimization of bioprotonic devices that incorporate biocompatible proton-conducting polymer membranes.

**8:48AM A34.00005: Effects of Homopolymer Additives on Conductivity of Salt-Doped Block Copolymers from Molecular Dynamics Simulations**

MENGDI FAN (Presenter), LISA HALL, Ohio State Univ - Columbus — As promising solid electrolyte materials for batteries, salt-doped block copolymers (BCP) simultaneously have ionic conductivity and mechanical robustness, due to the combination of two distinct polymer types. Recent experiments revealed that homopolymer additives, at high enough molecular weight (MW), can increase ionic conductivity in such systems. To understand this effect and guide further study, we employ coarse-grained molecular dynamics (MD) simulations. We analyze the microphase distribution of added homopolymers in salt-doped BCPs and relate this to the overall dynamics and ion conductivity. In particular, we find that longer homopolymers form an interlayer in the middle of the conducting microphase, while shorter chains are more fully integrated across the conducting microphase. This leads to a greater degree of overlap of the ion and homopolymer density profiles with increasing homopolymer MW, which may explain the increased conduction with MW. Ion concentration, segregation strength, and ion solvation energy also affect the ion distribution and can potentially be adjusted to enhance ionic conductivity.

*This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Award DE-SC0014209*
9:00AM A34.00006: Can solvation free energy rationalize the phase behavior of ion-doped copolymers?  JIAN QIN (Presenter), KEVIN J HOU, Stanford Univ, WHITNEY LOO, NITASH BALSARA, Chemical Engineering, University of California Berkeley — Previous experimental studies have established the pronounced effects of salt-doping on the morphological behavior of copolymers. The ionic solvation free energy has been recognized as an important factor for this doping effects, which has been encapsulated into an effective $\chi$ parameter that scales linearly with salt concentration. However, no general agreement between experimental and theoretical phase diagrams has been reached. By employing a recently developed ‘free’ ion model for salt-doped copolymers and cultivating the rich experimental data in literature, we show that, for two different molecular weights and over a range of compositions, the morphological variations can be captured by the solvation free energy alone, if the solvation radius is treated as an adjustable parameters.

9:12AM A34.00007: Densely Grafted Polyelectrolyte Brushes Trigger “Water-in-Salt” like Scenarios and Ultraconfinement Effect*  HARNOOR SINGH SACHAR (Presenter), TURASH HAQUE PIAL, PARTH RAKESH DESAI, SAI ANKIT ETHA, YANBIN WANG, PETER W. CHUNG, SIDDHARTH DA, Mechanical Engineering, University of Maryland, College Park — Polyelectrolyte (PE) brushes find use in a plethora of applications like current rectification, ion sensing, biosensing, nanoscale energy conversion etc. We carry out all-atom Molecular Dynamics (MD) simulations of fully ionized PE brushes for various degrees of polymerization and grafting densities. Our brush height results show an excellent match with the existing scaling laws of the non-linear osmotic brush regime. We observe a most remarkable ultraconfinement effect created by the brushes, quantified by orders of magnitude reduction in the mean squared displacement (MSD) of counterions and water molecules. Moreover, we observe that within the PE brushes, the counterion – PE brush complex supersedes the water molecules by both mass and volume above a critical grafting density. This gives rise to a hitherto unknown “water-in-salt” like behavior inside the brushes, with the counterions acting as the cations and the PE brush repeating units acting as the anions. Our calculations reveal a significant lowering of the dielectric constant of water within the brushes due to strong electrostatic binding with the negatively charged PE’s.

9:24AM A34.00008: Ion Transport in Pendant and Backbone Polymerized Ionic Liquids

ATSUSHI MATSUMOTO (Presenter), Okinawa Inst of Sci & Tech, PREEYA KURAY, The Pennsylvania State University, TAKERU NODA, Osaka University, CIPRIAN G. IACOB, National Research and Development Institute for Cryogenic and Isotopic Technologies, TADASHI INOUE, Osaka University, MICHAEL A HICKNER, JAMES PATRICK RUNT, The Pennsylvania State University — Polymerized ionic liquids (PILs) are single ion conductors, in which one of the ionic species is incorporated in the polymer chain while the other is nominally free to be transported. PILs are attractive as electrolytes in battery applications and other areas where liquid electrolytes are undesirable. In PILs, the ionic species can either be directly incorporated into the polymeric backbone (backbone PILs (B-PILs)) or placed as pendant groups to the chain (pendant PILs (P-PILs)). Here, we examined the ion transport, morphology, and dynamics of imidazolium-based pendant and backbone PILs with TFSI, CPFSI, and NfO counter-anions. We found that P-PILs yielded higher ionic conductivity when scaled to Tg, but B-PILs exhibited higher ionic conductivity on an absolute temperature scale, likely because of differences in the Tgs of the two systems. We also found that ion transport for B-PILs was coupled to the segmental dynamics below Tg, where the decoupling of ionic conductivity from segmental relaxation was observed for P-PILs. This study gleans insight on relating conductivity of equivalent backbone and pendant PIL structures to morphology, leading to a deeper understanding on the fundamental relationship between conductivity and morphology in PILs.

9:36AM A34.00009: Tailoring Ion Transport Properties of Block Copolymer Electrolytes with End-functionalized Homopolymer Addition

JIHOON KIM (Presenter), MOON JEONG PARK, Pohang Univ of Sci & Tech — Block copolymer electrolytes based on poly(ethylene oxide) (PEO) have been regarded as promising candidates for solid-state lithium batteries, attributed to the good lithium salt-solvating ability of PEO chains and their high ionic conductivity. However, the inherent crystallinity of PEO is tied to a drastic reduction in ionic conductivity at room temperature, limiting its uses in practically viable batteries. In this study, we report a new means of controlling PEO crystallinity of block copolymers by blending end-group functionalized PEO homopolymers. It has been found that the ionic conductivity and morphology of the resultant blends are related to the type and number of terminal moieties in embedded PEO homopolymers. This result suggests that chain folding of PEO is largely modulated by the end-group-driven intermolecular interactions in PEO phases. It has further shown that ion transport properties of blend electrolytes can be improved by this blend approach.
9:48AM A34.00010: Mechanisms of Ion Transport in Polymeric Ionic Liquids* [Invited]
VENKATRAGHAVAN GANESAN (Presenter), University of Texas at Austin — Polymeric ionic liquids (PILs) are an emerging class of materials which combines the attractive properties of ionic liquids with the sequence complexity and mechanical characteristics of macromolecules. While significant advances have occurred in the context of synthesis and characterization of such materials, comparatively less understanding exists on the mechanisms underlying ion transport in such materials. In this talk, I discuss some recent developments in the context of PILs relating to the issue of ion transport in such materials. We focus on the mechanisms of ion transport in such materials, the influence of counterions, and whether such materials do live up to the promise of high transference numbers.

10:24AM A34.00011: Quantifying Intrinsic Interfacial Transport Properties in Block Copolymer Electrolytes
PETER BENNINGTON, DANIEL SHARON, MICHAEL WEBB, JUAN DE PABLO, PAUL F NEALEY, SHRAYESH PATEL (Presenter), University of Chicago — Nanostructure-forming block copolymer electrolytes are of great interest related to their application towards a variety of electrochemical devices. However, questions remain about the nature of ion transport through these nanostructured materials. Specifically, decoupling extrinsic structural effects of tortuosity and grain boundaries from intrinsic phenomena occurring near the block copolymer domain interface has been challenging. This is due to the difficulty in precisely controlling or quantifying the film structure. Here, we present a new platform to probe defect-free single grains of any block copolymer electrolyte. We specifically focus on a model system of polystyrene-block-poly(ethylene oxide) (PS-b-PEO) with LiTFSI to quantitatively demonstrate that interfacial mixing is the predominant factor in reducing ionic mobility near the interface. Using SCFT calculations we directly correlate the interfacial width to reduced ionic conductivity as a function of lithium salt concentration. These findings are supported by atomistic simulations, which give further insight into the exact mechanisms by which this mixing layer restricts ion motion.
Multifunctional polymer electrolyte networks for energy harvesting and storage

HAMAD ALBEHAIJAN, THEIN KYU (Presenter), Polymer Engineering, University of Akron

A novel polymer electrolyte membrane (PEM) was developed based on poly(ethylene imine) (PEI)-co-polyethylene glycol diglycidyl ether (PEGDGE) network, containing lithium tri(fluoromethane sulphonyl) imide (LiTFSI) salt and succinonitrile (SCN) plasticizer. The polymer electrolyte multifunctional-networks have numerous advantages by virtue of the ion-dipole complexation facilitating facile ion conduction, multi-hydrogen bonding for self-healing to prevent electrode cracking, and covalently bonded networks to afford mechanical support. The tensile strength, modulus, and elongation-to-break of the PEI-co-PEGDGE/SCN/LiTFSI PEM films are all high, suggestive of highly flexible and stretchable nature. A wide electrochemical stability window of -0.5 ~ 5.1 V was achieved. In the symmetric Li/PEM/Li cell tests, dendrite formation of lithium crystal was discerned after cycling for 720 h, which motivates us to investigate the mechanism of Li$^+$ dendritic growth through the solid PEM network and develop strategy for preventing such dendritic growth during charge/discharge cycling. The same polymer network showed mechanoelectrical response to bending, exhibiting a flexoelectric coefficient of ~190 μC/m due to polarization/depolarization of oppositely charge dipoles, and dissociated ions.

Low-Voltage Reversible Electro-Adhesion of Ionoelastomer Junctions*

HYEONG JUN KIM (Presenter), LINDSAY PAGUIN, CHRISTOPHER BARNEY, Univ of Mass - Amherst, ZHIGANG SUO, Harvard University, ALFRED J CROSBY, RYAN HAYWARD, Univ of Mass - Amherst — An ionoelastomer is a soft and liquid-free ion conducting network formed by polymerization of an ionic liquid monomer and crosslinker into an elastomer network, such that one ion species is anchored by the network while the other species is mobile. An ‘ionic double layer’ (IDL) is formed at the interface between two oppositely charged ionoelastomers, analogous to the depletion (or space charge) layer formed at a p/n junction of electronic semiconductors. Here, we investigate how the voltage drop across the IDL can be modulated to reversibly control the adhesion between two ionoelastomers. The large electric field developed across the IDL allows for strong adhesion at potentials as low as ~ 1 V, while conventional dielectric electro-adhesives typically require much higher operating voltages (> 1 kV). These ionoelastomer electro-adhesives are also more efficient with regard to force capacity per electrostatic energy, and robust to defects or damage. Our findings provide new fundamental insight into low voltage electro-adhesion and broaden its possible applications.

8:00AM A35.00001: Fabrication and characterization of freestanding phononic thermocrystal membranes via block-copolymer directed-self assembly  ELIZABETH ASHLEY (Presenter), Pritzker School of Molecular Engineering, University of Chicago, NAOKI TAMBO, MASAKI FUJIKANE, YASUYUKI NAITO, KOUHEI TAKAHASHI, Technology Innovation Division, Panasonic Corporation, PETER J. DUDA, PAUL F NEALEY, Pritzker School of Molecular Engineering, University of Chicago — Block-copolymer (BCP) directed self-assembly (DSA) is a valuable technique that enables formation of defect-free, single crystal nanostructures over large areas. This is accomplished via a chemical template patterned via ebeam lithography. For perpendicularly oriented cylinder-forming BCPs, which spontaneously form a polycrystalline hexagonally close-packed lattice, controlling the orientation of the DSA pattern enables direct control of the in-plane lattice orientation, total pattern area, and number of periods. For BCPs such as PS-PMMA, the nanostructures can be transferred into an inorganic substrate, such as Si, and integrated into fabrication process flows for complex devices. Here, we present a methodology for integrating cylinder forming PS-PMMA DSA with a novel fabrication process to produce freestanding nanoporous Si membranes that scatter heat-carrying phonons. By controlling the orientation of the hexagonal lattice, a line-of-sight heat transport pathway can be opened or closed, which combined with nanometer scale of the BCP pores, provides the needed device length-scales to probe heat-carrying phonons. In this work, we report fabrication of and measurements on such membranes as a function of porosity, neck size, self-assembled vs DSA pores, and total pattern area.

8:12AM A35.00002: Engineering Block Copolymers To Achieve Equal Surface Free Energy and Tunable $\chi_N$ For Directed Self-Assembly Applications*  HONGBO FENG (Presenter), MOSHE DOLEJSI, University of Chicago, NING ZHU, NanJing Tech University, CHUN ZHOU, STUART J ROWAN, PAUL F NEALEY, University of Chicago — Directed Self-Assembly (DSA) of block copolymers (BCPs) is a promising technique for creating well-defined nanoscale features. The suitable BCPs for this application demand both blocks have equal surface free energies (SFE), a high enough Flory-Huggins parameter ($\chi$) for moderate phase separation but not so high as to prohibit defect annihilation, and high etch contrast. To date, the BCPs that meet these requirements are still very limited. Here we demonstrate a high throughput approach to create a series of BCPs with full pitch sizes from 8-15 nm that meet all these requirements. Furthermore, the capability of incorporation of etch resistant elements is shown to enable potential pattern transfer. We believe the work here will broaden the scope for DSA suitable materials and promote the next generation of nanolithography.

8:24AM A35.00003: Enhancing the Scale of Block Copolymer Lamellae Alignment using Ionic Liquid (IL) on a Planar Supporting Substrate*  ALI MASUD (Presenter), University of Houston-Main Campus, JACK DOUGLAS, NIST, SEAN BAILEY, Cornell University, ALAMGIR KARIM, University of Houston-Main Campus — Symmetric Block Copolymers (BCP) such as PS-b-PMMA when cast on Silicon wafer and ordered using thermal annealing assume a parallel lamellar structure in thin films. However, as molecular weight and film thickness increases, attaining complete parallel lamellar structure becomes elusive. Previous study has shown that increasing the thermodynamic driving force for microphase separation, $cN$, where $c$ is the Flory-Huggins interaction parameter between the polymeric blocks and $N$ is the number of segments in the BCP, enhances the degree of BCP ordering and alignment parallel to substrate. In order to control the microstructure of ordering, increasing $N$ or reducing temperature $T$ could be applied at the expense of either slower kinetics, or higher defect formation due to entanglements, higher glass transition temperature ($T_g$) and surface tension. In this work we present a method for parallel alignment of lamellar PS-b-PMMA over notably higher Mw and film thickness regime using IL to enhance $c$, thereby propagating substrate driven parallel layering, while lowering $T_g$ for enhanced molecular mobility for fast kinetics. Such films may be useful in applications barrier materials and batteries, solid state dielectric capacitors.

*NSF-DMR 1905996

8:36AM A35.00004: Combining polymer synthesis with self-assembly of block copolymers  ZHE QIANG (Presenter), School of Polymer Science and Engineering, University of Southern Mississippi, MUZHO WANG, Department of Chemical and Biological Engineering, Northwestern University — Polymer self-assembly is one of the most promising nanopatterning techniques due to its advantages of low cost and high versatility. The key challenge of conventional strategy is its very limited ability to control over chemistry during or after self-assembly in order to alter the nanostructures from its thermodynamic equilibrium state. In this talk, we will demonstrate our recent development of in-film photopolymerization technique for synthesizing polymers within an self-assembled film. The vapor phase monomer is first introduced to swell a photoinitiator-containing block copolymer film, which can be subsequently converted to polymers upon UV irradiation. The synthesized homopolymers blend with BCP films, which alter the thin film nanostructures by changing the underlying polymer composition. As these altered nanostructures are locally near equilibrium, common annealing techniques such as shear aligning can be combined to improve the degree of ordering. With successful integrating polymer chemistry with assembly physics, the in-film polymerization method provides an exciting platform for on-demand manipulation of polymer functionality as well as opening up a new area for radical polymerizations within such geometrically confined, swollen films.
8:48AM A35.00005: Hexagonal pattern coarsening in cylinder-forming PS-b-PMMA block copolymer thin films* GABRIELE SEGUINI (Presenter), MICHELE PEREGO, IMM-CNR — The grain coarsening in thin films (~30 nm) of cylinder forming PS-b-PMMA BCP (N=379-1281) was accomplished by tuning of the annealing temperature and time in a RTP machine. The order of the hexagonal pattern was quantified by measuring the correlation length. The weakly dependence on \( T \) of \( \chi_{S-MMA} \) allows decoupling the control of \( \chi N \) by means of \( N \), and that of the thermally activated kinetic barriers for ordering kinetics modulating \( T \), evidencing the order-disorder transition (ODT) and glass transition (GT) involved in BCP ordering.

Thermodynamically, weak and strong segregation limits are not distinguishable. In weak segregation limit the ordering process switches from a diffusion limited to a curvature driven mechanism. Both single chain and collective motions comply with the extensively evidenced kinetic limited coarsening and the reduced diffusivity, increasing \( N \) and moving away from ODT, and with the thermodynamic limited coarsening and the enhanced diffusivity, decreasing \( N \) and moving towards ODT.

The collective dynamic is further investigated discriminating the behavior of the penta-hepta defects within the hexagonal pattern to give a comprehensive description of thermodynamic, kinetic and topological characteristics of the hexagonal pattern coarsening.

9:00AM A35.00006: Selective Modification from PS-b-PMMA-b-PtBA Triblock Copolymer for Ultrafiltration Membranes TAESUK JUN (Presenter), Yonsei University, SUNGMIN PARK, Rensselaer Polytechnic Institute, HYE RIN YOON, SEONGJUN JO, CHANG RYU, DU YEOL RYU, Yonsei University — We demonstrate a feasible approach to fabricating nanoporous structures and their functionality using a triblock copolymer of polystyrene-b-poly(methyl methacrylate)-b-poly(tert-butyl acrylate) (PS-b-PMMA-b-PtBA). With casting the samples in the thin films, the continuous-type morphologies were formed as PS matrix consisting cylinders of PMMA and minor PtBA blocks. Perpendicular orientation of cylinder morphologies was exploited near two interfaces of air/polymer and polymer/neutral substrate, sandwiching the random orientation of cylinders in the interior of the film. Nondegradable, selective swelling–deswelling process of cylindrical (PMMA-b-PtBA) blocks generated nanopores with tunable pore sizes. Moreover, a simple hydrolysis of minor tBA blocks functionalized the nanopore surfaces and walls into poly(acrylic acid) layers. The pH-responsive water permeability of nanoporous membranes and their active switching with respect to biomolecules such as bovine serum albumin (BSA) were performed. These results suggest a platform to fabricate a stimuli-responsive ultrafiltration membrane using a tunable multiblock copolymer.
**9:12AM A35.00007: Irreversible Physisorption of PS-b-PMMA for Neutral Layer**

WOOSEOP LEE (Presenter), YEONGSIK KIM, SEUNGYUN JO, Yonsei University, HYUNGJU AHN, Pohang Accelerator Laboratory, DU YEOL RYU, Yonsei University — Polymer chains are irreversibly physisorbed (physically adsorbed) onto impenetrable substrates by intermolecular forces (i.e. H-bonding, vdW force or dipole moment), as the chains favor the conformations which maximizes the segmental contact to compensate the conformational entropy loss. In this study, we succeeded in guiding perpendicular microdomains of polystyrene-b-poly(methyl methacrylate) (PS-b-PMMA) film with the aid of the irreversibly-adsorbed neutral layer made of PS-b-PMMA and evaluated its compositional randomness in terms of the correlation length ($\xi$) between the two phases of PS and PMMA. This method is widely applicable to various substrates without any necessity of random copolymer brushes or mats other than PS-b-PMMA itself.

---

**9:24AM A35.00008: Failure and mechanical properties of block copolymer thin films**

TIANREN ZHANG (Presenter), NING WANG, ROBERT RIGGLEMAN, University of Pennsylvania — The physical properties of glassy polymer films can change drastically under nanoscale confinement. These changes are often attributed to increased average molecular mobility and reduction in entanglement density, and both are known to alter mechanical behavior. While most previous work has focused on the properties of homopolymers under confinement, and the mechanical response of block copolymer thin films is still comparatively unexplored. We have used molecular dynamics simulations to investigate the mechanical response of free standing, lamellar-forming block copolymer thin films made from polymer chains that span from slightly entangled to highly entangled at different film thicknesses. We noticed that the failure and mechanical properties become substantially distinct from bulk as the thickness is decreased. The dynamic response of the thinnest films studied show a different local response compared to thicker films. For all the block copolymer films, we find that the plastic rearrangements initially concentrate at the boundary between the two phases of the lamellae until close to failure, when the plasticity moves to the center of a domain.

9:36AM A35.00009: Advanced metrology and molecular dynamics simulations for quantifying counterion condensation in block copolymer electrolyte thin films* QI LEI (Presenter), CHRISTOPHER G ARGES, Louisiana State University, Baton Rouge — Ionic conductivity is an important property of polymer electrolyte membranes and electrode binders. The impact of counterion condensation, a proxy for the extent and strength of ionic group dissociation in polymer electrolytes, on ionic conductivity has received less attention and is not clearly known. This talk highlights our effort to quantify counterion condensation in self-assembled block copolymer electrolyte (BCE) thin films. Advanced metrology (GI-SAXS, QCM, ICP-OES, and LC-MS) were applied to quantify counterion condensation in BCEs. These techniques identified the Donnan concentration during ion-partitioning experiments and determined the activity coefficients of these ions in thin films. Experimental results were compared against the Gibbs-Donnan Model and Manning’s Theory of Counterion Condensation, as well as classical molecular dynamics simulations. The agreements and differences between the experimental and modeling techniques will be presented and discussed.

*The authors acknowledge funding for this work from U. S. Department of Energy, Office of Science, Basic Energy Sciences, Chemical Sciences, Geosciences, and Biosciences Subprogram, Award # DE-SC0018989.

9:48AM A35.00010: Modeling Surface Interactions for Block Copolymers and Polymer Brushes under Soft Confinement* JUN-QING SONG, YI-XIN LIU (Presenter), HONG-DONG ZHANG, Fudan Univ — The surface interaction is one of the most important factors that control the nanostructures formed by block copolymers/polymer brushes under soft confinement. In this talk, we introduce a simplified model for surface interactions where the role of soft substrates is decomposed into two independent contributions: the surface preference and the surface softness. Soft substrates are modeled by polymers grated onto hard walls. Their structures on both repulsive and attractive walls are studied by SCFT.[1] Based on this model, we perform a numerical analysis of the stability competition between perpendicular and parallel lamellae of symmetric diblock copolymers on substrates modified by homopolymers.[2] The effects of the surface preference and the surface softness on the alignment of lamellar domains are carefully examined. Applications of this model on understanding the defect removal process in DSA of block copolymer thin films are also demonstrated.[3]

10:00AM A35.00011: Degradation of Block Copolymer Films*  RYAN SAYKO (Presenter), ZILU WANG, University of Akron, MATTHEW L. BECKER, Duke University, ANDREY DOBRYNIN, University of Akron — We use coarse-grained molecular dynamics simulations to study degradation of films of multiblock copolymers in a solvent. Our simulations were designed to mimic degradation dynamics of glycine, valine, and phenylalanine based poly(ester urea)s in vitro. Simulations show that the rate of copolymer degradation is a result of a fine interplay between chain breaking kinetics, solvent diffusion, and swelling of the domains made of solvophilic blocks. The evolution of the film structure during the degradation process was monitored by calculating the scattering function \( S(q) \) of the copolymer film. The solvent diffusion into the films results in a monotonic shift of the peak position to smaller \( q \). This shift is also accompanied by the increase in scattering intensity at \( q \ll 1 \) in such a way that the peak completely disappears at the later stages of the film degradation. This results in the scattering function \( S(q) \) to have two characteristic power law regimes with \( S(q) \sim 1/q^2 \) and \( S(q) \sim 1/q^4 \), represented by interconnected vesicles with thin shells. The number average degree of polymerization of the copolymer fragments monotonically decreases with time. However, the polydispersity index of the copolymer fragments first increases as a function of time and then decreases.

10:12AM A35.00012: WITHDRAWN ABSTRACT —

10:24AM A35.00013: New insight into self-assembly of block copolymers at the solid-polymer melt interface*  [Invited] TAD KOGA (Presenter), Stony Brook University — I present new pieces of experimental findings on the self-assembling process of block copolymers (BCPs) near nonneutral silicon (Si) substrate surfaces. The key is concurrent physisorption of preferred blocks and non-preferred blocks on the surface. Using an optimized solvent-rinsing approach, we successfully uncovered two different kinds of adsorbed BCP chains: one is the inner strongly adsorbed BCP chains where all constituent blocks lie flat and form a two-dimensional percolating network structure regardless of their chain architectures, microdomain structures, and interfacial energetics. The other is outer "loosely adsorbed chains" which form a poorly packed perpendicularly oriented microdomain structure. I will show that the inner microdomain structures and orientations of BCP thin films are negatively impacted by the loosely adsorbed BCP chains. Interestingly, this undesirable substrate-field effect propagates into the film interior up to the distance of \( \sim 70 \text{ nm} \). Finally, a new surface modification approach to prevent the substrate-field effect is proposed. I will demonstrate that homopolymer chains composed of one of the constituent blocks adsorbed on the Si substrates act as a “structurally neutral” surface coating for directed self-assembly of block copolymer thin films.

Superconducting quantum processors are controlled and measured in the analog domain and the design of the associated classical-to-quantum interface is critical in optimizing the overall performance of the quantum computer. Control of the processor is achieved using a combination of carefully shaped microwave pulses and high-precision time varying flux biases. Measurement of quantum states is typically achieved using dispersive readout, which requires a low-power pulsed microwave drive and a near quantum-limited readout chain. For control of a single qubit, a typical system employs two high-speed high-resolution (e.g., 1 Gsps/14 bit) digital-to-analog converters (DACs) and a single-sideband modulator to generate microwave control pulses. A third DAC with similar specifications is used for flux-bias control. A typical readout channel may service on the order of five qubits and contains yet another pair of DACs, with a single-sideband modulator employed to generate a stimulus signal. For measurement, the readout chain also employs a series of cryogenic amplifiers followed by further amplification, IQ demodulation, and high-speed digitization at room temperature. For today's prototype systems with on the order of 50-100 qubits, keeping most of the electronics at room temperature makes sense. However, achieving fault tolerance—a long term goal of the community—will require implementing systems with on the order of $10^6$ qubits and today's brute force control and readout approach will not scale to these levels. Instead, a more integrated approach will be required. In this talk, we will present a review of recent work towards implementing a scalable cryogenic quantum control and readout system using silicon integrated circuit technology. After motivating the work, we will describe the design and characterization of a prototype cryogenic XY controller for transmon qubits. Detailed measurement results will be presented. The talk will conclude with a discussion of future work.
Kalman-based IQ Mixer Calibration for Circuit QED

SHAN WILLIAMS (Presenter), RICCARDO BORGANI, MATS OLOV THOLÉN, DAVID HAVILAND, Nanostructure Physics, KTH Royal Inst of Tech — Quantum measurements with superconducting circuits require the generation and detection of signal frequencies in the 2 - 12 GHz range, where frequency conversion is performed by analog devices known as IQ mixers. These mixers generate unwanted image signals upon upconversion, which crowd the already limited frequency spectrum, and become superimposed with the desired signal upon downconversion. Image signals are particularly problematic for frequency-multiplexed qubits [1] as they are a possible source of dephasing when accidentally driving another qubit. These detrimental effects can be minimized by calibrating the IQ mixers.

In this talk we present some simple but elegant methods which do not require a spectrum analyzer, to calibrate both up and downconversion mixers in situ (i.e. without disconnecting the device under test). The downconversion mixer is calibrated with a Kalman filter, providing a minimally distorted estimate of the image-to-signal power ratio. This ratio is then used to calibrate the up-conversion mixer. These techniques, originally developed for wide-band digital communication [2], are well suited for frequency-multiplexed experiments in circuit QED.

Reversible Fluxon Logic with shift registers

WALTRAUT WUSTMANN (Presenter), KEVIN OSBORN, LPS at the University of Maryland, College Park — Reversible digital logic can improve energy efficiency over irreversible logic. Reversible logic gates in superconducting circuits are currently made in the adiabatic type, where drive fields evolve the bit state, but we are developing Reversible Fluxon Logic (RFL) in the ballistic type – key gates are solely powered by bit state inertia. RFL represents the bit states by the two topological charges (flux polarities) of fluxons in a Long Josephson Junction (LJJ). Ballistic gates consist of at least two LJJ connected by a circuit interface and use a resonant conversion of an input fluxon to and from a localized field at the interface. At the end of this process a new fluxon is created in another LJJ and its polarity may deterministically differ from the input bit, thus enabling bit switching. In simulations 1- and 2-bit RFL gates can restore 97% of the input fluxon energy in the output fluxons. While previous RFL 2-bit gates require synchronous input bits, newly developed gates store an internal flux state by which the timing restriction is lifted (asynchronous). This is demonstrated with the shift register – the input state is stored as internal flux while the previously stored flux state transfers to a ballistic output fluxon. We apply a model developed to describe RFL dynamics.
9:00AM A36.00004: Practical Microwave Direct Digital Synthesis for Superconducting Qubit Control*  WILLIAM KALFUS (Presenter), DIANA F. LEE, SPENCER FALLEK, GUILHEM RIBEILL, ANDREW WAGNER, MARTIN V GUSTAFSSON, THOMAS A OHKI, Raytheon BBN Technologies, BRIAN DONOVAN, Systems & Technology Research, DIEGO RIST&Egrave;; Raytheon BBN Technologies — To conduct experiments with higher numbers of superconducting qubits, the availability of scalable control hardware is essential. To address this, we have incorporated custom superconducting qubit control logic into off-the-shelf hardware employing direct RF synthesis at 5 GHz for low-noise and low-latency pulse generation up to 7.5 GHz. Our approach eliminates the need for upconversion (which requires precise calibration to prevent leakage) and highly stable microwave sources (which can be expensive). The wide bandwidth enables efficient experiment configurations, such as control and readout using a single channel. We characterize the performance of the hardware using a five-transmon IBM device and demonstrate no additional decoherence or gate error for one- and two-qubit gates compared to traditional configurations, establishing a foundation for scalable quantum control beyond intermediate-scale systems.

9:12AM A36.00005: A scalable FPGA platform for qubit readout and control*  MATS THOLEN (Presenter), RICCARDO BORGANI, SHAN WILLIAMS JOLIN, DAVID HAVILAND, KTH Royal Inst of Tech — Readout and control of superconducting qubits requires high bandwidth signal generation, acquisition and processing, together with the possibility of implementing low latency feedback. These requirements are fulfilled in a new category of Field Programmable Gate Arrays (FPGA) designed for applications in software-defined radio. We adapted the Xilinx Zynq Ultrascale+ RFSoC hardware platform by implementing firmware for pulsed control and readout of qubit circuits. We have also implemented firmware for coherent multifrequency modulation and demodulation of continuous signals. Using the second Nyquist band we perform direct digital synthesis and measurement at microwave frequencies, without analog mixers. With 8 analog input and 8 analog output channels, on-chip integration of DAC, ADC and FPGA, the RFSoC is a promising new platform for experiments with circuit QED.

9:36AM A36.00007: Single Flux Quantum based electronics for control and readout of superconducting qubits. MANUEL CASTELLANOS-BELTRAN (Presenter), ADAM J. SIROIS, National Institute of Standards and Technology Boulder, JUNLING LONG, Physics, University of Colorado-Boulder, ANNA FOX, DAN SCHMIDT, PAUL DAVID DRESSELHAUS, PETER F. HOPKINS, JOEL N ULLOM, DAVID PAPPAS, SAMUEL P BENZ, National Institute of Standards and Technology Boulder — Superconducting quantum information systems require a mix of continuous-wave AC, pulse-modulated AC, and DC signals for control and readout. There are significant advantages in terms of scaling, physical footprint, latency, signal integrity, and power consumption by moving these sources to 4 K or below, inside the cryostat. In this talk we present an experimental demonstration generating spectroscopy tones at 4 K to measure a transmon qubit’s energy level spacings at 100 mK. The spectroscopy tones are generated by a series of Josephson junctions at 4 K driven by a sigma-delta pulse stream from room temperature. This experiment was our first step in optimizing the Josephson arbitrary waveform synthesizer (JAWS) circuit for controlling quantum systems in a scalable manner. We also discuss further steps needed to generate pulsed signals for qubit preparation, cryogenic readout, and digital superconducting circuits at 4K for signal processing and feedback.
9:48AM A36.00008: Unconditional reset of superconducting qubits and readout resonators using a quantum-circuit refrigerator* VASILII SEVRIUK, JANI TUORILA, JOHANNES HEINSOO (Presenter), CASPAR OCKELOEN-KORPPI, IQM Finland Oy, JONI IKONEN, Department of Applied Physics, Aalto University, KUAN YEN TAN, IQM Finland Oy, ERIC HYYPPÄ, MATTI SILVERI, MATTI PARTANEN, MÁTÉ JENEI, GIACOMO CATTO, TIMM MÖRSTEDT, Department of Applied Physics, Aalto University, LEIF GRÖNBERG, VTT Technical Research Center of Finland Ltd., JAN GOETZ, IQM Finland Oy, MIKKO MOTTONEN, Department of Applied Physics, Aalto University — In quantum information processing with logical qubits, increasing the clock rate of the error correction cycles improves the qubit fidelity. The clock rate is limited by the duration of logical gates, qubit state readout, and initialization of qubits and readout circuits. Linear and non-linear superconducting resonators can be quickly initialized using a quantum-circuit refrigerator based on fast voltage pulsing of an SINIS junction [1,2]. We discuss our latest results to this end.

10:00AM A36.00009: Simple, smooth 50ns QND circuit-QED measurement pulses FELIX MOTZOI (Presenter), Juelich Forschungszentrum, CHRISTIAN DICKEL, University of Cologne, LUKAS F BUCHMANN, Aarhus University — We demonstrate a technique for greatly reducing the duration and error in circuit QED measurement tasks. We show how to suppress different errors including state discrimination, cavity reset, non-linear cavity effects, bandwidth, filtering, all while retaining QND-ness and staying within a single quadrature. The technique works for a variety of different circuit configurations, including Purcell filters, where two different cavities need to be simultaneously emptied. Moreover, the speed and quantum non-demolition nature is retained as one scales up to more qubits or quantum states, providing a blueprint for scaling up to simultaneously measure leakage state populations, multiple qubits, or multiple network modes. We show for realistic circuit parameters that not only speed can be improved by an order of magnitude but errors as well with 99.9% fidelity well within reach. The technique can be understood in terms of control-theoretic transfer function formalism or shortcuts to adiabaticity, where we can also leverage the adiabatic methodology to cancel unwanted nonlinear effects such as Kerr nonlinearity.
10:12AM A36.00010: Predictive feedback for active noise canceling in superconducting quantum processors* AMIR KARAMLOU (Presenter), ANTTI VEPSALAINEN, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology MIT, DAVID K KIM, JONILYN YODER, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology MIT — Superconducting qubits are amongst the most promising platforms for building near term practical quantum information processors. However, the coherence time (T2) of these qubits is negatively impacted in the presence of dephasing noise. In this work, we show how to efficiently estimate the noise spectrum experienced by the qubit, employ techniques from machine learning to predict the correlated noise in the future and use fast-feedback with an FPGA to cancel the noise. We propose using this estimate-predict-feedback sequence as a tool to increase gate fidelities while running a quantum circuit.

10:24AM A36.00011: QubiC - An open FPGA based Qubit Control system* GANG HUANG (Presenter), YILUN XU, Lawrence Berkeley National Laboratory, RAVI KAUSHIK NAIK, BRADLEY MITCHELL, Physics, University of California, Berkeley, DAVID SANTIAGO, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, Physics, University of California, Berkeley — As the number of qubits increases, the flexibility and scalability of the control system become one of the issues limiting the experiments to expand. We developed an FPGA based qubit control system named QubiC. The system generates the physical RF pulses which implemented the quantum algorithm and process the readout and present them to the higher level. Multiple FPGAs can be synchronized via optical fiber, making the system scalable. As a proof of concept, we build a module with the COTS FPGA carrier boards and DAC/ADC boards together with analog frontend boards. We developed the firmware and software to implement the algorithm and demonstrate the basic functionality. In this talk, we describe the system structure, the firmware implementation and the design of the analog front end boards.

A Scalable Multi-Channel Cryogenic Controller for Spin Qubits/Transmons with Frequency Multiplexing Capability Implemented in Intel 22nm FinFET Technology

BISHNU PATRA, JEROEN P. G. VAN DIJK, Delft University of Technology, Delft, The Netherlands, SUSHIL SUBRAMANIAN (Presenter), Intel, Hillsboro, OR, ANDREA CORNA, XIAO XUE, Delft University of Technology, Delft, The Netherlands, CHARLES JEON, FARHANA SHEIKH, Intel, Hillsboro, OR, ESDRAS JUAREZ HERNANDEZ, BRANDO PEREZ ESPARZA, Intel, Guadalajara, Mexico, HUZAIFA RAMPURAWALA, BRENT CARLTON, Intel, Hillsboro, OR, NODAR SAMKHARADZE, TNO, Delft, The Netherlands, SUREJ RAVIKUMAR, CARLOS NIEVA, SUNGWON KIM, HYUNG-JIN LEE, Intel, Hillsboro, OR, AMIR SAMMAK, TNO, Delft, The Netherlands, GIORDANO SCAPPUCCI, MENNO VELDHORST, LIEVEN M VANDERSYPEN, MASoud BABAIe, FABIO SEBASTIANO, Delft University of Technology, Delft, The Netherlands, EDOARDO CHARBON, EPFL, Neuchatel, Switzerland, STEFANO PELLERANO, Intel, Hillsboro, OR — Scaling a fault-tolerant quantum computer to a very large number of qubits is a daunting challenge. Innovation is required in qubit fabrication, integration and control. Current approaches for controlling qubits operating at cryogenic temperature using room-temperature electronics will not scale to large qubit arrays. We have recently proposed to bring integrated electronics close to the qubits at cryogenic temperatures. Leveraging deeply-scaled CMOS process technologies, complex System-on-Chips (SoCs) with digital, analog and RF capabilities can be integrated with sufficiently low power consumption to be compatible with dilution refrigerators. We demonstrate a cryo-CMOS controller SoC designed to operate at 4K and implemented in Intel 22nm FinFET technology. The SoC is capable of addressing 128 frequency-multiplexed qubits across 4 separate channels over 1GHz RF bandwidth from 2 to 20GHz. The maximum output power is -16dBm at 6GHz with 40dB gain control. Such flexibility enables the control of both spin qubits and transmons with the same chip. By operating our cryo-CMOS controller on the 4K plate in a dilution refrigerator also hosting a Si-based qubit sample at 20mK, we demonstrate Rabi oscillations and coherent x-y rotations of the spin qubit at both 13.7 and 17.5GHz.

Design, Modeling, and Measurement of Through-Silicon Via (TSV) Structures for Superconducting Quantum Computing*

WAYNE WOODS (Presenter), DANNA ROSENBERG, MOLLIE SCHWARTZ, DONNA YOST, JONILYN YODER, WILLIAM OLIVER, MIT Lincoln Lab — We have integrated high-aspect ratio superconducting through silicon vias (TSVs) into routing and control circuitry for superconducting qubits, as well as for dedicated grounding of on-chip ground planes, and for the elimination of chip box modes. We describe our electromagnetic modeling of TSV-embedded routing elements, and we demonstrate their incorporation into design and measurement of superconducting qubits. We also describe the robust modeling and design methodology we use to optimize the combination of compactness, electrical reflections, and dielectric losses.

Session A37 FGSA: The Postdoctoral Experience at Universities, Industry Labs, and Military Labs 605 - Tag(s): Careers, Invited, Undergrad Friendly

8:00AM A37.00001: Panel Discussion [Invited] — Invited Panelists are:
Krista Freeman, University of Pittsburgh
Christopher Safranski, IBM TJ Watson Research Center
Ibrahim Boulares, US Army Res Dev & Eng Command

Session A38 FPS: AI and Humanity: Governance, Design, and Ethics 607 -
Savannah Thais, Princeton University - Tag(s): Invited, Undergrad Friendly

8:00AM A38.00001: Theodora Dryer Invited Talk [Invited] —

8:40AM A38.00002: Joaquin Candela Invited Talk [Invited] —

9:20AM A38.00003: An Ecological Approach to Data Governance [Invited] JASMINE MCNEALY (Presenter), University of Florida — Data are currency. They provide the fuel for both decision-making and profit-making. Data offer evidence for enhancing health services, infrastructure, zoning, and for addressing environmental concerns. But data collection and use is spurring conflicts between cities, corporate and civil society organizations, and constituents on the grounds of data ownership, access, privacy, and security, spilling into the courts, the media, and public discourse.
In this talk I trace these conflicts to our perception of data as a singular piece of property. A better metaphor for data would be that of a networked representation or observation in an ecosystem. I argue that we require an ecological approach for understanding this era of emergent technology and data -- both for creating adequate policy, and for protecting the vulnerable.

10:00AM A38.00004: Physicists' Involvement in AI and AI Ethics [Invited] SAVANNAH THAIS (Presenter), Princeton University — Physicists in many subfields are increasingly employing Machine Learning and Artificial Intelligence techniques in their research; furthermore, in some cases physics principles and research are informing the development of new algorithms and learning methods. Physics and AI are now inextricably linked and thus physicists must critically consider the broader impact of AI developments on people and society. This talk will summarize current areas of physics-informed AI research and will provide suggestions and context for how physicists can meaningfully engage in these discussions.

10:15AM A38.00005: Panel Discussion [Invited] —
8:00AM A39.00001: Plasmon-induced excited-state catalysis understood via embedded correlated wavefunction theory [Invited] JOHN MARK P. MARTIREZ, Department of Chemical and Biomolecular Engineering, University of California, Los Angeles, JUNWEI L. BAO, Department of Mechanical and Aerospace Engineering, Princeton University, EMILY CARTER (Presenter), Office of the Chancellor, University of California, Los Angeles — Metallic nanoparticles (MNPs) with nearly-free-electron-like valence electrons have enhanced ability to scatter/absorb light by means of local surface plasmon resonances (LSPRs). Such LSPRs produce amplified electric fields that can excite molecules or other materials coupled to the MNPs. Photocatalysis mediated by MNPs exploits this unique optical phenomenon. First-principles quantum mechanics can aid in understanding such light-driven chemistry but the methods used must properly account for both electronic excitations and surface reactions. Embedded correlated wavefunction (ECW) theory is ideally suited for this purpose, wherein the extended surface is described by an embedding potential derived from density functional embedding theory (DFET). The chemical reaction then is treated with CW theory subject to this DFET-derived potential. ECW calculations of a variety of endoergic reactions on pure and doped surface-plasmon-active metals reveal that enhanced kinetics can occur on excited-state reactive potential energy surfaces accessed via plasmon-enhanced light absorption or resonance energy transfer. Our calculations explain experimentally observed plasmon-driven enhanced rates and suggest candidate MNPs for photocatalytic nanoplasmonics.
8:36AM A39.00002: Ultrafast dynamics of plasmons and strong plasmon-molecule coupling at the nanoscale: Insights from first-principles modeling*  
TUOMAS ROSSI (Presenter), PAUL ERHART, Department of Physics, Chalmers University of Technology — Localized surface plasmons render metal nanoparticles efficient light absorbers at their resonance frequencies. After light absorption by the plasmon mode, the system can display different femtosecond-scale processes: The plasmon can decay into incoherent electrons and holes or a coherent energy exchange can take place between plasmon and other strongly-coupled electronic excitations. In this presentation, we employ time-dependent density-functional theory (TDDFT) for providing first-principles insights on these ultrafast processes at the nanoscale. We analyze the electron-hole transitions involved in photoabsorption and in the subsequent dynamics of the electronic system, which enables us to scrutinize the plasmonic character [1], follow the plasmon decay into hot electrons and holes [2], and dissect the symmetric and antisymmetric hybrid modes caused by strong coupling between plasmon and molecular excitation [3]. Our work paves the way for addressing spatiotemporal dynamics of plasmon-enhanced processes down to the atomic-scale details.

8:48AM A39.00003: Decoherence in First-Principles Simulation of Excited Electron Dynamics in Nanomaterials and at Interfaces*  
JIAN CHENG WONG (Presenter), YOSUKE KANAI, Univ of NC - Chapel Hill — Understanding hot carrier dynamics in nanomaterials and at molecule-material interfaces is central to gain scientific insights into the operation of various future optoelectronic technologies. We investigate the excited electron dynamics at molecule-material interfaces using first-principles simulation based on the fewest switches surface hopping (FSSH) method. Within the FSSH method, identification of trivial crossings poses a major numerical challenge in practice as it can influence simulation results in a few different ways. In particular, calculation of the decoherence rate from the energy autocorrelation function is found to be rather sensitive to the trivial crossings. In addition to discussing how decoherence influences both hot electron relaxation and transfer at interfaces, we propose a numerical method to treat trivial crossings and discuss the extent to which trivial crossings affect the calculated decoherence rate.

9:00AM A39.00004: First-principles calculations of the ultrafast dynamics of coupled electrons and phonons
XIAO TONG (Presenter), MARCO BERNARDI, Caltech — Progress on experiments probing the ultrafast electron dynamics calls for the development of accurate simulations of materials in the time domain. However, widely employed approaches to model the coupled nonequilibrium dynamics of electrons and atomic vibrations (phonons) employ empirical or approximate interactions, or are limited to femtosecond timescales. Here we show a numerical approach to evolve in time the coupled Boltzmann transport equations (BTEs) of electrons and phonons, using ab initio electron-phonon and phonon-phonon interactions together with a parallel algorithm to explicitly time step the BTEs. Our approach can simulate the dynamics up to hundreds of picoseconds (with a femtosecond time resolution) and provide microscopic insight into the scattering mechanisms. The accuracy of the interactions used in the calculations can be validated by computing transport properties. We show example calculations on graphene and semiconductors, for which we compute carrier cooling rates, mode-resolved phonon dynamics, transient absorption, structural snapshots and diffuse X-ray scattering. Possible extensions to include static electric or electromagnetic fields will also be discussed. Our findings open new avenues for quantitative simulations of ultrafast dynamics in materials.

9:12AM A39.00005: Spin-phonon relaxation in diverse materials from a universal ab initio density matrix approach*
JUNQING XU (Presenter), University of California, Santa Cruz, ADELA HABIB, SUSHANT KUMAR, Rensselaer Polytechnic Institute, FENG WU, University of California, Santa Cruz, RAVISHANKAR SUNDARARAMAN, Rensselaer Polytechnic Institute, YUAN PING, University of California, Santa Cruz — We present a new, universal first-principles methodology based on Lindbladian dynamics of density matrices to calculate the spin-phonon relaxation time of solids with arbitrary spin mixing and crystal symmetry. In particular, this method describes contributions of the Elliott-Yafet and D’yakonov-Perel’ (DP) mechanisms to spin relaxation, corresponding to systems with and without inversion symmetry, on an equal footing. Our \textit{ab initio} predictions are in excellent agreement with experiment data for a broad range of materials, including metals and semiconductors with inversion symmetry (silicon and iron), and materials without inversion symmetry (MoS$_2$ and MoSe$_2$). We find strong magnetic field dependence of electron and hole spin relaxation in MoS$_2$ and MoSe$_2$. As a function of temperature, we find the spin relaxation time to be proportional to carrier/momentum relaxation time in all cases, consistent with experiments but distinct from the commonly-quoted inverse relation for simplified models of the DP mechanism. We emphasize that first-principles spin-orbit coupling and electron-phonon scattering is crucial for general, accurate prediction of spin relaxation in solids.

*We acknowledge financial support from the National Science Foundation under Grant No. DMR-1760260.
9:24AM A39.00006: Predicting weak-to-strong light-matter coupling in cavities from first principles*  
DEREK WANG (Presenter), TOMAS NEUMAN, JOHANNES FLICK, PRINEHA NARANG, Harvard University — Quantum electrodynamical density functional theory (QEDFT) is a first principles, non-perturbative framework for interactions of quantum matter with quantized electromagnetic fields. QEDFT studies have usually considered lossless cavities. Experimentally accessible cavities, however, exhibit finite photon lifetimes leading to incoherences that dominate dynamics of the light-matter excitations. Here we extend QEDFT by considering lossy cavity modes. This allows us to study ab initio correlated optical interactions in matter ranging from the weak-coupling to strong-coupling regime. As an example, we study excited-state dynamics and spectral responses of benzene and chlorobenzene under weak-to-strong light-matter coupling. By tuning the coupling we achieve cavity-mediated energy transfer between electronic excited states. We interpret the first principles results using a Fano-like model parametrized with the (QE)DFT data. This extension to QEDFT moves toward closing the loop between first principles calculations employed in electronic structure theory and parametric models of the quantum optics community.

9:36AM A39.00007: Local basis formulation for the Floquet theory of electronic stopping of ion projectiles*  
NICOLO' FORCELLINI, MARJAN FAMILI (Presenter), EMILIO ARTACHO, Univ of Cambridge — Ions shooting through solids are slowed down by electronic excitation in the so-called electronic stopping process. This century-old problem is of fundamental and applied interest in various contexts, including nuclear, space and biomedical industries. The electronic stopping problem is approached theoretically from two prevalent paradigms, one based on linear response for weak effective interactions, the other on the homogeneous electron liquid, a successful model for simple metals. A more general theory for crystalline solids has been introduced recently based on exploiting a discrete translational invariance along a space-time diagonal, the Floquet theory of electronic stopping [1]. Here we will present how to formalise this theory using a local basis for the practical solution of the unconventional scattering problem that arises from the theory.

*This work was supported by the EPSRC grant EP/N509620/1 (NF), Leverhulme Trust, UK, RPG-2018-254 (MF, EA)
9:48AM A39.00008: The effect of pressure ($P$) on the intrinsic optical dynamics of nitrogen-vacancy NV$^+$ colored centers in diamond: reexamining the intersystem crossing (ISC) with $\Delta$SCF calculations within density functional theory (DFT) combined to the extended Hubbard model

MARIYA ROMANOVA (Presenter), Ecole Polytechnique, Laboratoire des Solides Irradiés, JELENA SJAKSTE, CNRS, Laboratoire des Solides Irradiés, MICHELE CASULA, CNRS, Sorbonne Université, Institut de Minéralogie, de Physique des Matériaux, et de Cosmochimie, NATHALIE VAST, CEA-Saclay, Laboratoire des Solides Irradiés — The sensitivity of the NV center to its surrounding magnetic field is expected to be a powerful tool to detect the onset of superconductivity at ultrahigh $P$ in diamond anvil cells. In this work, we propose a combined approach to study the many-body excited states of the NV$^+$ center under $P$: the extended Hubbard model with all of the parameters fit on $\Delta$SCF-DFT calculations of the differences of total energies with constrained occupations, thereby including the electron-hole interaction for any $P$.

We study the behavior of all of the many body states under $P$. In particular, we compute for the first time the pressure coefficients of the singlet-singlet emission consecutive to the ISC for the two models reported in the literature [1,2], and show that they are widely different, the application of hydrostatic pressure being an effective tool to discriminate between them.

*Results have been obtained with the Quantum ESPRESSO package and our home-developed code, and computer time granted by PRACE (Project No. 2019204962) and by French GENCI-CINES and GENCI-TGCC (Project 2210). Support from labex PALM and DIM SIRTEQ (région Île-de-France) is acknowledged.

10:00AM A39.00009: Magnetocrystalline Anisotropy and Potential Switching in Antiferromagnetic Fe$_2$As

KISUNG KANG (Presenter), KEXIN YANG, DAVID CAHILL, ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Antiferromagnetic Fe$_2$As attracts interest due to its tetragonal chemical structure with easy-plane magnetism and metallic electrical conductivity. To understand the electrically-activated switching process of the Néel vector in this material, anisotropy energy becomes an important parameter as an energy barrier. Anisotropy energy originates from spin-orbit interaction (SOI) and magnetic dipole-dipole interaction (MDD). We use density functional theory and classical modeling to investigate SOI and MDD, and find that in-plane anisotropy is dominated by SOI, which is two times larger than the MDD contribution to out-of-plane anisotropy. The in-plane anisotropy presents four-fold symmetry and is 276.5 J/m$^3$ which is confirmed by torque magnetometry, and total out-of-plane anisotropy energy is 829772 J/m$^3$ with two-folded symmetry. Based on anisotropy energy and magnetic susceptibility, the lowest frequency spin wave is predicted to have a frequency of 0.64 THz and out-of-plane anisotropy dominates. This suggests that easy-plane antiferromagnetic materials might exhibit fast dynamics and high speed of switching similar to uniaxial materials. However, these materials might suffer from low thermal stability, due to the extremely small in-plane anisotropy.

*Illinois MRSEC NSF DMR-1720633
First-principles study of the phonons and crystal-field excitations in the magnetodielectric regime of Ce2O3* YUEQING CHANG (Presenter), ASTHA SETHI, JOHN SLIMAK, LUCAS WAGNER, S. LANCE COOPER, University of Illinois at Urbana-Champaign — The mechanism associated with the giant magnetodielectric effect that was recently reported in A-type Ce2O3 remains an open question [1]. Recent Raman measurements indicate that there are vibronic excitations in its magnetodielectric regime, which in turn suggest a strong coupling between its spin, lattice and electronic degrees of freedom [2]. In this study, we apply density functional theory with LDA+U+SOC functional to disentangle the multiple coupling channels. The results show that strong coupling exists between the phonons and crystal-field excitations. This study helps to elucidate the underlying mechanism of the strong magnetodielectric effect in Ce2O3.

*This work was funded by the grant DOE FG02-12ER46875 (SciDAC).

Matter-Beam Interactions: Photochemistry with Virtual Photons?* DAVID LINGERFELT (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JACEK JAKOWSKI, Center for Nanophase Materials Sciences & Computational Sciences and Engineering Division, Oak Ridge National Laboratory, PANCHAPAKESAN GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, BOBBY SUMPTER, Center for Nanophase Materials Sciences & Computational Sciences and Engineering Division, Oak Ridge National Laboratory — It has recently been appreciated that the convergent electron beams used in scanning transmission electron microscopes (STEMs) can not only be employed for purposes of structural determination, but also for inducing local chemical transformations. STEMs have already been used to build heterostructures from substitutional defects in two-dimensional materials with atomic precision; a feat with transformative technological implications. However, the mechanisms underlying the chemical processes initiated by the matter-beam interaction are not yet well-understood. I will present our recent progress towards first principles methods for describing the electronic response of materials to high energy electron irradiation. I will also discuss the selection rules for electronic excitations that can occur in the materials, which depend explicitly on the incident electron's point of impact. Finally, I will give an overview of a study in which these methods are applied to reveal defect-centered excited states of silicon-doped graphene nanostructures, and the effects of beam-induced population of these exited states on the reactivity of the silicon defect.

*This work was performed at the Center for Nanophase Materials Sciences, a U.S. Department of Energy Office of Science User Facility.
10:36 AM A39.00012: Discretized Diagonalization for Efficient Berry Curvature Integration: Application to Electric Polarization  
JOHN BONINI (Presenter), DAVID VANDERBILT, KARIN M RABE, Rutgers University, New Brunswick — An important property in characterizing the response of a material to an electric field is the induced change in electric polarization. For periodic systems, the modern theory of polarization relates this change to a change in the Berry phase, raising the question of the correct choice of branch. In this talk, I present a new method for predicting the electric-field-induced change in polarization using only the wavefunctions of only the initial and final states, based on finely subdividing the relevant phase change into gauge-invariant pieces. The underlying assumptions are automatically checked within the method and are valid for most known ferroelectrics, allowing the computation of switching polarization without the need to identify an explicit path or to perform calculations for intermediate states. The extension of this approach to the computation of other quantities expressed in terms of Berry curvature, notably topological invariants, will be discussed.

10:48 AM A39.00013: Study of the near-edge optical properties of monoclinic HfO$_2$ from first-principles*  
XIAO ZHANG (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — HfO$_2$ is a wide band gap dielectric material, that has applications in optical coatings, rendering the importance of a precise description of its optical properties. The full understanding, however, has been limited by the lack of a consistent explanation of a shoulder-like feature near the absorption onset, reported in multiple experimental studies. In this work, by solving the Bethe-Salpeter equation (BSE) for the optical polarization function, we compute the optical spectra of monoclinic HfO$_2$ from first-principles. From these results we show that the shoulder-like effect is intrinsic to the crystal and is related to excitonic effects. Further, we show that since HfO$_2$ is a polar material, lattice screening, especially beyond the current static screening approximation, can potentially be important in describing dielectric screening of the electron-hole Coulomb interaction. In this work, we explored the effect of \textit{dynamical} lattice screening in HfO$_2$, and aim at describing the influence of lattice screening on the near-edge optical spectra.

*This work is supported by the National Science Foundation (No. DMR-1555153) and is part of the Blue Waters sustained-petascale computing project, supported by the NSF (No. OCI-0725070 and ACI-1238993) and the state of IL.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A40 DCOMP DCMP DPOLY DBIO: Building the Bridge to Exascale: Applications and Opportunities for Materials, Chemistry, and Biology | 705 - Jack Wells, Oak Ridge National Lab - Tag(s): Focus
8:00AM A40.00001: A Path to the Exascale for Atomistic Simulations with Improved Accuracy, Length and Time Scales* [Invited] MITCHELL WOOD (Presenter), AIDAN THOMPSON, STEVEN JAMES PLIMPTON, Sandia National Laboratories, ANDERS NIKLASSON, DANNY PEREZ, Los Alamos National Lab — With exascale super computers arriving in the near future, it is timely to ask whether our simulation software is capable of matching this unprecedented computing capability. While many research challenges in material physics, chemistry and biology lie just out of reach on peta-scale machines due to length and time restrictions inherent to Molecular Dynamics(MD), questions of the accuracy of our simulations will continue to linger. Simply running the same peta-scale simulations with more atoms on a larger computer (weak scaling) does not advance the accessible timescales, nor does it avoid the pitfalls of empirically developed constitutive models. This talk will overview the U.S. Department of Energy* EXAALT (EXascale Atomistics for Accuracy, Length and Time) project and our efforts to provide software tools for MD that not only scale efficiently to huge atom counts, but also enable efficient MD simulations for smaller systems too. New parallel time-acceleration methods such as sublattice-ParSplice and local hyperdynamics have been developed along with quantum accurate machine learned interatomic potentials to study damage accumulation in plasma facing materials.

*This work is funded through the Exascale Computing Project (No. 17-SC-20-SC), a collaborative effort of the U.S. Department of Energy Office of Science and the National Nuclear Security Administration.

8:36AM A40.00002: Accelerating Quantum Molecular Dynamics simulations: Can GPUs really help?* JEAN-LUC FATTEBERT (Presenter), Oak Ridge National Laboratory, CHRISTIAN F. A. NEGRE, JAMAL MOHD-YUSOF, TOKS ADEDOYIN, Los Alamos National Laboratory, DANIEL OSEI-KUFFUOR, Lawrence Livermore National Laboratory, SUSAN MNISZEWSKI, Los Alamos National Laboratory — GPU accelerators on the most powerful supercomputers give us an opportunity to speed up time-to-solution for large-scale Quantum Molecular Dynamics simulations that would otherwise be too slow for practical purposes. But using this type of hardware in an efficient manner presents serious challenges. Besides having to possibly rewrite large amounts of codes, algorithmic changes may be required for optimal efficiency. Even then, using GPUs at full capacity is not straightforward, in particular if there is not enough work for each GPU. In this talk we will present some software library solutions in development to facilitate porting electronic structure codes to new architectures, as well as parallel strategies and algorithms that can help speed up time-to-solution in real applications.

*This research was supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. Department of Energy Office of Science and the National Nuclear Security Administration. This research used resources of the Oak Ridge Leadership Computing Facility at the Oak Ridge National Laboratory, which is supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC05-00OR22725.
8:48AM A40.00003: Multibillion Atom Molecular Dynamics Simulations of Cellular Membranes  
NOAH TREBESCH (Presenter), Center for Biophysics and Quantitative Biology, Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, EMAD TAJKHORSHID, Department of Biochemistry, Center for Biophysics and Quantitative Biology, Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign — Membranes are the basic organizational and defensive unit of the cell, and they thus play a vital role in biological function. Electron microscopy (EM) can provide 3D structures of these membranes, and, with the advent of exascale computing, there is a new opportunity to use molecular dynamics (MD) simulations to elucidate the intricate biophysical connection between the complex structure and function of these membranes. To take advantage of this opportunity, we have developed xMAS (Experimentally-Derived Membranes of Arbitrary Shape) Builder, software designed to turn low resolution EM-based structures of cellular membranes into atomistic models that are suitable for MD. Using xMAS Builder, we have built the first cell-scale (~4.5 billion atom) model of a representative cellular membrane (a helicoidal system from the endoplasmic reticulum), and we have also built several models of a smaller synthetic system with equivalent complexity. Preliminary simulations of these models have demonstrated their potential to reveal fundamental insights into the general behavior of cellular membranes, supporting the expectation that xMAS Builder will soon enable MD simulations that leverage exascale computing to provide detailed biophysical characterization of these key biological systems.

9:00AM A40.00004: Unveiling the structural properties of HIV-1 vesicle from atomistic molecular dynamics simulations  
FABIO GONZALEZ, Univ of Delaware, TYLER REDDY, Los Alamos National Laboratory, JUAN PERILLA (Presenter), Univ of Delaware — The HIV-1 viral particle contains all the macromolecular components to infect host cells, typically CD4 + T human cells, by fusion of the viral envelope with the cell plasma membrane. Such macromolecular components correspond to phospholipids, membrane glycoproteins, genomic RNA, and gag polyproteins; which are assembled during infection to furthermore undergo maturation and structural re-arrangements to form the virion. Here, exploiting the advances of molecular modeling, we present the first insights towards the construction of an all-atomistic model of the HIV-1 mature and immature virion. The model includes a twenty-four lipids bilayer with membrane glycoproteins, and the capsid protein. We review over the techniques proposed to build and prepare the system, as well as the steps required to simulate, analyze and characterize the HIV-1 virion model, which contains over 800 million atoms.
9:12AM A40.00005: Molecular Understanding of Membranes for the Water-Energy Nexus in the Exascale Realm*  
DVORA PERAHIA (Presenter), Clemson University, GARY GREST, Sandia National Laboratories — Polymeric membranes are used for a large variety of clean energy, medical, and environmental applications. Their use remains limited by tradeoffs of permeability, selectivity and longevity. A fundamental paradigm shift from a descriptive continuum approach to a predictive atomic and molecular level understanding of ion transport is essential for transformative progress to programable smart membranes. The need to control the interrelation of membrane structure, dynamics, transport and stability over a wide range of length and time scales is in the core of design of new membranes. Here we will present molecular dynamics simulation results that depict the structured motion and transport in polymeric membranes that consists of units, or blocks, with different chemical structures, tailored into a macromolecule with targeted roles. The impact of fundamentals that underline the structure/processing/properties relations that will be attained through exascale computing will be discussed.

9:24AM A40.00006: Multi-GPU parallelization of Deep Potential Molecular Dynamics for high-performance computing  
DENGHUI LU (Presenter), College of Engineering, Peking University, Beijing 100871, P. R. China., WEILE JIA, University of California, Berkeley, CA, 94720, USA, MOHAN CHEN, College of Engineering, Peking University, Beijing 100871, P. R. China., HAN WANG, Laboratory of Computational Physics, Institute of Applied Physics and Computational Mathematics, Huayuan Road 6, Beijing 100088, People's Republic of China, LINFENG ZHANG, Program in Applied and Computational Mathematics, Princeton University, Princeton, NJ 08544, USA — The recently developed Deep Potential Molecular Dynamics [1,2] (DPMD) builds many-body potentials for atomic systems based on the deep neural network and has been successfully applied to a variety of systems. The DPMD model owns the quantum mechanical accuracy and the linear growth computational complexity. In this work, we develop the multi-GPU parallelization for DeePMD-kit [3], an implementation of DPMD, and optimize the workflows when the package interfaces with LAMMPS and TensorFlow. We demonstrate that the resulting package is well-suited for high-performance computing with the aim of performing large-scale molecular simulations with quantum mechanical accuracy.

9:36AM A40.00007: Scalable Frameworks for Reinforcement Learning for Control of Self-Assembling Materials and for Chemistry Design  PAUL WELCH (Presenter), Theoretical Division, Los Alamos National Laboratory, CHRISTINE SWEENEY, Los Alamos National Laboratory, MALACHI SCHRAM, Pacific Northwest National Laboratory, LOGAN WARD, Argonne National Laboratory — The ExaLearn Exascale Computing Project has developed scalable frameworks for reinforcement learning (RL) to control scientific processes such as the self-assembly of block copolymers and chemical design. These policies could drastically reduce the time required to navigate large parameter spaces, optimizing experimental protocols. This accelerated search methodology may thus guide materials annealing experiments, exploration of candidate structures for battery materials, or evaluation of the configurational space for low-energy water clusters. The frameworks use various RL algorithms, environments and fast-running scientific simulations for the training process. RL training can be thought of as creating a sequence of moves in a game; at each move the player (agent) may decide to exploit previous knowledge (a policy) or explore new parameters (run a simulation). Scalability is achieved by running many RL training episodes on different nodes and aggregating models. Challenges include developing simulations, fully utilizing CPU and GPU resources on each node, and aggregating policies so as not to impede learning. We present results for full single node and preliminary multi-node computing resource utilization performance.

9:48AM A40.00008: Exascale-ready neural network interatomic potentials with CabanaMD*  SAM REEVE (Presenter), Lawrence Livermore Natl Lab, SAKETH DESAI, Purdue University, JAMES BELAK, Lawrence Livermore Natl Lab — Computational predictions for materials require sufficiently accurate physics models which can be simulated in a reasonable amount of time. In the drive towards exascale computing, new hardware and software technologies are enabling more complex, accurate, and expensive models, but only with rethinking of algorithms, communication patterns, and data layouts. We exemplify this trend with a re-implementation of the Behler-style neural network potential (NNP), for classical molecular dynamics (MD) with near-quantum level accuracy. We use the Co-design center for Particle Applications (CoPA) Cabana particle library which, i) is built on Kokkos for on-node parallelism on various hardware, ii) provides performant particle-centric functionality, including MPI communication and neighbor lists, and iii) enables optimization of data structure for a given architecture through arrays-of-structs-of-arrays (AoSoA), intermediate between AoS and SoA. The NNP is added to the CabanaMD proxy app, where we show performance portability, including many-core CPU and GPU.

*Work performed under the auspices of the U.S. DOE by LLNL under contracts DE-AC52-07NA27344 and supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. DOE Office of Science and the NNSA.
10:00AM A40.00009: DOE Software Center for Non-perturbative Studies of Functional Materials Under Non-equilibrium Conditions (NPNEQ)*  

TADASHI OGITSU (Presenter), XAVIER ANDRADE, ALFREDO A. CORREA, Lawrence Livermore Natl Lab, LIANG TAN, DAVID PRENDERGAST, Lawrence Berkeley National Laboratory, SRI CHAITANYA DAS PEMMARAJU, SLAC, AARON LINDENBERG, SLAC/Stanford — Fundamental processes that underlie transformations of energy and information in material systems are intrinsically non-equilibrium in character as they involve additional coupling of electronic and ionic degrees of freedom to external time-dependent perturbations such as light or electrical voltages. Understanding and controlling the quantum non-equilibrium nature of functional materials on the characteristic Angstrom (Å, 10^{-10} m) length scales and femtosecond (fs, 10^{-15} s) time scales of electronic motion is a crucial component in the rational design of energy-relevant materials and devices. In this presentation, we will introduce the software center, NPNEQ, where the open-source real-time time-dependent density-functional-theory (RT-TDDFT) code is being developed. We will also discuss about joint theory-experiment scientific research plan that will fully take advantage of the RT-TDDFT code that exploits the full potential of the GPU-CPU architectures as well as the ultrafast experimental capability at SLAC.

*The work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344 and was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division.

10:12AM A40.00010: Towards fast and accurate exascale density functional theory calculations using DFT-FE -- a massively parallel real-space code using adaptive finite-element discretization*  

SAMBIT DAS (Presenter), PHANI MOTAMARRI, VIKRAM GAVINI, Univ of Michigan - Ann Arbor — Kohn-Sham density functional theory (DFT) calculations have been instrumental in providing many crucial insights into materials behavior and occupy a sizable fraction of world’s computational resources today. However, the stringent accuracy requirements in DFT needed to compute meaningful material properties, in conjunction with the asymptotic cubic-scaling computational complexity with number of electrons, demand huge computational resources. Thus, these calculations are routinely limited to material systems with at most few thousands of electrons. In this talk, we present a significant advance in the state-of-the-art for accurate DFT calculations -via- the development of DFT-FE, that has enabled fast, scalable and accurate large-scale DFT calculations on material systems with tens of thousands of electrons. This has been facilitated by (i) the development of efficient and accurate spatially adaptive discretization strategies using higher-order finite-element discretization; (ii) developing efficient and scalable algorithms in conjunction with mixed-precision strategies; (iii) implementation innovations, both on many core and hybrid architectures, that significantly improve performance.

*DoE-BES Award Number DE-SC0008637 and Toyota Research Institute
10:24AM A40.00011: Massively-Parallel Real-Time TDDFT Simulations of Electronic Stopping in Solvated DNA under Proton Irradiation* DILLON C YOST (Presenter), YI YAO, CHRIS SHEPARD, YOSUKE KANAI, Univ of NC - Chapel Hill — We discuss massively-parallel real-time, time-dependent density functional theory (RT-TDDFT) simulations for investigating electronic stopping in DNA solvated in water. We have developed RT-TDDFT capabilities within the Qbox/Qb@ll code, based on a planewave-pseudopotential formalism [1], which is applied to study the electronic excitation dynamics of solvated DNA under proton irradiation. In electronic stopping processes, massive electronic excitations are produced by fast energetic charged particles like protons. Electronic stopping is central to DNA damage by ion irradiation, which is central to ion beam cancer therapy. We discuss the scalable implementation and performance of the RT-TDDFT simulations and recent results for solvated DNA, a system which includes more than 13,000 electrons.

*This work was financially supported by the NSF under Awards No. CHE-1565714/OAC-1740204. Computer time was provided by the Innovative and Novel Computational Impact on Theory and Experiment (INCITE) program This research used resources of the Argonne Leadership Computing Facility (ALCF), which is a DOE Office of Science User Facility supported under Contract No. DE-AC02-06CH11357.

10:36AM A40.00012: Spatiotemporal Mapping of Polymer Dynamics* JIHONG MA (Presenter), JAN-MICHAEL CARRILLO, BOBBY SUMPTER, YANGYANG WANG, Oak Ridge National Laboratory — Polymers present unique challenges to computational science, as their structures and dynamics are characterized by a remarkably wide range of length scales and timescales. The recent advances in high performance computing systems have afforded new opportunities to investigate the slow dynamics in polymeric liquids. In this talk, we demonstrate a novel approach to resolve the fine spatiotemporal features of entangled polymer dynamics, by leveraging the computational resources at the Oak Ridge Leadership Computing Facility. Potential applications of this new method will also be discussed.

*The research is supported by the Laboratory Directed Research and Development Program (LDRD) of the Oak Ridge National Laboratory.
Towards adaptive exascale workflows for simulating long timescales

JOHN OSSYRA (Presenter), University of Tennessee, Knoxville, ADA SEDOVA, JEREMY SMITH, Oak Ridge National Laboratory — Molecular dynamics simulations integrate trillions of short simulation steps and are reaching hardware-bound performance limits for clock time per step. Despite this, most biologically relevant processes occur over seconds to hours, orders of magnitude slower than feasible simulation timescales. Workflow-based methods harnessing complex statistical mechanics analyses are increasingly used with the hope of achieving kinetic estimates on experimentally relevant timescales from swarms of short parallel simulations. We present a highly scalable workflow software, AdaptiveMD, that implements a massively parallel adaptive-sampling algorithm to build a Markov-state model of long-timescale biomolecular kinetics. The software was ported to the Summit pre-exascale machine at the Oak Ridge Leadership Computing Facility (OLCF), after initial development on OLCF Titan, and demonstrated excellent scalability and fault tolerance. Summits software and hardware features allow for an unprecedented ability to simulate large biomolecular systems within this framework. These results suggest that this method at exascale may allow us to tackle grand challenges in biomolecular simulations.

Session A41 GMAG DMP FIAP DCOMP: 2D Magnetic Materials

8:00AM A41.00001: Discovery of Intrinsic Two-dimensional Ferromagnetism in CrTe$_2$ Thin films

XIAOQIAN ZHANG, JACOB COOK (Presenter), QIANGSHENG LU, GUANG BIAN, Univ of Missouri - Columbia — Two-dimensional (2D) layered ferromagnetic (FM) materials have attracted much interest recently since the discovery of intrinsic 2D ferromagnetism in atomically thin layers. Due to the reduced dimensionality, 2D magnets usually exhibit weak magnetic ordering compared to conventional bulk magnets. In this work, we report robust 2D ferromagnetism in chromium ditelluride (CrTe$_2$) nanofilms whose electronic structure and magnetic properties are clearly resolved by angle-resolved photoemission spectroscopy (ARPES), superconducting quantum interference device (SQUID) and X-ray magnetic circular dichroism (XMCD). The robust ferromagnetism has been experimentally evidenced, and persists up to 250 K. In addition, the electron band structure of the ferromagnetic ground state was clearly resolved by in-situ ARPES. These experimental evidences establish CrTe$_2$ nanofilms as an outstanding 2D vdW magnet for spintronics applications.

8:12AM A41.00002: Magnetic field- and temperature-dependent resonant Raman spectroscopy of bulk CrI₃

SIWEN LI (Presenter), Univ of Michigan - Ann Arbor, ZHIPENG YE, Texas Tech University, XIANGPENG LUO, Univ of Michigan - Ann Arbor, GAIHUA YE, Texas Tech University, SHANGJIE TIAN, HECHANG LEI, Renmin University of China, KAI SUN, Univ of Michigan - Ann Arbor, RUI HE, Texas Tech University, LIUYAN ZHAO, Univ of Michigan - Ann Arbor — The van der Waals magnet CrI₃ has been thought to host ferromagnetism in its bulk form and interlayer antiferromagnetism in its few-layer form. The magnetic excitations in bulk CrI₃ have been probed by inelastic neutron scattering, while those in CrI₃ films have been studied with inelastic magneto-tunneling spectroscopy and Raman spectroscopy. Despite such intensive effort, it remains mysterious till now how the interlayer magnetism evolves from the ferromagnetic type in bulk to the antiferromagnetic one in thin films and what the low energy magnetic excitations are in CrI₃. In this talk, we will present our results on temperature- and magnetic field-dependent resonant Raman spectroscopy studies on bulk CrI₃. We will show our experimental evidences on the complex spin wave structures in bulk CrI₃ and their intricate magnetic field dependence. We will further discuss the magnetic field dependence of phonons and explore the interplay between the lattice and the spin degrees of freedom in bulk CrI₃.

*Supported by NSF CAREER Grants No. DMR-1760668 and No. DMR-1749774.

8:24AM A41.00003: Electric-Field Control of 2D Magnetism in Bilayer VI₃

THI PHUONG THAO NGUYEN (Presenter), KUNIHIKO YAMAUCHI, TAMIO OGUCHI, Institute of Scientific and Industrial Research Osaka University — The recent discovery of two-dimensional van-der-Waals (vdW) magnetic materials has received much interest owing to its potentials for future spintronics device applications. There is a large number of recent publications on two-dimensional honeycomb ferromagnet CrI₃, which belong to the family of transition-metal trihalides MX₃ with X = Cl, B, and I, as a promising candidate materials for spintronics and magnetoelectronic applications. VI₃ is a new discovered material that belongs to the transition-metal trihalides. While its structure and bulk properties have been investigated, there is a lack of information about the magnetism in the thin film. In this presentation, we will present our first-principle study on the magnetic properties in bilayer VI₃ and the influence of applied electric-fields on the magnetism. We predict that the magnetic stability of bilayer VI₃ systems can be tuned by external electric fields and the effect is comparable with the case of bilayer CrI₃. To understand the physics behind, the geometry, stability, and electronic and magnetic properties of bilayer VI₃ will be discussed by presenting the projected density of state and the band structure.
Light-controlled magnetism in vanadium-doped tungsten disulfide monolayers

VALERY ORTIZ JIMENEZ (Presenter), YEN THI HAI PHAM, VIJAYSANKAR KALAPPATTIL, Physics, University of South Florida, FU ZHANG, MAURICIO TERRONES, Materials Science and Engineering, Pennsylvania State University, MANH-HUONG PHAN, Physics, University of South Florida — Transition metal dichalcogenides (TMDs) have received growing attention for their outstanding electrical and optical properties. A promising way to induce long-range ferromagnetism (FM) in TMDs is by introducing magnetic dopants to form a dilute magnetic semiconductor. Our recent study shows room temperature (RT) FM in V-doped monolayer WSe$_2$ (V-WSe$_2$), which is an important step for TMDs based spintronics. In this work, we show light-mediated magnetism in V-WS$_2$ at RT. We probe this effect using the magnetic LC-resonance principle which employs a soft FM Co-based microwire coil driven near resonance with an RF signal. Combined with an excellent giant magneto-impedance effect, the coil becomes highly sensitive to changes in magnetic flux through its core. The monolayer, placed at the core of the coil, is excited with a laser as we measure the change in magnetization. Interestingly, the magnetization depends on laser power and doping concentration, demonstrating the light control of 2D magnetism. We attribute this to the generation of electron-hole pairs which mediate the magnetization of the monolayer. These findings provide a promising route to exploit light-controlled FM in 2D spintronic devices.

Strain Tuning of Magnetic Order in Two-dimensional Magnets

SHENGWEI JIANG (Presenter), HONGCHAO XIE, Cornell University, DANIEL WEBER, JOSHUA GOLDBERGER, Ohio State University, JIE SHAN, KIN FAI MAK, Cornell University — The recent discovery of two-dimensional (2D) van der Waals magnetic materials has received growing attention. Of particular interest are the thickness-dependent magnetic ground states in atomically thin CrI$_3$. The competing ferromagnetic and anti-ferromagnetic interlayer exchange interactions result in a competing magnetic order that is sensitive to external perturbations including magnetic field, electrostatic gating, and hydrostatic pressure. Here we demonstrate that the magnetic order in 2D CrI$_3$ can also be effectively tuned by applying in-plane strain. Our result demonstrates the potential for the application of 2D magnets in spin-mechanical devices.
9:00AM A41.00006: Tuning Magnetism of Monolayer Tungsten Disulfide by Transition Metal Doping* YEN THI HAI PHAM (Presenter), VALERY ORTIZ JIMENEZ, VIJAYSANKAR S KALAPPATTIL, Univ of South Florida, FU ZHANG, MAURICIO TERRONES, Pennsylvania State University, MANH-HUONG PHAN, Univ of South Florida — The recent discoveries of intrinsic ferromagnetism (FM) in two-dimensional (2D) materials have drawn particular attention on encoding the spin behavior at low dimensions. Theoretical investigations of 2D transition metal dichalcogenides (TMDs) have predicted promising perspectives for inducing intrinsic FM in 2D TMD semiconductors by transition metal doping. This has motivated us to experimentally exploit magnetic functionality in monolayer Fe- and V-doped WS₂ - a semiconducting TMD with outstanding optoelectronic and valleytronic properties. Pristine and Fe/V-doped monolayer tungsten disulfide films were grown on SiO₂ substrates by a single-step solution-based method. We observe that while monolayer WS₂ possesses a weak ferromagnetic ordering on its diamagnetic background, Fe:WS₂ and V:WS₂ monolayers exhibit strong, intrinsic FM at room temperature, which is also tunable by controlling dopant concentration. This, coupled with high-resolution TEM images, has suggested the mechanism of strong ferromagnetism in the films, resulting from the magnetic dopants and spatial-dependent ferromagnetic ordering between them. Our findings offer a prospect of developing novel 2D dilute magnetic semiconductors for future spintronic applications.

*Work was supported by VISCOSTONE (VS-1253113200).

9:12AM A41.00007: Magnetic Correlations in the Quasi-2D Semiconducting Ferromagnet CrGeTe₃ TRAVIS WILLIAMS (Presenter), ADAM ACZEL, Oak Ridge National Laboratory, BRENDEN ORTIZ, PAUL SARTE, STEPHEN WILSON, University of California, Santa Barbara — The quasi-two-dimensional, semiconducting ferromagnets CrSiTe₃ and CrGeTe₃ have been studied as candidates for spintronics applications due to the relatively accessible transition temperatures and large magnetic moments. While CrSiTe₃ has been more studied due to the ease of growing crystals, CrGeTe₃ is more interesting due to the higher transition temperature $T_C = 61$ K. In this study, we use neutron scattering to measure the static and dynamic magnetic properties. Neutron diffraction was used to study the 3D order below $T_C$, as well as two dimensional static correlations above the transition. Preliminary inelastic measurements shed light on the nature of the spin gap and magnetic correlations that drive the magnetism in this material, which can be contrasted to previous work on CrSiTe₃.
First-principles theory of proximity spin-orbit torque on a two-dimensional magnet: Current-driven antiferromagnet-to-ferromagnet reversible transition in bilayer CrI$_3$ KAPILDEB DOLUI (Presenter), MARKO PETROVIC, Department of Physics and Astronomy, University of Delaware, USA, KLAUS ZOLLNER, University of Regensburg, Germany, PETR PLECHAC, Department of Mathematical Science, University of Delaware, USA, JAROSLAV FABIAN, University of Regensburg, Germany, BRANISLAV NIKOLIC, Department of Physics and Astronomy, University of Delaware, USA — The recently discovered two-dimensional (2D) magnetic insulator CrI$_3$ is an intriguing case for basic research and spintronic applications since it is a ferromagnet in the bulk, but an antiferromagnet in bilayer form, with its magnetic ordering amenable to external manipulations. Using first-principles quantum transport approach, we predict that injecting unpolarized charge current parallel to the interface of bilayer-CrI$_3$/monolayer-TaSe$_2$ van der Waals heterostructure will induce spin-orbit torque (SOT) and thereby driven dynamics of magnetization on the first monolayer of CrI$_3$ in direct contact with TaSe$_2$. By combining calculated complex angular dependence of SOT with the Landau-Lifshitz-Gilbert equation for classical dynamics of magnetization, we demonstrate that current pulses can switch the direction of magnetization on the first monolayer to become parallel to that of the second monolayer, thereby converting CrI$_3$ from antiferromagnet to ferromagnet while not requiring any external magnetic field. The transition can be detected by passing vertical read current through the vdW heterostructure, encapsulated by bilayer of hexagonal boron nitride and sandwiched between graphite electrodes, where we find tunneling magnetoresistance of 240% [1].

Large anomalous Nernst effect in a van der Waals ferromagnet Fe$_3$GeTe$_2$ JINSONG XU (Presenter), WILLIAM ADAM PHELAN, CHIA-LING CHIEN, Johns Hopkins University — Anomalous Nernst effect, a result of charge current driven by temperature gradient, provides a probe of the topological nature of materials due to its sensitivity to the Berry curvature near the Fermi level. Fe$_3$GeTe$_2$, one important member of the recently discovered two-dimensional van der Waals magnetic materials, offers a unique platform for anomalous Nernst effect because of its metallic and topological nature. Here, we report the observation of large anomalous Nernst effect in Fe$_3$GeTe$_2$. The anomalous Hall angle and anomalous Nernst angle are about 0.07 and 0.09 respectively, far larger than those in common ferromagnets. By utilizing the Mott relation, these large angles indicate a large Berry curvature near the Fermi level, consistent with the recent proposal for Fe$_3$GeTe$_2$ as a topological nodal line semimetal candidate. Our work provides evidence of Fe$_3$GeTe$_2$ as a topological ferromagnet, and demonstrates the feasibility of using two-dimensional magnetic materials and their band topology for spin caloritronics applications.

Unconventional magnetic behavior in two-dimensional layered CrTe$_2$ films*  

HANG CHI (Presenter), YUNBO OU, Massachusetts Institute of Technology, DON HEIMAN, Northeastern University, JAGADEESH MOODERA, Massachusetts Institute of Technology — Quasi two-dimensional (2D) transition metal dichalcogenides (TMDs) often exhibit nontrivial topological phenomena. Here, we explore the behavior of a new van der Waals (vdW) TMD, CrTe$_2$ epitaxial films with apparent C$_6$ in-plane symmetry. Rich magnetic/transport properties develop upon varying film thickness. In the few monolayer (ML) regime, films display perpendicular magnetic anisotropy with a Curie temperature $T_C \sim 160$ K for 40 ML thickness. Apart from the ordinary Hall effect (OHE) with linear field dependence, the anomalous Hall effect (AHE) manifests a unique temperature-dependent sign reversal. Interestingly, a novel feature arising from the topological Hall effect (THE) is observed as well. These features likely originate from the strained substrate/film interface, which is believed to modify the topology of the electronic band structure and stabilize the formation of magnetic skyrmions in layered TMD. The vdW nature of CrTe$_2$ makes it appealing for interfacial Berry-phase engineering. The ferromagnetic CrTe$_2$ films with novel noncoplanar spin textures and novel electronic properties offer new opportunities for spintronics devices using vdW TMDC architectures.

*Supported by ARO W911NF-19-2-0015 and W911NF-19-2-0041, NSF DMR 1700137, ONR N00014-16-1-2657 and CIQM-NSF 1231319.

Ultimate tunability of ferromagnetic anisotropy in chromium mixed halides*  

FAZEL TAFTI (Presenter), THOMAS TARTAGLIA, FARANAK BAHRAMI, JOSEPH TANG, Boston College — In recent years, chromium iodide, bromide, and chloride have received attention due to exhibiting ferromagnetic ordering in 2D which is ideal for ultrathin magneto-optical devices. Also, it has been demonstrated that by alloying the halides, the magnetic easy axis can be tuned. Here, we show the ultimate case of such alloying, by presenting a new material CrClBrI where all three halides are mixed in one composition. The crystals of CrClBrI are thin and exfoliate. We present a phase diagram of all compositions of mixed halides and demonstrate how the critical temperature, Weiss constant, and magnetic anisotropy are continuously tuned across the series.

*NSF-DMR-1708929
10:12AM A41.00012: Spin-dependent scattering in 2D van der Waals ferromagnet Fe\textsubscript{0.29}TaS\textsubscript{2} and its heterostructure  
RANRAN CAI (Presenter), PENG LV, WENYU XING, YUNYAN YAO, YANG MA, HUIBIN ZHOU, BONING LI, YANGYANG CHEN, SHUANG JIA, Department of physics, ICQM, Peking University, IGOR ZUTIC, Department of physics, University at Buffalo, XINCHENG XIE, QING-FENG SUN, WEI HAN, Department of physics, ICQM, Peking University — The recent emergence of two-dimensional (2D) van der Waals ferromagnets has provided a new platform for exploring magnetism in the flatland and for designing 2D ferromagnet-based spintronics devices. In this talk, we will present the spin-scattering mechanisms in quasi-2D van der Waals ferromagnet. Via systematically measuring Fe\textsubscript{0.29}TaS\textsubscript{2} devices with different thickness, it is found that the dominant AHE mechanism is found to be skew scattering in bulk single crystal, and the contribution from intrinsic mechanism emerges and become more relevant as the Fe\textsubscript{0.29}TaS\textsubscript{2} thickness decrease. At the end, the spin-dependent scattering at the Fe\textsubscript{0.29}TaS\textsubscript{2}/superconductor interface will be discussed.

10:24AM A41.00013: Stacking Dependence of the Chern Number in a Ferromagnetic Topological Magnon Insulator Heterostructure*  
STEPHEN HOFER (Presenter), Physics, Southern Illinois University Carbondale, TRINANJAN DATTA, Chemistry and Physics, Augusta University, DIPANJAN MAZUMDAR, Physics, Southern Illinois University Carbondale — Recent advances in topological materials have shown that 2D magnetic insulators can be promising hosts for topologically non-trivial magnons. In this work we focus on the topological magnetic features of these materials as they might be grown in the few-layer regime. Particularly, we explore the AA and AB stacking dependencies on the Chern numbers of a layered ferromagnetic honeycomb topological magnon insulator heterostructure. Based on our bandstructure and Berry curvature calculations we show that the evolution of the Chern numbers depend non-trivially on the number of layers and the stacking arrangement, AA or AB. Additionally, we also discuss the physical consequences of sandwiching topological and non-topological ferromagnetic layers.

*NSF CAREER grant (ECCS: Award#1846829).

10:36AM A41.00014: Quantum critical point and ferromagnetic semiconducting behavior in p-type FeAs\textsubscript{2}  
BING-HUA LEI (Presenter), YUHAO FU, ZHENZHEN FENG, DAVID SINGH, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211-7010, USA — Ferromagnetic semiconductors are of interest due to the unusual combination of physical properties and because if tunable they may offer opportunities for studying magnetic quantum critical points. Here, we illustrate an approach for studying suitable materials based on itinerant magnetism, different from conventional magnetic semiconductors. We show that p-type FeAs\textsubscript{2} is an example. The complex non-parabolic band structure of this material leads to a ferromagnetic instability when doped, while at the same time allowing for a modest transport effective mass. This leads to an analogy between magnetic semiconductors and thermoelectric materials.

*This work was supported by the Department of Energy, award number DE-SC0019114.
Temperature Dependence of the Anomalous Hall Effect from Electron Interactions

SONGCI LI (Presenter), ALEX LEVCHENKO, University of Wisconsin - Madison — We consider the impact of electron-electron interactions on the temperature dependence of the anomalous Hall effect in disordered conductors. The microscopic analysis is carried out within the diagrammatic approach of the linear response Kubo-Streda formula with an account of both extrinsic skew-scattering and side-jump mechanisms of the anomalous Hall effect arising in the presence of spin-orbit coupling. We demonstrate the importance of electron interactions in the Cooper channel even for nominally non-superconducting materials and find that the corresponding low-temperature dependence of the anomalous Hall conductivity is asymptotically of the form $T^{1/2}/\ln(T_0/T)$ in three dimensions and $\ln[\ln(T_0/T)]$ in two dimensions, where the scale of $T_0$ is parametrically of the order of Fermi energy. These results, in particular, may provide an explanation for the recently observed unconventional temperature dependence of the anomalous Hall effect in HgCr$_2$Se$_4$.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A42 GMAG DMP: Chiral and Topological Spin Textures 709/711 -
Lucas Caretta, University of California, Berkeley - Tag(s): Focus
8:00AM A42.00001: Manipulation of topological spin structures at ultrathin magnetic interfaces by oxygen adsorption and interlayer exchange coupling* TZU-HUNG CHUANG (Presenter), Scientific Research Division, National Synchrotron Radiation Research Center, LIANG-WEI LAN, Department of Physics, National Sun Yat-sen University, MING-CHING WU, CHIA-CHI LIU, Scientific Research Division, National Synchrotron Radiation Research Center, YAO-JUI CHAN, Department of Physics, National Sun Yat-sen University, CHIH-HENG HUANG, International PhD Program for Science, National Sun Yat-sen University, DER-HSIN WEI, Scientific Research Division, National Synchrotron Radiation Research Center, CHIEN-CHENG KUO, Department of Physics, National Sun Yat-sen University — Magnetic skyrmions have been investigated from fundamental physics to applications for next generation high-density information encoding. Such non-collinear magnetic structures at interfaces are usually attributed to the Dzyaloshinskii-Moriya interaction (DMI) when the inversion symmetry is broken. Here we report two ultrathin ferromagnetic systems, where the first one demonstrates a microscopic insight on how the oxygen adsorption modulates the spin reorientation transition (SRT) of a Fe/Ni bilayer on Cu(100) and consequently impacts on the DMI of the interface. The second case shows that even in a negligible DMI interface, such as Co/Au(111), magnetic skyrmion bubbles can be stabilized at room temperature in the metastable phase of spin canting configuration within the SRT by interlayer exchange coupling across a non-magnetic spacer layer. The magnetic images are measured by X-ray magnetic circular dichroism (XMCD) based photoemission electron microscopy (PEEM), and the experimental results are discussed with the help of micromagnetic simulations.

*Supported by MOST 105-2112-M-213-012-MY2, MOST 107-2112-M-213-008, and National Synchrotron Radiation Research Center

8:12AM A42.00002: Equilibrium thermodynamic properties of chiral skyrmions in ferromagnetic materials* ROBERTO ZIVIERI (Presenter), Univ of Messina — The equilibrium statistical thermodynamics of chiral magnetic skyrmions developing in a ferromagnetic material having the shape of an ultrathin cylindrical dot is investigated. This is accomplished by determining via analytical calculations for both hedgehog and vortex-like skyrmions: 1) the internal energy of a single chiral skyrmion; 2) the skyrmion radius depending on magnetic and geometric parameters; 3) the skyrmion configurational entropy; 4) the partition function; 5) the free energy; 6) the pressure and 7) the equation of state of a skyrmion diameters population. For the calculation of the thermodynamic functions we make the analogy between the skyrmion diameters population and the three-dimensional Maxwell-Boltzmann distribution of particles of an ideal gas [1]. It is shown that, in correspondence of the average skyrmion volumes, the pressure curves of the skyrmion diameters population intersect the pressure curves of the ideal gas at different temperatures. These results could advance the field of materials science with special regard to skyrmionics.

*The author acknowledges support by Gruppo Nazionale per la Fisica Matematica (GNFM) and Istituto Nazionale di Alta Matematica (INdAM) “F. Severi.”
8:24AM A42.00003: Theory of the Lifetime of Metastable Skyrmions in Chiral Magnets*  
PO-KUAN WU (Presenter), JAMES R ROWLAND, MOHIT RANDERIA, Department of Physics, Ohio State University — Understanding the lifetime of metastable skyrmions in chiral magnetic materials is both of fundamental interest and of practical importance. We use the Landau-Lifshitz-Gilbert equation with thermal noise to derive the activated rate for an isolated metastable skyrmion to decay into the stable ferromagnetic state. Our formalism includes damping as well as the effects of entropic corrections to the energy barrier within a Gaussian approximation. We show that the nature of the saddle point that needs to be crossed for the decay of a skyrmion changes from a Bloch point singularity in 2D systems to a chiral bobber in films with thickness \( L > L_D = 2\pi J/D \). We will present numerical and variational results as a function of ferromagnetic exchange \( J \), Dzyaloshinskii-Moriya interaction \( D \), effective anisotropy \( K \), and the external field \( B \), and discuss the relation between the size and lifetime of metastable skyrmions.

*Research supported by DARPA Grant No. D18AP00008

8:36AM A42.00004: Melting the skyrmion lattice - from solid to liquid via a hexatic phase*  
[Invited]  PING HUANG, State Key Laboratory for Mechanical Behaviour of Materials, Xi'an Jiaotong University, THOMAS SCHOENENBERGER (Presenter), MARCO CANTONI, Ecole Polytechnique Federale de Lausanne, LUKAS HEINEN, Institut fuer Theoretische Physik, Universitaet zu Koeln, ARNAUD MAGREZ, Ecole Polytechnique Federale de Lausanne, ACHIM ROSCH, Institut fuer Theoretische Physik, Universitaet zu Koeln, FABRIZIO CARBONE, HENRIK RONNOW, Ecole Polytechnique Federale de Lausanne — The most commonly seen phase transition is possibly "melting", a transition from ordered crystalline solids to disordered isotropic liquids. While melting in three-dimensions is always a single, first-order phase transition, in two-dimensional systems a scenario of two continuous phase transitions separated by an intermediate "oriented liquid" state, the so-called hexatic phase, has been proposed theoretically and evidenced experimentally in colloidal systems, Wigner solids and liquid crystals. Fundamentally different from these real-matter particles, skyrmions are countable soliton configurations localized in continuous fields with non-trivial topology, and these emergent quasi-particles can form two-dimensional lattices, whose melting dynamics remains unexplored. Here we show, by direct imaging with cryo-Lorentz transmission electron microscopy, that the phase of the skyrmion ensembles in the material Cu2OSeO3 can be tuned by magnetic field from two-dimensional skyrmion solids, through the long-speculated skyrmion hexatic phase, to skyrmion liquids, with the local spin order preserved throughout the whole process. Remarkably, our quantitative analysis demonstrates that this mesoscopic phase transition can be well described as topological-defect-induced crystal melting in two dimensions. By uncovering the novel phase behaviors of skyrmionic quasi-particles, we demonstrate skyrmion ensembles as an ideal platform for exploring novel properties in two-dimensions.

9:12AM A42.00005: Quantifying Order in Magnetic Systems with Convolutional Neural Networks*  
GARY DOWNING (Presenter), MARIJAN BEG, HANS FANGOH, SRINANDAN DASMAHAPATRA, ONDREJ HOVORKA, University of Southampton — Quantifying the order parameters in simulations of disordered magnetic systems to reliably represent magnetic states requires efficient interpretation of the often irregular magnetic patterns contained in large data sets. In helimagnetic materials with impurities, or at non-zero temperatures, the helical and skyrmion textures become distorted and embedded in noisy backgrounds with varying topological properties. Standard approaches based on quantifying the order parameters by averaging the spin states over a lattice, or computing pair correlation functions often become inconclusive. In this presentation, we discuss an approach based on applying convolutional neural networks (CNNs) to extract representative features of skyrmionic textures from simulated snapshots of complex magnetic backgrounds. Using large-scale micromagnetic simulations of a broad class of helimagnetic materials we show that CNNs are capable of not only accurately resolving the underlying magnetic textures, but also allow for regression to accurately predict classes of micromagnetic models representative of the observable magnetic textures. We then draw general conclusions about the uniqueness and invertibility of micromagnetic models of helimagnetic materials.

*This work was supported by EPSRC grant EP/L015382/1

9:24AM A42.00006: Creation of magnetic skyrmions by surface acoustic waves in Pt/Co/Ir trilayer films  
TOMOYUKI YOKOUCHI (Presenter), Center for Emergent Matter Science (CEMS), RIKEN, SATOSHI SUGIMOTO, National Institute for Materials Science (NIMS), BIVAS RANA, Center for Emergent Matter Science (CEMS), RIKEN, SHINICHIRO SEKI, Department of Applied Physics and Institute of Engineering Innovation, The University of Tokyo, NAOKI OGAWA, Center for Emergent Matter Science (CEMS), RIKEN, SHINYA KASAI, National Institute for Materials Science (NIMS), YOSHICHIKA OTANI, Institute for Solid State Physics (ISSP), The University of Tokyo — A magnetic skyrmion, a particle-like noncoplanar topological spin structure characterized by a nonzero topological integer called the skyrmion number, has great potential for various spintronic applications. In particular, efficient and practical means to create skyrmions is an important technological issue. However, creation of skyrmions has been achieved by only using currents so far, and moreover, in these methods, the skyrmions are only created at a specific position in the films.

In this presentation, we demonstrate a novel approach for skyrmion creation by employing surface acoustic waves (SAWs); in asymmetric multilayers of Pt/Co/Ir, we experimentally observed at room temperature that skyrmions can be created by propagating SAWs in a wide area of the magnetic film due to the long propagation length of SAWs. Micromagnetic simulation reveals inhomogeneous torque arising from both SAWs and thermal fluctuations creates a pair of Néel and antiskyrmion-like structure, which subsequently transforms to Néel skyrmion due to the instability of antiskyrmion-like structure in systems with interfacial Dzyaloshinskii-Moriya interaction. Our finding provides a novel guiding principle for efficient manipulation of topological spin objects without Joule heating dissipation.
9:36AM A42.00007: Thermal Collapse of a Skyrmion* AMEL DERRAS-CHOUK (Presenter),
Physics, The Graduate Center, City University of New York, EUGENE M CHUDNOVSKY, DMITRY
GARANIN, Physics, Herbert H. Lehman College — Thermal collapse of an isolated skyrmion on a two-
dimensional spin lattice has been investigated. The method is based upon solution of the system
of stochastic Landau-Lifshitz equations for up to 104 spins. The recently developed pulse- noise
algorithm has been used for the stochastic component of the equations. The collapse rate
follows the Arrhenius law. Analytical formulas derived within a continuous spin-field model
support numerically-obtained values of the energy barrier. The pre-exponential factor is
independent of the phenomenological damping constant that implies that the skyrmion is
overcoming the energy barrier due to the energy exchange with the rest of the spin system. Our
findings agree with experiments, as well as with recent numerical results obtained by other
methods.

*Grant No. DEFG02- 93ER45487 funded by the U.S. Department of Energy, Office of Science.

9:48AM A42.00008: Operando study of chiral magnetic textures under electrical bias using
Lorentz scanning transmission electron microscopy* ALBERT PARK (Presenter), ZHEN CHEN,
LIJUN ZHU, ROBERT BUHRMAN, DAVID MULLER, GREGORY FUCHS, School of Applied and Engineering
Physics, Cornell University — We develop a device fabrication process that is compatible with
operando Lorentz Scanning Transmission Electron Microscopy (LSTEM) for studying chiral
magnetic textures and their electric current dependent behavior with nanometer-scale spatial
resolution. Chiral magnetic spin textures appear in our samples as a result of the interplay
between magnetic energy terms including interfacial Dzyaloshinskii-Moriya Interaction and
perpendicular magnetic anisotropy (PMA) at heavy metal/ferromagnet interfaces. High-resolution
LSTEM can resolve the internal structure of spin textures including details as small as a few nm.
As a first step, we examine stripe domain and field nucleated Néel Skyrmions in devices as we
vary the stack repetition and ferromagnet thicknesses. We find rich magnetic textures with a
strong history dependence as the magnitude of PMA approaches zero.

*We acknowledge support from the DARPA TEE program (D18AC00009).
10:00AM A42.00009: Robust magnetization dynamics and magnetocaloric anomalies across the phase diagrams of noncollinear magnets  ELEANOR CLEMENTS (Presenter), Univ of South Florida, RAJA DAS, Phenikaa University, GANESH POKHAREL, LING LI, DAVID MANDRUS, University of Tennessee, Knoxville, MICHAEL OSOFSKY, Naval Research Lab, HARIHARAN SRIKANTH, MANH-HUONG PHAN, Univ of South Florida — Incommensurate magnetic structures stabilized by the Dzyaloshinskii-Moriya interaction exhibit long-range phase coherence over macroscopic length scales. Depending on the crystal symmetry, the magnetocrystalline anisotropy controls the orientation of the propagation vector and may also enhance the robustness of the magnetic texture. We present recent studies on the magnetic phase evolution of noncollinear spin textures analyzing the nonlinear ac magnetic response and magnetocaloric effect for selected crystalline magnetic materials with broken inversion symmetry: Cr$_{1/3}$NbS$_2$, GaV$_4$S$_8$, and MnSi. Each realize solitonic spin textures of varying dimension and helicity due to distinct differences in magnetocrystalline anisotropy. By analyzing the anomalous nonlinear response and dynamic magnetic loss, we characterize the rigidity of the various spin textures against an ac magnetic field. Additionally, our magnetocaloric measurements uncover phase regimes characterized by field-induced spin fluctuations, where entropy increases across the metamagnetic transition. The combined analysis reveals details about the complex ordering and magnetization processes that may be useful for identifying new magnetic phases emerging from long-period spin textures.

10:12AM A42.00010: Surface acoustic waves (SAW) and pinning of magnetic domain walls in a ferromagnetic multilayer.*  ANIL ADHIKARI (Presenter), SHIREEN ADENWALLA, Physics and Astronomy, University of Nebraska - Lincoln — The pinning of magnetic domain walls (DW) results in reduced velocities and non-deterministic motion of domain walls. Perpendicular anisotropy (PMA) materials display narrow, stable DWs but the pinning barriers have a significant effect due to the small width. We investigate the effects of SAW on pinning and motion of domain walls in films of Cr(2nm)/Pt(2nm)/[Co(0.3nm)/Pt(0.6nm)]$_5$ that are patterned into micron wide stripes between a pair of inter-digital transducers (IDTs), all on a 128 -Y cut LiNbO$_3$ substrate. Measurements were made using a magneto-optical Kerr effect microscope. Preliminary measurements of DW motion using magnetic field pulses, varying both the width and the height of the pulse identified the location, pinning potential and critical field of highly reproducible strong pinning sites. The effect of SAW on these well characterized pinning sites indicate that SAW are able to depin DW even from deep pinning potentials. The standing wave generated by the IDT pair allows for measurements at both the and antinodes of the SAW. Between these deep pinning sites, DW motion is consistent with creep behavior, with increasing SAW amplitude increasing the DW velocity.

Skyrmions and antiskyrmions from current-induced boundary instabilities

SHANE SANDHOEFNER (Presenter), ALDO RAELIARJAONA, RABINDRA NEPAL, University of Nebraska - Lincoln, DALTON SNYDER-TINOCO, California State University at San Bernardino, ALEXEY KOVALEV, University of Nebraska - Lincoln — We study generation and dynamics of skyrmions and antiskyrmions using current-induced torques at interfaces between adjacent regions with differing properties such as DMI (Dzyaloshinskii-Moriya interaction), anisotropy, exchange, etc.. The generation of skyrmions and antiskyrmions can be interpreted as a current-induced Doppler shift acting on the magnons localized at the interface. These localized modes are analyzed by using the Bogoliubov-de-Gennes Hamiltonian written for magnons. We confirm our theoretical predictions using micromagnetics simulations, where we observe that a current pulse closes the magnon band gap, leading to instabilities in the magnetic texture at the interface between different regions. From micromagnetic simulations, we observe that the closure of the magnon band gap effectively causes the system to form skyrmions and/or antiskyrmions, depending on the type of DMI present.

Stability of biskyrmions in centrosymmetric magnetic films

DANIEL CAPIC (Presenter), DMITRY GARANIN, EUGENE M CHUDNOVSKY, CUNY-Lehman Coll — In [1], we investigate analytically and numerically the stability of biskyrmions in films of finite thickness, taking into account the nearest-neighbor exchange interaction, perpendicular magnetic anisotropy (PMA), dipole-dipole interaction (DDI), and the discreteness of the atomic lattice. The biskyrmion is characterized by the topological charge Q=2, the spatial scale λ, and another independent length d that can be interpreted as a separation of two Q=1 skyrmions inside a Q=2 topological defect in the background of uniform magnetization. We find that biskyrmions with d of order λ can be stabilized by the magnetic field within a certain range of the ratio of PMA to DDI in a film having a sufficient number of atomic layers Nz. The shape of biskyrmions has been obtained by the numerical minimization of the energy of interacting spins in a 1000×1000×Nz atomic lattice. It is close to the exact solution of the Belavin-Polyakov model when d is below the width of the ferromagnetic domain wall. We compute the magnetic moment of a biskyrmion and discuss ways of creating biskyrmions in experiment.

10:48AM A42.00013: Magnetic domain dynamics in an insulating quantum ferromagnet
CHRISTOPHER TANG (Presenter), DANIEL SILEVITCH, Caltech, JIAN XU, James Franck Institute,
University of Chicago, KARIN ANDREA DAHMEN, Department of Physics, University of Illinois at Urbana-
Champaign, THOMAS F ROSENBAUM, Caltech — The structure of free-energy manifolds with many
local minima are of great interest in the context of quantum computation and optimization. In
the disordered ferromagnet, LiHo_xY_1-xF_4, quenched disorder and frustration, driven by the
combination of chemical substitution and the anisotropic magnetic dipolar coupling, give rise to
one such example of a complex, traversable free-energy landscape. We probe the structure of
this landscape and the dynamics of the driven system by measuring the statistics and form of
magnetic avalanches due to domain-wall motion. For large avalanches at temperatures
approaching the Curie point, we find a response free of the signatures of drag effects. By
contrast, in the low temperature limit, drag effects contribute to the dynamics, which we attribute
to enhanced pinning from local random fields due to the disorder. Furthermore, as an applied
transverse magnetic field is increased, the dynamics of the system can be tuned by progressively
strengthening the random-field pinning and then increasing the quantum tunneling rate. Tuning
from a classical regime to a quantum regime dominated by tunneling reveals the structure of the
free-energy surface and barriers to domain reorientation, with applications to quantum
annealing.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A43 DCOMP DAMOP DCMP: Precision Many-Body Physics I: Ab
Initio Methods 702 - Moritz Binder, Duke University - Tag(s): Focus
**8:00AM A43.00001: Ab initio finite-temperature and excited state computations by auxiliary-field quantum Monte Carlo** [Invited] SHIWEI ZHANG (Presenter), Center for Computational Quantum Physics (CCQ), Flatiron Institute — Development in the ground-state auxiliary-field quantum Monte Carlo (AFQMC) approach over the past decade has allowed accurate computations in a broad array of systems ranging from Hubbard-like models, ultracold Fermi gases, to solids and quantum chemistry. I will discuss recent progress in generalizing the approach to non-zero temperatures. Two bottlenecks had to be removed. The first is the sign or phase problem which appears in most cases, similar to ground-state calculations. The second is the unfavorable scaling of finite-temperature, grand-canonical computations as \( N^3 \) (\( N \) is the size of the lattice or basis set) in contrast with \( N*M^2 \) in ground-state computations (\( M \) is the number of fermions), a major obstacle in any realistic calculations aiming to describe the continuum limit, where \( N/M \) needs to be extrapolated to infinity for convergence. We remove the sign or phase problem by constraining the path-integrals in field space with a gauge condition; a self-consistent procedure is formulated to improve the accuracy of the constraint iteratively [1]. We then introduce a systematically controllable low rank factorization which changes the scaling of the computations to \( N*M^2 \) [2]. The method is applicable to both models and real materials. Results will be presented on magnetic and stripe orders in the repulsive Hubbard model, as well as pairing and other properties in the strongly interacting two-dimensional Fermi gas as a function of temperature.

*Flatiron Institute is a division of the Simons Foundation. Partial support from NSF.

**8:36AM A43.00002: Effects of charge self-consistency in DFT+DMFT calculations for complex transition metal oxides** ALEXANDER HAMPEL (Presenter), Center for Computational Quantum Physics, Flatiron Institute, SOPHIE BECK, CLAUDE EDERER, ETH Zurich — During recent years, the combination of density functional theory (DFT) and dynamical mean-field theory (DMFT) has become a widespread tool to calculate properties in correlated materials. The basic idea of the method is that the electronic degrees of freedom can be separated into a weakly interacting part, for which a standard DFT treatment is adequate, and a correlated subspace, which requires a more elaborate treatment of the electron-electron interaction. The latter leads, in general, to a redistribution of electrons within the correlated subspace compared to the DFT result. This change should then enter, in a self-consistent way, the effective potential felt by the weakly interacting electrons, which is achieved by iterating between DFT and DMFT steps. However, such a charge self-consistent (CSC) DFT+DMFT calculation leads to a higher computational cost compared to simpler one-shot calculations, where this charge rearrangement is neglected. Here, we examine the effect of CSC in DFT+DMFT calculations compared to simpler one-shot calculations for two instructive example materials, CaVO\(_3\) and LuNiO\(_3\), to clarify in which cases the more complex CSC treatment is necessary and in which cases the simpler one-shot calculation is sufficient.
DFT+eDMFT Study of Finite-temperature Properties of Filled Skutterudite CeGe_{4}Pt_{12}∗

KHANDKER QUADER (Presenter), Physics, Kent State University, Kent, OH 44242, USA, GHEORGHE PASCUT, MANSiD Research Center and Faculty of Forestry, Stefan Cel Mare University (USV), Suceava 720229, Romania, KRISTJAN HAULE, Physics & Astronomy, Rutgers University, New Brunswick, NJ, USA 08854, MICHAEL WIDOM, Physics, Carnegie-Mellon University, Pittsburgh, PA 15213, USA — Current interest in the filled skutterudites stem from a range of observed physical phenomena, such as superconductivity, Kondo-lattice, heavy fermion, Fermi liquid behavior, etc, and due to thermoelectric properties at room temperature. Following up on our comprehensive density functional theory (DFT) study (PRB 100, 125114 (2019)) of the RPt_{4}Ge_{12} (R=La, Ce, Pr) compounds, we have been performing temperature dependent calculations on these systems using first-principles self-consistent density functional theory with embedded-dynamical mean field theory (DFT+eDMFT). Here we present results for CeGe_{4}Pt_{12}, namely the temperature dependence of spectral function, density of states, hybridization, effective mass, susceptibility, and resistivity, and compare with experiments. Based on our calculations, we suggest that CeGe_{4}Pt_{12} exhibits Curie-Weiss behavior at high temperature (indicating presence of local moments), a Kondo-lattice like behavior at intermediate temperatures (~80-50K), and a Fermi liquid state of screened local moments at low temperature (~10-5K).

Efficient implementation of ab initio dynamical mean-field theory for periodic systems

TIANYU ZHU (Presenter), ZHI-HAO CUI, GARNET CHAN, Division of Chemistry and Chemical Engineering, California Institute of Technology — We present an ab initio quantum chemical framework for dynamical mean-field theory (DMFT) in periodic systems. Our DMFT scheme employs ab initio Hamiltonians defined for impurities comprising the full unit cell or a supercell of atoms and for realistic quantum chemical basis sets. We avoid double counting errors by using Hartree-Fock as the low-level theory. Intrinsic and projected atomic orbitals (IAO+PAO) are chosen as the local embedding basis, facilitating numerical bath truncation. Using an efficient integral transformation and coupled-cluster Green's function (CCGF) impurity solvers, we are able to handle large embedded impurity problems with several hundred orbitals. We apply our ab initio DMFT approach to study a hexagonal boron nitride monolayer, crystalline silicon, and nickel oxide in the antiferromagnetic phase, with up to 104 and 78 impurity orbitals in spin-restricted and unrestricted cluster DMFT calculations and over 100 bath orbitals. We show that our scheme produces accurate spectral functions compared to both benchmark periodic coupled-cluster computations and experimental spectra.
9:12AM A43.00005: Efficient Hybridization Fitting for Dynamical Mean-Field Theory via Semi-Definite Relaxation* CARLOS MEJUTO ZAERA (Presenter), University of California, Berkeley, LEONARDO ZEPEDA-NÚÑEZ, Mathematics, University of Wisconsin-Madison, MICHAEL LINDSEY, Courant Institute of Mathematical Sciences, NORM TUBMAN, Quantum Artificial Intelligence Lab., NASA Ames Research Center, BIRGITTA K WHALEY, LIN LIN, University of California, Berkeley — Hamiltonian-based solvers for dynamical mean-field theory (DMFT) can compute spectral properties directly in the real axis and are applicable to impurity Hamiltonians presenting general interactions. This flexibility comes at the prize of having to truncate the formally infinite bath, transforming the DMFT self-consistent condition into a non-linear optimization problem. Fulfilling the self-consistency condition exactly with a finite bath is impossible. Furthermore, the large number of degrees of freedom in the optimization problem makes it likely to fall into local minima, which may result in the DMFT calculation converging to the wrong physical solution. As a consequence, the optimization step in Hamiltonian-based DMFT can become the most difficult part of the calculation. In this work¹, we propose a nested optimization procedure using semi-definite relaxation which addresses and improves many of the issues that plague the optimization step in Hamiltonian-based DMFT.

9:24AM A43.00006: Electronic Structure of Strongly Correlated f-electron System: DFT+DMFT Approach VIJAY SINGH (Presenter), Department of Physics, University of Illinois at Chicago Chicago, Illinois, 60607, USA, UTHPALA HERATH, Department of Physics, West Virginia University, Morgantown, WV 26506, USA, BENNY WAH, Department of Physics, University of Illinois at Chicago Chicago, Illinois, 60607, USA, ALDO H ROMERO, Department of Physics, West Virginia University, Morgantown, WV 26506, USA, HYOWON PARK, Department of Physics, University of Illinois at Chicago Chicago, Illinois, 60607, USA — Computational materials design of strongly correlated materials (SCM) has been challenging in modern condensed matter physics since it requires the development of more accurate methodologies beyond density functional theory (DFT). In the present talk, I will discuss our recent development of an efficient computational method so called DMFTwDFT to treat dynamical correlations in SCM accurately. I use dynamical mean-field theory (DMFT) in combination with DFT to compute the electronic structure of strongly correlated f-electron systems, specifically, rare-earth metals. The main point of the debate in f-electron system is related to the understanding of the role played by f electrons — they are localized or itinerant, or more exactly how many f electrons are localized or itinerant. For this reason, the theoretical and experimental investigations of the electronic structure of rare-earth metals have always occupied an important position in rare-earth research. Here, I use the DMFT+DFT method implemented using the maximally localized Wannier function as the local basis set and combining various DFT codes to study electronic properties of these materials. Our results will be also compared to other DMFT+DFT codes employing different local basis sets and DFT implementations.
**9:36AM A43.00007: Kondo route to quantum interference in prototypical single molecule transistors**

SUDESHNA SEN (Presenter), ANDREW MITCHELL, Univ Coll Dublin — Single molecule transistors offer a fascinatingly diverse range of physics due to their ultrasmall size, chemical complexity, and strong electronic interactions. They constitute a playground for exploring the fundamental physics of correlations on the nanoscale, and their signatures in transport. Understanding these systems is also an essential prerequisite for possible advanced technological applications utilizing their quantum characteristics. In this talk I examine prototypical molecular junctions π-conjugated hydrocarbon molecular junctions using a combination of perturbative scaling, numerical renormalization group, and machine learning methods [1] after reducing them to effective multi-orbital impurity systems. The interplay of Kondo effect and emergent many body quantum interference effects are explored in the context of quantum boosted functionalities.

**9:48AM A43.00008: Density Matrix Embedding Theory: From Lattice Models to Realistic Materials**

ZHI-HAO CUI (Presenter), TIANYU ZHU, GARNET CHAN, Caltech — In the past few years, density matrix embedding theory (DMET) [Phys. Rev. Lett. 109, 186404] has emerged as a successful wavefunction-based embedding scheme for both lattice models and molecules, but with few applications to ab initio periodic Hamiltonians. In this work, we will discuss a unified formalism for both lattice models and realistic solids. We will highlight some practical considerations in the simulation of realistic materials with DMET, including the choice of orbitals and mapping to a lattice, treatment of the virtual space and bath truncation, and the lattice-to-embedded integral transformation. We apply our DMET framework to both Hubbard-like lattice models and several realitic materials, e.g. hexagonal boron nitride monolayer, crystalline silicon, and nickel monoxide in the antiferromagnetic phase, using large embedded clusters with up to 300 embedding orbitals.

*This work is partially supported by US Department of Energy via award no. DE-SC19390. Additional support was provided by the Simons Foundation via an Investigatorship and through the Simons Collaboration on the Many-Electron Problem.
10:00AM A43.00009: Out of equilibrium thermometry with pump-probe x-ray photoemission spectroscopy  
OLEH MATVYEYEV (Presenter), Department of Physics, Georgetown University, ANDRIJ SHVAIKA, Department of Quantum Statistics, Institute for Condensed Matter Physics, JAMES FREERICKS, Department of Physics, Georgetown University — We calculate the spectral function of a deep core-level hole in a pump-probe x-ray photoemission spectroscopy experiment. Here, an intense light pulse pumps electrons to higher energies, and a second high-energy x-ray probe pulse is used to knock out an electron from a deep core-level. Electrons from the conduction band feel the effects of the core-hole potential and react by screening it. This creates particle-hole excitations within the conduction band until the core-hole has been filled. We examine the spinless Falicov-Kimball model, which possesses a metal-Mott-insulator transition, and has an exact solution within dynamical mean-field theory. In linear response, it is well known that the shape of the core-hole spectra depends strongly on temperature in the high-temperature regime. We employ this effect in nonequilibrium, and describe an ultrafast "thermometer," which can determine the energy content of the conduction electrons with a nondestructive in situ measurement on an ultrafast time scale.

10:12AM A43.00010: Electronic structure of bulk manganese oxide and nickel oxide from coupled cluster theory*  
YANG GAO (Presenter), Caltech, QIMING SUN, Tencent America LLC, JASON YU, UC Irvine, MARIO MOTTA, IBM Almaden Research Center, JAMES MCCLAIN, ALEC F WHITE, AUSTIN MINNICH, GARNET CHAN, Caltech — We describe the ground- and excited-state electronic structure of bulk MnO and NiO using coupled cluster theory with single and double excitations (CCSD). Starting from a Hartree-Fock reference, we find fundamental gaps of 3.46 eV and 4.83 eV for MnO and NiO respectively for the 16 unit supercell, slightly overestimated compared to experiment, although finite-size scaling suggests that the gap is more severely overestimated in the thermodynamic limit. From the character of the correlated electronic bands we find both MnO and NiO to lie in the intermediate Mott/charge-transfer insulator regime, although NiO appears as a charge transfer insulator when only the fundamental gap is considered. While the lowest quasiparticle excitations are of metal 3d and O 2p character in most of the Brillouin zone, near the Γ point, the lowest conduction band quasiparticles are of s character. Our study supports the potential of coupled cluster theory to provide high level many-body insights into correlated solids.

10:24AM A43.00011: The electronic structure of \( n \)-doped ABO\(_3\) perovskite metals from quantum Monte Carlo.*  

MICHAEL BENNETT (Presenter), GUOXIANG HU, PANCHAPAKESAN GANESH, JARON KROGEL, Oak Ridge National Laboratory — Some perovskites (PVs) are known to undergo metal-to-insulator transitions (MITs) when \( n \)-doped. In particular, the PV ferromagnet strontium cobaltite (SrCoO\(_3\)), undergoes an MIT when a critical level of ordered oxygen vacancies are present in the system. Concomitant topotactic and magnetic transitions can also occur, e.g., the oxygen-deficient SrCoO\(_{2.5}\) phase is an anti-ferromagnet with a brownmillerite crystal structure. The cause of this nonintuitive MIT in these oxygen-deficient systems is not well understood. Density functional theory (DFT) calculations suggest that charge disproportionation is often associated with the transition, but these systems have strong correlations that are beyond DFT. Furthermore, counting formal oxidation states in the oxygen-rich systems hints at the presence of ligand holes which would conceivably lead to passivation after \( n \)-doping. Here, we hypothesize that these systems are indeed self-hole doped and use diffusion Monte Carlo methods that include electron correlations exactly to gain clarity on the electronic/magnetic/structural transitions.

10:36AM A43.00012: ThetaPhi - a new program for calculation of Bardeen-Cooper-Schrieffer and Magnetic Superstructure Electronic States  

EVGENY PLEKHANOV (Presenter), Physics, Kings College London, ANDREI TCHOUGREEFF, A.N. Frumkin Institute of Physical Chemistry and Electrochemistry of RAS, Moscow, Russia — We propose the Theta-Phi package [1] which addresses two of the most important extensions of the essentially single-particle mean-field paradigm of the computational solid state physics: the admission of the Bardeen-Cooper-Schrieffer electronic ground state and allowance of the magnetically ordered states with an arbitrary superstructure (pitch) wave vector. Both features are implemented in the context of multi-band systems which paves the way to an interplay with the solid state quantum physics packages eventually providing access to the first-principles estimates of the relevant matrix elements of the model Hamiltonians derived from the standard DFT calculations. Several examples showing the workability of the proposed code are given.

We present a numerically exact Inchworm Monte Carlo method for equilibrium multi-orbital quantum impurity problems with general interactions and hybridizations. We show that the method, originally developed to overcome the dynamical sign problem in certain real-time propagation problems, can also overcome the sign problem as a function of temperature for equilibrium quantum impurity models. This is shown in several cases where the current method of choice, the continuous-time hybridization expansion, fails due to the sign problem. Our method therefore enables simulations of impurity problems as they appear in embedding theories without further approximations, such as the truncation of the hybridization or interaction structure or a discretization of the impurity bath with a set of discrete energy levels, and eliminates a crucial bottleneck in the simulation of ab initio embedding problems.

8:00AM A44.00001: Exploiting Orbital Locality in Real Space to Enable Large-Scale Condensed-Phase Ab Initio Molecular Dynamics with Hybrid Density Functional Theory
[Invited] ROBERT DISTASIO (Presenter), Cornell University — By including a fraction of exact exchange (EXX), hybrid functionals reduce the self-interaction error in semi-local density functional theory (DFT), and thereby furnish a more accurate and reliable description of the underlying electronic structure in systems throughout chemistry, physics, and materials science. However, the high computational cost associated with hybrid DFT has limited its applicability when treating large-scale condensed-phase systems. To overcome this limitation, we have devised a linear-scaling yet formally exact approach that utilizes a local representation of the occupied orbitals to exploit the sparsity in the real-space evaluation of the quantum mechanical exchange interaction in finite-gap systems. Here, we present a detailed description of the theoretical and algorithmic advances required to perform ab initio molecular dynamics (AIMD) simulations of large-scale condensed-phase systems with hybrid DFT. We focus our theoretical discussion on integrating this approach into the framework of Car-Parrinello AIMD, and provide a comprehensive description of our algorithm, which is implemented in the open-source Quantum ESPRESSO program and employs a hybrid MPI/OpenMP parallelization scheme to efficiently utilize the high-performance computing (HPC) resources available on supercomputer architectures. This is followed by a critical assessment of the accuracy and parallel performance (e.g., strong and weak scaling) of this approach when performing AIMD simulations of liquid water in the canonical (NVT) and isobaric-isothermal (NpT) ensembles. With access to HPC resources, we demonstrate that our algorithm enables hybrid DFT based AIMD simulations of condensed-phase systems containing ~1000 atoms with a wall-time cost that is comparable to semi-local DFT. In doing so, this work takes us one step closer to routinely performing AIMD simulations of large-scale condensed-phase systems for sufficiently long timescales at the hybrid DFT level of theory.

8:36AM A44.00002: Improving the Scalability of Condensed-Phase Hybrid Density Functional Theory: Computation, Communication, and Load Balancing
HSIN-YU KO (Presenter), JUNTEENG JIA, Cornell University, MARCOS ANDRADE, Princeton University, ZACHARY SPARROW, ROBERT DISTASIO, Cornell University — Ab initio molecular dynamics (AIMD) simulations at the hybrid density functional theory (DFT) level provide a semi-quantitative description of complex condensed-phase systems such as molecular liquids and crystals. For finite-gap systems, we have developed a linear-scaling and formally exact algorithm for computing the exact exchange interaction in real space based on a localized representation of the occupied orbitals (e.g., maximally localized Wannier functions). Although a massively parallel implementation of this algorithm in Quantum ESPRESSO already enables hybrid DFT based AIMD simulations of condensed-phase systems containing 500-1000 atoms, we have identified three nearly equal contributions to the walltime cost of this approach: computation events, communication overhead, and processor idling due to workload imbalance. In this work, we present a three-pronged strategy that we have employed to attack these contributions and reduce the overall walltime cost by approximately an order of magnitude.

9:00AM A44.00004: A Scalable Eigensolver for Real-space Pseudopotential Density Functional Theory: A Polynomial-filtered Spectrum Slicing Method*  KAI-HSIN LIOU (Presenter), University of Texas at Austin, CHAO YANG, Lawrence Berkeley National Laboratory, JAMES CHELIKOWSKY, University of Texas at Austin — First-principles electronic structure calculations are a popular avenue for understanding and predicting properties of materials. However, solving the electronic structures of the materials of interest, such as complex biomolecules, nanostructures, and interfacial systems can require descriptions of systems with many atoms, e.g., systems with over 10,000 atoms. Systems of this size pose a challenge to current electronic structure computation software. We will present recent work using a spectrum-slicing algorithm, which is implemented in a real-space pseudopotential density functional theory code, PARSEC. The spectrum slicing method builds an additional layer of parallelization on top of the Chebyshev-filtered subspace iteration. Our approach provides more flexibility to fully utilize the computing power of modern distributed parallel computers. We will demonstrate the scalability of the algorithm and discuss outstanding challenges.

*Work at Texas is supported by a subaward from the Center for Computational Study of Excited-State Phenomena in Energy Materials at LBNL, which is funded by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05CH11231, as part of the Computational Materials Sciences Program.
9:12AM A44.00005: Treecode-Accelerated Green's Iteration for Kohn-Sham DFT* NATHAN VAUGHN (Presenter), ROBERT KRASNY, VIKRAM GAVINI, Univ of Michigan - Ann Arbor — We present a real-space method for Kohn-Sham Density Functional Theory based on an integral equation formulation of the Kohn-Sham equations, called Treecode-Accelerated Green's Iteration (TAGI). In this approach, the eigenvalue problem for the Kohn-Sham differential operator is converted to a fixed point problem for an integral operator by convolution with a Green's function, then the fixed points are computed using Green's iteration. Essential to this method is the accurate and efficient evaluation of the convolution integrals arising in the iteration. TAGI achieves accuracy and efficiency through the use of adaptive mesh refinement to represent the fields, singularity subtraction schemes to reduce the quadrature error due to the singular Green's functions, and a GPU-accelerated treecode to reduce the computational complexity of the convolution integrals. We have performed all-electron calculations on non-periodic systems and demonstrated systematic convergence to chemical accuracy with respect to tightly converged reference values.

9:24AM A44.00006: Accelerating real-space methods by discontinuous projection* JOHN PASK (Presenter), Lawrence Livermore Natl Lab, QIMEN XU, PHANISH SURYANARAYANA, Georgia Institute of Technology — By virtue of multiple advances in the past two decades, real-space electronic structure methods have surpassed planewave methods in large-scale calculations of isolated and extended systems alike. Combining advances in both finite-difference and finite-element methods over the decades, we discuss a new approach to accelerate real-space methods further still, while retaining the simplicity, systematic convergence, and parallelizability inherent in the methodology. The key idea is to compress the large, sparse real-space Hamiltonian by projection in a strictly local, systematically improvable, discontinuous basis spanning the occupied subspace. We show how this basis can be constructed and employed to reduce the dimension of the real-space Hamiltonian by up to three orders of magnitude. Molecular dynamics step times of a few minutes for systems containing thousands of atoms demonstrate the scalability of the methodology in a discontinuous Galerkin formulation [1]. Results for 1D, 2D, and 3D systems demonstrate the additional advantages afforded by the new projection formulation [2].

*This work was performed, in part, under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.
A Space-filling Curve Based Grid Partition to Accelerate Real-space Pseudopotential Density Functional Theory Calculations

ARIEL BILLER (Presenter), Weizmann Institute of Science, KAI-HSIN LIOU, University of Texas at Austin, DEENA ROLLER, LEEOR KRONIK, Weizmann Institute of Science, JAMES CHELIKOWSKY, University of Texas at Austin — Density functional theory (DFT) has become a popular tool to verify, explain, and predict experimental discoveries in materials. In conjunction with pseudopotentials, we can now achieve simulations of systems with tens of thousands of atoms as “routine work.” Real-space DFT has advantages when simulating confined or semi-periodic systems, such as defects, charged systems, and interfaces. Within a finite-difference method, the Hamiltonian matrix is often large and sparse, and requires an efficient implementation of matrix-vector multiplication. We will show through space-filling curves that we can construct a real-space grid whose grid points have excellent locality. Consequently, the communication between compute nodes is reduced. We will also demonstrate that this space-filling curve based grid partition improves the scalability of the matrix-vector multiplications, which is beneficial to polynomial filtering based eigensolvers.

Work at Texas is supported by a subaward from the Center for Computational Study of Excited-State Phenomena in Energy Materials at LBNL, which is funded by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05CH11231, as part of the Computational Materials Sciences Program.

Reduce Noise in Stochastic Density Functional Theory

MING CHEN (Presenter), Department of Chemistry, University of California, Berkeley, DANIEL NEUHAUSER, Department of Chemistry and Biochemistry, University of California, Los Angeles, ROI BAER, Institute of Chemistry, The Hebrew University of Jerusalem, ERAN RABANI, Department of Chemistry, University of California, Berkeley — Large scale density functional theory (DFT) calculations are necessary for understanding the physics of complex materials. Steep numerical scaling of conventional DFT methods prohibits the routine application to large systems containing tens of thousands of electrons. An alternative to conventional DFT is based on representing the density and density matrix using stochastic sampling of the occupied subspace, allowing for linear or even sub-linear scaling DFT method at the cost of introducing a well-controlled statistical error. It becomes an important task to develop approaches that reduce the stochastic noise in order to improve accuracy and reliability of stochastic DFT. Two different noise reduction techniques have been introduced in stochastic DFT. One is based on decomposing the system into overlapped fragments and the other approach divides the occupied subspace into subspaces according to energy windows. Both noise reduction techniques can significantly reduce the noise level in electronic structures, which leads to orders of magnitude reduction in computational costs. This talk will provide a look into both methods including analysis of noise reduction, scaling, and performance. Illustrations will be given for semiconductor materials with nearly 16,000 electrons.
10:00AM A44.00009: A general approach towards continuous translational symmetry in finite difference real-space calculations  TIAN QIU (Presenter), University of Pennsylvania, LEO OR KRONIK, Weizmann Institute of Science, ANDREW MARSHALL RAPPE, University of Pennsylvania — We have developed a new scheme to install pseudopotentials on a finite real-space grid that significantly reduces unphysical fluctuations of quantities for fractional grid-point shifts in real space. Instead of interpolating the potential on the grid, this scheme chooses a reference position and use a translation method to represent positions of atoms in real space. This translation is exact for integer grid-point shifts and is designed to minimize the "egg box" effect for fractional grid-point shifts. It provides nonlocal but banded representations for local potentials and is compatible with nonlocal pseudopotential operators. As a demonstration, this scheme is tested in one dimension for three types of potentials: a local ionic potential, a local ionic potential plus a nonlocal operator, and a local ionic potential plus the Hartree and exchange-correlation potential. Fluctuations of examined quantities are reduced by four orders, four orders, and three orders, respectively. This scheme does not require the manipulation of grids and can be easily extended to the three-dimensional case.

10:12AM A44.00010: Discrete discontinuous basis projection (DDBP) method for large-scale electronic structure calculations.  QIMEN XU (Presenter), PHANISH SURYANARAYANA, Georgia Inst of Tech — The large number of grid points per atom required for accurate real-space Kohn-Sham Density Functional Theory (DFT) calculations restricts their efficiency. In this work, we present an approach to accelerate such calculations several fold, without loss of accuracy, by systematically reducing the cost of the key computational step: the determination of the Kohn-Sham orbitals spanning the occupied subspace. This is achieved by systematically reducing the dimension of the discrete eigenproblem that must be solved, through projection into a highly efficient discrete discontinuous basis. In calculations of quasi-1D, quasi-2D, and bulk metallic systems, we find that accurate energies and forces are obtained with 8–25 basis functions per atom, reducing the dimension of full-matrix eigenproblems by 1-3 orders of magnitude.
Fast all-electron density functional theory calculations in solids using orthogonalized enriched finite elements*  
NELSON DAVID RUFUS (Presenter), BIKASH KANUNGO, VIKRAM GAVINI, Univ of Michigan - Ann Arbor — We present a computationally efficient approach to perform real-space all-electron Kohn-Sham DFT calculations for bulk solids using an enriched finite element (FE) basis, wherein the classical FE basis are augmented with atom-centered numerical basis functions constructed from atomic solutions to the Kohn-Sham problem. We term these atom-centered numerical basis functions as enrichment functions. Notably, to improve the conditioning we orthogonalize the enrichment function with respect to the classical FE basis, without compromising on the locality of the resultant basis. In addition to improved conditioning, this orthogonalization procedure also renders the overlap matrix block-diagonal, greatly simplifying its inversion. Subsequently, we use a Chebyshev polynomial based acceleration technique to efficiently compute the occupied eigenspace in each self-consistent iteration. We demonstrate the accuracy and efficiency for periodic unit-cells and supercells, ranging up to 5000 electrons (containing as many as 500 atoms). We observe a staggering 50-100x speedup over the classical FE basis. We also benchmark with (L)APW(\(+lo\)) basis for accuracy and performance. Finally, we demonstrate parallel scalability for a system with ~216 Si and C atoms.

*DoE BES, Award Number DE-SC0017380
Under applied shear, amorphous solids flow via a succession of plastic rearrangements of localized particles. Numerous numerical and experimental studies have shown that plastic instabilities in glasses are triggered by spatially localized soft spots in direct analogy with dislocations present in crystalline solids, although the population and microscopic structure of the former are significantly different from the latter. In addition, many research groups have developed methods for identifying such defects, although these methods have not been systematically compared. Here we use a swap Monte Carlo algorithm to prepare equilibrium amorphous configurations with very different stabilities that exhibit a range of behaviors under shear, from ductile flow to brittle failure. We compute various structural indicators ranging from purely structural to highly non-linear metrics that require the knowledge of the interactions between constituents. We compare these metrics on the same data sets, quantifying how well these metrics perform in predicting plastic deformation across this range of glass stabilities. Moreover, we use these structural metrics to quantify the spatial distribution of plastic defects for different preparation protocols, as well as the evolution of these defects across the yielding transition, allowing us to precisely characterize how the microscopic structure encodes the differences between ductile and brittle materials.

8:36AM A45.00002: Yielding of Ultrastable Computer Glasses  MISAKI OZAWA (Presenter), Ecole Normale Superieure, LUDOVIC BERTHIER, Universite Montpellier, GIULIO BIROLI, Ecole Normale Superieure, ALBERTO ROSSO, Universite Paris-Sud, GILLES TARJUS, Sorbonne Universite, MURARI SINGH, Universite Montpellier, WEI-TING YEH, KUNIMASA MIYAZAKI, TAKESHI KAWASAKI, Nagoya University —

We study mechanical yielding of ultrastable computer glasses generated by optimized swap Monte-Carlo simulations for polydisperse particles [1,2] as well as more realistic multi-component metallic glass models [3]. We observe brittle yielding associated with a sharp system-spanning shearband in various rheological settings, such as uniform shear and oscillatory deformation in two and three dimensions [4,5,6]. The observed behaviors are qualitatively different from the standard computer glasses that have been studied previously. Thus, our computational scheme opens up new opportunities to investigate the mechanical behaviors of metallic glasses in experimentally relevant conditions. As an application, we numerically test the scenario of shearband nucleation by artificially inserting a soft spot into a stable glass sample. We argue that brittle yielding in macroscopic samples is triggered by rare droplets of the soft spot [4].

8:48AM A45.00003: When does local structure play a role in sheared jammed packings?*
SEAN RIDOUT (Presenter), University of Pennsylvania, JASON ROCKS, Boston University, ANDREA JO-WEI LIU, University of Pennsylvania — In jammed packings, it is usually assumed that local structure only plays a significant role in specific regimes. For instance, it is known that in jammed packings the variance of the relative excess coordination, $\delta Z/Z_c$, decays like $1/d$, so that local structure should play no role at high spatial dimensions. Furthermore, in any fixed dimension $d \geq 2$, lowering the pressure results in a diverging length scale, again suggesting that local structure should not be sufficient to describe response. Here we address the validity of the assumption that local structure does not matter in these cases. Focusing on jammed packings under athermal, quasistatic shear, we utilize machine learning to identify a local structural variable, softness, that has been shown to be strongly predictive of rearrangements in many disordered systems. We apply the softness analysis to plastic events in jammed packings across many dimensions and pressures, and find that local structure is perhaps more predictive than one might have guessed.

*This work was funded by the Simons Foundation through the collaboration “Cracking the glass problem” (454945) (for AJL and SAR), by the US Department of Energy under award DE-FG02-05ER46199 (JWR). the an NSERC PGS-D fellowship to SAR, and an NSF graduate fellowship to JWR.
Connecting thermal relaxation to local yield stress in glassy systems
MATTHIAS LERBINGER (Presenter), ARMAND BARBOT, SYLVAIN PATINET, DAMIEN VANDEMBROUCQ, PMMH, ESPCI Paris — We study a binary Lennard-Jones mixture in the supercooled regime using molecular dynamic simulations. At low temperatures, thermal relaxation proceeds in a series of activated jumps between inherent structures, i.e. local minima of the potential energy landscape. From these inherent dynamics we recover information about the location of thermally activated rearrangements. We observe a strong connection between the thermal relaxation and areas where the structure has been previously identified as being soft using a local, direct probing of shear stress thresholds. Using the probability distribution of local shear stresses we are able to capture features of the system’s dynamical relaxation processes. We thus can establish a link between structural and dynamical properties of the supercooled liquid. Furthermore, we extend our analysis to out of equilibrium dynamics by studying the effects of rejuvenation and aging on the local yield stress distribution in both glasses and liquids at different temperatures.

Correlation between local structural order and ductility of glasses
AYA NAWANO (Presenter), Department of Mechanical Engineering and Materials Science, Yale University, YUAN-CHAO HU, Institute of Industrial Science, University of Tokyo, JAN SCHROERS, Department of Mechanical Engineering and Materials Science, Yale University, MARK SHATTUCK, Department of Physics and Benjamin Levich Institute, City College of New York, COREY SHANE O’HERN, Department of Mechanical Engineering and Materials Science, Yale University — Bulk metallic glasses (BMGs) are amorphous metallic alloys with desirable material properties such as high yield strength and superior corrosion resistance compared to conventional crystalline alloys. However, their use as structural materials has been limited because of their brittle behavior, especially in tension. In this work, we identify atomic-scale structural signatures in undeformed metallic glasses that are able to predict their mechanical response to tension or pure shear tests. In particular, we employ molecular dynamics simulations to prepare different types of glasses using a range of cooling rates and interaction potentials, including highly polydisperse soft-repulsive spheres, binary Lennard-Jones spheres, atomic systems that interact via the Stillinger-Weber potential, and binary and ternary alloys described by the embedded atom method. We then perform quasi-static tension or pure shear tests on the glassy samples, and measure the shear stress and local structural order as a function of strain. For each model system, we find a strong correlation between the measure of local structural order in the undeformed sample and the mechanical response at finite strain.

*A. N. and C.S.O acknowledge support from NSF Grant No. CMMI-1901959.
9:24AM A45.00006: Understanding shear bands characteristics and formation in model glasses through the measure of the local yield stress. ARMAND BARBOT (Presenter), MATTHIAS LERBINGER, PMMH, CNRS UMR 7636, ESPCI Paris, PSL University, Sorbonne Université, Université de Paris, F-75005 Paris, France, ANAËL LEMAÎTRE, Université Paris-Est, Laboratoire Navier (UMR 8205), CNRS, ENPC, IFSTTAR, 2 allée Képler, F-77420 Marne-la-Vallée, France, DAMIEN VANDEMBROUCQ, SYLVAIN PATINET, PMMH, CNRS UMR 7636, ESPCI Paris, PSL University, Sorbonne Université, Université de Paris, F-75005 Paris, France — Many phenomena remain poorly understood in amorphous materials such as plasticity and shear banding, their brittleness and disordered structure making it difficult to study them experimentally. As a consequence, we employ a two-dimensional Lennard-Jones numerical model of glasses and measure their local yield stress, a measure of the local softness presented in [1]. This method is nonperturbative and gives access to a quantitative property on a well-controlled length scale. Applying it on deeply quench glasses under simple shear loading, we show that the plastic events create a local yield stress [2] decrease in the material which cause the emergence of a shear band [3]. We finally focus on the shear bands formation by looking for a relevant localization criterion to understand the influence of the system size and quench protocol.

9:36AM A45.00007: Atomic nonaffinity as structural indicator of protocol-dependent plasticity in amorphous solids* BIN XU (Presenter), Beijing Computational Science Research Center, MICHAEL FALK, Johns hopkins university, SYLVAIN PATINET, Physique de Mécanique des Milieux Hétérogènes laboratory, PENGFEI GUAN, Beijing Computational Science Research Center — Structural heterogeneity of amorphous solids challenges the prediction of plastic events which is intimately connected to their mechanical behaviors. Here we report the atomic nonaffinity, as a structural indicator with intrinsic orientation, which is derived from the total nonaffine modulus based on a perturbation analysis of the potential energy landscape. We find that the atomic nonaffinity can efficiently characterize the locations of plastic events, which is comparable to other indicators. More importantly, it can accurately predict the protocol-dependent response of plastic events by quantitatively analyzing the relation between its softest direction and shear loading direction. These results shed light on the characterization and prediction of the mechanical response of amorphous solids.

**9:48AM A45.00008: Unveiling the predictive power of static structure in glassy systems**

VICTOR BAPST (Presenter), THOMAS KECK, AGNIESZKA GRABSKA-BARWINSKA, CRAIG DONNER, DeepMind, EKIN DOGUS CUBUK, SAM SCHOENHOLZ, Google Brain, ANNETTE OBIKA, ALEXANDER NELSON, TREVOR BACK, DEMIS HASSABIS, PUSHMEET KOHLI, DeepMind — Despite decades of theoretical studies, the nature of the glass transition remains elusive and debated, while the existence of structural predictors of the dynamics is a major open question. Recent approaches propose inferring predictors from a variety of human-defined features using machine learning. We learn the long time evolution of a glassy system solely from the initial particle positions and without any hand-crafted features, using a powerful model: graph neural networks. We show that this method strongly outperforms state-of-the-art methods, generalizing over a wide range of temperatures, pressures, and densities. In shear experiments, it predicts the location of rearranging particles. The structural predictors learned by our network exhibit a correlation length which increases with larger timescales to reach the size of our system. Beyond glasses, our method could apply to many other physical systems that map to a graph of local interactions.

**10:00AM A45.00009: Identifying flow units by machine learning in a model metallic glass**

YICHENG WU (Presenter), Beijing Computational Science Research Center, HAIYANG BAI, Institutes of Physics, Chinese Academy of Sciences, PENGFEI GUAN, Beijing Computational Science Research Center — Characterizing and predicting the flow units directly from the atomic structure are longstanding challenges in metallic glasses. We report the successful identification of flow units in the model Zr<sub>50</sub>Cu<sub>50</sub> metallic glass above and below its glass transition temperature by machine learning methods. We find that the differences of the structural characteristics between flow units and the rest of the system are beyond short-range order, and further confirmed by the local structural entropy. Our study demonstrates that machine learning provides an unconventional tool to understand the intrinsic heterogeneities in metallic glasses, and sheds light on the structural indicator of heterogeneous dynamic behaviors in amorphous solids.

**10:12AM A45.00010: Residual stress distributions and mechanical noise in athermally deformed amorphous solids from atomistic simulations**

*CÉLINE RUSCHER, Quantum Matter Institute, University of British Columbia, JOERG ROTTLER (Presenter), Dept. of Physics and Astronomy and Quantum Matter Institute, University of British Columbia — The distribution P(x) of local residual stresses in amorphous packings governs the statistical properties of global collective failure events at the yielding transition. We reveal the evolution of P(x) upon deformation by combining atomistic simulations with the frozen matrix approach. A pseudogap form P(x) ~ x<sup>Θ</sup> is observed in the freshly quenched state and in the early stages of deformation. After a few percent strain, however, P(x) starts to develop a plateau p<sub>0</sub> in the small x-limit, where p<sub>0</sub> ~ L<sup>-p</sup> with L the system size. A direct comparison with the system size scaling of the stress drops shows that the distribution of avalanche sizes are controlled by Θ in the transient regime and the plateau exponent p in the steady state flow. The broad distribution of mechanical noise P(|Δx|) ~ |Δx|<sup>-1-µ</sup> is characterized by a Levy-exponent µ and can be related to the behavior of P(x) via a mean-field description.

10:24AM A45.00011: Interplay between rearrangements, strain, and softness and during avalanche propagation*  
GE ZHANG (Presenter), SEAN RIDOUT, ANDREA JO-WEI LIU, University of Pennsylvania — Disordered solids yield at a common shear strain of about 3%, but the behavior beyond yield is different for different systems and for systems with different histories. Foams can deform indefinitely without fracturing, many systems exhibit crackling noise or avalanche behavior, and still others exhibit shear banding and brittle fracture. Here we study an athermal, jammed packing of Hertzian particles that is sheared quasistatically. We identify the stress drops associated with rearrangements and then use steepest descent dynamics to study the evolution of the avalanches. We find that the avalanches consist of localized events that appear sequentially in well-separated locations of the sample. To understand this behavior, we study the interplay between rearrangements, strain, and softness, a machine-learned structural descriptor that predicts the propensity of a particle to rearrange. We find that each rearrangement gives rise to a shear strain field that can immediately trigger other rearrangements, while also causing an isotropic strain field that changes the softness of other particles; this may affect subsequent rearrangements over a much longer time scale. We compare our results to elasto-plastic and mean-field models of avalanches.

*We thank U.S. DOE award DE-FG02-05ER46199.

10:36AM A45.00012: Structural evolution of amorphous systems during avalanches*  
ETHAN STANIFER (Presenter), M. LISA MANNING, Syracuse University — Under applied shear strain, granular and amorphous materials deform. At zero temperature, the deformation can be separated into elastic branches where the particles do not change neighbors and rearrangements where they do. Some rearrangement events are small and localized, while others involve large or system-spanning avalanches. Using numerical simulations of soft spheres, we find that avalanches can be decomposed into a series of localized excitations, and we develop an extension of persistent homology to isolate these excitations. Next, we develop a method to study the linear response of unstable systems during an avalanche, by extending existing tools for identifying structural defects using the Hessian and study how the population of structural defects evolves during an avalanche. We find that localized excitations in the avalanche correlate strongly with localized excitations in the linear spectrum, and investigate how these excitations are created and coupled during the avalanche. These data should help to constrain elastoplastic models for glasses and granular matter.

*Simons Foundation MMLS grant #446222
10:48AM A45.00013: The behavior of jammed packings under correlated random forces*
SUDESHNA ROY (Presenter), ETHAN STANIFER, M. LISA MANNING, Syracuse University — Mean-field calculations suggest that the response of a system to global shear and random forces are essentially equivalent in infinite dimensions. However, it remains an open question whether this is true for systems in lower dimensions. To address this, Morse and collaborators have recently developed a method for driving 2D jammed packings of disks quasi-statically, with random, infinitely-persistent, active forces, and found striking similarities and differences between sheared and actively forced systems. Here, we extend that previous work by studying how changing correlation length of the random forcing affects the mechanical response. We find that both the effective modulus with respect to the random forcing direction, as well as the average effective strain between rearrangements or saddle points, does change systematically with correlation length. This paves the way for a deeper understanding of the connection between shear and active driving in lower dimensions.

Session A46 GMAG DMP: Magnon and Spin Dynamics 708 - Eric Montoya, University of California, Irvine

8:00AM A46.00001: Theoretical model for direct evidence of spatial stability of Bose-Einstein condensate of magnons*  
IGOR BORISENKO, BORIS DIVINSKIY, VLADISLAV DEMIDOV, Institute for Applied Physics and Center for Nanotechnology, University of Muenster, GANG LI (Presenter), Texas A&M Univ, THOMAS NATTERMANN, Institute of Theoretical Physics, University of Cologne, VALERY L POKROVSKY, Texas A&M Univ, SERGEJ DEMOKRITOV, Institute of Applied Physics and Center for Nanotechnology, University of Muenster — Bose-Einstein condensation of quasi-equilibrium magnons is one of few macroscopic quantum phenomena observed at room temperature. However, for a long time it remained unclear, what physical mechanisms can be responsible for the spatial stability of the magnon condensate. Indeed, since magnons are believed to exhibit attractive interaction, it is generally expected that the magnon condensate should be unstable with respect to the real-space collapse, which contradicts all the experimental findings. Here, we provide direct experimental evidence that magnons in a condensate exhibit repulsive interaction resulting in the condensate stabilization and propose a mechanism, which is responsible for the interaction inversion. Our experimental conclusions are additionally supported by the theoretical model based on the Gross-Pitaevskii equation. Our findings solve a long-standing problem and provide a new insight into the physics of magnon Bose-Einstein condensates.

*This work was supported in part by the Deutsche Forschungsgemeinschaft (Project No. 416727653). The theoretical work was supported by the University of Cologne Center of Excellence QM2 and by William R. Thurman’58 Chair in Physics, Texas A&M University.
8:12AM A46.00002: Thermal Hall Effect in Collinear Antiferromagnets on a Square Lattice*
NISHCHAY SURI (Presenter), YINHAN ZHANG, Carnegie Mellon Univ, SATOSHI OKAMOTO, Oak Ridge National Laboratory, DI XIAO, Carnegie Mellon Univ — We show that the thermal Hall effect is possible in collinear antiferromagnets on a square lattice once the magnon-phonon interaction due to the Dzyaloshinskii-Moriya interaction (DMI) is taken into account. We discuss the field- and DMI-dependence of the thermal Hall coefficient. We show that the thermal Hall conductivity is controlled by the resonant contribution from the anticrossing points between the magnon and phonon branches, and estimate its size in real materials.

*Work at CMU is supported by DE-SC0019443 and DE-SC0012509.
The research by S.O. is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

8:24AM A46.00003: Magnon contributions to dielectric constant in spiral magnets
FRANCESCO FOGGETTI (Presenter), Quantum Materials Theory, Italian Institute of Technology; University of Genova, SERGEY ARTYUKHIN, Quantum Materials Theory, Italian Institute of Technology — Magnetic frustration often results in interesting magnetic and dielectric properties. Spiral spin structures are common in magnetic perovskites due to competing exchange interactions and may give rise to ferroelectric polarization via inverse Dzyaloshinskii-Moriya mechanism. Here we model chiral domain walls in the spiral magnetic order and characterize the excitation spectrum using a model Hamiltonian describing spins interacting with polar ionic displacements. We explore the contributions of domain wall localized excitations to the low-frequency dielectric constant in spiral multiferroics (i.e. TbMnO$_3$, MnWO$_4$).

8:36AM A46.00004: Goos-Hänchen effect of spin waves at heterochiral interfaces
ZHENYU WANG (Presenter), YUNSHAN CAO, PENG YAN, University of Electronic Science and Technology of China — One of the most robust methods for measuring the Dzyaloshinskii-Moriya interaction (DMI) is the Brillouin light scattering spectroscopy (BLS) at present. But measuring the DMI parameter in a narrow magnetic strip is always a difficult problem because of the big laser spot size subjected to the diffraction limit of lights. In previous work, we proposed a nonlocal scheme to measure the DMI in a narrow magnetic strip by three-magnon processes, but it is only feasible for the magnetic strip with the width in the range of 50–100 nm. In this work, we observe a Goos-Hänchen shift of spin waves at the heterochiral interface when the spin-wave beam is totally reflected. We further explore the GH shift of spin waves by narrow DMI strips of different widths. It is found that the induced shift is independent of the strip width down to 10 nm, offering an approach to measure the DMI strength of ultranarrow magnetic strips of sub-50-nm scales. Our findings are helpful to understand the GH effect in chiral magnets and enable us to measure the DMI for ultranarrow magnetic strips via the magnonic GH shift, which fills in the gap of current technology.
8:48AM A46.00005: Magnon spectrum in Ferromagnet-Superconductor heterostructure
BISHAL PARAJULI (Presenter), University of California, Merced, SHIZENG LIN, Los Alamos National Lab, CHIH-CHUN CHIEN, University of California, Merced — Research on ferromagnet-superconductor heterostructures gives rise to novel quantum phases and excitations. Spin-waves (Magnons) can propagate in a ferromagnetic thin film while magnetic fields penetrate through a type-II superconducting thin film forming a vortex lattice. Here, we study the magnon spectrum in ferromagnetic thin films in the presence of a vortex lattice in a superconducting thin film separated by an insulating film. It was revealed that the spin-waves interact with the vortex lattice and the magnon spectrum is modified. Because of the periodic modulation of the magnetic field from the vortex lattice, the ferromagnetic film influenced by the vortex lattice acts as a magnonic crystal and results in the formation of bandgaps in the spin wave spectrum. The vortex lattice depends on the magnitude of the applied magnetic field, which can then be used to tune the spin wave band gaps for possible magnonic applications.

9:00AM A46.00006: Imaging spin-wave propagation and interference with electron spins in diamond
IACOPO BERTELLI (Presenter), JORIS JIP CARMIGGELT, BRECHT SIMON, COOSJE POTHOVEN, Delft University of Technology, JAN AARTS, Leiden University, TOENO VAN DER SAR, TAO YU, Delft University of Technology, GERRIT BAUER, Institute for Materials Research and WPI-AIMR and CSRN, Tohoku University, YAROSLAV M. BLANTER, Delft University of Technology — The coherent transport of spin information in magnetic insulators is not associated with the heat dissipation of electronic currents. Therefore, it is envisioned that the next generation of information-processing devices could be based on spin waves, the elementary excitations of magnets that can reach nanometer wavelengths and terahertz frequencies. Here we use electron spins in diamond to probe coherent spin-wave transport in the magnetic insulator yttrium-iron-garnet (YIG). We image propagating spin-waves and their interference, we extract the dispersion relation, demonstrate time-domain control and quantify the magnetization oscillations carried by these excitations. These results pave the way for fundamental studies of spin-wave transport and to harness spin-wave interference in magnonic devices.
**9:12AM A46.00007: Experimental observation of exceptional surface in synthetic dimensions with magnon polaritons**

XUFENG ZHANG (Presenter), Argonne Natl Lab, KUN DING, Imperial College London, XIANJING ZHOU, JING XU, DAFEI JIN, Argonne Natl Lab — Exceptional points (EPs) are singularities of eigen-energies in non-Hermitian systems. Intriguing phenomena have been previously observed around EPs. However, previous demonstrations are limited to 0-dimensional points and 1-dimensional lines. Here we report, to the best of our knowledge, the first experimental observation of an exceptional surface (ES) in a magnon polariton system. Magnon polaritons are hybrid excitations of electromagnetic waves and spin waves, which have recently emerged as a promising candidate for coherent information processing. We took advantage of the excellent tunability in magnon polaritons and introduced a 4-dimensional synthetic space, which enabled the observation of ES. In addition, we also observed an exceptional saddle point in the ES, which exhibits unique anisotropic behaviors in both the real and imaginary part of the eigenfrequencies. Our findings open up new opportunities for high-dimensional control of non-Hermitian systems and novel sensing applications.

**9:24AM A46.00008: Magnon spectrum of the chiral ferrimagnet Cu$_2$OSeO$_3$: a coarse-grained approach**

YI LUO (Presenter), GUY G MARCUS, Institute for Quantum Matter and Department of Physics and Astronomy, Johns Hopkins University, BENJAMIN TRUMP, NIST Center for Neutron Research, National Institute of Standards and Technology, JONAS KINDERVATER, Institute for Quantum Matter and Department of Physics and Astronomy, Johns Hopkins University, MATTHEW STONE, Neutron Scattering Division, Oak Ridge National Laboratory, TYREL MCQUEEN, OLEG TCHERNYSHYOV, COLLIN LESLIE BROHOLM, Institute for Quantum Matter and Department of Physics and Astronomy, Johns Hopkins University — We report a comprehensive neutron scattering study of low energy magnetic excitations in the breathing pyrochlore helimagnetic Cu$_2$OSeO$_3$. Fully documenting the four lowest energy modes that leave the ferrimagnetic configuration of the "strong tetrahedra" intact (ℏω<13 meV), we find quadratic dispersion at the Γ point for energies above 0.2 meV with any gap less than 0.19 meV, two doublets separated by 1.6(2) meV at the R point, and a bounded continuum at the X point. Our constrained rigid spin cluster model relates these features to Dzyaloshinskii-Moriya(DM) interactions and the incommensurate helical ground state. Combining conventional spin wave theory with a spin cluster form-factor accurately reproduces the measured equal time structure factor through multiple Brillouin zones. An effective spin Hamiltonian describing the complex anisotropic inter-cluster interactions is obtained.

*This work was supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award No. DESC0019331. 9:36AM A46.00009: Modeling Hall viscosity in magnetic Skyrmions  BOM KIM (Presenter), Loyola University Maryland — Magnetic Skyrmions are topologically stable objects that are made with a bunch of spins tightly arranged in a smooth fashion. Their topological nature provides unusual and complex transport properties, such as Skyrmion Hall effect. Extensive Hall data have further revealed asymmetry between Skyrmion and Anti-Skyrmion Hall angles, which cannot be accounted by known mechanisms. Here, we explain this asymmetry by utilizing another universal transport coefficient called ‘Hall viscosity,’ extensively studied in quantum Hall systems. Hall viscosity is modeled in steady-state Skyrmions motion by generalizing the Thiele equation with a transverse velocity component and is independent of the Skyrmion charge. Our analyses, based on available asymmetric Hall angle data, reveal this transverse force amounts 3% - 5.4% of the force due to Skyrmion Hall effect. Further clarification of Hall viscosity will be essential for designing next generation storage devices properly, not to mention for our deeper understanding of fundamental properties of nature.

9:48AM A46.00010: Spin dynamics in the skyrmion host lacunar spinel GaV₄S₈  GANESH POKHAREL (Presenter), HASITHA SURIYA ARACHCHIGE, Department of Physics and Astronomy, The University of Tennessee, GEORG EHLERS, Neutron Technologies Division, OakRidge National Laboratory, SEUNGHWAN DO, Materials Science and Technology Division, OakRidge National Laboratory, MATTHEW STONE, MARK D LUMSDEN, Neutron Scattering Division, OakRidge National Laboratory, HAO ZHANG, CRISTIAN BATISTA, Department of Physics and Astronomy, The University of Tennessee, YIMING QIU, NIST Center for Neutron Research, National Institute of Standards and Technology, RANDY FISHMAN, Materials Science and Technology Division, OakRidge National Laboratory, DAVID MANDRUS, Materials Science and Engineering, The University of Tennessee, ANDREW D CHRISTIANSON, Materials Science and Technology Division, OakRidge National Laboratory — In the lacunar spinel GaV₄S₈, the interplay of spin, charge, and orbital degrees of freedom results in a complex phase diagram that includes ferroelectric, orbitally ordered and Néel type skyrmion phases. Below 12.7 K, GaV₄S₈ exhibits a cycloidal state at zero field and a Néel type skyrmion spin structure with the application of field. To understand the physics driving the formation of these novel phases, we have carried out inelastic neutron scattering measurements on GaV₄S₈ above and below the ordering temperature of 12.7 K. Dispersive spin excitations with a zone boundary energy 5.65 meV are observed along the [100], and [110] directions within the magnetically ordered phase. The excitation spectrum softens along the third high symmetry direction, [111]. Using a Heisenberg model with near-neighbor exchange couplings and Dzyaloshinskii-Moria (DM) interactions, the excitation spectra are simulated. Simulation shows ferromagnetic inter-tetrahedral couplings with J= -0.69(3) meV. It is also observed that the DM interactions are around an order of magnitude weaker than the near-neighbor exchange interactions. A small and finite value of the DM interaction at 2 K provides evidence that the ground state of GaV₄S₈ is a cycloid below the ordering temperature in zero applied field.
**10:00AM A46.00011: Dynamics of a vortex near the edge of a thin-film ferromagnet**

MICHAEL BJERNGAARD (Presenter), Johns Hopkins University, DEREK REITZ, UCLA, OLEG TCHERNYSHYOV, Johns Hopkins University — The low-frequency dynamics of magnetization in a thin-film ferromagnet with an easy-plane anisotropy can be efficiently described by a mapping to electrodynamics in 2+1 dimensions. Magnons turn into photons, whereas vortices become massless particles with an electric charge equal to the vortex number. In a previous work [1], we showed that a vortex-antivortex pair with equal skyrmion numbers revolve around the geometrical center and gradually spiral down towards annihilation. Their motion was accurately modeled by considering the balance of forces acting on these topological defects: the Coulomb attraction, the gyroscopic forces, and the viscous force from Gilbert damping. A vortex-antivortex pair with opposite skyrmion numbers will move mostly in the same direction, gradually approaching each other. A similar motion is expected of a vortex near a straight edge, which creates the image of an antivortex attracting the vortex toward the edge. We study this motion numerically and model it analytically.

**10:12AM A46.00012: Soliton Bound States in Large-Spin Anisotropic Antiferromagnets**

HARRY LANE (Presenter), University of Edinburgh, FRANK KRÜGER, ELLIOT CHRISTOU, London Centre for Nanotechnology, University College London, CHRIS STOCK, University of Edinburgh, RUSSELL EWINGS, ISIS Facility, Rutherford Appleton Laboratory — It has long been known that the low-energy dynamics of spin systems are well-described by classical linear spin-wave theory. This is particularly true in the case of systems with a large spin moment, where one can expand in powers of $1/S$. For large-spin antiferromagnets, linear spin wave theory predicts dispersive magnon modes which are gapped in the presence of anisotropy. Such spectra are found time and again in the literature, but can the quantum nature of spin give rise to exotic excitations that are not well described by linear spin-wave theory?

Using a path integral approach [1], we show that the movement of domain walls in an anisotropic large-spin antiferromagnetic chain can be described by solitons. In the presence of coupling to other chains, the frustration induced by this soliton propagation leads to a nonlinear confinement potential that can support bound states. We will then show experimental evidence for these soliton bound states [2], demonstrate strong agreement with our theoretical model and offer insights into where one might expect to find such a phenomenon.

10:24AM A46.00013: Tuning high-Q nonlinear dynamics in a disordered quantum magnet*

DANIEL SILEVITCH (Presenter), CHRISTOPHER TANG, Caltech, GABRIEL AEPPLI, ETH Zurich, THOMAS F ROSENBAUM, Caltech — Quantum states cohere and interfere. Atoms arranged imperfectly in a solid rarely display these properties. Here we demonstrate an exception in a disordered quantum magnet that divides itself into nearly isolated subsystems. We probe these coherent spin clusters by driving the system nonlinearly and measuring the resulting hole in the linear spectral response. The Fano shape of the hole encodes the incoherent lifetime as well as coherent mixing of the localized excitations. For the Ising magnet LiHo$_{0.045}$Y$_{0.955}$F$_4$, the quality factor $Q$ for spectral holes can be as high as 100,000. We tune the dynamics by sweeping the Fano mixing parameter $q$ through zero via the ac pump amplitude as well as a dc transverse field. The zero crossing of $q$ is associated with a dissipationless response at the drive frequency. We then explore the dynamics of this dissipationless state, focusing on the decoherence of the extended spin clusters. Identifying localized two-level systems in a dense and disordered magnet advances the search for qubit platforms emerging from strongly interacting, many-body systems.

*The work at Caltech was supported by US Department of Energy Basic Energy Sciences Award DE-SC0014866.

10:36AM A46.00014: Enhanced self-focusing effect of spin-wave by a pulsed flat-top excitation field in a multi-domain state

KIM HYO SEOK (Presenter), JONGSEOK LEE, IN HYEOK CHOI, Gwangju Institute of Science and Technology — Spin-wave (SW) or its quantum, magnon, is studied with renewed interest as a basis for wave-based classic information processing. Along with other physical waves, SWs also have wave-like properties, such as radiation, propagation, reflection, and refraction, which have been extensively investigated in order to manipulate SWs. Especially, there have been many methods reported to focus the SW via a nonlinearity, a graded refractive index, and a phase-controlled SW sources. In this work, we explore another efficient way of the SW focusing by using the spatially and temporally tailored magnetic field excitations. Using a micro-magnetic simulation, we explain how the SW propagates and is focused in a ferromagnetic thin film with a perpendicularly magnetized anisotropy after its excitation by a pulsed magnetic field having a flat-top amplitude distribution. In particular, we observe that the focusing appears more efficiently in the multi-domain state divided by Bloch walls compared to that in the single-domain state. Based on these results, we suggest the flat-top excitation of the magneto-static wave as an efficient way to create magnetic droplets in a multi-domain state of a perpendicularly magnetized system.
We study in detail the structural and magnetic excitations of CrI$_3$ in single crystalline thin flakes using inelastic light scattering in a magnetic field. We find that for fields above 6 T we observe the scattering from the zone center magnon, the ferromagnetic resonance, with a linear dependence on the magnetic field in this range. This behavior is well explained by the classical Kittel formula that predicts a value of the zero-field resonance at approximately 45 GHz with an effective g-factor of ~ 2. We also find that as a function of the scattered polarization angle with respect to the incoming polarization, the intensity has a two-fold symmetric pattern without nodes (i.e. the signal does not vanish). We will discuss the possible reasons for this behavior and compare it to that expected for the lattice excitations for the expected magnetic point group symmetry.

8:00AM A47.00001: Low-temperature magnetic proximity effects in Mg(Al,Fe)₂O₄/Bi₂Se₃ bilayers* LAUREN RIDDIFORD (Presenter), Applied Physics, Stanford University, PENG LI, Electrical and Computer Engineering, Auburn University, ALEXANDER GRUTTER, National Institute of Standards and Technology, YURI SUZUKI, Applied Physics, Stanford University — Topological insulators (TIs) are of significant interest in spin current-based electronics due to their strong spin-orbit coupling from spin-momentum locking of surface states. Bi₂Se₃ is a 3D topological insulator with a semiconductor gap in the bulk and gapless surface states. However, conduction near room temperature is typically bulk-dominated due to Se vacancies. Bilayers of Mg(Al,Fe)₂O₄ (MAFO), a magnetic insulator, and Bi₂Se₃ show highly efficient spin pumping in the bulk-dominated regime at room temperature. At low temperature, below 45 K, we have found evidence of proximity-induced magnetism in the TI. To understand the underlying mechanism of this proximity-induced magnetism, we performed polarized neutron reflectometry which indicates a sharp interface and a magnetic moment in the TI up to at least 45 K. In transport measurements, we observed both the anomalous Hall effect (AHE) and a large unidirectional magnetoresistance in the TI. The AHE, around 1 Ω at 2 K, was observed up to ~40 K and was amplified by electrically gating Bi₂Se₃. These results suggest that the induced magnetism in Bi₂Se₃ is primarily due to the coupling between MAFO and the surface states of Bi₂Se₃.

8:12AM A47.00002: Exotic coupling in garnet-ferromagnet heterostructures* PATRICK QUARTERMAN, National Institute of Standards and Technology, YABIN FAN, LUQIAO LIU, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, ALEXANDER GRUTTER (Presenter), National Institute of Standards and Technology — Metallic and insulating ferromagnets (FM) have been extensively studied for use in spintronic like structures—the former for spin transfer and spin orbit torques and the latter for generation of magnon spin currents [1,2]. Recently, we have shown that in yttrium iron garnet (YIG)/permalloy (Py) bilayers, grown on Si, the YIG preferentially aligns antiparallel to the Py at low field and can be used to form a magnon spin valve [3]. However, the observed coupling in YIG/FM is quite complex and is heavily dependent on the sample geometry—for example when the same bilayers are grown on Gd₃Ga₅O₁₂ (GGG) substrates, no antiparallel coupling has been observed. In this work, we discuss the coupling of YIG to Py and Co when grown on Si and GGG substrates by measuring the magnetic depth profile using polarized neutron reflectometry. The effect of texture and choice of FM on coupling to the underlying YIG layer will be presented in detail.

8:24AM A47.00003: Angle-dependent magnetoresistance of Pt/EuO\(_{1-x}\) thin films

NARENDRA SHRESTHA (Presenter), JOSEPH R MURPHY, SUBASH KATTEL, WILLIAM RICE, JINKE TANG, Uni of Wyoming — Europium monoxide (EuO) has attracted a great deal of attention in spintronic research due to its unique ferromagnetic and semiconducting properties. Here, we have prepared Pt/EuO thin films by pulsed laser deposition. We study the magnetic and transport properties as a function of temperature and field. The magnetic data shows enhanced Curie temperature to 140 K, which is a signature of oxygen deficiency. Transport measurements reveal a metal-insulator transition below 70 K associated with the ferromagnetic ordering of EuO. Angle-dependent magnetoresistance exhibits behavior that cannot be explained solely on the basis of anisotropic magnetoresistance of EuO: rather, the MR shows a strong angular dependence as the magnetic field, \(H\), is rotated from in-plane to perpendicular-to-plane, while keeping \(H\) perpendicular to the current – a feature consistent with spin Hall magnetoresistance. We discuss the possible origins of the angular dependence by considering the strong spin-orbit coupling present in the system, magnetic proximity effect, interface properties, and the hetero-structure nature of the films.

8:36AM A47.00004: Magnetoresistance and second harmonic Hall measurement of Pt/CoFe\(_2\)O\(_4\) bilayers

ZEXUAN ZHANG (Presenter), PHILLIP DANG, JOSEPH CASAMENTO, XIANG LI, YONGJIAN TANG, TIANXIANG NAN, DANIEL C. RALPH, HUILI XING, DEBDEEP JENA, Cornell University — CoFe\(_2\)O\(_4\) (CFO), a room temperature ferrimagnetic insulating spinel ferrite, is a promising candidate for energy efficient spintronics. Magnetic proximity effect was believed to be absent in Pt/CFO bilayers grown by sputtering or pulsed laser deposition (PLD), but was recently observed in Pt/CFO (001) bilayers grown entirely by molecular beam epitaxy (MBE) [Amamou, Walid et al. Physical Review Materials 2, 011401 (2018)]. Here, we report the observation of magnetic proximity effect in \textit{ex situ} sputtered Pt on MBE grown CFO (001) at room temperature. Angle dependent magnetoresistance measurements in the direction insensitive to spin Hall magnetoresistance (SMR) indicates that magnetic proximity effect is a relatively robust phenomenon. We also studied high quality CFO (111) on multiferroic LuFeO\(_3\) (111) using MBE, since the impact of crystal orientation of CFO on magnetic interaction has been reported to be significant between Pt and CFO. In the same Pt/CFO (001) and Pt/CFO (001) stacks we also carried out the second harmonic Hall measurement and found Nernst effect dominating the signal.

8:48AM A47.00005: Hydroxide-based Magneto-ionics

ALBERTO QUINTANA-PUEBLA
(Presenter), Physics Department, Georgetown University, ABIGAIL A. FIRME, Physics Department, University of Wyoming, CHRISTOPHER J JENSEN, KAI LIU, Physics Department, Georgetown University —

Recently, magneto-ionics has attracted a lot of interests where controlled motion of ions, e.g., under an electric field, is employed to modify metal/oxide interfaces and their magnetic responses in a reversible and non-volatile fashion. Despite the promising initial oxygen-based magneto-ionic systems, it has been demonstrated that hydrogen-based system showed better performance.

In this work, we aim to study the magneto-ionic effects in cobalt hydroxide (Co(OH)₂) / gadolinium (Gd) heterostructures. In contrast to other works, in our system both O²⁻ and H⁺ are contained in the initial sample. Cobalt hydroxide films are grown by electrochemical methods from a cobalt nitrate electrolyte and confirmed by x-ray diffraction. Magnetometry results showed the paramagnetic character of the sample in the as-grown state. However, after the cobalt hydroxide film is sputter-coated with a Gd layer, a clear magnetic hysteresis loop arises. Since the Tc of Gd is 292 K, the observed magnetism arises solely from the spontaneous reduction of Co(OH)₂ to Co and the formation of Gd(OH)ₓ. Finally, we have also demonstrated that the magnetic moment can be tailored with electric fields.

*This work has been supported in part by the SRC/NIST SMART Center and the NSF (DMR-1659532, ECCS-1933527, DMR-1828420).

9:00AM A47.00006: Current-induced magnetization switching in all-oxide heterostructures

LIANG LIU (Presenter), QING QIN, WEINAN LIN, CHANGJIAN LI, QIDONG XIE, SHIKUN HE, XINYU SHU, CHENGHANG ZHOU, ZHISHIUH LIM, JIHANG YU, National University of Singapore, WENLAI LU, Shanghai University, MENGSHA LI, National University of Singapore, XIAOBING YAN, Hebei University, STEPHEN J PENNYCOOK, JINGSHENG CHEN, National University of Singapore —

The electrical switching of magnetization through spin-orbit torque (SOT) holds promise for application in information technologies. Materials with strong spin-orbit coupling, such as heavy metals can convert a charge current into a spin current. The spin current can then execute a transfer torque on the magnetization of a neighboring magnetic layer, usually a ferromagnetic metal like CoFeB, and reverse its magnetization. Here, we combine a ferromagnetic transition metal oxide with an oxide with strong spin-orbit coupling to demonstrate all-oxide SOT devices. We show current-induced magnetization switching in SrIrO₃/SrRuO₃ bilayer structures. By controlling the magnetocrystalline anisotropy of SrRuO₃ on (001)- and (110)-oriented SrTiO₃ (STO) substrates, we designed two types of SOT switching schemes. For the bilayer on the STO(001) substrate, a magnetic-field-free switching was achieved, which remained undisturbed even when the external magnetic field reached 100 mT. The charge-to-spin conversion efficiency for the bilayer on the STO(110) substrate ranged from 0.58 to 0.86, depending on the directionality of the current flow with respect to the crystalline symmetry.

Spin-charge interconversion in complex oxide SrIrO₃ has been studied extensively. Spin Hall angle of SrIrO₃ thin film has been reported, varying from 0.5⁴ to 1⁵. Given the large resistivity mismatch between semimetal SrIrO₃ thin films and typical metal ferromagnets such as CoFeB, CoFe and NiFe, spurious effects and current shunting would be unavoidable in transport measurements. The oxide ferromagnet La₀.₃Sr₀.₇MnO₃ (LSMO) exhibits high Curie temperature, small coercive field and resistance comparable to SrIrO₃ thin films, making it a more suitable candidate for the study of intrinsic spin Hall effects in SrIrO₃ thin films. Also, in situ epitaxial growth of LSMO/SrIrO₃ bilayer system by PLD provides us a platform for engineering the bilayer interface, realizing a fine control of spin dependent interface properties such as effective spin mixing conductance (g↑↓). g↑↓ that is one orders higher than NiFe/2DES, two orders higher than YIG/Heavy metals has been measured.

The relationship between spin-orbit coupling (SOC), emergent topological states, and spin Hall effects, which are highly relevant for spintronics, has driven the recent interest in materials with strong SOC. To probe the influence of SOC at 3d-5d complex oxide interfaces, we have investigated ferromagnetic La₀.₇Sr₀.₃MnO₃/SrIrO₃ bilayers deposited on SrTiO₃. We find that depending on the growth order, the coercive field of the magnetization loop differs significantly at low temperatures. Similar to previous reports, a net moment on Ir has been recorded with element specific XMCD experiments, which is aligned antiparallel to the Mn moments within the manganite. We find that the Ir moment does not follow the same temperature dependence as the magnetization of the manganite, and is limited to the interface. The origins and implications of this result will be discussed.

9:36AM A47.00009: Current-manipulated propagation of spin waves in antiparallel coupled stripe domains of La 0.67 Sr 0.33 MnO 3 thin films [Invited] HAIMING YU (Presenter), BeiHang University — Spin waves may enable low-power devices based on spin information transmission that is free of Joule heating. Antiferromagnetic-type spin waves have intrinsic advantages, such as high speed, dual-polarized and robust against external field perturbation. To date, antiferromagnetic-type propagating spin waves excitation and manipulation have remained challenging. Here, we demonstrate current-controlled stripe domains with alternating upward and downward magnetization in La 0.67 Sr 0.33 MnO 3 thin films, which host spin-wave propagation. A frequency mode around 10 GHz higher than the ordinary low-frequency modes is observed and the dispersion of this mode is different from the low-frequency ones. We developed a theoretical model based on two oppositely oriented coupled domains, which accounts the high-frequency mode an effective antiferromagnetic spin-wave mode. The spin waves can even propagate at zero magnetic field, with group velocities of 2.6 km s$^{-1}$. The orientation of the stripe domains can be controllably modified by an electric current pulse with a density of only 10 5 A cm$^{-2}$, which opens up perspectives for reconfigurable magnonic devices[1].

10:12AM A47.00010: Anisotropic magnon spin diffusion length in ultra-thin spinel ferrite thin films RUOFAN LI (Presenter), TIANXiang NAN, Cornell University, PENG LI, YURI SUZUKI, Stanford University, DANIEL RALPH, Cornell University — Magnon-mediated spin transport in magnetically ordered insulators is of interest in the field of spintronics as it enables transport of spin information with ultra-low-dissipation. Long-distance spin transport has been demonstrated previously in low-damping iron garnets with the film thickness typically above 100 nm. For this large thickness, strain relaxation in the film impedes the study of strain control of magnons. Here we demonstrate anisotropic magnon spin transport in coherently-strained ultra-thin epitaxial films of magnesium aluminum ferrite (MgAl$_{0.5}$Fe$_{1.5}$O$_4$, MAFO) with low Gilbert damping and thickness of 6 nm. Using nonlocal measurements with the spin polarization injected from Pt bars, we found a $\sim$50 % enhancement of the magnon spin diffusion length for propagation in the [110] direction compared to [100], for both electrically and thermally excited magnons. We correlate this anisotropy to the biaxial magnetic anisotropy in MAFO induced by tetragonal distortion. Our finding suggests that epitaxial strain can be used to further engineer magnon spin transport.
**10:24AM A47.00011: Low Magnetic Damping in Epitaxial Li$_{0.5}$Fe$_{2.5}$O$_4$ Thin Films**  
XIN YU ZHENG (Presenter), LAUREN RIDDIFORD, JACOB WISSE, YURI SUZUKI, Stanford Univ — One of the major challenges in the field of spin-current based electronics is the development of low-loss ferromagnetic insulators capable of generating spin currents without an accompanying charge current. Bulk phase Li$_{0.5}$Fe$_{2.5}$O$_4$ (LFO) is known to have the lowest Gilbert damping parameter ($\alpha \approx 0.002$) among the spinel ferrites, but the growth of LFO thin films with desirable microwave properties has remained elusive due to the volatility of lithium. In this talk, we demonstrate the realization of epitaxial LFO ultra-thin films (~3nm) on MgAl$_2$O$_4$ substrates with an ultra-low damping of $\alpha \approx 0.0005$ and an FMR linewidth of 7.5 Oe at 15GHz. These values rival those of yttrium iron garnet (YIG), the gold standard of low-loss magnetic insulators. LFO also offers distinct advantages over YIG such as smaller external field requirements and thinner interfacial layers crucial for magnetic switching. Our results place LFO as an attractive new candidate for low-loss microwave materials in the field of spintronics.

**10:36AM A47.00012: Interface ferromagnetism and anomalous Hall effect of CdO/ferromagnetic-insulator heterostructures**  
YANG MA (Presenter), Peking Univ — The experimental observation of quantum anomalous Hall effect (QAHE) in magnetic topological insulators has stimulated enormous interest in condensed-matter physics and materials science. For the purpose of realizing high-temperature QAHE, several material candidates have been proposed, among which the interface states in the CdO/ferromagnetic insulator heterostructures are particularly interesting and favorable for technological applications. Here, we report the experimental observation of the interfacial ferromagnetism and anomalous Hall effect in the Fe$_3$O$_4$/CdO/Fe$_3$O$_4$ heterostructures grown via oxide molecular-beam epitaxy. Systematical variation of the CdO thickness reveals the interface ferromagnetism as the major cause for the observed planar magnetoresistance and anomalous Hall effect. Our results might pave the way to engineer oxide interface states for the exploration of QAHE towards exotic quantum-physical phenomena and potential applications.
10:48AM A47.00013: Structural, Magnetic and Electrical Transport Properties of YIG Thin Films with Heavily Reduced Oxygen Content  SHU MI (Presenter), VENKATA SWAMY GOLLAPOTHU, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University, HAOLIANG HUANG, YALIN LU, CAS Key Laboratory of Materials for Energy Conversion, Hefei National Laboratory for Physical Sciences at the Microscale & National Synchrotron Radiation Laboratory, Universi, YONGGANG ZHAO, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University — Yttrium iron garnet (YIG) is very promising for spintronic devices due to its insulating nature, low damping and large magnon decay length. Moreover, YIG films have greatly facilitated the research on spin pumping, spin Seebeck effect and topological spintronics [1]. So far, many studies have shown that oxygen content is essential for tuning the structural and magnetic properties of YIG films [2]. But the effect was not so remarkable because only a small amount of oxygen content has been reduced. We have investigated the effect of oxygen content on structural, magnetic and electrical transport properties of YIG films with heavily reduced oxygen contents, obtained via annealing with the presence of carbon. Both the saturation magnetic moment and lattice parameter of YIG decrease with reduced oxygen content, and the electrical resistivity of YIG decreases several orders of magnitude with the lowest value of 0.23 Ωcm at 300 K. The electronic transport behaviors are analyzed in detail by variable-range hopping (VRH) and trap-controlled space charge limited (SCL) conduction. This work is helpful for understanding the effect of oxygen content on the properties of YIG.

Session A48 DCMP: Superconductivity: Critical Current and Vortex Dynamics  Mile High Ballroom 1A - Morten Eskildsen, University of Notre Dame

8:00AM A48.00001: Confined Vortex Matter with Anisotropic Interaction  LIHAO YAN (Presenter), BOLDIZSAR JANKO, XIAOYU MA, WENZHAO LI, University of Notre Dame — In this project, we study confined superconducting vortex matter, when Abrikosov vortices are confined into a mesoscopic container. When the container is large, the vortices are arranged in a triangular Abrikosov vortex lattice. In contrast, in a mesoscopic container, vortices are arranged in other geometries strongly influenced by the container symmetry. In order to systematically study the system of confined vortices, we use the Molecular Dynamics (MD) simulation. In this work, we investigate the stability and melting of mesoscopic vortex matter as a function of vortex number, container size, and container geometry. We identify the so-called “magic number” states which correspond to very stable vortex configurations. We investigate the effect of container symmetry and size on these magic number states and differentiate between the so-called angular melting and general melting transitions. Finally, we explore the influence of anisotropic vortex interactions on the structure of mesoscopic vortex matter.
8:12AM A48.00002: Solid and liquid vortex phases in superconducting Nb/V hybrids* JOSE VICENT (Presenter), Univ Complutense, VICTOR ROLLANO, IMDEA-Nanociencia, ALICIA GOMEZ, Centro de Astrobiología (CSIC-INTA), ALVARO MUNOZ-NOVAL, Univ Complutense, JAVIER DEL VALLE, UCSD, MARIELA MENGHINI, MARINA CALERO DE ORY, IMDEA-Nanociencia, JOSE LUIS PRIETO, ISOM-UPM, ELENA NAVARRO, ELVIRA MARIA GONZALEZ, Univ Complutense — We have studied the vortex dynamics in a periodic potential created by local enhancement of superconductivity. This has been achieved by an array of Nb nanodots embedded in a V film of slightly lower critical temperature. A sample of Cu nanodots embedded in a V film is used as witness sample. In the former hybrid (Nb/V) the array of superconducting Nb dots induces: i) vanishing of commensurability effect between the vortex lattice and the Nb array; ii) hysteresis effects of the vortex dynamics in the solid phase; iii) softening of the vortex lattice, and iv) broadening of the liquid vortex phase. These outcomes can be controlled varying the temperature and/or the in-plane applied magnetic field.

8:24AM A48.00003: Nonlinear Dynamics and Dissipation of a Curvilinear Vortex Driven by a Strong Surface Current* MANULA RANDHIKA PATHIRANA WALIVE PATHIRANAGE (Presenter), ALEXANDER V GUREVICH, Old Dominion University — We report extensive numerical simulations of large-amplitude oscillations of a trapped vortex line subject to a strong ac magnetic field $H(t) = H_0 \sin(\omega t)$ parallel to the surface. The power dissipated by an oscillating vortex segment driven by the Meissner current was calculated by taking into account the nonlinear vortex line tension, vortex mass and a nonlinear Larkin-Ovchinnikov (LO) viscous drag force. It is shown that oscillations of trapped vortices perpendicular to the surface can radically change the field dependence of a residual surface resistance $R_i(H_0)$ due to the LO decrease of the viscous drag coefficient with the vortex velocity. As the frequency increases, the conventional increase of $R_i(H_0)$ with $H_0$ at low $\omega$ evolves into a non-monotonic dependence of $R_i(H_0)$ at larger $\omega$, so that $R_i(H_0)$ decreases with $H_0$ at higher fields. As the electron mean free path on nonmagnetic impurities gets shorter, the field onset of the anomalous decrease of $R_i(H_0)$ shifts to smaller field, and the drop of $R_i(H_0)$ with $H_0$ becomes more pronounced.

8:36AM A48.00004: Melting of the 2D vortex lattice in thin α-MoGe films

BAL POKHAREL (Presenter), JASMINKA TERZIC, DRAGANA POPOVIC, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State University, SURAJIT DUTTA, JOHN JESUDASAN, PRATAP RAYCHAUDHURI, Tata Institute of Fundamental Research, ILLARIA MACCARI, KTH-Royal Institute of Technology, LARA BENFATTO, Dept. of Phys., Sapienza Univ. of Rome — The vortex lattice in a 2D type II superconductor is expected to melt via a BKT transition that involves an intermediate liquid phase ("hexatic fluid"), which preserves orientational order. Recent experiments combining transport and STM imaging made it possible to identify the hexatic state in α-MoGe thin films, showing that vortex diffusivity in the hexatic fluid state is strongly reduced with respect to the isotropic vortex liquid. To fully characterize the melting transition, we performed systematic transport measurements on weakly disordered, 22 nm-thick α-MoGe films down to 0.020 K and in magnetic fields up to 18 T. Our results unambiguously show that the persistence of orientational correlations in the hexatic phase significantly slows down the vortex motion, leading to vanishingly small flux-flow resistance. This effect is consistent with numerical simulations.

* Supported by NSF DMR-1707785 and NHMFL via NSF DMR-1644779 and the State of Florida.

8:48AM A48.00005: Strong irradiation-induced vortex pinning in (Cu,C)Ba$_2$Ca$_3$Cu$_4$O$_{11+d}$

WAI-KWONG KWOK (Presenter), ULRICH WELP, ALEXEI KOSHELEV, Argonne Natl Lab, ASGHAR KAYANI, PRASHANTA NIRAULA, Dept. of Physics, Western Michigan University, YUE ZHANG, CHENGPING HE, HAI-HU WEN, Dept. of Physics, Nanjing University — We report on the strong enhancement of vortex pinning in the 115K-superconductor (Cu,C)Ba$_2$Ca$_3$Cu$_4$O$_{11+d}$ following irradiation with 6 MeV protons. While $T_c$ decreases by only ~2K after doses of up to $10^{17}$ p/cm$^2$, the critical current density $J_c$ is enhanced by a factor of 40 in fields above 2 Tesla and at temperatures above 60 K, matching well the range of intended applications. We estimate $J_c$ from magnetization hysteresis measurements on polycrystalline samples using the Bean model. The whole-sample $J_c$ values, deduced by using the sample size as dimension in Bean's model, approach 5000 A/cm$^2$ at 77 K and 1 T. These values are comparable to those of grain-aligned YBa$_2$Cu$_3$O$_x$ intended for trapped-field magnets, underlining the application potential of this material if produced for instance in film form. The evolution of the field dependence of $J_c$ with irradiation dose is consistent with a model of strong pinning by large-size inclusions.

Sample synthesis at Nanjing University was supported by National Key R&D Program of China and National Natural Science Foundation of China.
The superconducting vortex lattice (VL) of MgB$_2$ hosts three structural phases associated with distinct rotations of the VL with respect to the crystal lattice. One of these phases, the L phase, contains two degenerate orientations with respect to the $a$ axis, causing the VL to fracture into domains. Domain boundaries inhibit structural transitions to and from the L phase, giving rise to robust metastability and an activation barrier which grows rapidly as the VL approaches equilibrium [1]. These domain-dominated kinetics are ubiquitous in material science, from martensitic phase transitions to ferroelectric domain switching, however, unique to the VL of MgB$_2$ is the ability to externally tune this behavior. By rotating the crystal with respect to the applied field, we can suppress the geometric degeneracy between the two domain orientations and inhibit domain wall formation. In this talk, we will discuss the effect of this broken symmetry on both the VL phase diagram and the kinetic behavior of the structural phase transitions.

9:24AM A48.00008: Peak effects in NbSe$_2$ with artificial pinning centers*  
TSUYOSHI TAMEGAI (Presenter), WENJIE LI, SUNSENG PYON, Department of Applied Physics, The University of Tokyo, SATORU OKAYASU, Advanced Science Research Center, Japan Atomic Energy Agency, ATARU ICHINOSE, Central Research Institute of Electric Power Industry, Electric Power Engineering Research Laboratory — Irradiations of swift particles into superconductors modify their vortex states and lead to the enhancement of critical current density, $J_C$, via creation of point defects (PDs) or columnar defects (CDs). Such an enhancement of $J_C$ was demonstrated in cuprate superconductors [1] as well as in conventional [2] and iron-based superconductors [3]. However, how the $J_C$ is enhanced depends strongly on the target material and ion species, energy, and density of swift particles. In some cases, $J_C$ is monotonically enhanced, while in other cases, non-monotonic magnetic field dependence of $J_C$, peak effect, is observed after the irradiation. In the present study, we compare the effect of PDs and CDs on the $J_C$ - $H$ behavior of NbSe$_2$. With increasing the density of PDs by proton irradiation, the field range for the peak effect close to $H_{c2}$ broadens significantly. In the case of CDs, the $J_C$ - $H$ behavior changes sensitively as a function of the direction of CDs and magnetic field with respect to the c-axis.

9:36AM A48.00009: Large and uniform critical currents in finite magnetic fields  
IVAN SADOVSKYY (Presenter), Microsoft Corp, ANDREAS GLATZ, ALEXEI KOSHELEV, ULRICH WELP, WAI-KWONG KWOK, Argonne National Lab — Loss-free superconducting transport is tremendously important for technological and energy applications. Heat dissipation from drifting magnetic vortices is one of the main limiting factors for superconductors usage. Here we discuss defect configurations that trap vortices almost independently of their direction. As a result, such pinning configurations produce near uniform critical current as a function of applied magnetic field angle. To cover the broadest class of pinning landscapes we employ a genetic algorithm varying the size, position, and orientation of each defect individually. We report several notable results and analyse them in details. The highest uniform critical current is 22% of the depairing current at the magnetic field 10% of the second critical field.
9:48AM A48.00010: New paradigm for a disordered superconductor in orbital magnetic field  AMIT GHOSAL (Presenter), ANUSHREE DATTA, ANURAG BANERJEE, IISER Kolkata, NANDINI TRIVEDI, Physics, Ohio State University — Orbital magnetic field, as well as disorder, weaken superconductivity when acting individually on a s-wave superconductor. The Abrikosov vortex lattice in a clean type-II superconductor, resulting from an orbital magnetic field, transforms into a metal beyond a critical magnetic field $H_c$ once vortices start overlapping. Similarly, disorder drives a transition from a superconductor to an insulator past a critical disorder strength. Here we show that acting simultaneously on a two-dimensional superconductor, disorder and magnetic field lead to an intriguing evolution of the superconducting state. While for weak disorder, the critical field $H_c$ for the suppression of superconducting energy gap matches the critical field at which the superfluid density collapses, the two diverge from each other with increasing disorder creating a pseudogap phase. Our results provide a natural explanation of the long standing puzzle of a strong magnetoresistance peak observed as a function of orbital magnetic field in thin disordered superconducting films. Our results also explain why the characteristic Caroli-de Gennes-Matricon zero bias peak in the local density of states in the vortex core of a clean superconductor might be absent in the presence of disorder, as observed in some recent experiments.

10:00AM A48.00011: Microwave flux-flow Hall effect of superconductors: (1) Method RYO OGAWA, FUYUKI NABESHIMA, ATSUTAKA MAEDA (Presenter), Dept. of Basic Sci., Univ. Tokyo — The bound states in the vortex core of superconductors can be classified in terms of the cleanliness of the vortex core. High $T_c$ cuprate superconductors are expected to be in the clean limit because of the large superconducting gap. However, previous measurements of the effective viscous drag coefficient, $\eta^*$, for wide range of cleaness found that the vortex cores of high $T_c$ cuprates were in the moderately clean limit, as a universal trend [1]. These results may suggest that there exists an extra dissipation mechanism due to the vortex motion which have not been considered so far. However, $\eta^*$ is the mixture of the longitudinal viscous drag coefficient and the Hall coefficient [2]. Thus, $\eta^*$ measurement may not reflect the true electronic states in the vortex core. Therefore, it is necessary to directly measure the flux flow Hall effect and to evaluate the true core states. In order to neglect pinning, we need high frequencies. Thus, we developed a new method for microwave Hall effect measurement using a cross shaped bimodal cavity. In this talk, we will show the detail of the measurement and the analysis. We applied our system to Bi, and obtained a good result.
10:12AM A48.00012: Microwave flux-flow Hall effect of superconductors: (2) Experiments in Bi$_2$Sr$_2$CaCu$_2$O$_y$  
RYO OGAWA (Presenter), FUYUKI NABESHIMA, ATSUTAKA MAEDA, Dept. of Basic Sci., Univ. Tokyo — We have developed a new system to measure the microwave flux-flow Hall effect [1]. The new method enables us to measure microwave Hall effect of materials with high conductivity at low temperatures. Using the system, we investigate the flux flow Hall effect of high T$_c$ cuprate superconductor, Bi$_2$Sr$_2$CaCu$_2$O$_y$. In the vortex state, with increasing magnetic field, Hall angle, tanq, approaches to a constant value at each temperature. We obtained $\omega_0\tau \approx 2-3$ in the low temperature limit ($\omega_0$ and $\tau$ are the level spacing of quasiparticle in the vortex core and the quasiparticle scattering time in the vortex core, respectively), which is larger than the estimated value by the effective viscous drag coefficient $\eta^*$. In this talk, we will discuss the implication of the results.

10:24AM A48.00013: Dynamic Penetration Field of Vortices in a Superconductor in a Time-Dependent Magnetic Field*  
AHMAD SHEIKHZADA, ALEXANDER V GUREVICH (Presenter), Old Dominion University — We address the nonlinear dynamics of penetration of vortices in a superconductor subject to a periodic magnetic field $H(t) = H_0 \sin \omega t$ parallel to the surface. The time-dependent Ginzburg-Landau equations for a gapped superconductor were simulated numerically to calculate the frequency and temperature dependencies of the field onset $H_p(T, \omega)$ of vortex penetration at $T \approx T_c$. It is shown that $H_p(T, \omega)$ can exceed the dc superheating field $H_s$ at which the Meissner state becomes unstable. Here $H_p(T, \omega)$ increases with $\omega$ and approaches $\sqrt{2}H_s(T)$ at $\omega \tau \geq 1$, where $\tau(T)$ is the energy relaxation time of quasiparticles on phonons. We also investigated the effect of surface topographic defects on $H_p(T, \omega)$ and showed that they can substantially reduce $H_p(T, \omega)$ and cause additional power dissipation.

*This work was supported by DOE under grant No. DE-SC0010081.
Glassy and plastic vortex creep regimes in superconducting (Y,Gd)Ba$_2$Cu$_3$O$_y$ films and coated conductors$^*$ LEONARDO CIVALE (Presenter), BORIS MAIOROV, IVAN NEKRASHEVICH, Los Alamos Natl Lab, MASASHI MIURA, Graduate School of Science and technology, Seikei University — Large thermal fluctuations in high $T_c$ superconductors give rise to fast vortex dynamics that promotes the time relaxation of the metastable supercurrents, which is detrimental for applications. We are pursuing a general understanding of the lowest achievable flux creep rate ($S$) for a superconductor at any temperature ($T$) and magnetic field ($H$). Initially, we found that there is a universal lower limit for $S$ in the Anderson-Kim (A-K) regime at $T<<T_c$ (Eley et al., Nat. Mat. 2017). Later, we expanded our quest to higher $T$ and $H$ outside the A-K limit, where the universality is lost and different regimes occur. We will present results on (Y,Gd)Ba$_2$Cu$_3$O$_y$ coated conductors with randomly distributed BaHfO$_3$ nanoparticles. These samples exhibit extremely strong vortex pinning, with critical current densities among the highest in any known superconductor. We identify several glassy and plastic dynamics regimes, the boundaries among which are determined either by intrinsic vortex properties or by thickness effects. In particular, we find a thickness-controlled “second A-K regime” at high $T$, which sets the lowest $S(T,H)$ limit in thin samples in technologically relevant $T$-$H$ conditions.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A49 DCMP: Superconducting Proximity Effect and Josephson Junctions Mile High Ballroom 1B - Dmitry Smirnov, National High Magnetic Field Laboratory
8:00AM A49.00001: Gate-Dependent Transport in Multi-Terminal Josephson Junctions*
GINO GRAZIANO (Presenter), University of Minnesota, JOON SUE LEE, SEAN HARRINGTON, MIHIR PENDHARKAR, CHRIS J PALMSTROM, University of California, Santa Barbara, VLAD PRIBIAG, University of Minnesota — Josephson coupling of three or more superconducting leads through a material with few conducting modes has been predicted to give rise to topological effects. Such behavior, of relevance for topologically-protected quantum bits, would lead to specific transport features measured between terminals, with topological phase transitions occurring as a function of relative phase and voltage biases. Here we study the effects on transport of several top-gating arrangements on multi-terminal Josephson junctions with many conducting modes based on an InAs 2DEG proximitized with an epitaxial aluminum layer and many conducting modes. The superconducting features can be accurately simulated by a network of RCSJ junctions. [1]

*This work was supported primarily by the National Science Foundation under Award No. DMR-1554609. The work at UCSB was supported by the Department of Energy under Award No. DESC0019274. The development of the epitaxial growth process was supported by Microsoft Research.

8:12AM A49.00002: Gate tunable multi-terminal Josephson effect
NATALIA PANKRATOVA (Presenter), HANHO LEE, ROMAN KUZMIN, KAUSHINI S WICKRAMASINGHE, University of Maryland, College Park, MAXIM G VAVILOV, University of Wisconsin - Madison, JAVAD SHABANI, New York University, VLADIMIR MANUCHARYAN, University of Maryland, College Park — Junctions of more than two superconducting terminals are required for implementing braiding operations on Majorana fermions. Moreover, such multi-terminal Josephson Junctions (JJ) were predicted to support topological state and host zero-energy quasiparticles. Unlike conventional two-terminal JJs where the value of critical current is a number, the multi-terminal JJs exhibit a novel feature – the critical current contour (CCC) [1]. We report the measurement of non-trivial CCC shapes as a function of gate voltage and magnetic field in hybrid semiconductor/superconductor (InAs/Al) multi-terminal JJs. Multi-terminal junctions can host two different regimes: a strong neighbor-coupling regime and a multi-terminal regime, depending on the gate voltage. The geometry of a junction is also an important factor defining the operating regime. The effect of an out-of-plane magnetic field indicates an observation of the Fraunhofer interference pattern in multi-terminal JJs.

8:24AM A49.00003: Unconventional Superconductivity in monolayer Transition Metal Dichalcogenides via proximity  VIVEK AJI (Presenter), ROBERT DAWSON, University of California, Riverside — Single layer Transition Metal Dichalcogenides (TMDCs) provide a unique platform to study the interplay of spin-orbit coupling, topology and electron-electron interactions. In addition, the ultrathin 2D geometry allows for proximal coupling to other materials particularly magnets and superconductors. In this talk we report on the nature of the induced superconducting state when coupled to a conventional superconductor. Going beyond the tunneling model we solve a self-consistent Bogoliubov-De Gennes equations for the heterostructure to establish the nature of the paired state. Introducing a third device component, a ferromagnet such as Chromium tri-iodide, breaks time reversal allowing access to the topologically nontrivial electronic states of the TMDC. Modifications of the induced phase and conditions for realizing topological superconductivity will be discussed.

8:36AM A49.00004: Induced superconductivity and multiple Andreev reflections in multilayer WTe$_2$ Josephson junctions*  XURUI ZHANG (Presenter), XIAOYAN SHI, University of Texas at Dallas — Introducing superconductivity into topological materials has become a focus of attention in condensed matter physics as an effective way to realize Majorana modes. It has been predicted that Majorana bound states could arise from the proximity effect between an s-wave superconductor and the surface states of a strong topological insulator (TI). As one of the transition metal dichalcogenides, the topological properties of WTe$_2$ have been verified in both bulk (type-II Weyl semi-metal) and monolayer materials (topological insulator). Here we fabricated SNS junctions based on multilayer WTe$_2$ flakes. We report the observations of the proximity effect induced superconductivity revealed by magnetoresistance (MR) and I-V measurements. Distinct zero-bias conductance peaks in differential conductance measurements, might be as a sign of Majorana state, were also observed. In addition, the multi-dips of differential resistance at low temperature and magnetic field marks multiple Andreev reflections which might result from the intrinsic multi-gap superconducting states of WTe$_2$.

8:48AM A49.00005: Proximity induced Superconductivity in low carrier density Bi$_x$Sb$_{2-x}$Te$_3$*

YANG BAI (Presenter), XIANGYU SONG, GUANG YUE, ALEXEY BEZRYADIN, DALE J VAN HARLINGEN, JAMES ECKSTEIN, University of Illinois at Urbana-Champaign — To investigate superconductivity in topological insulators, we have fabricated and measured arrays of islands of diameter about 160nm on topological insulators grown by molecular beam epitaxy. Typical island spacing is about 40 nm. The superconductivity is induced via the proximity effect which is strongly dependent on the electronic properties of the underlying TI film. Earlier work with n-type Bi$_2$Se$_3$ where the carrier density was 3E13 carriers per square cm showed the emergence of superconductivity with a 2D critical current density of more than 1A/m at 0.7 mK. In these samples, both bulk and 2D topological surface states were made superconducting. To study proximity effect coupling into only the topological surface states we used thin films of the alloy Bi$_x$Sb$_{2-x}$Te$_3$. In these materials, the total carrier density can be tuned such that the Fermi surface is completely topological and no bulk states are occupied. In samples with carrier density of 7E12 carriers per square cm, we observed the superconducting proximity effect coupling through the surface states above 0.8 K. Nonlinear transport and magnetoresistance results will be presented and discussed. This study reveals how surface and bulk carriers participate in superconductivity in TIs.

9:00AM A49.00006: Superconducting Proximity Effect in Magnetically-Doped Topological Insulators using Bulk Single Crystals*  
RIKIZO YANO (Presenter), KOHEI TSUMURA, Applied Physics, Nagoya University, HISHIRO T. HIROSE, Laboratory for Materials and Structures, Tokyo Institute of Technology, MASAHIRO YAMAMOTO, Applied Physics, Nagoya University, ANDREI KUDRIASHOV, TQPSS, Moscow Institute of Physics and Technology, MASAO KOYANAGI, HIROMI KASHIWAYA, National Institute of Advanced Industrial Science and Technology, YASUHIRO ASANO, Center of Topological Science and Technology, Hokkaido University, VASILY STOLYAROV, TQPSS, Moscow Institute of Physics and Technology, TAKAO SASAGAWA, Laboratory for Materials and Structures, Tokyo Institute of Technology, SATOSHI KASHIWAYA, Applied Physics, Nagoya University — Superconducting proximity effect on magnetic topological insulators (TIs) is expected to induce unconventional superconductivity, some of which can host the Majorana fermion. Recently, we observed some unusual behaviors on Nb/Fe-doped TI/ Nb Josephson junctions: e.g., a unique three-peak structure and a $4\pi$-periodic Josephson current. However, those origins are still under debate due to possible contributions from the bulk and the edge modes to the proximity effect.

In this study, we prepared another magnetic TI with a high bulk resistivity and fabricated its Josephson junctions without edge contacts. As a result, a similar three-peak structure was also observed, suggesting that the observed unique behaviors found in the former junction also came from the surface contribution. Furthermore, we observed a unique magnetic response possibly related to bulk magnetic properties. We believe that those results promote our understanding of the proximity effect on topological materials.

9:12AM A49.00007: Compensated CoGd Ferrimagnets in Magnetic Josephson Junctions*  
ALEXANDER MADDEN (Presenter), JOSHUA WILLARD, REZA LOLOEE, NORMAN BIRGE, Michigan State Univ — The rare earth-transition metal ferrimagnet Co$_{1-x}$Gd$_x$ has been studied for application in superconducting electronics. At a carefully chosen Gd concentration, the Co and Gd moments perfectly cancel leading to a zero-moment compensation point. Point-contact Andreev reflection measurements [1] have shown that at the compensation point there is still a net spin polarization of the transport current. This raises the possibility of application in electronics requiring a magnetic material with little stray field, such as cryogenic magnetic memory. As the compensation point can vary significantly as a function of temperature and thickness, we present SQUID VSM data on thin films taken at cryogenic temperatures. We also present the results of transport measurements on superconductor-ferrimagnet-superconductor Josephson junctions over a range of thicknesses for CoGd alloys near their compensation point.

*This research is based upon work supported by the ODNI, IARPA, via ARO contract number W911NF-14-C-0115. Superconducting pairing symmetry and spin-orbit coupling in proximitized graphene

ABDULRHMAN ALSHARARI (Presenter), University of Tabuk, SERGIO E ULLOA, Ohio University — Graphene has been shown to exhibit unusual topological phases upon proximity to different dichalcogenide substrates [1]. However, the effect of these perturbations in the presence of superconducting correlations has not been explored. We study the effect of different superconducting symmetry pairings over a range of chemical potential. We analyze the symmetry and identify the topological characteristics of the resulting quasiparticle spectrum at the mean field level.

Interestingly, the system with nearest neighbor spin-singlet superconductivity order parameter may exhibit inverted bands in the quasiparticle band structure, reminiscent of the electronic bands [1]. As the system parameters change, the corresponding edge states in such phase appear after a transition to a regime that closes the bulk bandgap. As we will show, however, both gapped phases belong to a topologically trivial regime, as the results of their invariant number Z2 indicate.

Our results also show that the phases in a time-reversal-invariant 2D-superconductor are not dependent on the magnitude of the singlet and triplet order parameter, and/or the chemical potential, as the topological invariant number remains unchanged.

Chaos and Chimera in Hysteretic RF SQUID Metamaterials*

JINGNAN CAI (Presenter), STEVEN ANLAGE, University of Maryland, College Park — RF SQUIDs have been established as viable building blocks for microwave frequency metamaterials [1,2]. The RF SQUID resonance is tunable under applied DC flux, with upper-frequency range scaling as $\sqrt{1+\beta_{rf}}$. Our previous design restricted the parameter $\beta_{rf}$ below unity to avoid hysteresis, thus limited the resonance range. We have built new arrays of RF SQUID meta-atoms in the hysteretic regime to explore their interesting properties with the ultimate goal of extending the resonance frequency tunability. In particular, a strong and positive out-of-plane coupling among the SQUIDs is achieved through an alternating-overlapping-loop geometry, potentially mitigating the hysteresis from high-$\beta_{rf}$ SQUID meta-atoms. Much theoretical work has predicted chaotic dynamics and chimera states in such systems. Observations of the above nonlinear phenomena in microwave transmission measurements and laser scanning microscopy [3] will be reported.

**9:48AM A49.00010: Josephson current mediated by odd-frequency equal-spin triplet pairing on the surface of Weyl nodal loop semimetals**  PARAMITA DUTTA (Presenter), ANNICA M BLACK-SCHAFFER, Department of Physics and Astronomy, Uppsala University — We explore proximity-induced pairing on the surface of a Weyl nodal loop semimetal (WNLS) sandwiched between two conventional spin-singlet s-wave superconductors in a Josephson junction set-up. The fully spin-polarized drumheadlike surface states (DSSs) and the intrinsic spin-orbit interation of the WNLS cause odd-frequency (odd-ω) equal-spin triplet pairing to be induced on the surface of the WNLS, whereas, the spin-singlet pairing decays inside the WNLS very fast. We show finite Josephson current in the junction contributed by the equal-spin triplet odd-ω pairing. Odd-ω mixed-spin triplet pairing can be generated by placing an additional ferromagnet in the junction if the direction of the magnetization of the ferromagnet opposes the spin-polarization direction of the DSSs. The pairing and the current are not affected if the magnetization direction is orthogonal to the DSS spin polarization, which further confirms the equal-spin structure of the odd-ω pairing.

**10:00AM A49.00011: Critical Current Decay in Josephson Junctions Containing Antiferromagnetic Ni$_{41}$Mn$_{59}$**  ROBERT M KLAES (Presenter), REZA LOLOEE, NORMAN BIRGE, Michigan State University — We report on the fabrication and measurement of antiferromagnetic (AF) S/N/AF/N/S Josephson junctions where Ni$_{41}$Mn$_{59}$ is used as the AF layer, Nb as the S layer, and Cu as the N layer. From measurement of critical current in samples with NiMn thicknesses in the range from 1.2 nm to 6.0 nm, we measure the characteristic decay length within NiMn to be 2.1 nm. One potential application of AF layers inside Josephson junctions is to pin the magnetization of an adjacent ferromagnetic (F) layer by exchange bias. We have characterized NiMn/NiFe and NiMn/Ni bilayer sheet films magnetically to confirm the pinning behavior of NiMn. Such a bilayer AF/F system could potentially be used as a pinned hard layer in a proposed cryogenic memory cell whose design takes the form of an S/F/F'/S spin valve where the two ferromagnetic layers [F, F'] have different switching fields [1]. This design requires a robust magnetization of the hard layer which would be strengthened by the exchange bias effect.

Magneto-transport of electrons in near surface InAs quantum wells in contact with NbTiN* Mehdi Haftepour (Presenter), William Mayer, Noah Gooss, William Makoto Strikland, Joseph Yuan, Kaushini S Wickramasinghe, Kasra Sardashti, New York University, Tzu-Ming Lu, Sandia National Laboratories, Javad Shabani, New York University — Indium Arsenide (InAs) near surface quantum wells have become the focus of recent interest for their use in heterostructures with superconductors. An interface between a superconductor and quantum Hall edges is predicted to exhibit excitations with non-abelian statistics. NbTiN-InAs is a promising candidate as NbTiN can sustain strong magnetic fields where InAs can host integer quantum Hall states. In this work, we study the proximity effect by monitoring the current flow along the superconductor-semiconductor interface. The data suggest the enhanced conductance is due to Andreev reflection when edge states are formed in the presence of a strong magnetic field.

This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc. for the U.S. DOE's National Nuclear Security Administration under contract DE-NA0003525. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government. This work was supported partially by NSF EAGER under award number DMR-1836687.

Superconductor-Semiconductor Devices with 2D Holes in Germanium* Kushagra Aggarwal (Presenter), Andrea Hofmann, Daniel Jirovec, Ivan Prieto Gonzalez, Institute of Science and Technology Austria, Amir Sammak, Menno Veldhorst, Giordano Scappucci, QuTech, Delft University of Technology, Georgios Katsaros, Institute of Science and Technology Austria — The coupling of superconductors to semiconductors receives widespread interest due to their potential for realizing topological superconductivity, interferometers and Andreev Bound State devices [1, 2]. The quality of the induced gap, heavily influenced by the transparency of the superconductor-semiconductor interface, presents a crucial challenge for realizing such devices. Here, we study proximity induced superconductivity in germanium quantum wells coupled to aluminium. The presence of strong spin-orbit interaction, tunable g-factor and high mobility make germanium an attractive semiconducting platform. Combined with the ease of ohmic contact formation due to Fermi level pinning, Ge-Al is a promising material system for hybrid semiconductor-superconductor devices. We achieved transparencies of 65% and $I_C R_N$ products of up to 50μV, about three times higher than previously reported [3, 4].

*The project received financial support from NOMIS foundation.
Transport properties of ultra-scaled Ge/Si core/shell nanowires with highly transparent Al contacts. *JOVIAN DELAFORCE (Presenter), Université Grenoble Alpes, CNRS, Institut NEEL UPR2940, Grenoble, France, MASIAR SISTANI, Institute of Solid State Electronics, TU Wien, Gußhausstraße 25-25a, 1040 Vienna, Austria, ROMAN KRAMER, NICOLAS ROCH, Université Grenoble Alpes, CNRS, Institut NEEL UPR2940, Grenoble, France, MINH-ANH LUONG, Université Grenoble Alpes, CEA, IRIG-DEPHY, F-38054 Grenoble, France, MARTIEN DEN-HERTOG, Université Grenoble Alpes, CNRS, Institut NEEL UPR2940, Grenoble, France, ERIC ROBIN, Université Grenoble Alpes, CEA, IRIG-DEPHY, F-38054 Grenoble, France, JUERGEN SMOLINER, Institute of Solid State Electronics, TU Wien, Gußhausstraße 25-25a, 1040 Vienna, Austria, JUN YAO, Department of Electrical and Computer Engineering, Institute for Applied Life Sciences, University of Massachusetts, Amherst, Massachusetts, 01003, USA, CHARLES M LIEBER, Department of Chemistry and Chemical Biology, Harvard University, Cambridge, Massachusetts, 02138, USA, CÉCILE NAUD, Université Grenoble Alpes, CNRS, Institut NEEL UPR2940, Grenoble, France, ALOIS LUGSTEIN, Department of Chemistry and Chemical Biology, Harvard University, Cambridge, Massachusetts, 02138, USA, OLIVIER BUISSON, Université Grenoble Alpes, CNRS, Institut NEEL UPR2940, Grenoble, France — Superconducting-semiconducting hybrid systems provide a rich domain for the investigation of electronic and quantum transport. Further, promising developments in their application in high performance nanoelectronics and quantum devices has motivated significant research and development. Nanowire heterostructures are of particular interest due to their quantum confinement properties allowing one to investigate transport in quasi one-dimensional systems. However, critical to their success is the fabrication of high quality and reproducible semiconductor-superconductor interfaces. Using a novel annealing technique, we have realised nanowire heterostructures consisting of crystalline-Al/Si core/shell leads contacting tuneable Ge/Si core/shell segments with atomically precise interfaces. We will present results of temperature dependent DC transport measurements on ultra-scaled devices. Reporting on the gate tuneable transport properties of these highly transparent devices including quantized conductance, tuneable Josephson current and multiple Andreev reflections and their applications as quantum devices.

10:48AM A49.00015: Gate-tunable proximity effect in epitaxial Al-InAs Josephson junctions using hBN gate dielectric*  JOSHUA THOMPSON (Presenter), Physics, University of Arkansas, WILLIAM MAYER, FATEMEH BARATI, JOSEPH YUAN, KAUSHINI S WICKRAMASINGHE, KASRA SARDASHTI, Physics, New York University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, JAVAD SHABANI, Physics, New York University, HUGH CHURCHILL, Physics, University of Arkansas — The transparent interface of epitaxial Al-InAs heterostructures provides an excellent platform for potential advances in topological superconductivity and superconducting quantum computation. Josephson junctions built on these heterostructures can be gated, allowing for tuning of the supercurrent. We report the fabrication and measurement of gate-tunable Al-InAs Josephson junctions in which the gate dielectric in contact with the InAs was mechanically exfoliated hexagonal boron nitride (hBN). We discuss fabrication processes that enable compatibility between layered material transfer and Al-InAs heterostructures. By comparing these devices with others using a conventional AlOx gate dielectric, we show that hBN is a suitable gate dielectric for the Al-InAs material platform. Specifically, the product of normal resistance and critical current, is comparable for both types of devices, but higher $R_N$ for the hBN-based devices suggests the possibility of less unintentional doping of the InAs by the gate dielectric.

*We acknowledge support from NSF DMR-1610126 and NSF DMR 1836687.

Ballroom 1C - Md Mofazzel Hosen
8:00AM A50.00001: First single crystals of a new itinerant antiferromagnet without magnetic elements

JAIME MOYA (Presenter), Rice University, ALANNAH HALLAS, Physics and Astronomy, University of Bristish Columbia, EMILIA MOROSAN, VAIDEESH LOGANATHAN, ANDRIY NEVIDOMSKY, Rice University, FRANZISKA WEICKERT, Los Alamos National Laboratory, JAMES W BEARE, YIPENG CAI, GRAEME LUKE, McMaster University, CHIEN-LUNG HUANG, Rice University — Magnetism exists on a spectrum spanning the local to itinerant limit. Theory in the local moment extreme is experimentally confirmed in many magnetic insulators where the magnetism originates from unfilled electronic shells. However, in the itinerant limit, where magnetism stems from band effects, experiment lags theory as there are only three known purely itinerant magnets: ZrZn$_2$ and Sc$_{3.1}$In, both FM, and TiAu an AFM. While ZrZn$_2$ has been made in single crystal form, no single crystals have been made of a purely itinerant AFM, until now. We present the results on single crystals of a new itinerant AFM with no magnetic constituent elements which orders at $T_N = 11$ K. The paramagnetic moment is large, 1.0 $\mu_B$/FU, compared to the saturated moment of 0.25 $\mu_B$/FU, leading to a Rhodes-Wohlfarth ratio of 4. The entropy release is small, just 0.7%$R\ln 2$, yet muon spin relaxation measurements confirm the order is intrinsic. DFT calculations confirm the small moment and conclude a Fermi surface nesting mechanism is responsible for the magnetic order. Having the first purely itinerant AFM crystal paves the way for advance experiments that will allow a fundamental understanding of this class of materials for the first time.

*This work supported by NSF DMR 1903741.

8:12AM A50.00002: Magnetochiral dichroism in a collinear antiferromagnet MnTiO$_3$ with zero magnetization

TATSUKI SATO (Presenter), NOBUYUKI ABE, Univ of Tokyo-Kashiwanoha, SHOJIRO KIMURA, Tohoku University, YUSUKE TOKUNAGA, TAKA-HISA ARIMA, Univ of Tokyo-Kashiwanoha — Symmetry breaking induces specific optical effects. Magnetochiral dichroism (MChD) - nonreciprocal directional asymmetry in the propagation of unpolarized light - has been found to be induced by simultaneous breaking of the space-inversion and time reversal symmetries. After the first discovery [1], it has been established that net magnetization along with the light path causes MChD in various chiral magnets. In contrast, MChD in antiferromagnets without magnetization is less explored. Here we report the MChD in a collinear antiferromagnet MnTiO$_3$ in the absence of magnetization. We observed some asymmetry in the absorption coefficient between the light beams propagating parallel and antiparallel to the net staggered magnetization. Exploiting the linear magnetoelectric coupling [2], we also demonstrate the electric-field and magnetic-field induced switching of absorbance in MnTiO$_3$. In our presentation, we will propose the microscopic description of the origin of the MChD in MnTiO$_3$ from the viewpoint of local symmetry on each Mn site.

Highly nonlinear magnetoelectric effect in antiferromagnetic $\text{Co}_4\text{Ta}_2\text{O}_9$ single crystals

DONGGUN OH (Presenter), NARA LEE, Yonsei University, SUNGKYUN CHOI, Rutgers University, JAE YOUNG MOON, JONG HYUK KIM, HYUN JUN SHIN, HWAN YOUNG CHOI, Yonsei University, SON KWANGHYO, Max Planck Institute for Intelligent Systems, MATTHIAS J GUTMANN, Rutherford Appleton Laboratory, GIDEOK KIM, Max Planck Institute for Solid State Research, VALERY KIRYUKHIN, Rutgers University, JURGEN NUSS, Max Planck Institute for Solid State Research, YOUNG JAI CHOI, Yonsei University — A class of antiferromagnetic honeycomb lattices compounds, $\text{A}_4\text{B}_2\text{O}_9$ ($\text{A} = \text{Co, Fe, Mn}; \text{B} = \text{Nb, Ta}$), have been explored owing to the occurrence of linear magnetoelectricity. We observe a highly nonlinear magnetoelectric effect on single crystals of $\text{Co}_4\text{Ta}_2\text{O}_9$ (CTO), distinctive from the linear behavior in the isostructural $\text{Co}_4\text{Nb}_2\text{O}_9$.

Ferroelectricity emerges primarily along the [110] direction under magnetic fields, with the onset of antiferromagnetic order at $T_N = 20.5$ K. For in-plane magnetic field, a spin-flop occurs at $H_C \approx 0.3$ T, above which the ferroelectric polarization gradually becomes negative and reaches a broad minimum. Upon increasing magnetic field further, the polarization crosses zero and increases continuously to $\sim 60 \mu\text{C/m}^2$ at 9 T. In contrast, the polarization for a magnetic field perpendicular to the hexagonal plane increases monotonously and reaches $\sim 80 \mu\text{C/m}^2$ at 9 T. This observation of a strongly nonlinear magnetoelectricity suggests that two types of inequivalent $\text{Co}^{2+}$ sublattices generate magnetic field-dependent ferroelectric polarization with opposite signs. These results motivate fundamental and applied research on the intriguing magnetoelectric characteristics of these honeycomb lattice materials.

Gapless antiferromagnetic behavior in newly synthesized marcasite-phase $\text{CoAsSe}$

YIYAO CHEN (Presenter), GEORGE YUMNAM, ASHUTOSH DAHAL, Univ of Missouri - Columbia, JOSE RODRIGUEZ-RIVERA, GUANGYONG XU, National Institute of Standards and Technology, THOMAS HEITMANN, DEEPAK K SINGH, Univ of Missouri - Columbia — $\text{CoAsSe}$ belongs to the CoXY chalcogenide family and is reported to crystalize in different phases depending on the synthesizing temperature and pressure, including a half metallic phase according to DFT calculations. For the first time, we have synthesized marcasite-phase $\text{CoAsSe}$ in large amount to perform neutron scattering measurements. Elastic neutron scattering measurements revealed weak magnetic peaks below $T \sim 38$ K at momentum transfer positions of $(0, 0.5, 0)$ and $(1, 0, 0)$ in reciprocal lattice units. Detailed inelastic measurements in low temperature revealed a broad excitation spectrum in the energy transfer-momentum transfer map. We will present the magnetic structures of the newly synthesized marcasite phase $\text{CoAsSe}$ and discuss its relationship to electrical measurement results.

*The research at MU is supported by DOE, Office of Basic Energy Sciences under grant no. DE-SC0014461.
8:48AM A50.00005: Microscopic insights to ARPES spectra of doped quantum anti-ferromagnets  FABIAN GRUSDT (Presenter), Department of Physics and Arnold Sommerfeld Center for Theoretical Physics (ASC), Ludwig-Maximilians-Universität München, Theresienstr. 37, München D-80333, Germany, ANNABELLE BOHRDT, Department of Physics and Institute for Advanced Study, Technical University of Munich, 85748 Garching, Germany, FRANK POLLMANN, Department of Physics, T42, Technical University of Munich, D-85748 Garching, Germany, MICHAEL KNAP, Department of Physics and Institute for Advanced Study, Technical University of Munich, 85748 Garching, Germany — The phase diagram of cuprates, often modeled by the 2D Fermi Hubbard or $t-J$ model, remains poorly understood at low doping. Here we present new theoretical insights to the ARPES spectrum of quantum anti-ferromagnets at low doping: We argue that, at strong coupling $t \gg J$, the spectrum directly reflects the spectral function of a spinon which forms a universal bound state with the chargon created in the measurement. Our result is relevant to cuprates in the pseudogap regime: we interpret the observed Fermi-arcs in a fractionalized Fermi liquid (FL*) picture and argue that the strongly suppressed spectral weight on the back-side of the hole pocket is a signature for the Dirac-fermion nature of the underlying spinons. We present DMRG calculations of the one-hole spectrum, which support the existence of the universal spinon-chargon bound state we assume at strong couplings. Our results are also relevant for the search of Dirac spinons in a larger class of frustrated quantum magnets.

9:00AM A50.00006: Optical conductivity of CrAs across the paramagnetic to antiferromagnetic transition  ALEXANDRE ZIMMERS (Presenter), RICARDO LOBO, ESPCI, CNRS, Sorbonne University, Paris-France, AMIR-ABBAS HAGHIGHIRAD, MATTHIEU LE TACON, Institute for Solid State Physics, Karlsruhe Institute of Technology, Germany — We report the optical spectroscopy of monopnictide crystal CrAs. This system exhibits a PM to AF transition at $T_N \approx 265K$. This AF phase gradually disappears under pressure with the emergence of 2.2K superconductivity at 0.7GPa. To understand this rich phase diagram, various technics have investigated similarities of this material with the parent iron-pnictide superconductors. Here we studied the PM to AF transition by measuring the reflectivity from 300K to 5K at ambient pressure from 17meV to 3eV. As a function of incident photon energy, the reflectivity shows a gradual decay for all temperatures. The optical conductivity was extracted using Kramers–Kronig. Below 50meV, a Drude peak is clearly found only for temperatures below $T_N$. Extrapolation to zero frequencies of the conductivity is in agreement with previous reported DC transport measurements. In the mid-infrared range, the optical response of the AF order ($T=250K$) shows a rounded gap features with respect to the PM phase ($T=300K$): suppression in the low frequency optical conductivity, alongside a spectral weight transfer from low to high frequencies. The spectral weight transfer dip-hump structure will be compared to previous SDW gaps found in iron-based superconductors and electron doped cuprates.
9:12AM A50.00007: Gapless spin liquid state of the spin-1/2 honeycomb antiferromagnetic Gamma model*  XIAOQUN WANG (Presenter), School of Physics and Astronomy, Shanghai Jiao Tong University, QIANG LUO, Department of Physics, Renmin University of China, JIZE ZHAO, School of Physical Science and Technology & Key Laboratory for Magnetism and Magnetic Materials of the MoE, Lanzhou University — We propose a choreographed model by introducing a bond-modulated Heisenberg interaction J in addition to the Gamma term. With varying an angular parameter of vartheta=atan(Gamma/J)in[0,pi], the ground state is shown to change from a zigzag magnetic order to a stripy magnetic order through a mixed phase as well as a noncoplanar phase based on a parallel tempering Monte Carlo simulation. In the quantum case where we resort to large scale density matrix renormalization group calculations, two classical intermediate phases merge into one which is gapless and nonmagnetic, signaling a quantum spin liquid (QSL), in a wide range of 0.50\leq vartheta/pi\leq 0.66(1) for the thermodynamic limit. It turns out that the ground state of HCGammaA is affirmed to be the gapless QSL since it corresponds to vartheta=\pi/2 in the phase diagram. Our findings are further verified with scanning the variable parameter vartheta on a long cylinder.

*Natural Science Foundation of China (Grant No. 11874188, No. 11574200 and No. 11974244) and the Fundamental Research Funds for the Central Universities and Key Research Project (Grant No. 2016YFA0300501)

9:24AM A50.00008: Evidence for a Field-Induced Quantum Phase Transition in Ising-like D-Er$_2$Si$_2$O$_7$*  GAVIN HESTER (Presenter), TIM DELAZZER, DANIELLE YAHNE, COLIN SARKIS, KATE ROSS, Colorado State University — Exploring the magnetic properties of the rare-earth pyrosilicate (RE$_2$Si$_2$O$_7$) family of compounds is of interest due to their variety of crystal structures and anisotropic pseudo-spin ½ moments. D-Er$_2$Si$_2$O$_7$ (space group P2$_1$/b) was previously found to have a large g-tensor anisotropy (g$_{xx}$ = 2.6, g$_{yy}$ = 3.4, g$_{zz}$ = 13.4) and magnetization consistent with Ising exchange [1]. In this work we have performed specific heat, magnetometry, and inelastic neutron scattering (INS) on a polycrystalline sample to further characterize the magnetism of D-Er$_2$Si$_2$O$_7$. The zero-field specific heat and magnetometry data corroborate previous measurements indicating antiferromagnetic ordering at 1.9 K. The INS data shows a gapped excitation at 0.6 meV in zero field, consistent with Ising exchange. This gap closes with the application of a magnetic field of ~1 T, consistent with a quantum critical point. Magnetization measurements on single crystal samples suggest that the mode softening is due to the field acting on the direction perpendicular to the Ising moments. Our data suggests that D-Er$_2$Si$_2$O$_7$ could be a new experimental system in which to study the quantum Ising model.

Nonthermal interacting-magnon dynamics in an optically driven 2D Heisenberg antiferromagnet

MONA KALTHOFF (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, DANTE KENNES, Institut für Theorie der Statistischen Physik, RWTH Aachen University, ANDREW MILLIS, Center for Computational Quantum Physics, Flatiron Institute, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter — Recent theory results demonstrate a dynamical phase transition involving nonthermal magnon populations in the antiferromagnetic phase of the 2D Hubbard model upon laser driving [Walldorf et al., Phys. Rev. B 100, 121110(R) (2019)]. These results were obtained in a one loop non-interacting magnon theory. Here we present first steps towards a full interacting theory of this dynamical phase transition using a Dyson Maleev large Spin expansion and a Boltzmann formalism to investigate the effects of magnon-magnon interactions on the dynamical phase transition. The dynamical phase transition will be more completely characterized and implications for pump-probe experiments and ultrafast materials design of strongly correlated magnetism will be discussed.

*DFG Emmy Noether program SE 2558/2-1, US Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering Grant No. DE SC0012375, the Flatiron Institute is a Division of the Simons Foundation, the Max Planck-New York Center for Nonequilibrium Quantum Phenomena

Coherently driven phonons coupled to antiferromagnetic order

VALENTIN KASPER, SERGI JULIA (Presenter), RAVINDRA CHHAJLANY, MACIEJ A LEWENSTEIN, ICFO — The possibility to coherently drive single phonon modes in strongly correlated materials opens the possibility to analyze and manipulate quantum matter via the electron-phonon coupling. In this work we study the effect of a single coherent phonon mode coupled to antiferromagnetic order. In particular, we calculate the dynamic spin structure factor and discuss the possibility of an emergent quasiparticle due to the coupling between phonons and magnons. Further, we explore the possibility to observe self-similar behavior in the occupation number of magnons.
10:00AM A50.00011: Refinement of exchange parameters and magnetic form factor of Mn$_3$Ir from neutron spectroscopy measurements.* MARTIN D LEBLANC, Physics and Astronomy, Memorial University of Newfoundland, ADAM ACZEL, GARRETT E GRANROTH (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, BYRON W SOUTHERN, Physics and Astronomy, University of Manitoba, STEPHEN E NAGLER, Neutron Scattering Division, Oak Ridge National Laboratory, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, JOHN P. WHITEHEAD, MARTIN PLUMER, Physics and Astronomy, Memorial University of Newfoundland — Inelastic neutron scattering measurements of the fcc kagome antiferromagnet Mn$_3$Ir were performed using the SEQUOIA spectrometer at the Spallation Neutron Source (SNS) at Oak Ridge National Laboratory (ORNL). Comparison of the observed magnetic excitations to calculated spin waves, using exchange parameters derived from Density Functional Theory (DFT) calculations\(^1\), confirms that 4 exchange parameters are needed to describe the spectra. However the values from DFT underestimate the bandwidth of the excitations. Using these values as initial parameters, fits to the model modified the 2 largest exchange parameters to match the bandwidth. A spin orbit correction to the the magnetic form factor was also provided by the fit. These results are consistent with effective spin orbit coupling mentioned in\(^2\). Physically this means the magnetic moment is more extended than the free ion value.

*This work was supported by the Natural Sciences and Engineering Council of Canada, the Canada Foundation for Innovation, and Compute Canada. A portion of this research used resources at the SNS a DOE Office of Science User Facility, and the CADES cloud computing resource at ORNL.

10:12AM A50.00012: Orbital magnetization in magnetic neutron scattering HUA CHEN (Presenter), Colorado State University — Magnetic neutron scattering has been a powerful tool to reveal the microscopic magnetic structures of ordered and disordered magnetic systems. For magnetically ordered crystalline systems it has been a common practice to fit the elastic neutron cross-section to models of periodically arranged localized magnetic moments. However, it is unclear how the orbital magnetization which has an itinerant nature manifests in neutron scattering. The question is relevant to, e.g., metallic antiferromagnets and 4d/5d transition metal materials. We show that magnetic neutron scattering in general maps out the equilibrium electric current distribution inside the material but leaves the magnetization density unfixed because of a gauge freedom. We discuss the connection between the equilibrium current density and the modern theory of orbital magnetization, and provide examples on calculating the orbital contribution to elastic neutron cross-section using models and first-principles methods.
10:24AM A50.00013: Numerical evidence for a continuous phase transition between Neel and valence bond solid phases on a spin-ladder system  TAKUHIRO OGINO (Presenter), RYUI KANEKO, SATOSHI MORITA, NAOKI KAWASHIMA, Univ of Tokyo-Kashiwanoha — We investigate the possibility of deconfined quantum criticality in the J-Q-like model in one spatial dimension. As the simplest example, we study a spin-1/2 two-leg XXZ ladder with a four-spin interaction by using the Variational Uniform Matrix Product State (VUMPS), which can directly calculate physical quantities in the thermodynamic limit. We focus on the quantum phase transition between Neel and valence bond solid phases, which are characterized by breaking of SU(2) and space inversion symmetry, respectively. We find evidence for a continuous phase transition between the two phases, which is unconventional according to the Landau-Ginzburg-Wilson paradigm.

10:36AM A50.00014: Monte Carlo study of microscopic models for Néel-to-plaquette VBS transition on 2D square lattice*  JUN TAKAHASHI (Presenter), Institute of Physics, Chinese Academy of Sciences, ANDERS W SANDVIK, Boston Univ — The theory of deconfined quantum criticality (DQC) predicts an interesting connection between the Néel and the valence-bond solid (VBS) states, resulting in critical quantum phase transitions beyond the Ginzburg-Landau paradigm with emergent higher symmetry [1]. DQC with columnar VBS (CVBS) phase has been numerically confirmed in microscopic models [2]. Although there are interesting recent proposals on the possibility of the plaquette VBS (PVBS) phase behaving differently from CVBS due to the immobility of the spinons [3], there were no sign-problem free microscopic models that exhibits the Néel-PVBS transition that could be studied in detail. Here, we construct such a model, and probe the nature of the transition with quantum Monte Carlo simulations. Our results show that the transition is weakly first-order with enhanced SO(5) symmetry, similar to previous results of a system with different symmetry [4].

*A. W. S. was funded by the NSF under Grant No. DMR-1710170 and by the Simons Foundation.
10:48AM A50.00015: Terahertz 2D coherent spectroscopy of transverse field quantum Ising model with further neighbor interactions  YIHUA QIANG (Presenter), YURIY SIZYUK, Department of Physics and Astronomy, Iowa State University, THAIS VICTA TREVISAN, Ames Laboratory, PETER ORTH, Department of Physics and Astronomy, Iowa State University — Recent advances in optical experimental methods in the terahertz range made terahertz 2D coherent spectroscopy (2DCS) possible. It has been a successful tool to probe interactions in various systems ranging from biexcitons in semiconductors to magnons in magnetic insulators. Here, we report results for the nonlinear 2DCS susceptibilities in the transverse field quantum Ising model including further neighbor interactions. Using a Jordan-Wigner transformation the model can be mapped to interacting fermions, for which we compute the 2DCS spectrum in a field-theoretical Keldysh approach. Information contained in the 2DCS can be used to identify interactions among the fermions, corresponding to next-nearest neighbor spin exchange couplings in the magnetic system.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A51 DCMP: Electronic Properties of Graphene Based Twisted Heterostructures: Transport Studies

8:00AM A51.00001: Dynamic rotation of monolayer van der Walls heterostructures  JOSH SWANN (Presenter), SHAOWEN CHEN, NATHAN FINNEY, DERICK GONZALEZ-ACEVEDO, MATTHEW A YANKOWITZ, CORY DEAN, Columbia University — Emerging at a twist angle of around 1.1 degrees, the flat band dispersion of twisted bilayer graphene (tBLG) provides an exciting means of studying the physics of strongly correlated states. These strong correlations have recently been shown in a number of studies to give rise to superconducting and correlated insulating states as well as anomalous Hall effects. However, the physics of these states is highly sensitive to slight changes in the twist angle away from the so called ‘magic angle’. We report on a new technique for fabricating twisted bilayer graphene devices using an Atomic Force Microscope to control this angle with a high degree of precision. Techniques that enable monolayers to be rotated to arbitrary angles while also preventing the twist angle from relaxing to the Bernal stacking phase will be discussed.

8:12AM A51.00002: Shear phonon modes in twisted bilayer 2D crystals  SEOUNG-HUN KANG (Presenter), KISUNG CHAE, Korea Inst for Advanced Study, MIKITO KOSHINO, Department of Physics, Osaka University, YOUNG-WOO SON, Korea Inst for Advanced Study — Based on large scale first-principles computations and molecular dynamics simulations, we present variation of low energy in-plane phonon modes in twisted bilayer 2D crystals such as graphene and transition metal dichalcogenides. It is shown that the shear phonon modes soften as the twisted angle increases to 30 degrees while layer breathing modes does not. Discussions regarding on relation between the shear phonon softening, stability of quasicrystalline ordering and interlayer friction will be present.
Correlated insulating and superconducting states in twisted bilayer graphene below the magic angle

EMILIO CODECIDO (Presenter), Ohio State Univ - Columbus, QIYUE WANG, The University of Texas at Dallas, RYAN KOESTER, SHI CHE, HAIDONG TIAN, RUI LV, SON TRAN, Ohio State Univ - Columbus, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, FAN ZHANG, The University of Texas at Dallas, MARC BOCKRATH, CHUN NING LAU, Ohio State Univ - Columbus — The emergence of flat bands and correlated behaviors in “magic angle” twisted bilayer graphene (tBLG) has sparked tremendous interest, though its many aspects are under intense debate. Here we report observation of both superconductivity and the Mott-like insulating state in a tBLG device with a twist angle of ~0.93°, which is smaller than the magic angle by 15%. At an electron concentration of ±5 electrons/moiré unit cell, we observe a narrow resistance peak with an activation energy gap ~0.1 meV. This indicates additional correlated insulating state, and is consistent with theory predicting a high-energy flat band. At doping of ±12 electrons/moiré unit cell we observe resistance peaks arising from the Dirac points in the spectrum. Our results reveal that the “magic” range of tBLG is in fact larger than what is previously expected, and provide a wealth of new information to help decipher the strongly correlated phenomena observed in tBLG.

Interaction effects in ultra-clean ABC trilayer/hexagonal boron nitride moire heterostructures

TIAN XIE (Presenter), HAOXIN ZHOU, University of California, Santa Barbara, JAMES R. EHRETS II, Department of Physics, Harvard University, ERIC SPANTON, California NanoSystems Institute, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, ANDREA YOUNG, University of California, Santa Barbara — ABC-stacked trilayer graphene aligned to hexagonal boron nitride hosts narrow, isolated low energy bands which have been shown to ferromagnetism and superconductivity. In addition, these bands can be tuned with an out-of-plane electric field. The main challenge of fabricating this type of samples is the metastability of the ABC-stacking order, which tends to relax to the lower-energy ABA-stacking during the fabrication process. Here we will describe techniques to identify and isolate ABC domains in trilayer graphene and incorporate them into dual-graphite gated heterostructures while preserving the stacking order. Preliminary transport data reveals electric field tunable transitions between resistive states at partial band filling.
8:48AM A51.00005: Characterization of correlated insulating states and superconductivity in twisted bilayer graphene: Part 1*  Harpreet Arora (Presenter), Robert Polski, Watson Laboratory of Applied Physics, California Institute of Technology, Yiran Zhang, Youngjoon Choi, Department of Physics, California Institute of Technology, Hechen Ren, Watson Laboratory of Applied Physics, California Institute of Technology, Kenji Watanabe, Takashi Taniguchi, National Institute for Materials Science, Stevan Nadj-Perge, Watson Laboratory of Applied Physics, California Institute of Technology — Magic Angle Twisted Bilayer Graphene (MATBG) has emerged as an exciting platform to explore correlated insulating states and unconventional superconductivity due to its gate tunable nature. Even though several theoretical models have been proposed, the nature of the many body physics leading to these exotic states is not fully understood. Here we study correlated insulating and superconducting states for a range of angles around the magic angle value. Transport measurements as a function of carrier density, temperature and magnetic field reveal new insights in this correlated system.

*This work has been supported by the GIST-Caltech memorandum of understanding and partly by NSF CAREER program (DMR-1753306). S. N-P also acknowledges support from the IQIM (NSF funded physics frontiers center).

9:00AM A51.00006: Characterization of correlated insulating states and superconductivity in twisted bilayer graphene: Part 2*  Robert Polski (Presenter), Harpreet Arora, Watson Laboratory of Applied Physics, Caltech, Yiran Zhang, Youngjoon Choi, Physics, Caltech, Hechen Ren, Watson Laboratory of Applied Physics, Caltech, Kenji Watanabe, Takashi Taniguchi, National Institute for Materials Science, Stevan Nadj-Perge, Watson Laboratory of Applied Physics, Caltech — Near magic-angle (~1.1°) twisted bilayer graphene (TBG) has emerged as a promising system for studying electron correlations due to the wide tunability of its band structure—using twist angle—and electron/hole density through gating. However, many details on the nature of correlations and their evolution with twist angle have yet to be resolved. We report sub-Kelvin magnetotransport measurements on TBG for several angles near the magic angle, including measurements of correlated insulators and superconductivity on both hole and electron sides.

*This work has been partly supported by the NSF CAREER program (DMR-1753306) and Gist-Caltech memorandum of understanding. S. N-P also acknowledges support from the IQIM (NSF funded physics frontiers center). R. P and S. N-P also acknowledge the support of the DARPA Topological Excitations in Electronics (TEE) program.
9:12AM A51.00007: Engineering Low-Disorder Superlattice Potentials in Graphene-Based Van der Waals Heterostructures  LIAM COHEN (Presenter), ERIC SPANTON, ANDREA YOUNG, University of California, Santa Barbara, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science — Long wavelength periodic potentials have led to the observation of a variety of electronic phenomena in graphene, including the Hofstadter butterfly, fractional Chern insulators, and flat band physics at zero magnetic field. Typically, such potentials arise due to Moiré patterns generated through lattice or rotationally mismatched layers. While Moiré patterns produce high quality, low-pitch potentials, they do not allow tuning of lattice strength, symmetry, or pitch. Here we present the fabrication of sub 40nm pitch, ultra-clean, lithographically defined metal superlattices. Using bulk capacitance measurements, we show that integrating the superlattices into a multilayer heterostructures allows controllable screening of the disorder potential while preserving a finite strength superlattice potential. I will present our progress towards engineering correlated states in artificial superlattices.

9:24AM A51.00008: Transport study of transition metal dichalcogenide morié superlattices  TINGXIN LI (Presenter), LIZHONG LI, YANHAO TANG, JIACHENG ZHU, Cornell University, SONG LIU, KATAYUN BARMAK, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JIE SHAN, KIN FAI MAK, Cornell University — Morié superlattices formed in van der Waals materials have emerged as a new platform to explore strongly correlated physics and other emergent phenomena in two-dimensional electronic systems. Superconductivity, correlated insulating states, and ferromagnetism have recently been discovered in the twisted bilayer graphene and ABC trilayer graphene/boron nitride systems. In contrast to the graphene systems, in which spin, valley, and layer degeneracies are all present, the spin and layer degeneracies are lifted in semiconducting transition metal dichalcogenide (TMD) heterobilayers by strong spin-orbital interactions and layer asymmetry. The large band mass and band gap of the TMDs also allow the flat bands to be present for a large range of twist angle. In this talk, we will present a transport study of angle aligned WSe$_2$/WS$_2$ bilayers and discuss properties of the observed correlated insulating states at half filling (i.e. one particle per morié site).

9:36AM A51.00009: High sensitivity thermodynamic measurements of fractional quantum Hall states in graphene  FANGYUAN YANG (Presenter), ALEXANDER A ZIBROV, RUIHENG BAI, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, ANDREA YOUNG, University of California, Santa Barbara — Thermodynamic quantities such as chemical potential and entropy provide information about many-body ground states that cannot be directly revealed by conventional transport measurements. In this talk, I will present a technique for high sensitivity measurement of the chemical potential in ultra-clean graphene heterostructures, based on a multilayer heterostructure with an embedded graphene layer that functions as an electrometer. An integrated on-chip heater further allows rapid modulation of the temperature, from which we extract the entropy per particle, $\Delta S/\Delta N = -\Delta \mu/\Delta T$. We apply this technique to a high mobility monolayer graphene 2D electron gas at high magnetic fields, measuring the chemical potential and entropy of fractional quantum Hall states in $N = 0$ and $N = 1$ Landau levels (LLs) and electron solid states in the $N = 2$ and N=3 Landau levels. We compare our experimental sensitivity with that required to detect the ground state entropy associated with non-Abelian anyons, as are thought to appear at several filling factors in bilayer graphene.
**9:48AM A51.00010: Van der Waals Force Driven Ultrahigh-Density Piezoelectric Nano-Generators Arrays**  
YUHANG JIANG (Presenter), JINHAI MAO, University of Chinese Academy of Sciences, COLIN ROBERT WOODS, School of Physics & Astronomy, University of Manchester, SLAVISA MILOVANOVIC, FRANCOIS M PEETERS, Departement Fysica, University of Antwerp, KONSTANTIN S NOVOSELOV, School of Physics & Astronomy, University of Manchester, EVA ANDREI, Department of Physics and Astronomy, Rutgers University — The elegance of Van der Waals heterostructure emerges as the possibilities to design its function on-demand when choosing different functional materials. When two layers materials are taken to form moire lattice, the Van der Waals force between the two layers could stimulate even more fascinating features forming spontaneously. Here we show, when graphene and single layer BN (SLBN) are minimally twisted superposed, the interlayer interactions propel the two lattices rearrangement and induces a spatial modulated strain configuration. The moire pattern reconciled strain superlattice in single layer BN, companied by its inversion symmetry broken, induces an oscillating charge polarization as revealed by the scanning tunneling microscope. This moire pattern driven charge polarization in SLBN allows us to get a highly ordered nano-generators array with a giant density.

*DOE-FG02-99ER45742 , NSF-DMR 1708158

**10:00AM A51.00011: Tunable extra Dirac points in one-dimensional graphene superlattice induced by periodic ferroelectric domains**  
TIANLIN LI (Presenter), HANYING CHEN, KUN WANG, YIFEI HAO, LE ZHANG, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — In this work, we investigate the transport signature of one-dimensional superlattice (SL) in monolayer graphene induced by pre-patterned periodic domains in an interfacial ferroelectric bottom layer. We work with 50 nm single crystalline ferroelectric Pb(Zr,Ti)O$_3$ (PZT) films deposited on (La,Sr)MnO$_3$ buffered SrTiO$_3$ substrates, and create periodic polarization up (P$_{up}$) and down (P$_{down}$) stripe domains on PZT using conductive atomic force microscopy. The domain periodicity varies from 200 nm to 300 nm, and the number of periods changes from 60 to 100. We then transfer hBN-graphene stacks onto the pre-patterned domains and fabricate them into top-gated field-effect devices. The difference in carrier density between the two polarization regions reaches around 3$\times$10$^{13}$ cm$^{-2}$ at 2 K due to the pyroelectric effect. We observe extra Dirac points in R(V$_g$) by applying voltage to the hBN top gate, which is attributed to the SL modification of the band structure. We discuss the effects of the SL period and the width ratio between the P$_{up}$ and P$_{down}$ domains on the position of the extra Dirac points, and the magnetotransport properties of these SLs.

*This work was primarily supported by the U.S. Department of Energy, BES, under Award No. DE-SC0016153.
Contact electrodes with high workfunctions can enable significant enhancement in optoelectronic device performance due to their important role in efficient extracting/injecting carriers especially from optically active materials. With such materials becoming increasingly important in emerging solar cell technologies, the need for high workfunction electrodes has become of timely importance. In this work, p-doped graphene is investigated using first principles calculations, as a potential high workfunction contact electrode material for device applications. We found that chemical doping based on the adsorption of different non-metallic adatoms on graphene allows tuning the workfunction which can reach as high as 5.76 eV due to charge transfer from the graphene to the p-dopants. Therefore, our results are necessary to bring out the capabilities graphene-based electrodes.

*Thanks, Qatar National Research Foundation for the support Grant No.NPRP X-107-1-027.
Heat transfer in nanostructures is of fundamental and practical interest. Sufficient cooling is critical for the operation of superconducting nanowire single-photon detectors (SNSPDs), which can support large current densities (~5 MA/cm²) just prior to being switched into a high resistivity (~250 μΩ·cm) normal state by an incident photon, leading to substantial local heating. The thermal boundary conductance (TBC) between the nanowire and the substrate determines the cooling rate, and hence the reset time, and potentially impacts the quantum efficiency of SNSPDs. Despite the TBC’s importance, open questions remain about its correct description in few-nm thick films, and little experimental data exists on patterned nanowire devices.

Here, we show that simple DC electrical measurements can be used to estimate the TBC between the nanowire and the substrate. Our results suggest that the heat transfer from these devices is well-described by phonon black-body radiation into the substrate, with a phonon-emissivity that depends on the acoustic properties of the wire and substrate. Calculations using the acoustic mismatch model assuming two semi-infinite elastic media match the phonon-emissivity extracted from measurements. One-dimensional numerical simulations validate our approach.
**10:36AM A51.00014: Conductance quantization in cleaved edge overgrowth GaAs quantum wires**

HENOK WELDEYESUS (Presenter), TARAS PATLATIUK, CHRISTIAN SCHELLER, Department of Physics, University of Basel, CH-4056, Basel, Switzerland, GILAD BARAK, AMIR YACOBY, Department of Physics, Harvard University, Cambridge, MA, 02138, USA, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, Princeton, NJ, 08544, USA, DOMINIK ZUMBUHL, Department of Physics, University of Basel, CH-4056, Basel, Switzerland —

Cleaved Edge Overgrowth (CEO) quantum wires (QW) are among the cleanest 1D systems available, showing conductance quantization and Luttinger liquid effects such as charge fractionalization and spin-charge separation. Previously, we have studied the conductance quantization of CEO QWs as a function of temperature in Scheller et al. PRL112, 066801 (2014), finding that the first wire plateau goes from \(2 \frac{e^2}{h}\) at high \(T > 10K\) to \(1 \frac{e^2}{h}\) at low \(T < 0.1K\). This was interpreted as evidence for a nuclear spin helix, as proposed theoretically by Braunecker, Simon and Loss PRB80, 165119 (2009).

Here, we look at the dependence on wire length, and observe a steeper slope over increasing temperatures in short 2 μm wires compared to 6 μm wires. This is consistent with theory from Aseev et al. PRBB95, 125440 (2017) and may allow an estimate of the Luttinger charge interaction parameter.

Further, we report on the velocities of quantum Hall edge states measured on the same CEO sample using momentum resolved tunneling spectroscopy. Using a multi terminal measurement of the voltage drop, the velocities agree very well with theory. In the future, fractional and topological edge states could be studied with this technique.

*Supported by Swiss NSF, Swiss Nano Institute, and European Microkelvin Platform*

**10:48AM A51.00015: Emergence of dynamical energy gap in an oscillating graphene membrane**

NANCY SANDLER (Presenter), Ohio University, DAWEI ZHAI, The University of Hong Kong —

One intriguing aspect of graphene is the effect of strain on its electronic properties, which manifests as a pseudo-magnetic field producing peculiar local charge distributions and Landau level-like flat bands. It is challenging however, to generate global energy gaps for semiconductor applications- the strain needed is either too large or requires precise engineering. Irradiation with polarized light has been proposed as a mechanism for gap generation, but the high frequency and intensity needed may induce sample damage. Oscillating mechanical deformations appear like an alternative that is particularly well suited for suspended samples. Besides, spatial strain variation allows more flexibility in gap engineering. We study the effect of a Gaussian-shaped deformation in graphene with a time-periodic amplitude. Using an effective Floquet Hamiltonian, we predict the appearance of anisotropic dynamical gaps with Green's function methods and degenerate perturbation theory. The profile of the gap closely follows the modulations in the local density of states caused by strain. We find that the optimal regime for gap generation occurs when a deformation extends over the whole sample, with a magnitude determined by its geometrical parameters.

Session A52 DCMP: Surface Adsorption, Dynamics, and Defects Mile High Ballroom 1E - Daniel Dougherty, North Carolina State University

8:00AM A52.00001: Quantitative measurements of total yields from electron stimulated desorption of ice  BRIAN FERRARI (Presenter), KATERINA SLAVICINSKA, CHRIS BENNETT, Univ of Central Florida — Sputtering yields from electron stimulated desorption (ESD) are typically neglected by planetary science models, although mid-energy (200-1000eV) electrons can produce significant sputtering yields. Here, we investigated the total and relative yields from ESD on comet ice analogs in an Ultra-High Vacuum (UHV) chamber with base pressure of 3x10^{-11} torr. Gas was introduced to the chamber, then condensed on a sample holder, which was then irradiated with an electron source at various energies. A quartz-crystal microbalance (QCM) was used for precise mass desorption measurements, while a quadrupole mass spectrometer (QMS) was used to measure the positive, negative and neutral species that desorbed off the ice. These processes are relevant for various planetary science environments which are subjected to high intensity of electron bombardment, such as the rings of Saturn, Icy Moons, and interstellar ices. The results of our experiments will provide more accurate yields for modeling sputtering from airless bodies.

8:12AM A52.00002: Investigation of atomic layer deposited amorphous alumina films for the prevention of water-based corrosion of glass  MIRIAM ELISABETH HIEBERT, ETHAN HYDE, MSE, University of Maryland, College Park, EDWARD P VICENZI, Museum Conservation Institute, Smithsonian Institution, JAMIE WEAVER, NCNR, NIST, RAYMOND PHANEUF (Presenter), MSE, University of Maryland, College Park — Water is corrosive to a wide range of materials, including silicate glasses, for which contact results in an exchange of modifier ions for protons, swelling of the altered glass, and eventually crack network evolution leading to mechanical failure; this process is referred to commonly as “glass disease”. Atomic layer deposition (ALD) of metal oxide thin films provides a seemingly near-ideal approach toward the protection of silicate glass from water-based corrosion, combining optical, transparency, and potentially high resistance to permeation by water. In this talk I’ll discuss the results of accelerated aging experiments in which ALD alumina-coated silicate glass is immersed in water at elevated temperatures and the rate of ion leaching into the water is monitored as a function of time. We find the application of such films to be capable of slowing water-mediated corrosion by at least an order of magnitude. Finally, I’ll discuss the role of film defects that limit the effectiveness of ALD alumina in preventer water-based corrosion.

*Work supported by a Big Ten Academic Alliance Smithsonian Fellowship and a UM/SI Seed Grant
8:24AM A52.00003: Tuning single-atom electron spin resonance in a vector-magnetic field*
PHILIP WILLKE, APARAJITA SINGA, XUE ZHANG, TANER ESAT, Center for Quantum Nanoscience, Institute for Basic Science, CHRISTOPHER LUTZ, IBM Almaden Research Center, ANDREAS J HEINRICH, TAEYOUNG CHOI (Presenter), Center for Quantum Nanoscience, Institute for Basic Science — Scanning tunneling microscopy (STM) has been one of highly versatile surface science tools to investigate electronic and magnetic properties of individual atoms and molecules on surfaces. Recently, successful combination of electron spin resonance (ESR) technique and STM has demonstrated electron spin of individual atoms on ultrathin insulating MgO films can be coherently driven. Utilizing a 2D vector magnetic field and the local stray field from the magnetic STM tip, we optimize the ESR signal and characterize the role of the tip field. We demonstrate single atom ESR using the tip-field only, under zero external magnetic field, which promises to make this technique available in many existing STM systems.

*We acknowledge support from the Institute for Basic Science under grant IBS-R027-D1 and Ewha Womans University.

8:36AM A52.00004: Reactive MD simulation on the formation of amorphous sub-nano alumina layer* YUXUAN LU (Presenter), DEVON ROMINE, Missouri State Univ, JAGARAN ACHARYA, JUDY WU, University of Kansas, RIDWAN SAKIDJA, Missouri State Univ — In this study, we systematically performed the large-scale classical reactive molecular dynamics (MD) simulations of Atomic Layer Deposition (ALD) processes to model the formation of amorphous alumina sub-nanolayer water. The ALD process used water and (Trimethyl-Aluminum) TMA precursors deposited onto the surface of an aluminum wetting layer. We varied the sizes of the substrate and the concentrations of water/hydroxide precursors with a range of temperature to design the most favorable configurations for the subsequent TMA precursors to add onto. The role of crystallographic orientation of the Al wetting layer was also investigated and compared with the experimental findings.

*The support from NSF (Grant No. 1809284) “Collaborative Research: Development of Atomically Thin Tunnel Barriers for High-Performance Tunnel Junctions” from the Electronics, Photonics and Magnetic Devices (EPMD) Program is gratefully acknowledged.
8:48AM A52.00005: Quantum-well states and electronic coherence in bimetallic Pb/Ag thin films  
CHI-RUEI PAN, Georgia Institute of Technology, WOOJOO LEE, CHIH-KANG SHIH, University of Texas at Austin, MEI-YIN CHOU (Presenter), Academia Sinica — It has been well established that the presence of quantum-well states in metal thin films plays an essential role in determining the thickness dependence of many physical properties. Here we present first-principles calculations and measurements by angle-resolved photoemission spectroscopy for electronic states in a bimetallic film composed of 10 layers of Pb and 9 layers of Ag in the (111) direction on a Si substrate. It is found that the original quantum-well states in individual Pb and Ag films evolve into new states in the bimetallic film by extending into the additional space, instead of directly coupling with each other as one would have expected. The new set of quantum-well states therefore have modified effective masses and energy values compared with the parent ones. Even though the Pb/Ag interface is incommensurate, the coherence of the electronic states across the whole bimetallic film is verified by supercell configurations with different rotational arrangements in the calculation. The excellent agreement between theory and experiment in the energy dispersion of the quantum-well states confirms the physical picture proposed in this work, which could form the basis in exploring the electronic structure in multiple stacked thin films.

9:00AM A52.00006: Investigation of oxidation mechanisms of Pt nanoparticles in water – a molecular dynamics study  
KARIM GADELRAH (Presenter), NATHAN CRAIG, Research and Technology Center, Robert Bosch LLC — Platinum oxide (PtO) formation has a direct link to nanoparticle passivation as well as Pt dissolution in proton exchange membrane fuel cells (PEMFCs). During potential sweep, place exchange mechanism between Pt and O atoms is first triggered followed by irreversible Pt surface roughening at high potential. In this work, we employ molecular dynamics (MD) to capture atomic level processes of Pt extraction by O atoms from Pt(111) surface. As a benchmarking system, we correlate oxygen coverage with the onset of different Pt surface evolution mechanisms in the presence of water. Local O coordination of Pt atoms, concurrent Pt extraction, and generation of surface vacancies are major factors shaping the final surface structure. In addition, the MD simulation is employed to investigate the oxidation process of Pt nanoparticles. Our results show that in addition to PtO formation on faceted surfaces, Pt atoms desorption into water is a strong function of oxygen coverage. This is particularly true for under-coordinated atoms at edges and corners. The atomistic details described by the MD setup provides valuable insights into Pt-O interaction and stability of Pt nanoparticles in a complex environment.
9:12AM A52.00007: Atomic Defects of the Hydrogen-Terminated Silicon Surface Imaged with nc-AFM  JEREMIAH CROSHAW (Presenter), THOMAS DIENEL, TALEANA R HUFF, ROBERT A WOLKOW, Univ of Alberta — The hydrogen-terminated silicon (H:Si) surface has been shown to be a viable candidate for the development of atom-scale devices\textsuperscript{1,2}; however, the creation of such devices is currently limited by the need for constant user-guided interaction during the fabrication process. Attempts to automate fabrication using deep learning successfully demonstrated the training of a neural network which was able to identify common defects\textsuperscript{3}. Building upon these recent works we present our efforts at creating a comprehensive catalog containing many of the commonly found defects of the H:Si-100(2x1) surface. By imaging the defects using different imaging parameters in STM and two different tip contrasts in non-contact AFM\textsuperscript{4}, we determine the structures of the defects, their likely origins and potential removal, and a path to improved accuracy for their automated detection. A deeper understanding will enable the creation of better defect-free samples for atomic fabrication.

9:24AM A52.00008: A first-principles study of the physical properties and secondary electron emission of 4d and 5d FCC metal surfaces with and without a vacancy defect* LEOPOLDO DIAZ III (Presenter), MAHDI SANATI, Department of Physics and Astronomy, Texas Tech University, RAVINDRA P JOSHI, Department of Electrical and Computer Engineering, Texas Tech University — In this study we have introduced a vacancy defect to the 100, 110, 111 surfaces of the 4d and 5d FCC metals to understand the impact the defect will have on their physical properties and secondary electron emission. We have used density functional theory (DFT) to calculate the formation energy (FE), the work function (WF), and the dielectric constant for each metal surface. To ensure accuracy, the calculations were performed using both the local density approximation (LDA) and the generalized gradient approximation (GGA) exchange correlation functionals. For all the FCC metals we have identified the following trend for the vacancy FE and the WF: $\varphi_{111} > \varphi_{100} > \varphi_{110}$ for surfaces with and without a vacancy. We have also calculated the Q-factor for each of the metals allowing for predictions to be made about the secondary electron yield expected by each metal, including which metal would be best for vacuum or near-vacuum devices.

Probing non-equilibrium dynamics of photoexcited polarons on a metal oxide surface with atomic precision

CHAOYU GUO, Xiangzhi Meng, Physics, Peking University, Huixia Fu, Physics, Chinese Academy of Sciences, Qin Wang (Presenter), Physics, Peking University, Sheng Meng, Physics, Chinese Academy of Sciences, Ying Jiang, Physics, Peking University — Understanding the non-equilibrium dynamics of photoexcited polarons at atomic scale is of great importance for improving the performance of photocatalytic and solar-energy materials, but remains a grand challenge in experiment so far. Using a pulsed-laser-combined scanning tunneling microscopy and spectroscopy, we succeeded to resolve the photoexcitation and recovery dynamics of single polarons bound to oxygen vacancies on a prototypical photocatalyst, rutile TiO$_2$(110). The visible-light excitation of the defect-derived polarons leads to depletion of the polaron states and delocalized free electrons in conduction band. We found that the formation time of polarons becomes considerably shorter when the polaron is bound to two surface oxygen vacancies than that to one. In contrast, the lifetime of photogenerated free electrons is insensitive to the atomic-scale distribution of the defects but correlated with the averaged defect density within a nanometer-sized area. The results shed new lights on the photocatalytically active sites at the metal oxides surface.

TDDFT approach on laser field enhancement by carbon nanotube and photo-decomposition of water

Hong Zhang (Presenter), Physics, Sichuan University, China — In this presentation, we discuss field enhancement of femtosecond laser by carbon nanotubes and application to accelerating water photo-decomposition. The real-time time-dependent density functional theory (TDDFT) was employed for simulating water photo-decomposition near (8,0) semiconducting carbon nanotube. A short pulse with full-width of half-maximum 10fs was considered. When optical field is perpendicular to the tube axis, we found significant laser field enhancement corresponding to laser-power enhancement by factor 2 with laser wavelength 800 nm, and by factor around 8 with wavelength 400 nm. The enhancement is due to polarizability and wall-curvature of carbon nanotube that helps to reduce threshold power for photo-decomposition of water.

The dissociative adsorption of O₂ on the bimetallic Pd₃M₂ clusters (M=Ag, Au, Co, Cu, Mn, Ni, Pt, and Ru) by density functional theory

NUSAIBA ZAMAN (Presenter), ABDELKADER KARA, Univ of Central Florida — We use density functional theory to systematically investigate the adsorption and reactivity of oxygen on the bimetallic Pd₃M₂ clusters (M = Ag, Au, Co, Cu, Mn, Ni, Pt, and Ru). This is because small bimetallic clusters with high surface area to volume ratio often offer higher stability, greater selectivity and sometimes superior activity than the pure metal counterparts. We explore different adsorption sites for molecular oxygen, which can be oriented in a vertical or horizontal direction with respect to the cluster, as well as atomic oxygen on these bimetallic Pd₃M₂ clusters. The reaction path for dissociation of oxygen molecule on these bimetallic clusters is studied using the nudge elastic band method. We will present our result for the calculated energy barriers for O₂ dissociation on these bimetallic clusters and how it changes depending on the composition of the bimetallic clusters. Moreover, we will present the effect of O₂ adsorption on the electronic properties of these Pd₃M₂ clusters. Bader charge analysis is performed to probe how the charges are transferred between the molecule and the clusters.

Partial support is provided from the U.S. Department of Energy Basic Energy Science under Award number DE-SC0007045. We used computational resources of NERSC and UCF-Stokes.

Impact of solvation on the structure and reactivity of the Co₃O₄(001)/H₂O interface: a molecular dynamics study.

STEPHANE KENMOE (Presenter), TIM KOX, ECKHARD SPHR, Univ Duisburg — The spinel Co₃O₄ has many beneficial properties of potential use in catalysis. In operando, water is always present and alters the properties of the catalysts. To improve these properties and allow a rational design of catalysts, a fundamental understanding of the active crystal facets and their reactivity upon water adsorption is essential. We use ab initio molecular dynamics to understand the effect of water, aqueous solutions and solvation on the structure and reactivity of the Co₃O₄(001) surface.

Confined Catalysis under 2D silica: A CO Oxidation Study

CALLEY EADS (Presenter), J. ANIBAL BOSCOBOINIK, ASHLEY HEAD, DARIO STACCHIOLA, SAMUEL TENNEY, Brookhaven National Laboratory — Open metal surfaces play an active role in heterogeneous catalysis reactions such as the prolific CO oxidation reaction to produce CO₂. The addition of a nanostructured film on the metal surface changes the reaction kinetics and dynamics due to confinement effects under the cover. We illustrate the role of porous 2D silica grown on Pd(111) in the model reaction of CO oxidation at the interface of palladium and silica using in situ infrared reflection-absorption spectroscopy (IRRAS), mass spectroscopy (MS) and ambient pressure X-ray photoelectron spectroscopy (APXPS). Our findings suggest that 2D silica more effectively converts CO and O₂ to CO₂ under industrially-relevant conditions than the bare Pd(111) alone. 2D confinement effects enhance CO₂ production even with less CO bound species involved in the reaction.
**A52.00014: Probing two-dimensional ices with scanning probe microscopy**

YE TIAN (Presenter), RUNZE MA, DUANYUN CAO, International Center for Quantum Materials, School of Physics, Peking University, CHONGQIN ZHU, Department of Chemistry and Department of Chemical & Biomolecular Engineering and Department of Mechanical & Materials Engineering, University of Nebraska-Lincoln, Lincoln, N, JINBO PENG, JING GUO, International Center for Quantum Materials, School of Physics, Peking University, JI CHEN, XIN-ZHENG LI, School of Physics, Peking University, Beijing 100871, P. R. China, JOSEPH S FRANCISCO, Department of Earth and Environmental Sciences, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA, XIAO CHENG ZENG, Department of Chemistry and Department of Chemical & Biomolecular Engineering and Department of Mechanical & Materials Engineering, University of Nebraska-Lincoln, Lincoln, N, LIMEI XU, International Center for Quantum Materials, School of Physics, Peking University, ENGE WANG, University of Chinese Academy of Sciences, Beijing 100190, P. R. China, CAS Center for Excellence in Topological Quantum Computation, YING JIANG, International Center for Quantum Materials, School of Physics, Peking University — Two-dimensional (2D) water/ices are responsible for a broad spectrum of phenomena in materials science, chemistry, and biology. Particularly, the edges of 2D ice play key roles in the ice growth, melting and catalytic reaction, but atomic-scale structural characterization still remains a big challenge due to the fragileness and high reactivity of the ice edges. Here we report atomic-scale imaging of the edge structures of a 2D bilayer ice grown on Au(111) surface with weakly perturbative non-contact atomic force microscopy (1, 2). We found a new type of edge, aligning along the armchair direction but reconstructed with 5756-member rings, coexisting with the zigzag edge commonly observed in two-dimensional hexagonal crystals. We were further able to deduce different growth behaviors for the zigzag and armchair edges from the frozen metastable structures at the two edges. In addition, we explore the impact of alkali metal ions on the structure of 2D ice. By changing the concentration of alkali metal ions, various new ice phases can be obtained. Those results reveal new understanding of the stability and growth of 2D ices.

8:00AM A53.00001: Electron-hole liquid in a van der Waals heterostructure photocell at room temperature [Invited] NATHANIEL GABOR (Presenter), TREVOR ARP, DENNIS PLESKOT, VIVEK AJI, University of California, Riverside — Condensation - the familiar process underlying the formation of clouds and the distillation of ethyl alcohol into whiskey - is the phase transition of gas into liquid droplets. In semiconductors, at sufficiently high electron-hole (e-h) densities or low temperatures, the gas of non-equilibrium electrons and holes may undergo condensation into one of several potential liquid-like phases. In this talk, I present recent results on the gas-to-liquid phase transition of electrons and holes in ultrathin van der Waals heterostructure photocells revealed through multi-parameter dynamic photoresponse microscopy (MPDPM). By combining rich visualization with comprehensive analysis of very large data sets acquired through MPDPM, we find that ultrafast laser excitation at a graphene-molybdenum ditelluride-graphene interface leads to the abrupt formation of ring-like spatial patterns in the photocurrent response as a function of increasing optical power. These patterns, together with extreme sublinear power dependence and picosecond-scale photocurrent dynamics, provide strong evidence for the formation of a two-dimensional e-h liquid. While our imaging experiments mark the first observation (in over 50 years of study) of an e-h liquid at room temperature, I will discuss our results within the greater context of strongly correlated electronic condensates.

8:36AM A53.00002: Intrinsic disorder effects on device performance of few-layer MoS₂ field-effect transistors* HAO-WEI TU, CHE-CHI SHIH, CHIN-LUNG LIN, JIAN-JHONG LAI, WEN-BIN JIAN (Presenter), CHENMING HU, Natl Chiao Tung Univ — Field-effect transistors (FETs) made by two dimensional (2D) materials attract attention because of high on-off ratios and negligible short-channel effects. The 2D material of MoS₂ has been studied for years while problems from contact, interface, and structural disorders have not been solved. There are a lot of reports to give a wide range of electron mobility and the best performance of a single-layer MoS2 FET is still in debate. We present a large variation of disorders in MoS₂ flakes exfoliated from the same bulk. The disorder dominate the low performance of FETs. In particular, for high performance devices, the mobility increases with decreasing temperature and the device reveals metallic behaviors. Setting the FET in an on state, the conductivity of high-performance devices is close to e²/h, giving a standard to check the quality. There are some disorders resulting in a large decrease in conductance as well as in the FET mobility. On the other hand, the subthreshold swings are independent from the mobility. The disorder effects dominate to low performance thus growth of perfect 2D crystals is essential for the application of 2D FETs.

8:48AM A53.00003: Control of valley-polarized exciton currents in 2D heterostructures*

ALBERTO CIARROCCHI (Presenter), DMITRII UNUCHEK, AHMET AVSAR, ZHE SUN, Ecole Polytechnique Federale de Lausanne, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ANDRAS KIS, Ecole Polytechnique Federale de Lausanne — Valleytronics is an alternative to charge-based electronics aiming at encoding data in the valley degree of freedom, which could enable new paradigms for computing devices. Transition metal dichalcogenides (TMDCs) are an ideal platform for this due to the combination of unique spin-valley physics and direct bandgap, allowing optical initialization and readout of the valley state. Recent developments in the control of interlayer excitons in heterostructures of these materials offer an effective way to realize valley-optoelectronic devices [1]. Here, we show the generation and transport over mesoscopic distances of valley-polarized excitons in a device based on a type-II TMDC heterostructure. Engineering of the interlayer coupling results in enhanced diffusion of valley-polarized excitons, which can be controlled and switched electrically [2]. Furthermore, using electrostatic traps we can increase the exciton concentration by an order of magnitude, reaching densities higher than $10^{12} \text{ cm}^{-2}$, a promising approach to obtain coherent quantum states of excitons.

9:00AM A53.00004: Frequency Stability of MoS$_2$ drum resonators at Room Temperature*

NISHTA ARORA (Presenter), AKSHAY NAIK, Indian Institute of Science — Nanomechanical resonators hold great promise for ultrasensitive mass and force sensing. The discovery of two-dimensional (2D) materials having ultralow mass and exceptional mechanical properties have made them an ideal choice for NEMS. 2D resonators tend to be a great platform for sensing applications since the minimum detectable mass is proportional to mass of the resonator itself. The limit of detection is also, directly dependent on the measurement uncertainty of resonant frequency ($\delta f/f$). Thus, frequency stability is an important performance metric for such resonators. We report frequency stability at room temperature on MoS$_2$ drum resonators. The Allan deviation (AD) was observed to be of the order of $10^{-5}$ at 150ms integration time for 24V VgDC and AC drive of 70mV. This corresponds to a mass sensitivity of few attograms. We observe that increasing VgAC leads to more improvement in AD as compared to that of VgDC drive. This is due to an enhanced signal to noise ratio. We estimate various types of noise associated with MoS$_2$ resonator. This work holds promise for ultrasensitive sensing and realizing ultrastable oscillators from 2D materials.

9:12AM A53.00005: Probing anisotropic transport in atomically thin ReS$_2$ via ferroelectric domain controlled nanowire patterning*  
DAWEI LI (Presenter), SHUO SUN, ZHIYONG XIAO, JINGFENG SONG, DING-FU SHAO, EVGENY Y TSYMBAL, STEPHEN P DUCHARME, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — The layered van der Waals material ReS$_2$ exhibits highly anisotropic band structure in the 1T' phase. In this work, we probe the effect of the band anisotropy on the transport properties of single- and few-layer ReS$_2$ via ferroelectric field effect combined with ferroelectric domain patterning. We fabricated mechanically exfoliated ReS$_2$ flakes into two-point transistor devices sandwiched between a SiO$_2$/Si back gate and a ferroelectric polymer PVDF-TrFE thin film top layer. The polarization of PVDF was then controlled at the nanoscale using conductive atomic force microscopy. By uniformly polarizing the ferroelectric top layer into the up ($P_{up}$) and down ($P_{down}$) directions, we induced up to $10^5$ current switching in bilayer ReS$_2$ channel at 300 K. We then polarized the entire channel into the insulating state, and created a nanoscale line-domain across the channel, leading to a conductive nanowire. By creating nanowires at different orientations, we mapped out the angular dependence of ReS$_2$ conductivity, which reveals more than one order of magnitude difference between the directions along and perpendicular to the $b$-axis. We compared the results with DFT calculated band structure of ReS$_2$.

9:24AM A53.00006: Electronic transport in two-dimensional MXenes for energy storage*  
NESRINE BOUSSADOUNE (Presenter), OLIVIER NADEAU, GABRIEL ANTONIUS, Hydrogen Research Institute, Université du Québec à Trois-Rivières — MXenes are a large family of two-dimensional transition metal carbides and carbonitrides, which is attracting great research attention in the energy storage devices, including supercapacitor, due to their excellent electrical conductivity. In order to assist the design of supercapacitor electrodes based on these materials, we study the electronic conductivity of selected MXenes from first principles, and we aim to understand how their conductivity depends on their chemical composition and surface termination. We use the Abinit software to perform first-principles calculations. First, the total energy, the electronic band structure and the density of state (DOS) are investigated using density functional theory (DFT). Second, we employed density functional perturbation theory (DFPT) to obtain the phonon band structure and electron-phonon coupling. Finally, we solve the linearized Boltzmann equation in order to obtain the phonon-limited electronic mobility. We will show preliminary results for Ti$_3$C$_2$F$_2$ and Ti$_3$C$_2$(OH)$_2$.

9:36AM A53.00007: Anisotropic carrier transport of black phosphorus encapsulated by h-BN*  MYEONGJIN LEE (Presenter), WON JONG YOO, Sungkyunkwan Univ — Anisotropic two-dimensional (2D) materials are promising candidates for novel electronics and optoelectronics because in-plane anisotropy in 2D materials can be used for polarization controlled infrared sensors, directionally controlled heat dissipators, and the angle control between adjacent 2D layered materials. Black phosphorus (BP), one of the anisotropic 2D materials, is known to have strong p-type in-plane anisotropic properties [1]. But, researches of anisotropic properties of BP in the tightly controlled fabrication environment and device structure are still elusive. Here, we report the anisotropic electrical properties of the BP field effect transistor (FET) by precisely aligning the FET channel along its pre-determined in-plane directions. Using angle-resolved polarized Raman spectroscopy (ARPR), we were able to identify BP into zigzag (ZZ) and armchair (AC) directions. Field effect mobility and resistances of AC direction was found to be better than that of ZZ direction at room and low temperature respectively.

9:48AM A53.00008: Characterization of the metal/MoS₂ top contact based on first-principles quantum transport calculations  TAE HYUNG KIM (Presenter), YONG-HOON KIM, School of electrical engineering, KAIST, MYUNG HO BAE, KRISS — We have recently reported the experimental achievement of Ohmic van der Waals (vdW) contacts at the indium (In)/MoS₂ devices thorough a novel thermal evaporation process, and based on the combined density functional theory and matrix Green's function calculations concluded that the nature of the ideal Ohmic contact is characterized by the abrupt and rigid shift of TMDC bands across the In/MoS₂ interface (i.e. no band bending) together with the formation of metal-induced gap states (MIGS) [1]. In this work, we extend the analysis by considering four other metal species, Ag, Au, Sc, and Pd. Systematically considering how the electrode contact-region MoS₂ electronic structure develops into that of the channel region in different metal cases, we conclude that the identification of MIGS (rather than band bending) as the main determining factor for the clean metal/MoS₂ contacts is generally valid irrespective of the differences in the metal work function and wettability.

**10:00AM A53.00009: Photo-Induced Anomalous Hall Effect in 2D Transition-Metal Dichalcogenide**  
*PHUONG NGUYEN (Presenter), WANG KONG TSE, Department of Physics and Astronomy, University of Alabama, Tuscaloosa — Illumination of a circularly polarized a.c. pump field induces a valley polarization in two-dimensional transition metal dichalcogenides (TMDs), which results in an anomalous Hall voltage in response to a d.c. bias. In this work, we develop a theory for this photovoltaic valley-resolved anomalous Hall effect in undoped TMDs. A quantum kinetic equation is used to study the non-equilibrium carrier populations and time-averaged transport currents under the simultaneous influence of the strong a.c pump field and the weak d.c probe field. Our results for the photo-induced longitudinal and Hall conductivities show strong resonant features when the pump field frequency reaches the spin-split band-to-band transition energies.

**10:12AM A53.00010: Density-functional prediction of a strong Orbital Hall effect in the monolayer WX2 (X = Te, S)**  
*PRATIK SAHU (Presenter), SAYANTIKA BHOWAL, SASHI SEKHAR SATPATHY, Univ of Missouri - Columbia — The orbital Hall effect (OHE) is the transverse flow of the orbital angular momentum in response to the applied electric field, analogous to the charge current flow in the standard Hall effect. Even though the OHE has been proposed about a decade ago, it has not been directly observed experimentally to our knowledge. We have recently proposed that the 2D transition metal dichalcogenides (TMDC) with non-centrosymmetric crystal structure may be a good candidate for a robust OHE. In this talk, we evaluate the effect for the 2D-TMDC materials WTe2 and WS2 where there is a strong spin-orbit coupling present, both for the non-centrosymmetric (2H) and the centrosymmetry (1T') cases. As anticipated, the OHE in the 2H structure is much stronger, due to the existence of the intrinsic orbital moment in different parts of the Brillouin zone, which flow in different directions, as opposed to the centrosymmetric (1T') structure, where the OHE occurs due to the induced orbital moment in the presence of the Hall electric field. Our results are based on density-functional calculations as well as minimal tight-binding models.

Heterojunctions from Coulomb-Engineered Transition Metal Dichalcogenides  
MALTE ROESNER (Presenter), Theory of Condensed Matter Department, Radboud University, CHRISTINA STEINKE, TIM WEHLING, Institute for Theoretical Physics, University of Bremen — The band structure and the band gap of semiconducting layered materials are strongly affected by the Coulomb interaction between carriers within the layer. At the same time we can externally modify this interaction by means of dielectric substrates or dielectric coating. This Coulomb-engineering can thus be used to tailor the fundamental electronic properties of layered materials.

Here we use a combination of the GdW [1] and WFCE [2] approaches to systematically study the environmental-screening effects to monolayers of semiconducting transition metal dichalcogenides on a material-realistic level. We compare static and dynamic screening effects of homogeneous substrates and derive an effective modeling scheme for spatially-varying heterogeneous substrates. The latter allows for the external and non-invasive induction of heterojunctions within the otherwise homogeneous monolayer. Our calculations show that spatial band gap modulations on the length scale of a few lattice constants are possible and are just limited by the heterogeneous substrate.

Quasi-1D TiS₃ Nanoribbons: Mechanical Exfoliation, Thickness-Dependent Raman Spectroscopy and Electronic Properties  
ALEXANDER SINITSKII (Presenter), University of Nebraska - Lincoln — Quasi-one-dimensional (quasi-1D) materials enjoy growing interest due to their unusual physical properties and promise for miniature electronic devices. We investigated the micromechanical exfoliation of representative quasi-1D crystals, TiS₃ whiskers, and demonstrate that they typically split into narrow nanoribbons with very smooth edges and clear signatures of 1D TiS₃ chains. Theoretical calculations show that the energies required for breaking weak interactions between the 2D layers and between 1D chains within the layers are comparable, and in turn are considerably lower than those required for breaking the covalent bonds within the chains. We systematically studied the exfoliated TiS₃ crystals by Raman spectroscopy and identified the Raman peaks whose spectral positions were most dependent on the crystals’ thickness. Finally, we fabricated TiS₃-based electronic devices and tested their transport properties. The conclusions established in this study for the exfoliated TiS₃ crystals can be extended to a variety of transition metal trichalcogenide materials as well as other quasi-1D crystals. The possibility of exfoliation of TiS₃ into few-nm wide crystals with smooth edges is important for realization of miniature device channels with reduced edge scattering.
Molybdenum disulfide (MoS$_2$) has emerged as a prototypical material among the 2D transition metal dichalcogenides for its stability, low cost and unique electronic, optical and mechanical properties. Its electronic properties can be tuned using different control parameters. This great sensitivity presents an opportunity to functionalize its properties through defect engineering, strain or by proximity to another material. We use high resolution low temperature STM/STS to study the local electronic properties of monolayer MoS$_2$. We were able to induce strains up to 3% before slipping effects take place and relaxation mechanisms prevail. We found a reduction of the quasiparticle bandgap of about 400 meV per percent local strain with a minimum gap of 1.2 eV. Heterostructures based on MoS$_2$ offer another viable possibility to tune its electronic properties. In this case, interactions between the planes of different materials are expected to modify the electronic properties of the constituent materials and open unprecedented possibilities of combining them for technological use.

8:00AM A54.00001: Evidence for topological surface states in amorphous Bi$_2$Se$_3$*  PAUL CORBAE (Presenter), SAMUEL CIOCYS, University of California, Berkeley, DANIEL VARJAS, QuTech and Kavli Institute of NanoScience., Delft University of Technology, ADOLFO G GRUSHIN, Néel Institute, ALESSANDRA LANZARA, FRANCES HELLMAN, University of California, Berkeley — Crystalline symmetries and classification schemes have played a central role in the identification of topological materials [1-3]. We address whether amorphous topological materials, which lie beyond this classification, exist in the solid state [4]. Amorphous Bi$_2$Se$_3$ thin films show a metallic behavior and an increased bulk resistance. The low field magnetoresistance due to weak antilocalization reveals a significant number of two-dimensional surface conduction channels. Angle-resolved photoemission spectroscopy data is consistent with a dispersive two-dimensional surface state with a distinct node. Spin resolved photoemission spectroscopy shows this state has an anti-symmetric spin-texture resembling that of the surface state of crystalline Bi$_2$Se$_3$.

Experimental results are consistent with an amorphous tight-binding model that utilizes a realistic amorphous structure. Evidence of amorphous materials with topological properties uncovers topological matter outside the current classification scheme, enabling materials discovery and scalable topological devices.

*PC is funded by the NSF GRFP Grant No. 1752814.

8:12AM A54.00002: Atypical Highly-Dispersive Band Structure in Putative Amorphous Topological Insulator*  SAMUEL CIOCYS (Presenter), PAUL CORBAE, University of California, Berkeley, DANIEL VARJAS, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, ADOLFO G GRUSHIN, Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, FRANCES HELLMAN, ALESSANDRA LANZARA, University of California, Berkeley — In typical amorphous and highly disordered materials, Anderson Localization guarantees flat valence bands. This effect is so dramatic and pervasive in the amorphous field of study that the density of states is assumed to be momentum-independent, serving as the full characterization of an amorphous system's electronic structure. In this work, we discover an exception to this rule in amorphous Bi$_2$Se$_3$ films. Angle-resolved photoemission spectroscopy uncovers an amorphous surface-state band structure with strong momentum-dependence and spin-momentum locking. We observe a Fermi surface with repeated annuli and reveal a spherically-parameterized momentum-space picture that warrants a re-evaluation of amorphous band structure on the most fundamental level.

Towards Realistic Amorphous Topological Insulators

MARCIO COSTA, GABRIEL SCHLEDER, Brazilian Nanotechnology National Laboratory (LNNano), CNPEM, Brazil, MARCO BUONGIORNO NARDELLI, Department of Physics, University of North Texas, USA, CAIO LEWENKOPF (Presenter), Physics Institute, Universidade Federal Fluminense, Brazil, ADALBERTO FAZZIO, Brazilian Nanotechnology National Laboratory (LNNano), CNPEM, Brazil — The topological properties of materials are, until now, associated with the features of their crystalline structure, although translational symmetry is not an explicit requirement of the topological phases. Recent studies of hopping models on random lattices have demonstrated that amorphous materials can display a non-trivial topology. Using ab initio calculations we show that amorphous materials can also display topological insulator properties. More specifically, we present a realistic study of the electronic and transport properties of amorphous bismuthene systems, showing that they are topological insulators. These systems are characterized by the topological index \( Z_2 = 1 \) and bulk-edge duality, and their linear conductance is quantized, \( G = \frac{2e^2}{h} \), for Fermi energies within the topological gap. Our study opens the path to the investigation of amorphous topological insulator materials.

This work was partially supported by the Brazilian funding agencies CNPq, FAPESP, and FAPERJ.

Numerical signatures of disordered topological phases

DOMINIC REISS (Presenter), FENNER HARPER, RAHUL ROY, University of California, Los Angeles — We investigate a number of numerical signatures which distinguish the topological and trivial phases of clean and disordered insulators. In particular, we consider two dimensional systems and suggest a procedure for numerically constructing a sequence of maximally localized mutually orthogonal states which span the Hilbert space. The localization lengths of states constructed using our procedure is numerically shown to diverge as a power law for systems with non-zero Chern number, and conversely saturate for systems with zero Chern number. We construct and numerically verify a scaling argument which suggests this exponent is universal. Finally, we discuss extensions of this approach to other spatial dimensions and symmetry classes.

D. R., F. H., and R. R. acknowledge support from the NSF under CAREER DMR-1455368 and the Alfred P. Sloan Foundation.

Topological Phase Transition in a Disordered Inversion-Symmetric Chain

SAAVANTH VELURY (Presenter), BARRY BRADLYN, TAYLOR L HUGHES, University of Illinois at Urbana-Champaign — Topological crystalline phases are states which are protected by crystalline symmetries. When translational invariance is broken by bulk disorder, the topological nature of these states may change depending on the type of disorder that is applied. In this work, we characterize the phases of a one-dimensional (1D) chain with inversion and chiral symmetries where the disorder preserves the inversion symmetry on every configuration. By using a basis-independent formulation for the inversion invariant and chiral winding number, we are able to construct phase diagrams for both quantities when disorder is present. Unlike the chiral winding number, the inversion invariant is prone to fluctuations past the spectral gap closing at strong disorder. Using the real-space renormalization group, we are able to compare how differently the inversion invariant and chiral winding number behave at low energies when disorder is present.
**9:00AM A54.00006: Dislocation defect as a bulk probe of monopole charge of multi-Weyl semimetals**

RODRIGO SOTO GARRIDO (Presenter), ENRIQUE MUNOZ, Pontif Univ Catolica de Chile, VLADIMIR JURICIC, NORDITA — We consider the electronic scattering in multi-Weyls semimetals due to dislocations defects which can be represented as an emergent effective magnetic field. We use partial wave analysis to analytically obtain the transmitted current and the conductance. From the conductance peaks as a function of the bias voltage, we can deduce monopole charge $n$ of the corresponding multi-Weyl semimetal as well as the effective flux of the dislocation defect. We argue that this provides a simple and a robust way to measure the monopole charge of a multi-Weyl semimetal.

**9:12AM A54.00007: Bound-state spectrum of superconductors with magnetic-texture defects**

 DANIEL STEFFENSEN (Presenter), BRIAN M. ANDERSEN, Niels Bohr Institute, PANAGIOTIS KOTETES, ITP-CAS — Recent experiments [1] provided evidence for zero-energy Majorana bound states (MBSs) when magnetic adatoms are deposited onto a superconductor. Such observations are reconcilable by means of 0D-like defects which trap MBSs. Existing explanations rely on the presence of isolated magnetic skyrmions or vortices in the spin-orbit coupling field. These need to be contrasted to the standard mechanism, in which MBSs are trapped in vortices of the superconducting order parameter. Inspired from the above, we explore a novel promising path towards realizing MBSs, which relies on 0D defects in the order parameter describing a textured magnetic order that coexists with spin-singlet superconductivity. This scenario appears relevant for iron-pnictides, where a theoretical study [2] has revealed that textured magnetism is accessible in doped BaFe$_2$As$_2$ and LaFeAsO. Here, we perform a thorough numerical investigation of the bound-state energy spectrum arising when vortices are introduced in the order parameter of spin-spiral and -whirl magnetic orders. Our preliminary results indicate that the defect-induced MBSs are accessible in superconductors which yield a nodal spectrum in the absence of the magnetic order.

In-gap excitations due to defects in topological superconductor with spin-orbit coupling

*ANDREJ MESAROSH (Presenter), Laboratoire de Physique des Solides, CNRS, GERBOLD MÉNARD, Niels Bohr Institute, Copenhagen, Denmark, CHRISTOPHE BRUN, FRANÇOIS DEBONTRIDDER, DIMITRI RODITCHEV, Institut des NanoSciences de Paris, Sorbonne Université, PASCAL SIMON, Laboratoire de Physique des Solides, Université Paris-Sud, TRISTAN CREN, Institut des NanoSciences de Paris, Sorbonne Université — Recent microscopy experiments on superconducting monolayer of lead(Pb) grown over clusters of cobalt atoms have raised urgent questions about in-gap electronic states in presence of strong spin-orbit coupling and magnetism.

Using analytics and numerics we find that a topological defect in Rashba spin-orbit coupling (in contrast to a vortex in superconducting pairing) fully explains puzzling features of this experiment: 1) Two different zero-modes, one point-like at center of cluster and the other ring-shaped around it; 2) The zero mode pair is protected by a large energy gap; 3) The localization lengthscale inside the cluster is far smaller than superconducting coherence length, but comparable to it outside. The theory predicts that this is a Majorana pair, with remarkable isolation in energy thanks to the defect in strong spin-orbit coupling. We discuss the role of magnetic textures in our theoretical scenario.

CT-symmetric Non-linear Topological Defect Modes

*DO HYEOK JEON (Presenter), Wesleyan University, MATTIS REISNER, FABRICE MORTESSAGNE, ULRICH KUHL, Institut de Physique de Nice (INPHYNI), TSAMPIKOS KOTTOS, Wesleyan University — Topologically protected states have recently been a subject of increasing interest due to their unique robustness against disorder. Such property is beneficial for a variety of photonics applications ranging from lasers to optical isolators and receiver protectors. On the other hand, an essential piece of information associated with the interplay between optical nonlinearity and topological protection is still missing. Such a question cannot be ignored, since nonlinearity is prevalent in realistic circumstances. Using a non-linear SSH model we have theoretically analyzed the topological nature of an emerging nonlinear defect mode associated with a non-linear defect. To this end, we have devised a theoretical formalism which is based on Green’s functions and prove that for certain type of nonlinearities the nonlinear defect mode is spectrally protected by a charge-conjugation (CT) symmetry. We demonstrate the validity of our study via direct measurements using a CROW SSH array in the microwave domain.

*Partial support under NSF Grant EFMA1641109 and ONR Grant N00014-19-1-2480.
9:48AM A54.00010: Aperiodic Topological Boundary Modes: Revisiting Quasi-Periodic Localization  
DAN BORGNIA (Presenter), ROBERT-JAN SLAGER, ASHVIN VISHWANATH, Harvard University — Although physical systems are generically aperiodic, most work on non-interacting topological materials focuses on translation-invariant cases. These systems are well described by band theory and perturbatively resistant to the disorder of real world conditions, however, the regime of strong aperiodicity is not frequently discussed in the context of topological materials. Aiming to better understand such systems, this work generalizes key results in translation-invariant systems to their aperiodic counterparts. We then apply these techniques to the canonical Andre-Aubrey-Harper (AAH) Model and its 1D Metal-Insulator Transition (MIT). We uncover a deep connection between the known non-commutative topological properties of the model and the MIT. This not only highlights the power of this non-commutative technology, but also separates the AAH model from its disordered counterparts. The 1D MIT in the AAH model and its peculiar properties are indeed topological in nature. This suggests quasiperiodic systems form their own special class of topological materials distinct from their translation-invariant counterparts.

10:00AM A54.00011: The existence of robust edge currents in Sierpinsky Fractals* 
MIKAEL FREMLING (Presenter), MICHAL VAN HOOFT, CRISTIANE MORAIS SMITH, LARS FRITZ, Univ of Utrecht — We investigate the Hall conductivity in a Sierpinski carpet, a fractal of Hausdor dimension \( d_f = \ln(8) / \ln(3) \approx 1.893 \), subject to a perpendicular magnetic field. We compute the Hall conductivity using linear response and the recursive Green function method. Our main finding is that edge modes, corresponding to a maximum Hall conductivity of at least \( \sigma_{xy} = \pm e^2/h \), seems to be generically present for arbitrary finite field strength, no matter how one approaches the thermodynamic limit of the fractal. We discuss a simple counting rule to determine the maximal number of edge modes in terms of paths through the system with a fixed width. This quantized edge conductance, as in the case of the conventional Hofstadter problem, is stable with respect to disorder and thus a robust feature of the system.

10:12AM A54.00012: Tracking the mechanism behind graphene ripple inversion with LAMMPS  JAMES MANGUM (Presenter), PAUL M THIBADO, Univ of Arkansas-Fayetteville — Freestanding graphene spontaneously forms ripples. If a sheet is under sufficient compressive strain, the ripples form a bi-stable system (concave or convex). The rate at which a ripple inverts is lower than the small thermal oscillation frequency. This rate decreases with increased compressive strain, and increases with increased temperature. We ran ten simulations, using LAMMPS molecular dynamics simulation software, for a single ripple of graphene, with different compressive strains at 3000 K. The z-component (out of plane) average and center values were tracked to identify when inversion occurs. Atoms that make up a cross-section of the ripple were also tracked. Changes in the cross-section profile that occur during inversion show that the mechanism behind inversion is the formation of smaller sub-ripples.

10:24AM A54.00013: Anomalous Hall effect in chiral superconductors from impurity superlattices* ZHIQIANG WANG (Presenter), James Franck Institute, University of Chicago, YU LI, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, WEN HUANG, Shenzhen Institute for Quantum Science and Engineering and Department of Physics, Southern University of Science and Technology — Unlike anomalous quantum Hall insulators, clean single-band chiral superconductors do not exhibit intrinsic Hall effect at the one-loop approximation. Finite ac Hall conductance was found to emerge beyond one-loop, such as with vertex corrections associated with extrinsic random impurity scatterings. In this work, we consider the effect of impurities embedded in chiral superconductors in a superlattice pattern, instead of in random distributions. The impurity-induced Bogoliubov quasiparticle bound states hybridize to form subgap bands, constituting an emergent low-energy effective theory whose anomalous Hall effect can be studied with ease. We demonstrate that the occurrence of the Hall effect depends on the superlattice geometry and the parity of the chiral pairing. In particular, due to the composite particle-hole character of the subgap states, the Hall conductance arises at the one-loop level of the current-current correlator in our effective model. Generalized to random impurities, our theory sheds new light on the physics of impurity-induced anomalous Hall conductivity in chiral superconductors.

*This work is supported in part by a startup grant at the Southern University of Science and Technology.
We consider the interplay between topology and disorder on the surface fluids of topological superconductors (TSCs). In the case of a single 2D Majorana cone, only “quenched gravitational disorder (QGD)” is allowed, i.e. a static modulation of the effective speed of light. Although disorder effects near zero energy have been understood for a long time, recent numerical results uncovered an unexpected result: finite energy TSC surface states form “stacks” of quantum critical wave functions, with universal, energy-independent statistics [1,2,3]. In classes CI and AIII, one finds stacks of quantum Hall plateau transition states [1,2]. For the single Majorana cone with QGD in class DIII, the stacked critical states appear to belong to a new class [3]. In order to shed light on the DIII results, we consider a semiclassical approach. We find that kinetic theory predicts a divergent conductivity at all temperatures. We further study the statistical properties of the null geodesics in the 2+1-D quenched random spacetime metric that can be associated to QGD.

10:48AM A54.00015: Antisite defect enhanced thermoelectric performance of topological crystalline insulators*  
MUHAMMAD USMAN MUZAFFAR, SHUNHONG ZHANG, PING CUI (Presenter), University of Science and Technology of China, Hefei 230026, China, JIAQING HE, Southern University of Science and Technology, Shenzhen 518055, China, ZHENYU ZHANG, University of Science and Technology of China, Hefei 230026, China — As the first experimentally established topological crystalline insulator (TCI), SnTe also exhibits superior thermoelectricity upon proper doping; yet to date, whether such doping will preserve or destroy the salient topological properties in achieving outstanding thermoelectric performance remains elusive. Using first-principles calculations combined with Boltzmann transport theory, we uncover the elegant role of antisite defect in optimally enhancing the thermopower of SnTe while simultaneously preserving its topological nature. We first show that Sn\textsubscript{Te} antisite defect effectively induces pronounced variations in the low-energy density of states rather than rigidly shifting the chemical potential, resulting in higher Seebeck coefficient and power factor. Next, we demonstrate that in a wide temperature range the Seebeck coefficient of antisite doped SnTe distinctly outperforms previously identified systems invoking extrinsic dopants. We further confirm that such intrinsic antisite doping preserves the nontrivial topology, which in turn favors high electrical conductivity and thermoelectricity. These findings render antisite doping as a natural and powerful avenue to optimize the overall thermoelectric performance of TCIs and related systems.

Session A55 DCMP: Dirac and Weyl Semimetals: Theory I  
Mile High Ballroom 2B - Herbert Fertig, Indiana Univ - Bloomington

8:00AM A55.00001: Chiral Qubit: Implementing a Qubit Using Chiral Charge and Chiral Anomaly*  
EVAN PHILIP (Presenter), SAHAL KAUSHIK, DMITRI E KHRZEEV, State Univ of NY - Stony Brook — Dirac and Weyl semimetals are capable, due to chiral anomaly, of a nearly dissipationless current in the presence of a chirality imbalance and magnetic field (Chiral Magnetic Effect). We propose an implementation of the qubit based on this. Superconducting qubits require low operating temperatures and are limited in operating frequency by the superconducting gap—two limitations that the "chiral qubit" could potentially overcome. I will present our theoretical model and estimates regarding the chiral qubit.

*U.S. Department of Energy Awards DE-FG-88ER40388 (E. P. and D. K.), DE-SC-0017662 (S. K. and D. K.), and DE-AC02-98CH10886 (D. K.)
8:12AM A55.00002: Two-body interaction induces axion/phason field in Weyl semimetals
DAVID SCHMELTZER (Presenter), The City College of New York, AVADH SAXENA, Los Alamos National Lab — Following our results that the two-body interaction can induce a space and time dependent topological axion term $\theta(z,t)\left[\frac{e^2}{2\pi \hbar}\right](E,B)$, we show that by applying this theory to a Weyl semimetal with two nodes in a magnetic field a one-dimensional sliding charge density wave (CDW) emerges which replaces the asymptotic effective topological representation, in agreement with the recent experimental finding of J. Gooth et al. [Nature, https://doi.org/10.1038/s41586-019-1630-4 (2019)].

8:24AM A55.00003: Chiral vector field-induced collective fermionic excitations in Weyl semimetals
ALBERTO CORTIJO (Presenter), CSIC - Madrid, ERIK VAN DER WURFF, Institute for theoretical physics, Utrecht University — We study the single-particle fermionic spectrum of Weyl semimetals in three dimensions taking into account the axial vector character of the electron-phonon interaction. We find that, together the expected standard quasi-particle peak, a second peak appears in the spectral function. The main features of this new fermionic excitation are to be intrinsically anisotropic and gapped. We will discuss also the potential impact of these collective fermionic modes on the transport phenomena in Weyl semimetals.

*E.C.I. van der Wurf acknowledges financial support from the Stichting voor Fundamenteel Onderzoek der Materie (FOM), part of the D-ITP consortium, a program of the Netherlands Organisation for Scientific Research (NWO) that is funded by the Dutch Ministry of Education. C. acknowledges financial support through MINECO/AEI/FEDER, UE Grant No. FIS2015-73454-JIN and European Union structural funds and the Comunidad Autonoma de Madrid (CAM) NMAT2D-CM Program (S2018-NMT-4511).

8:36AM A55.00004: Theoretical Study of Resonant Inelastic X-ray Scattering for Monopole Density-wave Order and Superconductivity in Weyl Semimetals
ERIC BOBROW (Presenter), Johns Hopkins University, PETER ABBAMONTE, University of Illinois at Urbana-Champaign, YI LI, Johns Hopkins University — Resonant Inelastic X-ray Scattering (RIXS) spectra can provide useful information for phase-sensitive bulk detection. A difference of RIXS spectra for cross-polarized X-rays has been previously proposed to detect the topological windings of single-particle Weyl nodes in, for example, TaAs. We generalize this idea to investigate various topological excitations near the emergent Weyl nodes in exotic nodal superconducting and density-wave ordered Weyl semimetal systems characterized by monopole harmonic symmetry.

*This work is supported by NSF CAREER DMR-1848349 and in part by the Alfred P. Sloan Research Fellowships and the Gordon and Betty Moore Foundations EPiQS Initiative through Grant No. GBMF4305.
8:48AM A55.00005: Nonlinear Planar Hall as Another Signature of Chiral Anomaly in Weyl Semimetals*  RUIHAO LI (Presenter), SHULEI ZHANG, Department of Physics, Case Western Reserve University, ANTON BURKOV, Department of Physics and Astronomy, University of Waterloo, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory — Weyl semimetals (WSMs) are a newly discovered class of quantum materials which can host a number of exotic quasiparticles called Weyl fermions. One of the defining properties of WSMs is chiral anomaly – a pair of Weyl nodes with opposite chirality act as source and drain of electrons in the presence of electric and magnetic fields that are not perpendicular to each other. To date, the most remarkable phenomenon induced by chiral anomaly is the longitudinal negative magnetoresistance, which is a linear response effect. In this work, we theoretically investigate the transport properties of WSMs in the nonlinear regime, and predict a nonlinear planar Hall effect as another manifestation of chiral anomaly in transport. Intuitively, a steady-state density difference between a pair of Weyl nodes may be established when the chiral pumping and internode relaxation reach a balance, which conspires with anomalous velocity to give rise to the nonlinear Hall effect. In contrast to the intrinsic quantum nonlinear Hall effect, this effect does not rely on a finite Berry curvature dipole.

9:00AM A55.00006: Viscosity as a probe of nodal topology  MARIANNE MOORE (Presenter), University of British Columbia, PIOTR SUROWKA, Max Planck Inst, VLADIMIR JURICIC, NORDITA, BITAN ROY, Lehigh University — Electronic materials can sustain a variety of unusual, but symmetry protected touchdowns of valence and conduction bands, each of which is identified by a distinct topological invariant. Well known examples include linearly dispersing pseudo-relativistic fermions in monolayer graphene, Weyl and nodal-loop semimetals, bi-quadratic (-cubic) band touching in bilayer (trilayer) graphene, as well as mixed dispersions in multi-Weyl systems. We here show that depending on the underlying band curvature, the shear viscosity in the collisionless regime displays unique power-law scaling with frequency at low temperatures, bearing the signatures of the band topology, which are distinct from the ones when the system resides at the brink of a topological phase transition into a band insulator. Therefore, besides density of states (governing specific heat, compressibility) and dynamic conductivity, shear viscosity can be instrumental to pin nodal topology in electronic materials.

9:12AM A55.00007: Large enhancement of thermopower at low magnetic field in compensated Dirac/Weyl semimetals  XIAOZHOU FENG (Presenter), BRIAN SKINNER, Ohio State Univ - Columbus — We theoretically study the thermoelectric properties of compensated Dirac/Weyl semimetals subjected to a magnetic field. Previous work has shown that Dirac/Weyl semimetals without compensation can exhibit a large enhancement of thermopower in the extreme quantum limit of magnetic field. Here we show that in compensated systems a huge enhancement of thermopower can be obtained even at much smaller magnetic field, provided that $\omega_c \tau \gg 1$. We discuss our results in light of recent measurements on the compensated Weyl semimetal tantalum phosphide, in which an enormous magnetothermoelectric effect was observed.
A55.00008: Charged Domain Wall of Electric Polarizations in Topological Nodal-Line Semimetals  AKIHIKO SEKINE (Presenter), RIKEN, NAOTO NAGAOSA, RIKEN & University of Tokyo — We study theoretically the electronic structure of three-dimensional topological nodal-line semimetals. We show that, in the presence of a gap-opening spatially dependent mass term that forms a domain wall, an in-gap charged localized mode emerges at the domain wall. It turns out that such a domain wall is realized by head-to-head (or tail-to-tail) bulk electric polarizations. The localized mode has a topological origin, i.e., a topological confinement is realized, which is understood by a semiclassical topological number defined in the semiclassical momentum-real space. Namely, a stable charged domain wall of electric polarizations is realized in nodal-line semimetals. In sharp contrast to the well-known band bending mechanism, the origin of the charged domain wall in this study is purely electronic, i.e., due to the band topology. Moreover, in contrast to previous studies, our study demonstrates a topological confinement at the interface between two insulators without bulk topological numbers. The dispersion of the localized mode evolves from gapless to gapped as the bulk bandgap increases, which means that its conductivity is externally tunable. We discuss a possible experimental realization of the stable, electrically-tunable charged domain wall.

A55.00009: Spin and Pseudo-Spin Collective Modes in Doped Graphene  ABHISHEK KUMAR (Presenter), DMITRII MASLOV, University of Florida — Collective modes in graphene has been an active area of research during the last decade. As any two-dimensional electron system, graphene harbors a gapless plasmon mode which disperses as $q^{1/2}$. Gapped collective modes in graphene are, however, less explored. The goal of this work is two-fold: a comprehensive study of collective modes in graphene (a) without spin-orbit coupling (SOC) and (b) in the presence of Rashba and valley-Zeeman SOC. For a short-range electron-electron interaction, we find that in case (a) there exists a collective mode below the continuum, corresponding to oscillations of pseudospin. In case (b), we show that, in graphene with Rashba SOC, there exists a collective spin mode consisting of three branches: a double-degenerate branch, corresponding to oscillations of in-plane magnetization, and a non-degenerate branch corresponding to oscillations of out of plane magnetization. For graphene with valley-Zeeman SOC, there exists only a single branch of the collective mode corresponding to out of plane oscillation of the magnetization. We also study the case of an unscreened Coulomb interaction, solved by reducing the sum of ladder diagrams for a vertex function to a Dirac equation with non-local interaction.

A55.00010: Quantum oscillations in Dirac magnetoplasmons  JOHANNES HOFMANN (Presenter), Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Centre for Mathematical Sciences, University of Cambridge — The plasmon frequency in standard electron gases with a parabolic single-particle dispersion is a purely classical quantity that is not sensitive to electron interactions or the equation of state. We demonstrate that this canonical result no longer holds for plasmons in three-dimensional semimetals, which can thus be used to probe many-body effects. In particular, we show that the plasmon frequency in an external magnetic field displays quantum oscillations, which is not the case for the electron gas. Using the random phase approximation, results are presented for the magnetoplasmon dispersion and the loss function in Dirac semimetals. We include a full discussion of the loss function in a magnetic field as a function of the direction of propagation with respect to the magnetic field direction and discuss the transition from large magnetic fields to the low-field limit.
10:00AM A55.00011: Fermi-arcs and non-local collective modes in thin-film Weyl systems
SONU VERMA, DEBASMITA GIRI, Physics, Indian Institute of Technology Kanpur, HERBERT FERTIG, Physics, Indiana university Bloomington, ARIJIT KUNDU (Presenter), Physics, Indian Institute of Technology Kanpur — Fermi-arcs in Weyl semimetals carry signatures of their topological origin. In a thin-film geometry, in the presence of Coulomb interactions, particle-hole excitations can take place either on the same surface, or between the two surfaces, giving rise to the possibility of unique non-local collective modes. We study, in particular, plasmonic modes that are non-locally bound in a thin-film Weyl semimetal carrying the signature of bulk and surface mixing and analyze the possibility of their application.

10:12AM A55.00012: Effect of charge renormalization on electric and thermo-electric transport along the vortex lattice of a Weyl superconductor
GAL LEMUT (Presenter), MICHAL PACHOLSKI, Leiden University, INANC ADAGIDEI, Sabanci University, CARLO W J BEENAKKER, Leiden University — Building on the discovery that a Weyl superconductor in a magnetic field supports chiral Landau level motion along the vortex lines, we investigate its transport properties out of equilibrium. We show that the vortex lattice carries an electric current $I=1/2(Q_{\text{eff}}^2/h)(\Phi/\Phi_0)V$ between two normal metal contacts at voltage difference $V$, with $\Phi$ the magnetic flux through the system, $\Phi_0$ the superconducting flux quantum, and $Q_{\text{eff}}<e$ the renormalized charge of the Weyl fermions in the superconducting Landau level. Because the charge renormalization is energy dependent, a nonzero thermo-electric coefficient appears even in the absence of energy-dependent scattering processes.

* This project has received funding from the Netherlands Organization for Scientific Research (NWO/OCW), from the TUBITAK grant No. 114F163, and from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation program.

10:24AM A55.00013: Effect of Disorder on Edge States in Nodal Topological Materials
SAUMITRAN KASTURIRANGAN (Presenter), XUZHE YING, FIONA BURNELL, ALEX KAMENEV, University of Minnesota — Many nodal topological materials exhibit gapless flat-band boundary modes which are protected by non-trivial topology in momentum space. Here we ask the question of whether, as is the case for weak topological insulators [1], these boundary flat-bands maintain their integrity in the presence of disorder – and whether this leads to observable signatures in transport. To do this, we study the effects of various types of quenched short-range disorder on the energy spectrum, localization, and transport properties of the boundary states of a 2D topological semi-metal in symmetry class BDI. Our primary example is graphene with time-reversal and particle-hole symmetry. We discuss the implications of our results for experimentally detecting the boundary modes of nodal topological superconductors in 2D.

* This work was partially supported by NSF: DMR-1352271 and NSF: DMR-1928166
10:36AM A55.00014: Topologically protected Landau level in the vortex lattice of a Weyl superconductor*  
MICHAL PACHOLSKI (Presenter), CARLO W J BEENAKKER, Leiden University, INANC ADAGIDELI, Faculty of Engineering and Natural Sciences, Sabanci University — The question whether the mixed phase of a gapless superconductor can support a Landau level is a celebrated problem in the context of $d$-wave superconductivity, with a negative answer: The scattering of the subgap excitations (massless Dirac fermions) by the vortex lattice obscures the Landau level quantization. Here we show that the same question has a positive answer for a Weyl superconductor: The chirality of the Weyl fermions protects the zeroth Landau level by means of a topological index theorem. As a result, the heat conductance parallel to the magnetic field has the universal value $G = \frac{1}{2} g_0 \Phi / \Phi_0$, with $\Phi$ the magnetic flux through the system, $\Phi_0$ the superconducting flux quantum, and $g_0$ the thermal conductance quantum.

*This research was supported by the Netherlands Organization for Scientific Research (NWO/OCW), an ERC Synergy Grant, and by the TUB ITAK grant No. 114F163.

A55.00015: Nonlocal Response Mediated by Weyl Orbits*  
ZHE HOU (Presenter), QING-FENG SUN, Peking Univ — Nonlocality is always an interesting topic in quantum physics and is usually mediated by some unique quantum states. Nonlocal phenomena in three dimensional systems mediated by trivial bulk states are rarely reported however. Here we investigate a Weyl semimetal slab and find an exotic nonlocal correlation effect when placing two potential wells merely on the top and bottom surfaces. This nonlocal response is totally carried by the bulk states inside the Weyl orbit, which is a result of the peculiar band structure of Weyl semimetals. A giant nonlocal transport signal and a body breakdown by the Weyl fermions are further uncovered, which can serve as signatures for verifying this nonlocal phenomenon experimentally. Our results extend a new member in the nonlocality family and have potential applications for designing new electric devices with fancy functions.

**Session A56 DCMP GMAG: Kitaev Model Theory and Experiment**  
Mile High Ballroom 2C - Joseph Paddison, Oak Ridge National Lab
8:00AM A56.00001: Pressure Induced Quantum Spin Liquids in Extended Kitaev Model
JIUCAI WANG (Presenter), ZHENG-XIN LIU, Department of Physics, Renmin University of China, Beijing 100872, China — The Kitaev's Honeycomb lattice model has exactly solvable spin liquid ground states and has attracted lots of research interest. However, most Kitaev materials possess both Kitaev and non-Kitaev interactions, resulting in magnetically ordered ground states. A possible way to suppress the magnetic order and to drive the system to quantum spin liquid phases is exerting high pressure, assuming that the bond-dependent interaction strength can be adjusted by the external pressure. We illustrate this possibility by studying a (pressure caused) anisotropic spin model with variational Monte Carlo method. While the anisotropic pure Kitaev model contains only two phases, the presence of non-Kitaev interactions result in a much richer phase diagram and give rise to several gapless spin liquids whose low-energy spinon excitations contain different number of cones. We show that these gapless spin liquids can be distinguished experimentally. Furthermore, a small out-of-plane magnetic field opens a gap to these spin liquids and results in different chiral spin liquids, all of which are belonging to the Kitaev 16-fold classification.

8:12AM A56.00002: Transport and chaos in lattice Sachdev-Ye-Kitaev models* HAOYU GUO (Presenter), YINGFEI GU, SUBIR SACHDEV, Department of Physics, Harvard University — We compute the transport and chaos properties of lattices of quantum Sachdev-Ye-Kitaev islands coupled by single fermion hopping, and with the islands coupled to a large number of local, low energy phonons. We find two distinct regimes of linear-in-temperature (T) resistivity, and describe the crossover between them. When the electron-phonon coupling is weak, we obtain the “incoherent metal” regime, where there is near-maximal chaos with front propagation at a butterfly velocity $v_B$, and the associated diffusivity $D_{\text{chaos}} = (v_B)^2/(2\pi T)$ closely tracks the energy diffusivity. On the other hand, when the electron-phonon coupling is strong, and the linear resistivity is largely due to near-elastic scattering of electrons off nearly free phonons, we find that the chaos is far from maximal and spreads diffusively. We also describe the crossovers to low T regimes where the electronic quasiparticles are well defined.

*This research was supported by the U.S. Department of Energy under Grant No. DESC0019030. Y.G. is also supported by the Gordon and Betty Moore Foundation EPiQS Initiative through Grant (GBMF4306). 8:24AM A56.00003: Low-rank Sachdev-Ye-Kitaev Models*  JAEWON KIM (Presenter), XIANGYU CAO, EHUD ALTMAN, University of California, Berkeley — Motivated by recent works on atom-cavity realizations of fast scramblers, and on Cooper pairing in non-Fermi liquids, we study a family of solvable variants of the (q=4) Sachdev-Ye-Kitaev model in which the rank and eigenvalue distribution of the coupling matrix J are tuneable. When the rank is proportional to the number of fermions, the low temperature behavior is sensitive to the eigenvalue distribution. We obtain a complete classification of the possible non-Fermi liquid quantum phases. These include two previously studied phases whose fermion scaling dimension depends continuously on the rank; we show that they are maximally chaotic, but necessitate an extensively degenerate or negative semidefinite coupling matrix. More generic distributions give rise to "almost Fermi liquids" with a scaling dimension Delta = 1/2, but which differ from a genuine Fermi-liquid in quasi-particle decay rate, quantum Lyapunov exponent and/or specific heat.

*We acknowledge support from the ERC synergy Grant UQUAM and DOE grant DE-SC0019380.

8:36AM A56.00004: Soft modes in the complex Sachdev-Ye-Kitaev model*  YINGFEI GU, Harvard University, ALEXEI KITAEV, Physics, Caltech, SUBIR SACHDEV, GRIGORY TARNOPOLSKY (Presenter), Harvard University — We discuss soft modes in the Sachdev-Ye-Kitaev model for complex fermions with large N flavors and a global U(1) charge. The conserved charge leads to a compact scalar field in the effective action, from which we derive the many-body density of states and extract the charge compressibility. We compute the latter via three distinct numerical methods and obtain consistent results.

Dynamical and thermal magnetic properties of the Kitaev spin liquid candidate α-RuCl₃*

PONTUS LAURELL (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory — α-RuCl₃ is a promising Kitaev spin liquid candidate, but orders magnetically, the description of which necessitates additional interaction terms. The nature of these interactions, their magnitudes and even signs, remain an open question. In this work we investigate dynamical and thermal magnetic properties of proposed effective Hamiltonians. We calculate $T=0$ inelastic neutron scattering (INS) intensities using exact diagonalization, and magnetic specific heat, $C(T)$, using a thermal pure quantum states method. We find that no single current model satisfactorily explains all observed phenomena of α-RuCl₃. In particular, we find that Hamiltonians derived from first principles can capture the experimentally observed high-temperature peak in $C(T)$, while overestimating the magnon energy at $q=0$. In contrast, other models reproduce important features of the INS data, but do not adequately describe $C(T)$. We propose a modified ab initio model that is consistent with both magnetic specific heat and low-energy features of INS data.

*This work was supported by the Scientific Discovery through Advanced Computing (SciDAC) program funded by U.S. Department of Energy, Office of Science, Advanced Scientific Computing Research and Basic Energy Sciences, Division of Materials Sciences and Engineering.

Thermal and magnetoelastic properties of a-RuCl₃ in the field-induced low temperature states

RICO SCHOENEMANN (Presenter), Los Alamos National Laboratory, SHUSAKU IMAJO, University of Tokyo, FRANZISKA WEICKERT, Los Alamos National Laboratory, YASUMASA TAKANO, University of Florida, STEPHEN E NAGLER, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee, MARCELO JAIME, Los Alamos National Laboratory — Magnetocaloric effect, thermal expansion, and magnetostriction measurements on single crystal α-RuCl₃ samples in applied magnetic fields are discussed. α-RuCl₃ has been established as a promising candidate for the sought-after physical realization of the Kitaev model, which describes $S=1/2$ spins on a honeycomb lattice with bond dependent Ising interactions, hosting Majorana fermions as well as a topological quantum spin liquid (QSL) ground state. Recent experimental data indicate signs of a QSL state that emerges in applied magnetic fields, once the antiferromagnetic (AFM) transition temperature $T_N$ observed in zero field below 7K is suppressed. In order to identify the nature of the phase transitions below $T_N$ and to map the phase diagram as a function of magnetic field, we conducted measurements of the magnetocaloric effect in pulse magnetic fields as well as thermal expansion and magnetostriction measurements in static fields up to 15 T. The results are discussed in the context of possible quantum critical and QSL behavior in α-RuCl₃.
9:12AM A56.00007: Multipartite Entanglement in the Kitaev Honeycomb Model  JAMES LAMBERT (Presenter), ERIK SORENSEN, McMaster Univ — Quantum spin liquid (QSL) phases of matter have proven extremely elusive from both experimental and theoretical perspectives. In the theoretical domain, examining the topological entanglement entropy has been a primary tool for diagnosing whether or not a model exhibits QSL physics in its groundstate. We study the Kitaev honeycomb model, a prototype of QSL physics in two dimensions, using the quantum Fisher information (QFI), which is both experimentally accessible and well defined at finite temperature. We explore he behaviour of the QFI in both the gapped and gapless phases and in the regions around the transition.

9:24AM A56.00008: Spin-one Kitaev-Heisenberg model on a two-dimensional honeycomb lattice  XIAOYU DONG (Presenter), Ghent University, DONNA SHENG, California State University, Northridge — We study the Kitaev-Heisenberg model with a spin-1 local degree of freedom on a two-dimensional honeycomb lattice numerically by density matrix renormalization group method. We obtain the phase diagram with two spin liquid phases and four symmetry broken phases. We identify that the spin liquid is gapless and has short-ranged spin-spin correlations within the whole phase. Comparing to its spin-1/2 counterpart, the spin-1 spin liquid has more gapless modes.

9:36AM A56.00009: Microscopic route to magnetic anisotropy in higher-spin honeycomb lattice: application to CrI$_3$  PANAGIOTIS PETER STAVROPOULOS (Presenter), HAE-YOUNG KEE, Univ of Toronto — In the past decade transition metal (TM) compounds have generated a wealth of theoretical and experimental research on frustrated magnetism, especially TM compounds that host local 1/2 moments. Spin-orbit coupling (SOC) of the TM cation sites plays a key role for the appearance and dominance of frustrated terms such as the Kitaev spin-1/2 term. Very recently it has been recognized that SOC of the anion sites is a viable route to realizing frustrated higher spin model terms from super-exchange paths [1]. We present the microscopic origin of frustrated S=3/2 model terms in d$^3$ systems. The appearance and competition of the Kitaev term with conventional spin model terms are presented. Applications of the theory to CrI$_3$ and related materials are also discussed.

9:48AM A56.00010: Two-Magnon Bound States in the Kitaev Model in a [111]-Field
SUBHASREE PRADHAN (Presenter), NIRA CVKUMAR PATEL, NANDINI TRIVEDI, Ohio State Univ - Columbus — It is now well established that the Kitaev honeycomb model in a magnetic field along the [111]-direction harbors an intermediate gapless quantum spin liquid (QSL) phase sandwiched between a gapped non-abelian QSL at low fields $H<H_c^1$ and a partially polarized phase at high fields $H>H_c^2$. Here, we analyze the low field and high field phases and phase transitions in terms of single- and two-magnon excitations using exact diagonalization (ED) and density matrix renormalization group (DMRG) methods. We find that the energy to create a bound state of two-magnons $\Delta_p$ becomes lower than the energy to create a single spin flip $\Delta_s$ near $H_c^2$. In the entire Kitaev spin liquid $\Delta_p<\Delta_s$ and both gaps vanish at $H_c^2$. We make testable predictions for magnon pairing that could be observable in Raman scattering measurements on Kitaev QSL candidate materials.

10:00AM A56.00011: Phase diagram of the spin-1/2 Kitaev-Gamma chain and emergent \`\`partial" SU(2) symmetry  WANG YANG (Presenter), ALBERTO NOCERA, TARUN TUMMURU, Physics, University of British Columbia, HAE-YOUNG KEE, Physics, University of Toronto, IAN AFFLECK, Physics, University of British Columbia — We study the phase diagram of a one-dimensional version of the Kitaev spin-1/2 model with an extra \`\` $\Gamma$'-term", using analytical, density matrix renormalization group and exact diagonalization methods. Two intriguing phases are found. In the gapless phase, the low energy theory is described by an emergent SU(2)$_1$ Wess-Zumino-Witten (WZW) model though the exact symmetry group is discrete. On the other hand, the relations between the local spin operators and the WZW currents and primary field contain SU(2) breaking coefficients. A modified nonabelian bosonization formula is proposed to capture such exotic emergent \`\`partial" SU(2) symmetry. In the ordered phase, there is numerical evidence for an $O_h \rightarrow D_8^\infty$ spontaneous symmetry breaking.

10:12AM A56.00012: Ab initio quantum chemical study of magnetic interactions in the honeycomb Kitaev-Heisenberg systems $\text{Cu}_2\text{IrO}_3$ and $\text{H}_3\text{LiIr}_2\text{O}_6$  MOHAMED ELDEEB (Presenter), RAVI YADAV, IFW - Dresden, NIKOLAY BOGDANOV, Max Planck Institute for Solid State Research, RAJYAVARDHAN RAY, SATOSHI NISHIMOTO, JEROEN VAN DEN BRINK, LIVIU HOZOI, IFW - Dresden — The magnetic interactions in honeycomb iridium oxide compounds are studied using quantum chemical wavefunction-based methods. Mapping the results onto the corresponding effective spin model shows the crucial dependence of the anisotropic magnetic couplings, in particular Kitaev exchange, on the precise position of inter-layer species and on additional geometrical factors such as Ir-O-Ir bond angles and Ir-O bond lengths. While the latter define the actual superexchange path between magnetic centers, the former may come into play through strong out-of-plane polarization of ligand 2p orbitals mediating intersite hopping [1,2].

**10:24AM A56.00013: Kitaev material candidates beyond the Iridates**

ARUN RAMANATHAN (Presenter), MARCUS DAUM, MARTIN MOURIGAL, HENRY S LA PIERRE, Georgia Inst of Tech — Na2MO3 (M = a tetravalent metal) based Mott insulators have been studied recently as potential candidates to realize Kitaev spin model. 4d5 or 5d5 systems on a Honeycomb lattice exhibit spinorbit assisted Mott insulating ground states. At the strong SOC regime, the ground state for these ions in an octahedral crystal field is dominated by Jeff=1/2 states resulting in bond-dependent anisotropic magnetic exchange in the plane, essential to realize the Kitaev spin model. However, candidates to realize the Kitaev spin model are not limited to 4d/5d systems. Lanthanide elements with significant SOC and inherent anisotropy can also be considered in this context. In this talk, I will present our work on a new lanthanide-based, Kitaev material candidate with a potential Jeff=1/2 ground state. Synthesis and structure of the material will be discussed. Physical property measurements coupled with inelastic neutron scattering results will be utilized to understand the single-ion characteristics of the lanthanide and to unveil the rich low-temperature physics of the material.

**10:36AM A56.00014: Ferrimagnetism and anisotropic phase tunability by magnetic fields in Na2Co2TeO6**

WEILIANG YAO (Presenter), YUAN LI, Peking Univ — Na2Co2TeO6 is a honeycomb-lattice compound with a zigzag antiferromagnetic order [1,2]. It has recently been proposed to be a Kitaev-like magnet based on high-spin d7 electron configuration [3,4]. To assess how close it is to realizing Kitaev quantum spin liquids, we have measured magnetization and specific heat on high-quality single crystals in magnetic fields applied along high-symmetry directions [5]. With small training fields, we find a canonical ferrimagnetic behavior below 27 K, which reveals additional Neel-type order of canted moments. Moreover, moderate fields in the honeycomb plane can suppress the thermal transition at 27 K, and seem to partly reverse the moment-canting when applied perpendicular to the zigzag chains. In contrast, out-of-plane fields leave the transition largely unaffected, but promotes another transition below 10 K, possibly also related to canting reversal. Our study indicates the magnetism of Na2Co2TeO6 is highly anisotropic and close to tipping points between competing phases.

We study magnetic structures and excitations in the series of A2PrO3 (A: alkali metals) by performing neutron scattering experiments. In these compounds, tetravalent praseodymium ions reside in edge-sharing PrO6 octahedra and the 4 f1 electrons exhibit Jeff=1/2 ground state doublet which result from a strong spin-orbital coupling and a weak octahedral crystal field. Furthermore, it was proposed that for A=Li, Na, the interactions are anti-ferromagnetic and dominantly Kitaev-type and therefore offer a potential playground for quantum spin liquid. We show evidence of anti-ferromagnetic phase transitions in such materials and provide possible effective Hamiltonians that will guide further searches for Kitaev spin liquids in rare earth compounds.

8:00AM A57.00001: Substituient Modified Covalent Organic Frameworks for Applications in Size Selective Separations*  VALERIE KUEHL (Presenter), PHUOC H.H. DUONG, JIASHI YIN, KATIE LI-OAKEY, WILLIAM D. RICE, BRUCE PARKINSON, JOHN HOBÉRG, Univ of Wyoming — Despite efforts, controlled placement of atoms, dopants, vacancies, and intercalates into crystalline lattices is only achieved in few systems and limited circumstances. Recent developments using metal or covalent organic frameworks (MOFs/COFs) show promise as synthetically configurable motifs. COFs are frameworks whose crystals are punctuated by a lattice of ordered nanopores where size, spacing, and filling are controlled. These nanopores are populated with substituents creating tailored properties for charge/size selective separations, particular emission properties, and Fermi level control. Here, we present the synthesis, characterization, and functional properties of four different COFs. Characterization includes atomic force microscopy, X-ray diffraction, and electron microscopy to show that the COFs are 2D, crystalline, and uniform, respectively. Finally, we show that COFs can be used to separate ions and proteins by size/charge, demonstrating the technological utility of these materials.

8:12AM A57.00002: Anharmonic renormalization of flexural acoustic modes in graphene and their effect on the mechanical stability of the membrane UNAI ASEGINOLAZA (Presenter), AITOR BERGARA, ION ERREA, Centro de Física de Materiales — The mechanical stability and long-range crystalline order of two dimensional materials has always been under debate [1], however, since the discovery of graphene, the debate is only theoretical. 2D materials are invariant upon any rotation by putting the axis in the plane where the system is. This symmetry obliges the harmonic dispersion of the acoustic out-of-plane modes to be quadratic close to the point gamma in the first Brillouin zone, instead of linear, and this functionality makes the membrane unstable. The instability is translated as diverging atomic displacements as a function of the sample size and finite line width of phonons with very low crystal momentum [2].

These instabilities arise within the harmonic approximation, however, an anharmonic approach may suppress them. In this work we apply an anharmonic method named stochastic self-consistent harmonic approximation [3]. We see that the inclusion of anharmonic effects suppresses the divergence in the atomic displacements and provides a vanishing line width to the phonons with very low crystal momentum.

8:24AM A57.00003: Phonon lifetimes and scattering processes in carbon fiber systems JENNIFER NIEDZIELA (Presenter), ANDREW MISKOWIEC, JOHN J LANGFORD, ZACHARY BRUBAKER, SARA B ISBILL, ASHLEY SHIELDS, ROGER J KAPSIMALIS, Oak Ridge National Lab — Carbon fibers show ultrahigh strength to weight ratio and are sought as a replacement for steel in numerous industries. The basic morphology of carbon fiber is a collection of graphitic regions, with a higher degree of graphitization correlated with a higher stiffness fiber. Currently carbon fiber applications are limited by the inability to obtain high strength and high stiffness in the same fiber, which is presumably due to the effect of defects in the carbon fiber matrix. Here we present an overview of the microstructure and spectral features of carbon fiber obtained from Raman and x-ray scattering spanning a broad range of carbon fiber mechanical properties. The combined results show a direct correlation between estimated interdefect distance and ultimate fiber strength and a reduction in overall phonon lifetime for defect-mediated modes for high strength fibers. Efforts to understand phonon transport across defect boundaries in large scale models of defected graphite analogues are underway and will be briefly discussed.
8:36AM A57.00004: Role of grain orientation mismatch in friction of graphene layers using the Lennard-Jones and DRIP potentials*  HUYAN LI (Presenter), WOO KYUN KIM, Univ of Cincinnati — Graphene, as a one-atom thick 2-D material, is an ideal solid lubricant for small length scale devices such as micro/electro-mechanical systems. Without an accurate interatomic potential, the friction property of graphene is difficult to predict properly. In this study, two interatomic potentials, Lennard-Jones (LJ) and dihedral-angle-corrected registry-dependent interlayer (DRIP), are used to model interlayer interactions in friction simulations of multilayer graphene models. Both potentials have similar attractive interactions, but the DRIP potential considers the dihedral angle as well as the bond distance to model the repulsive interaction. We investigate the friction properties between a pristine layer and a single grain layer with different orientation angles using molecular dynamics (MD) simulations. The simulation results reveal that the LJ potential shows an increase in friction at misorientation angle of about 0.3° compared to a model with an angle of 0°. On the contrary, the DRIP models exhibit a monotonous decrease with increasing misorientation angle, which is attributed by the change in potential energy surface due to the dihedral angle.

8:48AM A57.00005: Particle swarm optimized interatomic potentials for novel 2D materials for temperature dependent vibrational properties  OGUZ GULSEREN (Presenter), ARASH MOBARAKI, Bilkent Univ, CEM SEVIK, Mechanical Engineering, Eskisehir Technical University — Two-dimensional materials are expected to become key components for novel applications because of their exotic properties. Predicting the mechanical and thermal properties of two dimensional materials is an essential task necessary for their implementation in device applications. Fully understanding of most of the material properties needs an atomistic description. Although, rigorous density functional theory based calculations are able to predict mechanical and electronic properties, mostly they are limited to zero temperature. Classical molecular dynamics facilitates the investigation of temperature dependent properties, but its performance highly depends on the potential used for defining interactions between the atoms. In this study, we calculated temperature dependent phonon properties of several single layer 2D systems including graphene, silicene, group III nitrides, i.e GaN, AlN and BN, and TMDs by developing particle swarm optimized Stillinger-Weber type potentials with respect to the first-principles datasets. These potentials validated by comparing the resulted phonon dispersion curves and thermal conductivities with available first-principles and experimental results.
Several layered transition metal dichalcogenides (TMDs) exhibit unusually high transition temperatures to different charge-density-wave (CDW) symmetry-reducing phases, revealing interesting physics, and opening possibility for practical applications of such materials. One of the most promising materials, 1T-TaS2, has the CDW transition between the nearly-commensurate (NC-CDW) and the incommensurate (IC-CDW) phases at 350 K, the transition to the normal metal phase at 550 K – 600 K. In this invited talk, I will review our recent results on controlling the CDW phase transitions in 2D materials with applied electric bias, and monitoring them via low-frequency electronic noise spectroscopy [1-6]. The noise spectroscopy has been particularly effective for monitoring the switching from the IC-CDW phase to the normal metal phase in 1T-TaS2. The noise spectral density exhibits sharp increases at the phase transition points, which correspond to the step-like changes in resistivity. The noise spectroscopy was instrumental in revealing the “hidden phase transitions” in vertical 1T-TaS2 devices. Preliminary data on the “narrow-band noise” in quasi-2D CDW devices will also be presented. We found that the 1T-TaS2 CDW devices reveal exceptional hardness against X-ray and proton radiations. We explained this property of the CDW devices by the high carrier concentration in all their phase states, two-terminal design, and the thin-film channel geometry.

Impact of intrinsic and extrinsic imperfections on the electronic and optical properties of MoS$_2$* [Invited]  

URSULA WURSTBAUER, University of Muenster, JULIAN KLEIN (Presenter), Walter Schottky Institute of Munich Technical University — Substrate, environment and lattice imperfections have strong impact on the local electronic structure and the optical properties of atomically thin transition metal dichalcogenides. Moreover, luminescent centers can be created on demand and with nm lateral precision using a focused helium ion beam [1,2]. We report on a combined optical and scanning tunneling spectroscopy (STS) study of MoS$_2$ on SiO$_2$ and hBN substrate. We demonstrate that apparent band gap for MoS$_2$ on SiO$_2$ is significantly reduced compared to MoS$_2$ what can be explained by a substantial amount of band tail states near the conduction band edge of MoS$_2$. The presence of those states in STS can be linked to a broad red-shifted PL peak that are all strongly diminished or even absent using high quality hBN substrates [3]. Suppression of the L peak by hBN encapsulation enables to spectrally isolate a very narrow emission potentially serving as single photon source that can be precisely engineered by the focused helium ion beam [4].

Nanocharacterization of 2D Hybrid Materials by Near-Field Microscopy*  

TETYANA IGNATOVA (Presenter), Nanoscience, Univ of NC - Greensboro, SLAVA V. ROTKIN, Engineering Science and Mechanics, Penn State University — Methods of Near-Field Microscopy are high-throughput non-destructive techniques, which can be used for characterization of 2D Hybrid Materials with sub-micrometer resolution as well as for device inspection. Here we show near field data on 2D samples with various electronic properties, from metals to semiconductors. Simple physical models are proposed for near-field analysis.

10:24 AM A57.00009: One Dimensional Electronic Structure Studies on Monolayer MoS$_2$ Grain Boundaries  
JUN JUNG (Presenter), YONG-HYUN KIM, Department of Physics, KAIST — On the boundary of the material, low dimensional electronic states, which are localized on the boundary, can be created. In this research, we have investigated grain boundaries of monolayer MoS$_2$ as a platform of one-dimensional (1D) physics. We have studied the electronics structures by density-functional theory calculations. We have designed a specific atomic structure of the boundary so that defect states show significantly low bandwidth, comparing to the bulk band. Due to low bandwidth, electrons can create spin or charge order on the boundary. Magnetism is obtained when electron doped case, which can be realized by MoS$_2$/Graphene heterojunction. Energetically the system favors antiferromagnetism compared to ferromagnetism. These magnetic orders solely derived from electronic structure instabilities. In addition to that, charge density wave can also be formed on the boundary of the grains. Our research suggests possibility of 1D interacting electrons on transition metal dichalcogenide grain boundaries.

10:36 AM A57.00010: Analysis of Raman scattering spectra of single-layer graphene doped with an ionic liquid*  
DAIKI INUKAI (Presenter), TAKESHI KOYAMA, Nagoya Univ, KENJI KAWAHARA, HIROKI AGO, Kyushu Univ, HIDEO KISHIDA, Nagoya Univ — Fundamental understanding of the electronic states of electrochemically doped single-layer graphene is essential for achievement of electric and electronic graphene devices. We fabricated a planar-type electrochemical cell operated with an ionic liquid, which is suitable for spectroscopic measurements. In the cell, the electric double layer induced by application of voltage results in high doping density. We observed Raman active phonon modes of graphene at various doping levels. The spectral shape of the G phonon mode reflects the effect of Fano resonance between the phonon excitation and the electronic excitation and becomes asymmetric depending on the degree of the effect. We performed a fitting analysis using a Breit-Wigner-Fano function to estimate the strength of the Fano coupling. On basis of the analysis, we discuss the electronic states of the single-layer graphene doped with ionic liquid.

The Predictive Power of Exact Constraints and Appropriate Norms in Density Functional Theory

JOHN P. PERDEW (Presenter), Depts. of Physics and Chemistry, Temple University — Approximations to the density functional for the exchange-correlation energy of Kohn-Sham theory can be constructed by fitting to data sets for bonded systems, or by satisfying exact mathematical constraints on the functional and appropriate norms (such as the uniform electron gas), or both. Fitting is interpolative, and can predict accurately for systems similar to those in the data sets, while satisfying exact constraints makes a functional more widely predictive over the immense space of possible molecules and materials. For example, the SCAN (strongly constrained and appropriately normed) functional [1] satisfies all 17 exact constraints that a computationally-efficient meta-generalized gradient approximation can, and has been remarkably successful for some complex materials (like liquid water [2]) and some strongly-correlated materials (like the cuprate high-temperature superconducting materials [3,4]). Prospects for an improved SCAN and for the correction of its residual self-interaction error will also be discussed.

**8:36AM A58.00002: Assessment of DFAs in predicting the magnetization of transition metal solids**

ALBERTO VELA (Presenter), CINVESTAV-IPN, KARLA A BOTELLO MANCILLA, ESIQIE, IPN, ANGEL M ALBAVERA MATA, CINVESTAV-IPN, SAMUEL TRICKEY, Quantum Theory Project, Department of Physics and Department of Chemistry, University of Florida, JOSE L GAZQUEZ, Chemistry, UAM-Iztapalapa — It has been recently reported that SCAN over stabilizes higher magnetic moments for the itinerant magnets Fe, Co and Ni.[1-4] Here we present and discuss the performance of a variety of generalized and meta-generalized gradient approximations, including our recently proposed locally parameterized GGAs, on the magnetic properties of a set composed of 3d, 4d and 5d metals, a total of 29 solids. Detailed analyses of the itinerant magnets further show different behaviors between the band structures calculated with SCAN versus those with PBE [5] and SCAN-L [6,7] at the magnetization saturation.

**8:48AM A58.00003: The Importance of Smoothness with Exact Constraints in Functional Design**

JAMES FURNESS (Presenter), Physics and Engineering Physics, Tulane University, AARON KAPLAN, JOHN P. PERDEW, Temple University, JIANWEI SUN, Physics and Engineering Physics, Tulane University — There are two core goals in exchange-correlation functional design: accuracy and efficiency. Whilst modern semi-local functionals have greatly improved accuracy, this has often been at the cost of efficiency. Our previous work [1], and that of others [2], has shown the iso-orbital indicator $\alpha$ as a key component in this sensitivity, compounded by sharply varying interpolation functions. In a recent publication [2] Bartók and Yates propose a regularised SCAN (rSCAN) that resolves these numerical problems for the SCAN functional [3] at the expense of breaking some exact constraints. The uniform electron gas and slowly varying density limits are broken, along with incorrect coordinate scaling of the regularised iso-orbital indicator $\alpha_r$.

We restore these constraints while preserving regularisation to give a new functional, $r^2$SCAN. We explore how constraint restoration affects accuracy and efficiency in simple systems for which exact constraints are important.

Analysis of over-magnetization of elemental transition metal solids from the SCAN and three related density functionals.*

DANIEL MEJIA-RODRIGUEZ (Presenter), SAM TRICKEY, University of Florida — Recent investigations have found that the strongly constrained and appropriately normed (SCAN) meta-generalized gradient approximation exchange-correlation functional significantly over-magnetizes elemental Fe, Co, and Ni solids [1]. The difficulty does not occur in SCAN-L (deorbitalized SCAN) [2]. The problem have been traced to the tendency to favor integer occupations, similar to a DFT+U treatment [3]. We discuss what properties of the SCAN, revSCAN and rSCAN functional forms are responsible for such errors, and why the SCAN-L functional does much better in this respect [2].

S.B.T. also was supported by U.S. Department of Energy Energy Frontier Research Center grant DE-SC0019330.

Failure of the SCAN functional for itinerant magnets and the reasons*

DAVID SINGH (Presenter), YUHAO FU, Univ of Missouri - Columbia — The SCAN functional fails dramatically in its description of itinerant magnets including the elements Fe, Ni and Co. We report that SCAN is closer in behavior to functionals that yield localized behavior, such as hybrid functionals, than other semilocal functionals that are tested. The results are understood in terms of a tendency to differentiate orbitals, favoring integer occupation, which is necessary for a correct description of atomic systems, but inappropriate for the open shell metallic ferromagnetic metals. This has to do with the fitted nature of SCAN where it reproduces selected “norms”.

*Work supported by the U.S. Department of Energy, Basic Energy Sciences, Award DE-SC0019114.
9:24AM A58.00006: Assessment of SCAN and regularized SCAN functional with and without self-interaction correction

ALAN SALCEDO (Presenter), YOH YAMAMOTO, TUNNA BARUAH, RAJENDRA ZOPE, University of Texas at El Paso — The Strongly Constrained and Appropriately Normed (SCAN) is a non-empirical meta-GGA functional that satisfies all the known 17 exact constraints that a meta-GGA functional can. Its numerical implementation is challenging and its use requires extremely fine numerical grids. The numerical issues become even more pronounced for the Perdew-Zunger (PZ) self-interaction correction (SIC) method as it requires evaluating the functional and its derivatives with orbital density that varies rapidly compared to total density. Bartok and Yates recently proposed a modification to SCAN, called regularized SCAN (rSCAN) to remove some of the numerical instabilities of SCAN. We have implemented rSCAN functional in our Fermi-Lowdin Self-Interaction Correction code and performed assessment of rSCAN for various molecular properties using standard datasets. We find rSCAN gives similar results to SCAN despite violation of some of the constraints and requires comparatively coarser grids than SCAN. However, like SCAN, rSCAN also shows numerical instabilities in PZ-SIC calculations where orbital densities are used. This problem is due to the use of variable $\alpha$ in these functionals. A solution to this numerical instability is suggested and implemented.

*U.S. DOE under grants DE-SC0018331 and DE-SC0006818.

9:36AM A58.00007: Systematizing Approximate Density Functional Design

AARON KAPLAN (Presenter), Temple University, JAMES FURNESS, JIANWEI SUN, Tulane University, JOHN P. PERDEW, Temple University — A meta-GGA with well-rounded accuracy and efficient numerical performance for all many-electron systems has proved to be elusive. TPSS, while accurate for many systems, never reaches predictive accuracy. SCAN [1], motivated by a need to systematize development of approximate density functionals, is often predictive, but falters for metallic systems [2]. In this talk, I'll discuss the need to further systematize the construction of approximate density functionals. The design of possible successors to SCAN, with results for transition metals and weakly-bonded systems, as well as improvements in meta-GGA numeric efficiency from new iso-orbital indicators [3] will also be discussed.

*This work was supported by DOE, BES, grant No. DE-SC001255.
Evaluating exchange correlation performance on structural prediction from GGA to metaGGA*  
PEDRAM TAVADZE (Presenter), Department of Physics, West Virginia University, MATTHIEU J VERSTRAETE, Department of Physics, Université de Liège, ALDO H ROMERO, Department of Physics, West Virginia University — The use of density functional theory in materials prediction and structural characterization is a very well-established field. We use this methodology in a high throughput framework, where thousands of materials are analyzed and classified in databases. This step has become quite standard and many databases do not discuss their most basic approximation: which exchange correlation functional has been used. While much work has been done on the functional dependency of the cell parameters and ground state space group, little is known for the internal degrees of freedom. A crystal structure can be reduced to the cell parameters and the Wyckoff positions (WPs), some of which can add additional degrees of freedom to the crystal structure. In this work we analyze the effect on the internal degrees of freedom of more than 1500 structures, both metallic and semiconductor materials from completely local functionals as LDA up to meta-GGAs using the recently introduced SCAN.

Single Hamiltonian for self-interaction corrected DFT with Fermi-Lowdin orbitals  
TUNNA BARUAH (Presenter), MARK PEDERSON, University of Texas, El Paso — The self-interaction error in density functional approximation arises from the incomplete cancellation of self-Coulomb by self-exchange. The self-interaction correction proposed by Perdew and Zunger corrects for this error through an orbital by orbital scheme. The resulting SI corrected potential for the electrons becomes orbital dependent. The original SI corrected energy was not unitarily invariant with respect to orbital transformations. The energy minimization requires finding the set of orbitals that minimizes the total energy. Recent development of Fermi-Lowdin orbital based self-interaction correction scheme is a step forward in that energy is unitarily invariant under orbital transformation to localized Fermi Lowdin orbitals. We show that within the Fermi-Lowdin orbital based self-interaction correction scheme it is also possible to derive a single Kohn-Sham multiplicative Hamiltonian for all orbitals which decreases the computational complexity. Implementation of this method is discussed and the results show that the energy is slightly lower and required time is significantly less than other approximate methods for obtaining the canonical orbitals.
10:12AM A58.00010: Self-interaction correction and dielectric properties of molecules
KUSHANTHA WITHANAGE (Presenter), ALEXANDER I JOHNSON, JUAN PERALTA, Central Michigan Univ, YOH YAMAMOTO, RAJENDRA ZOPE, TUNNA BARUAH, Physics, University of Texas, El Paso, KOBLAR ALAN JACKSON, Central Michigan Univ — We recently used the Fermi-Löwdin orbital implementation of the Perdew-Zunger self-interaction correction (FLO-SIC) to study the impact of self-interaction error on the prediction of dipole moments of molecules and polarizabilities for atoms (DOI: 10.1103/PhysRevA.100.012505). Using FLO-SIC in conjunction with the local spin density approximation (LSDA), the Perdew-Burke-Ernzerhof (PBE) generalized gradient approximation, and the strongly-constrained and appropriately normed (SCAN) meta-GGA, we have found that application of SIC generally improves predictions, but typically results in overshooting reference values. In this talk, we examine this overcorrection and discuss simple approaches to overcome it.

*This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Award Number DE-SC0018331.

10:24AM A58.00011: Fermi-Löwdin self-interaction correction for ground and excited states
SANTOSH ADHIKARI (Presenter), Department of Physics, Temple University, RAJENDRA RZOPE, CARLOS DIAZ, Department of Physics, The University of Texas at El Paso, ADRIENN RUZSINSZKY, Department of Physics, Temple University — Self-interaction error (SIE) is strongly present in ground-state density functional theory (DFT) and propagates into time-dependent DFT as well. A significant requirement of the self-interaction correction (SIC) is the localization of the orbitals, as required by size-consistency. In 2014, Pederson and collaborators recommended a computationally much more attractive version of the earlier Perdew-Zunger (PZ) SIC [1]. This SIC utilizes Fermi orbitals, greatly restricting the number of possible unitary transformations of the occupied Kohn-Sham orbitals. This work is a straightforward continuation of the Fermi orbital PZ-SIC to test crucial physical properties relevant for both ground, and excited states, with the potential to eliminate SIE for excitation energies.

*This work was supported by the Department of Energy under Grant No. DE-SC0018331.
Assisting the performance of self-interaction-corrected SCAN meta-GGA functional using an orbital scaling approach

YOH YAMAMOTO (Presenter), RAJENDRA ZOPE, TUNNA BARUAH, University of Texas at El Paso — Semilocal density functional approximations (DFAs) suffer from self-interaction (SI) error which limits their applicability. The Perdew-Zunger SI correction (PZSIC) improves the description of properties such as barrier heights or dissociation energies where SI error is dominant but it degrades already good performance of DFAs when applied to GGA and meta-GGA functionals. We implemented the orbital scaling approach of Vydrov et al.[1] that scales down orbital wise PZSIC in the FLOSIC code and use it with SCAN functional to assess its performance for a wide range of properties such as total energies, ionization potentials, and electron affinities for atoms, and atomization energies, dissociation and reaction energies, and reaction barrier heights of molecules. Our results show that orbital scaling recovers the performance of SCAN that is lost with SIC. We suggest a modification to recover \(-1/r\) asymptotic behavior of the potential lost by the scaling scheme of Vydrov et al. We also discuss the cases where the orbital scaling is not successful. General strategies of applying the scaling and how to improve its performance will be discussed in this talk.

*U.S. DOE under grants DE-SC0018331 and DE-SC0006818.

Stabilizing ferromagnetism in the Weyl semimetal candidate EuCd$_2$As$_2$*

BRINDA KUTHANAZHI (Presenter), NA HYUN JO, YUN WU, Iowa State University/Ames Laboratory, TAE-HOON KIM, LIN ZHOU, Ames Laboratory, ERIK I TIMMONS, Iowa State University/Ames Laboratory, LIN-LIN WANG, ANDRIY PALASYUK, Ames Laboratory, KYUNGCHAN LEE, BENJAMIN SCHRUNK, Iowa State University/Ames Laboratory, BENJAMIN UELAND, Ames Laboratory, ANTON BURKOV, University of Waterloo, RUSLAN PROZOROV, SERGEY L. BUD’KO, ADAM KAMINSKI, PAUL C CANFIELD, Iowa State University/Ames Laboratory — EuCd$_2$As$_2$ is predicted to host a variety of topological features in its band structure depending on its magnetic ground state. A ferromagnetic state with spins oriented along the crystallographic c axis is expected to have a single pair of Weyl points near the Fermi energy. [1] Previously published work on EuCd$_2$As$_2$ report it to have an antiferromagnetic ground state. [2,3] Here, we present the synthesis and characterization of single crystals of EuCd$_2$As$_2$ that, with varying initial stoichiometries, can be tuned from an antiferromagnetic ground state (T$_N$ ~ 9.5 K) to a ground state with a clear ferromagnetic component (T$_C$ ~ 30 K). Measurements of magnetization, magneto-optical Kerr rotation, specific heat and resistivity will be presented and discussed.

*This work was carried out at Iowa State University and supported by Ames Laboratory, US DOE, under Contract No. DEAC0207CH11358 and the Center for Advancement of Topological Semimetals, an Energy Frontier Research Center funded by the U.S. DOE, Office of Basic Energy Sciences and by the Gordon and Betty Moore Foundation (NHJ).

A New Magnetic Topological Quantum Material Candidate by Design: EuSn$_2$P$_2$

XIN GUI (Presenter), Louisiana State University, Baton Rouge, IVO PLETIKOSIC, Princeton University, HUIBO CAO, Oak Ridge National Lab, HUNG-JU TIEN, National Cheng Kung University, XITONG XU, Peking University, RUIDAN ZHONG, Princeton University, GUANGQIANG WANG, Peking University, TAY-RONG CHANG, National Cheng Kung University, SHUANG JIA, Peking University, TONICA VALLA, Brookhaven National Lab, WEIWEI XIE, Louisiana State University, Baton Rouge, ROBERT J. CAVA, Princeton University — Magnetism, when combined with an unconventional electronic band structure, can give rise to forefront electronic properties such as the quantum anomalous Hall effect, axion electrodynamics and Majorana fermions. Here we report the characterization of high-quality crystals of EuSn$_2$P$_2$, a new quantum material specifically designed to engender unconventional electronic states plus magnetism. EuSn$_2$P$_2$ has a layered, Bi$_2$Te$_3$-type structure. Ferromagnetic interactions dominate the Curie-Weiss susceptibility, but a transition to antiferromagnetic ordering occurs near 30 K. Neutron diffraction reveals that this is due to two-dimensional ferromagnetic spin alignment within individual Eu layers and antiferromagnetic alignment between layers - this magnetic state surrounds the Sn-P layers at low temperatures. The bulk electrical resistivity is sensitive to the magnetism. Electronic structure calculations reveal that EuSn$_2$P$_2$ might be a strong topological insulator, which can be a new magnetic topological quantum material (MTQM) candidate. The calculations show that surface states should be present, and they are indeed observed by ARPES measurements.
8:24AM A59.00003: Angle resolved photoemission spectroscopy study on EuCd$_2$As$_2$*  

HYUN JO (Presenter), YUN WU, Department of Physics and Astronomy, Ames Laboratory/Iowa State University, LIN-LIN WANG, Ames Laboratory, KYUNGCHAN LEE, BRINDA KUTHANAZHI, BENJAMIN SCHRUNK, SERGEY L. BUD'KO, PAUL C CANFIELD, ADAM KAMINSKI, Department of Physics and Astronomy, Ames Laboratory/Iowa State University — Recently, DFT calculations on EuCd$_2$As$_2$ in a FM ordered state with Eu moments aligned along the c-axis revealed a single pair of Weyl points. However, previous experimental studies on EuCd$_2$As$_2$ show that the magnetism is an A-type AFM with $T_N \approx 9.5$ K. Here, by discovering and taking advantage of EuCd$_2$As$_2$ chemical tunability, we report successful growths of single crystals of EuCd$_2$As$_2$ with two different magnetic ground states: FM-EuCd$_2$As$_2$ and AFM-EuCd$_2$As$_2$. Angle resolved photoemission spectroscopy shows an anomalous suppression of scattering in ferromagnetic Weyl semimetal candidate EuCd$_2$As$_2$. Unexpectedly, scattering rate is suppressed only in one of the bands over limited energy range that is controlled by presence of another, completely filled band. Such selectivity is highly unusual and can have potential impact on spin transport.

8:36AM A59.00004: Ultrafast carrier dynamics in the ferromagnetic semimetal EuCd$_2$As$_2$*  

KENNETH O'NEAL (Presenter), LAMOYNE TYLER MIX, MIN-CHEOL LEE, Los Alamos National Laboratory, BRINDA KUTHANAZHI, NA HYUN JO, SERGEY L. BUD'KO, PAUL C CANFIELD, Ames Laboratory, Iowa State University, ROHIT P PRASANKUMAR, DZMITRY YAROTSKI, Los Alamos National Laboratory — We report the near-infrared pump-probe ultrafast response of the ferromagnetic candidate for Weyl semimetal EuCd$_2$As$_2$. A non-pulsewidth limited rise dynamic is followed by two distinct decay processes – a sub-picosecond decay attributed to electron-phonon relaxation and a several picosecond long process which stems from demagnetization of the in-plane magnetic moment. Exponential fits of the decay processes down to 6 K reveal sensitivity to the long range magnetic ordering. These findings indicate strong coupling between charge and spin degrees of freedom, a step towards magnetic field or light control of topological Weyl states.

*Research presented in this presentation was supported by the Laboratory Directed Research and Development program of Los Alamos National Laboratory under project number E1TT.
8:48AM A59.00005: Single crystal growth of Weyl semimetal candidates  SUDHA KRISHNAN (Presenter), TIGLET BESARA, Missouri State Univ — Following the discovery of topological Weyl semimetals in non-magnetic materials, ferromagnetic Weyl semimetals have now been discovered with materials such as YbMnBi$_2$, Co$_2$MnGa, and Co$_3$Sn$_2$S$_2$. With the different structures of the already discovered ferromagnetic Weyl semimetals, this suggests that more ternary intermetallic compounds can be found displaying the connection between ferromagnetism and topology. Here, we report a systematic growth study and search for other ternary intermetallics displaying magnetism and topology. We utilize metallic self-flux methods to grow single crystals of compounds isostructural to YbMnBi$_2$ and Co$_2$MnGa.

9:00AM A59.00006: Giant room temperature anomalous Hall effect and magnetically tuned topology in the ferromagnetic Weyl semimetal Co$_2$MnAl* PEIGANG LI, Tulane University, JAHYUN KOO (Presenter), Weizmann institute of science, WEI NING, Pennsylvania state University, JINGUO LI, Chinese Academy of Sciences, LEIXIN MIAO, LUJIN MIN, YANGLIN ZHU, YU WANG, NASIM ALEM, CHAO-XING LIU, Pennsylvania state University, ZHIQIANG MAO, Tulane University, BINGHAI YAN, Weizmann institute of science — Weyl semimetals have been extensively studied due to their exotic properties such as topological surface states and anomalous transport phenomena. Their band structure topology is usually predetermined by material parameters and can hardly be manipulated once the material is formed. By calculations and experiments, we reveal a tunable, giant anomalous Hall effect in the ferromagnet Co$_2$MnAl. The transition between Weyl points and nodal rings occurs when rotating the magnetization axis. We propose a material recipe to generate the giant anomalous Hall effect by gaping nodal rings without requiring the existence of Weyl points. In addition, experiments show the strong anomalous Hall effect even at room temperature with a large Hall angle 21%. Our work reveals an ideal intrinsically magnetic platform to explore the interplay between magnetic dynamics and topological physics for the development of a new generation of spintronic devices.

9:12AM A59.00007: Magnetotransport properties and fermiology in a layered rare-earth intermetallics*  TAKASHI KURUMAJI (Presenter), MIN GU KANG, Physics, MIT, SHIANG FANG, Physics, Harvard University, DAVID E GRAF, NHMFL, LINDA YE, Physics, MIT, YANG ZHAO, NIST, MUN K. CHAN, NHMFL, TAKEHITO SUZUKI, RICCARDO COMIN, Physics, MIT, JEFFREY LYNN, NIST, JOSEPH G CHECKELSKY, Physics, MIT — While a growing number of nonmagnetic topological phases are being proposed and discovered, the search for materials that combine nontrivial electronic topology with strong correlations has advanced at a slower pace [1]. Most studies have focused on doping magnetic elements into nonmagnetic topological materials [2] in which random disorder and low magnetic transition temperature are inevitable. Realization of magnetic topological state in stoichiometric compounds has the potential to enable an approach to the intrinsic properties of the system, and provide a chance to design candidates for higher temperature quantized anomalous Hall effect and axion electrodynamics [3]. We will discuss our recent attempts to design, synthesize, and characterize magnetic topological semimetals with a focus on layered materials with non-trivial magnetic order arising from rare-earth ions. We will describe transport, spectroscopic, and neutron scattering measurements as well as ab-initio calculations to develop an understanding of their underlying electronic/magnetic structure.

9:24AM A59.00008: Layered Rare-Earth Intergrowth Compounds: A Platform for Correlated and Topological Properties*  [Invited] JULIA CHAN (Presenter), ASHLEY WEILAND, GREGORY MCCANDLESS, Chemistry, University of Texas at Dallas — The single crystalline growth of lanthanide based intermetallics has garnered much interest in the last two decades, primarily due to their unusual magnetic and electrical properties. To study the intrinsic and physical properties of highly correlated quantum systems, the growth of single crystalline intermetallics is critical. With our ongoing efforts to grow single crystals of rare earth materials, the opportunity exists to discover new compositions or robust structure types enabling subsequent substitution for correlation studies for compounds with competing magnetic behavior. In this talk, examples of the strategic selection of rare earth layered intergrowth compounds will be presented. In particular, we will present a new class of Ce-based intermetallics for fundamental correlation between the subunits and structural motifs common in highly correlated materials. To advance the field, discovering new families of highly correlated material is vital to the advancement of correlated and topological materials.

10:00AM A59.00009: Synthesis and characterization of a new topological semimetal enabled by a charge density wave*  SHIMING LEI (Presenter), JINGJING LIN, Princeton University, ANDREAS TOPP, CHRISTIAN R AST, Max Planck Institute for Solid State Research, N. PHUAN ONG, LESLIE SCHOOP, Princeton University — Formation of charge density waves (CDWs) is a known mechanism to induce an energy gap or partial energy gap at the Fermi surface. Therefore, introducing a CDW can be a way to modify the band structure. In this work, we discuss the potential of a CDW being the key to realize materials with clean topological semimetal band structures, by gapping out unwanted trivial states at the Fermi level. We will introduce a class of materials that exhibits CDWs and discuss the effect of the structural distortion on the electronic structure. Finally, we will present electrical transport and angle resolved photoemission spectroscopy (ARPES) data on one magnetic topological semimetal candidate, which was identified through this method.

10:12AM A59.00010: Quantum Anomalous Hall Effect in Intrinsic Magnetic Topological Insulator MnBi₂Te₄  YUJUN DENG (Presenter), YIJUN YU, Fudan University, MENG ZHU SHI, University of Science and Technology of China, ZHONGXUN GUO, Fudan University, ZIHAN XU, SixCarbon Technology, JING WANG, Fudan University, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — In a magnetic topological insulator, nontrivial band topology conspires with magnetic order to produce exotic states of matter that are best exemplified by quantum anomalous Hall (QAH) insulators and axion insulators. Here, we probe quantum transport in MnBi₂Te₄ thin flake—a topological insulator with intrinsic magnetic order. In this layered van der Waals crystal, the ferromagnetic layers couple anti-parallel to each other, so bulk MnBi₂Te₄ is an antiferromagnet. Atomically thin MnBi₂Te₄, however, becomes ferromagnetic when the sample has odd number of septuple layers. Signatures of QAH effect are observed in few-layer MnBi₂Te₄ samples. Our results establish MnBi₂Te₄ as an ideal arena for further exploring various topological phenomena.
10:24AM A59.00011: Routes to quantum anomalous Hall effect from superlattice-like magnetic topological insulators* QIHANG LIU (Presenter), HONGYI SUN, PENGFEI LIU, Department of Physics, Southern University of Science and Technology, NI NI, CHAOWEI HU, Department of Physics and Astronomy, University of California, Los Angeles, KYLE GORDON, DANIEL DESSAU, University of Colorado, Boulder — Recently, MnBi$_2$Te$_4$ thin films were observed to manifest the quantum anomalous Hall effect (QAHE) at a temperature of 4.5 K under magnetic field. By realizing a bulk MnBi$_4$Te$_7$ with alternating [MnBi$_2$Te$_4$] and [Bi$_2$Te$_3$] layers, we suggest that MnBi$_4$Te$_7$ is a Z$_2$ antiferromagnetic topological insulator with a small out-of-plane saturation field of ~ 0.2 Tesla [1]. Using model Hamiltonian analysis and first-principle calculations, we then establish a topological phase diagram and map on it with different two-dimensional configurations, which is taken from the recently-grown magnetic topological insulators MnBi$_4$Te$_7$ and MnBi$_6$Te$_{10}$. These configurations manifest various topological phases, including quantum spin Hall effect with and without time-reversal symmetry, as well as QAHE. We then provide design principles to trigger QAHE by tuning experimentally accessible knobs, such as slab thickness and magnetization [2]. Our work reveals that superlattice-like magnetic topological insulators with tunable exchange interaction serve as an ideal platform to realize the long-sought QAHE in pristine compounds.

10:36AM A59.00012: A new method for tuning topological insulators with large carrier densities (~10$^{20}$/cc) to CNP and beyond* HAIMING DENG (Presenter), LUKAS ZHAO, The City College of New York, KYUNGWHA PARK, Physics, Virginia Tech, LIA KRUSIN-ELBAUM, The City College of New York — We report a new powerful method for tuning chemical potential in topological materials, capable of changing carrier densities by more than 10$^{20}$/cc. It involves the incorporation of H$^+$ into the device structure. The process is reversible by low-temperature annealing (< 100°C), and a finetuning of the chemical potential is easily achieved. We demonstrate this method to be effective in a variety of 3D bulk topological insulators (TIs) (e.g. Bi$_2$Te$_3$ and Sb$_2$Te$_3$), as well as in intrinsic magnetic TIs, such as Mn(Bi, Sb)$_2$Te$_4$. For example, Bi$_2$Te$_3$ which is initially p-type with hole carrier densities of >10$^{19}$/cc is converted to n-type with n >10$^{19}$/cc. This electron doping method should apply to other materials as well. Using a proper annealing protocol, the chemical potential is finetuned across the charge-neutral point (CNP), where the Hall resistance exhibits the ambipolar behavior and $R_{xx}$ has a maximum at the type conversion. This method does not create additional defects that reduce carrier mobility, nor induce any significant top-bottom surface asymmetries typical of electrostatic gating. The mechanism responsible for the H$^+$ doping will be discussed.

Session A60 DMP: Topological Materials: Thin Films and Hybrid Structures Mile High Ballroom 4A - Seongshik Oh, Rutgers University, New Brunswick - Tag(s): Focus

8:00AM A60.00001: Exploring topological superconductivity in topological insulator – superconductor hybrid devices* [Invited] MORTEZA KAYYALHA (Presenter), Pennsylvania State University — Topological insulators (TIs) coupled to s-wave superconductors (SC) are predicted to harbor a topological superconducting phase. In this talk, I will first talk about the SC-TI-SC junctions, where an anomalous enhancement of the critical current at low temperatures and a highly non-sinusoidal current-phase relation were observed. These results suggest superconductivity is induced in the spin-helical topological surface states and point toward nearly ballistic nature of superconducting transport. I will then introduce our recent work about the induced SC in a quantum anomalous Hall (QAH) insulator, as a potential platform for the realization of “chiral Majorana modes”. A recent transport experiment claimed the half-quantized two-terminal conductance plateau in a millimeter-size QAH – Nb hybrid structure as evidence for the chiral Majorana modes. However, there are serious concerns about this interpretation because non-Majorana mechanisms can also generate similar signatures, especially in a disordered QAH system. I will present a systematic study of the superconducting contact transparency and its influence on the two-terminal conductance measurements and provide a non-Majorana explanation for the appearance of the half-quantized plateau in the QAH – Nb hybrid devices.

8:36AM A60.00002: Majorana π-junctions in full-shell nanowire SQUIDs* DAVYDAS RAZMADZE (Presenter), EOIN C O’FARRELL, PETER KROGSTRUP, CHARLES MARCUS, Niels Bohr Institute, University of Copenhagen — Recent studies of InAs nanowires covered by full-shell Al superconductor showed signatures of Majorana zero modes (MZMs) around one applied axial-flux quantum [1]. Here, we study such wires in dc-SQUID geometry with a naturally-formed normal quantum dots in the Josephson junctions. In the trivial regime around zero axial-flux we find 0-π transition as the occupancy of a quantum dot is changed; the transition vanishes at one axial-flux quantum. In addition, we find that the critical currents of the Josephson junctions increase in the topological regime. Tunneling spectroscopy of a junction in the π-state reveals a discrete zero-energy state at one applied axial-flux quantum. Our observations are consistent with the theoretical models of MZMs coupling through a normal quantum dot [2,3].

8:48AM A60.00003: Quantum anomalous Hall effect using interfacial Green’s function method for an accurate mass gap  JINWOONG KIM (Presenter), DAVID VANDERBILT, Rutgers University, New Brunswick — By using a Green’s function method with DFT-based tight-binding parameters, we investigate the quantum anomalous Hall (QAH) effect at the interface between topological insulators (SnTe, SnSe) and magnetic insulators (EuS, EuSe, EuTe). QAH or axionic states, a subject of recent broad interest, are achieved by introducing an effective Zeeman field to a topological insulator whose surface Dirac cone then acquires a mass gap, resulting in exotic electromagnetic responses within the mass gap. A number of studies have demonstrated the appearance of such states by using diverse interfacial, magnetic-element-doped, and magnetic-topological systems in agreement with predictions. Although achieving a large mass gap is critical for further investigations and room temperature devices, the microscopic mechanisms determining the size of the mass gap have not been clearly addressed. In this study, we enumerate several combinations of topological crystalline insulators and magnetic insulators in a search for an optimal electronic structure, where a large mass gap is isolated inside a bulk insulating gap. The underlying mechanisms and their dependence on factors such as an external field will be discussed.

9:00AM A60.00004: Topological phase transition in epitaxial single layer FeTe$_{1-x}$Se$_x$/SrTiO$_3$(001)*  QIANG ZOU (Presenter), ZHUOZHI GE, CHENHUI YAN, HUIMIN ZHANG, LIAN LI, West Virginia University — Recent work shows evidence of topological superconductivity on the (001) surface of FeTeSe bulk crystals. In this work, we demonstrate both superconducting and topological phase transitions at higher temperature in FeTe$_{1-x}$Se$_x$ thin films, by reducing its thickness down to one atomic layer. High quality single layer FeTe$_{1-x}$Se$_x$ films are grown on SrTiO$_3$(001) substrate by molecular beam epitaxy and characterized by in situ scanning tunneling microscopy/spectroscopy and angle-resolved photoemission spectroscopy. We find the topological and superconducting properties to be strongly dependent on the Te concentration, which controls spin-orbit coupling. With increasing Te, the top of the valence band at the Γ point moves towards and then crosses the Fermi level, accompanied by a change of the band profile from parabolic to linear. Above a critical Te concentration of 80%, the linear valence band reverts back to parabolic and shifts back down below the Fermi level, characteristic of a topological phase transition. These findings and their implications for the emergence of topological phases in Fe-based superconductors at reduced dimensions will be presented at the meeting.

Tuning the electrical properties of GdSb thin films by epitaxial strain

HADASS INBAR (Presenter), Materials, University of California, Santa Barbara, SHOUVIK CHATTERJEE, MIHIR PENDHARKAR, Electrical & Computer Engineering, University of California, Santa Barbara, YU HAO CHANG, MAXWELL MILES BOCHEFF, TAOZHI GUO, TOBIAS L BROWN-HEFT, Materials, University of California, Santa Barbara, ALEXEI V FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, DAN READ, School of Physics and Astronomy, Cardiff University, CHRIS J PALMSTROM, Materials and Electrical & Comp. Eng, University of California, Santa Barbara — Early studies of rare-earth monopnictide (RE-V) thin films have focused mainly on their applications as buried ohmic contacts for III-V semiconductors, THz emitters and detectors, thermoelectrics, diffusion barriers, and plasmonic heterostructures. Recent predictions of topological semimetallic states and observations of extremely large magnetoresistance (XMR) in RE-Vs, and specifically GdSb, have opened up a new research front aimed at studying the interplay between magnetic ordering and XMR. Here we demonstrate the epitaxial growth and characterization of GdSb thin films with thickness varied from 3-60 nm and biaxial strains ranging from -2% to +2% lattice-mismatch. Utilizing x-ray diffraction, in-vacuo angle-resolved photoemission spectroscopy, SQUID magnetometry and magnetotransport measurements we map out shifts in energy bands and trends in exchange interaction parameters due to dimensional confinement and biaxial strain.

*Synthesis and ARPES experiments are supported by the US DOE (Contract No. DE-SC0014388). Development of the growth facilities and low temp. magnetotransport measurements are supported by the ONR VBFF Award No. N00014-15-1-2845. This research used resources of the ALS, which is a DOE Office of Science User Facility under contract No. DEAC02- 05CH11231.
Quantum transport in in-plane selective area InSb-Al nanowire quantum networks

DI XU (Presenter), QuTech and Kavli Institute of Nanoscience, Delft University of Technology, ROY OP HET VELD, Department of Applied Physics, Eindhoven University of Technology, VANESSA SCHALLER, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JASON JUNG, Department of Applied Physics, Eindhoven University of Technology, QINGZHEN WANG, MICHIEL DE MOOR, BART HESSELMANN, KIEFER VERMEULEN, JOURI BOMMER, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JOON SUE LEE, California Nanosystems Institute, University of California Santa Barbara, MIHIR PENDHARKAR, CHRIS J PALMSTROM, Electrical and Computer Engineering, University of California Santa Barbara, ERIK BAKKERS, Department of Applied Physics, Eindhoven University of Technology, LEO P KOUWENHOVEN, HAO ZHANG, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Strong spin-orbit semiconductor nanowires coupled to a superconductor are predicted to host Majorana zero modes. Exchange (braiding) operations of the Majorana modes form the logical gates of a topological quantum computer and require a network of nanowires. Here, we implement an in-plane selective-area growth technique for InSb-Al allowing complex semiconductor-superconductor nanowire networks with excellent quantum transport properties. Essential quantum transport phenomena for topological quantum computing are demonstrated in these structures including phase-coherent transport up to 5 harmonics of Aharonov-Bohm oscillations with a phase coherence length of ~10 μm. Tunneling spectroscopy on hybrid InSb-Al nanowires demonstrates a hard superconducting gap, accompanied by 2e-periodic Coulomb oscillations with an Al-based Cooper pair island integrated in the nanowire network. The results, together with possible Majorana signatures, confirm the high quality of the InSb nanowire networks, holding great promise for this platform for scalable topological networks.
Microwave spectroscopy reveals the quantum geometric tensor of topological Josephson matter*  
RAFFAEL KLEES (Presenter), GIANLUCA RASTELLI, Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany, JUAN CARLOS CUEVAS, Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain, WOLFGANG BELZIG, Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany — Quantization effects due to topological invariants such as Chern numbers have become very relevant in many systems, yet, key quantities as the quantum geometric tensor [1] providing local information about quantum states remain experimentally difficult to access. Recently, it has been shown that multiterminal Josephson junctions constitute an ideal platform to synthesize topological systems in a controlled manner [2]. We theoretically study properties of Andreev states in topological Josephson matter and demonstrate that the quantum geometric tensor of Andreev states can be extracted by synthetically polarized microwaves [3]. The oscillator strength of the absorption rates provides direct evidence of topological quantum properties of the Andreev states.

Observation of the non-Hermitian Skin effect in topoelectric circuits*  
TOBIAS HELBIG (Presenter), TOBIAS HOFMANN, University of Wurzburg, CHING HUA LEE, National University of Singapore, MARTIN GREITER, RONNY THOMALE, University of Wurzburg — A contemporary frontier of metamaterial research is the challenge non-Hermitian systems pose to the established characterization of topological matter. There, one of the most relied upon principles is the bulk-boundary correspondence (BBC): energy eigenvalues and eigenstates exhibit a perturbatively small change as the boundary conditions are modified from periodic to open by changing a single bond. The framework of BBC captures the emergence of protected surface states at the boundary of a system with non-trivial bulk topology. In this talk, we present a periodic circuit network, where gain and loss conspire with the violation of reciprocity to affect this principle dramatically. Switching from periodic to open boundary conditions results in a non-perturbative change of all eigenmodes in this system. We experimentally observe the non-Hermitian Skin effect with extensive mode localization at open boundaries for the first time.

10:00AM A60.00009: Reciprocal skin effect and its realization in a topolectrical circuit*

TOBIAS HOFMANN (Presenter), TOBIAS HELBIG, Institute for Theoretical Physics and Astrophysics, University of Wurzburg, FRANK SCHINDLER, Department of Physics, University of Zurich, CHING HUA LEE, Department of Physics, National University of Singapore, MARTIN GREITER, Institute for Theoretical Physics and Astrophysics, University of Wurzburg, TITUS NEUPERT, Department of Physics, University of Zurich, RONNY THOMALE, Institute for Theoretical Physics and Astrophysics, University of Wurzburg —

The non-Hermitian Skin effect constitutes a new paradigm in synthetic metamaterial research. The established notion of the Skin effect requires specifically tailored gain and loss conspiring with the breaking of reciprocity. In this talk we present a model which shows extensive eigenmode localization at its boundaries while preserving reciprocity. In contrast to non-reciprocal implementations of the Skin effect requiring external energy supply, this model can be realized with exclusively passive components. We demonstrate this novel phenomenon in a passive RLC circuit network. The reciprocal Skin effect suggests itself for realizations in further metamaterial platforms with limited availability of active components.

10:12AM A60.00010: Tuning Electronic Band Properties in Binary Chalcogenides with Extrinsic and Intrinsic Strain: A First-Principles Study  THOMAS REID (Presenter), Institute of Materials Science, University of Connecticut, SANJEEV K NAYAK, Materials Science and Engineering, University of Connecticut, R.M. GEILHUF, NORDITA, KTH Royal Institute of Technology; Department of Physics, University of Connecticut, PAMIR ALPAY, Materials Science and Engineering, University of Connecticut, ALEXANDER BALATSKY, NORDITA, KTH Royal Institute of Technology; Department of Physics, University of Connecticut — We assess the relationship of the electronic band structure and atomic relaxation in Bi$_2$Se$_3$ and Bi$_2$Te$_3$. We use first-principles Density Functional theory (DFT) method to control for the influence of the exchange-correlation functional (XCF) and slab thickness. After a thorough analysis, in which we modulate the input parameters over a broad swathe of the computational space, we conclude that the GGA+vdW functional reproduces experimental results with best relative computational efficiency. In addition, we conclude that the use of experimental lattice parameters (ELP)—instead of ab initio ones—is sufficient to generate accurate descriptions of the electronic properties. After making this determination, we study the effect of doping on the electronic structure of As$_2$Te$_3$ and Bi$_2$Se$_3$, in the context of another study on the effect of biaxial strain on the same. In accordance with the first set of results, we use GGA+vdW as the XCF, and we use the ELP as the basis of both materials’ unrelaxed structure. Our results are valuable for the development of mechanisms for tuning the electronic properties of topological and trivial insulators.

10:24AM A60.00011: Predicting two-dimensional topological phases in Janus materials by substitutional doping in transition metal dichalcogenide monolayers*  ANICETO B. MAGHIRANG III, ZHI-QUAN HUANG, ROVI ANGELO B. VILLAOS, CHIA-HSIU HSU, LIANG-YING FENG, Physics, National Sun Yat-sen University, EMMANUEL FLORIDO, Institute of Mathematical Sciences and Physics, University of the Philippines Los Baños, HSIN LIN, Institute of Physics, Academia Sinica, ARUN BANSIL, Physics, Northeastern University, FENG-CHUAN CHUANG (Presenter), Physics, National Sun Yat-sen University — Ultrathin Janus two-dimensional (2D) materials are attracting intense interest currently. Substitutional doping of 2D transition metal dichalcogenides (TMDs) is of importance for tuning and possible enhancement of their electronic, physical and chemical properties toward industrial applications. Using systematic first-principles computations, we propose a class of Janus 2D materials based on the monolayers MX$_2$ (M=V, Nb, Ta, Tc, or Re; X=S, Se, or Te) with halogen (F, Cl, Br, or I) or pnictogen (N, P, As, Sb, or Bi) substitution. Nontrivial phases are obtained on pnictogen substitution of group VB (V, Nb, or Ta), whereas for group VIIB (Tc or Re), the nontrivial phases are obtained for halogen substitution. Orbital analysis shows that the non-trivial phase is driven by the splitting of M-d$_{yz}$ and M-d$_{xz}$ orbitals. Our study demonstrates that the Janus 2D materials have the tunability and suitability for synthesis under various conditions.

Controlling in-gap states in graphene nanoribbons via tunable topological phases  
FANGZHOU ZHAO (Presenter), STEVEN LOUIE, University of California, Berkeley — Graphene nanoribbons (GNRs) possess distinct symmetry-protected electron topological phases that depend on structure and termination. We show, through first-principles calculations, that by applying an experimentally accessible transverse electric field, certain designer GNRs may be tuned from a topologically trivial to a nontrivial phase or vice versa. With a spatially varying field, junctions of GNRs with distinct topological phases can be created, with localized topological in-gap interface states emerging at these junctions. We further study the formation of in-gap end states inside different energy gaps around the Fermi level for a finite GNR segment, including the conditions for end state to emerge in energy gaps other than the charge-neutrality gap. This work is supported by the National Science Foundation and the Office of Naval Research under the Muri Program. Computational resources have been provided by DOE at Lawrence Berkeley National Laboratory's NERSC facility.

Dynamic nuclear spin polarization induced by Edelstein effect at Bi(111) surfaces*  
ZIJIAN JIANG (Presenter), VICTORIA SOGHOMONIAN, JEAN J HEREMANS, Virginia Tech — Nuclear spin polarization and its Overhauser field, induced by hyperfine interaction and the Edelstein effect, were investigated by quantum transport in individual micrometer-sized Bi(111) thin film samples. A high current density was applied at low temperatures to generate a non-equilibrium carrier spin polarization in the Bi(111) surface states by the Edelstein effect and strong spin-orbit interaction, which then induced dynamic nuclear polarization by hyperfine interaction. The antilocalization magnetotransport measurements showed that as the polarization duration or the polarization current increased, the carrier quantum phase decoherence times decreased while the spin-orbit decoherence times increased, which allowed a quantification of the Overhauser field from the nuclear polarization. By using delay times between polarization and measurement, an exponential decay of the Overhauser field was observed, driven by a nuclear spin relaxation time. Application of an external magnetic field during polarization showed that the carrier spin polarization itself was sufficient to overcome dipolar interactions between nuclear spins. Comparative studies of the transport properties of Bi(111)-on-mica and Bi(111)-on-Si(111) will also be discussed.

8:00AM A61.00001: Specific Heat and Critical Behavior in BaFe$_2$(As$_{1-x}$P$_x$)$_2$* [Invited] CAMILLA MOIR (Presenter), CRIEPI, SCOTT C. RIGGS, JOSE A GALVIS, PAULA GIRALDO-GALLO, NHMFL, JIUN-HAW CHU, Physics, University of Washington, PHILIP WALMSLEY, IAN FISHER, Stanford University, ARKADY SHEKHTER, GREGORY SCOTT BOEBINGER, NHMFL — With $T_c$'s below 40 K and evidence of a quantum critical point [1], the iron-based high-temperature superconductor BaFe$_2$(As$_{1-x}$P$_x$)$_2$ is an appealing system for investigating the behavior underlying superconductivity in high-$T_c$ superconductors. By applying magnetic fields up to 35 T, we are able to suppress superconductivity and reveal the normal state of overdoped BaFe$_2$(As$_{1-x}$P$_x$)$_2$. We observe $\sqrt{H}$ behavior indicating a nodal superconducting gap, saturation of the heat capacity at a magnetic field corresponding to the onset of the normal state, and enhancement of the quasiparticle mass sum as calculated from electronic specific heat coefficient as optimal doping is approached [1]. Our comparison of specific heat as a function of magnetic field to specific heat as a function of temperature, as well as other measurements, forms a consistent treatment of specific heat measurements in high-temperature superconductors.

*BaFe$_2$(As$_{1-x}$P$_x$)$_2$ samples were grown at The Geballe Laboratory for Advanced Materials at Stanford University supported by the Department of Energy, Office of Basic Energy Sciences under contract DE-AC02-76SF00515 and the Gordon and Betty Moore Foundation. DC-field measurements were performed at the DC Magnet Facility of the National High Magnetic Field Laboratory (NHMFL) in Tallahassee, FL. Thermometer calibrations were performed in the Pulsed Field Facility of the NHMFL in Los Alamos, NM. The work at the NHMFL was supported through the National Science Foundation Cooperative Agreements DMR-1157490 and DMR-1644779, the United States Department of Energy, and the State of Florida.
Quantum critical nematic fluctuations and spin excitation anisotropy in the iron pnictides*  

CHIA-CHUAN LIU (Presenter), Rice Univ, ELIHU ABRAHAMS, University of California, Los Angeles, QIMIAO SI, Rice Univ — Quantum criticality in iron pnictides involves nematic and antiferromagnetic degrees of freedom in a concurrent way [1,2], but the relationship between the two types of fluctuations has yet to be clarified. To elucidate the nematic correlations, we study the spin excitation anisotropy defined by the difference between the dynamical spin susceptibilities at (π,0) and (0,π) [3]. We start from an effective Ginzburg-Landau theory for both the Ising-nematic and antiferromagnetic fluctuations in the presence of a small external uniaxial potential, which breaks the C4-symmetry in B1g channel, and establish an identity that connects the spin excitation anisotropy with the dynamical magnetic susceptibility and static nematic susceptibility. Using this identity, we show that the dynamical nematic susceptibility in the quantum critical regime can be determined, and we illustrate it by considering the case of the optimally Ni-doped BaFe2As2 [3].

Quantum phase transition of correlated iron-based superconductivity in LiFe$_{1-x}$Co$_x$As*

NANA SHUMIYA (Presenter), JIAJIN YIN, SONGTIAN SONIA ZHANG, Princeton University, GUANGYANG DAI, Institute of Physics, Chinese Academy of Sciences, YUANYUAN ZHAO, School of Physics and Optoelectronic Engineering, Nanjing University of Information Science and Technology, ANDREAS KREISEL, Institut für Theoretische Physik, Universität, GENNEVIEVE MACAM, National Sun Yat-Sen University, BRIAN M. ANDERSEN, University of Copenhagen, FENG-CHUAN CHUANG, National Sun Yat-Sen University, HSIN LIN, Institute of Physics, Academia Sinica, ZIQIANG WANG, Boston College, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, YUNKYU BANG, Asia Pacific Center for Theoretical Physics and Department of Physics, POSTECH, ZAHID HASAN, Princeton University — We use scanning tunneling microscopy (STM) to image the electronic impact of Co atoms on the ground state of the LiFe$_{1-x}$Co$_x$As system. We observe that impurities progressively suppress the global superconducting gap and introduce low energy states near the gap edge, with the superconductivity remaining in the strong-coupling limit. Unexpectedly, the fully opened gap evolves into a nodal state before the Cooper pair coherence is fully destroyed. Our systematic theoretical analysis shows that these new observations can be quantitatively understood by the nonmagnetic Born-limit scattering effect in a $s\pm$-wave superconductor, unveiling the driving force of the superconductor to metal quantum phase transition.

*Experimental and theoretical work at Princeton University was supported by the Gordon and Betty Moore Foundation (GBMF4547/ Hasan) and the United States Department of energy (US DOE) under the Basic Energy Sciences programme (grant number DOE/BES DE-FG-02-05ER46200).

Nematic and Antiferromagnetic Quantum Criticality in a Multi-Orbital Hubbard Model for Iron Pnictides*

LEI CHEN (Presenter), Rice University, WENJUN HU, University of Tennessee, HAOYU HU, Rice University, RONG YU, Renmin University, HSIN-HUA LAI, Rice University, LUCA FAUSTO TOCCHIO, DISAT, Politecnico di Torino, FEDERICO BECCA, University of Trieste, QIMIAO SI, Rice University — The extent to which quantum criticality drives the physics of iron pnictides is a central question in the field. While the issue had been addressed by effective field theories [1,2], how to approach it in the multi-orbital Hubbard model has been a long-standing challenge due to the limitation in methods for intermediate correlations. Here [3] we study this problem within a multi-orbital Hubbard model containing both the Hubbard and Hund's interactions, by a variational Monte Carlo method based on Jastrow-Slater wave functions that allow for a non-perturbative treatment of the electron correlations. We find strong evidence for the existence of a unique quantum critical point, where both nematic and ($\pi$, 0) antiferromagnetic orders develop, in the bad-metal regime of the phase diagram. A robust signal for unconventional superconducting pairing is also found as the system approaches the quantum critical point from the paramagnetic side.

*DOE BES Award # DE-SC0018197 and Welch Foundation Grant No. C-1411
9:12AM A61.00005: Fluctuating orders induced non-Fermi-liquid behavior near quantum critical point in iron-based superconductors  RONG LI (Presenter), ZHEN-SU SHE, Peking Univ — The non-Fermi-liquid behavior near quantum critical point (QCP) in iron-based superconductors (IBSCs) is a matter of considerable debate. Recently, we have proposed a novel transport theory quantifying scattering by multi-order fluctuations, yielding a new resistivity model, i.e., $\rho = \rho_a + (\rho_b + \alpha^2 T^2 + \beta^2 B^2)^{1/2}$ (see also another contributed talk, She and Li, "A symmetry-breaking analysis for non-Fermi-liquids induced by order fluctuations in correlated electron systems"). For IBSCs near QCP, the theory quantitatively explains the widely observed low-$T$ plateau as a result of scattering by antiferromagnetic (AFM) fluctuations, and the unusual linear $T$ and $B$ scaling at high $T$ and $B$ induced by thermal- and magnetic-vortex fluctuations. Furthermore, the scaling transition from $T^2$ to $T$ under increasing $T$ and doping is explained by the increase of vortex fluctuations relative to AFM fluctuations. We present supporting evidence by comparing the predictions with data of dozens of samples. It thus forms a novel framework to clarify the difference between IBSCs and cuprates, successfully quantifying the feature of weaker AFM fluctuations in LiFe$_{1-x}$Co$_x$As, and stronger vortex fluctuations in BaFe$_2$(As$_{1-x}$P$_x$)$_2$ based on the link between macroscopic resistivity and microscopic fluctuating orders.

9:24AM A61.00006: Manifestation of the multiband nature in the BCS-BEC crossover of FeSe$_{1-x}$S$_x$  TAKAHIRO HASHIMOTO (Presenter), YUICHI OTA, AKIHIRO TSUZUKI, TSUBAKI NAGASHIMA, AKIKO FUKUSHIMA, Institute for Solid State Physics, University of Tokyo, SHIGERU KASAHARA, YUJI MATSUDA, Department of Physics, Kyoto University, KOHEI MATSUURA, YUTA MIZUKAMI, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo, SHIK SHIN, University of Tokyo, KOZO OKAZAKI, Institute for Solid State Physics, University of Tokyo — The crossover from the superconductivity of Bardeen-Cooper-Shrieffer (BCS) regime to Bose-Einstein condensation (BEC) regime holds the key to understanding the nature of pairing and condensation of fermions [1]. In electron systems in solids, however, it is generally difficult to control the pairing strength of the electrons, and complete evidence of the BCS-BEC crossover has been elusive so far. Here, we provide the first example of complete evidence for the BCS-BEC crossover in an iron-based superconductor FeSe$_{1-x}$S$_x$ from laser-excited angle-resolved photoemission spectroscopy, and propose a multiband mechanism for BCS-BEC crossover in this system.

Unusual BCS-BEC crossover in FeSe$_{1-x}$S$_x$ superconductors* YUTA MIZUKAMI (Presenter), Univ of Tokyo-Kashiwanoha, MASAHIRO HAZE, Kyoto University, OHEI TANAKA, KOHEI MATSUURA, Univ of Tokyo-Kashiwanoha, DAIKI SANO, Kyoto University, JAKOB BÖKER, ILYA EREMIN, Ruhr-Universität Bochum, SHIGERU KASAHARA, YUJI MATSUDA, Kyoto University, TAKASADA SHIBAUCHI, Univ of Tokyo-Kashiwanoha — The BCS-BEC crossover from strongly overlapping Cooper pairs to non-overlapping composite bosons in the strong coupling limit has been a long-standing issue of interacting many-body fermion systems. It has been extremely challenging to realize such a crossover state in electronic systems over the past decade. Recently, FeSe semimetal emerged as a high-$T_c$ superconductor located in the BCS-BEC crossover regime, owing to its very small Fermi energies. In FeSe, however, an ordinary BCS-like heat-capacity jump is observed at $T_c$, posing a fundamental question on the characteristics of the BCS-BEC crossover. Here we report on high resolution heat capacity, magnetic torque, and scanning tunneling spectroscopy measurements in FeSe$_{1-x}$S$_x$. When the nematic order is suppressed at $x > 0.17$, an unusual BEC-like transition is found in the thermodynamic quantities with giant superconducting fluctuations extending far above $T_c$. However, no pseudogap formation is observed in the tunneling spectra. These results illuminate highly unusual features of the BCS-BEC crossover in superconductors with multiband electronic structure and competing electronic instabilities.

FeSe as a Polymorphous Network* ZHI WANG (Presenter), XINGANG ZHAO, University of Colorado, Boulder, SIMON J L BILLINGE, Department of Applied Physics and Applied Mathematics, Columbia University, ALEX ZUNGER, University of Colorado, Boulder — The observed electronic structure of FeSe has lower apparent symmetry than the one that would be suggested by its macroscopic crystallographic structure. It has been argued that such nematicity must be electronic symmetry lowering, driven by strong correlations, rather than a local structural symmetry lowering, the latter being judged on the basis of global structural probes to be too small. Standard structure predictions use small unit cells that cannot accommodate structural symmetry lowering. Using a predictive first principles minimization of the internal total energy without restricting it to a small unit cell reveals that the lowest energy configuration whose average macroscopic symmetry is tetragonal consists, in fact, of a distribution of different local low-symmetries. This polymorphous network explains the PDF pattern in both the local and long-range regions without a fit. When used as input to electronic structure calculations, the predicted polymorphous structure reveals electronic symmetry breaking that is unique to this unusual compound.

*supported by NSF-DMREF-1921949.
The recent discovery of superconductivity in the two-leg ladder compounds BaFe$_2$X$_3$ ($X$=S, Se) started the novel field of quasi-one-dimensional iron-based superconductors. Here, we predict that the previously barely explored ladder compound RbFe$_2$Te$_3$ should be magnetic with a CX-type arrangement[1]. Moreover, at $n = 6.0$ our DFT phase diagrams (with/without lattice tetramerization) reveal that the stable magnetic states could be either a 2x2 magnetic Block-type, as for $X$=Se, or a previously never observed before CY-type state. In the Te-based studies, electrons are more localized than in S, implying that the degree of electronic correlation is enhanced for the Te case. This potential relevance of strong correlation in $n$=6 Te-123 ladders could also induce exotic phenomena [2], such as Block-type order, the orbital selective Mott physics, and superconductivity under high pressure. Our overarching conclusion is that experimental studies of iron ladder tellurides are worth pursuing.

*U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, National Natural Science Foundation of China.

For insight into the composition-dependent electronic structure of iron pnictides, we performed a systematic study of spatial structure and electronic states by x-ray diffraction and x-ray absorption. A large number of compositions in the (Ba,Sr)(Fe,$TM$)$_2$(As,P)$_2$ family of compounds was investigated, covering the substitution of Ba by Sr; of Fe by transition metals ($TM$); and of As by P. Our observations on doping effects upon such substitutions include “reluctant” doping (charge carriers are only partially transferred away from the substituent) or “site-decoupled” doping (transferred charge carriers affect either Fe sites or As sites but not both). Here, we focus on isovalent substitutions. Our findings suggest that Indirect, structural effects of substitution appear to be more important for magnetism and superconductivity in iron pnictides than the direct, charge-carrier doping effects.
10:24AM A61.00011: Isovalent S and Te substitution effect on superconductivity in FeSe thin films* FUYUKI NABESHIMA (Presenter), TOMOYA ISHIKAWA, NAOKI SHIKAMA, YUKI SAKISHITA, SOTA NAKAMURA, HODACA KUROKAWA, ATSUTAKA MAEDA, Univ of Tokyo — We investigated chemical pressure effects from positive to negative (S and Te substitution) and in-plane strain effect from tensile to compressive on physical properties in FeSe thin films. Both S and Te substitution suppresses the structural transition temperature. The behavior of superconducting transition temperature, \( T_c \), is completely different between S and Te substitution at the composition when the structural transition disappears. \( T_c \) increases drastically for Te substitution at the ortho.-tetra. boundary, while \( T_c \) shows monotonic decrease in S substituted samples. These results demonstrate that the relationship between the nematicity and the superconductivity is not universal in FeSe[1]. A magneto-transport study revealed a positive correlation between carrier densities and \( T_c \) in our films[2,3]. Our results suggest that the structural transition affects the electronic structure differently between Fe(Se,S) and Fe(Se,Te) and that this is the direct cause of the difference in the \( T_c \) behaviors at the ortho.-tetra. boundary[3].

10:36AM A61.00012: Resistivity and Magnetic Susceptibility Under Pressure (0–2.0 GPa) of \( \text{Fe}_{1+\varepsilon}\text{Te}_{0.5}\text{Se}_{0.5} \) and \( \text{R}_{1-x}\text{Ce}_x\text{NiO}_3 \) \( \text{[R = (La,Y), Pr]} \)** ZACHARY P. KUKLINSKI, GREGORIO PONTI, QUINN D. B. TIMMERS, RABIA HUSAIN (Presenter), JOHN MARKERT, Department of Physics, University of Texas at Austin — We report measurements of the ac magnetic susceptibility of the iron-based mixed-chalcogenide superconductor \( \text{Fe}_{1+\varepsilon}\text{Te}_{0.5}\text{Se}_{0.5} \), and of the electrical resistivity of doped nickel-oxide compounds \( \text{R}_{1-x}\text{Ce}_x\text{NiO}_3 \), with \( \text{R = Pr or (La,Y)} \), over the pressure range 0–20 kbar (0–2.0 GPa). Our iron-based material is optimized \((\varepsilon \approx 0.07)\) for bulk superconductivity, exhibiting an ambient-pressure superconducting transition at \( T_c \approx 14 \text{ K} \), well above the transition of bulk FeSe \((T_c = 9 \text{ K})\). With applied pressure, we observe an immense, nearly linear increase of \( T_c \), with \( dT_c/dP = +7.0\pm0.5 \text{ K/GPa} \). We have prepared bulk “113” doped nickelates using high-oxygen-pressure (150–200 bar), high-temperature \((T \approx 1000^{\circ}\text{C})\) synthesis. For undoped \( \text{PrNiO}_3 \), the metal insulator transition temperature decreases with pressure, with reported \( dT_{\text{MI}}/dP \approx -42 \) to \(-76 \text{ K/GPa} \) [1,2]. For \( \text{Pr}_{1-x}\text{Ce}_x\text{NiO}_3 \) with \( x \approx 0.0–0.2 \), we are exploring variations in \( dT_{\text{MI}}/dP \). We consider both steric (e.g., band-broadening, bond-straightening), electron-doping, and hole-filling contributions to this behavior.

**10:48AM A61.00013: Unconventional quantum criticality in a two-dimensional fermion-boson coupled system**  
JIANQIAO LIU (Presenter), RYUICHI SHINDOU, Peking Univ — We study a two-dimensional two-band Fermi system with finite Fermi surfaces that couples with a $\phi^4$ action of O(3) vector boson field with dynamical exponent $z = 1$ through Yukawa-type coupling. By using RG analysis, we show that quantum criticality associated with an ordering of the O(3) vector field is controlled by a new saddle-point fixed point instead of the Wilson-Fisher fixed point. The new fixed point has a finite fermion-boson coupling and the boson velocity is strongly renormalized by the Yukawa coupling. We discuss possible superconducting instability near such a quantum critical point.

**8:00AM A62.00001: Flying Micro-Lightsails: Optical Levitation and Propulsion of Nanostructured Ultralight Macroscopic Objects**  
HARRY ATWATER (Presenter), Applied Physics and Materials Science, California Institute of Technology — The Breakthrough Starshot Initiative initiated in 2016 defined an audacious goal of sending a spacecraft beyond to a neighboring star, Proxima Centauri within the next half-century. Its vision for an ultralight spacecraft that can be accelerated by laser radiation pressure from an Earth-based source to ~20% of the speed of light demands the use of materials with extreme properties. Here we examine stringent criteria for the lightsail materials design, thermal management and dynamical stability, and discuss lightsail design and first experimental steps by exploration of small (<1 mm$^2$) microscale lightsails. We explore nanophotonic design of materials, thermal management, and self-stabilizing optical manipulation, levitation and propulsion of lightweight macroscopic (i.e., mm, cm, or even meter-scale) micro-lightsails via radiation pressure. We consider the materials characteristics required to realize robust, thermally stable building blocks, and find that stable trajectories for dynamic motion of macro-objects can be achieved by controlling the anisotropy of light scattering along the object surface. With radiative cooling being the sole mechanism for passive thermal management in vacuum or space, we quantify the stringent requirements on material absorptivity that enable these structures to withstand high laser intensities and prevent excessive heating and mechanical failure. Achievement of stable optical manipulation and propulsion of macroscale (i.e., >> wavelength in size) structures, via radiation pressure appears to be possible by the use of structured optical beams and tailored nanophotonic design. Reaching this goal requires the conception and design of new ultralight photonic structures composed of materials with extreme optical, mechanical and thermal properties.

8:36AM A62.00002: Fundamental Limits on Electromagnetic Scattering in Nanostructured Materials: Upper Bounds on Extinction, Purcell Enhancement, and Absorption* PENGNING CHAO (Presenter), SEAN MOLESKY, PRASHANTH S VENKATARAM, Princeton University, WEILIANG JIN, Stanford University, ALEJANDRO RODRIGUEZ, Princeton University — Advances in computational optimization (inverse design) and experimental fabrication techniques suggest the possibility of approaching the fundamental limits of optical control, which remain largely unknown. Through algebraic analysis of the scattering properties of Maxwell's equations, we formulate new constraints on various optical scattering processes, such as extinction and absorption, and apply these to establish upper bounds on thermal emission, radiative heat transfer, and Purcell enhancement in nanostructured materials. These bounds are general and useful in that they apply to arbitrary structures while incorporating the most relevant aspects of any photonic design problem: the material a given structure will be made of and the volume it will occupy. In particular, the bounds demonstrate the degree to which large metallic response and nanostructuring can be exploited to enhance light-matter interactions, with applications to single-photon extraction, photovoltaics, LEDs, and Raman scattering. They also reveal a transition from quasistatic (subwavelength) to ray optics behavior, and are shown to be nearly tight by comparison with structures discovered through inverse design.

*The authors would like to acknowledge support from NSF (DMR-1454836) and DARPA (HR0011182004).

8:48AM A62.00003: Hot-Electron Generation and Photothermal Effect in Plasmonic Nanostructures and Metamaterials ALEXANDRE GOVOROV (Presenter), Ohio Univ, LUCAS VAZQUEZ BESTEIRO, UESTC, China and INRS, Canada — Generation of energetic (hot) electrons and photo-heating are intrinsic properties of any plasmonic nanocrystal under illumination [1,2]. While the photo-heating effect is well described classically, the generation of hot electrons (HEs) is a quantum process and its theoretical description requires advanced quantum approaches [2]. The energy efficiency of such hot-electron processes is always limited. However, there are interesting possibilities to achieve the hot-electron enhancement [1]. The generation of high-energy HEs is a key mechanism for several applications such as plasmonic photodetectors, photocatalysis and ultrafast spectroscopy [1,2]. In particular, photochemistry induced by HEs and heating represent a very active area, which also involves chiral metamaterials and chiral photocatalysis [3].

9:00AM A62.00004: Optical and Thermal Metamaterials for Scalable Applications [Invited]
XIAOBO YIN (Presenter), University of Colorado Boulder — Micro/nano-structured materials offer significantly new opportunities for high efficiency devices and systems for energy harvesting, conversion and storage. Fundamental understanding at the small scale enables us to design structures and materials with unprecedented performances. However, there is a tremendous gap between the proof-of-principle demonstration at small scale and the intrinsically large scale real-world thermal and energy systems. In this talk, I will give an overview on our research and, more specifically, present our recent metamaterial development for emerging food, energy and water applications.

9:36AM A62.00005: Self-Cleaning and Tunable Structural Color Generation by TiO$_2$/Ti nanostructures* Gaurav Shukla (Presenter), Angappane Subramanian, Centre for Nano and Soft Matter Sciences — Structural colors are known for its long term sustainability in comparison to dyes, pigments, etc., but generating self-cleaning structural colors by nano/micro structuring is quite challenging. Here, we report self-cleaning structural color generation by TiO$_2$ nanorods and thin films on Ti sputtered glass and polyethylene terephthalate (PET) substrates deploying glancing angle deposition (GLAD) method. Reflected colors are tuned by varying height of TiO$_2$ nanorods or thin film on Ti films. Both the front and back surface of the samples show different colors, called Janus optical effect, due to altered dielectric constant on both sides of Ti film. All as-deposited TiO$_2$ nanorods and thin film samples are hydrophobic and hydrophilic respectively while both is transformed to reversible superhydrophilic state, a self-cleaning state, by UV irradiation. Further, annealing of samples on glass substrates has made the samples semi-transparent or transparent having superhydrophilic surface. Besides, structural colors are demonstrated for information encryption and optical ethanol sensing. Nevertheless, these structural colored specimens are promising for immense applications in the field of color printing, smart windows etc.

*S.A. thanks DST-Nanomission for the funding (SR/NM/TP-25/2016).
Two-dimensional nanostructured materials for catalytic activities: a combined experimental and theoretical study

TEKALIGN TERFA DEBELA (Presenter), Institute for Application of Advanced Materials, Jeonju University, HONG SEOK KANG, Department of Nano and Advanced Materials, College of Engineering, Jeonju University — Two-dimensional (2D) MoS$_2$ nanostructures have attracted much attention in recent years because of their excellent electrocatalytic activity toward the hydrogen evolution reaction (HER). Herein, we report unique 2D hybrid nanostructures of MoS$_2$ and melamine synthesized via a one-step solvothermal process.[1] The hybrid complexes with 7% intercalated melamine exhibited excellent HER Performance, with a current of 10 mA cm$^{-2}$ at 0.136 V (vs. RHE) and a Tafel slope of 37 mV dec$^{-1}$. Our first-principles calculations showed that the intercalation of hydrogen-bonded melamine clusters could stabilize the $1T'$ phase MoS$_2$ via substantial charge transfer. In addition, I will discuss our results on the selective reduction of CO$_2$ to formic acid using indium-zinc bimetallic nanocrystals.[2]

This study was supported by grants 2017H1D3A1A01014082 and 2018R1A2B2006474, which were funded by the Ministry of Science and ICT of Korea. We would also like to thank Jeonju University for providing partial financial support.

Nanostructured gold thermocouple for photodetection

MAHDIYEH ABBASI (Presenter), CHARLOTTE EVANS, LONGJI CUI, XIFAN WANG, DOUGLAS NATELSON, Rice Univ — The Seebeck coefficient of a metal depends on the energy-dependent electrical conductivity, which in turn depends on the energy-dependent electron mean free path and the material band structure. At the nanoscale, when the geometric size is comparable with the mean free path of the electrons, single metal thermocouples can be fabricated by changing the material geometry across the thermocouple. By using plasmonically-resonant structures, different device geometries and sizes can be used for wavelength sensitive light detection. We will present experimental data and simulations of single metal gold nanostructures with different geometries that are plasmonically active with IR laser illumination. We will discuss how these devices can be used for photodetection and discuss future applications for these measurements.

*The authors acknowledge support from NSF ECCS 1704625.
The advances on hybrid metamaterial design using bottom-up fabrication technique bring multiple advantages toward sensing and large-scale nanophotonic device integration. In our work, a two-phase plasmonic framework with Au nanoantenna arrays being embedded inside a titanium nitride (TiN) matrix was demonstrated, with easy access of controlling the packing density or aspect ratio. Advantages include sub-10 nm nanoantenna arrays, high crystalline quality, inch-scale throughput as well as high durability. Such geometrical flexibility brings tunable resonance frequency and anisotropic dielectric dispersion at optical regime. We demonstrate effective molecular sensing affected by the surface-enhanced plasmonic substrate with built-in Au antenna array. Our functional hybrid thin film template, as a first step, can be applied to multiple three-dimensional metamaterial designs. We will show some of our latest research progress on nanostructures and applications using such hybrid template.

*National Science Foundation (DMR-1565822)
10:36AM A62.00010: Three-dimensional printing of piezoelectric materials with designed anisotropy and their applications in underwater transducers  
HUACHEN CUI (Presenter), RYAN HENSLEIGH, DESHENG YAO, University of California, Los Angeles, DOMINIC LOPINTO, Virginia Tech, XIAOYU ZHENG, University of California, Los Angeles — We describe design and manufacturing routes to previously inaccessible classes of piezoelectric materials that have arbitrary piezoelectric coefficient tensors. Our scheme is based on the manipulation of electric displacement maps from families of structural cell patterns. We implement our designs by additively manufacturing free-form, perovskite-based piezoelectric nanocomposites with complex three-dimensional architectures. The resulting voltage response of the activated piezoelectric metamaterials at a given mode can be selectively suppressed, reversed or enhanced with applied stress. To demonstrate our novel design method and fabrication capability, we designed and fabricated underwater transducers consisting of rationally designed metamaterials to accommodate diverse situations, in which the piezoelectric composites convert mechanical vibrations into electrical voltages and vice versa. Through tuning geometry of the micro-architectures, resonance frequencies of these transducers can vary from 100Hz to 10MHz while the impedance is close to water. Moreover, we showed the feasibility and applicability of these transducers for the purpose of source detection, liquid quality monitoring, and directional sensing.

10:48AM A62.00011: 3D printable multi-directional piezoelectric sensor  
DESHENG YAO (Presenter), HUACHEN CUI, RYAN HENSLEIGH, XIAOYU ZHENG, University of California, Los Angeles — The electromechanical coupling behaviors of the piezoelectric materials enable their wide applications in sensing systems. However, the comprehensive measurement of the stress tensor presented significant challenges for current piezoelectric sensing devices. Notably, the evaluation of the surface shear stress requires complicated structural designs along with intricate fabrication processes. Herein, we present the design methodology and manufacturing route to simultaneously extracting all individual components of the stress tensor. Our scheme is based on manipulating the deformation mechanism of each individual ligament within the piezoelectric micro-lattice structures. We implement our design principle via three-dimensional printing of free-form, piezo-active feedstock with high-resolution micro-architectures. The presented piezoelectric multi-mode sensor owns the capability of isolating the target stress components when subjecting to multiple external inputs. Innovated by these findings, the applicability of the multi-mode sensors is demonstrated by embedding them to the gas-solid interface as the conformal, flexible airflow sensor that is able to monitor the status of the airflow, as well as a self-sensing fluid pipe for liquid velocity field mapping.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A63 DMP: Structure and Crystallography of Halide Perovskites

Mile High Ballroom 4D - Luisa Whittaker-Brooks
8:00AM A63.00001: Deciphering the nature of anharmonicity in CH$_3$NH$_3$PbI$_3$ by THz range Raman crystallography  
RITURAJ SHARMA (Presenter), Department of Materials and Interfaces, Weizmann Institute of Science, Israel, ZHENBANG DAI, Department of Chemistry, University of Pennsylvania, Philadelphia, USA, THOMAS M. BRENNER, LENA YADGAROV, Department of Materials and Interfaces, Weizmann Institute of Science, Israel, LINGYUAN GAO, Department of Chemistry, University of Pennsylvania, Philadelphia, USA, YEVGENY RAKITA, ROMAN KOROBKO, Department of Materials and Interfaces, Weizmann Institute of Science, Israel, IDDO PINKAS, Department of Chemical Research Support, Weizmann Institute of Science, Israel, ANDREW MARSHALL RAPPE, Department of Chemistry, University of Pennsylvania, Philadelphia, USA, OMER YAFFE, Department of Materials and Interfaces, Weizmann Institute of Science, Israel — Methylammonium lead iodide (CH$_3$NH$_3$PbI$_3$ or MAPI) shows many seemingly contradictory characteristics, like low diffusion but high carrier lifetime, small Urbach energy but defect tolerance etc., which are intimately connected to its anharmonic structural dynamics. Therefore, the fundamental understanding of the anharmonicity in MAPI is critical for harnessing its full potential in future optoelectronic devices. We combine THz-range Raman crystallography and ab initio computation to elucidate the microscopic mechanisms governing the strongly anharmonic structural dynamics in MAPI. Correlation between observed Raman intensity modulations with PbI$_6$ octahedral tilting patterns provides a direct evidence of highly anharmonic and anisotropic nature of such low-frequency vibrations. The anisotropy and anomalous broadening of the Raman features throughout the tetragonal phase is manifested by athermal anharmonicity. Conversely, thermally induced all-axes relaxational rotation causes anharmonicity and consequently, isotropy in cubic phase. Our study delineates the anharmonic structural dynamics of the technologically relevant tetragonal phase MAPI and offer insights to utilize anharmonicity to engineer favorable optoelectronic properties in materials with long term stability.

8:12AM A63.00002: Local Structure of 3D Halide Perovskites at High Pressure  
SAMUEL GIRDZIS (Presenter), Stanford University, YU LIN, SLAC National Accelerator Laboratory, WENDY MAO, Stanford University — Over the past decade, halide perovskites have emerged as promising materials for solar cells, due to their low-cost synthesis and robust semiconducting properties. Challenges remain in terms of improving the chemical stability of these materials, for instance to air, water, and heat, and in terms of reducing their toxicity, as the best performing halide perovskites still incorporate a lead (Pb) cation. Numerous studies have used compression to investigate structure-property relationships in these materials. However, previous structural investigations have only looked at long-range periodicity changes at high pressure. Here, we have performed in situ synchrotron X-ray total scattering at high pressure on a selection of 3D halide perovskites, including the archetypal composition, methylammonium lead iodide (MAPbI$_3$), to understand the evolution of their short-range, local structure. Preliminary results indicate local disorder due to octahedral tilting which has not been observable through conventional diffraction experiments. Insight into the local structural behavior has the potential to guide future synthetic efforts toward stable, non-toxic perovskite photovoltaics.
8:24AM A63.00003: Bias stress effects in organic-inorganic halide perovskites  LAURA FLANNERY (Presenter), DANIEL POWELL, LUISA WHITTAKER-BROOKS, University of Utah — The power conversion efficiencies of organic-inorganic halide perovskites (OIHP) have been improved over the last decade using a wide variety of methods, such as composition manipulation, dopant introduction, and interfacial buffers. These methods, however, have taken little regard for the electronic and interfacial effects such alterations may cause within devices under voltage bias stress. A condition required for most device operation. Using two efficient and commonly studied OIHP compositions, CH$_3$NH$_3$PbI$_{2.87}$Cl$_{0.13}$ and Cs$_{0.1}$(MA$_{0.17}$FA$_{0.83}$)$_{0.9}$Pb(I$_{0.83}$Br$_{0.17}$)$_3$, we investigate the effect of halide and cation substitution in OIHP structures to understand the unique current behavior while under a range of voltage bias stress in both light and dark conditions. With the use of a second device structure, without transport layers, the same bias stress effects unique for the different OIHP structures are observed. Confirming the difference in the current trends, for the two materials, is due to intrinsic behavior of the perovskite material itself, rather than the interfacial recombination and interactions with the transport layers. In this study, we continue to flush out how the changes in morphological defects and ion migration in the two OIHP materials are influencing charge transport.

8:36AM A63.00004: Structural phase transitions and photoluminescence mechanism in a layer of 3D hybrid perovskite nanocrystals  YURI GLINKA (Presenter), RUI CAI, XIAN GAO, DAN WU, RUI CHEN, XIAO WEI SUN, Electrical and Electronic Engineering, Southern University of Science and Technology — Although the structural phase transitions in the single-crystal hybrid methyl-ammonium (MA) lead halide perovskites (MAPbX$_3$, X = Cl, Br, I) are common phenomena, they have never been observed in the corresponding nanocrystals. Furthermore, although these materials are promising for the future electronics, optoelectronics, and solar energy harvesting applications, the nature of quasiparticles governing their unique photoluminescence (PL) and transport properties is still unclear. Here using two-photon excited PL spectroscopy, we provide evidence that the structural phase transitions in a layer of 3D MAPbBr$_3$ nanocrystals may occur at about the same temperatures as those in the corresponding single crystals. We also show that room-temperature PL originates from the radiative recombination of the optical-phonon vibrationally excited polaronic quasiparticles with energies might exceed the ground-state Fröhlich polaron and Rashba energies due to optical-phonon bottleneck. Because of small masses and large radii of these polaronic quasiparticles, their high mobility and long-range diffusion become possible.
**8:48AM A63.00005: Doping of Halide Perovskites**  
ZHIQIANG ZHANG (Presenter), ANDERSON JANOTTI, Univ of Delaware — Methylammonium lead iodide (MAPbI3) based organic-inorganic hybrid perovskites (OIHP) have emerged as promising solar photovoltaic absorbers, with power conversion efficiency increasing from 3.8% to 23.7% in the last 10 years. Such high efficiency combined with low-temperature solution fabrication process make OIHP promising candidates for the next generation of photovoltaic materials. Current solar cell designs use semi-insulating or low carrier density layers coupled to hole and electron transport contact materials. Controlled doping, both n and p-type, would allow for tuning electrical conductivity and fabrication of p-n homojunctions, opening great opportunities in device applications that go beyond solar cells. In this presentation we discuss possible approaches to doping of MAPbI3, exploring substitutional and interstitial impurities, on both organic and inorganic sites. Using density functional theory and hybrid functional calculations we explore all possible configurations of the various dopants, analysing formation energies, thermodynamic transition levels, and dopant solubilities.

**9:00AM A63.00006: Anharmonic Lattice Dynamics in CsPbBr3**  
TYSON LANIGAN-ATKINS (Presenter), XING HE, Duke University, MATTHEW KROGSTAD, RAYMOND OSBORN, STEPHAN ROSENKRANZ, DUCK YOUNG CHUNG, Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern University, DANIEL PAJEROWSKI, GUANGYONG XU, Oak Ridge National Laboratory, OLIVIER DELAIRE, Duke University — CsPbBr3 is a promising material for use in solar cells and thermoelectrics. The suitability of halide perovskites as photovoltaics derives from the long lifetimes of photoexcited carriers before recombination and it has been theorized that this is due to local polar fluctuations. Furthermore, CsPbBr3 has been shown to exhibit ultralow thermal conductivity which makes it attractive for use in thermoelectrics. CsPbBr3 has several lattice instabilities undergoing a cubic to tetragonal transition at ~400K before transforming to an orthorhombic phase at ~360K.

We report inelastic neutron scattering (INS) studies, supported by anharmonic first-principles simulations, on CsPbBr3 across its three phases. These momentum-resolved measurements allow us to investigate phonon behavior across the Brillouin zone and hence phonon-phonon scattering rates which directly impact thermal conductivity. We find large overall broadening of phonons, even at low temperature, but also a large temperature-dependent anisotropy in the anharmonicity.

*U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Award No. DE-SC0019299.*
Structural Studies of Halide Perovskite Photovoltaic Systems

SIZHAN LIU, New Jersey Inst of Tech, MAHALINGAM BALASUBRAMANIAN, SUYIN WANG, YU-SHENG CHEN, Argonne National Laboratory, ROGER LALANCETTE (Presenter), Rutgers University, SANJIT GHOSE, Brookhaven National Laboratory, YONG YAN, San Diego State University, TREVOR TYSON, New Jersey Inst of Tech — The lead halide perovskite systems have been studied intensively recently for applications as photovoltaic materials due to their very high conversion efficiency. To develop accurate models of these systems, it is critical to understand their structural phases and atomic level properties. High-resolution single crystal x-ray diffraction, Raman spectroscopy, x-ray absorption spectroscopy, x-ray pair distribution function measurements, and differential scanning calorimetry measurements are being used to determine the long-range and local structures and assess the stable phases. A discussion of the structure on different length scales over a broad temperature range will be given.

This work is supported by NSF Grant No. DMR-1809931.

Particle Ordering and A-site Composition Effects in Hybrid Organic-Inorganic Metal Halide Perovskite Quantum Dot Films

JULIAN VIGIL (Presenter), Stanford Univ, MICHAEL TONEY, SLAC National Accelerator Laboratory, JOSEPH LUTHER, National Renewable Energy Laboratory — The promising optoelectronic properties of bulk metal halide perovskite semiconductors have motivated recent developments in nanoscale and quantum well perovskite congeners, including layered structures and nanocrystalline quantum dots (QDs). In addition to the ability to tune the optical bandgap and improve photoluminescence efficiency, confining the nanocrystalline dimensions has proven valuable in accessing compositions[1] and crystallographic phases[2] that are unstable in the bulk.

Herein, we report on structural studies of FA$_x$Cs$_{1-x}$PbI$_3$ (FA = formamidinium) QD films by synchrotron X-ray scattering techniques. 15-nm FA$_x$Cs$_{1-x}$PbI$_3$ QDs (x = 0, 0.1, 0.25, 0.5, 0.75, 1) were deposited from colloidal solution and investigated by grazing incidence wide-angle X-ray scattering (GIWAXS). GIWAXS patterns indicate coherent particle ordering on the substrate for thin spin-coated films, while the subsequent ligand exchange and particle depositions lead to isotropic ordering of the particles. The patterns also show evidence of crystallographic phase inhomogeneities and a transition from cubic (FAPbI$_3$) to tetragonal (Cs$_{0.5}$FA$_{0.5}$PbI$_3$) to orthorhombic (CsPbI$_3$) character in the composition series.

9:36AM A63.00009: Stress effects on vibrational spectra of orthorhombic and tetragonal hybrid perovskites.* KUNTAL TALIT (Presenter), DAVID STRUBBE, University of California, Merced — Strain plays an important role in semiconductor performance and stability. Strains may develop in organic metal-halide perovskites which affect carrier mobility, non-radiative recombination, degradation and other optoelectronic properties. Measuring spatially varying strains is difficult but imperative for understanding these effects. We have used DFT to investigate effects of applied strain on the vibrations of tetragonal and orthorhombic methylammonium lead iodides (MAPI), building on our previous study of the high-temperature pseudo-cubic phase [arXiv:1907.03673]. Applying small uniaxial strains along three crystal axes, we have analyzed changes in frequency and phonon displacement patterns. We identified favorable modes for experimental measurements of local strain by Raman microscopy, and we calculated mode Grüneisen and Grüneisen parameters in different directions to connect with reports of negative thermal expansion in c-direction. Our study gives insight into the interaction between strain, structural changes and vibrational modes which may help to understand degradation.

9:48AM A63.00010: Pressure-induced Phase Changes in Cesium Lead Bromide Perovskite Nanocrystals with Planar Defects* SORB YESUDHAS (Presenter), Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA, MARIA V MORRELL, Department of Chemical Engineering, University of Missouri - Columbia, Missouri 65211, USA, MATTHEW J ANDERSON, CARSTEN A. ULLRICH, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA, CURTIS KENNEY-BENSON, HPCAT, X-ray Science Division, Advanced Photon Source, Argonne National Laboratory, Lemont IL, 60439, USA, YANGCHUAN XING, Department of Chemical Engineering, University of Missouri - Columbia, Missouri 65211, USA, SUCHISMITA GUHA, Department of Physics and Astronomy, University of Missouri, Columbia, Missouri 65211, USA — Lead halide perovskites have a rich landscape of structural and optical properties, which can be explored and possibly controlled by applying high pressure. CsPbBr$_3$ NCs with Ruddlesden-Popper (RP) faults, formed via post-synthetic fusion growth, are significantly larger in size than as-synthesized NCs and display exceptional emission stability. We compare synchrotron-based high pressure X-ray diffraction and photoluminescence (PL) properties of CsPbBr$_3$ (without RP) and RP-CsPbBr$_3$ (with RP), and resolve their crystal structure under pressure for the first time. CsPbBr$_3$ undergoes a phase transition from ambient orthorhombic (S.G: Pnma) to cubic (S.G: Pmm) phase at 1.7 GPa and RP-CsPbBr$_3$ transforms from Pnma to monoclinic (S.G: P2$_1$/m) phase at 0.74 GPa in addition to several isostructural transitions. Density-functional calculations predict a narrowing of the band gap with pressure, concomitant with the PL energies. The RP-CsPbBr$_3$ NCs exhibit enhanced PL intensity at 1 GPa and show band gap opening at high pressures. This study opens new strategies for tuning not just the structural properties but also tuning planar defects in alkali lead halide crystals for improved optical properties.

*This work was supported by National Science Foundation under Grant No. ECCS-1807263
Two-dimensional (2D) Ruddlesden-Popper (RP) perovskites, with high quantum efficiency, good photostability and chemical stability, are promising for optoelectronic devices. Blancon et al. reported firstly the lower photoenergy edge emission at those \((BA)_{2}(MA)_{n-1}Pb_{n}I_{3n+1}\) 2D RP perovskites when \(n\geq3\) in 2017[1]. Then, significant attention was attracted to explore the mechanism of edge emission. A theoretical work following them was published to assert that this edge emitting originates from interface strain[2]. After that, another work declared that the edge emission is induced by water molecules[3]. The discussion of Zhao et al. indicated that the loss of part BA at edges should be responsible for the edge emission[4]. While, a reliable and consistent explanation is still missing till now. In this work, we observe the edge emission in 2D exfoliated perovskites and clarify the mechanism of edge emission. This work reveals the nature of the edge emission and pave a way for developing the new optoelectronic devices based on the 2D RP hybrid perovskites.

The air-stable, optically active CsPbI\(_3\) perovskite phase is one of the promising candidates for applications in solar cells. However, the black CsPbI\(_3\) perovskite is thermodynamically unstable and spontaneously converts to a yellow non-perovskite phase at room temperature. We report that a black perovskite phase can persist at room temperature by tuning the tilt of \([PbI_6]^{4-}\) octahedra of high temperature perovskites with pressure, which shows improved stability and remains unchanged after releasing pressure to ambient conditions. Synchrotron X-ray diffraction, Raman spectroscopy, and photoluminescence measurements indicate that the preserved CsPbI\(_3\) crystallizes into an orthorhombic perovskite structure and has a robust PL signal at ~702 nm. First-principles calculations reveal that the tilt of the \([PbI_6]^{4-}\) octahedra play a significant role on stabilizing CsPbI\(_3\) perovskite to room temperature. Our results present a promising approach to prepare superb stable black CsPbI\(_3\) for perovskite solar cells.

Monitoring Electron−Phonon Interactions in Lead Halide Perovskites Using Time-Resolved THz Spectroscopy

DAMING ZHAO (Presenter), HONGWEI HU, REINHARD HASELSBERGER, Nanyang Tech Univ, RUDOLPH A MARCUS, California Institute of Technology, MARIA-ELISABETH MICHEL-BEYERLE, YENG MING LAM, Nanyang Tech Univ, JIAN-XIN ZHU, Los Alamos National Laboratory, CHAN LA-O-VORAKIAT, King Mongkut's University of Technology Thonburi, MATTHEW C BEARD, National Renewable Energy Laboratory, EE MIN CHIA, Nanyang Tech Univ — Lead halide perovskites have low-frequency phonon modes within the lead halide sublattice and thus are considered to be soft. The soft lattice is considered to be important in defining their interesting optoelectronic properties. Electron−phonon coupling governs hot-carrier relaxation, carrier mobilities, carrier lifetimes etc. Directly observing the interplay between free charge carriers and phonons can provide details on how phonons impact these properties. Here, we observe a delicate interplay among carriers, phonons, and excitons in mixed-cation and mixed-halide perovskite films by simultaneously resolving the contribution of free carriers and phonons in time-resolved THz photoconductivity spectra. We observe directly the increase in phonon population during carrier cooling and discuss how thermal equilibrium populations of carriers and phonons modulate the carrier transport properties, as well as reduce the population of carriers within band tails. We are also able to observe directly the formation of free carriers when excitons interact with phonons and dissociate and to describe how free carriers and exciton populations exchange through phonon interactions. Finally, we also time-resolve how the carriers are screened via the Coulomb interaction at low and room temperatures.

Stabilizing Metal-Halide Perovskites via Nanoconfined Crystallization

XIAOQING KONG, STEPHANIE LEE, YI YANG (Presenter), Stevens Inst of Tech — Metal-halide perovskites undergo multiple polymorph transitions, with the smallest bandgap phases thermodynamically favored at elevated temperatures. We explore nanoconfinement as a strategy to shift the thermodynamics of polymorph transitions in order to stabilize high-performance phases against temperature-induced polymorph transitions and humidity-induced degradation. Specifically, when crystal sizes are reduced, the surface free energy contribution to the total Gibbs free energy of the crystals becomes increasingly important. By exploiting the dependence of the surface free energy on the symmetry of the crystal structure, it is possible to shift polymorph transitions to lower temperatures under nanoconfinement compared to the bulk. These nanoconfined crystals also exhibit excellent stability against humidity-induced degradation, with no change in their X-ray diffraction patterns over a period of at least two years of storage in air.

*We acknowledge support from the Public Service Enterprise Group to advance energy innovation at Stevens.
10:48AM A63.00015: Dimensional Confinement-Deconfinement Along the Crystallographic C Axis: A Desorption Mediated Band Engineering of Methylammonium Lead Iodide
SAYANTAN SASMAL (Presenter), Material Science Programme, IIT Kanpur — Strong optical absorption, long diffusion length, benign intrinsic defects established organic-inorganic hybrid perovskites as one of the most important materials in the area of photovoltaics. Unfortunately, the formation of photogenerated halide rich trap centers during conventional halide exchange methods limits the use of hybrids perovskite in multi-junction solar cells.

In this report, we demonstrate band gap engineering of MAPbI$_3$ film due to systematic dimensional deconfinement along the crystallographic c axis during gas induced growth. There are some distinct interrelated events occurring during gas induced reaction, which involves (i) in situ formations of hexylamine from 2D (HA)$_2$PbI$_4$ upon exposure to methylamine, (ii) selective adsorption of hexylamine on the Pb sites of growing MAPbI$_3$ leading to the anisotropic growth, (iii) systematic desorption of hexylamine during exposure of methylamine leading to continuous band gap tuning (2.18 eV to 1.69 eV). Most importantly, this dimensional confinement-deconfinement leads to extremely smooth, homogeneous film without having the halide rich trap centres, thereby establishing the importance of this novel route in the context of hybrid perovskite photovoltaics.

Monday, March 2, 2020 8:00 AM - 11:00 AM

Session A64 DMP: High Mobility, Wide Bandgap Oxides for Electronics
Mile High Ballroom 4E - Turan Birol, University of Minnesota - Tag(s): Focus

8:00AM A64.00001: Complex Oxide Heterointerfaces - New Materials, Terminations, and Orientations [Invited]  MARK RZCHOWSKI (Presenter), University of Wisconsin - Madison — In this talk I discuss our recent research activity in complex oxide heterostructures, addressing effects arising from spin-orbit coupling, novel spin structures, and interface modifications across a range of systems, highlighting similarities and differences. I will discuss two-dimensional charge liquids at heterointerfaces and their dependence on new materials, crystallographic orientation, and termination, magnetoelectric coupling in multiferrioc and composite oxide heterostructures, and materials and heterostructures exhibiting Berry curvature effects and interfacial coupling arising from crystalline and spin structure.
8:36AM A64.00002: Structural, Electronic, and Optical Properties of 2D Titanium Oxide Layers on MgO (001)*  STEPHEN ELTINGE (Presenter), KIDAE SHIN, SANGJAE LEE, JUAN JIANG, CHARLES H AHN, FREDERICK J WALKER, SOHRAB ISMAIL-BEIGI, Yale University — Two-dimensional transition metal oxides (2DTMOs) are a promising addition to the growing array of functional 2D materials, with potential applications related to their long-lived, strongly bound excitons. In addition, 2DTMOs are expected to be more stable than other 2D materials since they do not react with water or oxygen species. However, unlike some other chalcogenides, 2DTMOs do not naturally occur in stackable van der Waals-bonded layers, so they present challenges for structural prediction and characterization. We report on ab initio density functional theory simulations of 2D titanium oxide layers on the (001) surface of MgO. We consider both monolayer TiO$_2$, including various surface reconstructions, and few-layer Mg$_2$TiO$_4$ based on a bulk inverse spinel structure. We examine the feasibility of various interfaces between the Mg$_2$TiO$_4$ overlayer and the MgO(001) substrate. We report on calculations of the optical absorption spectrum of low-energy structures in order to compare to experiment. Finally, we describe the improved treatment of the orbital energies of low-energy structures using a nonlocal hybrid functional.

*This work is supported by the NSF EAGER program, award 1838463. SE is also supported by an NSF Graduate Research Fellowship.

8:48AM A64.00003: Ab initio calculation of ionic oxidation states in metal oxides*  SOHRAB ISMAIL-BEIGI (Presenter), Yale University — The concept of the oxidation state of ions is intuitive and useful for determining or predicting the stability, metallicity, and/or magnetism of metal oxides (as well as other materials). Determining the oxidation state of an ion is almost always a straightforward exercise in the use of the periodic table together with atomic electronegativities. However, calculating the charge state of an atom in a crystal, i.e., assigning electrons to atoms, is a notoriously difficult and ill-defined problem. After a brief discussion of some of the most popular approaches used for assigning electrons to atoms and their relative merits, we discuss the relation of oxidation state to the band structure, band occupancy and band symmetry in metal oxides and what is required and what it means to compute oxidation states from the band structure. Examples of insulating and metallic bulk metal oxides as well as superlattices and interfacial systems will illustrate the ideas.

*This work was supported primarily by the NSF via MRSEC DMR-1119826 (CRISP).
9:00AM A64.00004: Radical-based MBE growth, chemical doping, and electronic transport in SrSnO$_3$ films
TRISTAN TRUTTMANN (Presenter), FENGDENG LIU, ABHINAV PRAKASH, JIN YUE, Chemical Engineering and Materials Science, University of Minnesota - Twin Cities, THOMAS E MATES, Materials Department, University of California, Santa Barbara, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota - Twin Cities — In this talk, we present our recent study of radical-based molecular beam epitaxy (MBE) growth, and controlled doping in coherent, epitaxial $n$-doped SrSnO$_3$/GdScO$_3$ (001) films using La and Nd as dopants. By combining detailed growth, structural characterizations, secondary ion mass spectroscopy (SIMS) and temperature-dependent magnetotransport measurements, we show films with one-to-one correlation between dopant and activated carrier concentration. Carrier density exceeding $1 \times 10^{20}$ cm$^{-3}$ was achieved in doped SrSnO$_3$ films, which is in excellent agreement with the dopant-solubility limit predicted by density functional theory calculations. A record-high room-temperature mobility of 70 cm$^2$ V$^{-1}$ s$^{-1}$ at $1 \times 10^{20}$ cm$^{-3}$ was obtained in a 12 nm La-doped SrSnO$_3$ film, making this the thinnest perovskite oxide semiconductor with electron mobility exceeding 25 cm$^2$ V$^{-1}$s$^{-1}$ at room temperature. We discuss the structure - dopant - scattering mechanisms - transport property relationships, providing essential knowledge for the design of electronic devices using these materials.

9:12AM A64.00005: Electronic and Magnetic Characterization of Doped Perovskite Stannate Epitaxial Thin Films*
EMILY LINDGREN (Presenter), Geballe Laboratory for Advanced Materials, Stanford University, HANJONG PAIK, Platform for the Accelerated Realization, Analysis, & Discovery of Interface Materials (PARADIM), Cornell University, CAROLINA ADAMO, Geballe Laboratory for Advanced Materials, Stanford University, ALPHA T. N’DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, DARRELL SCHLOM, Platform for the Accelerated Realization, Analysis, & Discovery of Interface Materials (PARADIM), Cornell University, YURI SUZUKI, Geballe Laboratory for Advanced Materials, Stanford University — La-doped BaSnO$_3$ thin films have been identified as a promising high mobility semiconducting oxide, which could play an important role in the development of an all-oxide power electronics platform. In order to incorporate spin functionality into these materials, we explore magnetic doping of the conducting perovskite stannates. We have fabricated La and Ru doped BaSnO$_3$ and SrSnO$_3$ films on (001) SrTiO$_3$ substrates grown by molecular beam epitaxy (MBE) and pulsed laser deposition (PLD). X-ray diffraction (XRD) was used to verify epitaxial growth and confirm high crystalline quality, with typical omega rocking curve FWHM of 0.05° deg. Films are optically transparent as verified by UV-vis spectrometry. They are also conductive, with room temperature mobilities up to 105 cm$^2$/Vs, and standard carrier electron concentrations of 1-2x10$^{20}$ /cm$^3$. Films show evidence of paramagnetism both in the field and temperature dependence of magnetization.

*We acknowledge support from the National Science Foundation (Platform for the Accelerated Realization, Analysis, and Discovery of Interface Materials (PARADIM)) under Cooperative Agreement No. DMR-1539918, as well as the National Science Foundation under grant #1762971.
9:24AM A64.00006: Weak Electron-Electron Interaction effects in La-doped SrSnO$_3$ Films
TIANQI WANG (Presenter), JIN YUE, LAXMAN R. THOUTAM, ABHINAV PRAKASH, BHARAT JALAN, Department of Chemical Engineering and Materials Science, University of Minnesota — Alkaline-earth stannates with perovskite structures have attracted significant research interest recently due to their wide bandgap, high optical transparency, and high room temperature mobility. These characteristics make them promising candidates for transparent electronics and power electronics applications. Significant progress has been made in the synthesis, characterization and device demonstration, but there are still many open fundamental questions regarding the electronic transport in stannates.

In this talk, we present the temperature and magnetic field dependent transport study of La-doped SrSnO$_3$ (SSO) films. We demonstrate that the electron-electron interaction effect is primarily responsible for an increase in the Hall coefficient in the La-doped SSO films below 50 K accompanied by an increase in the sheet resistance. Magnetoresistance fitting yielded a large electron phase coherence length exceeding 450 nm at 1.8 K and revealed the electron-electron interaction to be the electron phase-coherence breaking mechanism in La-doped SSO films. These results while providing critical insights into the fundamental transport behavior in doped stannates also indicate the potential applications in quantum coherent electronic devices owing to their large phase coherence length.

9:36AM A64.00007: Large Hysteretic Magnetoresistance in La-doped SrSnO$_3$

**Heterostructures: An Evidence of Magnetism?**
LAXMAN RAJU THOUTAM (Presenter), TRISTAN TRUTTMANN, ANIL K RAJAPITAMAHUNI, BHARAT JALAN, University of Minnesota — In this talk, we present our recent observation of a robust, hysteretic magnetoresistance (MR) in low-doped Sr$_{1-x}$La$_x$SnO$_3$ films grown on GdScO$_3$ (001)$_{pc}$ using radical-based MBE approach. At low temperatures, sample showed a transport behavior consistent with Efros-Shklovskii variable range hopping. The MR shows negative values for 6 K ≤ T ≤ 200 K whereas it crosses over to positive values at lower temperatures, 1.8 K ≤ T ≤ 5 K. A large anisotropy was observed at 1.8 K between the out-of-plane and the in-plane MR values with MR exceeding 100% for magnetic field in the plane of the sample. Significantly, a robust hysteretic behavior was observed at low temperatures, which disappears only at temperature above 5 K. We discuss the physical origin of the hysteresis, and the origin of large in-plane MR in low-doped SrSnO$_3$ providing important and critical insights into the role of defects, strain and the choice of substrates on the electronic and magnetic properties.

*Work supported by UMN NSF MRSEC*
Strain Dependent Characterization of Flexible BaSnO$_3$ Nanomembranes

PRASTUTI SINGH (Presenter), Department of Applied Physics, Stanford University, SEUNG SAE HONG, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory & Stanford University, VARUN HARBOLA, Department of Physics, Stanford University, HAROLD HWANG, Department of Applied Physics, Stanford University — Doped BaSnO$_3$ is a wide band-gap semiconductor that is known to exhibit high electron mobility at room temperature, showing great prospects as an alternative transparent conducting oxide to the industry standard indium-tin-oxide. Flexible transparent conducting oxides are of special interest for future photonics and optoelectronic devices but realizing high-quality films as flexible materials has been a challenge. In this work, we will discuss our efforts to fabricate nanometer thick, freestanding La-doped BaSnO$_3$ film that are highly conducting and transparent using a water-soluble and lattice matched Ba$_3$Al$_2$O$_6$ buffer layer$^1$. Using this technique, we can transfer the nanomembranes onto a flexible device platform and characterize the physical and electronic properties of La-doped BaSnO$_3$ as a function of strain.

Structural characterization and optimization of PAMBE-grown Ga$_2$O$_3$ on STO (001)*

TOBIAS HADAMEK (Presenter), Physics, University of Texas at Austin, ERIC DOMBROWSKI, Staib Instruments, AGHAM POSADAS, Physics, University of Texas at Austin, MARTHA R. MCCARTNEY, DAVID JOHN SMITH, Physics, Arizona State University, ALEXANDER DEMKOV, Physics, University of Texas at Austin — Wide band-gap semiconductor Ga$_2$O$_3$ is in the focus of research as a promising material for high-power device applications. Here, we report on the structural properties of Ga$_2$O$_3$ grown by plasma-assisted MBE on STO as a function of growth temperature. At elevated temperatures above 550 °C we observe two out-of-plane orientations of the beta-polymorph (1-2-2) and (100), each with four in-plane rotational domain orientations by XRD and RHEED. As we lower the temperature the high-energy surface (1-2-2) becomes suppressed and we obtain single-out-of-plane oriented (100) beta-Ga$_2$O$_3$. The possibility of thin interfacial layers of gamma-Ga$_2$O$_3$ is investigated by means of STEM. The relevance of the integration of Ga$_2$O$_3$ on STO is that STO can be epitaxially grown directly on Si (001) and hence, can function as a template layer for the integration of Ga$_2$O$_3$ onto the Si platform. A low temperature growth is therefore preferable.

Temperature-dependent Magnetotransport Study of Si-doped β-Ga$_2$O$_3$ Films

ANIL RAJAPITAMAHUNI (Presenter), LAXMAN RAJU THOUTAM, Department of Chemical Engineering and Materials Science, University of Minnesota-Minneapolis, PRANEETH RANGA, SRIRAM KRISHNAMOORTHY, Department of Electrical and Computers Engineering, The University of Utah, BHARAT JALAN, Department of Chemical Engineering and Materials Science, University of Minnesota-Minneapolis. — Monoclinic β-Ga$_2$O$_3$ has generated significant excitement due to the wide bandgap, high electrical breakdown and high electron mobility at room temperature. In this work, we will discuss temperature-dependent magnetotransport study of homoepitaxial Si-doped β-Ga$_2$O$_3$ (010) films grown via metal-organic vapor-phase epitaxy (MOVPE). Temperature dependent Hall measurements were carried out using Van der Pauw configuration. Hall measurement at room temperature yielded a linear slope and a carrier density ($n$) of ~ 4 x 10$^{17}$ cm$^{-3}$. A non-linear Hall resistance was however observed at 10 K < T < 150 K indicating the presence of multiple channel conduction. A transport model using two-channel conduction was used to fit the experimental magnetotransport data resulting in carrier densities, $n_1$, $n_2$ and the corresponding mobilities of $\mu_1$, and $\mu_2$ respectively. With decreasing temperature, $n_1$ showed a freeze-out behavior with an activation energy of ~ 15 meV, whereas $n_2$ remained nominally unchanged. By combining electrostatic gating using ion-gel as a gate-dielectric, detailed magnetotransport and transport modeling, we will discuss the origin of multiple carriers, defect-mobility relationship, and the relevant scattering mechanisms in MOVPE grown Si-doped β-Ga$_2$O$_3$.

Stabilizing extraordinary disorder in single crystal high entropy oxides

WENRUI ZHANG (Presenter), ALESSANDRO MAZZA, ELIZABETH SKOROPATA, THOMAS ZAC WARD, Oak Ridge National Lab. — In functional oxides, compositional changes to the cation sublattice(s) enables tunability to electronic and/or magnetic phases. For correlated systems, even low levels of cation substitution can have a dominating influence on behavior due to the near degeneracy of the spin/charge/orbital energy scales. Further, the local distortion fields near doping sites often act as the catalysis for phase transitions. Controlling the type, number, and magnitude of these local distortions is highly desirable but often not experimentally accessible. We demonstrate the creation of exceptionally high disorder fields in single crystal oxides. Examples of epitaxial perovskite, spinel, and layered Ruddlesden-Popper phases possessing 5 or more elements randomly distributed on one or more of their cation sublattices. Synthesis of these materials relies on precise control of configuration entropy to dominate the free energy landscape, thus avoiding phase separation generally inherent in complex multinary systems. The impact of changing spin, charge, and lattice distortion field uniformity in these high entropy oxides will be discussed.

10:36AM A64.00012: Epitaxial Oxides on Glass: A Platform for Integrated Oxide Devices*

JOHN E ORTMANN, University of Texas at Austin, MARTHA R. MCCARTNEY, Arizona State University, AGHAM POSADAS (Presenter), University of Texas at Austin, DAVID JOHN SMITH, Arizona State University, ALEXANDER DEMKOV, University of Texas at Austin — The fabrication of epitaxial, ultra-thin SrTiO$_3$ (STO) on thick SiO$_2$ without the need for complicated wafer-bonding processes has been demonstrated. The resulting transition metal oxide (TMO)-on-glass layer stack is analogous to traditional silicon-on-insulator (SOI) wafers, where the crystalline device silicon layer of SOI has been replaced by a crystalline functional TMO layer. Fabrication starts with ultra-thin body SOI on which crystalline STO is grown epitaxially by molecular beam epitaxy. The device silicon layer is subsequently fully oxidized by ex situ high-temperature dry O$_2$ annealing, as confirmed by X-ray photoelectron spectroscopy, X-ray reflectivity, and high-resolution electron microscopy. STO maintains its epitaxial registry to the carrier silicon substrate after annealing and no evidence for degradation of the STO crystalline quality as a result of the TMO-on-glass fabrication process is observed. The ease of fabricating the TMO-on-glass platform without the need for wafer bonding will enable rapid progress in the development of state-of-the-art TMO-based electronic and photonic devices.

10:48AM A64.00013: Growth and structure of Mg$_2$TiO$_4$ on MgO (001)*

KIDAE SHIN (Presenter), STEPHEN ELTINGE, SANGJAE LEE, Yale University, HYUNGKI SHIN, University of British Columbia, JUAN JIANG, Yale University, HAWOONG HONG, Argonne National Laboratory, BRUCE DAVIDSON, KE ZOU, University of British Columbia, SOHRAB ISMAIL-BEIGI, CHARLES H AHN, FREDERICK J WALKER, Yale University — The unique properties of two-dimensional (2D) materials, such as graphene and transition metal dichalcogenides, have been used for applications such as high mobility channels and as hosts for quantum optical phenomena. In transition metal oxides (TMOs), a similarly broad range of properties and devices may be possible to realize by leveraging the diverse properties and structures found in these materials and synthesizing them as ultrathin 2D films. In order to use 2D TMOs, understanding the limits of 2D oxide heteroepitaxy is crucial. Here, we report that growth of TiO$_2$ on MgO using molecular beam epitaxy (MBE) results in formation of epitaxial Mg$_2$TiO$_4$. Using a combination of in situ crystal truncation rod (CTR) measurements and first-principles density functional theory (DFT) calculations, the layer-resolved structure of Mg$_2$TiO$_4$ that is a few unit cells thick is determined, and the thermodynamic driving force behind Mg$_2$TiO$_4$ formation is calculated. These measurements resolve distinct structural features at the Mg$_2$TiO$_4$ interface with MgO, which is due to the polarity of Mg$_2$TiO$_4$, pointing to new ways to synthesize distinct 2D electronic structures in thin films.

Monday, March 2, 2020 8:00 AM - 11:00 AM
It was found recently that 2D electron fluids can support collective excitations that are not subject to Landau's $T^2$ dissipation [1,2,3]. This surprising collective behavior originates from the head-on carrier collisions, a process that dominates angular relaxation at not-too-high temperatures $T<<T_F$ due to the interplay of Pauli blocking and kinematic constraints. As a result, a large family of exceptionally long-lived excitations emerges, associated with the odd-parity harmonics of momentum distribution. This leads to "tomographic" dynamics: fast 1D spatial diffusion along the unchanging velocity direction accompanied by a slow angular dynamics that gradually randomizes velocity orientation. The abnormally slow angular relaxation originates from correlated angular dynamics involving "lock-step" angular displacements along the Fermi surface occurring in collinear two-particle collisions. The slow loss of directional memory is described as non-Brownian angular random walk, "superdiffusion" on the Fermi surface. The collective behavior with directional memory dominates at moderately long times, pushing the onset of conventional hydrodynamics to abnormally large timescales. The tomographic regime features an unusual hierarchy of time scales and scale-dependent transport coefficients manifest in fractional-power current flow profiles and unusual conductance scaling vs. temperature and sample size. This exotic behavior can be directly probed by transport measurement techniques, as well as by momentum-resolved tunneling measurements.

8:36AM A66.00002: Levy flights and non-local transport in Dirac and Weyl systems* [Invited]
JOERG SCHMALIAN (Presenter), Karlsruhe Institute of Technology — We show that hydrodynamic collision processes of Dirac and Weyl systems can be described in terms of a Fokker-Planck equation with fractional derivative, corresponding to a Lévy flight in momentum space. Thus, electron-electron collisions give rise to frequent small-angle scattering processes that are interrupted by rare large-angle events. The latter give rise to superdiffusive dynamics of collective excitations. We argue that such superdiffusive dynamics is of more general importance to the out-of-equilibrium dynamics of quantum-critical systems.

9:12AM A66.00003: Mirage and hidden collective modes in two dimensional Fermi liquids* [Invited] AVRAHAM KLEIN (Presenter), University of Minnesota, DMITRII MASLOV, University of Florida, ANDREY CHUBUKOV, University of Minnesota — I will show that two-particle correlation functions in 2D Fermi liquids have a nontrivial topological structure. The structure manifests itself in two exotic types of zero-sound collective modes: sharp propagating “hidden” modes that cannot be detected by spectroscopy and “mirage” modes that appear as sharp peaks in spectroscopy but don’t determine the Fermi liquid’s response. I will discuss how these features are associated with the existence of a two-sheet Riemann surface defined by the dynamical susceptibility $\chi(q,\omega)$. The hidden modes reside below the branch cut gluing the sheets, and the illusory modes reside on an unphysical sheet of the Riemann surface. Although neither the existence of a hidden mode, nor the illusory nature of a mirage mode, appear in spectroscopic probes, both can be readily identified in time-dependent measurements in pump-probe configurations.

Motivated by the recent development of terahertz pump-probe experiments, we investigate the short-time dynamics in superconductors with multiple attractive pairing channels. Studying a single-band and multiband superconductors, we find the signatures of collective excitations of the pairing symmetries (known as Bardasis-Schrieffer modes) as well as the order parameter amplitude (Higgs mode) in the short-time dynamics of the spectral gap and quasiparticle distribution after an excitation by a pump pulse. We show that the polarization and intensity of the pulse can be used to control the symmetry of the non-equilibrium state as well as frequencies and relative intensities of the contributions of different collective modes. We find particularly strong signatures of the Bardasis-Schrieffer mode in the dynamics of the quasiparticle distribution function. In the multiband superconductors we particularly address the collective modes and the short time dynamics of the superconducting state with $s + i s$-wave order parameter using an effective four-band model with two hole and two electron pockets. The amplitude and phase modes are coupled giving rise to a variety of collective modes and we further uncover a new coupled collective soft mode. Our work shows the potential of modern ultrafast experiments to address the collective excitations in unconventional superconductors and highlights the importance of sub-dominant interactions for the non-equilibrium dynamics in these systems.

10:24AM A66.00005: Spectroscopies of superconducting collective modes: new advances and open questions [Invited] LARA BENFATTO (Presenter), Sapienza University of Rome, Italy — In the last few years, a number of experiments carried out with very intense THz fields, either in transmission or in pump-probe configuration, have shown the possibility to excite superconducting collective modes via light pulses. The signatures of the superconducting excitations manifest either in third-harmonic generation, in the case of narrowband pulses, or in well-defined oscillations of the transmitted field as a function of the pump-probe delay, in the case of broadband pulses. In the latter case, the phenomenon is completely analogous to the well-known excitations of Raman-active phonons in insulating and metallic systems. Despite the clear interest in the fundamental and applicative aspects of these techniques, a clear theoretical paradigm for the description of these experiments is still lacking. In this talk I will present a general scheme we recently developed [1,2] to describe step-by-step the processes behind the pump-probe detection of collective excitations, that can be equally well applied to ordinary phonons as well as electronic collective modes. I will then discuss a direct application of our interpretative scheme to the light-induced excitation of the so-called superconducting phase Leggett mode in the multi band MgB2 superconductor[2], and its connection to the phenomenon of the third-harmonic generation in superconductors[3,4]. Finally, I will present some recent results [5] on the role of the superconducting phase mode for the non-linear optical response in unconventional curate superconductors.

Session A67 DCMP: Thermal Hall Effect in Quantum Materials Four Seasons
2-3 - Leon Balents, University of California, Santa Barbara - Tag(s): Invited

8:00AM A67.00001: Thermal Hall conductivity of spin liquids at low temperatures* [Invited] N. PHUAN ONG (Presenter), PETER CZAJKA, TONG GAO, Physics, Princeton University — I will describe results on low-temperature thermal Hall conductivity Kxy of several quantum spin liquids based on honeycomb and triangular lattices, primarilty α-RuCl3, and Na2BaCo(PO4)2. In α-RuCl3, I will describe recent evidence suggesting the existence of a neutral Fermi surface. Results on the thermal Hall conductivity at temperatures performed at temperatures down to 0.4 K will be presented. The difficult challenges facing Kxy measurements will be discussed.

*Supported by Dept of Energy (Contract DE-SC0017863), NSF MRSEC (award DMR 1420541) and the Gordon and Betty Moore Foundation (Grant GBMF4539).
For several years, the compound $\alpha$-RuCl$_3$ is considered as one prime candidate material to host a Kitaev topological quantum spin liquid (TQSL). Such a TQSL has been predicted for the spin-1/2 Kitaev model on a honeycomb lattice in an external magnetic field [1]. The zero field ground state is a quantum spin liquid with itinerant Majorana fermions and immobile gauge fluxes as elementary excitations. An external magnetic field gaps out the Majorana bulk states and topological Majorana edge states emerge. Indeed, for $\alpha$-RuCl$_3$ there is evidence for a significant Kitaev interaction acting between neighboring $j_{\text{eff}}=1/2$ moments. However, the ground state of $\alpha$-RuCl$_3$ shows long-range antiferromagnetic order, indicative of additional Heisenberg-type and anistropy terms in the spin Hamiltonian. An in-plane field of about 8 T suppresses the magnetic order, which opens the question whether the field-induced ground state bears the main signatures of the Kitaev TQSL. In this talk, I will discuss our experimental efforts to probe the elementary magnetic excitations of $\alpha$-RuCl$_3$ by thermal transport. After summarizing the main findings for the longitudinal heat conductivity $\kappa_{xx}$ [2], and briefly discussing new data which extend our findings to very large magnetic fields and lower temperature, I will focus on the surprising and sizeable thermal Hall effect $\kappa_{xy}$ with a field perpendicular to the RuCl$_3$-planes [3] as well as on our attempts to study this quantity for different field orientations.

*We acknowledge financial support from the DFG through SFB 1143 (project-id 247310070) and through projects HE3439/12 and HE3439/13.
The nature of the pseudogap phase of cuprates remains a major puzzle. Although there are indications that this phase breaks various symmetries, there is no consensus on its fundamental nature [1]. Fermi-surface, transport and thermodynamic signatures of the pseudogap phase are reminiscent of a transition into a phase with antiferromagnetic order, but evidence for an associated long-range magnetic order is still lacking. Here we report measurements of the thermal Hall conductivity $\kappa_{xy}$ in the normal state of four different cuprates and show that a large negative $\kappa_{xy}$ signal is a property of the pseudogap phase, appearing with the onset of that phase at the critical doping $p^*$ [2]. It is also a property of the Mott insulator at $p \approx 0$, where $\kappa_{xy}$ has the largest reported magnitude of any insulator. Since this negative $\kappa_{xy}$ signal grows as the system becomes increasingly insulating electrically, it cannot be attributed to conventional mobile charge carriers. Nor is it due to magnons, since it exists in the absence of magnetic order. Our observation is reminiscent of the thermal Hall conductivity of insulators with spin-liquid states [3, 4, 5] pointing to neutral excitations with spin chirality in the pseudogap phase of cuprates.

9:48AM A67.00004: Thermal Hall effect in quantum paramagnets and cuprates [Invited] JUNG HOON HAN (Presenter), Physics, Sungkyunkwan University — Several theoretical aspects of thermal Hall transport in magnetic insulators are discussed in light of recent experimental progress in frustrated magnets and in undoped cuprates. A general formalism for calculating thermal Hall conductivity in magnets is presented[1,2] and used to compute such quantity for kagome ferromagnets[1] and antiferromagnets[3] under the perpendicular magnetic field. Both calculations bear close resemblance to actual experimental data. Furthermore I discuss our recent theoretical effort to understand the remarkable yet puzzling observation of large thermal Hall conductivity in undoped to lightly doped cuprates[4]. A tentative scenario in terms of spinon Fermi surface is presented to work, to a certain extent, in matching the observation, albeit on weak experimental foundation. The talk covers materials learned from collaboration with Hyunyong Lee, Jin-Hong Park, Patrick Lee, and Yamashita group at ISSP.

10:24AM A67.00005: Thermal Hall effect in square-lattice spin liquids: an application to cuprates* [Invited] MATHIAS SCHEURER (Presenter), Harvard University — Recent experiments [1] have revealed an enhanced thermal Hall effect in the pseudogap phase of several different cuprates compounds. The large signal even persists in the undoped system and, thus, challenges our understanding of the antiferromagnetic phase fundamentally. In this talk, I will analyze possible mechanisms that can give rise to a thermal Hall effect in the square-lattice Heisenberg antiferromagnet [2,3]. In particular, I will discuss the possibility [3] that the magnetic field drives the Néel state close to a transition to a phase where Néel order coexists with a chiral spin liquid. A spinon lattice model for this transition is shown to give rise to a large thermal Hall conductivity that also features a similar magnetic field and temperature dependence to experiment. We will derive the low-energy continuum field theory for the transition, which is characterized by an emergent global SO(3) symmetry and has four different formulations that are all related by dualities.

Session A68 DPOLY: 100 Years of Polymer Science  Four Seasons 4 - Connie Roth, Emory University - Tag(s): Invited, Undergrad Friendly

8:00AM A68.00001: Equilibration and Dynamics in Block Copolymer Micelles  [Invited]
TIMOTHY LODGE (Presenter), University of Minnesota — Block copolymers provide a remarkably versatile platform for achieving desired nanostructures by self-assembly, with length scales ranging from a few nanometers up to several hundred nanometers. In particular, block copolymer micelles in selective solvents are of great interest across a range of technologies, including drug delivery, imaging, catalysis, lubrication, and extraction. While block copolymers generally adopt the morphologies familiar in small molecule surfactants and lipids (i.e., spherical micelles, worm-like micelles, and vesicles), one key difference is that polymeric micelles are typically not at equilibrium. The primary reason is the large number of repeat units in the insoluble block, \( N_{\text{core}} \), which makes the thermodynamic penalty for extracting a single chain (“unimer exchange”) substantial. As a consequence, the critical micelle concentration (CMC) is rarely accessed experimentally; however, in the proximity of a critical micelle temperature (CMT), equilibration is possible. We use time-resolved small angle neutron scattering (TR-SANS) to obtain a detailed picture of the mechanisms and time scales for chain exchange, for systems at or near equilibrium. The dependence of the rate of exchange on the key variables – concentration, temperature, \( N_{\text{core}} \), \( N_{\text{corona}} \), and chain architecture (diblock versus triblock) – will be discussed. We will also address measurements of micelles prepared far from equilibrium, which equilibrate by fragmentation processes, using dynamic light scattering, small-angle X-ray scattering, and liquid-state TEM.
Over the last few decades, there has been rapidly growing interest in soft, stimuli-responsive polymeric materials ("mushy, squishy systems") that exhibit a global response to a local signal. One motivation for creating such polymers arises from a technological need to produce energy efficient devices that can amplify or convert a small-scale input into a large-scale action. Another inspiration for focusing on responsive polymers comes from biology. One of the exquisitely evolved properties of biological systems is the ability to convert local information into a global action. Few synthetic materials can match the ability of biological systems to undergo large-scale, rapid motion in response to local changes. There are a number of design challenges that must be met in order to create such efficient systems. First, the polymeric material must be capable of not only sensing a local signal, but also reacting in a specified manner. Second, the polymers should ideally be capable of transducing one form of energy (e.g., electromagnetic, optical, chemical) into a mechanical action and thus must be "active". Developing such responsive polymeric materials poses significant and intriguing scientific challenges, and necessitates the development of robust theoretical and computational models for the behavior of active materials systems. A few examples of these kinds of modeling approaches will be discussed, highlighting efforts that are valuable for developments in future technologies, such as soft robotics and autonomously operating devices.
The surprising flow behavior of entangled polymer melts and solutions has been a subject of enduring interest. In the last 30 years, substantial progress has been made in mechanistic understanding of entangled polymer rheology, based on the tube ansatz of Edwards and de Gennes. I will summarize the essential physics of the “success stories”: 1) linear dynamic rheology of entangled linear chains, stars, star-linear blends, H-polymers, polydisperse multiply branched chains, and polydisperse linear chains; and 2) nonlinear extensional flow of linear chains and branched polymers.

With that progress, how well do we understand where the tube comes from? Simulations have been helpful: we can observe the “skeleton” of the tube with various chain-shrinking methods, and “see” the tube using isoconfigurational averaging. And, we can relate the tube to a measure of how many knots the melt can tie, the “topological entropy”.

But can we predict the tube diameter from chain architecture? I will describe a new scaling theory that joins previous predictions for flexible chains and stiff chains. Overall, entanglement is governed by close encounters between chains, when they can “zig” one way or “zag” the other as they pass. These encounters are governed by 1) the larger of the packing length $p$ or chain diameter $d$, and 2) whether an entanglement strand is flexible.

Scaling based on packing length and flexible chains (Lin-Noolandi, or LN) describes a wide range of real polymers; but commonly simulated linear bead-spring chains behave as entangled “threads”, with no role for $p$. However, if we “bulk up” linear bead-spring chains with sidegroups, we can observe LN scaling in simulations. This raises the question of how to *measure* the packing length, which we do by asking how far from a given monomer most of the density comes from its own chain. Packing length measured this way is consistent with LN scaling, and differs from simple estimates based on the effective diameter of chains.
From the first numerical simulations of single polymer chains in dilute solution to current exascale simulations of highly entangled polymer melts, computer simulations have played a critical role in polymer physics. Numerical simulations have provided microscopic insight into macroscopic behavior. Here the potential of computations to polymer physics in the realm of new computer architectures will be introduced in view of the fundamental insight connecting theory and experiments attained thus far. Capturing the wide range of coupled length and time scales that govern the unique macroscopic, viscoelastic behavior of polymers has been one of the major challenges to surmount. Starting with the simple bead-spring models, through atomistically inspired coarse-grained approaches, it is now possible to capture not only the mobility of the chain but also the viscoelastic properties of entangled polymers. With current and future computational resources, numerical simulations will provide the understanding of viscoelastic response and shear and extensional viscosity of entangled melts for complex architectures bridging the dynamics on the length scale of the atomic level with the macroscopic response.

*This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under Contract No. DE-NA-0003525.
We first introduce the field of “Entangled Active Matter”. Active systems span an enormous range of length scales, from the cytoskeleton of individual living cells to tissues and animal groups such as fish or insect swarms. We will focus on “entangled active matter”, where the building blocks are transiently bound. We will point out strong similarities of mechanical properties between aggregates of cells, swarm of ants, of cells and inert viscous pastes.

We characterize the tissue mechanical properties (surface tension, elasticity, viscosity) using pipette aspiration technique. Cellular aggregates exhibit a viscoelastic response in analogy to ultra-viscous polymer melts. When we apply oscillating pressures, we observe a reinforcement of the tissue at high frequencies. We developed a model to determine the main mechanical properties of the system as a function of the oscillation frequencies. Unlike inert polymer melts, we observe aggregate's reinforcement with pressure, which gives rise to pulsed contractions or “shivering”, interpreted as a mechano-sensitive active response of the acto-myosin cortex.

We then describe the spreading of aggregates on rigid and soft substrates, varying both intercellular and substrate adhesion. We find both partial and complete wetting, with a precursor film forming a dense cellular monolayer in analogy with the stratified spreading of viscous polymer melts. On soft substrate, the precursor film is unstable, leading to a symmetry breaking of cells polarity causing the aggregate to move spontaneously as a giant keratocytes.

8:00AM A70.00001: Dynamics of nanoparticles in polyelectrolyte solutions* ALI H SLIM, Univ of Houston, RYAN POLING-SKUTVIK, University of Pennsylvania, JACINTA CONRAD (Presenter), Univ of Houston — Recent theories indicate that nanoparticle dynamics in semidilute solutions of neutral, flexible polymers couple to the segmental relaxations of polymer chains. How nanoparticle dynamics couple to relaxations of charged, semiflexible polymers remains incompletely understood. Here, we probe the dynamics of polystyrene nanoparticles in solutions of a polyelectrolyte, sodium polystyrene sulfonate, using fluorescence microscopy. When the ionic strength of the solution is high, such that the polymer adopts a Gaussian conformation, the nanoparticle dynamics are coupled to the bulk solution viscosity across the dilute and semidilute regimes of polymer concentration. In near-salt-free solutions, in which the polymer adopts an extended conformation, the nanoparticle dynamics do not follow the Stokes-Einstein prediction based on the bulk viscosity across all polymer concentrations, and furthermore do not collapse onto a master curve as a function of normalized length scales. This result suggests that the coupling of nanoparticle and polymer segmental dynamics are altered by polymer conformation.

8:12AM A70.00002: Correcting the Generalized Stokes-Einstein Relation to Include Effects of Hydrodynamic Interactions from Periodic Images* JEFFREY ETHIER (Presenter), Illinois Institute of Technology, POURIA NOURIAN, RAJESH KHARE, Texas Tech University, JAY SCHIEBER, Illinois Institute of Technology — In microrheology, the mean squared displacement (MSD) of micron-sized particles is measured to extract linear viscoelastic properties of entangled polymer melts using the generalized Stokes-Einstein (SE) relation. Probe rheology from molecular dynamics (MD) simulations has a significant computational cost due to the large simulation box sizes required to reduce the effect of the probe’s hydrodynamic interactions with its periodic images. Here, we use an analytical solution for Stokes flow around a body-centered cubic array of spheres to introduce a correction factor to the generalized SE relation. We show that this correction factor is a function of the ratio ($R/L$), where $R$ and $L$ are particle radius and simulation box length, and the fluid mass fraction. We then predict the dynamic moduli of an entangled melt of bead-spring polymer chains from the MSD of a probe particle at various $R$ and $L$. Lattice Boltzmann simulations are also performed to calculate the transient drag force and velocity of a particle in a Newtonian fluid to account for effects of inertia at higher frequencies. This added correction factor should allow a reduction of at least one order of magnitude in MD simulation costs.

8:24AM A70.00003: Resolving structure-property-dynamics relationships in model polymer nanocomposite systems* BENJAMIN YAVITT (Presenter), DANIEL SALATTO, ZHIXING HUANG, MAYA ENDOH, State Univ of NY - Stony Brook, LUTZ WIEGART, ANDREI FLUERASU, YUGANG ZHANG, MASAFUMI FUKUTO, RUIPENG LI, Brookhaven National Laboratory, VERA BOCHAROVA, Oak Ridge National Laboratory, ALEXEI SOKOLOV, University of Tennessee, Knoxville, TAD KOGA, State Univ of NY - Stony Brook — Understanding the origins of mechanical enhancement in polymer-nanoparticle composites (PNC) is necessary to design materials with optimized mechanical properties. We use a combination of techniques to resolve the dynamics-structure-property relationships governing mechanical enhancement in a model PNC system of attractive SiO2 nanoparticles embedded in a glassy P2VP polymer matrix over a wide range of NP concentrations (1 – 25 vol.%). By tuning the interparticle distance between neighboring NPs, the formation of the proposed “structural bridge” and the resulting contribution to mechanical enhancement are resolved [1]. The nanoscale structure is investigated by SAXS and TEM while the micro/macro dynamics are resolved by x-ray photon correlation spectroscopy (XPCS) and shear rheology respectively. As concentration increases, the characteristic relaxation times increase dramatically. The dynamics transition to collective motion at the gel point, which correlates to the formation of a sample spanning network. Identification of “rubbery” and “glassy” bridges are discussed in the context of the observed dynamics. [1] Chen, Q.; et al. ACS Macro Lett. 2015, 4 (4), 398–402.

8:36AM A70.00004: Role of soft interactions in enhanced diffusivity of polymer-grafted nanoparticles in heterogeneous environments RYAN POLING-SKUTVIK (Presenter), University of Pennsylvania, JACINTA CONRAD, RAMANAN KRISHNAMOORTI, University of Houston — The dynamic behavior of dilute solutions of polymers is well described by the colloidal model or the Zimm model. In denser systems, the colloidal description fails as interactions with the environment become important. Here, we investigate the behavior of polymer-grafted nanoparticles (PGNPs), where the grafting to the nanoparticle surface causes a high self-concentration of the polymer chains. When dispersed in semidilute polymer solutions, the grafted polymer chains compress and their dynamics are confined by neighboring chains. This change in grafted polymer dynamics arises from the soft repulsive interaction between PGNPs and surrounding polymer chains. This soft interaction profile also affects the dynamics on longer length and time scales. Whereas hard sphere diffusivity decouples from bulk predictions in polymer solutions when the particle becomes comparably sized to the polymer, the diffusivity of soft PGNPs decouples from solution viscoelasticity even when they are larger than the surrounding polymer. Furthermore, the PGNP dynamics strongly depend on the ratio of free to grafted polymer molecular weights. These findings indicate that soft interactions allow PGNPs to diffuse faster than hard spheres in heterogeneous materials.
8:48AM A70.00005: Dynamic Behavior of Polystyrene Soft Nanoparticles by Neutron Spin Echo  
JACOB FISCHER (Presenter), MARK DADMUN, University of Tennessee, Knoxville, ANTONIO FARAOONE, NCNR, NIST — The inclusion of soft polystyrene nanoparticles improves the dynamic properties of bulk polystyrene, a behavior that is not yet fully understood. To provide insight into this phenomenon, the dynamics of the nanoparticles are evaluated using neutron spin echo (NSE) spectroscopy. These particles consist of a crosslinked polystyrene core with loosely connected loops and tails, which we term a fuzzy interface. NSE spectroscopy of dilute solutions of the nanoparticles (NPs) show the nanoparticle with the lowest crosslinking density and molecular weight exhibits the most Zimm-like dynamics. Varying the synthetic procedure to create nanoparticles with lower molecular weights and fuzzier surfaces results in more heterogeneous relaxation processes, indicating that the dynamics of the core differs significantly from that of the outer shell. Combined with our previous studies showing the relationship between the fuzziness of the nanoparticle and diffusion of bulk polystyrene, these results exemplify the importance of the NP molecular weight and the interaction of the fuzzy interface with linear chains in determining the dynamics of all polymer nanocomposite system.

9:00AM A70.00006: Universality in Microstructural Evolution of Deformed Polymer Melts as Revealed by Small-Angle Neutron Scattering and Molecular Dynamics Simulation*  
WENSHENG XU, CHRISTOPHER N LAM, JAN-MICHAEL CARRILLO, BOBBY SUMPTER, YANGYANG WANG (Presenter), Oak Ridge National Lab — The viscoelastic properties of polymers are strongly influenced by the entanglement phenomenon. Historically, distinct theoretical models have been developed to understand the rheology of entangled and unentangled polymer melts. Using small-angle neutron scattering and nonequilibrium molecular dynamics simulations, we show that the microstructural evolutions of deformed entangled and unentangled polymer melts share a number of universal traits that cannot be comprehended within the classical theoretical framework. Our analysis suggests that interchain correlations play a fundamental role in nonlinear polymer melt rheology.

*The research is supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, Early Career Research Program Award KC0402010, under Contract DE-AC05-00OR22725.
Nanoparticle effect on multiscale polymer dynamics in nanocomposites: insights from neutron and x-ray spectroscopy [Invited]  ERKAN SENSES (Presenter), Koc University — Dynamics of polymers in presence of nanoparticles has attracted much attention due to immediate consequences on the rheological behavior of polymer nanocomposites. Bulk techniques are usually insufficient to study the component dynamics mainly due to lack of space-time resolution required for intrinsically complex relaxation mechanisms. In our studies, we applied extensive neutron and x-ray scattering techniques, specifically backscattering, neutron spin echo, and x-ray photon correlation spectroscopy to gain microscopic insight on the role of nanoparticle size, shape, loading, dispersion state, polymer-particle interfaces and confinement on multiscale polymer dynamics as well as on slow nanoparticle relaxation in attractive nanocomposites [1, 2]. These interconnected and often competing effects result in the unusual rheological behavior, the origin of which has long been debated. By simultaneously accessing time scales from sub-nanosecond to hundreds of nanoseconds, and length scales from monomers to entanglement spacing, we directly measured the key dynamical parameters- Rouse rate and reptation tube size- in nanocomposites, and correlated them with the macroscopic mechanical relaxation and the nanoscale particle motion [3].

Molecular Dynamics Simulations of a Polymer Star under Shear Flow
JAN-MICHAEL CARRILLO (Presenter), YANGYANG WANG, BOBBY SUMPTER, WEI-REN CHEN, Oak Ridge National Lab — We performed large-scale coarse-grained molecular dynamics simulation of a polymer star in a melt of short polymer chains under shear flow in dilute star concentrations. The temperature of the system was maintained using a dissipative particle dynamics (DPD) thermostat to conserve momentum and model hydrodynamic interactions. Simulations at the quiescent state was used to determine the timescale for which the end-to-end vector of the star’s arm as it relaxes. The star has sixteen arms and its motion under shear in high Weissenberg numbers is characterized by a cycle of collapse and extension of the star’s arm, which is in line with expected tank-treading motion. We used the trajectories of these simulations to calculate quantities pertinent to neutron scattering experiments, such as small angle neutron scattering under high shear stress, or SANS in the rheo-SANS environment, and predict the resulting spectra from these experiments. Specifically, we calculate the star’s anisotropic single-molecule structure factor through the spherical harmonic expansion approach.
**10:00AM A70.00009: Dynamics and Rheology of THF Swollen Ionic Polymer Melts: Molecular Dynamics Simulation Study**

SHALIKA D. K. MEEDIN (Presenter), CHATHURIKA KOSGALLANA, MANJULA SENANAYAKE, Department of Chemistry, Clemson University, Clemson, SC, United States, 29634., GARY GREST, Sandia National Laboratories, Albuquerque, NM 87123, DVORA PERAHIA, Department of Chemistry, Clemson University, Clemson, SC, United States, 29634. Department of Physics, Clemson University, Clemson, SC, United States, 29631. — The macroscopic dynamics of ionic polymers are often constrained by the formation of ionic clusters. Traces of solvents however affect the structure, dynamics and viscoelastic response of these melts. Here, we probe the effects of THF on the dynamics of polystyrene sulfonate (PSS) melts by fully atomistic molecular dynamics simulations. We hypothesize that THF penetrates both hydrophilic and hydrophobic domains, affecting their interrelation. Melts swollen with THF as the sulfonation fraction is varied were studied. We find that with the addition of THF the average cluster size decreases. The number of THF molecules associated with ionic groups increases with increasing sulfonation fraction \( f \). Shear measurements show that the addition of small amounts of THF decreases the viscosity dramatically. Correlations of the dynamics of swollen melts on different time and length scales as determined by MSD and \( S(q, t) \) with the rheology studies will be discussed.

*DOE funding DE-SC0019284

**10:12AM A70.00010: Influence of Chain Architecture on the Kinetics of Chain Exchange Between BCC-Ordered Copolymer Micelles: A Dynamical Self-Consistent Mean-Field Theory Study**

MARK HOLDEN (Presenter), ROBERT WICKHAM, Univ of Guelph — Motivated by recent time-resolved small-angle neutron scattering results, we study the kinetics of symmetric ABA and BAB triblock copolymer exchange between BCC-ordered spherical micelles using dynamical self-consistent field theory simulations. We characterize the equilibrium properties of micelles in pure melts of AB, ABA, and BAB copolymers, and systematically examine the decay time of the fraction of core (A) blocks remaining in their original micelle, as well as the chain self-diffusion constant, as a function of segregation. Differences in the equilibrium micelle structure between these cases complicate comparison of the dynamical behaviour for the different chain architectures. This complication is overcome by simulating tracer triblock copolymers in a constant background of BCC-ordered diblock micelles, allowing for direct comparison of the chain diffusion for the different chain architectures, as a function of segregation.
10:24AM A70.00011: Revealing Structures and Dynamics of Bound Chains in Filler-Reinforced Elastomers  
DANIEL SALATTO (Presenter), BENJAMIN YAVITT, MAYA ENDOH, Stony Brook University, TOMOMI MASUI, HIROYUKI KISHIMOTO, Sumitomo Rubber Industries Ltd., JAN-MICHAEL CARRILLO, ORNL, TAKASHI TANIGUCHI, Kyoto University, MICHIIRO NAGAO, NIST, TADANORI KOGA, Stony Brook University — Filler-reinforced elastomers have been of great interest to the broad materials community for at least the last three decades. The addition of nanofillers such as carbon black or silica to elastomers affects the overall rheological and mechanical properties mainly due to the creation of a few nanometer-thick bound polymer layer (BPL) on a filler surface at which the polymer is expected to have different structural and dynamical behavior from the bulk. However, the detailed descriptions of the BPL remain a challenge due to the lack of experimental techniques that directly probe the BPL. In this presentation, using simplified industrial carbon black (CB) filled polybutadiene in conjunction with contrast-matched neutron scattering and spectroscopy techniques, we resolve the buried structure at the nanometer-scale and the dynamics at the picosecond-to-nanosecond time scales in the polymer matrix.

10:36AM A70.00012: The Effect of Rubbery/Glassy Block Copolymer Brushes on the Dynamic Behaviors of Silica Particles in Nanocomposite Elastomer  
CHAO-HUNG CHENG (Presenter), SHIORI MASUDA, NATTANEE DECHNARONG, KENTO FUKADA, KIYU UNO, KAZUTAKA KAMITANI, Kyushu Univ, TAIKI HOSHINO, SPring-8 Center, RIKEN, KEN KOJOI, ATSUSHI TAKAHARA, Kyushu Univ — Matrix-free elastomer nanocomposites with high strength was prepared by rubbery/glassy block copolymer-grafted silica nanoparticles (BCP-g-SiNP). Investigation of dynamic behavior of the nanocomposites can help us to know the dynamic structure and properties. However, the dynamic behavior of SiNP in the BCP-g-SiNP has not been well-studied. In this study, X-ray photon correlation spectroscopy (XPCS) was utilized to analyze the dynamics of BCP-g-SiNP with inner poly(butyl acrylate) and outer poly(methyl methacrylate). The XPCS measurement revealed that the relaxation rates of SiNP were proportional to $q$ value, indicating that the behavior of SiNP in the block copolymer-grafted SiNP was non-Brownian and hyperdiffusion motion. At the same $q$ value, the relaxation rates increased dramatically as the temperature exceeded $T_g$. This is due to the outer PMMA phase changed to the rubbery state, and the restriction of SiNP motion by PMMA decreased. Moreover, during elongation, the relaxation rates of SiNP in the direction perpendicular to elongation was faster than in the direction parallel to elongation. The extended polymer chains might restrict the motion of SiNP, leading the slower relaxation rate of SiNP in the direction parallel to elongation.
The Role of Fast Relaxations in Cross-Linked Polymer Networks for Impact Mitigation

CHRISTOPHER SOLES (Presenter), KANAE ITO, ADAM B BURNS, MADHUSUDAN TYAGI, National Institute of Standards and Technology, DANIEL KNORR, KEVIN A MASSER, JOSEPH L LENHART, Army Research Laboratory — Composites for ballistic impact resistance integrate high strength reinforcements, such as high strength fibers or ceramic, with a polymeric binder that imparts ductility to the system. Together these components provide the strength plus ductility to realize tough ballistic composites. The binder is often a cross-linked polymer networks where the reactive liquid monomers can be impregnated into the composite structure and then be cross-linked into a rigid component. To this end, there is a significant interest in the molecular origins of toughness in cross-linked networks - why some systems lead to tough resins whereas others lead to a brittle response. Here we explore a series of model epoxy networks with moderate toughness to a series dicyclopentadiene networks which display incredible toughness deep into the glassy state. Quasielastic neutron scattering (QENS) is used to quantify molecular motions on the time scale of ps to ns in these networks. This reveals a strong correlation between these fast polymer relaxations and toughness. Collective many atom vibrations are important for toughness, but not enough. The many atom vibrations must lead to dissipative, many atom relaxations in order to dissipate energy and enhance toughness under ballistic impact conditions.

Session B01 DAMOP DCMP: Disorder and Localization in AMO Systems

Many-body delocalization of ultracold bosons in lattices [Invited]

CHRISTIAN GROSS (Presenter), Max-Planck-Institute of Quantum Optics — Many-body localization describes the phenomenon of localization and vanishing charge transport in closed quantum many-body systems. It is well accepted by now that MBL is stable in one dimension and many of its properties have been revealed. Much less is known in two dimensions. Here we present our recent results on the study of the stability of the localization in 2d bosonic lattice systems. Our observation is consistent with persistent localization if the system is brought in contact with a small quantum bath, but localization is clearly destroyed for larger baths. The dynamics towards the steady state differs strongly in the two cases.
11:51AM B01.00002: Instability of subdiffusive spin dynamics in strongly disordered Hubbard chain

MAKSYMILIAN SRODA (Presenter), Department of Theoretical Physics, Wroclaw University of Science and Technology, PETER PRELOVSEK, J. Stefan Institute, MARCIN MIERZEJEWSKI, Department of Theoretical Physics, Wroclaw University of Science and Technology — We study spin transport in a Hubbard chain with a strong, random, on-site potential and with spin-dependent hopping integrals $t_\sigma$. For the SU(2) symmetric case $t_\uparrow = t_\downarrow$, such a model exhibits only partial many-body localization with localized charge and (delocalized) subdiffusive spin excitations [1,2]. In our work [3], we demonstrate that breaking the SU(2) symmetry by even weak spin asymmetry, $t_\uparrow \neq t_\downarrow$, localizes spins and restores full many-body localization. To this end, we derive an effective spin model where the spin subdiffusion is shown to be destroyed by arbitrarily weak $t_\uparrow \neq t_\downarrow$. Instability of the spin subdiffusion originates from an interplay between random effective fields and singularly distributed random exchange interactions.

12:03PM B01.00003: Many-body localization from a one-particle perspective in the disordered 1D Bose-Hubbard model

MIROSLAV HOPJAN (Presenter), FABIAN HEIDRICH-MEISNER, Institute for Theoretical Physics, University of Göttingen, Germany — We numerically investigate 1D Bose-Hubbard chains with onsite disorder by means of exact diagonalization. Consistent with previous studies, we observe signatures of transition from the ergodic to the many-body localized (MBL) regime when increasing the disorder strength or energy density. Apart from the entanglement entropy as a conventional but indirect measure for the ergodic-MBL transition we utilise the one-particle density matrix (OPDM) to characterize the system [1]. We show that the natural orbitals (the eigenstates of OPDM) are extended in the ergodic phase and real-space localized when one enters into the MBL phase. Furthermore, the distributions of occupancies of the natural orbitals as well as the diagonal part of OPDM (i.e., the site occupancies) can be used as measures of Fock-space localization in the respective basis [2]. Moreover, the full distribution of the densities of the physical particles provides a one-particle measure for the detection of the ergodic-MBL transition which could be directly accessed in experiments with ultra-cold gases.

12:15PM B01.00004: Localization dynamics in a centrally coupled system  NATHAN NG (Presenter), University of California, Berkeley, RAJAGOPALA SEELAM, SEBASTIAN WENDEROTH, University of Freiburg, MICHAEL KOLODRUBETZ, University of Texas at Dallas, ERAN RABANI, University of California, Berkeley, MICHAEL THOSS, University of Freiburg — We investigate a disordered Ising chain in which all spins couple to a central qudit, through which spin flip interactions are mediated. For small but finite coupling, the trivial localization of the non-coupled limit survives as a form of many-body localization (MBL). By using an exact wavefunction propagation method, we are able to observe the dynamics of large system sizes (L~50-100) to intermediate timescales and establish the existence of slow or vanishing relaxation. This allows us to address the question of the proper scaling of the qudit size with L in the thermodynamic limit, the suppression of effective all-to-all coupling to protect MBL, and the dependence of localization on energy density.

12:27PM B01.00005: Strongly resonating clusters around the ergodic-MBL transition* BENA JM VILLALONGA (Presenter), BRYAN CLARK, University of Illinois at Urbana-Champaign — An interacting quantum system can transition from an ergodic to a many body localized (MBL) phase under the presence of sufficiently large disorder. Both phases are radically different in their dynamical properties, which are characterized by highly excited energy eigenstates. One of the differences between both phases is in the statistics of their energy levels: while in an ergodic phase levels experience repulsion and follow GOE statistics, in MBL they largely lack repulsion and follow Poisson statistics. Here, we argue that the transition between both behaviors is accompanied by the formation of resonating clusters in the eigenstates of the Hamiltonian. Using a basis of local integrals of motion (l-bits), we observe that these clusters take the form of cat states over a subset of l-bits on a 1D spin chain. While such resonances are rare in MBL, they proliferate around the transition, and are absent well into the ergodic phase. Finally, the spatial structure of the resonating clusters suggests correlations that are scale invariant in the chain, which we check numerically for finite size systems.

12:39PM B01.00006: Inverted many-body mobility edge in a central qudit problem SAEED RAHMANIAN KOSHAKI (Presenter), MICHAEL KOLODRUBETZ, University of Texas at Dallas — We study the disordered Ising model with transverse and longitudinal fields coupled globally to a d-level system (qudit). In the center of the many-body spectrum, earlier work [PRL 122, 240402 (2019)] found a regime where many-body localization (MBL) survives global coupling to the cavity. In this work, we study the dependence of MBL on energy. Most strikingly, we discover an inverted mobility edge, where high energy states are localized while low energy states are delocalized. Our results are supported by shift-and-invert eigenstate targeting and Krylov time evolution up to L=13 and 18 respectively, with large central spin d=12 that is effectively infinite. We argue for critical energy of the MBL to thermal phase transition which scales as $E_c \sim L^{\frac{1}{2}}$, consistent with finite size numerics. We also show evidence for a reentrant MBL phase at even lower energies despite the presence of strong effects of the central qudit in this regime.
Emergent ergodicity at the transition between many-body localized phases — RAHUL SAHAY (Presenter), BINGTIAN YE, FRANCISCO MACHADO, NORMAN YAO, University of California, Berkeley — Due to their failure to thermalize, systems in the many-body localized (MBL) phase can support non-trivial order (e.g., order characterized by spontaneously broken symmetries or symmetry-protected topological order) even in highly excited, many-body eigenstates. However, the stability of MBL as a system transitions between different ordered phases remains a mystery. In particular, it is unknown whether the competition between two orders near a phase boundary inevitably destabilizes the MBL and restores ergodicity to the system. Here, we present evidence that, indeed, a direct transition between different MBL phases cannot occur, and between any two MBL phases, an intervening finite-width thermalizing phase emerges. We probe the emergence of this thermalizing phase by numerically studying the level statistics of a variety of different models exhibiting either symmetry broken order or symmetry-protected topological order, both in the static and driven case. We complement our numerical analysis by providing an analytic picture for the instability of MBL around the phase transition.

Critical properties of the many-body Aubry-Andre model localization-delocalization transition — TAYLOR COOKMEYER (Presenter), University of California, Berkeley, JOHANNES MOTRUK, Lawrence Berkeley National Lab, JOEL MOORE, University of California, Berkeley — As opposed to random disorder, which localizes single-particle wave-functions in 1D at arbitrarily small disorder strengths, there is a localization-delocalization transition for quasi-periodic disorder in the 1D Aubry-Andre model at a finite disorder strength. On the single-particle level, many properties of the ground-state critical behavior have been revealed by applying a real-space renormalization-group scheme; the critical properties are determined solely by the continued fraction expansion of the incommensurate frequency of the disorder. We investigate the many-particle localization-delocalization transition in the Aubry-Andre model with and without interactions. In contrast to the single-particle case, we find that the critical exponents depend on a Diophantine equation relating the incommensurate frequency of the disorder and the filling fraction which generalizes the dependence, in the single-particle spectrum, on the continued fraction expansion of the incommensurate frequency. Numerical evidence suggests that interactions may be irrelevant at at least some of these critical points, meaning that the critical exponent relations obtained from the Diophantine equation may actually survive in the interacting case.

Single doublons as ergodic bubbles — ULRICH KRAUSE, Frei Universität Berlin, THÉO PELLEGRIN, Univ of Geneva, PIET W BROUWER, Frei Universität Berlin, DMITRY ABANIN, MICHELE FILIPPONE (Presenter), Univ of Geneva — We illustrate a remarkably simple mechanism in which single doublon excitations trigger the generation of ergodic bubbles, which thermalize extensive localized systems. We provide analytical estimates showing how the critical disorder strength for such mechanism depends on singlon densities, which are nicely supported by numerical exact-diagonalization simulations. Our predictions equally apply to fermionic and bosonic systems and are definitively accessible by ongoing experiments simulating synthetic quantum lattices.

*FNS/SNF Ambizione Grant PZ00P2 174038
1:27PM B01.00010: Quasi-1D limit of the integer quantum Hall transition as a disordered Thouless pump* MATTEO IPPOLITI (Presenter), Stanford Univ, RAVINDRA NAUTAM BHATT, Princeton University — We study the quantum Hall plateau transition on rectangular tori. As the torus aspect ratio is increased, the 2D critical behavior (where a subextensive number of topological states exist in a vanishing energy window around a critical energy) changes drastically. In the thin-torus limit, the entire spectrum is Anderson-localized; however, an extensive number of states retain a nonzero Chern number. This apparent paradox is resolved by mapping the thin-torus quantum Hall system onto a disordered Thouless pump. We show that the Chern number maps onto the winding number of an electron’s path in real space during a pump cycle, and that the electrons’ paths become random walks of diverging length, giving rise to the proliferation of large and essentially random Chern numbers across the spectrum. Building on this thin-torus limit result, we characterize quantitatively the crossover between the 1D and 2D regimes for large but finite aspect ratio. Possible realizations of this physics in quantum simulation platforms (e.g. cold atoms, microwave cavity arrays) are discussed.

1:39PM B01.00011: Spin transport in disordered long-range interacting spin chain* BENEDIKT KLOSS (Presenter), Chemistry, Columbia Univ, YEVGENY BAR LEV, Physics, Ben-Gurion University of the Negev — We numerically study spin transport and spin-density profiles after a local quench in a disordered one-dimensional spin-chain with long-range interactions, in the regime where delocalization is predicted by all existing theories. We observe a transient super-diffusive transport, followed by asymptotic diffusive behavior. We provide a phenomenological explanation by properly generalized Griffiths picture.

*This research was supported by the Israel Science Foundation (grants No. 527/19 and 218/19). Benedikt Kloss acknowledges funding through the National Science Foundation (Grant No. CHE-1464802).
1:51PM B01.00012: Complex network description of phase transitions in the classical and quantum disordered Ising Model*  MINA FASIHI (Presenter), HALEY COLE, LINCOLN CARR, Colorado School of Mines, GUILLERMO GARCIA PEREZ, SABRINA MANISCALCO, Physics and Astronomy, University of Turku — Complex network analysis is a powerful tool to describe and characterize classical systems such as the Ising model in a transverse magnetic field. Measuring spin-spin correlations gives rise to the adjacency matrix, representing a weighted network. In this study, the spin-spin correlations at different temperatures are analytically calculated, yielding phase-dependent complex networks, from simple networks in the low temperature ferromagnetic limit to random ones at high temperature. The network structure varies as the transverse field and temperature change, recovering the phase diagram and providing initial insight into correlations in the critical region. Analyzing the resulting complex network using a variety of network measures such as the degree histogram, average clustering, betweenness centrality and the graph entropy, the complexity is characterized. This method is applied for both the disordered classical Ising and quantum Ising lattice, demonstrating the role of finite temperature and disorder in generation of complexity.

2:03PM B01.00013: Probing Slow Scrambling in MBL and the Random Singlet Phase  IAN MACCORMACK (Presenter), MAO-TIAN TAN, JONAH L KUDLER-FLAM, SHINSEI RYU, University of Chicago — We characterize the spreading of operators and entanglement in two paradigmatic non-thermalizing phases - the many body localized phase and the random singlet phase - using out-of-time-ordered correlators, the entanglement contour, and operator entanglement. We contrast these phases with strongly thermalizing holographic conformal field theories and fully localized Anderson insulators. We obtain a phenomenological description of the operator and state dynamics of these phases and provide credence to the utility of the entanglement contour and operator entanglement measures as useful probes of slowly scrambling and non-thermalizing dynamics.

Monday, March 2, 2020 11:15 AM - 2:03 PM

Session B02 DAMOP: Strongly Interacting Bose and Fermi Gases
11:15AM B02.00001: Fermionic superfluidity in confined one-dimensional spin-imbalanced systems: A configuration-space Hartree-Fock-Bogoliubov approach* KELLY PATTON (Presenter), Physics and Astronomy, Georgia Southern University, DANIEL E SHEEHY, Physics and Astronomy, Louisiana State University — We study pairing and density correlations in imbalanced one-dimensional Fermi systems with short-range interactions that are spatially confined by either a harmonic or a hard-wall (or “box”) trapping potential. It has been hoped that such systems, which can be realized using ultracold atomic gases, would exhibit the long-sought-after Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superfluid phase. Our approach applies a general Hartree-Fock-Bogoliubov (HFB) transformation to handle spatially-inhomogeneous pairing and density correlations on an equal footing to yield predictions for the ground state of confined 1D Fermi gases in harmonic and hard-wall traps. We find that while both cases yield a spatially modulated FFLO pairing amplitude in the imbalanced regime, in the case of a harmonic trap the corresponding signature in the local density is rather weak. In contrast, in the hard-wall case, we find a strong reflection of the FFLO pairing in the local in situ densities. In particular, we find that the excess spins are strongly localized near nodes in the pairing amplitude, thus creating an unmistakable signature of the FFLO state in a hard-wall box trap.

*K.P. would like to thank Georgia Southern University for generous startup funding, which contributed to this work.

11:27AM B02.00002: Ferromagnetism in the SU(n) Hubbard model with nearly flat band* KENSUKE TAMURA (Presenter), HOSHO KATSURA, Univ of Tokyo — Recently, the SU(n) (n>2) Hubbard model describing multi-component fermions with SU(n) symmetry has been a focus of interest, as it is expected to exhibit a rich phase diagram. However, very little is known rigorously about the model with n>2. Here we study the model on a one-dimensional Tasaki lattice and derive rigorous results for the ground states. We first study the model with a flat band at the bottom of the single-particle spectrum. We prove that the ground states are SU(n) ferromagnetic when the number of particles is half the number of lattice sites, generalizing the previous result in Ref. [1]. To discuss SU(n) ferromagnetism in a non-singular setting, we perturb the flat-band model and make the bottom band dispersive. Then we find that SU(n) ferromagnetism in the ground states of the perturbed model at the same filling can be proved if each local Hamiltonian (independent of the system size) is positive semi-definite (p.s.d.). Furthermore, we prove that the local Hamiltonian is p.s.d. for sufficiently large interaction and band gap [2].

11:39AM B02.00003: One-dimensional Spin-polarized Fermi Gas near resonances*  YUTA SEKINO (Presenter), RIKEN, YUSUKE NISHIDA, Department of Physics, Tokyo Institute of Technology — We study a quantum field theory for resonantly interacting spinless fermions in one dimension. This fermions are known to correspond to one-dimensional bosons with delta-function interaction [1]. We perform the renormalization group analysis and clarify that three-body coupling, which is zero in the ultraviolet theory, emergently appears in the infrared limit [2]. This running coupling allows us to rederive the energy relation, i.e., the expression of energy in terms of a momentum distribution and contact parameters characterizing local corrections of the system. The obtained energy relation is consistent with that previously derived in the first quantization formalism [3].

*The work is supported by JSPS KAKENHI Grants No. JP15K17727 and No. JP19J01006.

11:51AM B02.00004: Dynamical Fermionization and Scaling Behaviour for a Strongly Repulsive Spinor Gas after Quench*  SHAH SAAD ALAM (Presenter), TIM SKARAS, LI YANG, HAN PU, Rice Univ — Dynamical fermionization has been theoretically demonstrated for trapped 1D bosonic and anyonic gases in the Tonks-Girardeau limit. It refers to the phenomenon where, after the initial harmonic confinement is turned off, the momentum distribution of the system asymptotically approaches that of a trapped Fermi gas. Evidence of dynamical fermionization was experimentally shown for 1D hard core bosonic gases recently. We extend this study to a harmonically confined 1D spinor gas in the hard core and strongly repulsive regimes, and analytically prove the existence of dynamical fermionization. We further discuss numerical investigation of two particle and few particle calculations for specific spinor systems. Finally, we present the Tan contact for a strongly interacting spinor system, as well as its scaling during expansion.

*NSF, Welch Foundation
12:03PM B02.00005: Dynamics of Macroscopic Quantum Tunneling from Superfluid to Mott Insulating Regimes*  
DIEGO ALCALA (Presenter), MARIE MCLAIN, LINCOLN CARR, Colorado School of Mines — In 1928 quantum tunneling was discovered to explain alpha decay, and in 2002 the Mott-Superfluid quantum phase transition was experimentally observed. How would the transition between a Superfluid and Mott insulator alter the tunneling dynamics of a many-body system? Specifically, we study bosons in a quasi one-dimensional meta-stable trap, modeled by the Bose-Hubbard Hamiltonian, using matrix product state methods which grant access to many-body observables, and compare to mean-field, which fails for strong interactions. We quantify how the barrier and interaction energies can amplify or reduce number fluctuations by an order of magnitude. Bond entropy is found to maximize when nearly half of the atoms have escaped in a Superfluid, while Mott-dominated interactions result in a maximum when only one quarter of the atoms have escaped. Mott-dominated dynamics also produce strong, long-range, and off-diagonal correlations. We find significantly different time scales in observables, i.e., when bond entropy and fluctuations maximize. Periodic fluctuations in time derivatives are found for several observables, scaling with the size of the meta-stable trap. Finally, preliminary results suggest that interaction energies can alter the escape velocity of atoms.

*Funded by NSF.

12:15PM B02.00006: On the possible existence of an effective momentum-momentum coupling in a correlated electronic system  
AMIR O. CALDEIRA (Presenter), THAIS VICTA TREVISAN, State University of Campinas, GUSTAVO MONTEIRO, The City College of New York — In this talk, we present a study on how to partly reincorporate the effects of localized binding electrons on the dynamics of their itinerant counterparts in Hubbard-like Hamiltonians. This is done by relaxing the constraint that the former should be entirely frozen in the chemical bonds between the underlying lattice sites through the employment of a Bohr-Oppenheimer ansatz for the wavefunction of the whole electronic system. Accordingly, the latter includes itinerant as well as binding electron coordinates. It is then argued that going beyond the adiabatic approximation, which will be properly justified in due time, we are able to show that the net effect of virtual transitions of binding electrons between their ground and excited states is to furnish the itinerant electrons with an effective inter-electronic momentum-momentum interaction. Once expressed in a localized orbital basis, this term generates new two-body processes which cannot be found even among those neglected in obtaining the Hubbard Hamiltonian. Although we have applied these ideas to the specific case of rings, we are sure they can be easily generalized to higher dimensional systems sharing the required properties of which we have made use herein.
12:27PM B02.00007: Superfluid vs. Mott-Insulator Phase in Imperfect Multi-Rods Lattices*
OMAR ABEL RODRÍGUEZ-LÓPEZ (Presenter), M. A. SOLÍS, Theoretical Physics, Universidad Nacional Autónoma de México — We calculate the ground state (GS) energy and the static structure factor at zero temperature of an interacting Bose gas confined by a one-dimensional, periodic, multi-rods lattice created by an external Kronig-Penney potential. We employ the Diffusion Monte Carlo (DMC) method to estimate the physical properties exactly up to a statistical error. In the limit of zero external potential, we recover the results for the well-known Lieb-Liniger model. Using the Luttinger Liquid formalism for the low-energy properties of 1D systems, we find a phase transition from the superfluid state to the Mott insulator state as the lattice height increases. Also, we report that the introduction of a barrier defect in the lattice favors the superfluid phase with respect to the Mott insulator phase.

12:39PM B02.00008: Optimized pairing from repulsive interactions in Fermi-Hubbard ladders and its static and dynamic signatures*
THOMAS KOEHLER (Presenter), ADRIAN KANTIAN, Uppsala Univ — Experiments on Fermi-Hubbard models, implemented via lattice-confined ultra-cold gases, are moving towards temperatures where their charge gap and possibly their spin gap can be resolved. It is thus important to obtain accurate quantitative theory for those systems in order to optimize the chance of observing any possible unconventional pairing from repulsive interactions at the given temperatures of the ongoing experiments. In this talk we will present such results for the Fermi-Hubbard ladder, which is proven to have unconventional pairing, and that allows us to optimize this pairing via changes in ladder structure and interactions based on highly accurate numerical theory such as matrix-product-state-based methods. We further demonstrate quantitatively how the temperature ranges at which repulsively mediated pairing may be experimentally observable is very strongly dependent on these optimizations, and how it may be detected with established techniques in both the static regime as well as via dynamically generated excitations.

*Funding through the ERC Starting Grant from the European Union's Horizon 2020 research and innovation programme under grant agreement No 758935 is greatfully acknowledged.
12:51PM B02.00009: Matrix Product States in the Continuum and Cold Atomic Gases*
JOSEPH PEACOCK (Presenter), ALEKSANDAR LJEPOJA, C. J. BOLECH, University of Cincinnati — Cold atomic gases are an ideal laboratory to explore the physics of interacting degenerate quantum gases due to the high degree of tunability possible in the experiments. In particular, special trapping arrangements allow, among other things, to control the effective dimensionality of the systems. In this talk we present an update on the continuum formulation of Matrix Product States (cMPS) to describe one dimensional dilute quantum gases. The goal is to develop cMPS as an accurate predictive tool to plan and analyse past and future experiments. To that end, we shall present results for the cases of trapped single-species and multi-species bosonic and fermionic atoms, as well as their mixtures. When available, we make quantitative comparisons of cMPS results with the exact results for solvable cases.

*We acknowledge support from NSF (Grant No. PHY-1708049) and the Ohio Supercomputing Center.

1:03PM B02.00010: Spin Imbalance Effect in a Mixture of Spinor Fermions and Hard-Core Bosons
RAMÓN GUERRERO SUÁREZ (Presenter), Universidad Nacional de Colombia, Bogota, JUAN MENDOZA ARENAS, Universidad de los Andes, ROBERTO FRANCO PÉALOZA, JERESON SILVA VALENCIA, Universidad Nacional de Colombia, Bogota — Mixtures of bosons and fermions have been the subject of research since the first studies of $^3$He-$^4$He system. With the current cold atoms setups, these types of mixtures can be realized and the inter- and intraspecies interactions can be readily tuned. By means of a Bose-Fermi Hubbard Hamiltonian, mixtures of bosons and fermions can be studied theoretically. Different superfluids, Mott Insulators, phase separation, spin and charge density waves, together with Wigner crystals have been reported for these systems. We study numerically the effect that spin imbalance can have in these mixtures, specifically for a system of spinor fermions and in the hard-core bosonic limit. Using DMRG we explore the phase diagram of the ground state, finding new insulator states that appear only when there is imbalance in the system. This happens for both attractive and repulsive intraspecies interactions and for both attractive and repulsive fermionic interactions, implying that the new insulator states are due to the coupling between bosons and fermions.
1:15PM B02.00011: *Ab initio* auxiliary-field quantum Monte Carlo study of finite-temperature properties of the two-dimensional Fermi gas*  
YUAN-YAO HE (Presenter), HAO SHI, SHIWEI ZHANG, Center for Computational Quantum Physics, Flatiron Institute  
Finite-temperature properties of the two-dimensional unpolarized Fermi gas with a zero-range attractive interaction are studied by a numerically exact auxiliary-field quantum Monte Carlo method [1]. This system has generated strong experimental and theoretical interest as a clean and well-controlled testground for a rich set of physics combining strong interaction and superfluidity in two dimensions. To reliably reach the continuum limit, we adopt a new finite-temperature algorithm [1], which has computational scaling as linear in lattice size instead of cubic as in the standard algorithm. Numerically exact results for the equation of state, contact parameter, momentum distributions as well as pairing properties are obtained across the BCS-BEC crossover, spanning the entire temperature range and connecting with exact zero-temperature results [2]. We also investigate the Berezinskii-Kosterlitz-Thouless transition and possible pseudogap physics in this system.

1:27PM B02.00012: Universal intrinsic high-rank spin Hall effects*  
JUNPENG HOU (Presenter), CHUANWEI ZHANG, University of Texas at Dallas  
Spin Hall effect (SHE) is one of the key concepts in modern condensed-matter physics since its first discovery more than two decades ago. In this work, we introduce the concept dubbed high-rank spin Hall effect, in which the usual (charge) Hall effects and SHEs are incorporated as rank-0 and rank-1 SHEs. The first non-trivial example is then rank-2 SHE and we showcase a minimal intrinsic model in a spin-1 Fermionic system (a three-component Fermion or triply-degenerate point), which exhibits an universal rank-2 spin Hall conductivity $e/4\pi$. As a generalization to larger spin, we further provide another model in a spin-3/2 system. A simple experimental setup is proposed based on recently experimentally realized 2-dimensional spin-orbit coupling in cold atoms and the effects of Zeeman fields are investigated. Our work reveals interesting spin transport phenomena in large-spin systems and may lead to novel applications in spintronic and quantum-mechanical devices.

Beyond mean-field corrections to the quasiparticle spectrum of superfluid Fermi gases

SENNE VAN LOON (Presenter), JACQUES TEMPERE, HADRIEN KURKJIAN, Univ of Antwerp — The notion of quasiparticles is an essential tool for the study of interacting many-body systems. In superfluid Fermi gases, two types of elementary excitations can be identified: the fermionic branch of broken pairs, and the bosonic collective mode describing the collective motion of the pairs. These can be observed in systems of ultracold fermionic atoms, where, due to Fesbach resonances, a whole range of superfluids can be studied. Measurements of the quasiparticle spectrum are already available [1], though the theoretical study of corrections to the fermionic branch remains limited [2]. Here, we investigate this quasiparticle branch in the BCS-BEC crossover and calculate the quasiparticle lifetime and energy shift due to its coupling with the collective mode. Close to the minimum of the branch the quasiparticles are undamped, allowing us to find the energy correction in a self-consistent way, that we express in experimentally relevant quantities.

Prediction of Exotic Electron Transport Properties using the Shape Effect of the Fermi Surface

ELENA DERUNOVA (Presenter), Max Planck Institute of Microstructure Physics, YAN SUN, Max Planck Institute for Chemical Physics of Solids, MAZHAR ALI, Max Planck Institute of Microstructure Physics — The intrinsic anomalous Hall and spin Hall effects (AHE/SHE) provided evidence of exotic electronic transport phenomena relating to a topological connection between bands around the Fermi energy. Currently, the calculation of Berry curvature and the Kubo formalism based on Green functions is used to quantify bands’ topological connection and predict the AHE, SHE and other effects. Here we show that the topological connection of the bands also leads to particular shapes of the corresponding Fermi surfaces (FS) and that geometric analysis of these shapes can be used to predict transport properties. For the AHE/SHE we developed a qualitative indicator, $H_F$, based on Gaussian curvature of the FS and found that $H_F$ is linearly correlated with the experimentally measured AHE (R-square 0.97) in a variety of famous AHE compounds as well correlated with the Kubo calculated SHE. We show that consideration of the geodesic flow on the FS gives rise to FS based equations in a semiclassical style, which contain information about the electron transport properties aside from longitudinal conduction. Going beyond just AHE/SHE, a full understanding of the Shape Effect of the FS (SEFS) opens the door to simple prediction of exotic electron transport property in materials in a novel and facile way.
B02.00015: Superfluidity of interacting fermions in optical lattices: Interplay of population imbalance, dimensionality, and lattice-continuum mixing*  QIJIN CHEN (Presenter), University of Science and Technology of China, JIBIAO WANG, LIN SUN, Department of Physics, Zhejiang University — In this talk, I will discuss the superfluid behavior of ultracold atomic Fermi gases in 1D and 2D optical lattices (OL), subject to a short range pairing interaction, and show the highly unusual behavior as a consequence of the interplay between population imbalance, dimensionality and more importantly lattice-continuum mixing. These systems are different from pure 3D continuum or 3D lattices, in that each lattice "site" now contains many fermions. Using a pairing fluctuation theory, we demonstrate that this feature leads to unexpected enhancement of pair hopping in the presence of population imbalance and thus possible enhancement of Tc on the BEC side of the unitary limit. For 1DOL, the superfluid phase exists only for a very limited range of parameters, and the truncated momentum space in the lattice dimension in combination with the enhanced pair hopping may give rise to enhance Tc in the BEC regime, with an constant BEC asymptote. For 2DOL, the further truncated momentum space helps to strongly suppress pairing fluctuation contributions to the pseudogap, so that Tc gradually approaches its high mean-field value in the deep BEC regime.

Session B03 GSCCM: Materials in Extremes: Energetic and Reactive Materials: Novel Approaches 107 - Pamela Bowlan, Los Alamos National Laboratory - Tag(s): Focus

11:15AM B03.00001: Safety and performance characteristics of thermite systems: from powders to 3D printed lattices [Invited]  KYLE SULLIVAN (Presenter), Lawrence Livermore Natl Lab — The reaction in thermite powders is a highly complex process. Developing a true understanding of this process involves an understanding of the various length and time scales, as well as the non-equilibrium and equilibrium processes as fuel and oxide particles react to form mixed-phase products on a rapid time scale. In this work, we present an overview of our work, which ranges from loose-powder combustion testing to 3D printed lattices of thermite. Specifically, we explored the dynamic formation of mesoparticles and the resultant multi-phase expansion of these particles as they are entrained in a gas stream. Additive manufacturing (AM) was then used to probe how the printed architecture can be used to manipulate the reactivity, by affecting the forward energy transport through design of the structure. A materials design plot (i.e., an "Ashby Diagram") was constructed to quantify the control AM offers for these materials.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
11:51AM B03.00002: High Velocity Impact Testing of Structural Reactive Projectiles*  ALAN WILLIAMS (Presenter), COLT CAGLE, MICHELLE PANTOYA, Texas Tech Univ — This study examined the dynamic response of structural reactive projectiles penetrating through an aluminum target then impacting an inert steel anvil at speeds up to 1500 m/s. The impact testing is performed using a High-velocity Impact-ignition Testing System (HITS). The projectiles consist of a thermite with a high loading ductile metallic binder, consolidated into a cylindrical pellet contained in a .410 caliber shot gun case. The thermite includes aluminum fuel particles that were stress altered prior to their consolidation. This study considers the effect of stress altering aluminum particles on the overall penetration dynamics and reactivity of the projectile. Results demonstrate the range of plate deformation mechanics and overall transient pressure data that can be used to interpret reactivity. A threshold impact velocity was observed that corresponds with fragmentation of the projectile and is a function of stress-altered particles. The differences in reactivity between stress altered and untreated aluminum powder likely stem from the fragmentation field created upon penetration of the plate. Results provide a fundamental understanding of penetration and impact events with structural reactive formulations.

12:03PM B03.00003: Modeling PBX 9501 High Explosive Cylinder Experiments and an Evaluation of WSD and AWSD Parameter Sets  MARVIN ZOCHER (Presenter), TARIQ D ASLAM, Los Alamos Natl Lab — Cylindrical assemblies are often used in experiments aimed at calibrating and validating continuum level models of reactive burn, and of the so-called equation of state model (constitutive model for the spherical part of the Cauchy tensor). Such is the case in work to be discussed here. In particular, work will be described involving the modeling of a series of experiments involving PBX 9501 encased in a copper cylinder. The objective of the work is to test and perhaps refine a set of phenomenological parameters for the Wescott-Stewart-Davis (WSD) and Arrhenius-WSD (AWSD) reactive burn models. The focus of this talk will be on modeling the experiments, which turned out to be non-trivial. Always difficult to handle due to the extremely short reaction zone of PBX 9501, scaling is employed to address issues related to detonation velocity. The modeling is conducted using ALE methodology.
12:15PM B03.00004: High Explosive Shock Initiation Model Based on Hot Spot Temperature

LAURENCE FRIED (Presenter), MATTHEW P KROONBLAWD, Lawrence Livermore Natl Lab — We describe a new shock initiation model based on the Cheetah thermochemical code. The model is based on a multiple stage picture of the shock initiation process and uses hot spot temperature as an auxiliary variable to control the initial stages of reaction. Unlike using rates controlled by other thermodynamic variables, this approach captures physical sub-zonal differences between the bulk temperature and the substantially higher local hot spot temperature that actually governs ignition chemistry. In the model, a single representative hot spot diameter is chosen and the hot spot temperature is controlled by shock pressure and thermal conductivity. The practical utility of a sub-zonal hot spot temperature model will be discussed, as well as evidence for co-existing hot spot and shear band ignition mechanisms in high explosive shock initiation.

12:27PM B03.00005: Multi criteria decision model for design of advanced energetic materials with tailored properties

MAIJA M KUKLA (Presenter), ROMAN TSYSHEVSKIY, University of Maryland, College Park — The search for new high energy density materials (HEDMs) with targeted high performance, low toxicity, and reliable stability remains challenging. New materials are typically developed by Edisonian trial and error approach that involves sophisticated synthesis protocols combined with extensive sensitivity characterization tests. Such efforts are time consuming and resource exhaustive while the successful outcomes are seldom guaranteed. A combination of ab initio, group additive methods, and statistical analysis represents a powerful tool for computational design and discovery of new advanced high energetic density materials. Here, we report a sophisticated approach for design of new HEDMs with tailored properties based on extensive state-of-the-art study of structure-property-function relationships of various classes of energetic and explosive materials. We also show how we use this approach for discovery and characterization of new linear and fused heterocyclic HDEMs with performance and stability parameters considerably superior to conventional O-, N- and C-nitro compounds such as PETN, RDX and TNT.

12:39PM B03.00006: Transition and Optimization of Particle Impact Mitigation Sleeve Design between Munitions of Different Physical Parameters  
DANIEL PUDLAK (Presenter), KEVIN MIERS, Combat Capabilities Development Command - Armaments Center, US Army — Military munitions that fall within the NATO portfolio must be tested in accordance with Insensitive Munitions AOP-4496 Fragment Impact (FI) Testing. Under this test, a conical, steel cylinder is launched at the munition at 8300fps, and the response of the munition is evaluated for reactions ranging from violent detonation, to benign burning reaction. Standard practice to mitigate a violent detonation reaction from occurring is to develop barrier technologies (e.g. armor) that can reduce the velocity, and overall kinetic energy of the fragment to a level that will not produce a violent response of the munition. Previously, a technology known as Particle Impact Mitigation Sleeve (PIMS) that was developed for a specific munition, successfully reduced the munition's response from a detonation, to a benign burn. This PIMS design is currently being evaluated for application to a different munition. While these different munitions produce similar responses without the PIMS, their energetic content, munition physical parameters, and packaging materiel are different, which can substantially affect the response of the munition to FI. This paper will describe the transition and optimization of the PIMS design to successfully mitigate the new munition's response to the FI threat.

12:51PM B03.00007: Dynamic Compression of RDX Single Crystal and High Explosives*  
CHENG LIU (Presenter), CARL M CADY, KYLE RAMOS, BENJAMIN M MORROW, CHRISTOPHER MEREDITH, Los Alamos National Laboratory — Dynamic compression and failure of energetic RDX single crystals and high explosive PBX 9501 are studied experimentally using a miniature Split Hopkinson Pressure Bar (SHPB) combined with high-speed photography and optical digital image correlation (DIC) technique. In addition to the strain gages mounted at the center of the incident and transmitted bars, high-speed camera, running at the rate of 5 million frames per second, was used to capture the deformation process of the RDX single crystal and the PBX 9501. A random speckle pattern was also printed on the sample surface and optical DIC technique was applied to map out the displacement and the strain fields over the sample surface, as well as to capture the crack initiation and extension process. A technique was developed for quantitatively identifying crack, the motion of the crack tip, and extracting the fracture toughness of a brittle material in compression. Combined with the dynamic compression setup, we will be able to study the deformation and failure processes in much detailed and quantitative fashion.

*This research is supported by the LDRD program and the JMP Program.
Performance Evaluation Methodology for Materials Subjected to Explosively-Driven Highly Non-Radial Implosive Motion

LAWRENCE HULL (Presenter), STEVE M GILBERTSON, JONATHAN A HUDSTON, THOMAS A BEERY, Los Alamos Natl Lab — Non-radial implosive motion is experienced during the early stages of various important device formation processes, such a shaped charge jet. If the response of the material can be characterized during this initial stage of motion, then often the subsequent motion will be predictable. Diagnostics are either available or are under development, such as Modulation Based Ranging (MBR), to address this initial stage of motion. The use of velocimetry to evaluate material response when non-radial flow occurs is complicated by the non-colinearity of the velocity the surface normal, and non-colinearity with the laser beam. The result is that ordinary velocimetry results in an incomplete measurement, that of the component of velocity in the direction of the laser beam. We introduce a method, MBR, that measures the position that any object that intersects the laser line as a function of time, approximately closing the measurement system and enabling the application of the velocity-based evaluation methodologies. We describe our use of simultaneous Photon Doppler Velocimetry (PDV) and MBR along with radiography to characterize and compare the response two geometrically identical hemispherical shells that were manufactured differently.

Shock-induced paracrystallinity in PPTA

PAULO BRANICIO (Presenter), SUBODH TIWARI, SUNGWOOK HONG, DANIEL SHEBIB, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Univ of Southern California — The outstanding strength-to-weight ratio of para-aramid fibers, such as Kevlar and Twaron, is largely attributed to their high content of crystalline p-phenylene terephthalamide (PPTA). Atomistic simulations of shock loading on PPTA are performed along the [100] and [010] crystallographic directions, using reactive molecular-dynamics simulations. The reactive forcefield utilized is fitted to PPTA properties using first principles data and the results are validated by *ab-initio* molecular dynamics (QMD) simulations. Simulation results reveal an anisotropic shock response displaying elastic, crosslinking, and phase transformation from crystalline to para-crystalline phases. While QMD simulations show elastic to amorphous planar transformation for shocks along [010] direction, long time simulations accessible by reactive molecular dynamics indicate the formation of a para-crystalline phase initiated by an amorphous planar transformation, which displays H-bond scission and rotation of chains. The rotation process reorients the polymer chains such that vdW interactions dominate chain-chain interactions leading to the formation of local domains where new H-bond interaction forms leading to the para-crystalline phase.
1:27PM B03.00010: Experiment and Numerical Simulation Study on Near-field Underwater Explosion of Aluminized Explosive  
YUANXIANG SUN (Presenter), State Key Laboratory of Explosion Science and Technology, Beijing Institute of Technology, China — Aluminized explosive can improve the energy output structure and power of detonation products. The application of aluminized explosive to underwater explosion enhances the brisance and damage capability of underwater weapons significantly. The near-field underwater explosion experiments of aluminized explosive RL_F and TNT were carried out using PVDF pressure sensor based on electrical measurement method, and Coupled Eulerian-Lagrangian (CEL) method was used for simulation. The numerical results agreed well with experimental and empirical ones. The results show that CEL method can be used to simulate the propagation process of near-field underwater explosion shock wave of TNT and aluminized explosive accurately if reasonable boundary conditions, calculation parameters and finite element model are adapted. Near-field underwater shock wave pressure attenuation of aluminized explosive is slower than TNT. Then, the approximate regression formulas of near field underwater explosion shock wave peak pressure of TNT within 6 times of charge radius and aluminized explosive in a certain distance range are obtained by fitting the simulation results.

1:39PM B03.00011: Thermal transport across diamond/copper interface functionalized by self-assemble monolayer  
BIN XU, SHIH-WEI HUNG, JUNHO CHOI, JUNICHIRO SHIOMI (Presenter), Univ of Tokyo — 
Copper and diamond composite is regarded as one of the most promising candidates for effective condensed heat dissipation. However, thermal boundary conductance (TBC) between copper and diamond becomes a key factor for deciding thermal conductivity. Interface functionalization using self-assemble monolayer (SAM) is a well-known method for enhancing TBC of a solid interface. While the underlying mechanism has been discussed in terms of strengthening the bonds or bridging of the lattice vibrational spectra, there is a need for more experiment-simulation coupled work on a well-defined system. In this sense, the copper and diamond system is ideal as the soft copper and hard diamond give rise to a large mismatch in the lattice vibration frequencies and the smoothness/uniformity. 
In this study, we measure the TBC of copper/SAM/diamond interface by the time-domain thermoreflectance method. By using ellipsometer, X-ray photo-electro spectroscopy, and Fourier transform infrared spectroscopy, morphology and the chemical bonding of the SAM on copper and diamond are clearly observed. In addition, molecular dynamics simulations are carried out to explain the measured dependence of TBC. We found that there is a comprehensive correlation between the chain length, functional group, and TBC.
B03.00012: Pressure- and Temperature-Dependent Structural Stability and Photoluminescence properties of LLM-105 Crystal  ZENGMING ZHANG (Presenter), ZILONG XU, JUNKE WANG, University of Science and Technology of China — Energetic material LLM-105 maintains its structure stability under high pressure below 30 GPa at room temperature or in the temperature range from 513 K to 5 K with ambient pressure. One structural phase transition occurs at about 30 GPa and is confirmed by pressure-dependent Raman and infrared spectra. The structure of LLM-105 crystal shows anisotropic compressibility under pressure. Debye temperature of 1225 K for this crystal is obtained. Raman and infrared spectra at extreme conditions suggest that the structure stability is contributed to the stronger inter- and intra-molecule hydrogen bonding networks within LLM-105 crystal. Photoluminescence, absorption spectroscopy and the DFT calculations were employed for LLM-105. With the pressure increasing, the luminescence first increases due to the limited molecular vibration, then over 9.0 GPa, the intensity decreases due to the lower electronic transfer efficiency. Results reveal that the band gap of LLM-105 crystal presents a strong pressure dependence. The high pressure phase transition has also been observed at about 30 GPa with a band gap suddenly decrease again. Moreover, the PV phase diagram has been completed.

Session B04 DCP DSOFT DPOLY DLS: Coherent Nonlinear Optical Microscopy I 109 - Marcus Cicerone, Georgia Inst of Tech - Tag(s): Focus

11:15 AM B04.00001: Coherent Nonlinear Optical Microscopy with Mid-infrared Radiation*
[Invited] DAVE KNEZ, RICHARD C. PRINCE, ADAM M. HANNINEN, ERIC POTMA (Presenter), University of California, Irvine — Fundamental vibrational modes are efficiently excited by mid-infrared (MIR) radiation, in a light-matter interaction that is many orders of magnitude stronger than vibrational excitation through the Raman effect. Despite this clear advantage, MIR microscopy is not ubiquitously used for imaging of biological samples due to practical limitations including low spatial resolution, the use of expensive cameras and the intrinsic limitation of absorption-based detection. Some of these limitations can be overcome when using nonlinear upconversion techniques to translate the driven MIR transition into a signal in the visible/NIR range of the spectrum. We will discuss several coherent nonlinear optical approaches that enable rapid laser-scanning microscopy in the MIR with high, three-dimensional resolution.

11:51AM B04.00002: Multidimensional spectroscopy on the microscale: Development of a multimodal imaging system incorporating 2D white-light spectroscopy, broadband transient absorption, and atomic force microscopy.* ANDREW JONES (Presenter), Los Alamos National Laboratory, NICHOLAS KEARNS, MIRIAM BOHLMANN KUNZ, JESSICA FLACH, MARTIN T ZANNI, Chemistry, University of Wisconsin — The dynamics of electronic transitions in solid-state materials are closely linked to microscopic morphology, but it is often challenging to simultaneously characterize their broadband spectral and temporal response with high spatial resolution. We present a combined coherent multidimensional spectroscopy and microscopy system using visible white-light supercontinuum pulses as a broadband light source. This system correlates ~nm scale sample morphology determined from atomic force topography measurements with broadband transient absorption hyperspectral images and ultrafast multidimensional spectra, all with a spatial resolution of ≤1 μm. We demonstrate the application of this technique to the mapping of spatial heterogeneity in the process of singlet fission within single microcrystals of an organic semiconductor material, TIPS-Pentacene. Here, we identify heterogeneity in the temporal and spectral response corresponding to presence of non-equilibrium molecular packing near edges and morphological defect structures.

12:03PM B04.00003: Image Formation in Coherent Nonlinear Optical Microscopy* [Invited] LORA RAMUNNO (Presenter), Univ of Ottawa — Coherent nonlinear optical microscopy has allowed real-time visualization of objects and biological processes on small length scales, where molecule-specific imaging can be achieved without the use of labels. Given the coherent nature of the nonlinear processes involved (which includes, for example, coherent anti-Stokes Raman scattering, second and third harmonic generation), the images produced are complex and not always straightforward to interpret, especially when object sizes are much smaller than the focal volume. Images are subject to, for example, interference from multiple scatterers, interference due to competing nonlinear processes, and distortion due to inhomogeneities. This can lead to bright spots that appear in the wrong place or are 10x brighter than they should be, unexpected shadows, false dark and bright signals, spectral shifts that depend on the spatial position of objects along the laser axis, and signals that depend on the precise shapes and relative positions of sub-wavelength objects within the focal volume (rather than just the total number of molecules present), to name a few. I will discuss the origin of these strange effects, and review our work and others in this area over the last several years.

12:39PM B04.00004: Strong-field-driven dynamics and high-harmonic generation in interacting 1D systems*  
FERNANDO SOLS (Presenter), Univ Complutense de Madrid, IMDEA Nanociencia, SANDRA DE VEGA, ICFO (Barcelona), JOEL COX, Danish Institute for Advanced Study (Odense), JAVIER GARCIA DE ABAJO, ICFO (Barcelona), ICREA — We explore the role of electronic band structure and Coulomb interactions in solid-state HHG by studying the optical response of linear atomic chains and carbon nanotubes to intense ultrashort pulses. Specifically, we simulate electron dynamics by solving self-consistently the single-particle density matrix equation of motion in the presence of intense ultrafast optical fields and electron interactions. Our 1D model provides insight on the temporal evolution of electronic states in reciprocal space. We demonstrate that electron interactions play an important role in the HHG yield. This model further predicts that doped semiconductors generate high harmonics more efficiently than their metallic and undoped counterparts. To complement this idealized system we also show results for HHG in more realistic quasi-1D structures such as carbon nanotubes, whose behavior is found to be in good qualitative agreement with that of the atomic chains. Our findings apply directly to extreme nonlinear optical phenomena and can be extended to optimize existing platforms for HHG or identify new solid-state alternatives in the context of nonlinear plasmonics.

12:51PM B04.00005: Broadband Coherent Anti-Stokes Raman Scattering (BCARS) MicroSpectroscopy [Invited]  
CHARLES HENRY CAMP (Presenter), National Institute of Standards and Technology — The ability to noninvasively image the dynamic chemical composition within cells and tissues would revolutionize our understanding of biology and disease. Molecular vibrational imaging techniques detect the small oscillations between bonded atoms, providing dense spectral information about composition and state without the addition of fluorophores or dyes. Technologies, such as Raman and infrared microscopies, have offered this capability for over half a century, but significant limitations in speed, resolution, or sample preparation have prevented their ubiquity. Coherent Raman imaging (CRI) methods, proposed as the solution, have been practically confined to small increments of the vibrational spectrum with limited chemical specificity. Broadband coherent anti-Stokes Raman scattering (BCARS), a particular CRI modality, on the other hand, has demonstrated an unprecedented combination of speed, sensitivity, and spectral breadth, enabling full hyperspectral imagery in minutes rather than hours. Furthermore, as a coherent anti-Stokes Raman scattering (CARS)-based method, a coherent background is generated that is molecularly sensitive and can be used as a built-in internal reference at each pixel; thus, enabling directly comparable results between samples and spectra collected on different microscope systems.

In this seminar, I will present an introduction to BCARS microscopy from a theoretical and practical perspective. Specifically, covering the physics of signal generation and extraction of Raman signatures. Further, I will touch upon application space examples and our efforts towards quantitative imaging.
1:27PM B04.00006: Studying the photodynamics of FRET paired fluorescent molecules near gold nanogratings*  JENNIFER STEELE (Presenter), CHAE RAMNARACE, Physics and Astronomy, Trinity University, WILLIAM FARNER, Physics, Drexel University — The plasmonic properties of structured metal surfaces can be engineered to enhance the output of nearby quantum emitters through the manipulation of the local density of optical states (LDOS). Although metal enhanced fluorescence (MEF) has been well understood for decades, the influence of plasmonic modes in Förster resonance energy transfer (FRET) is still a debated issue. Gold nanogratings provide a unique plasmonic substrate to study the effects of altering the LDOS on FRET efficiencies. Gratings support narrow plasmon resonances at a range of wavelengths, allowing for the comparison of FRET efficiencies by increasing the LDOS at donor and acceptor emission wavelengths on a single substrate. Previous work has shown an increase in efficiency when the surface plasmon modes overlapped the acceptor emission spectrum. In this talk, ongoing work on the optimizing the increase in efficiencies will be discussed. Furthering the understanding of the application of MEF to FRET will aid developing methods for the enhancement of FRET, expanding its use in biological systems, photosynthesis, and photovoltaic devices.

*This work was supported by an award from the Research Corporation for Science Advancement and from the W.M. Keck Foundation Undergraduate Education Program.

1:39PM B04.00007: Geophotonics: Multimodal Nonlinear Optical Microscopy in Geology [Invited]  ADRIAN PEGORARO (Presenter), Univ of Ottawa — Nonlinear optical microscopy offers label-free contrast and enhanced depth penetration in heterogeneous media compared to more traditional optical microscopy techniques. These advantages make it a natural fit for biological imaging where optical microscopy is frequently the tool of choice. For geologic materials, where electron microscopy is much more prevalent than optical imaging, the utility of newly developed nonlinear optical techniques was less obvious. Nonetheless, we show that these techniques, such as second harmonic generation, coherent Raman microscopy, and pump-probe microscopy, provide complementary contrast mechanisms for a host of geological systems. For some applications, the ability to image rapidly in 3D reveals previously unseen spatial correlations. Even in opaque systems, nonlinear optical signals can achieve comparable contrast to electron microscopy techniques which are inherently confined to the surface. This allows for much more rapid screening of samples with less sample preparation. We believe that by leveraging ongoing developments in biophotonics, it is possible to offer new and improved imaging tools for many other systems that are not traditionally studied using optical microscopy.

Monday, March 2, 2020 11:15 AM - 12:27 PM

Session B05 DCP DCMP DPOLY: The Chemical Physics of Molecular Polaritons II. Photophysics II 111 - Luis Angel Martinez Martinez, University of California, San Diego - Tag(s): Focus
11:15AM B05.00001: First principles approaches to excited states chemistry under strong light-matter coupling  
JOHANNES FLICK (Presenter), Center for Computational Quantum Physics, Flatiron Institute, PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — In recent years, research at the interface of chemistry, material science, and quantum optics has surged and now opens new possibilities to study strong light-matter interactions at different limits [1]. In these limits, electrons, nuclei and photons have to be treated on the same quantized footing. Towards this goal, we have introduced a general time-dependent density-functional theory [2].

In this talk, we use a novel linear-response formulation [3] within a density-functional framework to study excited states of strongly light-matter coupled systems. We study how the potential-energy surfaces (PES) of a CO bond stretching in a formaldehyde molecule is modified and show the influence of strong light-matter coupling on avoided crossings. These results demonstrate the novel abilities to alter and open new chemical reaction pathways as well as to create new hybrid states of light and matter [4].

Our work opens an important new avenue in introducing ab initio methods to the nascent field of collective strong light-matter interactions.

11:27AM B05.00002: Communication between polaritonic and excitonic manifolds in an electronically strong coupled system* [Invited]  
COURTNEY DELPO, KYU HYUNG PARK (Presenter), BRYAN J KUDISCH, FRANCESCA FASIOLI, GREG SCHOLES, Department of Chemistry, Princeton University — Optically dark states, which arise from intermolecular exciton coupling, are a crucial component in understanding the optical properties of natural and artificial light harvesters. Dark states also constitute a major density of states in the energy manifold of a strong-coupled system, which is generated from the interaction between a cavity photon and molecular excitons. Unlike optically bright upper and lower polariton states, dark state wavefunctions contain no photonic excitation and therefore have been considered to retain molecular character. In this framework, dark states not only serve as a deactivation pathway but also can participate in excitation energy exchange to states that are not coupled to cavity photons. We test this view by following the excited-state dynamics of bright to dark state interconversion in an electronically strong-coupled cavity composed of 1,2,3,5-tetrakis(carbazol-9-yl)-4,6-dicyanobenzene (4CzIPN). We show that dark states have a lifetime longer than that of uncoupled molecules indicating a significant change in the state character. Discussion on the communication between the dark states and the exciton manifold of uncoupled 4CzIPN triplet states will be presented.

Mixed Quantum-Classical Methods for Molecules in Cavities — Describing chemical processes that are strongly correlated with quantum light requires an accurate, flexible, and computationally efficient treatment of light-matter interactions. Thus, in order to develop ab-initio theoretical descriptions of cavity modified chemical systems, extensions to the traditional theoretical tool-kits for quantum optics and quantum chemistry are required. Here, we investigate the extension of mixed quantum-classical trajectory methods as well as the concept of time-dependent potential energy surfaces, both traditionally introduced for electron-nuclear problems, to the photonic degrees of freedom. Within our work we find that classical Wigner dynamics for photons can be used to describe quantum effects such as correlation functions, bound photon states and cavity induced suppression by properly accounting for the quantum statistics of the vacuum field while using classical/semi-classical trajectories to describe the time-evolution. Investigating the time-dependent potential energy surfaces for photons we find significant differences with the potential used in conventional approaches. Furthermore, we analyze the exact time-dependent potential energy surface driving the proton motion of a cavity-induced chemical suppression.

Mixed quantum-classical simulation of molecules in a cavity* — Photons in an optical cavity can strongly interact with electronic and vibronic state of molecules, which provides great promise to manipulate chemical reaction in cavity. Mixed quantum-classical methods, such as mean-field Ehrenfest, have been successfully applied to traditional photochemical reaction and provide many valuable insights into the reaction mechanisms. In this talk, we will present our recent results on how to generalize the mean-field Ehrenfest dynamics to the molecules in cavity by treating nuclei classically and other degrees of freedom quantum mechanically. The derived quantum force is general and can be used to include any number of electronic and photon states. As an example, we use our method to study the dissociation of LiF in cavity and compare the results with exact quantum simulation, which shows the reaction outcomes can be controlled by the coupling strength and the dipole self-energy term. Our approximate approach produces accurate results compared with exact quantum simulation, and can be broadly applied to investigate molecular reactions in the cavity.

11:15AM B06.00001: A statistical ensemble approach to understanding adaptive immunity: using sequence data to quantify the extraordinary diversity, in both sequence and protective specificity, of the T- and B-cells cells that make up an individual human’s immune system.* [Invited] CURTIS CALLAN (Presenter), Princeton University — Individual T cells of the adaptive immune system recognize specific pathogens via a certain protein expressed on the surface of the cell. The gene for this protein undergoes random editing each time a new immune cell is created. As a result, any individual’s immune system is an ensemble of distinct T cell types (in fact about $10^9$ in number) created by a stochastic process. I will explain how high-throughput DNA sequencing has made it possible to develop a precise quantitative understanding of this stochastic process. I will then explain some consequences of this understanding: a) that the stochastic gene editing process is nearly universal across the human species, b) that the diversity of the process is so large that the overlap between T cell repertoires of two individuals is small, c) that the one-shot generation probabilities of specific T cell types range over nearly twenty orders of magnitude, and, as a corollary, d) that certain specific T cell types will be found in all individuals, while others have negligible sharing likelihood. I will then discuss how these developments bring into sharp focus the central biophysical question of adaptive immunity, namely: what is the diversity of pathogenic molecules that a single T cell can recognize, and is the diversity of the T cells present in one individual large enough so that the entire space of pathogenic molecules can be recognized? Implications of these developments for cancer immunotherapy will be briefly discussed. References for this talk are:

11:51AM B06.00002: Evaluation of nuclear reaction cross sections via proton induced reactions for the production of $^{72}$As: a potential entrant for theranostic pairs WARIS ALI (Presenter), Physics, GC University Lahore — Theranostic applications of radiopharmaceuticals have revolutionized present era specially, dealing with cancer diseases. Increase in the uses of radionuclides in nuclear medicine has resulted in the demands of optimized new radionuclides to be produced focussing on the economy, simplicity and maximum yield. Some arsenic radionuclides have wide range of positron-emission, half-lives ranging from an hour to weeks and have potential to be used for nuclear medicine. Present work will elucidate all over the production of $^{72}$As on Germanium (Ge) and Selenium (Se). The experimental results obtained by several nuclear reactions were compared with the results of nuclear model calculations using the codes ALICE-IPPE, EMPIRE 3.2 and TALYS 1.9. The thick target yields (TTY) of $^{72}$As were calculated from the recommended excitation functions. Analysis of radio-impurities was also discussed. A comparison of the various radio-impurities showed that to produce $^{72}$As, $^{72}$Ge(p, n)$^{72}$As and $^{76}$Se(p, x)$^{72}$As reactions in different energy ranges. We have identified the nuclear process which gives high yield with minimum impurities to make it as a potential candidate for theranostic applications and in particular in Positron Emission Tomography (PET).
12:03PM B06.00003: Improving blood vessel tortuosity measurements via highly sampled numerical integration of the Frenet-Serret equations*  
ALEX BRUMMER (Presenter), VAN M SAVAGE, University of California, Los Angeles — Measures of vascular tortuosity, how curved and twisted a vessel is, are associated with a variety of vascular diseases. Consequently, accurate measurements of vessel tortuosity are greatly needed yet have proven problematic. Some researchers do not measure it at all, and others' results have been mismeasured, null, or contradictory. We present a new method that ensures accurate measurement of vessel tortuosity from medical image data that relies on numerical integration of the Frenet-Serret equations. By reconstructing vessel coordinates from tortuosity measurements, our approach identifies a minimally-sufficient sampling rate based on vessel radius. This work further identifies a key failing in current practices of filtering asymptotic measurements, and also highlights inconsistencies between existing tortuosity metrics. We demonstrate the utility of our method on published data for a range of healthy human vessels including: cerebral and coronary vascular networks and individual carotid, abdominal, renal and iliac arteries. Preliminary application to disease data will also be discussed.

*NSF Grant #1254159

12:15PM B06.00004: Diffeomorphic morphometry of the tibio-femoral joint for quantitative assessment of osteoarthritis*  
NICOLAS CHARON (Presenter), ASEF ISLAM, WOJCIECH ZBIJEWSKI, Johns Hopkins University — We present an application of the framework of Large Diffeomorphic Deformation Metric Mapping (LDDMM) for statistical analysis of morphological variants of knee anatomy associated with osteoarthritis (OA). The LDDMM models the morphological variability by associating each population member – here, a tibial surface – with a diffeomorphic transformation that maps the shape of that member to a common template (mean shape). Compared to conventional Active Shape Models, LDDM has the significant advantage in that it does not require a priori point correspondences between the surfaces in the population. We also investigated an extension of LDDMM (functional shapes, fshapes) that jointly considers the variations in shape and variations in a function on the shape (signal) – here, the signal was a map of tibio-femoral joint space width. The diffeomorphic modeling was applied to 34 CT scans of normal and OA subjects. To validate that the resulting model captures the morphology of OA, we measured the accuracy of a Support Vector Machine (SVM) classifier using either only the shape features or the joint shape+signal features. We achieved correct classification (OA vs. normal) in 91% of subjects using shape features and in 85% of subjects using shape+signal.

12:27PM B06.00005: Probabilistic approach to treatment planning in radiation therapy*

PETER FERJANCIC (Presenter), ROBERT JERAJ, University of Wisconsin - Madison — Radiation therapy (RT) is a common treatment for cancer. Current RT planning uses binary tumor definitions and accounts for uncertainties by simply expanding target volume by margins. This approach has several limitations and oversimplifies complex processes that are not linear in nature.

Here, we present a probabilistic approach to RT planning. First, mapping of tumor occupancy probability density functions was performed by sampling existing segmentation methods. Voxel-based microscopic tumor infiltration likelihood was simulated using CT imaging-derived anatomical constraints and clinically measured ranges of cellular infiltration. Desired voxel-level ranges of RT dose were prescribed based on this infiltration likelihood and its uncertainty.

Realistic dose plans were created using an in-house treatment planning software modified to use minimax robust optimization over a range of uncertainty realizations. Finally, traditional and probabilistic dose plans were compared, and their performance quantified.

Using this approach, traditional expansion by margins was replaced with non-binary tumor maps and robust optimization, which more realistically represent treatment planning and delivery.

12:39PM B06.00006: Evolutionary dynamics of cancer on complex stress landscapes*

YUSHA SUN (Presenter), KE-CHIH LIN, TRUNG PHAN, Princeton University, GONZALO TORGA, SARAH AMEND, KENNETH J. PIENTA, Johns Hopkins University, JAMES STURM, ROBERT AUSTIN, Princeton University — Understanding the evolutionary dynamics of cancer progression requires explicit consideration of both spatial and environmental heterogeneities. We have recently developed a purely diffusion-based cancer-on-chip microfluidic platform, enabling the quantitative study of various cell types on chemotherapeutic gradients on long time scales. In a co-culture of bone-metastatic prostate cancer cells (PC3-EPI) with bone marrow stromal cells (HS5), we found a marked transition in population dominance across a docetaxel gradient. To interpret these results, we employ evolutionary game theory (EGT) as a predictive framework for cancer-stroma dynamics. We generate a spatial interacting-agent EGT model comprised of interconnected habitats in various network topologies. Informed by our experimental findings, we explore distinct strategies utilized by populations under stress by considering system parameters as a function of both space and time as well as by modulating migrational probabilities. This model will be adapted to probe interactions between drug-resistant cancer subpopulations, stromal cells, and immune cells, providing clinical implications for therapeutic approaches.

*This work was supported by NSF PHY-1659940.
Doppler Spectroscopy of Intracellular Dynamics During Chemotherapy in Tumor Biopsies  ZHEN HUA (Presenter), JOHN TUREK, MICHAEL CHILDRESS, DAVID DOUGLAS NOLTE, Purdue Univ — Biodynamic imaging is a high-content optical imaging technology based on Doppler spectroscopy and digital holography that uses dynamic speckle as high-content image contrast to probe living tissue. Biomarkers from the living tissues were extracted using fluctuation spectroscopy from intracellular Doppler light scattering in response to the molecular mechanisms of action of therapeutic drugs that modify a range of intracellular motions. Biodynamic imaging measurements of canine B-cell cancer tissues with unknown outcomes were performed and the drug-response spectrograms were compared to results from tissues of 22 pre-clinical trial dogs with known outcomes. A machine learning classifier was constructed based on feature vector correlations and linear separability in high dimensional feature space. The prediction of resistance or sensitivity to chemotherapy for unknown patient clinical outcomes was demonstrated. These results point to the potential for biodynamic profiling to contribute to personalized medicine by aiding the selection of chemotherapy for cancer patients.

Quantifying Similarity in Histopathology Images Using Pathology-specific Deep-learned Features  QIAN CAO (Presenter), ASEF ISLAM, ZIHANG FANG, JAYLEN KANG, ALEXANDER BARAS, WOJCIECH ZBIJEWSKI, Johns Hopkins University — Interpretation of histopathology slides is often labor intensive and operator dependent. This work aims to support the pathologists by matching unknown slides with reference slides of similar characteristics (normal, benign, type of carcinoma, etc) from an annotated collection. We expand on prior efforts in this area by developing a set of pathology-specific deep-learned features for the similarity matching. The features were extracted from digitized breast histopathology slides using a convolutional autoencoder (CAE). For training, random patches of 256x256 pixel ROIs (tiles) were extracted from each slide and augmented with random affine transformations and perturbations in HSV color space to consider variability in orientation, magnification, staining and lighting conditions. Batch sizes of 128 were used in training for 2000 epochs. To assess the ability to detect similar images using the deep-learned features, we compared feature vectors of neighboring tiles of the same slide using a separate validation slide set. For inference, input tiles extracted from unknown slides are featurized with the encoder and a kNN search is performed on feature vectors derived from an annotated reference collection, returning similar tiles and corresponding slides for the pathologist.

Mathematical Models for Living Forms in Medical Physics Submodel 1: The Information Processing from Teeth to Nerves*  CHRISTINA POSPISIL (Presenter), Physics, Mathematics and Computer Science Student at University of Massachusetts Boston and Research Trainee at Harvard Medical School — This talk continues the presentations at APS March Meeting 2019 and APS April Meeting 2019. In this part of the project the first submodel is presented; The information processing from teeth to the nerves. Information processing is modeled via p-waves passing through the tooth layers enamel and dentin. Odontoblasts located in the liquid in the tubules of the tooth dentin layer perform finally the transformation into electrical information (an electrical signal) that passes along nerves.

* I fund the project currently on my own.
1:27PM B06.00010: Potential Efficacy of the Monte Carlo Dose Calculations of 6MV Flattening Filter-Free Photon Beam of M6™ Cyberknife® System  
TAINDRA NEUPANE (Presenter), Florida Atlantic University, CHARLES SHANG, Medical Physics, South Florida Proton Therapy Institute, WAZIR MUHAMMAD, THEODORA LEVENTOURI, Florida Atlantic University — Retrospective MapCheck measurements of 50 patient’s treatment plans have suggested that MapCheck could be effectively employed in routine patient specific quality assurance in M6 Cyberknife with beams delivered at different treatment angles. However, for smaller MLCs segments (< 8 mm) a correction of (-4 %) was used to match the planned dose with MapCheck. To generalize this correction, a Monte Carlo (MC) simulation is required for such types of treatment plans. In doing so, MC simulations were performed for the M6 Cyberknife using the EGSnrc program. A total of 2-5 and 10-20 millions of incident particles histories in BEAMnrc and DOSXYZnrc, respectively were simulated. Preliminary results showed dose uncertainties ≤ 3% for all the standard fields (7.6 x 7.7 mm² to 100 x 100 mm²). During the simulation, an incident electron beam of 7 MeV with a FWHM of 2.2 mm was used to match with the stated nominal energy by comparing the simulation and corresponding measurement results. Good agreements for the dose profiles (≤ 2%) and dose outputs (≤ 3%) were found between the simulations and measurements at 800 mm Source to Axis Distance (SAD).

1:39PM B06.00011: Thermal transport simulation in healthy and arthritic fingers*  
URBAN SIMONCIC (Presenter), University of Ljubljana, ELMAR LAISTER, Medical University Vienna, MATIJA MILANIC, University of Ljubljana — Infrared thermography can distinguish rheumatoid arthritic (RA) joints from healthy joints by measuring elevated skin surface temperature caused by the inflammation present in RA joints. However, infrared thermography is more sensitive for the assessment of small joints.
Thermal transport simulations of healthy and arthritic fingers were implemented by solving the bio-heat diffusion equation within joint models using finite elements method (FEM). FEM models were based on high resolution MR images. Arthritic joint models were simulated by increasing the metabolic heat generation of healthy joint models. Simulated thermographic images were compared to real images.
Our simulations confirmed that elevated internal joint temperature results in elevated surface temperature. Internal and surface temperature depended on internal heat generation, heat dissipation due to perfusion, joint geometry, and finger surface cooling. Patterns of finger surface temperature from simulation were similar to that in thermographic images.
Thermal transport simulations relate thermographic images of the finger, finger geometry, internal temperature distribution and internal heat sources or sinks. Understanding these relations facilitate better RA diagnostics with infrared thermography.

*ARRS: P1-0389, J2-8171
1:51PM B06.00012: A fast and effective denoising solution using deep learning for real time X-ray Acoustic Computed Tomography*  DAVID THOMAS (Presenter), FARNOUSH FORGHANI, ADAM MAHL, BERNARD JONES, Radiation Oncology, University of Colorado Denver, MARK BORDEN, University of Colorado, Boulder, MOYED MIFTEN, Radiation Oncology, University of Colorado Denver — The X-ray acoustic (XA) computed tomography has recently been proposed as a method for real-time 3D in-vivo patient dosimetry for radiation therapy. The XA effect follows the same principles as the photoacoustic effect: acoustic waves are induced due to the absorption of heat energy by the tissue from a pulsed photon beam. XA signals are small in amplitude and suffer from interference from RF noise generated by the Linear Accelerator electronics. For a real time dose reconstruction, a fast and effective denoising solution is required to increase the signal to noise in the measured XA signals. Here, we present a method to denoise the XA signals using deep learning neural networks. A Convolutional Neural Network (CNN) that operates on the spectral domain of XA signals is used. Given a noisy XA spectrogram, the CNN predicts clean XA signals. An advanced numerical model for time domain propagation of XA waves (kWave) is used to generate the training data for the CNN. Theoretical and experimental clean and noisy XA signals are obtained by megavoltage energy X-rays with long pulse width (4 us) generated from a clinical linear accelerator.

2:03PM B06.00013: Modeling polymer precursors for preparation of molecularly imprinted polymers for drug delivery and sensing  OLEKSANDR KOBRYN (Presenter), Nanotechnology Research Centre, National Research Council Canada — Molecularly imprinted polymers (MIPs) are synthetic receptors and are promising alternatives to natural receptors (e.g. antibodies) for a range of applications requiring specific and selective molecular recognition (e.g. sensing, drug delivery, sample clean and separation, etc.). In the absence of a rational approach to the design of MIPs, monomer selection is often made on the basis of previous experience or chemical intuition which can be time intensive and very expensive. Here, we present an example of a careful computational analysis of selected monomers with the main purpose to screen out the least suitable and identify the most appropriate ones. The modeling is based on the statistical mechanical theory of molecular liquids in terms of the Reference Interaction Site Model (RISM). With this instrument, we are be able to yield one- and three-dimensional distribution functions of interaction sites constituting the molecules and predict the solution structure and thermodynamics of its species on the nanometer scale. The recommendations for synthesis and subsequent experimental verification of selected monomers are based on visual examination of the solvent nanomorphology and quantitative analysis of their thermodynamic properties, both predicted by modeling.

Monday, March 2, 2020 11:15 AM - 2:03 PM

Session B07 DQI: Electron and Hole Based Spin Qubits in Heterostructures 102 - Manuel Rispler, Delft University of Technology
**11:15AM B07.00001: Electric dipole-induced spin resonance of holes in Ge/Si nanowires**

FLORIAN FRONING, LEON CAMENZIND, University of Basel, ANG LI, Institute of Microstructure and Property of Advanced Materials, Beijing University of Technology, ERIK BAKKERS, Applied Physics, Eindhoven University of Technology, DOMINIK ZUMBUHL, FLORIS BRAAKMAN (Presenter), University of Basel — Electric dipole-induced spin resonance (EDSR) forms a basic tool in quantum information processing with spin qubits. It enables electrically driven quantum gates and forms a way to accurately probe the energy spectrum of spin qubits. We demonstrate EDSR of hole spins confined in a double quantum dot in a Ge/Si nanowire. The spin-orbit interaction of hole spins in this system has a unique character, as it is predicted to be very strong, potentially enabling GHz Rabi oscillation frequencies, as well as electrically tunable. Recent experiments support this with a demonstration of a 30 nm spin-orbit length and Rabi frequencies exceeding 400 MHz.

Here we perform hole spin spectroscopy through the measurement of EDSR transitions between double dot spin states under various resonance conditions. In particular, we characterize the hole g-tensor as well as the direction of the effective spin-orbit magnetic field through an investigation of EDSR transitions as a function of the magnitude and orientation of an applied external magnetic field. Knowledge of these parameters allows tuning the system towards optimized Rabi oscillation frequencies and minimized decoherence.

*Supported by the Swiss National Science Foundation, the Swiss Nanoscience Institute, and the European Microkelvin Platform.

**11:27AM B07.00002: Electric control of the single hole g-factor by 400% in a silicon MOS quantum dot.**

SCOTT LILES (Presenter), FREDERICO MARTINS, Univ of New South Wales, DMITRY MISEREV, University of Basel, IAN THORVALDSON, MATTHEW RENDELL, FAY E. HUDSON, Univ of New South Wales, MENNO VELDHORST, University of Twente, OLEG SUSHKOV, ANDREW STEVEN DZURAK, ALEX HAMILTON, Univ of New South Wales — Holes in silicon quantum dots are attracting significant attention for their potential use as fast, highly coherent spin qubits [1]. However, there are still gaps in the understanding of the physics of hole spins. For example, the full effects of confinement and spin-orbit coupling on hole spin states remains an open problem. Studies of the Lande g-tensor are valuable for characterizing this underlying spin physics, however most studies of holes have been performed in an unknown orbital configuration where spin-orbit coupling can lead to complex non-trivial spin effects. Studies of a single hole in a known and reproducible orbital state can therefore provide valuable insight into the complex spin physics.

In this work we confine a single hole in a known orbital state [2] and study the Lande g-tensor using a 3D vector magnet. We compare the g-tensor for different confinement profiles and find the g-tensor can be strongly modulated and even rotated by up to 30 degrees. These results show that the anisotropy of the single hole g-tensor is due to symmetries in the tunable electric confinement. This tunability can be harnessed for further use of holes in spin qubit applications.

11:39AM B07.00003: Fast and tunable Rabi oscillations of hole spins in Ge/Si nanowires*

FLORIAN FRONING (Presenter), LEON CAMENZIND, University of Basel, ANG LI, ERIK BAKKERS, TU Eindhoven, DOMINIK ZUMBUHL, FLORIS BRAAKMAN, University of Basel — The strong confinement of holes to one dimension in Ge/Si core/shell nanowires gives rise to direct Rashba spin-orbit interaction which is predicted to be both very strong and electric field tunable. The full electrical control promises to switch the spin-orbit interaction either on, enabling fast qubit operations, or off, protecting the spin state in order to achieve an increased qubit lifetime. These properties make Ge/Si nanowires a very promising system for the implementation of hole spin qubits. Recent experiments have found a spin-orbit interaction length on the order of only 30 nm, paving the way to very fast spin manipulation by electric dipole spin resonance. This mechanism allows us to drive very fast Rabi oscillations above 400 MHz at a Larmor frequency of 3.4 GHz, thus entering the strong driving regime. Furthermore, we find the Rabi oscillation frequency as well as the g-factor to be highly tunable with small changes in gate voltages, indicating the feasibility to electrically control the spin-orbit interaction strength.

*Supported by Swiss NSF, Swiss Nanoscience Institute SNI, and European Microkelvin Platform EMP.

11:51AM B07.00004: Towards scalable hole spin qubits in silicon* RAMI EZZOUCH (Presenter), SIMON ZIHLMANN, ALESSANDRO CRIPPA, ROMAIN MAURAND, AGOSTINO APRÀ, ANTHONY AMISSE, XAVIER JEHL, BENOIT BERTRAND, LOUIS HUTIN, MAUD VINET, BENJAMIN VENITUCCI, JING LI, YANN-MICHEL NIQUET, CEA Grenoble, MATIAS URDAMPILLETA, TRISTAN MEUNIER, Institut Néel, CNRS, MARC SANQUER, SILVANO DE FRANCESCHI, CEA Grenoble — Since the first proof-of-concept demonstration of a silicon hole spin qubit based on industry-standard CMOS technology [1], our research efforts have focused on acquiring a better understanding of the mechanism for electric-field-driven hole-spin manipulation [2], as well as on the development of spin readout based on rf gate reflectometry [3]. All of these studies were carried out on p-type silicon-nanowire devices with two crossing gates in series. Here we report the first implementation of hole-qubit functionality in a face-to-face gate geometry [4]. This more scalable geometry can be regarded as the elementary building block of a one-dimensional chain of qubits were each qubit on the chain is read through a facing helper quantum dot via the Pauli spin blockade mechanism and rf gate reflectometry [5].

12:03PM B07.00005: Hole spin echo envelope modulations  PERICLES PHILIPPOPOULOS (Presenter), McGill University, STEFANO CHESI, Beijing Computational Science Research Center, JOE SALFI, University of British Columbia, SVEN ROGGE, University of New South Wales, WILLIAM COISH, McGill University — An anisotropic hyperfine coupling can give rise to a substantial spin-echo envelope modulation that can be Fourier-analyzed to accurately reveal the hyperfine tensor. We give a general theoretical analysis for hole-spin-echo envelope modulation (HSEEM), and apply this analysis to the specific case of a boron-acceptor hole spin in silicon [1]. For boron acceptor spins in unstrained silicon, both the hyperfine and Zeeman Hamiltonians are approximately isotropic leading to negligible envelope modulations. In contrast, in strained silicon, where light-hole spin qubits can be energetically isolated, we find the hyperfine Hamiltonian and g-tensor are sufficiently anisotropic to give spin-echo-envelope modulations. We show that there is an optimal magnetic-field orientation that maximizes the visibility of envelope modulations in this case. Based on microscopic estimates of the hyperfine coupling, we find that the maximum modulation depth can be substantial, reaching ~ 10%, at a moderate laboratory magnetic field, B < 200 mT.

12:15PM B07.00006: Effects of Valley-Orbit Coupling on the Exchange Interaction in a Si/SiGe Double Quantum Dots*  BILAL TARIQ (Presenter), XUEDONG HU, State Univ of NY - Buffalo — We investigate the effects of the phase and magnitude of the valley orbit coupling on the tunnel coupling matrix elements and the exchange interaction in a Si double quantum dot. Our results show that a difference in the phase between the two quantum dots modifies the single-electron tunnel coupling between different valley eigenstates. In particular, valley-blockade between the ground valleys of individual dots could be obtained when the valley phase difference between the dots is π. For the two-electron case, exchange interaction at the symmetric point (zero detuning) is suppressed when valley phase difference is finite, and reaches its minimum value when the phase difference is 180 degrees. The energy spectrum at finite detuning also depends on the magnitudes and phases of the valley orbit couplings of the two dots. Our results shed new lights on the controllability of Silicon based spin qubit for its application in quantum information processing.

12:27PM B07.00007: Singlet-triplet splitting of two electrons in a Si/SiGe quantum dot*

EKMEL ERCAN (Presenter), University of Wisconsin - Madison, SUSAN NAN COPPERSMITH, University of Wisconsin-Madison, The University of New South Wales, MARK G FRIESEN, University of Wisconsin - Madison — We theoretically study the effects of quantum dot confinement strength on the singlet-triplet (ST) splitting of two-electron dots in Si/SiGe quantum wells. Our analysis includes valley effects and disorder at the quantum well interface by combining full configuration interaction (FCI) scheme with tight-binding (TB) calculations. While TB provides an accurate description of single-electron wave functions by taking microscopic effects like interface disorder into account, and captures the valley physics of silicon, FCI allows us to calculate multielectron energies and corresponding wave functions by including the effects of electron-electron interactions. We show that these interactions can have unexpectedly strong or unexpectedly weak effects on the ST splitting, depending on the confinement strength and anisotropy.

12:39PM B07.00008: Operation of a four-qubit device in isotopically enriched Si/SiGe*

ANTHONY SIGILLITO (Presenter), MICHAEL GULLANS, JASON PETTA, Princeton University — Quantum processors based on electron spins in silicon are rapidly becoming a strong contender in the race to build a quantum computer. Over the past few years, quantum-dot spin qubits have been shown to offer high fidelity single-qubit [1] and two-qubit [2-5] control at levels approaching the fault tolerant threshold. However, most experiments have been conducted in one-qubit, or two-qubit devices. Recently, we have demonstrated operation of a four-qubit device in isotopically enriched Si/SiGe [6]. Here we outline improvements to our four-qubit device design and present new data on one- and two-qubit operation in the device including recent randomized benchmarking results.

*We thank L. F. Edge and M. Borselli of HRL Laboratories for providing the isotopically enriched heterostructure. Research sponsored by ARO grant No. W911NF-15-1-0149 and the Gordon and Betty Moore Foundation's EPIQS Initiative through grant GBMF4535. Devices were fabricated in the Princeton University Quantum Device Nanofabrication Laboratory.
12:51PM B07.00009: Coherent spectroscopy of a Si/SiGe double quantum dot molecule
JOELLE BAER (Presenter), JOHN DODSON, BRANDUR THORGRIMSSON, EKMEL ERCAN, MERRITT LOSERT, TREVOR KNAPP, NATHAN HOLMAN, THOMAS MCJUNKIN, SAMUEL NEYENS, EVAN R MACQUARRIE, RYAN H FOOTE, University of Wisconsin - Madison, LISA F EDGE, HRL Laboratories, LLC, MARK G FRIESEN, SUSAN NAN COPPERSMITH, MARK ALAN ERIKSSON, University of Wisconsin - Madison — We report the wideband microwave spectroscopy of a gate-defined double quantum dot qubit. The double quantum dot, operated with a total of five electrons, has a series of molecular energy levels that can be manipulated coherently. Working in the (4,1)-(3,2) charge configuration, we use a two-step Ramsey pulse sequence to characterize the energy levels of the (3,2) charge configuration as a function of the double-dot detuning. Using this procedure, we demonstrate differences in the dispersion for two closely spaced levels (<2GHz separation in energy). We present measurements of the broadband spectrum, discovering seven energy levels that can be addressed coherently, each with distinct Rabi oscillation characteristics. The double quantum dot is formed in an undoped Si/SiGe heterostructure using an overlapping gate architecture [1]. The measurements are acquired using a tunable latched measurement scheme similar to that in Ref. [2], made possible by the presence of independent reservoirs and corresponding tunnel barriers for each quantum dot.

1:03PM B07.00010: Towards coupled valley qubits in silicon* JOHN ROONEY (Presenter), BLAKE M FREEMAN, NICHOLAS PENTHORN, University of California, Los Angeles, LISA F EDGE, HRL Laboratories, LLC, HONGWEN JIANG, University of California, Los Angeles — Valley states in silicon are a promising candidate for encoding qubits in gate-defined quantum dots due to their protection against charge noise, fast operation times, and ability to operate without a magnetic field. Recently, two-axis quantum control of a valley qubit using gate pulse sequences with X and Z rotations, occurring within a fast operation time of 300 ps, has been demonstrated [1]. In this talk, we present our progress on coupling two such valley qubits. We have fabricated a device consisting of two double-quantum dots on a SiGe heterostructure for our experiments. We further measure the capacitive coupling between the two double dots in the few electron region, showing sufficiently large and tunable coupling. By exploiting this electrostatic interaction, we discuss our plan for employing the two coupled valley qubits to realize a two-qubit logic gate.

1:15PM B07.00011: Hyperfine effects in a single hole GaAs/AlGaAs double quantum dot device* SERGEI STUDENIKIN (Presenter), JORDAN DUCATEL, MAREK J KORKUSINSKI, D. G. AUSTING, PIOTR ZAWADZKI, ANDREW STANISLAW SACHRAJDA, National Research Council Canada, PERICLES PHILIPPOPOULOS, WILLIAM COISH, Department of Physics, McGill University, LISA A TRACY, JOHN RENO, TERRY HARGETT, Sandia National Laboratories — Hole spin qubits are attractive because, compared to electrons, they are predicted theoretically to have significantly weaker interactions with host nuclei, resulting in longer coherence times [1]. As a result it is more challenging to quantify hyperfine (hf) effects with holes. In Ref. [2], in a quantum point contact device, Dynamic Nuclear Polarization (DNP) through the hf interaction with holes was undetectable. In this work, we detect and explore small DNP effects in a single hole GaAs/AlGaAs gated DQD device using a modified EDSR technique [3]. As compared to our previous studies [3], the device is tuned to a much smaller inter-dot coupling regime to minimize spin-orbit effects and to make nuclear spin effects detectable.

1:27PM B07.00012: A realistic GaAs-spin qubit device for a classical error-corrected quantum memory and beyond* MANUEL RISPLER (Presenter), Delft University of Technology, PASCAL CERFONTAINE, VEIT LANGROCK, JARA-FIT Institute Quantum Information Forschungszentrum Jülich and RWTH Aachen, BARBARA MARIA TERHAL, Delft University of Technology — Based on numerically-optimized real-device gates and parameters we study the performance of the phase-flip (repetition) code on a linear array of GaAs quantum dots hosting singlet-triplet qubits. We first examine the expected performance of the code using simple error models of circuit-level and phenomenological noise, reporting a.o. a 3% circuit-level depolarizing noise threshold. We then perform density-matrix simulations using a maximum-likelihood and minimum-weight matching decoder to study the effect of real-device dephasing, read-out error, quasi-static as well as fast gate noise. Considering the trade-off between qubit read-out time versus dephasing time (T2), we identify a sub-threshold region for the phase-flip code which lies within experimental reach.

1:39PM B07.00013: Developing atom-based solid-state quantum simulators: understanding charge-stability diagrams of dopant arrays in Si  
GARNETT BRYANT (Presenter), EMILY TOWNSEND, XIQIAO WANG, RICHARD SILVER, National Institute of Standards and Technology — Atomically precise fabrication of dopant arrays in Si provides exciting opportunities to perform quantum simulations and to study the dynamics of engineered quantum systems. Here we describe theoretical simulations done for two-dimensional arrays of dopants in Si used to implement an extended range Fermi-Hubbard model. Simulations are done with and without atom disorder, as a function of the electron-electron interaction to test the limits of weak and strong interaction, and with and without a spin/valley degree of freedom. Results are used to understand charge-stability diagrams, recently obtained for two-dimensional arrays of dopants in Si. The nature of transport through these arrays depends critically on the ratio of the inter-dopant tunneling to tunnel coupling of the dopants to the source and drain. We consider n x m arrays of different sizes to identify the array states that are probed in transport. We further consider the effect of array orientation relative to the source and drain on the tunnel coupling and on the capacitive coupling to side gates. Implications for using dopant arrays as a quantum lab on a chip are discussed.

1:51PM B07.00014: Controlling textured hole spins in InAs quantum dots with oscillating electric fields*  
ARTHUR LIN (Presenter), Joint Quantum Institute, University of Maryland, MATTHEW F DOTY, Department of Materials Science and Engineering, University of Delaware, GARNETT BRYANT, Nanoscale Device Characterization Division, National Institute of Standards and Technology — Recently, we have shown that hole spins in InAs quantum dots (QDs) exhibit spatially dependent texture, caused by the spin-orbit properties of the material and the geometry of the dot. Utilizing this spin texture, we demonstrated the ability to flip the overall hole spin by reversing the in-plane electrical bias across the dot. To fully capture the spin texture of the hole states, we used an atomistic tight-binding model that is able to resolve the wavefunction at the atomic level. However, atomistic tight-binding calculations are computationally expensive. Here, we present a reduced Hamiltonian capable of describing the evolution of the lowest hole state tight-binding wavefunctions, simulating the effect of oscillating electric fields, while fully preserving the effects of the spin texture. We calculate the timescale at which the spatial texture of the hole spin evolves, how the spin texture changes as the field oscillates, and how oscillating fields drive the overall net spin. We briefly discuss how our results can be used to design new control schemes for holes in QDs.

11:15AM B08.00001: Extending Modern C++ for Heterogeneous Quantum-CLASSICAL Computing*  ALEXANDER MCCASKEY (Presenter), EUGEN DUMITRESCU, PAVEL LOUGOVSKI, SARAH POWERS, SHIRLEY MOORE, TIFFANY MINTZ, Oak Ridge National Lab — Software frameworks for quantum computing have progressed significantly over the past few years. Most approaches have put forward vendor-specific frameworks leveraging high-level languages like Python. As quantum hardware improves, we expect that these high-level approaches will detract from overall performance gains garnered from quantum computation. Tighter integration models will require low-level, system software and compilers extending commonly-used languages. We present QCOR, a C++ language extension specification with an associated compiler that enables the programming of quantum expressions alongside standard C++ in a single-source context. Our specification puts forward abstractions and concepts that are common to typical quantum-classical algorithmic workflows. We implement this language extension via light-weight extensions to Clang and build off the system-level, quantum-classical XACC framework. Our approach represents the state-of-the-art with regards to enabling quantum programming alongside standard languages leveraged in existing high-performance domain scientific computing.

11:27AM B08.00002: OpenPulse: Software for Experimental Physicists in Quantum Computing  LAUREN CAPELLUTO (Presenter), THOMAS ALEXANDER, IBM TJ Watson Research Center — The quantum computing industry provides public access to superconducting qubit systems through open-source quantum computing frameworks such as Qiskit. Compilation techniques play a critical role in leveraging these small scale, noisy devices by driving down error rates in program execution. The compiler backend decomposes quantum operations into microwave pulses which aim to realize the desired quantum operations with the highest fidelity possible. We introduce OpenPulse, a pulse-level programming component of Qiskit, that hands over analog control of quantum computing systems to the user. Using OpenPulse, the user can specify the exact time dynamics of a program by scheduling arbitrary waveforms on control system resources, and can recover the time dynamics of the measured output. This is sufficient to allow the user to freely characterize, verify and validate the quantum system, and to explore gate optimization and error mitigation techniques to enhance system performance. OpenPulse enables the community to collectively push the field onwards towards practical computation.
11:39AM B08.00003: qupulse: A quantum computing pulse parametrization and sequencing framework

PASCAL CERFONTAINE (Presenter), SIMON HUMPOHL, LUKAS PREDIGER, PATRICK BETHKE, EUGEN KAMMERLOHER, LARS SCHREIBER, JARA-FIT Institute for Quantum Information, RWTH Aachen University, STEFANIE MEYER, Central Institute of Engineering, Electronics and Analytics ZEA-2, Forschungszentrum Jülich GmbH, BERNHARD RUMPE, Chair of Software Engineering, RWTH Aachen University, HENDRIK BLUHM, JARA-FIT Institute for Quantum Information, RWTH Aachen University — We present an open source python package for the operation of advanced qubit control experiments, which emerged from our experimental work on spin qubits. It allows for hierarchical definition of control pulses and pulse sequences with an arbitrary nesting depth in a hardware-independent way.

Pulses can be described in terms of symbolic parameters. Reparametrization by mathematical expressions, for example when combining or sequencing pulses, is possible. This enables the simple generation of parameter sweeps and the reuse of predefined pulses. qupulse also exploits the sequencing capabilities of different arbitrary waveform generators for efficient use of waveform memory. Furthermore, serialization to JSON allows for a straightforward documentation of experiments and simplifies exchanging pulses between researchers.

In order to automatically configure acquisition hardware and simplify the data analysis, measurements can be specified as part of the pulse definition. We designed qupulse to interact with different instrument control and data acquisition frameworks such as QCodeS, special-measure (currently implemented) and labber.

qupulse is available at github.com/qutech/qupulse or quantuminfo.physik.rwth-aachen.de/code, accompanied by extensive documentation.

11:51AM B08.00004: Compiled Quantum Optimization Algorithms in NISQ Processors*

DAVIDE VENTURELLI (Presenter), QuAIL, USRA, NASA, MINH DO, NASA Ames Research Center, BRYAN O’GORMAN, QuAIL, Berkeley University, NASA, ZHIHUI WANG, QuAIL, USRA, NASA, ELEANOR RIEFFEL, QuAIL, NASA, JEREMY FRANK, NASA Ames Research Center, RYAN M LAROSE, QuAIL, UMich, USRA, NASA, VANESA GOMEZ GONZALEZ, USRA — We discuss resource estimation and synthesis optimization results related to compilation of a variety of structured variational algorithms. Specifically, we look at software tools and methods for finding a swap network that allows the efficient execution of algorithms on different superconducting chips (Rigetti’s Aspen Chip, Google’s Sycamore, IBM’s Tokyo). Efficiency is measured in terms of the total temporal makespan of execution of the compiled quantum circuit. Examples include algorithms for scheduling and asset allocation with both soft and hard constraints. We address two different regimes: where near-optimal compilations can be found, and where only heuristics (e.g., temporal planning methods) are available.

12:03PM B08.00005: Optimizing compiler for Fermion simulation circuits* QINGFENG WANG (Presenter), University of Maryland, College Park, YUNSEONG NAM, IonQ, CHRISTOPHER ROY MONROE, University of Maryland, College Park — Jordan-Wigner and Bravyi-Kitaev transformations are the two widely known examples of the Fermion → qubit operator mappings. There exist however at least $O(2^{n^2})$ possible such mappings. Thus, an appropriate choice of the mapping can result in the reduction of quantum resource cost in practice, such as two-qubit gate counts in Fermion-simulation circuits. In this talk, I will present a methodology that may be used to optimize these simulation circuits, leveraging the vastly large space from which a suitable mapping may be drawn. A series of heuristics will be explored to arrive at the post-optimization quantum circuits.

12:15PM B08.00006: Heuristics for Quantum Compiling with a Continuous Gate Set MARC DAVIS (Presenter), Physics, UC Berkeley, COSTIN IANCU, Lawrence Berkeley National Laboratory — Abstract
We present an algorithm for compiling arbitrary unitaries into a sequence of gates native to a quantum processor. As accurate CNOT gates are hard for the foreseeable Noisy-Intermediate-Scale Quantum devices era, our A* inspired algorithm attempts to minimize their count, while accounting for connectivity. We discuss the search strategy together with “metrics” to expand the solution frontier. For a workload of circuits with complexity appropriate for the NISQ era, we produce solutions well within the best upper bounds published in literature and match or exceed hand tuned implementations, as well as other existing synthesis alternatives. In particular, when comparing against state-of-the-art available synthesis packages we show $2.4 \times$ average (up to $5.3 \times$) reduction in CNOT count. We also show how to re-target the algorithm for a different chip topology and native gate set, while obtaining similar quality results. We believe that empirical tools like ours can facilitate algorithmic exploration, gate set discovery for quantum processor designers, as well as providing useful optimization blocks within the quantum compilation tool-chain.
Introducing Control Flow in Qubit Allocation for Quantum Turing Machines

MICHAEL CUBEDDU (Presenter), WILL T FINIGAN, PRINEHA NARANG, Harvard University; Aliro Technologies, VITALI VINOKOUR, Aliro Technologies — To make NISQ devices practical for quantum software engineers, novel programming tools with maximal flexibility have to be developed. Several proposed algorithms and error-correcting codes for near term devices require the ability to execute classical control statements based on quantum measurements. However, the unpredictable nature of control flow on a quantum device complicates the compilation process in the presence of variable noise. The functionality of control flow allows for expanded algorithmic power of the programming language in the form of conditional statements and loops, which a linearly-executed program is incapable of computing. In this work, we introduce a framework to reconcile the non-deterministic properties of quantum control flow when allocating virtual qubits from a given quantum circuit to physical qubits on a specific NISQ device in the pre-processing and compiling stage. We consider the respective connectivity and fidelity constraints, with the goal of reducing the expected error rate of the computation. Our protocols will allow for quantum developers and NISQ devices together to more efficiently exploit the compelling algorithmic power that the quantum Turing machine model provides.

Noise-Aware Qubit Allocation Techniques for NISQ Devices

MICHAEL CUBEDDU, WILL FINIGAN (Presenter), Harvard University; Aliro Technologies, VITALI VINOKOUR, Aliro Technologies, PRINEHA NARANG, Harvard University; Aliro Technologies — With a growing diversity in devices, control systems, topologies, programming languages, and applications, computation in the NISQ era needs to be navigated through adaptable cloud-based software. In order to provide the highest fidelity results to users, it is essential that this software employs hardware-aware optimizations at all levels of the stack, both in the pre-processing and post-processing stages. We present our work in pre-processing error mitigation through variation-aware qubit allocation techniques for gate-based quantum computers, with a focus on superconducting platforms. We formulate a description of the “allocation problem” and propose several solutions: a deterministic algorithm for finding the optimal solution as well as a more scalable and flexible randomized heuristic approach. We will present and validate the implications of these different techniques on various NISQ devices.

*This work is supported by Harvard University OTD's PSE Accelerator Grant.
12:51PM B08.00009: Benchmarking NISQ Devices Using qFlex*
SALVATORE MANDRA (Presenter), NASA Ames Research Center, BENJAMIN VILLALONGA, University of Illinois at Urbana-Champaign, DMITRY LIAKH, Oak Ridge National Lab, SERGIO BOIXO, Google Inc. — Quantum supremacy is the task to perform a quantum calculation on a Noisy-Intermediate Scale Quantum (NISQ) device that cannot be performed on the latest and most powerful supercomputer by using the best known classical simulator. To this end, the Google team has designed a series of benchmarks, based on the sampling of Random Quantum Circuits (RQCs), to challenge classical supercomputers. In a programming-like language, the RQC sampling corresponds to the first “Hello, World!” program in the quantum computing era. In my talk I will present qFlex, a fast and flexible software to simulate large RQCs to both verify and benchmark NISQ devices. qFlex is a NASA-Google-ORNL collaboration and it's now publicity available at https://github.com/ngnrsaa/qFlex. As part of my talk, I will show some live demos and present our latest results on benchmarking available NISQ devices.

1:03PM B08.00010: Characterization of State-dependent Noise in NISQ Processors*
RONALD J SADLIER (Presenter), he Bredesen Center for Interdisciplinary Research and Graduate Education, University of Tennessee, Knoxville, TRAVIS HUMBLE, Quantum Computing Institute, Oak Ridge National Laboratory — Characterization of the quantum operations in current NISQ devices reveal noise spectra that are highly dependent on the underlying quantum state. These results indicate that a state-dependent noise model is needed to accurately control the behavior of quantum computing programs on today's noisy hardware. We develop a method for characterizing state-dependent errors based on classical truth tables for the gate operations, and we use these results to compute the amplitudes of the corresponding channel operators. Using this method, we characterize a 20-qubit fixed-frequency superconducting transmon processor to develop a noise model for this device. We then use this noise model to estimate the fidelity of quantum circuits executed on the hardware and compare these results with tomographic fidelities.

*This work was supported by the Department of Energy Office of Science Early Career Research Program.
1:15PM B08.00011: Strategies for reducing the number of controlled gates on noisy intermediate scale quantum circuits*  KOSUKE MITARAI (Presenter), KEISUKE FUJII, Graduate School of Engineering Science, Osaka University — We show that certain kind of controlled gates can be decomposed into a sequence of single-qubit operations when expectation values of some operators are needed. It is performed by decomposing the corresponding quantum channels into linear combination of single-qubit channels. Firstly, we discuss the usefulness of the presented method in variational algorithms which runs on quantum computer by showing that it can extract information about the derivatives of the parametrized state without adding ancilla qubit. It can also be applied for measuring the time correlation of observables in quantum simulations. Finally, we show that the method can decompose a large, in the number of qubits, quantum circuit into smaller ones. Although the runtime of this method scales exponentially in the number of decompositions performed, it reduces the requirement on the hardware by reducing the number of gates and qubits in the trade-off of increased runtime.

1:27PM B08.00012: qubit-ADAPT-VQE: An adaptive algorithm for constructing hardware-efficient ansätze on a quantum processor*  HO LUN TANG (Presenter), Physics, Virginia Tech, HARPER GRIMSLEY, NICHOLAS J. MAYHALL, Chemistry, Virginia Tech, EDWIN BARNES, SOPHIA E. ECONOMOU, Physics, Virginia Tech — The variational quantum eigensolver, being a promising algorithm on near-term quantum devices, is extensively used for finding the ground state energy of molecular Hamiltonians. The classical and quantum resources needed by this algorithm, the number of variational parameters in the wavefunction ansatz and the depths of the state preparation circuits, critically depend on the choice of ansatz. Recently, an algorithm termed ADAPT-VQE was introduced to build system-adapted ansätze with substantially fewer variational parameters compared to other approaches. However, deep state preparation circuits remain a challenge. Here, we present a hardware-efficient variant of this algorithm called qubit-ADAPT. By numerical simulations, we show that with a well-designed operator pool, qubit-ADAPT can reduce the circuit depth by one order of magnitude while maintaining the same accuracy as the original ADAPT-VQE. This result highlights the promise of adaptive ansätze algorithms on near-term quantum devices.

Session B09 DQI: NISQ: Algorithms 106 - Hari Krovi, BBN Technologies
11:15AM B09.00001: Noise-resilient quantum algorithm design for adiabatic quantum computers  JIAN LIN (Presenter), XIAOPENG LI, Department of Physics, Fudan University — We have developed a novel architecture for automated design of quantum adiabatic algorithm by combining deep reinforcement learning and simulation annealing techniques. Through numerical test, we find that our architecture is adaptable for noise-resilient quantum algorithm design, which is of great current demand in the era of noisy intermediate-scale quantum computing. We show that in solving Grover search, our method automatically reaches the optimal performance in terms of time-complexity scaling. Our approach offers a recipe to make the noise-resilient adiabatic quantum computing, and is also generalizable to optimizing quantum simulations.

11:27AM B09.00002: Preserving symmetries in NISQ algorithms*  MICHAEL STREIF (Presenter), Quantum AI Lab, USRA and NASA Ames, ELEANOR RIEFFEL, Quantum AI Lab, NASA Ames Research Center, ZHIHUI WANG, Quantum AI Lab, USRA and NASA Ames — Many classical optimization problems display local or global symmetries. In the Quantum Alternating Operator Ansatz (QAOA), these symmetries can be used to design mixers which restrict the evolution of the system to a subspace which is exponentially smaller than the full Hilbert space [1,2]. However, in realistic scenarios, errors can break the symmetry and yield invalid solutions to the optimization problem. In this talk, we show an analysis of the probability of staying in the correct subspace under the influence of realistic noise models. Moreover, for the example of 3-coloring, we show that it is possible to exploit the natural redundancy of the qubit encoding to bring back the evolution into the correct subspace.

Using Grover’s search algorithm to test a three-level quantum system*

VASILY GEYKO (Presenter), ALESSANDRO CASTELLI, ILON JOSEPH, YUAN SHI, FRANK R GRAZIANI, STEPHEN BERNARD LIBBY, JEFFREY PARKER, YANIV J ROSEN, JONATHAN L DUBOIS, Lawrence Livermore Natl Lab — In the present work, Grover’s search algorithm is modified and studied for application to a three-level “qutrit” quantum device. The modified algorithm constructs the superposition of all states via the discrete Fourier transform instead of the standard Hadamard gate. Then, the analogous Grover’s diffusion operator is applied $m$ times. The probability of determining the correct answer as a function of $m$ is derived and shown to be very close to unity for specific choices of $m$. In a real device, the measured probability will deviate from theoretical predictions due to decoherence effects, and, since different energy levels of the qutrit have different decoherence properties, this can potentially affect the performance of the algorithm depending on the marked state. To address these issues, the algorithm has been specifically designed for implementation on the LLNL Quantum Design and Integration Testbed (QuDIT) hardware platform. This device is based on superconducting circuit architecture where the first three-levels of a transmon are used to define the qutrit.

*This work was performed under the auspices of US DOE by LLNL under Contract DE-AC52-07NA27344 and was supported by DOE FES under Project No. AT1030200-WA-OP SCW-1680 and LLNL-LDRD under Project No. 19-FS-072.

Utilizing NISQ devices for evaluating quantum algorithms*

ELEANOR RIEFFEL (Presenter), NASA Ames Research Center — With the advent of quantum supremacy, we have an unprecedented opportunity to explore quantum algorithms in new ways. The emergence of general-purpose quantum processors opens up empirical exploration of quantum algorithms. Classically, heuristic algorithms, empirically tested on benchmark and real-world problems, work well in practice. With the empirical evaluation NISQ hardware enables, we enter the era of quantum heuristics, where we can expect a broadening of established applications of quantum computing. What to run, and how best to utilize these still limited quantum devices, remain open research questions. We discuss opportunities and challenges for using NISQ devices to evaluate quantum algorithms, including in elucidating quantum computational mechanisms, in designing novel quantum algorithms, in compilation and error-mitigation, and in techniques for evaluating quantum algorithms empirically.

*We are grateful for support from NASA Ames Research Center, from the AFRL Information Directorate under grant F4HBKC4162G001, and from the Office of the Director of National Intelligence (ODNI) and the Intelligence Advanced Research Projects Activity (IARPA), via IAA 145483.

What we’ve learned from NISQ application experiments on Sycamore

RYAN BABBSH (Presenter), Google Inc. — Does implementing larger and more accurate examples of VQE, QAOA and the like actually teach us anything useful about quantum computing? Or are we wasting our time on refinements of these NISQ favorites if none of them are going to scale to the classically intractable regime without a significant breakthrough? In this talk, I will reflect on these questions in the context of Google’s recent application demonstration experiments on the Sycamore quantum processor.
12:15PM B09.00006: Sequential minimal optimization for quantum-classical hybrid algorithms*  
KEN M. NAKANISHI (Presenter), Graduate School of Science, The University of Tokyo, KEISUKE FUJII, Graduate School of Engineering Science, Osaka University, SYNGE TODO, Graduate School of Science, The University of Tokyo — We propose a sequential minimal optimization method for quantum-classical hybrid algorithms, which converges faster, is robust against statistical error, and is hyperparameter-free. Specifically, the optimization problem of the parameterized quantum circuits is divided into solvable subproblems by considering only a subset of the parameters. In fact, if we choose a single parameter, the cost function becomes a sine curve with period $2\pi$, and hence we can exactly minimize with respect to the chosen parameter. By repeatedly performing this procedure, we can optimize the parameterized quantum circuits so that the cost function becomes as small as possible. We perform numerical simulations and find that the proposed method substantially outperforms the existing optimization algorithms. This accelerates almost all quantum-classical hybrid algorithms readily and would be a key tool for harnessing near-term quantum devices.

*KMN thanks IPA for its support through MITOU Target program. 12:27PM B09.00007: Systematically Improving Quantum Approximate Optimization Algorithm with an Adaptive Ansatz*  
SOPHIA E. ECONOMOU (Presenter), LINGHUA ZHU, HO LUN TANG, GEORGE S. BARRON, EDWIN BARNES, Department of Physics, Virginia Tech, NICHOLAS J. MAYHALL, Department of Chemistry, Virginia Tech — The quantum approximate optimization algorithm (QAOA) is a hybrid variational quantum eigensolver (VQE) algorithm that uses a variational ansatz of an alternating form to minimize a classical (‘problem’) Hamiltonian. The two alternating operators are given by exponentiation of the problem Hamiltonian and by the ‘mixing’ layer, which in the original formulation of QAOA is a rotation of all the qubits about the x axis. It has been discussed in the literature that by using more general mixers the performance of QAOA can be improved. However, determining how to choose these mixers is an open question. Here we provide a solution by employing the recently introduced ADAPT-VQE\(^1\) algorithm, an iterative approach to creating ansatze for VQEs. We show that the performance of QAOA can be improved considerably by allowing more freedom in the single qubit gates and even further by allowing for entangling operations in the mixing layer.

US Department of Energy (Award No. de-sc0019318)
12:39PM B09.00008: Bounds on classical simulation of simple quantum models from quantum supremacy. PETER LOVE (Presenter), Tufts Univ — Quantum simulation is a central application of quantum computing. Quantum supremacy defines systems whose efficient classical simulation is unlikely given complexity-theoretic assumptions. We consider simple physically motivated quantum models that can display quantum supremacy and hence whose efficient simulation by classical means is unlikely. We consider quantum extensions of classical hydrodynamic lattice gas models. We find that the existence of local conserved quantities strongly constrains such extensions. We find the only extensions that retain local conserved quantities correspond to changing the local encoding of a subset of the bits. These models maintain separability of the state throughout the evolution and are thus efficiently classically simulable. We then consider evolution of these models in the case where any of the bits can be encoded and measured in one of two local bases. For quantum extensions of classical models that are computationally universal such quantum extensions can encode Simon’s algorithm and demonstrate quantum supremacy, thus presenting an obstacle to efficient classical simulation.

12:51PM B09.00009: Maximum weighted independent set and quantum alternating operator ansatz ZAIN SALEEM (Presenter), Argonne Natl Lab — We study the maximum weighted independent set problem of graph theory using the quantum alternating operator ansatz. We perform simulations on the Rigetti Forrest simulator and analyze the dependence of the algorithm on the depth of the circuit, initial states and the weights of the vertices. We point out that the probability distribution of observation of the feasible states representing maximum independent sets is asymmetric for the Maximum Independent Set problem unlike the MaxCut problem where the probability distribution of feasible states is symmetric. We also give a numerical comparison of the approximation ratios for the algorithm when we choose different initial states in our graph.

1:03PM B09.00010: Multi-block ADMM Heuristics for Mixed-Binary Optimization on Classical and Quantum Computers CLAUDIO GAMBELLA (Presenter), ANDREA SIMONETTO, IBM Research Ireland — Solving combinatorial optimization problems on noisy intermediate-scale quantum (NISQ) devices is currently being advocated for (and restricted to) binary polynomial optimization with equality constraints. This is achieved using, e.g., the variational quantum eigensolver (VQE), a hybrid quantum/classical heuristic approach. We present a decomposition-based approach to extend the applicability of current approaches to mixed binary optimization (MBO) problems, so as to solve a broad class of real-world optimization problems. In the MBO framework, we show that the alternating direction method of multipliers (ADMM) can split the MBO into a binary unconstrained problem (that can be solved via variational quantum approaches), and continuous constrained convex subproblems (that can be solved cheaply with classical optimization solvers). The validity of the approach is then showcased by numerical results obtained on several optimization problems via simulations with VQE on the quantum circuits implemented in Qiskit, an open-source quantum computing software development framework.
1:15PM B09.00011: Learning unitaries via gradient descent optimization  BOBAK KIANI, Mechanical Engineering, Massachusetts Institute of Technology, REEVU MAITY (Presenter), Physics, University of Oxford, SETH LLOYD, Mechanical Engineering, Massachusetts Institute of Technology — We study the learnability of unitary operations within the framework of the quantum alternating operator formalism using gradient descent method. Gradient descent algorithms are first order optimization methods which are of particular interest to the machine learning community due to their greater computational efficiency over second order techniques. However, the manifold of unitaries is non-convex in general and it is well known that gradient descent does not converge to the global minimum in such spaces. This motivates the question of how hard it is to learn a unitary with an alternating operator circuit using gradient descent. In this work, we find that gradient descent requires at least d^2 parameters in an alternating operator sequence to learn an arbitrary unitary in U(d) with a desired accuracy. The rate of convergence rapidly increases when gradient descent is performed in over-parameterized spaces greater than d^2. We heuristically argue the onset of a phase transition when gradient descent is performed on all d^2 parameters to learn a unitary. We present a greedy algorithm that can learn low-depth unitaries with much less than d^2 parameters in an alternating operator sequence. However, the success probability of the greedy algorithm is low.

1:27PM B09.00012: Practical demonstration of quantum approximate optimization on Google's superconducting qubit processor  MATTHEW HARRIGAN (Presenter), Google Inc. — The quantum approximate optimization algorithm (QAOA) has attracted significant interest as an algorithm suitable for noisy, intermediate-scale quantum (NISQ) computers. QAOA seeks to find approximate ground states of classical Hamiltonians, typically representing binary optimization problems. We demonstrate a practical implementation of QAOA on three problem families at various qubit counts and circuit depths. We show good performance at larger problem sizes and on more complicated problems than has been previously reported. We investigate practical considerations for implementing near-term quantum algorithms. QAOA is a hybrid algorithm involving a classical “outer-loop” optimizer to find optimal parameters. We profile traditional and novel classical outer-loop optimizers to minimize algorithm run-time in a real-world scenario.
Running large quantum circuits on small quantum computers

François-Marie Le Régent, Atos Quantum Lab, Argonne National Lab, Thomas Ayral (Presenter), Atos Quantum Lab, Zain Hamid Saleem, YuriAlexeev, Martin Suchara, Argonne National Laboratory — With the advent of NISQ computers, the question of running quantum programs whose number of qubits exceeds the capacity of today's small processors becomes pressing. In this work, we have implemented a recent theoretical proposal [1] consisting in splitting a large circuit into smaller fragments that can be run on smaller processors. As a test case, we have taken circuits used by the quantum approximate approximation algorithm (QAOA [2]) to solve combinatorial optimization problems. We have implemented, run and assessed the method on the IBM Poughkeepsie 20-qubit superconducting quantum processor, and have compared the obtained results with simulations in the presence of noise that we characterized via tomography.

Reverse engineering a pairwise entanglement witness for a near-term N-qubit computer

Nathan Thompson (Presenter), Nam Nguyen, Elizabeth Behrman, James Steck, Wichita State Univ — Designing and implementing new and general algorithms for the noisy intermediate scale quantum (NISQ) computers that will soon be available is not easy. In previous work we have suggested, and developed, the idea of using machine learning techniques to train a small quantum system such that the desired process is "learned," thus obviating the algorithm design difficulty. Here, we extend our results towards implementation on NISQ machines. We reverse engineer our learned two-qubit entanglement witness for implementation on Microsoft's Quantum Development Kit and IBM's Quantum Experience; and, using the machine learning technique called "bootstrapping", we infer the pattern for mesoscopic N from simulation results for three-, four-, five-, six-, and seven-qubit systems. The learned witness is robust to noise and decoherence. Our results suggest a fruitful pathway for general quantum computer algorithm design and computation.

Session B10 GIMS: Advances in Scanned Probe Microscopy 2: High Frequencies and Optical Techniques

Christopher Lutz, IBM Research – Almaden - Tag(s): Focus
**11:15AM B10.00001: Measurement of fluorescent quantum yield using photothermal deflection spectroscopy**  
STEPHEN JOHNSON (Presenter), BRANDON T COUCH, ANDREW MEYER, BRANDON HELLER, Transylvania Univ — Photothermal deflection spectroscopy (PDS) is technique best known for its ability to measure weak optical absorptions various media. In this presentation we demonstrate an extended application for PDS, namely, measurement of the fluorescent quantum yield ($\Phi_f$) of fluorophores. Starting from first principles of energy conservation, a simple model for the photothermal deflection spectrum as a function of $\Phi_f$ is fit to the spectral data using $\Phi_f$ as a single fitting parameter. Using this method, extracted values of $\Phi_f$ for standard fluorophores such as Rhodamine 6G match closely with literature values. Given that this measurement technique requires no calibration standard, this method could potentially be used as a new standard procedure for determining $\Phi_f$ in fluorescent materials.

**11:27AM B10.00002: Imaging chiral optical excitations through inelastic electron-light scattering**  
TYLER HARVEY (Presenter), JAN-WILKE HENKE, OFER KFIR, CLAUS ROPERS, IV. Physicalisches Institut, University of Göttingen — Circular dichroism spectroscopy offers rich insight into biomolecular structure and nanoscale magnetic domain structure, but resolution is limited by the optical wavelength. We demonstrate a nanometer-resolution circular dichroism technique that employs electrons to probe optical near fields.

Electrons can exchange integer multiples of the photon energy with an optical field near a material [1,2]. The strength of the coupling between electron momentum states and photon number in the optical field depends on material structure and optical properties. Because sub-nanometer spotsize is routine in electron microscopes, this interaction can be employed to image optical fields with nanometer spatial resolution. By illuminating with left- and right-circularly polarized light and measuring the difference in coupling strength with electrons, we probe chiral optical near fields. This technique may enable the investigation of chiral optical and electronic states in plasmonic nanostructures, molecules and atoms with sub-nanometer spatial resolution.

11:39AM B10.00003: Visualization of Surface Acoustic Wave by Transmission Mode Microwave Impedance Microscopy  LU ZHENG (Presenter), University of Texas at Austin, LINBO SHAO, Harvard University, QICHENG ZHANG, ALAN T JOHNSON, University of Pennsylvania, MARKO LONCAR, Harvard University, KEJI LAI, University of Texas at Austin — Surface acoustic wave (SAW) devices based on piezoelectric materials play a critical role in modern information technology and the research field of phononic metamaterials and quantum computing. High-resolution real-space mapping of the phononic modes is therefore of fundamental importance for the understanding of propagation, scattering, diffraction, and localization of the acoustic waves. However, it was challenging to image the GHz-range acoustic properties in piezoelectrics directly. Using a transmission-mode microwave impedance microscope (T-MIM), we demonstrate the ability to visualize SAW in multiple systems, including band-pass filter, resonator, and phononic crystals. Our results show that T-MIM can be used to locally probe acousto-electronic behaviors in various platforms with nanoscale spatial resolution.

11:51AM B10.00004: Experimental and numerical studies of near-field infrared phenomena at nanometer length scales*  P. MCARDLE (Presenter), D. LAHNEMAN, H. JIANG, M. M. QAZILBASH, Department of Physics, College of William and Mary, T. SLUSAR, H.-T. KIM, Metal-Insulator Transition Laboratory, Electronics and Telecommunications Research Institute, A. BISWAS, Department of Physics, University of Florida, F. KEILMANN, Fakultät für Physik & Center for NanoScience (CeNS), Ludwig-Maximilians-Universität, J. CHEN, Department of Chemistry and Biochemistry, University of Arkansas — Broadband near-field infrared spectroscopy is fast emerging as a valuable experimental probe of nanomaterials. Light-matter interactions in polaritonic materials at nanometer length scales can be probed effectively with this experimental technique. When there is strong coupling of light to the probe-sample system in highly polar materials such as insulating SrTiO₃, the phonon-polariton resonances should be described by detailed numerical simulations. More generally, experimental data needs to be accurately modeled to obtain optical properties at nanometer length scales in non-trivial geometries such as multilayered samples (for example, insulating SrTiO₃ crystal with metallic surface), and materials with physical boundaries comparable to the probe apex (for example, nano-platelets of Cu₂S). Near-field infrared spectra of materials with anisotropic dielectric function can also be modeled numerically (for example, rutile TiO₂). We will present our results on the materials described above, thereby establishing the efficacy of detailed numerical simulations for analyzing experimental spectra.

* M.M.Q. acknowledges support from ETRI and the National Science Foundation (NSF). Simulation work was performed, in part, using computing facilities at the College of William and Mary.

**Session B11 APS/SPS: Undergraduate Research III**

11:15AM B11.00001: Linear Optimum Filtering for Axion Dark Matter Search*

SUKHMANPREET SINGH (Presenter), Yale University — The Haloscope At Yale Sensitive To Axion CDM (HAYSTAC) Experiment is a microwave cavity search for cold dark matter (CDM) axions in the galactic halo. It attempts to detect a resonant photon signal produced by axion conversion in a magnetic field, the detection of which would provide useful insights on the nature of dark matter. Thus, the data acquisition from this experiment necessitates efficient filtering out of noise and other interfering signals, along with minimal scan times.

In this project, we present the theory and applications of linear optimum filters, namely the Wiener-Hopf and matched filters that minimize the mean-squared-error between processed and desired signals on MATLAB. By injecting random noise into an initially known signal, we present filtering techniques that allow us to perform the following three things: first, obtaining the best linear estimate of the desired signal \( d(n) \) from noisy data \( x(n) \); second, predicting a signal \( d(n+m) \) for \( m>0 \) from data \( x(n) \); and lastly, carrying out an a posteriori estimation of \( d(n+m) \) for \( m<0 \) from data \( x(n) \). By incorporating principles of optimization theory, this project helps speed up data analysis during the operation of the HAYSTAC experiment.

*I would like to thank Professor Steve Lamoreaux for funding this project.

11:27AM B11.00002: Simulation of Light Propagation Through CsI for the Mu2e Experiment

VICTORIA LLOYD (Presenter), Harvey Mudd College — The Mu2e experiment will search for charged lepton flavor violating neutrino-less conversion from a negative muon into an electron in the field of a nucleus. This reaction is extremely suppressed in the Standard Model of particle physics and an observation would be a clear sign of new physics. Mu2e plans to improve the current sensitivity on mu-to-e conversion by four orders of magnitude. The experiment relies on a crystal calorimeter to separate electrons from muons to reduce background. Using the Geant4 framework, we model the transit time taken by optical photons to reach the photomultiplier as a function of their origin for different crystal geometries. By cataloging these distributions, my project will improve the accuracy of the simulated time-of-flight data used to create the particle identification algorithms used in the experiment.
CONOR MCGIBBONEY (Presenter), ERIC BOOTH, Chemistry and Physics, Southeastern Louisiana University — The purpose of this research is to study the feasibility of Liquid Air Cycle Engines (LACE) and Air Collection and Enrichment System (ACES) for single stage to orbit (SSTO) space programs. Various thermodynamic properties such as Joule-Thomson, Para-to-Ortho with hydrogen, and general heat exchanger performance are used to determine feasibility on a fundamental theoretical level. For LACE we examined the condensation ratio (CR) kg air condensed by kg H\textsubscript{2} coolant used, and examined how much variations in pressure, as well as para-orthohydrogen conversion would aid heat-exchanger efficiency. No matter what is done, we cannot achieve a desired CR that is close to the needed stoichiometric ratio of 34.4. For ACES we examined CR with and without precooling with excess N\textsubscript{2}. Remarkably, precooling intake air with nitrogen worsens performance dramatically. The deficiency that causes ACES to be counterproductive is that, below 165 Kelvin, the proportional rise in the constant pressure heat capacity (Cp) of air is much greater than the proportional fall in the Cp of para-H\textsubscript{2}. Additionally, masses of system components needed for precooling and heat-exchange would need to be carried to space on the vehicle thus, further reducing efficiency.

11:51AM B11.00004: Search for Higgsino inside Large Hadron Collider via Vector Boson Fusion
CHENG TAO (Presenter), ALFREDO GURROLA, Physics, Vanderbilt University, ANDRES FLOREZ, NATHALIA CARDONA, Physics, University of Los Andes, PAUL DOUGLAS SHELDON, WILL JOHNS, Physics, Vanderbilt University — Supersymmetry (SUSY) is a theoretical extension of the standard model (SM) of particle physics that could describe the particle nature of Dark Matter (DM). In SUSY models assuming R-parity conservation, the lightest neutralino is neutral, stable, and interacts with SM particles in the early universe to give the DM relic density observed today. A Higgs-like neutralino (Higgsino) is known to be a promising candidate for DM. Current search methods for Higgsinos at the LHC mainly rely on Drell-Yan production mechanisms, however, are experimentally difficult in cases where the mass of the DM candidate is only slightly less than the masses of other neutralinos, making these so-called compressed spectrum Higgsino scenarios important search targets using new techniques. The focus of this talk is on the development of a search methodology for Higgsino DM at LHC using Vector Boson Fusion (VBF) processes, which offers an alternative and complementary search strategy. We combine the VBF topology with a final state of one and two soft leptons and large missing momentum. The requirement of one or two soft leptons combined with jets of large dijet mass can significantly reduce SM backgrounds, resulting in enhanced Higgsino discovery potential at the LHC.

*NSF Award PHY-1506406.
12:03PM B11.00005: Decoupling bosonic modes using sequential quantum transducers

SHOUMIK CHOWDHURY (Presenter), Yale University, MENGZHEN ZHANG, LIANG JIANG, Department of Molecular Engineering, University of Chicago — Quantum transducers are devices that can faithfully convert quantum signals from one mode to another. Building robust quantum transducers will be crucial to the development of hybrid quantum networks and scalable quantum computers. Previous studies have explored techniques to achieve perfect transduction using even imperfect transducers -- however, these methods either require infinite squeezing or apply only to the case of two modes. Here, we develop a new protocol that works for an arbitrary number of modes and requires only finite squeezing. Specifically, we show that by operating transducers in sequence, interspersed with appropriate single-mode operations, it is possible to decouple unwanted degrees of freedom and so reduce a three-mode transduction problem to the solved two-mode case. Furthermore, we investigate the dependence of the squeezing needed on the mode-coupling strength for a given transducer and propose some potential experimental setups.

12:15PM B11.00006: Dark Count Reduction in Superconducting Nanowire Single Photon Detectors (SNSPDs)

HYUNSEONG KIM (Presenter), ANDREW MUELLER, Division of Physics, Mathematics and Astronomy, Caltech, BORIS KORZH, MATTHEW SHAW, Jet Propulsion Laboratory — Superconducting nanowire single photon detectors are the fastest single photon detectors with high detection efficiency, record time-resolution, and ultra-low dark count rate. However, for applications in dark matter search and quantum information, the dark count rate of SNSPDs must be further improved. In order to push these limits, we implemented a cryogenic differential bias-tee circuit, which filters high frequency noise from the current source and reduces electromagnetic noise coupling into the circuit thanks to a balanced architecture. We demonstrate that this differential architecture exhibits lower dark count rates compared to a single-ended device referenced to ground. We show, using a gaussian noise model, that the difference in dark counts for these two configurations can be attributed to electromagnetic noise.

12:27PM B11.00007: Etaloning Laser Interference Analysis Spectrometry (ELIAS)

JASON PORTER (Presenter), JAROM S JACKSON, DALLIN S. DURFEE, RICHARD SANDBERG, Brigham Young University — Many fields of research require precise wavelength measurement, but commercially available wavemeters are often too expensive, too large, or too fragile to be practical. We have designed and constructed a robust, compact, and inexpensive wavelength meter that analyzes the interference patterns caused by a series of etalon-like structures. Measuring this etaloning across a range of known wavelengths provides a set of wavelength-dependent reference functions which can be used to calculate an unknown wavelength within the same range. We present data showing that this device can measure a laser's wavelength with an average error less than a picometer, and a standard deviation less than 2 picometers.

*Funded by Brigham Young University.
**12:39PM B11.00008: Temperature dependence of the index of refraction of TOPAS cyclic olefin copolymer in the terahertz range**

TIMOTHY KRITZELL (Presenter), EVAN JASPER, YUFEI LI, NICHOLAS CRESCIMANNO, THUC MAI, REBEKAH SMITH, DANIEL HELIGMAN, MATTHEW T WARREN, Ohio State Univ - Columbus, FRANK C PEIRIS, Kenyon College, ROLANDO VALDES AGUILAR, Ohio State Univ - Columbus — Past measurements on the cyclic olefin copolymer TOPAS reveal a spectrally-flat refractive index within the terahertz range, giving the material exciting potential applications in optical apparatuses. Here we use THz spectroscopy to expand the understood frequency range, and as a probe to extract information regarding the temperature dependence of the refractive index, in which we find that the index of refraction increases with decreasing temperature. In hopes to understand this counterintuitive behavior, we report the temperature dependence of the reflectivity due to vibrational modes within the C-H band via Fourier-Transform Infrared Spectroscopy.

**12:51PM B11.00009: Protonic Bipolar Semiconductor Melted Ice Periodic Lattice Model Explains the Abnormally High Electrical Mobility of Positive and Negative Ions in Pure Liquid Water.**

CINDY TIANHUI JIE (Presenter), Massachusetts Institute of Technology MIT, BIN JIE, CHIH-TANG SAH, Physics Department, Xiamen University — The mobility of positive and negative ions in pure liquid water are higher than impurity ions. This is not understood for 100+ years, but are accurately measured, tabulated in texts and manuals, and used in manufacturing. At the 2013 National Fall Meeting of the Chinese Physical Society, we proposed the melted-ice bipolar protonic semiconductor model to explain this high electrical mobility by drift-diffusion-generation-recombination-trapping of positive protons and negative prohols, including resolution of one protonic boson interacting with one protonic fermion. Our model extends the 1933 Bernal-Fowler Hexagonal Close Packed ice model, proven by 1935 Pauling residual entropy theory on Giauque specific heat measurements. Our 2013 idea arose from the many daily observed properties of nearly pure water, which suggest the persistent long-range-large-volume order when ice melts into liquid. This talk describes, in undergraduate language, the excellent agreement between our model and the three experimental properties of pure liquid water (the proton product or pH and the two protonic mobilities), by viewing the proton and prohol transport tracks through our atomic crystal lattice of pure water.

1:03PM B11.00010: Perturbation of Quantum Harmonic Oscillator and its effect on Quantum Electromagnetic Field Theory*  SANKARSHAN SAHU (Presenter), Indian Institute of Engineering Science and Technology, Shibpur — Here a special case of perturbation in quantum harmonic oscillator is studied. Here we assume the perturbed potential to be a Harmonic Oscillator that has been shifted in the position space. We construct the new creation and annihilation operators for the new Hamiltonian to find out its energy eigenstates. This paper mainly deals with why the coherent states provide a more complete picture of electric and magnetic field theory compared to just energy eigenstates. Here we find how our perturbation act as a coherent state generator and adds a new term in the Hamiltonian. The Perturbation is thought to arise from the only available interaction i.e. observation. The perturbation also explains how observation leads to coherence of photon states. We will find out how the new perturbation affects the time evolution of electromagnetic field. The Perturbation is also assumed to be instantaneous and time dependent such that sudden approximation can be applied in the time evolution of states. We also explain the results of the double slit experiment using our new mathematical model and thus try to come up with a new model for Quantum Mechanics.

1:15PM B11.00011: Revisiting the Wettability of Graphene*  CHRISTINA MCBEAN (Presenter), PRIYANKA MANCHANDA, PRATIBHA DEV, Howard University — Since its discovery in 2004, graphene has been the main focus of many researchers as they study its unique structure and properties. This two-dimensional, hexagonal carbon lattice has been proven to be a well-suited material for use in small molecule gas sensors, surface coatings, lubricants, etc. In studying the water wettability of graphene, studies first demonstrated that graphene is a hydrophobic material. However, more recent experiments have suggested that graphene is intrinsically hydrophilic. Based on the ambiguity of these conclusions, further studies must be done to find some clarity on the precise nature of the interactions between graphene and water. In this theoretical work, we use density functional theory to study the adsorption of water on graphene-based substrates and in the presence of ambient gases to determine surface water wettability of graphene.

Session B15 DFD DSOFT: Flow of Complex Fluids: Rheology, Structure, and Instabilities II  210/212 - Ehssan Nazockdast, Univ of NC - Chapel Hill
**11:15AM B15.00001: Cell nucleus as a microrheological probe to study the rheology of the cytoskeleton**  
EHSSAN NAZOCKDAST (Presenter), MOSLEM MORADI, Univ of NC - Chapel Hill —  
Mechanical properties of the cell are important biomarkers for probing its pathological changes, and are increasingly used for cancer diagnosis and detecting rare cells. Yet, determining the time-dependent contributions of different cellular components --including the cell membrane, the cell cytoskeleton and the nucleus-- to the mechanical response of the whole cell has remained challenging. We propose a novel method to decouple the mechanics of membrane and cytoskeleton, by analyzing the correlation between the membrane deformations that are induced by external microfluidic flows and nucleus displacements induced by those membrane deformations i.e. we use the nucleus as a microrheological probe to study the rheology of the interior cytoskeleton, independent of membrane rheology. To demonstrate the applicability of this method, we consider a proof of concept model consisting of a rigid spherical nucleus centered in a spherical membrane. We obtain analytical expressions for time-dependent nucleus velocity as a function of membrane deformations, when the interior cytoskeleton is modelled as a viscoelastic and a poroelastic material, and demonstrate how the nucleus velocity can be used to characterize the rheology of the cytoskeleton over a wide range of forces and time-scales.

**11:51AM B15.00002: The divergence-conforming immersed boundary method: Application to vesicles, capsules, and red blood cells under flow**  
HUGO CASQUERO (Presenter), YONGJIE JESSICA ZHANG, Carnegie Mellon Univ —  
The divergence-conforming immersed boundary (DCIB) method is presented to tackle a long-standing issue of immersed boundary (IB) numerical methods for fluid-structure interaction (FSI), namely, the challenge of accurately imposing the incompressibility constraint at the discrete level. In the DCIB method, the Eulerian velocity-pressure pair is discretized using divergence-conforming B-splines, which leads to \textit{inf-sup} stable, \textit{H}\textsuperscript{1}-conforming, and pointwise divergence-free Eulerian solutions. In order to discretize the higher-order derivatives that appear in vesicle and capsule formulations, we use \textit{C}\textsuperscript{2}-continuous cubic B-splines with periodic knot vectors and \textit{C}\textsuperscript{1}-continuous bi-cubic analysis-suitable T-splines in 2D and 3D settings, respectively. Non-negligible spurious changes of the fluid volume inside of closed co-dimension one solids is a well-known issue of IB methods. The DCIB method results in volume changes various orders of magnitude lower than conventional IB methods. Benchmark and application problems of vesicle, capsules and red blood cells are solved, including mesh-independence studies and comparisons with other numerical methods.

*PECASE Award N00014-16-1-2254 and NSF grant CBET-1804929*
12:03PM B15.00003: Flow-induced microstructural rearrangement and rheological consequences for model red blood cell suspensions in microvessels* YENG-LONG CHEN (Presenter), Inst of Physics Academia Sinica, CHIH-TANG LIAO, Engineering and System Science, National Tsing-Hua University — Flow-induced structural evolution of soft particle clusters in microflow is a key driver of non-Newtonian fluid response. We investigated how inter-particle attraction affect cluster and particle migration in microvessels, where the near wall particle depletion layers due to hydrodynamics significantly alters fluid viscosity. We found that strong particle aggregation correspond to structurally intact large clusters at low shear rates, resulting in large near wall depletion layer and low suspension viscosity. Shear-induced cluster break-up at moderate shear rates reduces the wall depletion layer, corresponding to viscosity increase akin to shear-thickening. At high shear rates, particle deformation and inter-particle ordering leads to shear-thinning.

12:15PM B15.00004: Cross-stream migration of non-spherical particles in a second-order fluid SHIYAN WANG (Presenter), CHENG-WEI TAI, VIVEK NARSIMHAN, Purdue Univ — Particle migration in viscoelastic suspensions is vital in many applications in the biomedical community and the energy industries. Previous studies have provided insight on the motion of spherical particles in simple viscoelastic flows, yet the combined effect of more complex flow profiles and particle shapes is underexplored. Here, we develop approximate, analytical expressions for the polymeric force and torque on an arbitrary-shaped particle in a second-order fluid, subject to a general quadratic flow field. This model is exact for the case when the first and second normal stress coefficients satisfy \( \psi_1 = -2\psi_2 \). In shear driven flows, we observe that spheroidal particles adjust their orientation to align their longer axis along the vorticity direction, although significant deviations from slender body theories occur for finite aspect ratios. In pressure driven flows, we identify scaling theories to quantify how the particle lift depends on shape for a wide variety of shapes. We find that prolate particles slowly transition to a log-rolling state as they approach the flow center, with the lift initially being larger than that of an equal-volume sphere, but then becoming smaller as log-rolling emerges. Lastly, we extend our analysis towards more complicated systems (\( \psi_1 \neq -2\psi_2 \)).

12:27PM B15.00005: Vortices in 2D Colloids MYEONGGON PARK (Presenter), Ulsan Natl Inst of Sci & Tech, BO LI, Institute of Basic Science, STEVE GRANICK, Ulsan Natl Inst of Sci & Tech — Particles and molecules composing real materials generally contain anisotropic properties such as a spin or an electric dipole. To understand their roles in material phase states, we observed colloidal crystals comprised of Janus colloids whose anisotropic properties can be controlled. Here, we found a BKT transition by tuning an interparticle interaction and could see dynamics of topological defects in real time. We think that this model system can eventually give an insight to apprehend roles of molecular and atomic orientational dynamics in 2D crystal phases.
12:39PM B15.00006: On the mechanisms of superspreading*  PANAGIOTIS THEODORAKIS (Presenter), Institute of Physics, Polish Academy of Sciences, EDWARD SMITH, Mechanical and Aerospace Engineering, Brunel University London, ERICH A MÜLLER, Chemical Engineering, Imperial College London, RICHARD V CRASTER, Mathematics, Imperial College London, OMAR K MATAR, Chemical Engineering, Imperial College London — Superspreading is the rapid and complete spreading of surfactant-laden droplets on hydrophobic substrates, which is caused by certain surfactant molecules known as superspreaders. Despite significant experimental efforts, the precise mechanisms of this phenomenon and the characteristic properties of superspreading surfactants had remained elusive. Here, we report on extensive molecular dynamics simulations of a coarse-grained model based on the SAFT force-field. Our studies highlight the mechanisms of superspreading, the features of superspreading surfactants and a range of parameters that affect the spreading efficiency of surfactant-laden droplets. We anticipate that our investigations will pave the way for the design of molecular architectures tailored specifically for applications that rely on the control of wetting.

12:51PM B15.00007: Microfluidic flow-processing of soft matter systems  LIVA DONINA (Presenter), JOAO CABRAL, Imperial College London — Arguably one of the most striking properties of soft matter systems is the propensity to have a major response to minor perturbations. One of such perturbations is flow, which allows to induce phase changes and structural rearrangements. Here, two pseudo-quaternary systems containing sodium dodecyl sulfate (SDS) and medium to long chain alcohols as co-surfactants in a lamellar phase (Lα) are studied. The structural transformation from planar lamellar sheets to multilamellar vesicles (MLVs) is observed upon the application of shear stress to the solution. This transformation is characterised with nuclear magnetic resonance (NMR), rheology and small angle neutron scattering (SANS). Furthermore, the kinetics of the transformation is resolved with realtime measurements within a microfluidic device to obtain well-defined shear fields. Time-resolved kinetics are investigated by tracking the changes in birefringence pattern employing cross-polarised microscopy. The results point to MLV formation and indicate that it is a time-dependent and shear rate dependent process. The combination of microfluidics with high resolution spatio-temporal measurements allows characterisation of out-of-equilibrium transformations in complex surfactant mixtures.
11:15AM B16.00001: Readout of fluxonium qubits in circuit QED*  KONSTANTIN NESTEROV (Presenter), University of Wisconsin - Madison, LONG NGUYEN, AARON SOMOROFF, QUENTIN FICHEUX, IVAN PECHENEZHSKIY, University of Maryland, College Park, JEREMY STEVENS, NATHANAEL PIERRE COTTET, BENJAMIN HUARD, Ecole Normale Superieure de Lyon, VLADIMIR MANUCHARYAN, University of Maryland, College Park, MAXIM G VAVILOV, University of Wisconsin - Madison — In the idealized dispersive model of circuit QED, a single-shot heterodyne qubit measurement can be made as accurate as desired by increasing the power of the microwave drive. However, in realistic systems, populating the microwave cavity with photons can have many detrimental effects: in addition to nonlinear effects in the cavity itself, its photons can increase qubit relaxation and excitation rates, including excitations to noncomputational states. In addition, a high drive power can induce resonance transitions between qubit states. In this talk, we present the results of the simulation of the readout process in the fluxonium circuit and discuss how the qubit states and integrated readout signal are affected by the cavity occupation.

*We acknowledge funding from the U.S. Army Research Office (Grant No. W911NF-18-1-0146).

11:27AM B16.00002: Microwave-activated entangling gates for fluxonium qubits*  YINQI CHEN (Presenter), KONSTANTIN NESTEROV, University of Wisconsin - Madison, LONG NGUYEN, AARON SOMOROFF, QUENTIN FICHEUX, IVAN PECHENEZHSKIY, VLADIMIR MANUCHARYAN, University of Maryland, College Park, MAXIM G VAVILOV, University of Wisconsin - Madison — The main qubit transition of the superconducting fluxonium circuit in its flux sweet spot is characterized by a low frequency and very long coherence time, which reaches 500 μs [1]. At the same time, the transition between the first and second excited states of the fluxonium is comparable to those in transmons: it has an order of magnitude higher frequency and stronger coupling to a microwave field, but shorter lifetime. In this talk, we analyze and compare two-qubit gates between such qubits activated by driving different transitions in the two-qubit spectrum. In one scheme [2], the microwave drive is applied in resonance with a higher-frequency transition leading outside of the computational subspace. In the second scheme, which is similar to the cross-resonance gate with transmons [3], the microwave drive is applied at a low frequency to keep the system in the computational subspace. We calculate fidelity metrics for both gates with decoherence effects accounted for.

*We acknowledge funding from the U.S. Army Research Office (Grant No. W911NF-18-1-0146).

11:39AM B16.00003: Single-shot dynamics of fluxonium in the strong dispersive coupling regime  HAONAN XIONG (Presenter), YEN-HSIANG LIN, LONG NGUYEN, QUENTIN FICHEUX, AARON SOMOROFF, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report single-shot measurement of a fluxonium qubit in the strong dispersive regime with maximum coherence time T2>200usec. Our results set the stage for a variety of quantum optics experiments where a combination of very strong anharmonicity and long coherence is desirable. In particular, we investigate temporal dynamics involving multiple transitions of fluxonium in order to reveal new information about solid state decoherence mechanisms.
11:51AM B16.00004: Fluxonium two-qubit gate with simultaneous Raman transitions
JACOB BRYON (Presenter), ANDREI VRAJITOAREA, Princeton University, YIDAN WANG, PRZEMYSŁAW BIENIAS, REX LUNDGREN, RON BELYANSKY, ALEXEY V GORSHKOV, ALICIA KOLLAR, University of Maryland, ANDREW HOUCK, Princeton University — Quantum computing applications rely on high-coherence qubits with two-qubit gates to control them. The Fluxonium circuit is a superconducting qubit with favorable coherence properties, but unlike the transmon qubit, there has been no experimental demonstration of a two-qubit gate. We propose a new scheme using a cavity to couple two fluxonium qubits and drive a two-qubit swap gate. We report experimental progress towards driving simultaneous Raman transitions in the two qubits, utilizing the coupling cavity and the lambda energy level structure of fluxonium. This work expands the available coherent controls for the fluxonium circuit and increases its viability for quantum computing as well for interesting quantum simulation applications.

12:03PM B16.00005: High Coherence Fluxonium Qubits [invited] VLADIMIR MANUCHARYAN (Presenter), University of Maryland — Vlad Manucharyan has led the push to ever longer fluxonium coherence.

12:39PM B16.00006: Fast flux qubit gates on a heavy fluxonium* HELIN ZHANG (Presenter), SRIVATSAN CHAKRAM, NATHAN D EARNEST, YAO LU, University of Chicago, ZIWEN HUANG, DANIEL WEISS, JENS KOCH, Physics, Northwestern University, DAVID I SCHUSTER, University of Chicago — A capacitively shunted fluxonium qubit has both long life time and coherence time at the half-flux sweet spot. However, the suppressed matrix elements and low transition frequency make it challenging to perform fast fluxon gates via charge coupling. Here, we present schemes for state initialization, fast single-qubit flux gates, and plasmon assisted readout for a fluxonium qubit, demonstrating the feasibility of controlling a superconducting qubit at background temperatures much higher than the operating frequency. This scheme improves the quantum control of fluxonium qubits, making it a strong candidate for quantum information processing. We additionally present schemes for fluxonium two-qubit gates without using lossier higher levels.

*This work was supported by ARO Grant No. W911NF-15-1-0421; SUB0000079
Spectroscopy and logic gates in a strongly coupled two-fluxonium device*  
EBRU DOGAN (Presenter), DARIO ROSENSTOCK, Univ of Mass - Amherst, LONG NGUYEN, AARON SOMOROFF, VLADIMIR MANUCHARYAN, University of Maryland - College Park, CHEN WANG, Univ of Mass - Amherst — The fluxonium is one of the leading candidates as an upgrade to the mainstream transmon qubits in large-scale superconducting quantum processors: With stronger anharmonicity, longer coherence times and the ability to engineer selection rules, it has the qualities to in principle deliver better logic gate fidelity than transmons. Towards validating fluxonium as a viable qubit for scaling up, it is essential to go from one fluxonium to two or more; yet two coupled fluxoniums in various coupling regimes still remain to be better explored. Our experimental study focuses on two fluxonium qubits under strong capacitive coupling and we analyze the hybridization of computational states and higher excited states as a function of external flux bias. We also show that the ZZ coupling between two fluxonium qubits makes it straightforward to realize single and two qubit operations and report our progress on benchmarking single and two qubit gates.

*We acknowledge support from Army Research Office (ARO) Grant # W911NF1810146.

Fluxonium-like qubit design for improved coherence*  
PRANAV MUNDADA (Presenter), ANDREW HOUCK, ANDRAS GYENIS, Princeton University, ZIWEN HUANG, JENS KOCH, Northwestern University — Fluxonium qubits provide high anharmonicity and can offer states with disjoint support and large relaxation time. There has been significant progress in exploring different parameter regimes of the fluxonium for optimizing coherence times. However, in traditional fluxonium qubits, the external flux sweet spot is only present when external magnetic flux threading through the superconducting loop is either 0 or 0.5 flux quantum. Additional sweet spots can be achieved via the careful engineering of the Hamiltonian. We present experimental data on the implementation of such a fluxonium-like qubit architecture with extra sweet spots.

*Supported by Army Research Office Grant No. W911NF1910016

The Most Coherent Superconducting Qubit?  
AARON SOMOROFF (Presenter), LONG NGUYEN, YEN-HSIANG LIN, RAY MENCIA, NICHOLAS GRABON, QUENTIN FICHEUX, University of Maryland, College Park, KONSTANTIN NESTEROV, MAXIM G VAVILOV, University of Wisconsin - Madison, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report superconducting fluxonium qubits with coherence times limited by energy relaxation and reproducibly satisfying $T_2 > 100 \mu s$ ($T_2 > 400 \mu s$ in one device). Moreover, given the state-of-the-art values of the surface loss tangent and $1/f$ flux noise amplitude, coherence times can be further improved beyond 1 ms. Our results violate a common viewpoint that the number of Josephson junctions in a superconducting circuit - over $10^2$ here - must be minimized for the best qubit coherence. We outline how the combination of long coherence times and large anharmonicity unique to fluxonium can benefit both gate-based and adiabtic quantum computing.
Preparing and stabilizing entangled states is critical to many quantum information tasks, including autonomous quantum error correction. Inspired by previous dissipation-engineering schemes[1,2], we propose an autonomous protocol that prepares and stabilizes an arbitrary Bell state between a pair of superconducting qubits. This is achieved by parametrically coupling the superconducting qubits to each other, and to two dissipative baths that are made of low-Q resonators. The parametric couplings are engineered through the dynamical modulation of the qubit-qubit and the qubit-cavity interaction strengths at three different frequencies with appropriate phases. Numerical simulation shows that high fidelities of >95% are reached for all the Bell states, under realistic circuit parameters well-achievable by current circuit-QED technology. We further demonstrate how this scheme is fully compatible and can be experimentally realized on the VSLQ circuit[1].

*This work was supported by ARO Grant No. W911NF-17-S-0001.

We report our experimental progress towards the stabilization of an arbitrary Bell-state. We first describe our circuit implementation of the Very Small Logical Qubit [1] that substantially reduces operational complexity by reducing the number of RF drive lines and is fully compatible with the stabilization scheme. The circuit is composed of two superconducting qubits coupled through a small Josephson junction with a time-dependent flux bias and two low-Q resonators each coupled to the qubits. The experiment requires calibration of the static circuit parameters under DC flux biasing and mitigation of the flux cross-talks. Next, we demonstrate the generation of various sideband interactions required for the stabilization scheme by modulating the coupler using RF drives with appropriate frequencies, amplitudes, and phases. Finally, we compare our experimental results with the simulation and discuss the scope for further improvements. Our results pave the way towards the realization of the passively protected arbitrary logical qubit states from single-qubit error channels [1].

Session B17 DQI: Hybrid Systems - Electro-Optics, Superconductors, & Helium 203 - Joseph Kerckhoff, HRL Laboratories - Tag(s): Focus
**11:15AM B17.00001: Strong-coupling physics with semiconductor spin qubits** [Invited]  JASON PETTA (Presenter), Princeton University — Electron spins are excellent candidates for solid state quantum computing due to their exceptionally long quantum coherence times, which is a result of weak coupling to environmental degrees of freedom. However, this isolation comes with a cost, as it is difficult to coherently couple two spins in the solid state, especially when they are separated by a large distance. Here we combine a large electric-dipole interaction with spin-orbit coupling to achieve spin-photon coupling. Vacuum Rabi splitting is observed in the cavity transmission as the Zeeman splitting of a single spin is tuned into resonance with the cavity photon. We achieve a spin-photon coupling rate as large as $g_s/2\pi = 10 \text{ MHz}$, which exceeds both the cavity decay rate $\kappa/2\pi = 1.8 \text{ MHz}$ and spin dephasing rate $\gamma_s/2\pi = 2.4 \text{ MHz}$, firmly anchoring our system in the strong-coupling regime [1]. We next utilize spin-photon coupling to achieve a resonant spin-spin interaction between two spins that are separated by more than 4 mm [2]. An enhanced vacuum Rabi splitting is observed when both spins are tuned into resonance with the cavity, indicative of a coherent spin-spin interaction. Our results demonstrate that microwave-frequency photons can be used as a resource to generate long-range two-qubit gates between spatially separated spins.

*In collaboration with Felix Borjans, Guido Burkard, Xanthe Croot, Michael Gullans, Xiao Mi, Stefan Putz, Jacob Taylor, and David Zajac. Devices were fabricated in the Princeton University Quantum Device Nanofabrication Laboratory.*

**11:51AM B17.00002: Control and readout of superconducting qubits over optical fiber using cryogenic photonic links**  JOHN TEUFEL (Presenter), FRANKLYN QUINLAN, FLORENT LECOCQ, SCOTT ALAN DIDDAMS, JOSE AUMENTADO, National Institute of Standards and Technology Boulder — As superconducting quantum circuits continue to increase in size and complexity, one bottleneck for scaling becomes the large number of microwave signals lines that must connect room temperature electronics to the cryogenic environment of the device. Typical experiments require multiple coaxial cables per qubit, each heavily filtered and attenuated to ensure excess noise will not degrade qubit coherence, gate fidelity or measurement efficiency. An alternative to this brute force method is to use optical fiber and cryogenic high-speed photodetection as an optical-to-microwave converter, capable of generating shot-noise limited microwave signals directly at millikelvin temperatures. Leveraging the low thermal conductivity, low loss and large intrinsic bandwidth of optical fiber would allow for efficient, massively multiplexed delivery of coherent microwave control pulses. In this talk we will present recent experimental progress toward the control and readout of a superconducting qubit using microwave signals transmitted over optical fiber to the ultracryogenic environment (< 20 mK), and show proof of principle results that this novel method can meet the stringent requirements for superconducting quantum information processing.
12:03PM B17.00003: A Lithium Niobate Electro-Optic Transducer for Quantum Networks
TIMOTHY MCKENNA (Presenter), JEREMY WITMER, RISHI PATEL, JASON F HERRMAN, WENTAO JIANG, PATRICIO ARRANGOIZ-ARRIOLA, EDWARD A WOLLACK, RAPHAEL VAN LAER, AMIR SAFAVI-NAEINI, Stanford University —
In order to create a quantum network in which superconducting qubit processors are connected over kilometer-scale distances, transducers capable of converting quantum information between microwave and optical frequencies are required to allow for fiber optical networking. We present the design and experimental demonstration of an electro-optic photon converter to connect superconducting qubit-based systems with light. We fabricate lithium niobate racetrack resonators with superconducting circuits and demonstrate microwave-to-optical photon coupling rates over 1.5 kHz at cryogenic temperatures. We characterize our transducer with resolved sideband spectroscopy to measure the electro-optically generated Stokes and anti-Stokes optical sidebands which show an extinction ratio of ~30 dB.

12:15PM B17.00004: Microwave-to-optical transduction in a silicon-organic-hybrid platform
JEREMY WITMER (Presenter), TIMOTHY MCKENNA, PATRICIO ARRANGOIZ-ARRIOLA, EDWARD A WOLLACK, RISHI PATEL, RAPHAEL VAN LAER, AMIR SAFAVI-NAEINI, Stanford Univ — In order to realize long distance quantum networks in which superconducting quantum processors are connected by optical fiber links, it is necessary to transduce quantum signals from the microwave domain to the optical domain and vice versa. Here, we present progress towards electro-optic photon conversion using a silicon-organic hybrid photonic platform. Our device uses a high-Q photonic crystal cavity and superconducting microwave resonator to simultaneously confine optical and microwave electric fields. We achieve a room temperature electro-optic tuning rate of 3.7 pm/V and demonstrate microwave-to-optical photon conversion in a milliKelvin dilution fridge environment. Our device provides nearly 10 dB selectivity between the generated Stokes and anti-Stokes sidebands, which we can resolve using a heterodyne spectroscopy technique. Finally, we examine the deleterious effects of quasiparticle generation due to stray light and discuss techniques to mitigate this.
Dispersive sensing of electron tunneling between quantum dots in proximitized InAs nanowires

DAMA DE JONG (Presenter), DAAN WAARDENBURG, Delft University of Technology, NEJC BLAZNIK, Utrecht University, LIN HAN, FILIP MALINOWSKI, CHRISTIAN PROSKO, JASPER VAN VEEN, Delft University of Technology, PETER KROGSTRUP, Center for Quantum Devices and Microsoft Quantum Lab Copenhagen, Niels Bohr Institute, University of Copenhagen, LEO P KOUWENHOVEN, WOLFGANG PFAFF, Microsoft Quantum Lab Delft, Delft University of Technology — Dispersive gate sensing (DGS) is a powerful technique that has enabled novel ways for probing condensed matter systems and reading out solid-state quantum bits, such as Josephson or spin qubits. DGS has also been proposed for the measurement of topological qubits based on Majorana zero-modes (MZMs). Such a measurement can be realized by detecting parity-dependent electron tunneling through a superconducting island hosting MZMs at its ends. Here, we demonstrate tunneling between two quantum dots separated by a superconducting island realized in an InAs nanowire, partially proximitized by Al. Using multiplexed coplanar waveguide resonators with tailored circuit parameters we can simultaneously detect tunneling between multiple quantum dots with high SNR to correlate tunneling events with sub-microsecond resolution. The resonator response depends -via the tunneling rate between the quantum dots- on the superconducting spectrum, and in particular on the presence of MZMs in the island. Importantly, dispersive readout allows the system to be probed in the floating regime without transport channels. This will be crucial for fast, non-invasive detection of the topological state of superconducting islands and parity readout of topological qubits.

A gate-tunable, field-compatible fluxonium*

MARTA PITA-VIDAL (Presenter), ARNO BARGERBOS, QuTech, Delft University of Technology, CHUNG-KAI YANG, DAVID J. VAN WOERKOM, WOLFGANG PFAFF, Quantum Lab Delft, Microsoft, NADIA HAIDER, Netherlands Organisation for Applied Scientific Research (TNO, PETER KROGSTRUP, Quantum Materials Lab Copenhagen, Microsoft, LEO P KOUWENHOVEN, GIJS DE LANGE, ANGELA KOU, Quantum Lab Delft, Microsoft — Hybrid superconducting circuits, which integrate non-superconducting elements into a circuit quantum electrodynamics (cQED) architecture, expand the possible applications of cQED and provide new insights into mesoscopic superconductivity. Extending the capabilities of hybrid flux-based circuits, which provide access to current-phase relations, to work in magnetic fields would be especially useful both as a probe of spin-polarized Andreev bound states and as a platform for topological qubits. Here, we present a new hybrid circuit: a magnetic-field compatible fluxonium with an electrostatically-tuned semiconducting nanowire as its non-linear element. We demonstrate in-situ gate-control of the Josephson energy of the fluxonium over more than an order of magnitude. We also operate the fluxonium in magnetic fields up to 1T, where we observe the anomalous Josephson effect. This combination of gate-tunability and field-compatibility opens avenues for the exploration and control of spin-polarized phenomena using superconducting circuits and enables the use of the fluxonium as a readout device for topological qubits.

*Research co-funded by the allowance for Top consortia for Knowledge and Innovation (TKI’s) from the Dutch Ministry of Economic Affairs and the Microsoft Quantum initiative.
The physics of conventional and exotic superconductors can be probed through their microscopic quasiparticle excitations. Recent advances in mesoscopic superconductor-semiconductor devices have created the opportunity to measure and control such excitations, such as Majorana zero modes in a topological superconductor regime. Here, our mesoscopic device is a Josephson element with an InAs nanowire weak link. Due to spin-orbit coupling in the nanowire, the spin states of a single quasiparticle trapped in the junction’s Andreev levels exhibit microwave-accessible energy splittings without an applied magnetic (Zeeman) field. This “superconducting spin” is readily coupled to a microwave resonator via its spin-dependent supercurrent. We will present our experimental platform demonstrating large spin-dependent dispersive shifts of a microwave resonator. We achieve single-shot, quantum-non-demolition readout of the spin as well as coherent manipulation of the quasiparticle state. We will discuss the real-time dynamics of the quasiparticle, which have implications for Majorana devices and Andreev spin qubits. In this first part of a joint presentation, we will present the background, experimental setup, and a theoretical model for our system.

*Work supported by: ARO, ONR, NSF, and AFOSR.
**1:03PM B17.00008: Dynamics and manipulation of a trapped, superconducting quasiparticle: Part 2/2**

MAX HAYS (Presenter), VALLA FATEMI, Applied Physics, Yale University, DANIËL BOUMAN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, KYLE SERNIAK, SPENCER DIAMOND, TOM CONNOLLY, GIJS DE LANGE, Applied Physics, Yale University, PETER KROGSTRUP, JESPER NYGÅRD, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, ATTILA GERESDI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, MICHEL H. DEVORET, Applied Physics, Yale University — The physics of conventional and exotic superconductors can be probed through their microscopic quasiparticle excitations. Recent advances in mesoscopic superconductor-semiconductor devices have created the opportunity to measure and control such excitations, such as Majorana zero modes in a topological superconductor regime. Here, our mesoscopic device is a Josephson element with an InAs nanowire weak link. Due to spin-orbit coupling in the nanowire, the spin states of a single quasiparticle trapped in the junction's Andreev levels exhibit microwave-accessible energy splittings without an applied magnetic (Zeeman) field. This “superconducting spin” is readily coupled to a microwave resonator via its spin-dependent supercurrent. We will present our experimental platform demonstrating large spin-dependent dispersive shifts of a microwave resonator. We achieve single-shot, quantum-non-demolition readout of the spin as well as coherent manipulation of the quasiparticle state. We will discuss the real-time dynamics of the quasiparticle, which have implications for Majorana devices and Andreev spin qubits. In this second part of a joint presentation, we will describe the experimental data and discuss its outlook.

**1:15PM B17.00009: Resonant phenomena in a microchannel-confined Wigner solid**

NIYAZ BEYSENGULOVA (Presenter), JUSTIN LANE, Michigan State Univ, DAVID G REES, EeroQ Inc., KOSTYANTYN NASYEDEKIN, TARYN V STEFANSKI, MARK DYKMAN, JOHANNES POLLANEN, Michigan State Univ — Collective excitations of an electron solid on the surface of liquid helium coupled to a bosonic field of surface capillary waves (ripplons) manifest in pronounced radio-frequency (RF) resonances that are detectable via transport. Theses coupled plasmon-ripplon resonances are modified in the presence of strong transversal confinement of the electron system, which can be realized in microchannel devices. We present new experimental results on the resonant response of electrons on helium confined in a single microchannel device and subjected to RF irradiation. The RF excitation causes heating of the electron system, which leads to a weakening of the Bragg-Cherenkov mobility limit. Additionally, we find that the nonlinear electron transport is modulated by the RF driving field and gives rise to a series of new resonant features. The origin of these resonances will be discussed. Understanding of the electron-ripplon dynamics and decoherence mechanisms in these hybrid devices will be essential for quantum information processing with electrons on helium.

*This work was supported by the NSF under Grant no. DMR-1708331.
**1:27PM B17.00010: Dynamical coupling of surface acoustic waves to electrons on helium**

HEEJUN BYEON (Presenter), KOSTYANTYN NASYEDKIN, NIYAZ BEYSENGULOV, JUSTIN LANE, BAOKANG BI, JOHANNES POLLANEN, Michigan State Univ — We report on the dynamical coupling between high-frequency piezoelectric surface acoustic waves (SAWs) and a two-dimensional (2D) system of electrons floating on liquid helium. This coupling leads to a reduction in the velocity of the SAW and attenuation of SAW energy, which reflects the high-frequency, wavevector-dependent conductivity of 2D electron sheet. In our device, a piezoelectric substrate incorporates a micro-channel array filled with superfluid helium above which a 2D ensemble of electrons are trapped. Underlying electrodes capacitively couple to the electron system and are used to control the areal density of electrons. Employing pulsed time-of-flight SAW techniques, we measure the attenuation and the velocity shift of SAWs as function of electron density at \( T = 1.5 \) K where the electron system is in liquid state. We also present SAW response near the phase transition regime from the electronic liquid to the Wigner crystal.

*This work is supported by the NSF (Grant no. DMR-1708331).

**1:39PM B17.00011: Dispersive readout of qubit states: towards realizing spin qubits using electrons on helium**

ERIKA KAWAKAMI (Presenter), ASEM ELARABI, DENIS KONSTANTINOV, Okinawa Inst of Sci & Tech — Electrons on the surface of liquid helium present an extremely clean two-dimensional electron system. Thanks to its cleanness, the quantum states of the electrons on helium are expected to have a long relaxation time, which provides a perfect platform to realize qubits with [1]. In particular, spin states are expected to have an extremely long relaxation time: \( T2 \sim 100 \) s [2].

Recently, we propose and experimentally demonstrate a new readout technique for the hydrogen-like quantized states (Rydberg states) of many electrons on helium [3]. This new technique was inspired by the dispersive readout technique used in semiconductor quantum dots [4] and in Penning traps [5]. Currently, we are working on the measurement of the relaxation time of the Rydberg state of the electrons on helium using this technique. We also show that this technique can potentially be used to detect spin states of a single electron by introducing an interaction between the Rydberg states and the spin states.

Superfluid helium is an extremely low-loss dielectric, an excellent thermal conductor, and harbors many unique collective excitations, making it an attractive candidate to incorporate into superconducting qubit systems. We controllably immerse a three-dimensional superconducting transmon qubit in superfluid 4He and measure the spectroscopic and coherence properties of the system. We find that the cavity, the qubit, and their coupling are all modified by the superfluid, which we analyze within the framework of circuit quantum electrodynamics (cQED). At temperatures relevant to quantum computing experiments, the energy relaxation time of the qubit is not significantly changed by the presence of the superfluid, while the pure dephasing time modestly increases, which we attribute to improved thermalization of the microwave environment via the superfluid.

**Session B18 DBIO FED: Bringing Together Biology, Medicine, and Physics in Education** 205 - Phil Nelson, University of Pennsylvania - Tag(s): Careers, Education, Invited, Undergrad Friendly
11:15AM B18.00001: What do 21st century biology students need to know and be able to do? The view from biology education research* [Invited] MICHELINE SMITH (Presenter), Cornell University — Many STEM undergraduate students take biology and physics courses, so it is important for both disciplines to understand what is happening in the other classrooms. When people picture undergraduate biology classrooms, they often think about students memorizing disconnected bits of information and repeating classic findings in cookbook labs. However, biology education is undergoing a revolution and today's classrooms look different from this stereotypical view. Transformed biology classes are emphasizing core concepts and skills that are described in reports supported by the major funding agencies and biological professional societies. Concepts are being integrated across subfields of biology and instructors are encouraged to explore them along a continuum from a single cell to a whole ecosystem. Laboratory courses have also changed; undergraduate students are exploring novel research questions and contributing data to advance the field. New assessment instruments that span multiple time points, including across the entire duration of the undergraduate program, are being used to motivate faculty to discuss and come to agreement on the essential learning outcomes of their program and consider how students will achieve these outcomes regardless of the specific courses they take. Notably, instructors are publishing their innovative lessons in peer-reviewed journals such as CourseSource and contributing to broader discipline-based education research questions. In this talk, I will explore what transformed biology education looks like and discuss connections with the skills learned in undergraduate physics classrooms. I will also explore how research on critical thinking conducted in undergraduate physics classrooms is directly affecting how we are studying the student experience in undergraduate biology field courses.

*This material is based on work supported by the National Science Foundation under grant nos. DUE-1725130 and DUE-1909602
11:51AM B18.00002: Transform and Thrive: Large-Scale Change in Introductory Physics for the Life Sciences* [Invited] LAURIE MCNEIL (Presenter), Univ of NC - Chapel Hill — The number of undergraduate degrees in biological sciences awarded each year exceeds the number of degrees awarded in physical sciences and engineering combined, so teaching introductory physics for the life sciences (IPLS) is a substantial part of a physics department’s responsibilities. Before Fall 2012 my department taught a very traditional (and not very effective) IPLS lecture/lab sequence that covered the same topics as our physical science sequence but in less depth. By Fall 2015 we were teaching a new sequence that incorporates physics education research (PER) findings and includes a range of physics topics important to the life sciences, such as diffusion, non-linear stress/strain, and nerve signal propagation. We accomplished this with a team of PER experts, PER users, biologists, chemists, and grad students (plus funding from NSF and AAU). We now teach all ~600 students who enroll in IPLS each semester this way, with much more success. The sequence is fully institutionalized, and faculty members routinely rotate through it. I will describe how we accomplished this transformation, the benefits (and difficulties) it affords, and offer advice to departments contemplating a similar reformation.

*Funding: NSF DUE-1323008 and AAU Undergraduate STEM Education Initiative

12:27PM B18.00003: Pre-health students may not know what physics is. [Invited] ALISON SWEENEY (Presenter), Department of Physics, Yale University — Unlike in introductory chemistry or biology courses, pre-health students in introductory physics courses often don't know the premise or purpose of the discipline. Popular stories about, e.g., black holes and quantum computing don't provide a route for lay observers to understand how these topics share fundamental rules about forces and energies, expressed mathematically. About half of U.S. high schools don't offer physics courses, and many that do exist teach a qualitative version of the subject rather teaching than the process of physical abstraction. As high-resource universities and physics departments continue the necessary work of diversifying their student bodies, it is important for us to recognize this divide, potentially new to our classrooms, and learn to teach to it. The traditional approach of diving into mathematically-motivated formalism at the beginning of the course will often leave the least-prepared students, who are most important to reach, bewildered and alienated. This talk discusses my experience and possible insights from reforming a traditional pre-health physics course, to teach the conceptual core of physics to students completely inexperienced with physics. For example, explicitly addressing questions such as "what is an equation in physics, and what is it for?", and initially prioritizing form equally with content in student work, have been helpful measures.
The Purpose of Homework Problems is Insight, Not Numbers: Crafting Exercises for an Intermediate Biological Physics Class [Invited]  
BRADLEY ROTH (Presenter), Oakland University — Richard Hamming famously said “The purpose of computing is insight, not numbers.” This view is true also for homework problems in an intermediate-level physics class. I constantly tell my students “an equation is not something you plug numbers into to get other numbers; it tells a story.” I will use examples from courses in Biological Physics and Medical Physics to illustrate this idea. A well-formed homework problem must balance brevity with storytelling. Often the problem is constructed by creating a “toy model” of an important biological system, and analysis of the toy model reveals some important idea or insight. A collection of such problems becomes a short-course in mathematical modeling as applied to medicine and biology, which is a skill that needs to be cultivated in biology majors, pre-med students, and anyone interested in using physical and mathematical tools to study biology and medicine.

Essential data science instruction for biophysicists [Invited]  
JUSTIN BOIS (Presenter), Division of Biology and Biological Engineering, Caltech — Biological physicists, along with researchers across nearly all biological sciences, obtain quantitative data in their experiments. Much of our training of students focuses on theoretical modeling of the phenomena underlying the measurements, often with state-of-the-art physics. As a necessary complement to this training, we should teach students how to manage their data sets and perform statistical inference using state-of-the-art techniques from the rapidly developing fields of data science and applied statistics. In this talk, I will discuss what I view as essential data science principles we should teach students. These are:

**Software development**: Modern principles including version control and test-driven development.

**Validation**: Ensuring that a data set from the data source meets expectations (format, missing values, etc.).

**Wrangling**: The process of converting data from the source to a more readily usable format.

**Preservation and sharing**: Strategies for long-term storage and easy sharing of data.

**Visualization**: Construction of instructive plots and interactive data displays.

**Bespoke statistical modeling**: Statistical inference custom built for the specific experiment, as opposed to off-the-shelf techniques.

I will discuss my approach to teaching these topics using hands-on, team-based analyses of real biological data sets.

Monday, March 2, 2020 11:15 AM - 2:15 PM

Session B19 GMAG: Skyrmions in Oxide Materials and Heterostructures 207 - Kai Liu, Georgetown University - Tag(s): Invited
11:15AM B19.00001: Harsh condition scanning probe microscopy vs. imaging detection of new magnetic structures and their topological protection [Invited]  QINGYOU LU (Presenter), University of Science and Technology of China — The scanning probe microscope has atomic resolution, which is a revolution in microscopy. But, it is sensitive to even weak vibration or sound (V/S) and requires well designed V/S isolation. However, many important researches must be performed in harsh conditions such as in ultra-strong water-cooled magnet (WM), cryogen-free (dry) superconducting magnet, dilution refrigerator or reactive solution. To this end, we have achieved high quality atomic resolution images in harsh and ultra-harsh conditions. Finally, we are successful in obtaining high clearance atomic resolution images in a WM [Ultramicroscopy 205(2019)20], dry magnet [Nano Res. 8(2015)3898] and active/reactive solution [Nano Res. 9(2016)2551; Nanoscale 8(2016)15142]. We will report these achievements as well as their applications in the imaging detections of new and weak magnetic structures with topological protection such as magnetic skyrmions in ultra-thin (only 5 layers of unit cells) oxide heterostructures BTO/SRO [Nature Mater. 17(2018)1087], artificially fabricated skyrmions [Adv. Funct. Mater. (2019)1907140], structural domain walls [Adv. Mater. 30(2018)1805353], multiply ordered electronic crystals [ACS Appl. Mater. Inter. 10(2018)20136] and phase competition in re-entrance process [Nature Comm. 6(2015)8980].

12:27PM B19.00003: Spin-Hall topological Hall effect in highly tunable Pt/ferrimagnetic-insulator bilayers* [Invited]  FENGYUAN YANG (Presenter), Ohio State Univ - Columbus — Electrical detection of topological magnetic textures such as skyrmions has been limited to conducting materials. Magnetic insulators offer key advantages for skyrmion technologies with high speed and low loss. We observe a prominent topological Hall effect in Pt/Tm$_3$Fe$_5$O$_{12}$ bilayers, where the pristine Tm$_3$Fe$_5$O$_{12}$ epitaxial films down to 1.25 unit cell thickness allow for tuning of topological Hall stability over a broad range from 200 to 465 K through atomic-scale thickness control [1]. Although Tm$_3$Fe$_5$O$_{12}$ is insulating, the topological magnetic textures can be detected through a novel phenomenon: “spin-Hall topological Hall effect” (SH-THE), where the interfacial spin-orbit torques allow spin-Hall-effect generated spins in Pt to experience the unique topology of the underlying skyrmions in Tm$_3$Fe$_5$O$_{12}$. This novel electrical detection phenomenon paves a new path for utilizing a large family of magnetic insulators in future skyrmion technologies.

*This work was primarily supported by DARPA under Grant No. D18AP00008. Partial support was provided by the Center for Emergent Materials, an NSF-funded MRSEC, under Grant No. DMR-1420451 for the bulk synthesis and film growth of TmlG.
1:03PM B19.00004: Observation of room temperature polar skyrmions

RAMAMOORTHY RAMESH (Presenter), University of California, Berkeley — Complex topological configurations are a fertile playground to explore novel emergent phenomena and exotic phases in condensed-matter physics. For example, the recent discovery of polarization vortices and the associated complex-phase coexistence and response under applied field in superlattices of (PbTiO3)n/(SrTiO3)n suggests the presence of a complex, multi-dimensional system capable of exotic physical responses. I will describe the discovery of polar skyrmions in a lead-titanate layer confined by strontium-titanate layers by atomic-resolution scanning transmission electron microscopy (STEM). Phase-field modeling and second-principles calculations reveal that the polar skyrmions have a skyrmion number of +1 and resonant soft X-ray diffraction experiments show circular dichroism confirming chirality. Such nanometer-scale polar skyrmions exhibit a strong signature of negative permittivity at the surface of the skyrmion, which is furthermore highly tunable with an electric field. They are a new state of matter and electric analogs of magnetic skyrmions, and may be envisaged for potential applications in information technologies. I will attempt to describe the exciting observations we have made through many collaborations.

*This work is supported by the US Department of Energy, Office of Science, Basic Energy Sciences.

1:39PM B19.00005: Nonequilibrium Skyrmion Dynamics under Oscillating Magnetic Fields

CHRISTINA PSAROUDAKI (Presenter), Physics, California Institute of Technology, DANIEL LOSS, Physics, University of Basel — We extend earlier studies on the quantum propagation of a skyrmion in chiral magnetic insulators [1], to include the effects of time periodic magnetic field gradients on skyrmion dynamics [2]. The unavoidable coupling of the external field to the magnons gives rise to time-dependent dissipation for the skyrmion, with measurable consequences on the skyrmion path. These ac fields act as a net driving force on the skyrmion via its own intrinsic magnetic excitations. We generalize the standard quantum theory of dissipation to include the stochastic effects of the driven bath on the skyrmion dynamics. We address the stochastic effects of the quantum driven bath on the skyrmion propagation [3], and provide a generalized version of the nonequilibrium fluctuation-dissipation relation for externally driven reservoirs. We also predict a novel fast thermal activation for the mean-square displacement that scales quadratically with temperature in the experimentally accessible low-temperature regime.

Monday, March 2, 2020 11:15 AM - 1:51 PM

Session B20 DBIO DCOMP: Physics of Proteins: Progress on Structure-Function Relationships II 301 - Wouter Hoff, Oklahoma State University-Stillwater - Tag(s): Focus
Proteins are commonly believed to be insulators, consistent with their appearance and the results of simple measurements. This is in line with the expected behavior of a disordered, wide bandgap solid with strong vibronic coupling. Yet some soil bacteria transfer electrons via thin protein filaments with near-metallic conductivities. Are they a special case? Motivated by calculations that indicate that many proteins have evolved towards a quantum critical structure\textsuperscript{1} we decided to measure the conductance of single molecules of proteins chosen precisely because they lack redox centers and lack any known electron transfer function. Unique to our approach is the use of specific chemical bonding between proteins and electrodes to minimize the effects of contact resistance.\textsuperscript{2} We find that nS conductances over distances of many nm are common. The conductance is limited by contacts, with very long electronic decay lengths inside the protein.\textsuperscript{3} What biological pressure could drive evolution towards this unlikely state? We have studied a functioning DNA polymerase, finding large changes in its internal conductance as it undergoes functional changes in conformation. This suggests a possible role for delocalized states in function. It also points to a new method for DNA sequencing based on direct electrical measurement of enzyme function.\textsuperscript{4}

*This work was supported by grants HG006323 and HG010522 from the National Human Genome Research Institute, by Recognition AnalytiX Corp and the Edward and Nadine Carson Endowment.

Nearly 150,000 of protein structures have been reported using X-ray crystallography, NMR technologies, and more recently cryogenic electron microscopy (Cryo-EM). Many of these structures played indispensable roles in our understanding of protein function. Then why do we need time-resolved infrared structural biology for proteins? Infrared structural biology is an emerging technology that offers unique advantages. Based on the 3D structure of a protein, can the functional mechanism of this protein be fully explained? In my talk, I will discuss important challenges we are facing in protein structural biology, and how to overcome some of these challenges using time-resolved infrared structural biology of proteins. More importantly, time-resolved infrared structural biology can bring new insight to the study of many proteins.

*Financial supports from National Science Foundation (DBI 1338097) and Oklahoma Center for the Advancement of Science and Technology (HR10-078) are greatly appreciated.
12:27PM B20.00003: Domain Swapping in Crystallin Proteins Can Drive Early Stages of Cataract Formation  GOVARDHAN PATLURI (Presenter), Indian Institute of Science — Crystallins (Crys) are densely packed, long-lived eye lens proteins responsible for the ocular functions of the lens. Physicochemical perturbations in the cellular environment disrupt the native state stability of Cry proteins and populate aggregation prone misfolded states. These misfolded states gradually accumulate to produce high molecular weight amorphous aggregates, which scatter visible light resulting in lens opacity or cataract. The molecular mechanism of cataract formation or structure of these aggregation prone precursors remain elusive to date. Using molecular dynamics simulations and coarse-grained protein model of human γC and γD Crys, we identified the aggregation prone misfolded states present in the unfolding pathways of these proteins. We further show that these partially misfolded conformations readily undergo dimerization by domain swapping revealing the early stages of aggregation leading to cataract formation.

12:39PM B20.00004: Evaluating molecular simulations of protein dynamics using novel experimental data  LAUREN MCGOUGH (Presenter), University of Chicago, JUSTIN KIM, EUGENE KLYSHKO, University of Toronto, RAMA RANGANATHAN, University of Chicago, SARAH RAUSCHER, University of Toronto — Proteins are evolved molecular machines that carry out the essential chemical reactions necessary for life. Like machines designed by humans, proteins execute their functions through an orderly set of motions and fluctuations - their “reaction coordinate”. However, proteins are also marginally stable, with the expectation that functional dynamics are embedded in a small subspace of a high dimensional pattern of overall motions and configurational changes. One approach to studying intramolecular fluctuations is computational simulation of atomic trajectories using molecular dynamics. Recent advances in experimental protein dynamics now open up the ability to test, validate, and possibly improve the process of molecular dynamics (MD) simulations through direct comparisons between computational predictions and data. We present a comparative analysis between MD and experiment using data from X-ray diffraction studies reporting electric field-stimulated excited state motions. The analysis develops methods for simulating a protein crystal while carrying out rigorous evaluations of structural conformation ensembles, atomic strain, force field differences, and more. This work represents an opportunity for MD and initiates a path towards understanding the physics of protein function.
12:51PM B20.00005: Effects of artificial mutations on topological features of proteins
HARU NEGAMI (Presenter), Engineering department, The University of Tokyo — Relationship between the mutations of the proteins and its physiological activities is an important research area for many reasons. One reason is that bacteria or viruses acquire their resistance to existing drugs by mutations. The conformational changes due to the mutations have a significant role on the affinity to their ligand.

To understand the relationships, we focus on a topological method called “Fatgraph models of proteins” [1]. Fatgraph models of proteins are topological two-manifold with boundary components (surface) which have one to one correspondence with three-dimensional protein structures listed on Protein Data Bank (PDB) [2] with only a few exceptions. Topological invariants represent geometrical features, and thus they are effective method to grasp the effects of local mutations on three dimensional structures of the proteins as a whole.

In this research we investigated the topological features of artificial proteins and showed the topological traits of mutants which have a drug resistant to antibiotics.

1:03PM B20.00006: Using Molecular Dynamics to Improve Molecular Docking
CONNOR MORRIS (Presenter), DENNIS DELLA CORTE, Brigham Young Univ - Provo — We have been developing an improved method of protein-ligand docking. In our study of an intrinsically disordered protein, SNAP25B, we discovered that docking on a single rigid protein structure alone does not give us complete information on how the protein-ligand pair would interact in vivo, since intrinsically disordered proteins can form multiple 3D structures. A docking-predicted binding pose on this rigid structure may not exist in vivo due to the tendency of the 3D structure of the protein to change under different conditions. However, running the protein through a molecular dynamics (MD) simulation and collecting multiple 3D protein structures gives information about how the protein structure changes in solution. Docking on these MD-derived 3D protein structures increases the probability of finding an accurate ligand binding position using molecular docking that matches in vivo interactions.
1:15PM B20.00007: Marburg VP24 Protein K-loop Cysteine Interactions with the Human Keap1 Protein  NISHA BHATTARAI (Presenter), BERNARD S GERSTMAN, PREM P CHAPAGAIN, Physics, Florida International University — Marburg and Ebola viruses are pathogenic viruses that belong to the Filovirus family and have up to 90% fatality rates. The Marburg VP24 protein (mVP24), has been found to bind with the Human Keap1 protein, which allows the nuclear accumulation of Nrf2, activating the antioxidant response elements during the viral life cycle. In this work, we investigate the molecular level details of the interactions between Marburg and Ebola VP24 proteins and Keap1 using molecular dynamics simulation. Sequence alignment of Ebola and Marburg VP24 reveals that two cysteine residues are present in mVP24 protein but absent in the Ebola VP24 protein (eVP24). Our results show that the presence of cysteine residues in the K-loop region of Marburg VP24 protein makes binding with Keap1 stronger, forming hydrogen bonding and pi-interactions. These cysteine residues are absent in eVP24 protein, which does not bind with Keap1. These computational results provide insights into how Marburg but not Ebola, is able to bind with Keap1 protein and activate antioxidant response pathways.

1:27PM B20.00008: Anomalous kinetics on low-fouling surfaces*  DIEGO KRAPF (Presenter), MOHAMMADHASAN HEDAYATI, MATT J KIPPER, Colorado State University — Protein-surface interactions were probed in terms of adsorption and desorption on a low-fouling surface using single-molecule localization microscopy. Strikingly the experimental data show anomalous kinetics, evident as a surface dwell time distribution that exhibits a power-law distribution, i.e. a heavy-tailed rather than an exponential distribution. As a consequence, the average desorption rate depends upon the time scale of the experiment and the surface protein concentration does not reach equilibrium. Further analysis reveals that the observed anomalous desorption emerges due to the reversible formation of a small fraction of soluble protein multimers, such that each one desorbs from the surface at a different rate. The overall kinetics can be described by a series of elementary reactions, yielding simple scaling relations that predict experimental observations. This work reveals a mechanistic origin for anomalous adsorption/desorption kinetics that can be employed to define design principles for non-fouling surfaces and to predict their performance.

*This work was supported by the National Science Foundation (award number 1511830).
1:39PM B20.00009: Single polypeptide antibody functionalized electrochemical probe development for enterovirus detection* YI-XIANG LU (Presenter), CHIA-YU CHANG, Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan, WEN-BIN FAN, JYH-YUAN YANG, Department of Health, Research and Diagnostic Center, Centers for Disease Control, Taipei, Taiwan, CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan — Enterovirus 71 affects global public health and causes the millions of infections in human via oral and respiratory infection every year. Conventional detection approaches are through cell culture and PCR assay processes. However, these processes are time consuming. Therefore, a rapid, sensitive detection of enterovirus is required. Electrochemical impedance spectroscopy (EIS) is widely used for antigen-antibody interaction to measure the impedance change of the bio-sensing probe. However, conventional antibody is not stable for EIS probe. We have developed a single polypeptide antibody for enterovirus 71 detection. This single polypeptide antibody can conjugate with EIS electrode directly via self-assembly process. Moreover, this functionalized sensing probe can bind with EV71 sensitively and selectively within a few minutes by EIS. This single polypeptide antibody is relatively stable to detect enterovirus and may reduce the risk of enterovirus outbreak.

Monday, March 2, 2020 11:15 AM - 2:15 PM

Session B21 GERA: Energy Storage - Electrolyte Physics 302

11:15AM B21.00001: High Ionic Conductivity Composite Solid-State Electrolytes* ERNESTO MARINERO (Presenter), ANDRES VILLA, JUAN CARLOS VERDUZCO, School of Materials Engineering, Purdue University — We report on the development of a solid-state electrolyte (SSE) with high ionic conductivity, having physical properties that allow their ready integration into current battery devices whose fabrication is amenable to large scale manufacturing. The prototype Composite SSE reported comprises a polymer-Li-salt matrix embedded with super-ionically conducting garnet nanoparticles. We employ polyethylene-oxide (PEO) + LiTFSI (salt) as a matrix incorporating Bi-doped lithium lanthanum zirconium oxide (LLZBO) ceramic nanoparticles (~350nm diameter). We study the role of Bi-aliovalent substitution in LiLaZrO on the microstructure and the ionic conductivity of the ceramic garnet material. We successfully reduce the synthesis temperature of LiLaZrO by Bi-additions utilizing sol-gel reactions. Additions of very small amounts (5% weight load) of the garnet nanoparticles to the polymer-salt matrix result in over two-orders of magnitude increments of the ionic conductivity of the polymer-salt matrix. This composite SSE is amenable to large-scale fabrication and integration into battery devices, furthermore given the small amount of ceramic particles needed, it is cost-competitive.

*Work supported by Purdue University and Mexico’s CONACYT partial support for A. Villa and J. C. Verduzco.
11:27AM B21.00002: Understanding ionic diffusivity in (meta)stable (un)doped solid state electrolyte from first principles: A case study of LISICON (Li$_4$SiO$_4$)  

DEEPIKA GILL (Presenter), Physics, IIT Delhi, India —
Solid electrolyte is expected to be an alternative to liquid electrolyte in Li-ion batteries. The former is believed to be safer, capable of delivering higher energy density, faster recharging, higher voltage capability and longer cycle life. Here, we have studied ionic diffusion and its correlation with dopants/defects by taking LISICON (Li$_4$SiO$_4$) as a test case. As a first step, using density functional theory (DFT), we compute the formation energies of different defects in LISICON to determine the thermodynamically stable configurations. Following this, we have performed ab initio Molecular Dynamics (AIMD) simulation on (meta)stable (un)doped systems to study the diffusion and ionic conductivity of Li-ions. Our results reveal that jumps between different planes are not same, leading to anisotropy in ionic conductivity. We observe that interplanar jumps are minimum in $bc$ planes that limits the ionic conductivity. We report that the limited jump rate can be enhanced at room temperature by point defects, viz. Li-vacancy and substitution at Si-sites with different elements viz. P, Ge, Al.

11:39AM B21.00003: Design of the sodium ionic conductor for all-solid-state battery

KAZUYUKI KAWAHARA (Presenter), SATOSHI HEGURI, Osaka Inst of Tech — The high ionic conductivity of solid electrolyte plays a key role in the performance of all-solid-state batteries. Therefore, the crystal structure is very important in the design of solid ionic conductor. Recently, various solid electrolytes for all-solid-state lithium-ion batteries, especially lithium thiophosphate system, have been reported. These materials generally exhibit high ionic conductivity and can be obtained by easy preparation methods. Kandagal et al. theoretically predicted a new sodium-ion conductor having same crystal structure of lithium thiophosphates [1]. To date, however, it has been not experimentally demonstrated. In the present study, we synthesize a new sodium-ion conductor using a mechanochemical technique and subsequent optimized thermal treatments. The details of the crystal structural analysis and characterization of the AC impedance will be discussed.

11:51AM B21.00004: First-principles study on electrode-contact chemical stability and Na ion dynamics of Na$_3$SbS$_4$ solid electrolyte for all-solid-state Na ion batteries*  RANDY JALEM (Presenter), YOSHITAKA TATEYAMA, Center for Green Research on Energy and Environmental Materials & Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute — To enhance safety, the replacement of the combustible organic-/liquid-based electrolyte in sodium ion batteries with a ceramic-based solid electrolyte has been sought. In this talk, we present our results on thermodynamic and ion dynamics analyses of Na$_3$SbS$_4$ solid electrolyte using first-principles calculations. Based from the calculated chemical potential diagram when Na$_3$SbS$_4$ is in contact with possible layered cathode compounds Na[TM]O$_2$ (where TM = {V, Cr, Mn, Fe, Co, Ni}), sulfur has the driving force to migrate across the electrolyte-cathode interface which may partly explain the experimentally observed formation of interface reaction layer in such all-solid state battery interfaces. From space-time correlation analysis of molecular dynamics trajectory, we determined a concerted migration behavior for Na ions which can explain for the material's superionic conductivity behavior (>10$^{-3}$ S/cm). The effects of halide doping on the conductivity behavior of Na$_3$SbS$_4$ will also be discussed.

*R.J.le is thankful for the JST Precursory Research for Embryonic Science and Technology (PRESTO) program for the financial support. This research has been supported by MEXT, Japan under “Elements Strategy Initiative for Catalysts and Batteries (ESICB)” and “Priority Issue (No. 5) on Post K computer.

12:03PM B21.00005: Tracking structural dynamics in operando sodium ion batteries*  OLEG GOROBTSOV (Presenter), Cornell University, HAYLEY HIRSH, Univeristy of California San Diego, DANIEL WEINSTOCK, RYAN BOUCK, Cornell University, DINA SHEYFER, Argonne National Laboratory, ZIYI WANG, Cornell University, MINGHAO ZHANG, Univeristy of California San Diego, WONSUK CHA, ROSS HARDER, Argonne National Laboratory, SHIRLEY MENG, Univeristy of California San Diego, ANDREJ SINGER, Cornell University — Sodium ion batteries are promising candidates for storage of energy produced by solar and wind sources. Alternative energy sources are by nature intermittent, and require storage facilities to compensate. Lithium ion batteries, while ubiquitous, are too expensive to satisfy this need. Sodium ion batteries promise to be a cheaper alternative to produce in mass. However, they currently suffer from much faster degradation than Li-ion batteries and often degrade after just a few charge-discharge cycles. Defects in the nanoparticles in lithium ion batteries have been studied by coherent diffraction imaging at X-ray sources (CXDI). We have applied CXDI to sodium ion batteries in operando and obtained information about the evolution of planar and linear defects in the nanoparticles in Na-ion battery cathodes, offering insights in how to improve the performance of Na-ion batteries.

*This research used resources of the Advanced Photon Source, a U.S. DOE Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under contract no. DE-AC02-06CH11357.
**12:15PM B21.00006: Prediction and analysis of a sodium ion electrolyte: Li$_2$Na$_2$P$_2$S$_6$**

YAN LI (Presenter), Department of Physics, Wake Forest University, ZACHARY D HOOD, Electrochemical Materials Laboratory, Massachusetts Institute of Technology, NATALIE A HOLZWARTH, Department of Physics, Wake Forest University — Recent experimental results of Hood et al.$^1$ show that Na$_4$P$_2$S$_6$, which crystallizes in the based-centered monoclinic structure C2/m (#12), has significant Na ion conductivity ($3 \times 10^{-6}$ S/cm) at room temperature. Using density functional theory and density functional perturbation theory within the harmonic phonon approximation, we predict that the Na ion conductivity can be enhanced by alloying this electrolyte with Li to form Li$_2$Na$_2$P$_2$S$_6$ having the same C2/m structure with compacted $a$ and $b$ lattice constants. The calculation of Helmholtz free energies suggests that the alloy material is stable for a range of temperatures at and above room temperature in terms of the energy difference $F$(Li$_2$Na$_2$P$_2$S$_6$ + 2Na) $-$ (F(Na$_4$P$_2$S$_6$ + 2Li) $\leq$ −0.35 eV. Molecular dynamics simulations indicate that Li$_2$Na$_2$P$_2$S$_6$ has larger Na ion conductivity than does Na$_4$P$_2$S$_6$ and therefore is promising as a possible solid-state electrolyte for all-solid-state Na ion batteries.

$^1$Z. D. Hood et al. to be published.

*Supported by NSF grant DMR-1507942.

**12:27PM B21.00007: Mg ion conducting solid polymer electrolyte for advanced energy storage system**

MEETA TRIVEDI (Presenter), HAMAD ALBEHAIJAN, THEIN KYU, Univ of Akron — Magnesium (Mg) batteries have the potential to replace the Li-ion technology because of superior safety and high abundance of Mg metal. However, the commercialization is hindered due to lack in development of electrolyte and cathode systems. A novel highly conductive, solvent-free, solid state polymer Mg ion electrolyte for advanced energy storage application is developed. Mg-ion conducting solid state polymer electrolytes (SPE) comprised of polyethylene glycol diacrylate (PEGDA) prepolymer, magnesium bis(trifluoromethanesulfonyl) imide (Mg(TFSI)$_2$) salt, and succinonitrile (SCN) plasticizer were systematically examined. Optimization of composition for solid polymer electrolyte to achieve superionic conductivity was performed in the isotropic region guided by ternary phase diagram. Addition of plasticizer decreases $T_g$ of the system, but it increases the ionic conductivity. By using various plasticizers and mixed Mg/Li salts in the development of SPE, the effect of plasticization and salt composition on the ionic conductivity, electrochemical stability window, thermal stability and mechanical properties will be demonstrated.

*Support by NSF-DMR 1502543.
AC conductivity studies of polyethylene oxide-garnet-type Li$_7$La$_3$Zr$_2$O$_{12}$ hybrid composite solid polymer electrolyte films

PARISA BASHIRI (Presenter), T. PRASADA RAO RAO, Physics and Astronomy, Wayne State University, VAMAN NAIK, Natural Sciences, Univ of Michigan - Dearborn, GHOLAM ABBAS NAZRI, RATNA NAIK, Physics and Astronomy, Wayne State University — We have investigated both AC dielectric permittivity and ionic conductivity of hybrid composite solid polymer electrolyte (CSPE) films (~100 mm) comprised of sub-micron sized aluminum substituted cubic Li$_7$La$_3$Zr$_2$O$_{12}$ (LLZO) particles dispersed in polyethylene oxide-LiClO$_4$ (PEO-LiClO$_4$) matrix with [EO]:[Li] = 15:1. The complex AC permittivity and conductivity were determined using the measured electrical impedance spectra in the range of 1 Hz to 300 kHz and analyzed using generalized power-law that accounts for the effect of electrode polarization. The ionic and segmental relaxation times obtained from fitting the experimental data indicate a strong coupling between the ionic motion and segmental dynamics. Further, the observed temperature dependent conductivity follows the Vogel-Tammann-Fulcher (VTF) behavior implying a close correlation between ionic conductivity and segmental relaxation in these polymer electrolytes. The VTF model yields an activation energy of 0.32 eV for PEO-LiClO$_4$ film, and 0.07 eV for PEO-LLZO-LiClO$_4$ composite film, consistent with the observed enhancement in conductivity by two orders of magnitude at 30 °C upon the addition of LLZO particles. Details preparation of CSPE films and the analyses will be presented.

A solid 3D Li-S battery design via stacking 2D conductive microporous coordination polymers and amorphous Li-S layers

GUOPING GAO (Presenter), Lawrence Berkeley National Laboratory — In order to make a Li-S battery practical, not only high gravimetric energy capacity is important, high volumetric energy capacity will also be required. The currently explored Li-S cathode designs often deploy systems with liquid electrolyte infiltration, hence with relatively low volumetric capacity. In the current study, we theoretically test a compact solid 3D design (more like a Li-ion battery cathode than a conventional Li-S cathode) consisted of a sandwich structure alternating between the 2D Mn-HAB layer and amorphous Li-S layer. We study the theoretical limits for both its gravimetric and volumetric energy capacity, as well as its structural stability and Li diffusion within the cathode system. In order to study the Li diffusion within an amorphous system, we also develop a pull-atom molecular dynamics (PA-MD) to calculate the barrier heights of such disordered systems. We reveal the mechanism which determines the Li diffusion in the amorphous layer of the system. Overall, we find such 3D solid Li-S cathode can be practical, with sufficient large gravimetric and volumetric energy capacity, as well as the Li diffusion constant. It also solves many other common Li-S cathode problems, from Li polysulfide dissolution, to electrical insulating, and structure instabilities.
1:03PM B21.00010: First Principles Study of Electrolyte Interactions in Calcium Ion Batteries

JOSHUA YOUNG (Presenter), Chemical and Materials Engineering, New Jersey Institute of Technology, PETER KULICK, TAYLOR JURAN, MANUEL SMEU, Physics, Binghamton University — Multivalent ion batteries, which use species such as Ca as the working ion, are gaining increasing attention. Compared to other multivalent ions, Ca exhibits a reduction potential close to that of Li, high volumetric capacity, and faster diffusion. However, the breakdown of organic electrolytes causes a passivating layer (the solid electrolyte interphase, or SEI) to form on the electrode surface, blocking Ca diffusion and preventing reversible plating and stripping of the Ca anode. In this work we use density functional theory (DFT) and ab initio molecular dynamics (AIMD) calculations to study the interaction of these solvents, including ethylene carbonate (EC), propylene carbonate (PC), and tetrahydrofuran (THF), with Ca ions and investigate their breakdown on the anode surface. [1,2] We find that Ca forms a large first solvation shell with EC and PC and a slightly smaller one in THF. We then compute the diffusion coefficient of Ca in each solvent using AIMD, and find that it diffuses fastest in THF, and slower in EC and PC. Finally, we use AIMD to study the decomposition of EC on Li, Ca, and Al surfaces and identify the principle components of the SEI on each.

1:15PM B21.00011: Proton conductivity mechanism of liquid imidazole - an ab initio molecular dynamics study

ZHUORAN LONG (Presenter), New York Univ NYU, AUSTIN ATSANGO, JOE ANTHONY NAPOLI, THOMAS E MARKLAND, Stanford University, MARK E TUCKERMAN, New York Univ NYU — Imidazole, as a fundamental organic compound, exhibits high proton conductivity comparable to water at similar temperatures relative to the melting point. Its potential application in fuel cells has motivated numerous experimental research efforts. However, details of the proton conductivity mechanism are still ambiguous. Using multiple time-step ab initio molecular dynamics simulations, we were able to accumulate trajectories totaling 1 ns in length. The predicted proton diffusion coefficient of imidazolium is 0.52 Å²/ps at 384K, and structural diffusion is the dominant mechanism. The proton transfer event is local and must go through a geometrically restricted Zundel-type transition state at a sub-picosecond time scale. Long hydrogen-bonded chains were detected in our liquid imidazole system within which the imidazolium defect undergoes frequent identity changes from individual proton transfer events. Chain diffusion is controlled by the dynamic hydrogen bond forming and breaking via rotational reorientation at a time scale of ~30ps. The decoupling of local proton transfer and chain diffusion together explains the fast proton hopping rate and relatively large diffusion coefficient of the charge defect.
**1:27PM B21.00012: Smart power system: Tuning energy storage by electrophoretic repositioning of TiO\(_2\) nanoparticles in electrolytes.** BIPALV ACHARYA (Presenter), CAITLIN M SEED, JACQUELINE KRIM, North Carolina State University — An effective strategy for efficient use of power is to deliver variable energy whose level depends on the fluctuating demand. Electric double layer capacitors are regarded as one approach suitable for such power management systems. Prior investigations of TiO\(_2\) nanomaterials have primarily focused on how they can be incorporated into a system's electrodes and not its electrolytes. We demonstrate here that TiO\(_2\) nanoparticles (NPs) dispersed directly into an electrolyte may also be an approach to smart energy storage applications. Cyclic voltammetry measurements are employed to explore charge storage capabilities and, together with repositioning of the TiO\(_2\) and Al\(_2\)O\(_3\) NPs in the electrolyte. TiO\(_2\) NPs are revealed to be actively positioned to form a transient film on the electrode surface, significantly enhancing the system's energy storage capabilities. In contrast, minimal enhancement is observed for the Al\(_2\)O\(_3\). This study shows that TiO\(_2\) NPs are intrinsically capable of being a component of a “smart power” system, designed to deliver variable power commensurate with a fluctuating demand.

**1:39PM B21.00013: Ab Initio Study of the Discharge Mechanism of Bi- and Cu- Modified MnO\(_2\)/Zn Rechargeable Batteries.** BIRENDRAG ALE MAGAR (Presenter), NIRAJAN PAUDEL, TIMOTHY N. LAMBERT, IGOR VASILIEV, Department of Physics, New Mexico State University, Las Cruces, New Mexico 88003, TIMOTHY N. LAMBERT, Department of Materials, Devices, and Energy Technologies, Sandia National Laboratories, Albuquerque, New Mexico 87185, IGOR VASILIEV, Department of Physics, New Mexico State University, Las Cruces, New Mexico 88003 — Bi and Cu additives have a great influence on the performance of rechargeable Zn/MnO\(_2\) batteries, however, the mechanism by which these additives affect the rechargeability and cyclability of the MnO\(_2\) electrode has not been explained in detail. We applied first-principles computational methods based on density functional theory to study the discharge mechanism of Bi- and Cu-modified \(\delta\)-MnO\(_2\) electrodes in rechargeable Zn/MnO\(_2\) batteries. Our calculations show the possibility of formation of Bi-Mn and Cu-Mn oxides in Bi/Cu-modified \(\delta\)-MnO\(_2\) cathodes during battery cycling. The results of our study suggest that the formation of intermediate Bi-Mn and Cu-Mn oxides could reduce the rate of accumulation of irreversible redox reaction products in the MnO\(_2\) electrode.

1:51PM B21.00014: Ab initio Analysis of Membrane Stability in Alkaline Environments: a Joint Density Functional Theory (JDFT) Study*  MARIEL TADER (Presenter), WEI YOU, GEOFFREY COATES, TOMAS ALBERTO ARIAS, Cornell University — Improving membrane stability in alkaline environments is crucial to the development of alkaline fuel cells (AFCs). Ab initio studies using the nudged elastic band (NEB) method, combined with a detailed transition-state theory analysis, allow us not only to predict quantitative lifetimes of alkali-stable membrane polymers, but also to uncover unexpected mechanisms for improving membrane lifetime. In this later regard, we find that the choice of a first-principles joint-density functional theory (JDFT) description of the solvent and consideration of the impact of the hydrophobic regions of the membrane are critical to understanding the polymer degradation process. This work is foundational to computation-enabled searches for yet more stable AFC membranes.

*This research is supported as part of the Center for Alkaline Based Energy Solutions (CABES) an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Award No. DE-SC0019445.

2:03PM B21.00015: Enhancement of Quaternized Ammonium Polyaromatic Anion Membrane Performance in Alkaline Fuel Cells by Deposition of Graphene Oxide and Catalyst Ink Optimization*  AVINASH RAO (Presenter), MICHAEL HAN, CARTER BIAN, MIRIAM RAFAILOVICH, STOYAN BLIZNAKOV, Stony Brook University — To bolster the performance of polyaromatic ionomer membranes in alkaline fuel cells (AFCs), two major modifications were made. First, catalyst ink composition was optimized to yield the maximum power performance for the low platinum loading (0.6 mg/cm²). From the tested compositions, an 80:20 (catalyst:ionomer) ratio produced the greatest results for quaternary ammonium biphenyl membranes, yielding an improved 66 mW/cm² power density despite reduced back-pressure. In addition to determining an optimal ink composition, partially reduced graphene oxide (PRGO) was deposited onto catalyst-loaded electrodes. The membrane electrode assembly (MEA) reached a power density of 66 mW/cm² at a low back-pressure of 50 kPa; likewise, the current density of 400 mA/cm² was unprecedented for this particular polyaromatic membrane in prior tests. By varying the composition of the catalyst ink, we demonstrated a 453% increase in power per milligram platinum (PPMP) from 58% ionomer by mass to 20% ionomer by mass. Through the direct application of PRGO to the gas diffusion electrode surface, we achieved the highest recorded PPMP membrane — 0.97 W/mgPt in MEA 6.

Session B22 DBIO: Biofluid Dynamics; Biological Pattern Formation; Biological Oscillators  303 - Ofer Kimchi, Harvard University
11:15AM B22.00001: Flow due to chirality in suspensions of magnetotactic bacteria
ANDREJS CEBERS (Presenter), Univ of Latvia — Phenomena due to chirality are observed in suspensions of magnetotactic bacteria. As a particular example that is simple enough for analysis we consider a layer of magnetotactic bacteria suspension with thickness h and width 2d above a solid wall. The torque dipoles of the bacteria are oriented by an oblique magnetic field, leading to torques distributed on the free interface of the layer. As a result a boundary value problem for the 2D Stokes equation is formulated with a jump of the fluid velocity on the free interface and a no-slip condition on the solid wall. It is solved by the known methods of complex analysis where the flow field is defined by two analytical functions. The solution shows fluid motion perpendicular to the plane defined by the normal to the solid wall and the oblique magnetic field. The numerical value of the velocity and its dependence on the angle of the field inclination is in good agreement with the experimental data [1].

11:27AM B22.00002: Active depinning of bacterial droplets due to gravity* HARSHITHA SHANKAR KOTIAN (Presenter), AMITH ZAFAL ABDULLA, HITHYSINI K. N., VARSHA SINGH, MANOJ M VARMA, Indian Institute of Science — A bacterial culture on a nutrient rich agar plate exhibits swarming motility. Many species of swarming bacteria collectively extract water from the underlying agar and produce surfactants to enhance the spreading of the bacterial droplet to colonise the entire plate. When the agar plate is placed on an incline, this bacterial droplet de-pins to slide down the surface. This de-pinning has so far been presumed to be due to the reduction in surface tension of the droplet by the surfactants produced by the bacteria. Contrary to this belief, we present experimental evidence that motility of the individual bacteria and the stiffness of the agar dominates the de-pinning dynamics to an extent that de-pinning can happen even in mutant strains incapable of producing surfactants. We also present a fluid dynamical model to describe this active de-pinning mechanism of droplets containing surfactant producing bacteria such as Pseudomonas aeruginosa and Bacillus subtilis.

**11:39AM B22.00003: Optimal Geometry of Perfusion in Flow Networks**

TATYANA GAVRILCHENKO (Presenter), ELENI KATIFORI, University of Pennsylvania — In organ capillaries, oxygen detaches from red blood cells and diffuses through a porous membrane into the nearby tissue, eventually getting absorbed by tissue cells. Motivated by this system, we study networks where flow is laden with nutrients able to diffuse out of the vessels and into the surrounding faces. In a uniform network with a single flow source and sink, the nutrients become depleted far from the source, forming a gradient of nutrient density that may leave some tissue undersupplied. Nonetheless, organs have developed capillary bed networks that avoid tissue starvation. In anticipation of engineering networks for artificial organs, we explore theoretical network designs for uniform perfusion over an extended area. Here, we first propose an algorithm with rules to induce local topological changes in a flow network, which serves to generate a wide range of network topologies. We then use vertex model dynamics to tune the vertex positions in a way that equalizes nutrient distribution. Ultimately, we hope to use this uniformly perfusing network ensemble to identify topological features that serve to dissipate an undesirable nutrient gradient.

*We gratefully acknowledge support from the National Science Foundation and the Burroughs Wellcome Fund.

**11:51AM B22.00004: Confined Diffusion of a Colloidal Particle Between Two Parallel Walls: Quantifying Diffusing Diffusivity**

GARY W. SLATER (Presenter), MAXIME IGNACIO, LE QIAO, Univ of Ottawa — "Anomalous yet Brownian" diffusion has been observed in numerous physical and biological systems over the last few years, both experimentally and in simulations. The concept of Diffusing Diffusivity, which we proposed to explain such phenomena, has also been studied extensively. As shown by the Bechhoefer group (PRE 96, 042604, 2017), the simplest experimental system is possibly that of a particle confined to a slit since its diffusion coefficient does depend on the distance to a wall. We revisit this problem using Lattice Boltzmann simulations of a particle between two walls in the absence of external forces, a simpler situation since no external force is present. Instead of using the Kurtosis as a measure of the non-ideality of the diffusion motion, we introduce a new empirical fitting function with a tunable exponent and a critical time scale. We test our results with an alternative Monte Carlo simulation and discuss the implications.

12:03PM B22.00005: Fluid flow dynamics in networks of compliant vessels  
SEAN FANCHER (Presenter), ELENI KATIFORI, Department of Physics and Astronomy, University of Pennsylvania — Flow networks appear in a wide variety of natural and artificial contexts, and as such, a significant number of works have aimed to study their properties. However, most of these previous efforts have focused on continuous and dynamically invariant flow through networks of rigid vessels. Here, we develop a theoretical model of pulsatile flow using compliant vessels that interact with the flow and are capable of storing material and elastic energy. Pressure pulses can propagate, dissipate and scatter in such a fluidic network, and the system can support complex and rich dynamics. We solve for the flow and pressure profiles at any point within the network as a function of the properties of the input and output pressure or current waveforms, and we study the sensitivity of the dynamic flow profile to alterations or complete removal of single vessels. We use this to calculate not only the necessary power needed to maintain such a flow profile but also the power required to alter the profile, and show how a network can be optimized with respect to both. Finally, we explore possible applications of this work to biological systems such as the human vasculature network.

12:15PM B22.00006: Optimization of solute dissemination in complex flow networks  
GEORGIOS GOUNARIS (Presenter), MIGUEL RUIZ GARCIA, ELENI KATIFORI, University of Pennsylvania — Flow networks efficiently transport nutrients in many physical systems, such as plant and animal vasculature. In the case of the animal circulatory system, the oxygen and nutrient distribution are crucial for the survival of tissue. Homogeneity of the nutrient distribution provides a fitness advantage as waste is minimized while all tissue gets enough nutrients to survive. Can biological flow networks self-organize and remodel to optimally perfuse the tissue? We propose a local adaptation rule for the vessel radii that is able to equalize perfusion, while minimizing energy dissipation to circulate the flow and a cost constraint. These different objective functions compete to produce complex network morphologies including hierarchy and asymmetry between the network input and output.

12:27PM B22.00007: Probing in-mouth texture perception with a biomimetic tongue  
ALEXIS PREVOST (Presenter), Sorbonne University, Laboratoire Jean Perrin CNRS UMR8237, Paris, France, JEAN-BAPTISTE THOMAZO, Sorbonne University, Laboratoire Jean Perrin CNRS UMR8237, Paris France & Nestlé Dairy Center, Lisieux, France, JAVIER CONTRERAS PASTENES, Sorbonne University, Laboratoire Jean Perrin CNRS UMR8237, Paris, France, CHRISTOPHER J PIPE, BENJAMIN LE RÉVÉREND, Nestlé Research Center, Lausanne, Switzerland, ELIE WANDERSMAN, Sorbonne University, Laboratoire Jean Perrin CNRS UMR8237, Paris, France — An experimental biomimetic tongue– palate system has been developed to probe human in-mouth texture perception. Model tongues are made from soft elastomers patterned with fibrillar structures analogous to human filiform papillae. The palate is represented by a rigid flat plate parallel to the plane of the tongue. To probe the behavior under physiological flow conditions, deflections of model papillae are measured using a novel fluorescent imaging technique enabling sub-micrometer resolution of the displacements. Using optically transparent Newtonian liquids under steady shear flow, we show that deformations of the papillae allow their viscosity to be determined from 1 Pa s down to the viscosity of water (1 mPa.s), in full quantitative agreement with an elastohydrodynamics model.
Towards a synthetic post-translational protein oscillator

Ofer Kimchi (Presenter), Carl Goodrich, Agnese Curatolo, Harvard University, Alexis Courbet, Nick Woodall, Dmitri Zorine, David Baker, University of Washington, Michael Phillip Brenner, Harvard University — Synthetic protein circuits have the potential to significantly change the landscape of biomimicry engineering. While synthetic gene circuits have already borne fruit over the past several decades, post-translational circuits engineered to bypass transcription/translation machinery can offer more immediate responses and more direct coupling to endogenous systems. However, engineering dynamic phenomena such as oscillations in these circuits remains an outstanding challenge. Only a few known biological systems, such as the KaiABC system regulating the circadian clock in cyanobacteria, offer examples of post-translational oscillators, creating a need for theoretical work to fill in the gaps. Here, we develop two distinct post-translational oscillators, each using a small number of components which interact only through reversible binding and phosphorylation/dephosphorylation reactions. Our designed oscillators rely on the self-assembly of two protein species into multimeric functional enzymes which respectively interfere with and enhance this self-assembly. We will describe the systems, the intuition behind them, and their dependence on the (few) kinetic parameters.

Protein recruitment through indirect mechanochemical interactions

Andriy Goychuk (Presenter), Atul Mohite, Erwin A Frey, Ludwig Maximilian University of Munich — Some proteins have the ability to recruit other proteins from the cytosol to phospholipid membranes. This binding cooperativity plays a major role for the formation of protein patterns, which provide spatiotemporal control over many cellular processes. For example, Min oscillations guide the positioning of division axis in E. coli, and members of the Rho family of GTPases control contractility and migration of eukaryotic cells. However, the physical basis for this recruitment is still unclear. We suggest a generic feedback mechanism that explains how cooperativity can directly arise from mechanochemical coupling between the membrane and proteins. Such a mechanochemical coupling leads to membrane deformation, which in turn affects the affinity of proteins for the membrane, leading to a positive feedback in the protein binding rates. Our theory predicts that the mechanical properties of the membrane strongly affect protein recruitment, and therefore also protein pattern formation.

Modelling the Ear with Electronic Oscillators: The Wien Bridge Oscillator as a Physical Analogue for the Hair Cell

COURTNEY FLEMING (Presenter), RANDALL TAGG, MASOUD ASADI-ZEYDABADI, University of Colorado, Denver — The hair cell is the sensory organ of the human ear. In the vestibule, hair cells allow us to detect linear accelerations and rotations of the head. In the cochlea, patterns of hair cell activation along the dynamic basilar membrane allow us to encode information about complex sounds such as speech and music. A particularly important feature of hair cells is their intrinsic nonlinearity which gives rise to both a quiescent and oscillatory regime. This nonlinearity has been approached in the literature by treating the hair cell as a Hopf-type oscillator, wherein cochlear hair cells are poised just below the bifurcation point. In our research, we sought to construct and model a simple physical system that exhibited this same Hopf-type nonlinearity. We chose as our model system the Wien bridge electronic oscillator, an affordable and relatively simple circuit which mimics many of the essential features of the hair cell. We will introduce our theoretical model for nonlinearity and resonance within the Wien bridge oscillator based on experimental results, and discuss parallels between the dynamics of the Wien bridge oscillator and the dynamics of the hair cell.

Bulk-surface coupling reconciles Min-protein pattern formation in vitro and in vivo

FRIDTJOF BRAUNS (Presenter), Ludwig Maximilian University of Munich, GRZEGORZ PAWLIK, Department of Bionanoscience, TU Delft, JACOB HALATEK, Microsoft Research (Cambridge), JACOB KERSSEMAKERS, Department of Bionanoscience, TU Delft, ERWIN A FREY, Ludwig Maximilian University of Munich, CEES DEKKER, Department of Bionanoscience, TU Delft — The Min system of E. coli exhibits a rich variety of protein patterns whose phenomenology differs qualitatively and quantitatively between in vitro and in vivo settings. Here, we combine experiments and theory to show that this variety of patterns originates from distinct pattern-forming mechanisms (oscillation modes) that operate at different ratios of cytosolic volume to membrane surface area. Experiments in vitro, using laterally wide microchambers show qualitatively distinct patterns at different bulk heights, from standing waves, and sustained large-scale oscillations, to traveling waves. Our theoretical analysis shows that in vitro patterns at low bulk height are driven by the same lateral oscillation mechanism as in vivo pole-to-pole oscillations. Two distinct vertical oscillation modes – anti-phase oscillations between the opposite membrane surfaces and membrane-to-bulk oscillations – set in at larger bulk heights, marking the transition from the in vivo to the in vitro regime. We predict and experimentally confirm vertical pattern-synchronization (in-phase and anti-phase) between the microchambers' top and bottom surface and multistability of patterns in the transition regime.
HECTOR VELASCO PEREZ (Presenter), FLAVIO H FENTON, Georgia Inst of Tech — Our understanding of cardiac dynamics is frequently limited by our lack of knowledge of the ionic interactions at the microscopic level and how they drive the macroscopic phenomena. This has generated a series of complex models that are computationally demanding, inflexible and not generalizable. Nevertheless, there are characteristics or patterns that consistently show up in all of them, such as traveling waves and spiral waves. These patterns turn out to be low dimensional structures in an optimal basis, and optimal frame of reference. Here, we will focus on the study of traveling waves with alternans, that is, the change in the action potential wave length and/or amplitude in time. It is known that alternans are one of the main contributors to the initiation of fibrillation, which can be lethal if not attended. I will illustrate the derivation and properties of two types of reduced order models of cardiac tissue exhibiting various levels of alternans. These model reductions are based on proper orthogonal decomposition and sparse regression methods. We will compare the properties of both models and discuss the applications to other systems.

DAIBHID O MAOILEIDIGH (Presenter), Stanford University, YUTTANA ROONGTHUMSKUL, Physics, Chulalongkorn University, AJ HUDSPETH, Rockefeller University — Our ears emit sounds spontaneously, known as spontaneous otoacoustic emissions (SOAEs). It is unclear, however, why some animals emit sounds with identical frequencies from their two ears. In most nonmammalian tetrapods, acoustic coupling between the eardrums through the head cavity might influence SOAE production.

We record SOAEs simultaneously from the two ears of the tokay gecko and find several synchronized SOAEs. A model describing the eardrums as acoustically coupled, stochastic, active oscillators also produces synchronized SOAEs. In agreement with our experimental observations, the model captures the frequency-dependent phase differences between ears, the complex alterations in emissions upon suppression of the contralateral ear by static pressure, the change in emission frequency as the contralateral oscillator’s peak frequency is varied, the synchronization of emissions as the peak frequencies converge, and the dependence of some SOAEs on the emission strength of the contralateral ear.

Moreover, the model predicts that the ears’ activities enhance the localization of weak sound sources. The two ears of a gecko evidently function together as a single active system that is sensitive to the location of weak sound sources.
Patterns make patterns: how hierarchical self-organization couples cell shape to biochemical dynamics

TZER HAN TAN (Presenter), Massachusetts Institute of Technology MIT, MANON WIGBERS, FRIDTJOF BRAUNS, Ludwig Maximilian University of Munich, ZACHARY SWARTZ, Massachusetts Institute of Technology MIT, ERWIN A FREY, Ludwig Maximilian University of Munich, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Many biological processes rely on the precise positioning of proteins on the membrane to perform complex tasks. Such protein patterns are susceptible to cell shape changes, raising the question of how these patterns can be robust in a mechanically dynamic environment. Here, we elucidate a mechanism that pattern protein localization on the membrane robustly despite cell shape deformations. By combining experiments in starfish oocytes with mathematical modelling, we find that cell shape information encoded in a cytosolic gradient can be decoded by a bistable front of a RhoA regulator. In turn, this bistable front precisely positions RhoA by locally triggering excitable dynamics. We posit that this hierarchical coupling between a biochemical gradient and protein self-organization provides mechanochemical feedback for cell shape sensing and control.

Session B23 DBIO DSOFT: Cellular Biophysics: structure, mechanics, and dynamics

11:15AM B23.00001: “Cellular Stokesian Dynamics“: a computational model for biological cells

ROSEANNA ZIA (Presenter), DREW ENDY, AKSHAY MAHESHWARI, EMMA DEL CARMEN GONZALEZ GONZALEZ, ALP M SUNOL, Stanford Univ — The frontier in operational mastery of biological cells arguably resides at the interface between biology and colloid physics: cellular processes that operate over colloidal length scales, where continuum fluid mechanics and Brownian motion underlie whole-cell scale behavior. It is at this scale that much of cell machinery operates and is where reconstitution and manipulation of cells is most challenging. This operational regime is centered between the two well-studied limits of structural and systems biology: the former focuses on atomistic-scale spatial resolution with little time evolution, and the latter on kinetic models that abstract space away. Colloidal hydrodynamics modeling bridges this divide by unifying the disparate length and time-scales of solvent-molecule and colloidal dynamics, and may hold a key to numerous open questions in biological cell function. I will discuss our physics-based computational model of a biological cell, where biomolecules and their interactions are physically represented, individually and explicitly. With it, we study a model process: translation elongation. We find that Brownian self-diffusion alone is insufficient to recover experimentally measured elongation rates but accounting for other colloidal forces improves agreement.
11:27AM B23.00002: The roles of patchy attractions and Brownian motion in fundamental biological processes in a model cell* JENNIFER HOFMANN (Presenter), ROSEANNA ZIA, Department of Chemical Engineering, Stanford University — Microscopic forces and physical phenomena at the colloidal scale are involved with fundamental processes inside living cells [Maheshwari et al., Phys. Rev. Fluids, 2019]. Examples of such phenomena include Brownian motion, confinement within the boundary of a cell membrane or wall, and hydrodynamic & electrostatic interactions between constituents of the cellular milieu (e.g. proteins). In the case of electrostatic interactions, isotropic inter-particle potentials are often insufficient to reproduce experimental results due to anisotropic charge distributions on protein surfaces [Bucciarelli et al., Sci. Rep., 2018]. To connect these microscopic forces to whole-cell functions, we examine the interplay between these colloidal-scale phenomena in dynamic simulations. Specifically, we use coarse-grained, patchy simulations to study the biological process of translation elongation in a model prokaryotic cell. Here, we present our results investigating the structure and dynamics of these coarse-grained systems, probing the inseparable connection between colloidal-scale transport and biological function.

*The authors gratefully acknowledge funding through the NSF Graduate Research Fellowship Program and use of computing resources from the Stanford Research Computing Center.

11:39AM B23.00003: The structure of tubular organelle networks can accelerate diffusive transport and kinetics AIDAN BROWN (Presenter), ELENA KOSLOVER, University of California, San Diego — Diffusion is an important, and often dominant, mode of transport for molecules inside cells. Many cell processes occur within specialized organelles with a variety of internal geometries, notably the tubular networks of the endoplasmic reticulum and mitochondria, which form a complex meshwork of loops spanning much of the cell. We describe how the structure of these tubular network organelles controls diffusive search times and kinetic rates, using both analytical calculation and computational simulation of diffusive first-passage times on organelle structures extracted from yeast and mammalian cells. We find that total network length alone is not a good predictor of search time. However, total length combined with the number of loops robustly determines search times. Strikingly, increasing the number of loops substantially accelerates diffusive search and reaction kinetics. Mitochondrial mutant networks deficient in fusion and fission have many fewer loops than wild-type networks. By comparing these two network types we show wild-type networks can nearly double diffusive reaction rates for sparse reactants, compared to mutant networks. Overall, we find that the looped structure of organelle networks can function to accelerate diffusive processes.
11:51AM B23.00004: Elucidating mechanics of vascular regression in *Botryllus schlosseri* using image analysis* ROOPA MADHU (Presenter), Univ of Denver, DELANY RODRIGUEZ, CLAUDIA GUZIK, SHAMBHAVI SINGH, ANTHONY TOMASO, Department of Molecular, Cellular and Developmental Biology, University of California Santa Barbara, MEGAN VALENTINE, Department of Mechanical Engineering, University of California, Santa Barbara, DINAH LOERKE, Univ of Denver — Epithelial tubules form critical structures in various body tissues; however, due to experimental inaccessibility, their architecture and dynamics are not well understood. We examined epithelial tube remodeling in vivo using a novel model system: *Botryllus schlosseri* vasculature. In *Botryllus*, blood vessel retraction can be triggered through disrupting (i) collagen crosslinking in the basement membrane using β-aminopropionitrile (BAPN); or (ii) integrin pathway through inhibition of focal adhesion kinase (FAK)(Rodriguez D et al. 2017). We performed stereographic projections of 3-dimensional confocal scans to ‘unwrap’ the blood vessels to enable quantitative analysis of morphology. In normal vessels, the cells are axially elongated with circumferentially aligned actin bundles. While we found no differences in morphology between normal and BAPN treated vessels, FAK-inhibited vessels have significantly smaller cells with circumferential cell orientation. Our results demonstrate the feasibility of *Botryllus* for imaging-based studies of the mechanics of epithelial tube remodeling; in addition, they suggest a critical role of integrin in the maintenance of epithelial morphology.

12:03PM B23.00005: Vesicle formation processes on the Golgi significantly altered by overexpression - Duel FRAP investigation* GARETT C SAGER (Presenter), Physics, Univ of Alabama - Birmingham, ELIZABETH S. SZTUL, Cell, Developmental and Integrative Biology, Univ. of Alabama - Birmingham, RYOICHI KAWAI, Physics, Univ of Alabama - Birmingham — Overexpression of a target protein is commonly used in fluorescence-based experiments, such as fluorescence-recovery-after-photobleaching (FRAP), to boost the fluorescence intensity. Since the order of magnitude of protein concentration is artificially altered, the biochemical processes under investigation might be altered as well. We have studied how overexpression could affect the way we understand vesicle formation using FRAP experiments and kinetic Monte Carlo simulation based on continuous-time random walk. Specifically, we are investigating two proteins that are vital during initial vesicle formation on the Golgi (GBF1 and Arf1). Traditionally, either GBF1 or Arf1 would be overexpressed during FRAP, but we also performed dual FRAP where both proteins are overexpressed and measured simultaneously. Comparing the single versus dual FRAP measurements with the computer simulation and a simple mathematical model, we show a significant difference between the two cases. More importantly, the difference would affect the way vesicle formation is understood in cell biology. This shows overexpression can affect biochemical dynamics enough to alter our conclusion(s) from the data.

**12:15PM B23.00006: Probing force balance in the S. pombe mitotic spindle by laser ablation**

PARSA ZAREIESFANDABADI (Presenter), MARY ELTING, Physics, North Carolina State University — A microtubule-based machine called the mitotic spindle segregates chromosomes when eukaryotic cells divide. In the fission yeast *S. pombe*, which undergoes closed mitosis, the spindle forms a single bundle of microtubules inside the nucleus. During elongation, the spindle extends via antiparallel microtubule sliding by molecular motors. These extensile forces from the spindle resist compressive forces from inside the nucleus. We probe the source of this force balance via laser ablation of spindles at various stages of mitosis. We find that spindle pole bodies collapse toward each other following ablation, but that spindle geometry is often rescued, allowing spindles to resume elongation. While this basic behavior has been previously observed [1,2], many questions remain as to the timing, mechanics, and molecular requirements of these phenomena. Here, we quantify the time scales of both the relaxation and rescue responses and probe their molecular requirements. We test the possible mechanical roles of nuclear envelope-, centrosome- and microtubule-based forces.

**12:27PM B23.00007: Theoretical framework for the description of transmembrane receptor cluster coalescence in cells**

KATHRIN SPENDIER (Presenter), University of Colorado, Colorado Springs, VASUDEV M KENKRE, University of New Mexico — Moving boundary problems that appear in many fields of science are notoriously difficult to formulate and solve. Due to their complexity, approximation methods play an important role and are widely used to analyze such systems. We present an approximation method for moving boundaries or traps in reaction-diffusion processes that is applied to investigate coalescence of receptor clusters in mast cells. To handle the complexity, which stems from boundary growth due to particle melding, the study is divided into three parts. The first is about stationary trapping problems investigated by the standard defect technique, and the second is about a validity study of an adiabatic approximation for moving boundaries. In the last part, a coalescence theory is developed, which is based on a completely self-consistent approach. Finally, the developed theoretical framework is applied to study the kinetics of immunoglobulin E receptors (FcεRI) cluster coalescence in rat basophilic leukemia cells.
Animal cells and bacteria are enveloped and sealed by lipid membranes and mechanically protected by cortical polymer networks. Cells typically actively maintain a small (eukaryotic cells) or large (prokaryotic cells) positive osmotic pressure against their environment. Volume and shape regulation impact the mechanical properties of cells. The mechanical properties of cells can be probed by exerting external force and measuring cell response. To interpret micro-mechanical optical trapping experiments with suspended rounded eukaryotic cells, we developed finite element simulations and modeled cells as pressurized elastic shells. During deformation, competition between osmotic pressure resulting from compression of the cytosol and the elastic stretching of the actin cortex determines the cell response. The finite element simulations suggest that (eukaryotic) cell deformations are essentially isovolumetric.

When cells divide, a microtubule-based machine called the mitotic spindle delivers chromosomes to two new daughter cells. Microtubule bundles called kinetochore-fibers (k-fibers) attach chromosomes to the spindle, and forces transmitted through k-fibers ultimately segregate chromosomes. Thus, the mechanical integrity of the k-fiber is critical to accurate chromosome segregation, which in turn is essential for cell and organismal health. Yet, the k-fiber itself as a mechanical object is not well understood. We do not fully understand how or where k-fiber microtubules attach to each other along their lengths, nor what molecules mediate these connections. To address these questions, we are probing the mechanics of the k-fiber by severing it via laser ablation, and by using single-molecule speckle microscopy to analyze intra-k-fiber microtubule movements. Speckle microscopy suggests that k-fiber microtubules move poleward together as a single mechanical unit. However, splaying of the k-fiber in response to laser ablation demonstrates that these intra-k-fiber connections can be disrupted. Furthermore, initial evidence suggests more splaying after perturbation of the molecular motor kinesin Kif15, supporting its role as an inter-k-fiber crosslinker.
1:03PM B23.00010: 3D particle diffusion in Escherichia coli cells. [1] DIANA VALVERDE MENDEZ (Presenter), BENJAMIN P BRATTON, JOSEPH P SHEEHAN, ZEMER GITAI, JOSHUA SHAEVITZ, Princeton University — We use Genetically Encoded Multimeric nanoparticles (GEMs) to probe the microrheology of the Escherichia coli cytoplasm. We reconstruct three-dimensional trajectories from optical microscopy images obtained with a custom-built biplane microscope. The use of different sized GEM particles enables us to explore diffusion of objects ranging in size from 20 to 50 nm, similar in scale to ribosomes and other macromolecular complexes in the cell. We also vary the total charge of the fluorescent proteins from -17 e to +48 e and investigate the effect on diffusion. Using specific small molecule drug treatment, we show progress towards understanding the effects of the nucleoid and cell metabolic state on the 3D diffusion of particles inside bacterial cells.

*This work was supported by the NSF Center for the Physics of Biological Function PHY-1734030 CPBF.

1:15PM B23.00011: Opto-genetic control of gene regulation in living fly embryos[2] ANAND SINGH (Presenter), PING WU, ERIC WIESCHAUSS, JARED TOETTCHER, THOMAS GREGOR, Princeton University — Gene regulation is a hallmark of most processes in biology, in particular for cell fate decisions and patterning during early development of an organism. Precise and highly coordinated dynamic gene activity dictates the functional output in the context of complex genetic networks. In order to construct causal relationships in the programs underlying gene regulatory networks and transcription, we developed a light-inducible system to directly interfere with these programs and to quantitatively measure the cellular response in living fly embryos. Our approach allows us to precisely control transcription factor (TF) levels and their immediate response in gene expression. We show how nuclear concentration and TF residence times affect the kinetic rates and expression levels of downstream gene targets, and we test the limits of natural expression patterns by altering the shapes and strengths of the input patterns and measuring their genetic responses. The following questions will be asked: How cells utilize the differential levels of TF to make cell fate decisions? How do downstream genes respond to spatially and temporally modulated doses of TF input concentration?

NMR and small-angle neutron scattering examination of dynamics and structure in a polymer-colloid model system directed at understanding macromolecular crowding in cells

SWOMITRA PALIT, Physics & Physical Oceanography, Memorial University of Newfoundland, LILIN HE, Biology and Soft Matter Division, Oak Ridge National Laboratory, WILLIAM A HAMILTON, Instrument and Source Division, Oak Ridge National Laboratory, ARUN YETHIRAJ, Chemistry, University of Wisconsin - Madison, ANAND YETHIRAJ (Presenter), Physics & Physical Oceanography, Memorial University of Newfoundland — The inside of a living cell is crowded (30 - 40% volume fraction) with many macromolecular components, so that each individual macromolecule is not necessarily highly concentrated. This unique system calls for a colloidal perspective to tease out the competing roles of size, shape, flexibility, charge, hydrodynamic interactions, and chemical specificity.

In this work[1], we study long-time self diffusion (using pulsed-gradient NMR) and size (via small-angle neutron scattering) of a linear polymer, polyethylene glycol (PEG, radius of gyration $R_g$, and a more compact crowder (polysucrose, radius $R_c$) of varying size ratio $R_g/R_c$. We find that polymer diffusion exhibits a universal exponential concentration dependence at all polysucrose volume fractions, suggestive of an entropic origin[2]. The crowder exhibits reversible clustering at a volume fraction of 5 - 10%, depending on crowder charge. In the crowding limit, the flexible PEG is up to 100 times mobile than the compact Ficoll.

Analysis and simulations of Bcl10 self-assembly and degradation in activated T cells - LEONARD CAMPANELLO (Presenter), University of Maryland, College Park, MARIA TRAVER, BRIAN SCHAEFER, Uniformed Services University, WOLFGANG LOSERT, University of Maryland, College Park — The adaptive immune system serves as a potent and highly specific defense mechanism against pathogens. A component of this system, the effector T cell, provides rapid pathogen-clearing responses upon detecting pathogen-associated signals. Stimulation of the T cell receptor leads to a signaling cascade resulting in pathogen eradication. Bcl10, a key regulatory protein in this cascade, rapidly assembles into filaments that form the core of the signal transduction machinery; simultaneously, Bcl10 is targeted for slow degradation to ensure tight control of immune activation. Despite the importance of Bcl10 for an effective immune response, the mechanisms and timescales of its assembly and degradation are poorly understood. Here, we will provide insights into Bcl10 filament formation and degradation via image analysis and Monte Carlo simulations. Using image-based bootstrapping, we show that Bcl10 preferentially colocalizes with autophagosomes and that the spatial organization of this complex is significant for immune function. Using stochastic Monte Carlo simulations, we shed light on key Bcl10 filament dynamics, including nucleation, growth, and degradation. Together, these data provide key insights into important mechanism that regulate adaptive immunity.

Investigating the eukaryotic CO2-fixing phase-separated organelle, the pyrenoid - GUANHUA HE (Presenter), SHAN HE, MARTIN JONIKAS, NED WINGREEN, Princeton University — In most eukaryotic algae, an organelle called the pyrenoid helps concentrate CO2 to enhance carbon fixation by the enzyme Rubisco. We recently found that in Chlamydomonas reinhardtii, the pyrenoid has liquid-like behavior including rapid condensation and dissolution during cell division. Our data suggests that the matrix is primarily composed of Rubisco and a linker protein, EPYC1. Rubisco and EPYC1 each have multiple binding sites for the other, allowing the two proteins to form a multivalent phase separation system. We showed that Rubisco and EPYC1 are sufficient to phase separate in an in vitro reconstitution experiment. Here, we measure the phase boundary in terms of concentration of both proteins, which is in the uM range. We use microscale thermophoresis (MST) to determine the dissociation constant (Kd) of EPYC1-Rubisco binding. And we use fluorescence correlation spectrometer (FCS) to determine the protein particle sizes. Combined together, our results suggest the existence of small oligomer complexes composed of EPYC1 and Rubisco in the dilute phase. Our work reveals that the stoichiometry of oligomer complexes is a key factor that regulates phase separation, which might be a general principle in multivalent phase separation system in biology.

2:03PM B23.00015: Dynamics of Self-Organized Organelle Transport in a Developing Macroscopic Single-Celled Organism*  
ELDAD AFIK (Presenter), Division of Biology and Biological Engineering, California Institute of Technology, ELLIOT M. MEYEROWITZ, Howard Hughes Medical Institute, California Institute of Technology — Caulerpa is a marine green alga exhibiting differentiated organs resembling leaves, stems and roots; while individuals can exceed a meter in size, each one is comprised of a single multinucleated giant cell. Thus, according to current understanding, the distinction between the cellular and organismal levels in Caulerpa does not exist. In turn, this challenges our intuition that morphogenesis on large scales necessitates division into cells. It has been hypothesized that active transport plays a key role in the development of the alga. Yet, the most recent reports studying organelle transport in Caulerpa are over three decades old. We have designed an imaging system based on the affordable Raspberry-Pi and its camera module. The system allows us to track over weeks the morphogenesis of tens of samples in parallel, each one in a separate well. Our observations of chloroplasts redistribution on whole-organism scales over hours reveal a pulse-like behavior. We further explore this macroscopic manifestation of the self-organized transport through perturbations, such as alternating illumination protocols and application of an external electric field. In this work we seek to establish a framework to study the dynamics of homeostasis and its stability.

Session B24 GSNP: Systems Far from Equilibrium 401 - John Bechhoefer, Simon Fraser University

11:15AM B24.00001: Thermodynamic uncertainty relations and fluctuation theorems for Bayes nets*  
DAVID WOLPERT (Presenter), Santa Fe Inst — The pioneering paper [1] analyzed the non-equilibrium statistical physics of a set $S$ of multiple interacting systems whose joint discrete-time evolution is specified by a Bayesian network. Their major result was an integral fluctuation theorem (IFT) governing the sum of two quantities: the entropy production (EP) of an arbitrary single one of the systems, $v \in S$, and the transfer entropy from $v$ to the other systems in $S$. Here I derive a detailed fluctuation theorem (DFT) for an arbitrary subset of the systems in $S$ (including the full set). I then derive an IFT for an arbitrary subset of the systems in $S$, extending the IFT in [1]. I also derive thermodynamic uncertainty relations for the precision of probability currents among joint states of the systems, and for the precision of the work performed by the full set of systems. Rather than the EP generated by a single system in $S$ and the transfer entropy from it to the other systems, these results involve the sum of the EPs generated by all of the systems in $S$ and the change in the multi-information of the joint system as it evolves.

A characteristic feature of nonequilibrium steady states is their ability to maintain nonzero fluxes in steady state. Here I will discuss mass fluxes in a class of nonequilibrium systems characterized by driving at the level of individual particles. By constructing an explicit mathematical representation of the full nonequilibrium steady state, I am able to quantitatively connect mass fluxes in the bulk with the boundary conditions. In particular, the emergence of nonzero mass fluxes is tied to the breaking of detailed balance at the boundaries.

We acknowledge support from the Brandeis Center for Bioinspired Soft Materials, an NSF MRSEC, DMR-1420382 (CGW, AB, MFH), NSF DMR-1149266 and BSF-2014279 (CGW and AB), and DMR-1855914 (MFH). Computational resources were provided by the NSF through XSEDE computing resources (MCB090163) and the Brandeis HPCC which is partially supported by the Brandeis MRSEC.

We introduce a new technique to bound the fluctuations exhibited by a physical system, based on the Euclidean geometry of the space of observables. Through a simple unifying argument, we derive a sweeping generalization of so-called Thermodynamic Uncertainty Relations (TURs). We not only strengthen the bounds but extend their realm of applicability and in many cases prove their optimality, without resorting to large deviation theory or information-theoretic techniques. In particular, we find the best TUR based on entropy production alone and also derive a novel bound for stationary Markov processes, which surpasses previous known bounds. Our results derive from the non-invariance of the system under a symmetry which can be other than time reversal and thus open a wide new spectrum of applications.

Project NanoThermo ERC-2015-COG agreement no. 681456 and FNR INTER mobility program.
**11:51AM B24.00004: Non-Gaussian diffusion and energy balance of a Brownian particle in active baths**  
JIN TAE PARK (Presenter), Department of Physics, Ulsan Natl Inst of Sci & Tech, GOVIND PANERU, Center for Soft and Living Matter, Institute for Basic Science, CHULAN KWON, Department of Physics, Myongji University, STEVE GRANICK, HYUK KYU PAK, Center for Soft and Living Matter, Institute for Basic Science — We present a minimal model to generalize the iconic feature of active matter that Brownian particles diffusing in a harmonic potential are kicked by external forces to engender mobility beyond that attributable to thermal energy. The wide time and length scales of usual active matter systems are mapped onto the generic concept of a single Brownian diffusion time (a particle diffusing in a harmonic potential) and kicks from external forces that arrive at random intervals with a defined, programmable, duration time for each kick. Our experiments using an optical trap agree in showing enhanced diffusion that is Gaussian only if the kick duration time is larger than the Poisson interval time. In addition, we conclude that maximum energy dissipation occurs at the time-scale of the geometric mean of the kick duration time and the particle thermal equilibration time. Usual active matter systems do not allow this independent variation of thermal motion, active motion, and the relative time scales of both. In this streamlined system they are varied independently, allowing one to rapidly prototype the limits of various stochastic thermodynamic models.

**12:03PM B24.00005: Periodic driving in a two-dimensional Brownian ratchet**  
TODD GINGRICH (Presenter), NILS STRAND, RUEIH-SHENG FU, Northwestern University — Brownian dynamics on a fixed potential landscape generates no steady-state current, but currents can be obtained by periodically switching between multiple landscapes. Even more interesting than the existence of such ratcheted currents is that the direction of the current can depend on the frequency of the switching. I will present numerical work on the behavior of current reversals in a two-dimensional system. I will discuss our efforts to make sense of the system by conditioning a time-periodic Markov process for a coarse-grained model. Interestingly, the low-frequency asymmetry between leftward and rightward motion appears at the level of typical events, but the high-frequency asymmetry only emerges for atypical events.
12:15 PM B24.00006: Equation of State for a Far-from-equilibrium Thermodynamic System with Emergent Scales at Steady-state  ATANU CHATTERJEE (Presenter), GERMANO SIANNACCHIONE, Department of Physics, 100 Institute Road, Worcester Polytechnic Institute — One of the hallmarks of soft-condensed matter systems is their ability to exhibit emergent order - spanning a wide range of length and time-scales - when driven out-of-equilibrium. Some of these patterns emerge and disappear at sub-nanosecond scales while some are large enough that they can be physically measured. We present a field theoretic formalism by defining the Lagrangian density as a function of a generic thermodynamic scalar. Our definition of the thermodynamic Lagrangian density involves two components, the internal work or the coherent part which gives rise to emergent order, and the internal dissipation or the incoherent part which acts as the internal sink. The salient feature of this formulation is that it takes into account the spatial and temporal gradients of the generic thermodynamic scalar as the system is driven out-of-equilibrium. On minimizing the action and solving the Euler-Lagrange equations, we obtain a generalized thermodynamic equation of state.

12:27 PM B24.00007: Thermodynamic Analysis of Non-Ergodic and Asymmetric Dimension  YU QIAO (Presenter), University of California, San Diego — We report an interesting Monte Carlo simulation result of a Billiard-type model system, wherein two larger ergodic areas are separated by a small non-ergodic barrier. The two ergodic areas have different heights in a gravitational field. In-plane pressure does work to the lower “plain” when the plain area varies, and gravitational force does work to the upper “plateau” when the plateau height changes. The steady-state is defined by the macroscopic variables measured from the system surface. The simulation results indicate that the particle density ratio spontaneously follows a non-Boltzmann distribution and remarkably, in an isothermal cycle the produced work is significantly greater than the consumed work. The non-ergodic barrier, referred to as the non-ergodic and asymmetric dimension (NEAD), is not “Maxwell's demon”. Its operation does not require detailed knowledge of system microstate. The particle motion is unmonitored, unforced, and random. The explanation of the system performance should be unrelated to the physical nature of information. The concept of NEAD is also being investigated experimentally, through the measurement of the cross-influence of chemical potential and electric potential of large ions confined in small nanopores.

12:39 PM B24.00008: Bounds on current fluctuations for periodically driven systems  KAREL PROESMANS (Presenter), Simon Fraser Univ — The thermodynamic uncertainty relation, in its original form, bounds the amount current fluctuations can be suppressed in terms of the dissipation in a mesoscopic steady-state system. We extend such bounds to systems with time-periodic driving, where they lead to a bound for the hysteresis of any thermodynamic flux. Our results are illustrated on the work fluctuations of an expanding gas.
12:51PM B24.00009: Entropy production bounds under Hamiltonian and rate matrix constraints* ARTEMY KOLCHINSKY (Presenter), DAVID WOLPERT, Santa Fe Inst — Entropy production (EP) is a fundamental measure of the thermodynamic inefficiency of a physical process. If there are no constraints on the rate matrices and Hamiltonians available to a driving protocol, one can transform a system from any initial Hamiltonian and state distribution to any final Hamiltonian and state distribution with zero EP. We investigate the minimal EP that must be incurred to implement such a transformation, if there are constraints on the set of allowed Hamiltonians and rate matrices. Our first result is that zero EP can be achieved even when the Hamiltonian has only a single controllable degree of freedom, as long as there are no constraints on the rate matrix (beyond detailed balance). We then derive non-trivial bounds on the EP that arise from the presence of simultaneous constraints on the Hamiltonian and the rate matrix. These bounds are determined by an effective non-equilibrium free energy, which reflects the work value of a distribution and Hamiltonian under a set of constraints.

1:03PM B24.00010: Pre-Cooling Strategy Can Generate Exponentially Faster Heating* OREN RAZ (Presenter), AMIT GAL, Weizmann Institute of Science — What is the fastest way to heat a system which is coupled to a temperature controlled oven? The intuitive answer is to use only the hottest temperature available. However, we show that in some cases it is possible to achieve an exponentially faster heating, and propose a strategy to find the optimal protocol. Surprisingly, this protocol can have a pre-cooling stage: cooling the system before heating it shortens the heating time significantly. This approach can be applied to many-body systems, as we demonstrate in the 2D antiferromagnet Ising model.

1:15PM B24.00011: The solution of the Metropolis dynamics on a complete graph with applications to anomalous thermal relaxations* MARIJA VUCELJA (Presenter), ISRAEL KLIICH, Univ of Virginia — We find analytically the complete set of eigenvalues and eigenvectors associated with Metropolis dynamics on a complete graph. As an application, we use this information to study an unusual relaxation phenomenon, called the Mpemba effect. This effect describes situations when, upon performing a thermal quench, a system prepared in equilibrium at high temperatures relaxes faster to the bath temperature than a system prepared at a temperature closer to that of the bath.

1:27PM B24.00012: Out-of-equilibrium chemical networks: dissipation shapes selection

DANIEL MARIA BUSIELLO (Presenter), SHILING LIANG, PAOLO DE LOS RIOS, Ecole Polytechnique Federale de Lausanne — Life has most likely originated as a consequence of processes taking place in non-equilibrium conditions (e.g. in the proximity of deep-sea vents) selecting states that would have been otherwise unfavorable at equilibrium. Here we present a simple chemical network in which the selection of states is driven by the dissipation rate, as previously suggested in the literature: states participating to faster reactions dissipate faster and are the most populated ones in non-equilibrium steady-state conditions. Building upon these results, we show that, as the complexity of the chemical network increases, the velocity of the reaction path leading to a given state determines its selection, giving rise to phenomena of global localization in state space. A byproduct of our studies is that, in the presence of a temperature gradient, thermophoresis-like behavior inevitably appears depending on the transport properties of each individual state, thus hinting at a possible microscopic explanation of this intriguing and long-standing phenomenon.

1:39PM B24.00013: Isometric uncertainty relations

HADRIEN VROYLANDT (Presenter), Northwestern University, KAREL PROESMANS, Simon Fraser University, TODD R GINGRICH, Northwestern University — We generalize the link between fluctuation theorems and thermodynamic uncertainty relations by deriving a bound on the variance of fluxes that satisfy an isometric fluctuation theorem. The resulting bound, which depends on the system's dimension $d$, naturally interpolates between two known bounds. The bound derived from the entropy production fluctuation theorem is recovered for $d=1$, and the original thermodynamic uncertainty relation is obtained in the $d \to \infty$ limit. We show that our result can be generalized to order parameters in equilibrium systems, and we illustrate the results on a Heisenberg spin chain.

1:51PM B24.00014: Quantum Thermodynamics of a Spin one System

MULUGETA BEKELE (Presenter), Addis Ababa Univ — We take a collection of large non-interacting spin one particles, each having an electric dipole of magnitude $m$ in contact with a heat reservoir at temperature $T$. We apply a strong static electric field, $E_z$, to the system along a $z$-axis causing three level split energy values. In addition to the strong electric field, we apply a weak AC electric field in the $xy$-plane. This weak field induces transitions between the three levels. Through a given protocol $\lambda(t)$, the system is taken from an initial state $F(T,\lambda_i)$ to a final non-equilibrium state with parameter $\lambda_f$. We analytically obtain the expressions for the probability amplitudes for a transition from one particular initial state to the other two final states. This will enable us to find the work distributions of a finite-time process of taking the system from one initial state to other final states. This finite-time non-equilibrium process will then enable us to extract equilibrium thermodynamic quantities like free energy from non-equilibrium process, which is what we call Jarzanski equality and its relation to the second law of thermodynamics.

B24.00015: Stochastic Thermodynamics with both Even and Odd Controlling Parameters*  
ZHANCHUN TU (Presenter), Beijing Normal Univ — Shortcuts to isothermality inspired development of stochastic thermodynamics with both even and odd controlling parameters, was developed to understand nonequilibrium phenomena of small systems. It is found that the definition of heat and the microscopically reversible condition are incompatible for small systems with odd controlling parameters. Such a contradiction also leads to a revision to the fluctuation theorems and nonequilibrium work relations. By introducing adjoint dynamics, we find that the total entropy production can be separated into three parts, with two of them satisfying the integral fluctuation theorem. Revising the definition of heat and the microscopically reversible condition allows us to derive two sets of modified nonequilibrium work relations, including the Jarzynski equality, the detailed Crooks work relation, and the integral Crooks work relation.

Session B25 GSNP DPOLY: From Responsive Matter to Actuated Structures 402 - Dong Yan, Ecole Polytechnique Federale de Lausanne - Tag(s): Focus

11:15AM B24.00001: Decentralized reinforced learning of emergent behavior in robotic matter [Invited]  
GIORGIO OLIVERI, LUUK CAROLUS VAN LAAKE, JOHANNES OVERVELDE (Presenter), AMOLF — Soft robots have the potential to be more robust, adaptable, and safer for human interaction than traditional rigid robots. State-of-the-art developments push these soft robotic systems towards applications such as rehabilitation and diagnostic devices, exoskeletons for gait assistance, and grippers that can handle delicate objects. However, despite these exciting developments, their inherent non-linear response limits the number of actuators that can be accurately controlled simultaneously, especially in complex or unknown environments. To enable modularly scalable and autonomous soft robots we have developed a new type of soft robot that is assembled from identical 1D building blocks with embedded pneumatic actuation, position sensing and computation. In this robotic system, motility might emerge from local interactions, rather than from a central brain. Here we shows that we are able to implement decentralized learning in this system. Using a stochastic optimization approach, each building block individually adjusts its actuation phase continuously, in order to find the fastest way to move in a predefined direction. We show that even for larger number of modules, this robotic system is still capable of learning. As a result, the system is robust to damage, as it will adjust its behaviour accordingly.
11:51AM B25.00002: Collective behavior of BOBbots, a robotic active matter system
SHENGKAI LI (Presenter), BAHNISIKHA DUTTA, DANA RANDALL, DANIEL I GOLDMAN, Georgia Inst of Tech — We introduce BOBbots (Behaving, Organizing, Buzzing Robots, named to honor the late Bob Behringer), a custom low-cost active matter system composed of disk-shaped “granular” robots. The robots are equipped with controllable vibration that can react to light and stress. The vibration couples to two bristles on the base of the robot which generates translation and rotation. The robots can attract each other via loosely constrained magnets in cavities on a robot's circumference. We first investigate the clustering of the collective which results from a competition between the attraction and driving. In experiments and discrete element method simulations, increasing magnet strength leads to a rapid increase in steady-state cluster size which saturates for sufficient attraction. The dynamics of this nonequilibrium system resemble those in an equilibrium lattice model. An algorithm by which robots decrease drive upon increased stress increases clustering rate at fixed magnet strength. Formation of clusters enables the collective to perform a task no individual can: transport of a free obstacle.

12:03PM B25.00003: Smarticle glider: Locomoting, spontaneous excitations in a shape changing active matter system* AKASH VARDHAN (Presenter), SHENGKAI LI, Physics, Georgia Institute of Technology, YUNBO ZHANG, Computer Science, Georgia Institute of Technology, KURT A WIESENFELD, DANIEL I GOLDMAN, Physics, Georgia Institute of Technology — Smarticles or smart active particles are 3 link robots which change their shape periodically through the actuation of the arms. Limited individually in their ability to translate or rotate in the current experimental setting, they exhibit interesting collective behavior (directed locomotion) as a result of stochastic mechanical interactions (W, Savoie et al., Science Robotics 2019). The glider, which is a two smarticle bound excitation, is the fundamental building block for these phenomena. It has a lifetime of about 90 periods and moves about 4 body lengths before dissociating. We seek to understand the mechanistic principle behind the creation of these states and their ensuing dynamics with an iterative map. Simulations reveal that for these excitations to locomote, there must be fluctuations in the coefficient of friction. Since the smarticles only interact with each other via collisions, gliders are essential to keep a cloud of smarticles connected and hence harness their collective behavior.

12:15PM B25.00004: Photothermal actuation of a fluidic soft muscle*  LUKE GOCKOWSKI
(Presenter), Department of Mechanical Engineering, University of California, Santa Barbara, SERENA
SESHADRI, Department of Chemistry, University of California, Santa Barbara, JAEJUN LEE, Department of
Mechanical Engineering, University of California, Santa Barbara, MIRANDA SRODA, Department of
Chemistry, University of California, Santa Barbara, MATTHEW HELGESON, Department of Chemical
Engineering, University of California, Santa Barbara, JAVIER READ DE ALANIZ, Department of Chemistry,
University of California, Santa Barbara, ELLIOT W. HAWKES, MEGAN VALENTINE, Department of
Mechanical Engineering, University of California, Santa Barbara. — Despite innovations in materials and
fabrication schemes that have enabled impressive soft robotic structures and devices, most soft
robots remain tethered to cumbersome power sources (e.g., compressed gas) and/or require
unwieldy valving. Developing soft robots capable of untethered actuation and remote control
requires new methods of actuation. Compared to conventional power and control, visible light
offers several advantages—including wireless remote control, spatial (~200 nm) and temporal
(~ms) precision, and tunability (e.g., wavelength, intensity). Here, we exploit a novel class of
photoswitches, donor-acceptor Stenhouse adducts (DASAs), for the remote actuation of soft
muscles. Guided by studies of DASA’s unique photoswitching and photothermal properties, we
achieve the remote actuation of a soft muscle via controlled photothermal phase changes
without valves or internal controls. Further, we demonstrate the force output of this muscle and
its promise for actuation in multi-scale soft robots.

Programmable Photothermal Actuation using Novel Negative Photochromic Donor-Acceptor Stenhouse Adduct (DASA) Polymers* JAEJUN LEE (Presenter), Department of Chemistry, Department of Mechanical Engineering, University of California at Santa Barbara, MIRANDA SRODA, Department of Chemistry, University of California at Santa Barbara, YOUNGHOON KWON, Department of Mechanical Engineering, University of California at Santa Barbara, SARA EL-ARID, SERENA SESHADRI, Department of Chemistry, University of California at Santa Barbara, LUKE GOCKOWSKI, ELLIOT W. HAWKES, Department of Mechanical Engineering, University of California at Santa Barbara, JAVIER READ DE ALANIZ, Department of Chemistry, University of California at Santa Barbara, MEGAN VALENTINE, Department of Mechanical Engineering, University of California at Santa Barbara — Light-driven actuation has significant advantages including untethered operation, precise spatiotemporal activation, and the ability to operate in complex surroundings without significant modification. Here, we use a new class of molecular photoswitches, called donor-acceptor Stenhouse adducts (DASAs), to generate a novel but conceptually simple photoresponsive polymer bilayer actuator, capable of repeatedly lifting a load against the force of gravity. We will present a synthesis pathway for chemically attaching DASA conjugates to poly(hexyl methacrylate) through norbornadiene click chemistry, and will demonstrate actuator performance. Importantly, we can leverage the different time scales of photothermal and photochemical responses of DASAs to achieve dynamic material control, including the ability to switch on and off actuation. Our results highlight the promising benefits of high molar absorptivity, negative photochromism, and visible light absorption of DASAs for actuation.

The realm of magnetorheological elastomers: experiments, theory and instabilities

KOSTAS DANAS (Presenter), CNRS, Ecole Polytechnique — In this talk, I will present a broad overview of our work on magnetorheological elastomers (MREs) including experiments, theory and numerical implementation. MREs are composite materials comprising metallic soft (e.g. iron) or hard (e.g. NdFeB) magnetic micron-sized particles. The latter have been called h-MREs. Out of these materials one can devise a number of interesting meso- and macrostructures, slender or not that can lead to a number of functionalities such as surface patterning, negative or positive swelling, network activation, negative Poisson ratio, evolving anisotropic magnetic properties, hierarchical buckling and others. The main idea lies in the ability to drive the systems by using two external loads, i.e. mechanical and magnetic ones and in particular to harness the resulting instabilities that are natural in magnetic structures. This allows, in turn, to reach a critically stable state by applying one of the fields (e.g. mechanical) and trigger patterning and instabilities at low energetic cost with the other (e.g. magnetic). As an example, we will discuss in more detail a recently obtained pattern, called crinkling. This pattern appears in slender magnetic structures such as MRE films bonded to soft (non-)magnetic substrates that are subjected to a combination of mechanical pre-compression and transverse to the film magnetic loads. In particular, the initial wrinkles evolve into crinkles, a bifurcation mode that is defined by the accompanied curvature localization and significant shearing of the side faces of the wrinkled geometry. Interestingly, the presence of the magnetic field prohibits the formation of creases and folds. The presentation will close with recent results on h-MREs and their potential ability to lead to unconventional responses mechanically and magnetically.

*ERC Starting Grant MAGNETO

Understanding the kinetic arrest in deswelling microgels

SVETOSLAV NIKOLOV, ALBERTO FERNANDEZ-NIEVES, ALEXANDER ALEXEEV (Presenter), Georgia Inst of Tech — Biofriendly microgels, like PNIPAM and dextran, find numerous applications as microscopic delivery agents for advanced therapies of cancer, diabetes, and bacterial infections. We use mesoscale computer simulations to model the deswelling kinetics of spherical microgels. Deswelling occurs as the result of gel-solvent phase separation, leading to the hydrogel network collapse and in certain conditions, to the formation of a dehydrated “skin layer” at the gel-solvent interphase. This dehydrated skin layer hinders solvent flow from the microgel interior which arrests the kinetics of the collapsing microgel. We examine the conditions at which the skin forms and probe how these conditions depend on the microgel size, porosity, and micromechanics. These findings can be useful for designing microgel based drug release systems with controlled release profiles, leading to more effective disease treatments.

1:27PM B25.00008: Tunable buckling strength of magnetically active elastomeric shells
DONG YAN (Presenter), MATTEO PEZZULLA, Ecole Polytechnique Federale de Lausanne, LILIAN CRUVEILLER, Ecole Polytechnique, PEDRO REIS, Ecole Polytechnique Federale de Lausanne — It has long been recognized that the buckling of shell structures is highly sensitive to material or geometric imperfections, leading to observed critical loads that are significantly lower than classic predictions. In this class of problems, the knockdown factor is defined as the ratio between the experimentally measured critical load and the classic theoretical prediction. This knockdown is typically regarded as an intrinsic property of the structure since the type and distribution of defects are encoded into the shell during fabrication. Here, we demonstrate the ability to actively tune the knockdown factor of pressurized spherical shells. We fabricate our spherical shells with a magneto-rheological elastomer (MRE) using a coating technique. The shells are first magnetized and then loaded by pressure under a uniform magnetic field. We find that, by adjusting the strength and polarity of the field, the knockdown factor of the magnetically active shells can be increased or decreased up to a maximum change of 30%. As such, we can externally tune their intrinsic buckling strength, on-demand. An axisymmetric shell model is used to rationalize the experimental results on how the magnetic field interacts with the buckling of imperfect shells.

1:39PM B25.00009: Tailoring magneto-mechanical properties of NdFeB particle-filled soft elastomers*
DIPAYAN MUKHERJEE (Presenter), KOSTAS DANAS, LMS, CNRS, Ecole Polytechnique — This work investigates the possibilities of tailoring the magneto-mechanical properties of hard (permanent) magnetic NdFeB particle-filled soft magnetorheological elastomers by proposing novel microstructures. Our numerical computations for the mechanical response of various regular and chiral unit cells with a permanently magnetized elliptic inclusion show distinct features depending on the aspect ratio and the orientation of the inclusion. It is observed that the mechanical deformations are selectively preferred at certain directions, which make the magnetic inclusions align themselves along their easy axes, reducing the net magnetic moment. In particular, for the microstructural orientation angle of 30-60 degrees, the simple shear mode is observed to facilitate easy magnetic alignments and thus becomes energetically favorable over the uniaxial tension/compression mode. Moreover, the overall (effective) magnetic coercivity of these composites are found to reduce considerably with a softer elastomeric matrix, which, in turn, facilitate easy particle alignments.

*This work is supported by the European Research Council (ERC) grant agreement no. 636903—MAGNETO.
Magnetically triggered thin-film instabilities for surface pattern control*  
MATTHIAS RAMBAUSEK (Presenter), KOSTAS DANAS, Ecole Polytechnique — The study under consideration is concerned with instabilities of a thin magnetic film attached to a soft (magnetic) substrate under general biaxial precompression and transverse magnetic fields leading to complex two-dimensional surface patterns. This study builds upon previous experimental work on one-dimensional surface patterns through magneto-elastic loading. Our findings contribute a key ingredient for the design of haptic displays and more general applications of surface actuation. For the characterization of the instabilities of interest we conduct numerical studies using finite-element and Fourier discretizations for a wide range of in-plane prestresses and applied magnetic field. By virtue of these results we obtain stability maps which are an important input for subsequent numerical and experimental studies in the post-buckling regime.

Session B26 DBIO DSOFT DFD DPOLY: Mechanics of Cells and Tissues Across Scales II

Force generation and self-organization in mitosis* [Invited]  
MEREDITH BETTERTON (Presenter), University of Colorado, Boulder — Life on earth depends on cells’ ability to duplicate. In order to divide successfully, cells must solve fascinating physics problems. A key step in cell division is ensuring that each of the daughter cells inherits a single copy of the genetic material. In eukaryotes, a self-organized machine called the mitotic spindle physically move the chromosomes. The spindle is composed of microtubules, molecular motors, and associated molecules. We are using theory, simulation, and experiment to understand how the mitotic spindle self-assembles and achieves the correct size, and how the spindle organizes and moves chromosomes. This talk will discuss how force is generated by motors, crosslinkers, and chromosomes over time during mitosis to correctly assemble the spindle. Depending on the dynamics of spindle molecules and microtubule-chromosome attachments, overall spindle length can be relatively constant in time, or undergo large fluctuations. I will explain our current understanding of spindle length stabilization.

11:51AM B26.00002: Intrinsic time-scales of active forces control the dynamics of soft living matter  GRZEGORZ GRADZIUK (Presenter), GABRIEL TORREGROSA CORTÉS, CHASE BROEDERSZ, Ludwig Maximilian University of Munich — Living cells are crowded with active agents which consume energy and perform work on their surrounding environment, constantly keeping the system out of thermodynamic equilibrium. These locally exerted active forces are propagated to larger distances by the cytoskeleton and the cytoplasm. Such activity is believed to play an important role in vital intracellular processes such as transport. The active agents involved in these processes - molecular motors - are characterized by their intrinsic correlation time, typically of the order of seconds. While the significance of these correlation times is not well understood, we argue that they may be tuned to improve the efficiency of particular processes taking place in the cell. We investigate this by analyzing a model comprised of elastic network embedded in a viscous fluid and driven by a collection of stochastic, time-correlated forces. We show how the interplay between the correlation times of the active agents and the relaxation times of the system can lead to qualitatively different behaviors at different length scales.

12:03PM B26.00003: Mechanical properties of intermediate filament networks under compression*  BOBBY CARROLL (Presenter), MAHESH CHANDRASEKHAR GANDIKOTA, Syracuse University, IMAN ELBALASY, JOERG SCHNAUSS, JOSEF A. KAS, Leipzig University, JENNIFER SCHWARZ, ALISON PATTESON, Syracuse University — Cell motility is a fundamental process that contributes to building and maintaining tissues as well as the progression of diseases such as fibrosis and cancer. The material properties of cells and tissues are a central feature of this process. The mammalian cytoskeleton is made up of a network of (semi-)flexible biopolymers, including actin, microtubules, and intermediate filaments. While the mechanical responses of fibrous biopolymer networks to shear deformation have been studied in great detail, their response to uniaxial loading remains poorly understood. Here, we study the mechanical response of reconstituted polymer networks comprised of the intermediate filament proteins vimentin and keratin using a parallel-plate rheometer. Our results indicate that reconstituted vimentin and keratin networks stiffen under axial compression, with cation concentration mediating network crosslinking. This stiffening contrasts with other biopolymer networks which compression soften but coincides with the compression stiffening behavior of cells themselves. These results motivate future work in cytoskeletal mechanics as well as the general phenomenon of compression stiffening in biopolymer environments.

*We acknowledge partial support from NSF award number DMR-1832002.
12:15PM B26.00004: Cytoskeletal Regulation of Three-Dimensional Epithelial Cell Shape*
THERESA CHMIEL (Presenter), MARGARET GARDEL, University of Chicago — Three-dimensional force distribution within the actin cytoskeleton of epithelial tissue regulates cell shape. While two-dimensional cell shape has been well characterized and heavily studied, three-dimensional cell shape regulation is less well understood despite its critical role in large scale epithelial processes such as invagination. By examining the relationship between cell height, density and biological components of the actin cytoskeleton, we explore the mechanisms by which epithelial cells regulate shape and volume. We observe that while cell density is not a strong indicator of epithelial height, osmotic shock drastically decreases both tissue height and cell volume while leaving the lateral shape of cells in the tissue undisturbed.

12:27PM B26.00005: Physical limits to sensing material properties*
FARZAN BEROZ (Presenter), Univ of Michigan - Ann Arbor, DI ZHOU, Georgia Institute of Technology, XIAOMING MAO, DAVID LUBENSKY, Univ of Michigan - Ann Arbor — Constitutive relations describe how materials respond to external stimuli such as forces. All materials respond heterogeneously at small scales, which limits what a localized sensor can discern about the global constitution of a material. In this talk, I will present the limits to the precision of such constitutional sensing for sensors embedded in disordered media. Our results reveal how one can construct microscopic devices capable of sensing near these physical limits, e.g. for medical diagnostics. I will show how our theoretical framework can be applied to an experimental system by estimating a bound on the precision of cellular mechanosensing in a biopolymer network.

*This work was supported in part by the National Science Foundation Grants DMR1056456 (to D.K.L.), DMR 1609051 (to X.M.), EFRI-1741618 (to D.Z. and X.M.), a Margaret and Herman Sokol Faculty Award (to D.K.L.), and a Michigan Life Sciences fellowship (to F.B.).
The shape of an adherent cell spread on a surface depends upon the biophysical properties of the cytoskeleton. However these are controlled by biochemical circuits and ultimately by gene expression. While shape of a single cell is dynamic, enough evidence has accumulated that cells in the same state adopt shapes that are, in a statistical sense, similar to each other, and distinguishable from cells in different states. If we could understand the major determinants of cell shape, we may be able to infer aspects of cell state merely by observing cell shape. We have imaged thousands of cells in different experimental conditions and have developed a large number of morphological parameters to quantify cell shape and cytoskeletal morphology. Using these we show that quantifiers of cell shape and cytoskeletal texture can be used to discriminate between different cell states. Projections of the data to lower-dimensional shape space can be used to distinguish between similar and dissimilar changes in shape. Pharmacological drugs that perturb the cytoskeletal can help to identify some of the biochemical circuits that control cell shape. Linking results of our experiments and data analysis with previous molecular biology studies on cytoskeletal proteins that affect cell shape, coupled with mathematical modeling, allow us to deconstruct some of the determinants of cell shape.

*NSF PHY-1151454

During cancer cell migration, cells on a 2D surface experience uniform mechanical cues whereas in a fibrous 3D environment there exists heterogeneity at cellular and sub-cellular levels, leading to dramatically different invasion strategies. Here, we physically characterize morphodynamics (the temporal fluctuations of cell shape) rather than real-space migration alone. By studying morphodynamics, we show that 3D cell migration is accompanied by spontaneous and rapid shape changes regulated by the extracellular matrix (ECM), in contrast to 2D migration. We employ machine learning to classify cell shape into five different morphological phenotypes corresponding to different migration modes. We systematically characterize the phenotype evolutions including occurrence probability, dwell time, transition flux, and 3D migrational characteristics. By tuning ECM density, pore-size, and fiber-alignment, we show local mechanical influence on migration mode switching. We find mechanosensing mediated by rho-signaling is important to the resultant morphodynamics. We demonstrate cell morphodynamics as an information-rich biomarker that is directly regulated by cell mechanosensing and contributes critically to the cell motility.

Switching between optimum substrate rigidity and focal adhesion reinforcement at the cell leading edge  

PARTHO SAKHA DE (Presenter), RUMI DE, IIISER Kolkata — It’s well known that substrate mechanical properties strongly influence cell behaviour and fate. There exists two well documented but contrasting responses of cells to substrate rigidity, namely the biphasic and the monotonic relationship of traction force and retrograde flow velocity with substrate stiffness. We have developed a theoretical model for the dynamics at the leading edge of a cell placed on a viscoelastic substrate, involving a pair of coupled reaction-diffusion equations. Motivated by experiments, the association and dissociation rates of focal adhesions are taken to be force dependent. Our model not only captures the experimentally observed stick-slip dynamics at the cell edge, but also can predict switching between both the biphasic relationship i.e. the presence of an optimum substrate stiffness where the retrograde flow is minimum and traction force is maximum; and the monotonic relationship between retrograde flow, traction force and substrate stiffness. Besides, our theory also elucidates the role played by substrate viscosity, predicts the presence of optimum viscosity as well as states the condition under which cellular rigidity sensing is lost.

Stick-slip dynamics of migrating cells on viscoelastic substrates

Mechanics of endocytosis under large osmotic pressure*  
RUI MA (Presenter), JULIEN BERRO, Molecular Biophysics and Biochemistry, Yale University — In this talk, I will discuss membrane deformations powered by a point force under the condition of high pressure and low tension, which is rarely studied but directly relevant for endocytosis in yeast cells with a cell wall. I will show that the force-height relationship of membrane deformations under this condition is drastically different from that under conditions of high tension and low pressure. In addition, the boundary conditions at the attachment points of the membrane with the cell wall have dramatic effects on the force-height relationship. In particular, if the membrane is allowed to freely rotate at the attachment points, proteins that induced membrane curvature can lift the membrane off the cell wall without any external forces. This result is in sharp contrast with the conclusion of a previous study which adopted boundary conditions that fix the angle between the membrane and the cell wall at the attachment points. I will also discuss possible ways to pull the membrane off the cell wall against the high osmotic pressure with a small amount of force that can be provided by actin polymerization.

1:51PM B26.00010: Plasticity in vertex model of epithelial tissues  MARKO POPOVIC (Presenter), VALENTIN DRUELLE, MATTHIEU WYART, École polytechnique fédérale de Lausanne — In order to properly develop living organisms are required to change and maintain shape. These properties exists in a class of materials called amorphous solids such as colloidal gels, emulsions and foams: they respond elastically when exposed to low external stress but at a critical value of stress they yield and permanently change shape, allowing them to retain the memory of past stresses. Could such plasticity play a role during biological morphogenesis? Motivated by this question in this work we study plastic properties of vertex model of epithelial tissues, in which mechanical properties of cells are prescribed and emerging tissue mechanics is obtained from their collective behaviour. We investigate mechanical properties of elementary plastic event, a so called T1 transition in which two pairs of cells exchange neighborship. We demonstrate that they are analogous to plastic events in amorphous solids and find that elastic interactions among T1 transitions lead to non-linear steady state rheology and mechanical stability in the vertex model that are the same as found in mesoscopic models of amorphous solids. Finally, we devise observables quantifying a ‘distance’ to the critical stress in flowing vertex model and epithelial tissues.

2:03PM B26.00011: Loops versus lines and the compression stiffening of cells  MAHESH CHANDRASEKHAR GANDIKOTA (Presenter), Syracuse University, KATARZYNA POGODA, Institute of Nuclear Physics, Polish Academy of Sciences, ANNE VAN OOSTEN, Leiden Academic Centre for Drug Research, Leiden University, TYLER ENGSTROM, Hobart and William Smith Colleges, ALISON PATTESON, Syracuse University, PAUL JANMEY, Institute for Medicine and Engineering, University of Pennsylvania, JENNIFER SCHWARZ, Syracuse University — Tissues exhibit a nonlinear phenomenon known as compression stiffening: an increase in moduli with increasing uniaxial compressive strain. Does such a phenomenon exist in single cells, which are the building blocks of tissues? One expects an individual cell to compression soften since the semiflexible biopolymer cytoskeletal network maintains the mechanical integrity of the cell. To the contrary, we find that mouse embryonic fibroblasts (mEFs) compression stiffen. To understand this finding, we uncover potential mechanisms for compression stiffening. First, we study a single semiflexible polymer loop modeling the actomyosin cortex enclosing a viscous medium modeled as an incompressible fluid. Second, we study a two-dimensional semiflexible polymer network interspersed with area-conserving loops, which are a proxy for vesicles and fluid-based organelles. Third, we study two-dimensional fiber networks with angular-constraining crosslinks. We find for the fiber network with area-conserving loops model that the stress-strain curves are sensitive to the packing fraction and size distribution of the area-conserving loops, thereby creating a mechanical fingerprint across different cell types. We make comparisons of these models with fibrin network experiments interlaced with beads.

Session B27 FIAP: Applications of Semiconductors, Dielectrics, and Complex Oxides 404 - Meeghage Perera, National Research Council
11:15AM B27.00001: Effects of residual stress on MEMS direction-finding sound sensors

MEEGHAGE PERERA (Presenter), RENATO RABELO, FABIO ALVES, GAMANI KARUNASIRI, Physics, Naval Postgraduate School — The hearing mechanism of the fly *Ormia Ochracea* has been studied and mimicked using micro-electromechanical system (MEMS) technology as an acoustic direction-finding sensor. A typical MEMS sensor consists of two wings connected by a bridge with the entire mechanical structure connected to a substrate. The sensors employed in this work were fabricated on a silicon-on-insulator (SOI) substrate using MEMSCAP’s SOIMUMPS process which found to generate a residual-stress induced curvature on the wings. This reduces the overlap between the wing and substrate comb fingers, which affects the electronic signal output. An in-depth study was performed to understand the stress dependence on geometry and substrate and device configurations. A set of sensors fabricated with different configurations were systematically studied using optical profilometry and scanning electron microscopy. The measured profiles show offsets between the edge of the wings and substrates as high as 40 um for metalized devices and as low as 10 um for non-metallized devices. The curvatures of the sensors were fitted using finite element models to provide the stress values for each configuration and designing parameters to minimize this effect in future designs.

11:27AM B27.00002: Alloying hexagonal/orthorhombic Ga$_2$O$_3$ with Al$_2$O$_3$*  

SIERRA SEACAT (Presenter), Department of Physics & Astronomy, University of Kansas, JOHN LYONS, Center for Computational Materials Science, US Naval Research Laboratory, HARTWIN PEELAERS, Department of Physics & Astronomy, University of Kansas — Ga$_2$O$_3$ is a wide-band-gap semiconductor with promising applications in high-power devices and UV photodetectors. It occurs in several polymorphs, with monoclinic β-gallia the thermodynamically stable phase. Other polymorphs of Ga$_2$O$_3$ can be stabilized as well, but are less studied. The ε- and κ-polymorphs are of interest as they possess ferroelectric properties and exhibit large spontaneous electrical polarizations. Here we use density functional theory with hybrid functionals to elucidate how alloying with Al$_2$O$_3$ can be used to modify the structural and electronic properties of Ga$_2$O$_3$. We focus on tuning lattice constants and band gaps as a function of Al concentration. We also report the absolute alignments of valence and conduction bands. Our quantitative results can be used to guide experimental design of new devices.

11:39AM B27.00003: Nanomaterials-based Color-Detection via Machine-Learning Algorithms* DAVOUD HEJAZI (Presenter), SHUANGJUN LIU, AMIRREZA FARNOOSH, SARAH OSTADABBAS, SWASTIK KAR, Northeastern University — Some of the major challenges in optical spectrum estimation include the necessity to create an array of thousands of identical photodetectors, or intricate mechanical systems that make the estimation system bulky and expensive. Using the spectral transmittance of an array of 11 solution-processed nanomaterial thin film filters fabricated from two layered semiconducting materials, Molybdenum-Disulfide and Tungsten-Disulfide, we have estimated the wavelength of any incoming light in a wide spectrum range. By applying machine learning techniques we have used the variations in spectral transmittance of nanomaterials as the alternative method for optical spectrum estimation. We have studied the efficacy of various machine learning algorithms including k-nearest neighbors, artificial neural networks, support vector machines, and Bayesian statistics in spectrum estimation problem and identified the key advantages and limitations of each algorithm for real-time applications such as accuracy and speed. Furthermore, we have modeled the temporal drift of filters' spectral transmittance over a period of one year and showed that it is possible to overcome the drift-induced inaccuracies over time using a modeled drift function.

11:51AM B27.00004: SiGe Devices with High-k Dielectric Gates JENNIFER DEMELL (Presenter), GREGORY STEPHEN, CHOMANI K. GASPE, CHRISTOPHER RICHARDSON, ADAM FRIEDMAN, Laboratory for Physical Sciences — SiGe is an attractive material for future advanced electronic devices desired for beyond Moore’s law high performance computing. In particular, for spintronic devices, it offers extremely high mobilities that can lead to long spin diffusion lengths and a spin-orbit coupling that can be used to control spin relaxation in spin valves—a prerequisite for any spinFET device. Moreover, it is amenable to scaling and is compatible with most commercial device fabrication facilities in foundries. Here, we grow a compressively strained Ge quantum well with relaxed Si$_{0.2}$Ge$_{0.8}$ barriers using molecular beam epitaxy. We fabricate devices to determine the basic properties of the films using both charge and spin state variables. We perform a systematic study to create a method of growing high-quality high-k dielectrics (hafnia and alumina) by atomic layer deposition to allow gating of the devices. We present magnetotransport results for both the charge- and spin-based devices from 3-300 K at fields up to 2.5 T.
A bifurcation study of the dynamics of TaO memristors

YURIY PERSHIN (Presenter), Department of Physics and Astronomy, University of South Carolina, VALERIY SLIPKO, Institute of Physics, Opole University — Pulse-driven memristors (resistance-switching cells) are interesting from the dynamical system point of view. When driven by periodic alternating-polarity pulses, their time-averaged dynamics may converge to fixed-point attractors [1]. Recently, we have shown that the maximum number of stable fixed points in a broad range of popular memristor models is one [2]. Here, we analyze the pulse-driven dynamics of tantalum oxide memristors using a sophisticated device model developed in Ref. [3]. Our main finding is the identification of a driving regime when two stable fixed points exist simultaneously [4]. To the best of our knowledge, such bistability is identified in a single memristor for the first time. Bifurcation curves separating pulse parameter regions corresponding to 0, 1, or 2 stable fixed points have been found analytically. Our results can be tested experimentally and are expected to be useful in future memristor circuit designs.

Parametric Coupling in Aluminum Nitride Lamb Wave Devices Through a Nonlinear Elastic Modulus

JOSEPH SCHNEIDER (Presenter), TING LU, SIDHANT TIWARI, XIATING ZOU, AJIT MAL, ROBERT CANDLER, YUANXUN ETHAN WANG, GREG P CARMAN, University of California, Los Angeles — Parametric coupling was intensely studied in the 1950s where a time varying circuit parameter (i.e. capacitance or inductance) is used to provide frequency conversion, allowing energy supplied at one frequency to be converted to another. The main advantage of this process is its low noise characteristic and is a promising step forward for low noise radio frequency (RF) devices. However, the realization of small devices relying on a time varying circuit parameter is difficult for lower frequency applications (100MHz – 1GHz) due to the long electromagnetic wavelength. In this research, Aluminum Nitride (AlN) Lamb wave devices are investigated as an option for parametric coupling in acoustic waves, significantly reducing the size of devices in the desired frequency range.

AlN Lamb wave devices are modeled, fabricated, and tested. Results show successful parametric mixing in the devices at both an up converted frequency and down converted frequency. The output power of the mixed signal is linearly dependent on the carrier power until gain compression is reached. A circuit model developed closely matches the experimental data. These devices provide evidence for next generation RF components that are 5 orders in magnitude smaller than the current state of the art.

Evidence for ferroelectric polaron in lead halide perovskites

XIAOYANG ZHU (Presenter), Columbia Univ — Lead halide perovskites are characterized by dielectric responses and phonon dynamics resembling those of liquids. We show that the dielectric function in the THz region in this class of materials may lead to dynamic and local ordering of polar nano domains by an extra electron or hole, resulting a quasiparticle which we call a **ferroelectric large polaron**, a concept similar to solvation in chemistry. Compared to a conventional large polaron, the collective nature of polarization in a ferroelectric large polaron may give rise to order(s)-of-magnitude larger reduction in the Coulomb potential. We show that the shape of a ferroelectric polaron resemble that of a Belgian waffle. Using two-dimensional coherent phonon spectroscopy, we directly probe the energetics and local phonon responses of the ferroelectric large polarons. We find that that electric field from a nascent e-h pair drives the local transition to a hidden ferroelectric order on picosecond time scale. The ferroelectric or Belgian waffle polarons may explain the defect tolerance and low recombination rates of charge carriers in lead halide perovskites, as well as providing a design principle of the “perfect” semiconductor for optoelectronics.

Surface structure and electronics of all-inorganic halide perovskites

**CsPbI\textsubscript{3}: A first-principles study of surface reconstructions**

AZIMATU SEIDU (Presenter), PATRICK RINKE, Applied Physics, Aalto University, JINGRUI LI, Xi'an Jiaotong University — The all-inorganic halide perovskite CsPbI\textsubscript{3} is emerging as a promising perovskite solar cell (PSC) material with a power conversion efficiency of 18%. To further improve the efficiency and stability of CsPbI\textsubscript{3}-based PSCs, better knowledge of the materials surface and interface properties is required. In this work, we use density-functional theory and atomistic thermodynamics to calculate the surface phase diagrams of the (001) surfaces of CsPbI\textsubscript{3} in the Pm-3m (α), P4/mbm and Pnma (γ) phases. We consider different add-atom and missing-atom reconstructions and investigate different growth regimes. For stable surface reconstructions in the surface phase diagram, we then calculate the electronic structure. Our results indicate that surfaces with CsI terminations, including the clean surface, are more stable. Surfaces with missing Pb atoms exhibit a unipolar self-doping behaviour with Cs and I atoms inducing transition energy levels in the valence and conduction bands, respectively. Even though the removal and addition of CsI and PbI\textsubscript{2} complexes leads to considerable surface reconstructions, they remain electronically neutral and do not donate charge to the valence or conduction band.

12:51PM B27.00009: Local Magnetic Field Effect on InSb Nanowire Devices  
YIFAN JIANG (Presenter), Univ of Pittsburgh, VINCE VAN DE SANDE, ELINE DE JONG, SASA GAZIBEGOVIC, GHADA BADAWY, ROY OP HET VELD, ERIK BAKKERS, Eindhoven University of Technology, SERGEY M FROLOV, Univ of Pittsburgh — Devices based on InSb nanowires are platforms for various of experiments, including quantum point contacts, quantum dots and Majorana zero modes. In most of such experiments, when a magnetic field is necessary, a large superconducting solenoid magnet is used to produce a global field. However, this homogenous magnetic field may limit device architecture. Instead of producing a global magnetic field, we can produce magnetic field locally by placing micro-magnets beside nanowire devices. In our experiment, we fabricate CoFe micromagnets next to InSb nanowire devices which also have Ti/Au ohmic contacts. Hysteretic magnetoresistance with sharp switches is observed, indicating penetration of local magnetic field from CoFe micromagnets into the nanowire. We also estimate that the magnitude of the local magnetic field into the InSb nanowire is several tens of mT. This successful demonstration of local magnetic field effect may bring a new approach for scalable topological computing.

1:03PM B27.00010: Comparison of spin photocurrent in devices based on in-plane or out-of-plane magnetized CoFeB spin detectors  
PIERRE RENUCCI (Presenter), Institut National des Sciences Appliquees de Toulouse, XIAODI XUE, LAIPAN ZHU, WEI HUANG, YU LIU, YANG ZHANG, XIAOLIN ZENG, JING WU, BO XU, ZHANGUO WANG, YONGHAI CHEN, Key Laboratory of Semiconductor Materials Science, Institute of Semiconductors, Chinese Academy of Sciences, Beijing Key Laboratory of Low Dimensional Semiconductor Materials, WEIFENG ZHANG, Beijing Institute of Nanoenergy and Nanosystems, Chinese Academy of Sciences, Beijing 100083, China, XAVIER MARIE, Institut National des Sciences Appliquees de Toulouse, YUAN LU, Université de Lorraine, Institut Jean Lamour, UMR CNRS 7198, campus ARTEM, 2 Allée André Guinier, 54011, Nancy, France — We have measured a helicity-dependent photocurrent at zero external magnetic field in a device based on a semiconductor quantum well embedded in a \textit{p-i-n} junction. The device is excited under vertical incidence with circularly polarized light. The spin filtering effect is evidenced in the temperature range 77–300 K owing to a CoFeB/MgO spin filter with \textit{out-of-plane} magnetization in remanence. The helicity-dependent photocurrent is explored as a function of the temperature and bias. These characteristics are compared with those of a spin photocurrent device with \textit{in-plane} magnetized CoFeB/MgO spin filter, excited under oblique incidence with circularly polarized light. In contrast to the in-plane spin filter device, the circularly polarized light asymmetry of the photocurrent in the out-of-plane device depends weakly on the external bias. The two devices are sensitive to the spin filtering of either the in-plane ($S_x$) or out-of-plane ($S_z$) photogenerated electron spin in the semiconductor quantum well. The photocurrent results can be explained by the Dyakonov-Perel electron spin-relaxation mechanism. Our study reveals the large spin relaxation anisotropy in III-V zinc-blende quantum wells in the presence of a vertical electric field. [1] Phys. Rev. B 100, 045417 (2019)
1:15PM B27.00011: Characterization of quantum tunneling devices by controlled current pulses
EDGAR J PATINO (Presenter), LEONARDO RIOS E, University of the Andes — Quantum tunneling devices constitute a prominent research area due to their use in fundamental and applied research investigations such as superconducting, magnetic and spintronic devices. The main difficulties in fabrication of such devices relies on two fronts directly related with; tunnel barrier quality i.e. absence of pinholes or hot spots, and low dissipation within the tunnel barrier material. A good tunnel barrier quality usually requires an oxygen plasma with pronounced uniformity and long oxidation time. Regarding the minimization of dissipation, in the present work, we show the development of a characterization technique based on controlled current pulses, which significantly reduces heat dissipation and thus allows a significant increase in the Tunnel Junctions lifetime. Acquiring data this way permits to reach higher tunneling current values compared to the ones obtained by standard DC characterization techniques, which are customary used in tunnel junction experiments.

1:27PM B27.00012: Topology-optimized Metal-Semiconductor Hybrid Structures to obtain Optimal Extraordinary Magnetoresistance
DEBANIK DAS (Presenter), SATHWIK BHARADWAJ, L RAMDAS RAM-MOHAN, Department of Physics, Worcester Polytechnic Institute — Semiconductor wafer with metallic inclusions generates extraordinary magnetoresistance (EMR) response [1]. This effect has found applications in high sensitivity magnetic sensors, and smaller magnetic read heads. Since its inception, efforts have been made to increase magnetoresistance through different choices of materials, by altering location of contacts, filling factor, and shape of the device. However, a systemic study to optimize topology of the metallic inclusions has not been considered in the literature. Here, we employ a topology optimization scheme based on the level set function. For evolution of the level set curve, topological derivative is used as the sensitivity term in the Hamilton-Jacobi equation. In contrast to conventional homogenization based methods, this optimization scheme will not produce gray region in the metal-semiconductor boundary. We are also able to control the complexity of the structure to design realistic geometries for fabrication of the physical prototype. The optimized geometry is robust and independent of the initial configuration. When combined with material optimization, this algorithm manifests a potential for significant improvements in EMR technology.

ARCHIT DHINGRA (Presenter), Physics and Astronomy, University of Nebraska - Lincoln, PAVLO V. GALIY, Electronics, Ivan Franko L'viv National University, LU WANG, CAS Key Lab of Materials for Energy Conversion, University of Science and Technology of China, TARAS M. NENCHUK, Electronics, Ivan Franko L'viv National University, ANDREW J. YOST, Physics, Oklahoma State University-Stillwater, WAI-NING MEI, Physics, University of Nebraska-Omaha, PETER A DOWBEN, Physics and Astronomy, University of Nebraska - Lincoln — In₄Se₃ (001) is a novel n-type semiconductor with great potential for 2D material phototransistors and beyond CMOS electronics. X-ray photoemission spectroscopy (XPS) measurements indicate that In₄Se₃ (001) system terminates in In (and not Se). These results disagree with density functional theory, which indicates that the Se termination of In₄Se₃ (001) is more stable. The interface between In₄Se₃ (001) and evaporated Au indicates toward the existence of Schottky barrier. This is very different from the interface between Au and TiS₃ (001), which exhibits Ohmic behavior. Additionally, the shift in binding energy (due to a barrier height) shows up only in one of the In core level photoemission components that is nearest to the interface.

This research was supported by the National Science Foundation (NSF), through grants NSF-ECCS 1740136, as well as by the nCORE, a wholly owned subsidiary of the Semiconductor Research Corporation (SRC), through the Center on Antiferromagnetic Magneto-electric Memory and Logic task #2760.002.

CHANDRASEKAR SIVAKUMAR (Presenter), GANG-HAN TSAI, MON-SHU HO, Department of Physics, National Chung Hsing University — Resistive memory is one of the promising next generation nonvolatile memories with advantages over other emerging nonvolatile memories like DRAM, PCRAM, CBRAM etc. Dielectric thin films as the resistive switching material have been studied extensively through the scientific community. In this study, we have taken advantage of controlled electron flow in 2D and 1D materials to study the resistive switching. High-density single crystalline β-Ga₂O₃ 2D-nanoleafs and 1D nanowires on Si (100) substrate are grown by vapor-liquid-solid growth technique. The structural features are explored by SEM, TEM and XRD analysis. The elemental compositions and binding characteristics are confirmed by the EDS spectrum from FESEM and TEM analysis and XPS respectively. The photoelectrical property is studied by Raman spectroscopy and absorption spectroscopy. Here we have compared the resistive switching performance of a single 2D β-Ga₂O₃ nanoleaf and 1D β-Ga₂O₃ nanowire ReRAM devices. The switching mechanism of both 1D and 2D nanostructures are governed by the oxygen migration between two electrodes by the formation and rupture of conducting filaments.

Keywords: Resistive memory, β-Ga₂O₃, nanoleaf, nanowire, VLS growth

11:15AM B28.00001: Flow of concentrated and highly polydisperse emulsions* [Invited] Eric Weeks (Presenter), Yonglun Jiang, Joaquim Clara-Rahola, Emory University — We study experiments and simulations of highly polydisperse emulsions under shear flow. By highly polydisperse, we mean with the largest droplet diameters being as much as ten times the smallest diameters. We’re studying how to best define and quantify non-affine motion in these highly polydisperse samples — motion where droplets move with displacements distinctly different from their neighbors, or from the overall imposed shear flow. The largest droplets typically move affinely, as if they are in a simple effective fluid formed by the other droplets. In contrast, the smallest droplets often move non-affinely. Additionally, we quantify how the non-affine motion diminishes as a function of droplet size. Our main conclusion is that highly polydisperse samples behave qualitatively differently than weakly polydisperse samples.

11:51AM B28.00002: Fingering in dense suspensions* [Invited] Sungyon Lee (Presenter), University of Minnesota — We experimentally inject silicone oil into the mixture of oil and non-colloidal particles inside a Hele-Shaw cell, to investigate the connection between miscible fingering and the flow structure that develops inside the dense suspension. Previous studies with pure fluids have demonstrated that the onset of miscible fingering coincides with the transition from a smooth tongue-like structure to a sharp front between invading and defending fluids inside the thin gap. Our current experiments with suspensions reveal the same general behavior at the onset of miscible fingering, which we capture qualitatively using a continuum model. However, beyond the onset, we observe distinctly different morphologies of miscible fingering, which depend on the ratio of the gap thickness to particle diameter. We present the new quantitative measurements that highlight these differences and discuss how the wall confinement may alter the particle dynamics and the resultant fingering patterns.

The mixing of a powder of 10- to 50-μm primary particles into a liquid to form a dispersion with the highest possible solid content is a common industrial operation. Building on recent advances in the rheology of such “granular dispersions,” we study a paradigmatic example of such powder incorporation: the conching of chocolate, in which a homogeneous, flowing suspension is prepared from an inhomogeneous mixture of particulates, triglyceride oil, and dispersants. Studying the rheology of a simplified formulation, we find that the input of mechanical energy and staged addition of surfactants combine to effect a considerable shift in the frictional jamming volume fraction of the system, thus increasing the maximum flowable solid content. We discuss the possible microscopic origins of this shift, and suggest that chocolate conching exemplifies a ubiquitous class of powder–liquid mixing.

*We thank Mars Chocolate UK Ltd. for initiating and funding part of this work. Other funding came from Engineering and Physical Sciences Research Council Grants EP/J007404/1 and EP/N025318/1. Research at New York University was supported partially by the Materials Research Science and Engineering Centers Program of the National Science Foundation under Award DMR-1420073.
Suspensions of non-Brownian particles in complex fluids (hereafter complex slurries) are relevant in industrial processes (e.g. waste disposal, concrete, drilling muds, metalworking chip transport, and food processing) and in natural phenomena (e.g. flows of slurries, debris, and lava). It is also relevant to mention that some biological and smart materials can be designed from various suspensions, drawing attention to applications in physiology, bio-locomotion and shock absorbers. This countless number of suspensions has a wide range of nonlinear rheological behaviors, such as shear thinning, shear thickening, shear banding, yield stress, and finite normal stress differences even when inertia is negligible.

This talk will introduce an array of experimental and modeling techniques that my research team uses to investigate rheological properties and fluid dynamical behavior of the complex slurries. The goal is to establish a continuum framework and refine it through a series of microstructure investigations. This continuum framework is formulated and explained via a mean field study, homogenization theory, as well as a computational study based on the Immersed Boundary Method. In addition, it will be presented that how confinement effects transition a suspension from one rheological behavior to another and how these observations can be explained beyond the framework of the mean field approaches. Finally, open questions will be disclosed, which must be answered in order to build a firm foundation for a long-term contribution to the area of complex slurries.

Force networks in shear thickening suspension [Invited] JEFFREY F MORRIS (Presenter), The City College of New York — From simulations shown to capture primary features of the shear thickening transition in suspensions -- with particles interacting through lubrication, short-range repulsive forces, and frictional contact forces -- we explore the microstructural development underlying this transition. In particular we study the statistics of the contact force network. Using methods of k-core analysis and persistent homology, we explore the role of the particle contact network connectivity, and will present signatures of the rheological transition in terms of both local and global measures of the connectivity.
11:15AM B29.00001: The Physics of Cold Active Matter: on how time-independent disorder affects the motion of self-propelled particles* [Invited] FERNANDO PERUANI (Presenter), University of Nice Sophia-Antipolis — Most examples of natural active matter systems, if not all, take place in heterogeneous media. Despite this, most experimental and theoretical efforts have focused on homogeneous media and the impact of environmental heterogeneities on individual and collective properties of active systems has remained, up to recently, unexplored. Here, we will see that the physics of active systems in heterogeneous media is fundamentally different from the one in homogenous environments. For instance, in heterogeneous environments, spontaneous particle trapping of particles and sub-diffusion can occur, while long-range order of two-dimensional polar active liquids is not possible. Furthermore, in the absence of dynamic noise, it is possible to show that when the equations of motion exhibit a Hamiltonian structure, particle trapping cannot occur, while the presence of attractors in these equations indicates the asymptotic convergence of particle trajectories to bounded areas in space, i.e. traps.

11:51AM B29.00002: The motion of active colloids and their induced flow field at fluid interfaces MEHDI MOLAEI, NICHOLAS G CHISHOLM, JIAYI DENG, TIANYI YAO, JOHN CROCKER, KATHLEEN JOAN STEBE (Presenter), University of Pennsylvania — Colloid motion is altered by adsorption to fluid interfaces, allowing for boundary guidance or directed assembly. This is particularly interesting for colloidal motion driven by external fields (driven colloids) or for self-propelled objects (active colloids or swimmers). However, the influence of a fluid interface on these hydrodynamic phenomena and the 2-d flow field induced by the motion of these active colloids are relatively unexplored. Here we image the motion of passive tracer probes at the interface to discern displacement fields generated by (1) a microbead undergoing thermal motion, (2) a magnetic disk forced to translate at constant velocity, and (3) actively swimming bacteria. We also theoretically quantify the flows generated by interfacially trapped colloids by developing an appropriate flow singularity model for both driven and active colloids. We consider an ideal flat "clean" interface characterized solely by a uniform interfacial tension. We also consider an incompressible fluid interface, as can occur even for trace surfactant adsorption. Theoretical results are compared with experimental flow field. Our results will be useful in future work on the use of active colloids to direct and enhance transport at interfaces
12:03PM B29.00003: Hydrodynamic attraction of bacteria to gas and liquid interfaces*
ADIB AHMADZADEGAN (Presenter), SHIYAN WANG, PAVLOS P VLACHOS, AREZOO M ARDEKANI, Purdue Univ — Motile microorganisms often encounter solid and fluid boundaries. Understanding the underlying physics of their accumulation near these boundaries can impact a wide range of applications from biofilm formation to micro-robot design. We combine experiments and numerical simulations to investigate bacteria (Escherichia coli) attractions to various fluid-fluid interfaces. We show that the strongest cell accumulation occurs near the lowest viscosity ratio (gas interfaces). We develop a new theory based on Brownian dynamics including hydrodynamics and short-range physio-chemical interactions between bacteria and surfactant-laden interfaces and explain our experimental findings. We include higher order singularities in our hydrodynamic model and study their effects on bacterial orientations, trajectories, and accumulation.

12:15PM B29.00004: Non-Markovian active droplets*
ADRIEN IZZET (Presenter), Center for Soft Matter Research, New York University, RUBEN ZAKINE, ERIC VANDEN-EIJNDEN, Courant Institute, New York University, JASNA BRUJIC, Center for Soft Matter Research, New York University — Active droplets are a model system for the chemotactic dynamics of microbes. They propel themselves through solute-mediated interactions. Previously, we showed that the motion of small droplets (~30µm diameter) is akin to active rotational diffusion whose speed and persistence time can be tuned by changing the salt and surfactant concentrations, respectively (Izzet et al., arXiv:1908.00581, 2019). Here we show that the trajectories of larger droplets display complex non-Markovian behaviors, such as self-interacting dynamics, that require a more complicated model than rotational diffusion. These results indicate that our tunable swimmers are ideal candidates for the study of the departure from equilibrium to high levels of activity, on both the single-particle level and their collective behavior, including the motility-induced phase separation (MIPS).

12:27PM B29.00005: Stigmergy in active furrowers  MD IMARAN (Presenter), IITB-Monash Research Academy, RANGANATHAN PRABHAKAR, Monash University, RAGHUNATH CHELAKKOT, MANDAR M INAMDAR, Indian Institute of Technology Bombay — Stigmergy is the emergence of spatiotemporal coordination between agents through interactions mediated by their environment. Pheromone trail-following in ants is a well-known example. Recently, a mechanical form of stigmergy has been observed in colonies of motile bacteria that create networks of furrows as they advance over soft agar [Gloag et al., PNAS, 2015]. Vanguard rafts of bacteria mechanically deform the substrate to create a physical signal that other cells follow. Under certain conditions, extensive furrow networks emerge with a distinctive morphology that spans a broad range of length scales. It is possible that the formation of such a sparse network of furrows is a strategy to loosely colonize large areas with a small number of cells. We investigate the conditions under which extensive furrow networks emerge using simulations of self-propelled rods that furrow through a passive elastic or plastic medium. The structure of the furrow network appears to critically depend upon the clustering behaviour of active rods at the advancing edge, which, in turn, depends on substrate stiffness and the self-propulsion velocity of the rods. We attempt to explain our observations through a coarse-grained, but general, model of stigmergy.

12:39PM B29.00006: Slip and distance effects on the self-propulsion of catalytic microswimmers close to a wall  STEFANIA KETZETZI (Presenter), Leiden University, JOOST DE GRAAF, Utrecht University, RACHEL PAMELA DOHERTY, DANIELA JUTTA KRAFT, Leiden University — Catalytic microswimmers are typically found self-propelling parallel to substrates. Although experimental observations have so far hinted at non-negligible substrate effects on the swimmer velocity, a quantitative examination of the effect of the substrate is still lacking. In this talk, we will present quantitative measurements of the effect of the substrate on the velocity of Pt-coated model microswimmers. We will show that under otherwise fixed conditions the velocity depends on the substrate wetting angle, which in turn relates to the associated hydrodynamic slip length of the substrate. We will further demonstrate that our hypothesis on slip dependent velocities is not only supported by qualitative and scaling arguments, but also by our measurements on swimmer-wall separation distance.

Our findings provide further understanding on the swimming behavior of synthetic microswimmers. Such understanding is desirable for future applications that may require microscopic devices to self-propel in liquid environments in confinement and along boundaries.
12:51PM B29.00007: Measuring chaotic advection in a biological active nematic in viscous environments*  AMANDA TAN (Presenter), KEVIN A MITCHELL, LINDA S. HIRST, University of California, Merced — Active flows are commonly found in nature ranging from macro-scale (bird flocks and schools of fish), to the micro-scale (cytoplasmic streaming and bacterial colonies). The common theme among these active materials is the individual entities consume energy leading to large-scale collective motion and flows. A widely studied example is the microtubule/kinesin based active network which is highly tunable. When this non-equilibrium system is confined in 2D at the oil/water interface, active topological defects emerge generating chaotic flows where the microtubules are advected within the network. An avenue of interest in nonequilibrium systems is to observe the material's response to external changes in its environment. Prior research has shown that changing the viscosity of the oil in contact with the active network changes the velocity and morphology of the network. Increasing the viscosity increases the number density of defects and decreases the network velocity. We investigate how the external changes from viscosity affect various quantitative parameters from chaotic advection theory, such as local fluid stretching rates within the network and topological entropy calculated from defect braiding.

1:03PM B29.00008: Hydrodynamic interactions between passive colloids in an active bacterial bath*  SHREYAS GOKHALE (Presenter), JUNANG LI, Massachusetts Institute of Technology MIT, ALEXANDRE SOLON, Sorbonne University, JEFFREY GORE, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — The dynamics of active particles has been a subject of intense scientific investigation owing to the complex nonequilibrium patterns observed in these systems. Nonequilibrium effects also have tangible consequences for interactions between active and passive objects, as evidenced by the spontaneous rotation of microscopic gears in suspensions of motile bacteria. Here, using video microscopy experiments and simulations, we show that motile bacteria have a profound impact on dynamical interactions between passive colloidal particles. By quantifying spatial velocity correlations and the short time pair diffusivity tensor for colloids, we show that bacterial motion leads to partial screening of long-ranged hydrodynamic interactions. Notably, for sufficiently dense bacterial suspensions, transverse velocity correlations develop a pronounced minimum at a characteristic length scale that is independent of the bacterial density, but depends on the bacterial species. We hypothesize that the observed length scale demarcates short-ranged interactions dominated by direct collisions between colloids and bacteria from long-ranged ones associated with hydrodynamics.

1:15PM B29.00009: Self-organization of swimmers drives long-range fluid transport in bacterial colonies*  XU HAORAN (Presenter), Department of Physics and Shenzhen Research Institute, The Chinese University of Hong Kong, JUSTAS DAUPARAS, DEBASISH DAS, ERIC LAUGA, Department of Applied Mathematics and Theoretical Physics, University of Cambridge, YILIN WU, Department of Physics and Shenzhen Research Institute, The Chinese University of Hong Kong — Motile subpopulations in microbial communities are believed to be important for dispersal, quest for food, and material transport. Here, we show that motile cells in sessile colonies of peritrichously flagellated bacteria can self-organize into two adjacent, centimeter-scale motile rings surrounding the entire colony. The motile rings arise from spontaneous segregation of a homogeneous swimmer suspension that mimics a phase separation; the process is mediated by intercellular interactions and shear-induced depletion. Our findings present a unique form of bacterial self-organization that influences population structure and material distribution in colonies.

1:27PM B29.00010: Linear instability and nonlinear dynamics of droplets and layers of active fluid*  DAVID STEIN (Presenter), Flatiron Institute, YUAN-NAN YOUNG, New Jersey Inst of Tech, MICHAEL JOHN SHELLEY, Courant Institute, New York University — Active suspensions are fluids with extra stresses from the energy-consuming activity of suspended particles. Coarse-grained continuum descriptions have successfully predicted instabilities and pattern formation observed in some experimental systems. In this work we focus on the effects of surface tension on the stability and nonlinear dynamics in droplets and layers of active fluid. Specifically we study the stability of a moving boundary between a viscous fluid and droplet- or layer-bound active suspension. Linear stability analyses predict parameter regimes for various dynamics such as rotation, self-propulsion, and chaotic dynamics. Weakly nonlinear analyses predict the equilibrium drop deformation as a function of activity magnitude in the suspension. Simulations of a small system of such active drops give insight into how the activity inside the drops dictates how they communicate with each other.

*Funding from Flatiron institute, part of Simons Foundation, is acknowledge.
1:39PM B29.00011: Swimming of active drops in confinements with external flows*  
RANABIR DEY (Presenter), CAROLA M. BUNESS, CHENYU JIN, CORINNA MAASS, Max Planck Institute for Dynamics and Self-Organization — Biological microswimmers commonly navigate through liquid flows in confinements, e.g. locomotions of spermatozoa in the reproductive tract and bacteria in blood vessels. Artificial microswimmers designed for drug delivery also swim in confinements having flows. So far, there are theoretical works explaining the dynamics of microswimmers in Poiseuille flow. However, there is little quantitative experimental data regarding swimming of active matter in confined microflows. Here, we elucidate the swimming behaviour of active drops in Poiseuille flow. The Marangoni stress dominated `self-propulsion' of these droplets serves as a model for studying the swimming hydrodynamics of microorganisms, specifically pushers like E. Coli. We quantitatively explain the upstream swimming and downstream tumbling motion of the active drops in externally imposed flows; we also provide a comparative analysis of the experimental data with the hydrodynamics based non-linear theory. We feel that understanding such swimming behaviour of active matter will make significant contribution towards better comprehension of certain important biological phenomena.

1:51PM B29.00012: Examining collective mechanical properties of fish schools using projected light fields*  
JAMES PUCKETT (Presenter), Physics, Gettysburg College, AAWAZ R POKHREL, Physics, Georgia Inst of Tech — Social animals including insects, fish, birds, and even humans exhibit self-organized collective behavior. Models have shown that simple local interactions between individuals gives rise to the emergent self-organized macroscopic states such as flocks, swarms, or schools. We investigate the material properties of laboratory fish schools by exploiting the negative phototaxicity of Rummy-Nose Tetra (Hemigrammus blehri). To do this, we use an overhead high speed camera to record individual fish trajectories in a quasi-two-dimensional tank. By projecting two dark regions moving in opposite directions, the school of fish is strained as individuals use both social and environmental information to determine their behavior. The school undergoes a large deformation before snapping back into one of the dark regions. Our results show that the school exhibits a stress-stain relationship similar to Hooke's law.

*This work is also supported by Gettysburg College and by the Cross-Disciplinary Science Institute at Gettysburg College (X-SIG).

Session B30 DSOFT GSNP: Morphing Matter: from Soft Robotics to 4D Printing II  
502 - Pierre-Thomas Brun, Princeton University
11:15AM B30.00001: Encoding kirigami bi-materials to morph on target in response to temperature*  DAMIANO PASINI (Presenter), LU LIU, CHUAN QIAO, HAICHAO AN, McGill Univ — Shape morphing in response to an environmental stimulus, such as temperature, light, and chemical cues, is currently pursued in synthetic analogs for manifold applications in engineering, architecture, and beyond. Existing strategies mostly resort to active materials, whose responsiveness is controlled by the chemical composition and/or arrangement of their constituents, which is dispensed through a specific fabrication process. Here, we demonstrate that a pair of off-the-shelf passive solids, such as wood and silicone rubber, can be topologically arranged in a kirigami bi-material to engage temperature to collectively deploy into a geometrically rich set of periodic and aperiodic shapes that can shape-match a predefined target. The results highlight reversible morphing by mechanics and geometry, thus contributing to relax the dependence of current strategies on material chemistry and fabrication.

11:27AM B30.00002: Assembly Behaviors Design with Magnetic Handshake Materials
CHRISY XIYU DU (Presenter), Harvard University, RAN NIU, Cornell University, EDWARD P ESPOSITO, University of Chicago, PAUL L MCEUEN, ITAI COHEN, Cornell University, MICHAEL PHILLIP BRENNER, Harvard University — Inspired by nature’s ability of assembling intricate materials, we recently developed an assembly platform that can create specific binding by encoding magnetic dipole patterns into panel-like building blocks. With this platform, which we term magnetic handshake materials, we are able to achieve controlled polymerization, complementary binding strands and 3D folding from 2D nets. However, in order to perform more systematic materials design that can match nature's ability, we need to develop design protocols to more efficiently search through the parameter space. Here, I will demonstrate how to use computational methods to systematically probe the design space. With the help of molecular dynamics and inverse design techniques, I will show that we can predict self-assembly behaviors of arbitrary panels based on their local interaction and optimize for specific structures.
11:39AM B30.00003: Photothermally Reconfigurable Shape Memory Magnetic Cilia*  
JESSICA A.-C. LIU, Materials Science and Engineering, North Carolina State University, BENJAMIN A. EVANS, Physics, Elon University, JOSEPH TRACY (Presenter), Materials Science and Engineering, North Carolina State University — Functional artificial cilia usually require maintaining an applied stimulus or are programmed to perform one-way processes that cannot be reset. Reconfigurable artificial cilia are desirable, whose shape can be set, locked, unlocked, and reconfigured. Magnetic iron microparticles were dispersed in a thermoplastic polyurethane shape memory polymer matrix and formed into artificial, magnetic cilia that respond simultaneously to magnetic fields and light. Temporary shapes obtained through combined magnetic actuation and photothermal heating can be locked by switching off the light and magnetic field. Subsequently turning on the light without the magnetic field drives recovery of the permanent shape of the magnetic cilia. The permanent shape can also be programmed after preparing the cilia by applying mechanical constraints and annealing at high temperature. Spatially controlled actuation of magnetic cilia is demonstrated by applying a mask for pattern transfer into the array of magnetic cilia. Development of a theoretical model aids understanding the behavior of reconfigurable magnetic cilia and provides guidelines for their design and optimization.

11:51AM B30.00004: Control of a Hydrogel Based Soft Robot Using Light*  
AAVEG AGGARWAL (Presenter), HANG YUAN, MONICA OLVERA DE LA CRUZ, Northwestern University — Soft robotics is an emerging field of research as robots built from soft materials can offer many advantages over conventional robots. Hydrogels are an interesting family of materials for realization of such soft robots as they can change their morphology by exchanging fluids with their environment. This further opens opportunities for biological applications. Remote control of these hydrogel robots with external stimuli such as light and magnetic fields can add useful functionality to them. Photo-responsive hydrogels provide an easy way to remotely control the shape of these robots by exposing them to light. This phenomenon can be exploited to design robots that can transit between multiple modes of operation by changing their geometry. To this end, we report our theoretical work on the light induced deformations in these robots and the corresponding changes in functionality.

*This work was supported by the Center for Bio-Inspired Energy Science (CBES), an Energy Frontier Research Center funded by the U.S. Department of Energy (DOE) Office of Basic Energy Sciences (DE-SC0000989)
12:03PM B30.00005: Semiflexible origami and their many minima*  MARY ELIZABETH LEE-TRIMBLE (Presenter), JI-HWAN KANG, RYAN HAYWARD, University of Massachusetts, Amherst, CHRISTIAN SANTANGELO, Syracuse University — Self-folding origami structures, which allow flat materials to be deployed into three dimensional structures, have many engineering applications. These applications, however, require that the structures fold without error and robustly. For infinitely rigid origami, many configuration space components meet at the flat, unfolded state, so even when every fold is programmed to the desired equilibrium result, the structure can misfold into an undesired branch of configurations. Here, we show how to relax the rigidity of origami by allowing a small amount of stretching along the folds, which in turn allows Gaussian curvature at the vertices. We map the energy landscape for simple origami and explore the bifurcations of the energy landscape that lead to multiple minima. Furthermore, we explore how the basins of attraction of different energy minima affect the potential to misfold.

12:15PM B30.00006: Morphing Colloidal Crystals with Active Additives  BRYAN VANSADERS (Presenter), SHARON C GLOTZER, Univ of Michigan - Ann Arbor — Active matter studies have focused mostly on homogenous systems where all elements are active. However, for dense systems the forces applied by small quantities of active matter can have far-reaching effects. Because the positions of particles in colloidal crystals are highly correlated, an active particle’s sphere of influence in such a medium can extend many particle diameters away. By controlling the creation and propagation of mobile defect species this range can be further extended. In this work we discuss how small clusters of active particles with variable diameter can cause long range shear displacement within a simulated colloidal monolayer. Such displacement can be confined to a single slip plane by the design of the embedded cluster. We approach the design of these heterogeneous active materials by focusing on the creation and migration of dislocation defects from the embedded cluster edges during expansion. We demonstrate the reconfiguration of large quantities of passive colloidal crystal with a small amount of active matter. Using a designed cluster shape with a single cyclic actuation mode, large plastic deformations can be accomplished over the course of many swell/shrink cycles, providing a new way of creating morphing matter for soft colloidal robotics.
12:27PM B30.00007: Generating multiple surfaces from a single inhomogeneous anisotropically deforming sheet* ITAY GRINIASTY (Presenter), ITAI COHEN, JAMES PATARASP SETHNA, Laboratory of Atomic and Solid State Physics, Cornell University — Can we make a flat sheet transform first into Rodin's thinker and then Michelangelo's David? Here, we derive a general solution to this inverse design problem for inhomogeneous, anisotropically deforming materials. Such actuating materials include 3D printed hydrogels that swell or "Baromorphing" pneumatic elastomers. In these materials local variations of the director field and deformation factors along and across the director field produce global shape changes. These multiple local degrees of freedom allow a single sheet to deform into multiple desired surface geometries in response to external actuation. Actuation by two external parameters, enables the sheet to cycle through a closed loop in conformation space to swim or do work. To solve the inverse problem, we use the curvatures of the target shapes to derive an integrable system of differential equations for the sheet's local degrees of freedom. We then provide an algorithm for integration of this system of equations that allows us to systematically find all solutions to the problem. This approach paves the way to find solutions optimized for different criteria including ease of manufacture, deformation pathway, and work efficiency.

12:39PM B30.00008: Morphing Surfaces for μ-Contact Printing* MITCHELL ANTHAMATTEN (Presenter), SOYOUN KIM, NAN LIU, ALEXANDER A SHESTOPALOV, Chemical Engineering, University of Rochester, JOHN LAMPROPOULOS, Mechanical Engineering, University of Rochester — Micro contact printing is an increasingly reliable technique to pattern various ink materials with microscale precision over large areas on flat or curvilinear substrates. The method involves contacting an elastomeric stamp to a transferable ink, pickup of the ink and transfer to a target substrate, and interfacial fracture to release the ink to a target substrate. Here, we employ shape-memory surfaces with thermo-mechanical programming to achieve large-area pattern transfer to multilayered films from donor substrates to receiving plates. We show that shape-memory can enable robust pattern transfer at higher resolution. New photolithography methods were applied to create patterns of SiO$_2$ microdiscs on a silicon wafer. High resolution pattern transfer of vapor deposited thin films was demonstrated by (i) pressing a shape-memory stamp against a donor substrate; (ii) cooling the system to encourage adhesion between the stamp and the ink; (iii) removing the stamp and pressing against a receiving substrate, and (iv) heating followed by stamp removal to transfer the material. Control experiments indicate that thermal mechanical programming is critical to successful pattern transfer.

11:15AM B31.00001: Viscous flows with thin, compliant boundaries* [Invited] DOMINIC VELLA (Presenter), University of Oxford — Viscous fluids flowing in channels with solid, but compliant, boundaries are common in a range of biological and industrial settings. The presence of such compliance can qualitatively alter the behaviour of such systems, forcing us to revisit the basic principles with which viscous flows are usually understood: the reversibility of Stokes flow no longer holds and the relationship between flux and driving pressure may be nonlinear. In other situations, the mere presence of boundary compliance, combined with capillarity is enough to spontaneously generate fluid motion. I will give examples of some of these unusual behaviours, focussing on situations in which the compliant boundary is in some sense thin, as well as discussing the validity of the different models of boundary compliance.

*ERC Starting Grant 637334

11:51AM B31.00002: Slicing Soft Materials STEVEN RHODES (Presenter), ERIC WEEKS, Emory University — We experimentally study the slicing of soft materials. We use a rheometer to press a circular cutting tool into these materials (a steel “cookie cutter”) at a controlled rotation speed and controlled speed in the normal direction. Typical rates are 100 rad/s angular speed and 10 microns/s normal speed. The rheometer allows us to measure the normal force and torque required to press the cutter through a material. The soft materials we use to experiment with are mainly Styrofoam and Clay. From examining the fluctuations of torque and normal force over time, we find that the most effective cutting occurs with slower normal speed, and that cutting is less sensitive to the rotation rate of the cutter.

12:03PM B31.00003: Valve Elasticity for Optimal Lymphatic Pumping* KI WOLF (Presenter), J. BRANDON DIXON, ALEXANDER ALEXEEV, Georgia Inst of Tech — The lymphatic system transports interstitial fluid, fatty acid, and immune cells and maintains this vital function by pumping the lymphatic fluid via networks of contracting lymphatic vessels and elastic valves. The interplay of peristaltic motion of the lymphatic vessels and valves achieve unidirectional flow against adverse pressure gradient while minimizing any backflow. Despite the significance, research into the lymphatic system has been limited, especially regarding the function of lymphatic valves. We use fully coupled, three-dimensional fluid-structure interaction model to study the performance of compliant lymphatic valves in the lymphatic vessel that undergoes peristaltic motion. Parameters such as adverse pressure gradient, contraction frequency, contraction amplitude, and elasticity of the lymphatic valves are varied to investigate their effects on the flow rate and pumping efficiency, which are compared against their valve-less counterparts. The results suggest that lymphatic valves significantly extend the range of operational adverse pressure gradients. Furthermore, the simulations reveal the optimum valve elasticity enhancing pumping performance.

VISHAL ANAND, IVAN CHRISTOV (Presenter), TANMAY C SHIDHORE, XIAOJIA WANG, Mechanical Engineering, Purdue University — The hydraulic resistance of conduits of any cross-section can be calculated from exact unidirectional flow solutions of the steady Stokes equations. Recently, however, experiments on internal flows in channels with soft boundaries have shown that wall deformation leads to a nonlinear relationship between the volumetric flow rate and the pressure drop. Thus, the soft hydraulic resistance is not simply a constant dependent on the cross-sectional shape. We propose a perturbative approach to solving soft hydraulics problems. The Stokes equations are coupled to the equations of linear elasticity. For a long and slender geometry, the flow problem is reduced to lubrication theory. The deformation of the elastic wall is reduced to a two-dimensional problem in each flow-wise cross-section. Closed-form solutions for the deformation (either from the full elasticity problem or through simplifications via plate theory) allow us to predict the resistance of soft hydraulic elements. Our theory compares favorably to microscale flow experiments, as well as to three-dimensional two-way coupled direct numerical simulations. The effect of non-Newtonian fluid rheology will also be addressed.

12:27PM B31.00005: Devising and characterizing a non-perturbative manipulator in 3D microfluidic channels

JEREMIAS GONZALEZ (Presenter), BIN LIU, Physics, UC Merced — Thanks to the lack of inertia of fluids, hydrodynamic forces in the Stokes regime, such as a microscale flow, are products of only flow pattern geometry. Consequently, an object entrained in a microfluidic flow cannot sense any variations if the surrounding flow remains uniform such that it is strain-free. This concept thus suggests the capacity of a microfluidic device for non-perturbative manipulations, which has not been fully explored. Here, we investigate the capability of such non-perturbative manipulations in a microscope-compatible 3D microfluidic device having vertically offset channels converging on a middle chamber. Using symmetry arguments, we illustrate a minimum of 6 channels are necessary to realize microscale manipulations along arbitrary directions, completely strain-free at the chamber center. By introducing two independent strain rate tensor invariants for characterizing flow perturbation, we demonstrate a finite volume with substantially low strain rate can be achieved around the strain-free center and can thus enable effectively non-perturbative manipulation over a spatial scale much greater than the size of the manipulated objects. We also fabricated such a microfluidic device and demonstrated its non-perturbative manipulation capabilities in experiments.
12:39PM B31.00006: The interaction of elastomeric coatings with viscous flows: how incompressible is PDMS?  THOMAS CHANDLER (Presenter), DOMINIC VELLA, University of Oxford — Elastic substrates bounding fluid flows are common in many experimental and industrial settings; their principal purpose is usually to drive or suppress the flow of fluid. In particular, PDMS is one of the most frequently used materials in microfluidic platforms, since it is easily designed into complex channel shapes. The deformation of such PDMS and other elastomeric layers is becoming increasingly recognised, but the model appropriate for describing its deformation depends on how close to incompressible the coating is. While the Poisson ratio is usually quoted as being in the range of 0.49 – 0.5, the precise value may change the behaviour of the coating and have knock-on consequences. We will present a model for thin, near-incompressible elastic foundations, and discuss how its application to examples of fluid-structure interaction problems at low Reynolds number can depend sensitively on how incompressible the coating is.

12:51PM B31.00007: Active Foam: Connecting Structure, Dynamics and Control*  LAUREL KROO (Presenter), Department of Mechanical Engineering, Stanford University, MATTHEW S BULL, Department of Applied Physics, Stanford University, MANU PRAKASH, Department of Bioengineering, Stanford University — By inflating and deflating voxels within a polydisperse 2-D air-liquid foam, we demonstrate a system where we perturb soft materials in a radially-symmetric manner. These cyclic perturbations can be coordinated spatially and temporally to encode (“write”) mechanical properties into the material. In addition to experiments, we will discuss a new simulation method used to test distributed local control strategies to achieve global behavior. We can estimate where regions of topological rearrangements occur by connecting microstructural mechanics with the dynamics of slowly oscillating sources and sinks in the material. We address the significant complexity that arises from polydispersity and initial topological disorder. The goal of this work is to understand fundamental principles of confluent tissues and develop functional synthetic analogs.

1:03PM B31.00008: Active sieving : from flapping nano-doors to vibrating nanotubes  SOPHIE MARBACH (Presenter), NYU, Courant Institute of Mathematical Sciences, DAVID DEAN, France, Universite Bordeaux, LYDERIC BOCQUET, France, Ecole Normale Superieure — Filtering specific molecules is a challenge faced for several vital needs: from biomedical applications like dialysis to the intensive production of clean water. The domain has been boosted over the last decades by the possibilities offered by nanoscale materials. Filtration is however always designed according to a passive sieving perspective: a membrane with small and properly decorated pores allows for the selection of the targeted molecules. This inevitably impedes the flux and transport, making separation processes costly in terms of energy. Here we investigate alternative approaches to separation and filtration. We explore the possibility of non-equilibrium sieving, harnessing the difference in the molecular dynamics of particles to separate them across "active" nanopores.
1:15PM B31.00009: Fibre-reinforced microfluidic droplets* HERVE ELETTRO (Presenter), FRANCOIS GALLAIRE, Ecole Polytechnique Federale de Lausanne — Soft microfibers can be strongly bent by capillary forces and even be reversibly coiled inside fluid cavities. If present, hydrodynamic forces may compete with capillary forces, uncoil the microfiber and induce its deployment from its original coiled state. Here we fabricate a microfiber coiled within a droplet that is attached on the wall of a microfluidic channel. This is done by photocuring a thin liquid jet of hydrogel (PEG-DA) and transporting the resulting soft microfibre to the carefully prepared droplet for adequate coiling. The mechanical response of the hybrid system is then investigated under increasing flow rates. The present results open opportunities to form the building blocks of microfluidic elements with high on-off ratio that may be useful for the design of on-chip tunable circuits for bioengineering applications.

1:27PM B31.00010: Pulp friction: lubricating properties of soft particle suspensions* JOSHUA DIJKSMAN (Presenter), Physical Chemistry and Soft Matter, Wageningen University, RAISA RUDGE, ELKE SCHOLTEN, Physics and Physical Chemistry of Foods, Wageningen University — Friction between two sliding surfaces is often reduced with a lubricant. Lubricants can contain particles that help mitigate dissipation. The mechanics of friction is complex, especially when soft substrates/particles and lubricating fluids are involved. We shine new light on the complex mechanics of particle based lubrication by evaluating the lubricating properties of particle suspensions. We synthesize custom soft micron-sized gel particles to create a soft particle suspension that acts as model lubricant. The suspension lubrication deviates from typical Striebeck behavior as we find four frictional flow regimes. These frictional regimes are influenced by the particle size, deformability and the amount of particles in suspension, which allows us to propose mechanisms for the different lubrication regimes. We verify some hypotheses by performing lubrication experiments with soft substrates and hard particles.

1:39PM B31.00011: Propagation and interactions of hydraulic fractures in model heterogeneous solids  STEFANO AIME (Presenter), DAVID A WEITZ, Harvard University — The propagation of cracks in heterogeneous environments is a very rich and complex scientific problem, with implications in many fields, from geology, to everyday life and industrially-relevant processes. Interactions of the propagating crack with material heterogeneities, defects, interfaces and other cracks ultimately determine the path that the crack follows, as well as the occurrence of crack branching and merging. Addressing such interactions in experiments is however extremely challenging, since it requires at the same time a fine control of the crack propagation and a detailed knowledge of the material response to the crack itself, which is typically nonlinear and dynamic. In this work we study the propagation of hydraulic fractures in model, well-controlled colloidal materials, using microfluidics coupled to an innovative dynamic light scattering technique providing time- and space-resolved information on the local strain and the microstructural damage caused in the material by the propagating crack. Our preliminary results suggest that combining such information with a fine control of the mechanical and structural properties of our model samples can pave the way for a more comprehensive understanding of crack propagation in heterogeneous media.

1:51PM B31.00012: Effect of the 3D swelling of microgels on their 2D phase behavior at the liquid-liquid interface*  STEFFEN BOCHENEK (Presenter), ANDREA SCOTTI, RWTH - Aachen, LUCIO ISA, ETH - Zurich, WALTER RICHTERING, RWTH - Aachen — We investigate soft, temperature-sensitive microgels at fluid interfaces and how changing temperature across the microgels' volume phase transition temperature, which leads to swelling/deswelling of the microgels in the aqueous phase, affects the phase behavior within the monolayer. We combine compression isotherms, AFM imaging, and ellipsometry. At low compression, the interaction between microgels is dominated by their highly stretched corona and the phase behavior of the monolayers is the same. The polymer segments within the interface lose their temperature-sensitivity. At high compression, the portions of the microgels located in the aqueous side of the interface become relevant and prevail in their interactions. These portions are able to collapse and, consequently, the isostructural phase transition is altered. Thus, the temperature-dependent swelling perpendicular to the interface (3D) affects the compressibility parallel to the interface (2D). Our results highlight the distinctly different behavior of soft, stimuli-sensitive microgels as compared to rigid nanoparticles.

2:03PM B31.00013: Underactuated fluidic control of continuous multistable structures
OFEK PERETZ, Technion - Israel Institute of Technology, ANAND MISHRA, ROBERT SHEPHERD, Cornell University, AMIR GAT (Presenter), Technion - Israel Institute of Technology — This work addresses the challenge of underactuated pattern generation in continuous multistable structures. The examined structure is a slender membrane, actuated by a viscous fluid, which can concurrently sustain two different equilibria states, separated by transition regions. We first demonstrate the formation and motion of a single transition region and then sequencing of several such moving transition regions to achieve arbitrary patterns by controlling the inlet pressure of the actuating fluid. Finally, we show that non-uniform membrane properties, along with the transient dynamics of the fluid, can be leveraged to directly control any segment of the membrane.

11:15AM B32.00001: Multiaxial Stretching of Nearly Critical Gels with Extremely Low Modulus  TAKUMA AOYAMA (Presenter), NAOTO YAMADA, KENJI URAYAMA, Kyoto Inst of Tech — Linear dynamic viscoelasticity of the gelation systems near the critical point has been investigated intensively, but the large deformation behavior of nearly critical gels, which are obtained slightly beyond the gelation point, remains to be characterized. In contrast to matured gels, nearly critical gels have very low modulus due to the extremely sparse network structures. In this study, we have characterized the large deformation of the nearly critical gels by using a custom-made biaxial tensile tester optimized for very soft gels. Biaxial tensile data varying the strains in two directions independently provide a definite basis to discuss the whole aspects of the large deformation behavior. The biaxial tensile data have revealed that the nearly critical gels exhibit minimal cross-effect of strains which results only from volume conservation in contrast to the matured gels with finite cross-effect. The feature of the nearly critical gels is attributed to their extremely sparse network structures.
Soft viscoelastic polymers and gels are commonly used as biomaterials and soft actuators owing to their ability to accommodate large deformations. Their applicability is however often limited by their tendency to abruptly fracture in ways that cannot be predicted by conventional elastic fracture mechanics. Our understanding of the fracturing process in these networks has particularly been hindered by the complex interplay between the viscous dissipation in the bulk and the accumulated damage around the crack tip.

To tackle this question, we explore the condition for a crack to initiate and propagate in transient polymer networks. We used a recently developed Transient Network Theory (TNT) that provides a statistical evolution of a transient network whose topology change as a result of macroscopic deformation and chain reconfiguration via transient crosslinks. This approach is particularly amenable to determine macroscopic measures characterizing the crack driving force. Based on the crack geometry and external loading, we determine the conditions that lead to crack blunting and crack propagation. By determining the interplay of these two mechanisms, we are able to predict fracture process of transient polymer networks with comparison to experiments.

11:39AM B32.00003: High-Rate Dynamics and Fracture Behavior of Model Swollen Polymer Network Characterized by Seeded Laser-Induced Cavitation*  SACCHITA TIWARI (Presenter), Mechanical and Industrial Engineering, University of Massachusetts, Amherst, IPEK SACLIGIL, Polymer Science and Engineering, University of Massachusetts, Amherst, YUE ZHENG, Mechanical and Aerospace Engineering, University of California, San Diego, CHRISTOPHER BARNEY, Polymer Science and Engineering, University of Massachusetts, Amherst, CAREY DOUGAN, Chemical Engineering, University of Massachusetts, Amherst, SHENGQIANG CAI, Mechanical and Aerospace Engineering, University of California, San Diego, ALFRED J CROSBY, Polymer Science and Engineering, University of Massachusetts, Amherst, SHELLY PEYTON, Chemical Engineering, University of Massachusetts, Amherst, GREGORY N TEW, Polymer Science and Engineering, University of Massachusetts, Amherst, JAE-HWANG LEE, Mechanical and Industrial Engineering, University of Massachusetts, Amherst — Mechanical characterization of soft materials at high strain rates is challenging due to their high compliance, slow wave speeds, and rate-dependent viscoelasticity. Swollen polymer networks are attractive model materials as they can be tuned to simulate the high-rate dynamics and damage mechanisms of soft tissues, such as the brain, under extreme mechanical stimuli. In this study, seeded laser induced cavitation (SLIC) is performed within polydimethylsiloxane gels containing a significant amount of solvent (50 - 80 wt.%), levels similar to those of soft tissues. Ultrafast stroboscopic observation of a laser-induced microscale cavity is exploited to characterize the viscoelastic response of the gels at strain rates of $10^6$ s$^{-1}$. By varying the molecular weight between crosslinks from 1.2 to 12 kg/mol, fracture initiation and post-cavitation characteristics of the gels are systematically controlled. The demonstrated SLIC framework can guide the development of tailored synthetic systems that precisely mimic the high-rate plastic behavior of soft tissues.

11:51AM B32.00004: Chemical tools for investigating the topology of polymer networks* [Invited]  JEREMIAH JOHNSON (Presenter), Chemistry, MIT — All polymer networks have topological heterogeneities that span various length scales and dictate their bulk properties. Nevertheless, these features have traditionally been difficult to quantify and control. Informed by classical crossover experiments in physical organic chemistry, we have developed experimental methods for the precise counting of cyclic topologies (loops) in polymer networks. These studies have enabled new theoretical advances pertaining to elasticity and the gel point, and have inspired new stimuli-responsive materials that leverage topology as a design principle.

*National Science Foundation (DMREF CHE-1629358)
12:27PM B32.00005: Cavitation and Fracture of Soft Materials*  CHRISTOPHER BARNEY (Presenter), IPEK SACLIGIL, GREGORY N TEW, ALFRED J CROSBY, Univ of Mass - Amherst — Rapid expansion of soft solids subjected to a negative hydrostatic stress can occur through an elastic cavitation mechanism or an inelastic fracture mechanism. Balancing how these two mechanisms relate is important to applications in materials characterization, adhesive design, and tissue damage. Significant research effort has focused on understanding how these two mechanisms relate; however, the available experimental data in this area has been limited by both the techniques employed and materials considered. Experimental investigation into the transition between cavitation and fracture requires 1) knowledge of the initial cavity geometry and 2) a material system where both the elastic and fracture properties are independently characterized. In this work, recent improvements in needle-induced cavitation and independent characterization of elasticity and fracture in a set of model end-linked tetra-PEG gels are exploited to experimentally probe the relationship between the elasto-fracture length and cavitation and fracture. The results indicate that three distinct regimes exist where expansion occurs through either cavitation, cavitation-initiated fracture, or fracture.

12:39PM B32.00006: Role of Topological Defects on Fracture of Polymer Networks*  AKASH ARORA (Presenter), TZYY-SHYANG LIN, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Chemically crosslinked polymer networks often possess various types of topological defects such as loops and bridges, which are shown to have a noticeable effect on elastic properties of the material. In this work, we use theory and simulations to investigate the influence of such defects on the fracture of the material. A Monte Carlo algorithm is first used to generate a series of 3D periodic networks having varying concentration of defects. The respective networks are then subjected to tensile deformation with the bond breaking events modeled using a kinetic theory of fracture incorporating the experimentally-measured mechanochemical characteristics of covalent bonds. We discuss the effect of both the fraction of primary loops and their spatial distribution on the fracture toughness of the material. Additionally, we use the classical Lake-Thomas theory to estimate the ultimate strength of defects-containing networks, and compare the resulting predictions to simulation results. Using both theory and simulations, this work provides insight into the molecular origins of fracture in polymer networks.

**12:51PM B32.00007: Indentation Rate Sensitive Relaxation of Soft Hydrogels**  
MOHAMMAD ISLAM (Presenter), MICHELLE L. OYEN, Department of Engineering, East Carolina University —  
Mechanical behavior of hydrogels is strongly time-dependent, often characterized as a combination of viscoelastic and poroelastic relaxation. Load-relaxation of hydrogels largely depends on gel composition. Here, we further demonstrate that mechanical loading conditions also influence load relaxation of hydrogels. Spherical indentation experiments are performed for agar, gelatin and polyacrylamide gels with a range of indentation rates. As expected, faster indentation results in more pronounced relaxation in all three gels. The rate-sensitivity is also indentation depth-dependent, such that the degree of relaxation decreases with depth for a constant rate. We interpret the findings within both viscoelastic and poroelastic frameworks. The theoretical analysis demonstrates that viscoelastic relaxation is more rate sensitive compared to poroelastic relaxation. Hydrogels become more viscous at higher indentation rates, indicating significant network reorganization at short time-scales. On the contrary, intrinsic permeability is observed to be largely indentation rate-independent, meaning solvent migration is not affected significantly. Overall, the findings emphasize the importance of loading conditions during mechanical characterization of hydrogels and hydrated biological materials.

**1:03PM B32.00008: Influence of polymer concentration and midblock length on the mechanical behavior of [ABA] triblock copolymer gels in a B-selective solvent**  
SATISH MISHRA, ROSA MARIA BADANI PRADO, Mississippi State Univ, THOMAS E. LACY, Mechanical Engineering, Texas A&M University, SANTANU KUNDU (Presenter), Mississippi State Univ — We present the effect of polymer concentration and midblock length on the large deformation behavior of [ABA] triblock copolymer gels in a midblock selective solvent. In our case, “A” represents poly(styrene) [PS], “B” represents poly(isoprene) [PI], and the solvent is mineral oil. The micellar microstructure of these gels consists of collapsed PS endblock aggregates acting as crosslinks, which are bridged by PI midblocks. The polymer concentration and polymer midblock lengths were varied to introduce midblock entanglement in the gels. Small-angle x-ray experiments capture the micellar microstructure of these gels. Tensile testing reveals a rate dependent moduli for the samples with entangled midblocks. The sample stretchability is governed by stretch rate, midblock length, and polymer concentration. Fracture experiments with a predefined crack reveal a linear dependence of energy release rate with the crack-tip velocity. Fracture in these gels occurs due to endblock pullout from the aggregates and we have estimated the theoretical energy release rate by considering all entropic and enthalpic processes.
1:15PM B32.00009: Fracture of Model End-Linked Networks*  
CHRISTOPHER BARNEY, Univ of Mass - Amherst, ZIYU YE, University of Pennsylvania, IPEK SACLIGIL, GREGORY N TEW, Univ of Mass - Amherst, ROBERT RIGGLEMAN, University of Pennsylvania, ALFRED J CROSBY (Presenter), Univ of Mass - Amherst — Advances in polymer chemistry over the last decade have enabled the synthesis of well-defined networks that exhibit homogeneous structure. These well-defined polymer gels create the opportunity to assess and verify novel and existing molecular models of network elasticity and fracture. A novel theory of network fracture that accounts for loop defects by drawing on recent advances in network elasticity is proposed. This loop modified Lake-Thomas Theory is tested against both MD simulations and experimental fracture measurements on model gels. Good agreement between the theory and measurement is obtained. These findings enable a priori estimation of fracture energy in swollen gels where chain scission becomes an important failure mechanism.

*ONR grant number N00014-17-1-2056

1:27PM B32.00010: Unveiling the effects of molecular topology on the viscoelasticity of entangled polymers under gelation  
WEIZHONG ZOU (Presenter), ALEXANDRA A. SOURAKOV, NATHAN REBELLO, TZYY-SHYANG LIN, BRADLEY OLSEN, JEREMIAH JOHNSON, Massachusetts Institute of Technology — When polymer molecules are constantly crosslinked during the curing process, the presence of intramolecular loops and tree-like hyperbranched structure make the prediction of viscoelastic properties rather complex due to the change of molecular topology. Based on the effective potential in primitive path fluctuations for the relaxation of star polymers [Milner & McLeish, Macromolecules 1997], we propose a novel strategy, i.e., by defining effective relaxation potentials at the “termini” of each polymer strand in a hierarchical manner, to determine the timely movement of the relaxation “front” [Read et al. Science 2011] between the fully relaxed outer layer and the unrelaxed inner core in an arbitrary molecular architecture. For monodisperse polymer systems with specified molecular structure, this model is shown to capture the stress relaxation quite well when compared to those from analytical theories and experimental data. By implementing a kinetic Monte Carlo method [Rui et al. PRL 2016] to access the topological information of crosslinked polymers, this model allows for the prediction of a change in the exponent of power law relationships for rheological moduli at intermediate frequencies with different conversions, which is consistent with the experimental measurements.
1:39PM B32.00011: Constitutive modelling of responsive and non-responsive polymer gels with limited compressibility* PRIYANKA NEMANI (Presenter), RAVI SASTRI AYYAGARI, PRATYUSH DAYAL, Indian Inst of Tech Gandhinagar — Design of futuristic synthetic materials to replicate biological mechanisms has been a challenge for science and engineering. Polymer gels that are intrinsically powered by self-oscillating Belousov Zhabotinsky (BZ) reaction are systems that utilize chemo-mechanical transduction to produce mechanical work from chemical energy. Here, we develop the chemo-mechanical theory for modelling these systems under isothermal conditions. Our approach harnesses the finite element framework to combine the reaction-diffusion phenomena with large elastic deformations of the non-gaussian compressible polymeric networks. In particular, we use Oregonator model to capture BZ kinetics while the modified Flory-Huggins theory is used to capture interactions between BZ-catalyst and polymer gel. Using our model we simulated the dynamics of BZ and non-responsive gels under equilibrium and transient conditions; we validated our results with the existing models and experimental results. In essence, we develop and establish a framework to design and study responsive materials with complex geometries. Moreover, we believe that by extending our methodology it is possible to capture large deformations akin to volume phase transitions in polymer gels under non-isothermal conditions.

*DST-SERB (EMR/2016/007778)

1:51PM B32.00012: New Insights into the Chain Dynamics and Microstructure of Highly Crosslinked Polymer Networks as a Function of Network Heterogeneity BRAD JONES (Presenter), TODD M ALAM, MATHIAS C CELINA, Sandia National Laboratories, SANGWOO LEE, Isermann Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute — Key physicochemical phenomena in polymer networks are critically impacted by the spatial distribution of crosslinks, i.e., network heterogeneity. Despite this fact, the chain dynamics and microstructure of heterogeneous networks, particularly bulk thermosets, have not been well characterized. To this end, we present a detailed investigation of novel photopolymerized thiol-ene networks. High glass transition temperatures and continuously tunable network heterogeneity were achieved by varying the stoichiometry between aromatic thiol and acrylate monomers. The chain dynamics and microstructure of these materials were characterized using a combination of dynamic mechanical analysis, solid-state nuclear magnetic resonance spectroscopy, and small angle x-ray scattering. We found that heterogeneous networks exhibited enhanced mobility deep in the glassy state, in contrast to their homogeneous counterparts. In addition, the heterogeneous and homogeneous networks were distinguished by their fractal structures. These new insights may help guide the future design of new crosslinked polymers with carefully controlled network heterogeneity.
Deformation of Inhomogeneous End-linked Polymer Networks

ZIYU YE (Presenter), ROBERT RIGGLEMAN, University of Pennsylvania — Polymer networks represent an important class of soft materials with a broad range of applications in adhesives, coatings, membranes and natural materials. In particular, synthetic end-linked polymer gels, where the network is swollen in solvent, has received growing attention in the biomedical field due to their structural and mechanical similarities to tissues. Failure of these materials during mechanical deformations is intimately tied to their elastic and fracture properties. Synthetic and natural gels have highly complex environments that contain defects and phase boundaries, and the interplay between these molecular structures and the elastic and fracture responses remains an open question. In this study, we use molecular dynamics simulations to prepare and characterize two-phase polymer networks with one glassy and one rubbery domain. We characterize their mechanical properties and how the strain localizes in the glassy and rubbery domains as a function of the polymer chain length. Our simulations reveal that structural features on multiple length-scales serve to localize the site of failure.

Session B33 DPOLY DSOFT GSNP: Polymer Nanocomposites: Interfaces

Designing Polymer Nanocomposites: Critical Role of the Interfacial Layer

ALEXEI SOKOLOV (Presenter), University of Tennessee, Knoxville — It is now well recognized that interfacial layer controls macroscopic properties in polymer nanocomposites (PNCs). In this talk we overview recent studies on structure and dynamics of the interfacial layer in various PNCs. We employ broad array of experimental techniques and MD-simulations that provide detailed characterization of the interfacial layer. These studies revealed a gradient in the interfacial layer dynamics, but no “glassy” or “dead” layer. The thickness of the interfacial layer increases upon cooling to Tg, and depends strongly on polymer rigidity, increasing from ~2nm in flexible polymers to ~5 nm in more rigid ones. We discuss a possible connection of the interfacial layer thickness to the dynamic heterogeneity length scale. We emphasize usually overlooked dynamic property of the interfacial layer – strong suppression of the amplitude of structural relaxation on time scale of segmental dynamics. At the end, we present a general picture how microscopic parameters control the interfacial layer, and how by tuning the interfacial layer we can tune macroscopic properties of polymer nanocomposites.

**11:51AM B33.00002: Dynamics in polymer and polymer-grafted nanocomposites: it's the interfacial zone after all**

EMMANUEL MAPESA (Presenter), DAYTON P. STREET, S. MICHAEL KILBEY II, JOSHUA SANGORO, University of Tennessee, Knoxville — Polymers exhibit deviations from their bulk physical properties in the vicinity of solid substrates due to changes in various properties arising in the interfacial regions. Broadband dielectric spectroscopy and differential scanning calorimetry are used to study molecular dynamics in poly(methyl methacrylate)/silica nanoparticle composites. By systematically examining nanocomposites based on non-functionalized Si NPs dispersed in PMMA matrices and on PMMA-grafted Si NPs in PMMA matrices, we investigate the effects of interfacial interactions and confinement in each of these cases on $T_g$ and the time-scales as well as breadth of the corresponding dielectric relaxations. We show that in addition to slower mobility, which is commonly reported in literature and assigned to interfacial relaxations, faster modes also arise due to confinement effects, and that these faster modes are more pronounced in nanocomposites with polymer-grafted nanoparticles. These faster relaxation modes are attributed to the increasing importance of chain wetting and packing in the interfacial zones around nanofillers.

**12:03PM B33.00003: Theory of coupled activated relaxation in dense polymer-particle mixtures: effects of size ratio, particle loading and interfacial attraction**

YUXING ZHOU (Presenter), KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Dense polymer-particle mixtures represent a wide range of systems including polymer nanocomposites, polymerized ionic liquids, and bio-related materials. Understanding and predicting the dynamical and mechanical properties of such hybrid systems is of practical importance and high theoretical interest. Here we study the dynamics of polymer nanocomposites using the Elastically Collective Nonlinear Langevin Equation (ECNLE) theory with structural correlations obtained from Polymer Reference Interaction Site Model (PRISM) approach. The latter captures the depletion, steric stabilization, and tight bridging states of structural organization. We focus on the effects of particle-segment size ratio, interfacial (cross) attraction strength, and particle loading on the segmental relaxation time, glass or gel like mechanical properties, and kinetic arrest. Cooperative motions of segments and particles is treated in a dynamically self-consistent manner, and compared to the limiting case of pinned particles. We find a rich dynamical behavior with both plasticization and anti-plasticization regimes, and a nanocomposite shear modulus which can be either softened or reinforced. The key physics relates to the interplay between geometric packing and physical bonding effects.
The interfacial zone around nanoparticles in polymer nanocomposites and in thin polymer films

WENGANG ZHANG (Presenter), National Institute of Standards and Technology, HAMED EMAMY, BEATRIZ PAZMINO BETANCOURT, FERNANDO VARGAS-LARA, FRANCIS STARR, Wesleyan University, JACK DOUGLAS, National Institute of Standards and Technology —

We perform coarse-grained simulations of polymer materials to quantify the range over which interfaces alter the structure and dynamics near the interface. We study the interfacial zone around nanoparticles (NPs) in polymer-NP composites with variable NP diameter, as well as the interfacial zone at the solid substrate and free surface of thin supported polymer films. These interfaces alter both the segmental packing and mobility in an interfacial zone. Variable NP size allows us to gain insight into the effect of boundary curvature, where the film is the limit of zero curvature. We find that the scale for perturbations of the density is relatively small and decreases on cooling for all cases. In other words, the interfaces become more sharply defined on cooling. In contrast, the interfacial mobility scale $\xi$ for both NPs and supported films increases on cooling and is on the order of a few nanometers, regardless of the polymer-interfacial interaction strength. Additionally, the dynamical interfacial scale of the film substrate is consistent with a limiting value for polymer-NP composites as the NP size grows. These findings are based on a simple quantitative model to describe the distance dependence of relaxation that should be applicable to many interfacial polymer materials.

**12:27PM B33.00005: Polymer NanoComposites, Interfaces and Data** [Invited]  
CATHERINE BRINSON (Presenter), Duke University — For polymer composites, nanocomposites and polymer thin film systems, the local properties of polymers can be altered by the chemical and physical interactions with substrates and embedded particles over a substantial length scale. In order to better understand and design nanocomposites, polymer coatings and electronic components, it is essential to develop better understanding and robust design strategies. Two key missing links are understanding of altered polymer properties near surfaces/particles and ability to quantitatively leverage prior data for these systems, predictively in a robust manner. Therefore there is great interest in utilizing scanning probe methods to quantify the local property changes in the polymer region near surfaces. Additionally, there is great need to harvest, record and be able to learn from the vast amount of data archived in journal articles. In this work, both experimental characterization and development of a data framework and infrastructure is presented. The ability of Atomic Force Microscopy (AFM) to characterize the local mechanical properties (elastic and viscoelastic) of the interphase region in model composites is presented and combined with numerical simulations to refine the analysis. A new platform for data, analysis tools and simulation portals for polymer nanocomposites will be presented: NanoMine. NanoMine utilizes a robust schema to hold the data in a software infrastructure with query, visualization and microstructure analysis tools. Case studies are demonstrated which connect the property-structure-property domains through a combination of machine learning and physics-based modeling, demonstrating the ability to identify the most critical features influence properties. Together this work illustrates a new approach to tackle materials design principles for the complex, high dimensional problems inherent in the multi-phase polymer space.

Chemical Heterogeneities and Architectures of Interfacial Layers in Polymer Nanocomposites

DI WU (Presenter), SIYANG YANG, PINAR AKCORA, Stevens Inst of Tech

Polymer coated nanoparticles have been widely used to achieve good dispersion in polymer matrices. Dynamics and glass-transition temperature of bound interfacial layers on nanoparticles of different sizes have been recently investigated to understand the effect of interfacial relaxations as they govern reinforcement in composites. We investigate the effect of chemical heterogeneities and varying chain architectures around nanoparticles on tuning the dynamics of interfacial polymers, hence the mechanical properties such as thermal-stiffening. Fe$_3$O$_4$ nanoparticles adsorbed or grafted with PMMA chains and dispersed in PMA matrices are prepared and their rheological behavior is characterized. Our findings show that short adsorbed chains lead to thermal-stiffening, whereas long adsorbed chains yield softening with increasing temperature. Conformations of adsorbed and grafted chains on the same particle sizes will be discussed together to reveal this unusual behavior which relies on the interfacial chemical heterogeneities in polymer nanocomposites. Further, other types of adsorbed chains of PA, P2VP, PMMA, with decreasing rigidity, are compared to understand the role of rigid chains on interfacial dynamics and relaxations.

Interfacial mechanics and viscoelastic properties of patchy graphene oxide reinforced nanocomposites

ZHAOXU MENG (Presenter), Clemson University

Graphene oxide (GO) is a promising building block for nanocomposites due to its excellent mechanical properties and tunable interfacial interactions with polymers. While experiments have shown that GO sheets consist of graphitic regions clustering into patches and oxidized regions constituting the remaining areas, the role that these heterogeneous patches play on interfacial and mechanical properties of GO reinforced nanocomposites have not yet been investigated. To address this issue at spatiotemporal scales beyond atomistic simulations, we employ recently developed coarse-grained models of GO sheet and polybutadiene to model patchy GO sheets and a representative GO/polybutadiene nanocomposite with GO sheets serving as fillers. We quantify how interfacial adhesion energy and polymer conformations depend on the size of patches and corroborate these findings with the viscoelastic behaviors of the nanocomposite. We find that heterogeneous patchy structures on GO sheets are responsible for variations in interfacial and viscoelastic properties of GO-based nanocomposites. Our study provides fundamental insights into the interfacial mechanisms of GO-polymer nanocomposites and the influence of heterogeneous functionalized surfaces on the mechanical properties of polymer nanocomposites.
1:27PM B33.00008: Theory and Simulation of Polymer Brushes - Interaction and Structure
SABIN ADHIKARI (Presenter), SANAT KUMAR, Chemical Engineering, Columbia University — Addition of polymer-grafted nanoparticles (NPs) to a polymer melt can result in hybrid materials with improved properties. Understanding of the structure and the interactions of polymer-grafted NPs in a melt is essential to improve their practical applicability. In this study, we focus on the fundamental aspects of the interactions and structure of polymer brushes in either a poor solvent (i.e., incorporating compressibility effects in the brush) or in a (compressible) polymer-matrix. First, we study two planar brushes in a poor solvent and then in a matrix-polymer melt by using theory and simulations. We study the dependence of monomer density distribution, brush height, and the interaction force between two brushes as a function of graft density and polymer chain length. Then we discuss the generalization of our results to a spherical geometry of relevance to the practically important testbed of polymer grafted nanoparticles.

1:39PM B33.00009: Aggregation of Grafted Nanoparticles in a Polymeric Matrix  CLEMENT KOH (Presenter), Columbia Univ, GARY GREST, Sandia National Laboratories, SANAT KUMAR, Columbia Univ — A common phenomenon for polymer-grafted nanoparticle (PGNP) systems is that NP aggregation spontaneously occurs at a specific ratio of the chain length $N_g$ of the grafted chains to the matrix chain length $N$. This aggregation is generally considered to be entropic in origin and can be attributed to the autophobic dewetting of the grafted chains. Here, we incisively probe the microscopic driving force governing PGNP aggregation through a series of large-scale multi-particle simulation studies. The matrix chain length, graft chain length, and volume fraction were varied. Analysis of our simulations indicate that aggregation take place only at unexpectedly low ratios of $N_g/N$. Further, simulations tuning the interaction mismatch between nanoparticles and polymer chains indicate that some form of enthalpic interplay between the polymer chains and NPs is significant in controlling the PGNP aggregation that is observed experimentally. These results suggest that entropy alone is probably not the only factor driving nanoparticle aggregation in nanocomposites.
Surface Segregation and Wetting of Nanoparticles in Polymer Nanocomposites

SHAWN MAGUIRE (Presenter), Materials Science & Engineering, University of Pennsylvania, JOHN DEREK DEMAREE, Weapons & Materials Research Directorate, Army Research Laboratory, CONNOR BILCHAK, Chemistry, University of Pennsylvania, NADIA KROOK, DuPont Co., Wilmington, DE, MICHAEL J. BOYLE, Materials Science & Engineering, University of Pennsylvania, ANDREEA-MARIA PANA, Chemical and Biomolecular Engineering, University of Pennsylvania, PATRICE RANNOU, MANUEL MARÉCHAL, UMR5819-SyMMES (CNRS/CEA/UGA), French National Centre for Scientific Research (CNRS), KOHJI OHNO, Polymer Chemistry, Kyoto University, RUSSELL COMPOSTO, Materials Science & Engineering, University of Pennsylvania — The segregation and wetting of polymer grafted nanoparticles (NP) to the free surface of a polymer nanocomposite film is driven by both surface energy and thermodynamic forces. Here, we probe these two contributions in a model system of PMMA grafted silica NPs in a poly(styrene-ran-acrylonitrile) (SAN) matrix using Rutherford backscattering spectrometry (RBS) and atomic force microscopy (AFM) as a function of thermal annealing temperature and time. Studies are performed above and below the critical point of this LCST system to decouple the thermodynamic and interfacial energy contributions. With increasing time, a monotonic increase in surface excess of PMMA grafted NPs is observed in the miscible regime, which is attributed to the difference in surface energies between the PMMA brush and SAN matrix. Upon annealing above the critical point, a much stronger increase in PMMA NP surface coverage is observed because of the thermodynamic driving force, namely the Flory-Huggins interaction parameter between the PMMA grafts and SAN matrix. Using the measured surface excess values of PMMA NPs at multiple annealing times and temperatures, we then extract the apparent diffusion coefficients of the particles and compare them to the systems homopolymer analogue.

2:03PM B33.00011: Initial Solvent-Driven Nonequilibrium Effect on the Adsorption Layer of Polymer Nanocomposites*

SOL MI OH (Presenter), Ulsan Natl Inst of Sci & Tech, MOZHDEH ABBASI, Martin-Luther University Halle-Wittenberg, TAE JOO SHIN, UNIST Central Research Facilities & School of Natural Science, KAY SAALWAECHTER, Martin-Luther University Halle-Wittenberg, SO YOUN Y KIM, Ulsan Natl Inst of Sci & Tech — There have been extensive efforts to characterize interfacial layers in polymer nanocomposites (PNCs), which determines the final structures and properties of PNCs. While tremendous studies have focused on intrinsic parameters of components such as size, shape, chemistry, an understanding for the variation of the structure and dynamics under different processing conditions is relatively lacking. In this work, we report that the initial dispersing solvent, which is not present in final PNCs, induces nonequilibrium effects on polymer chain dynamics at interfaces. By employing $^1$H NMR free induction decay, we probe that the quantity rather than the mobility of interfacial polymers can be changed depending on the initial solvent, which leads to a difference in thickness of interfacial layers. Accordingly, the particle microstructures and rheological properties are greatly influenced observed by small-angle X-ray scattering and oscillatory rheometry experiments. In addition, we reveal that the outcome of the nonequilibrium effect driven by the initial solvent becomes more prominent at effective range of particle volume fraction related to the polymer chain dimension.

Session B34 DPOLY DSOFT: Confinement, Dynamics, and Ion Interactions in Ion-Containing Polymers II 506 - Bryan Beckingham, Auburn University - Tag(s): Focus
**11:15AM B34.00001: Ion Confinement in Self-Assembled Precisely Segmented Polyolefin Ionomers**

KAREN WINEY (Presenter), LU YAN, JINSEOK PARK, University of Pennsylvania, STEFAN MECKING, University of Konstanz — Confining ions within self-assembled nanoscale structures is demonstrated in a series of single-ion conducting segmented polyolefins, nominally multiblock copolymers. We report a series of precisely-segmented polyethylene-like ionomers containing sulfonate groups (PES) with Li+, Na+, Cs+, or NBu4+ counterions synthesized from step-growth polymerization. At room temperature, the PES ionomers with long methylene units are semicrystalline with well-defined nanoscale ionic layers with spacings influenced by the spacer length and cation type. In situ X-ray scattering measurements reveal that the layered ionic aggregates in some of these polymers transform, upon melting the PE segments, into gyroid morphologies. The gyroid structure can further evolve into hexagonal symmetry as T increases. The ion transport behavior of these polymers is strongly dependent on the ionic aggregate morphologies. Specifically, a 3D interconnected gyroid morphology exhibits higher ionic conductivity than the isotropic layered or hexagonal morphologies. This innovative and versatile molecular design of ionomers leads to unprecedented percolated gyroidal ionic aggregate morphologies that provide a continuous pathway for improved ion transport.

*National Science Foundation - DMR/Polymers

**11:27AM B34.00002: Unraveling how nanoconfinement and phase-separation affect the transport properties of ionomer membranes**

RUI ZHANG (Presenter), Department of Chemistry and Macromolecules Innovation Institute, Virginia Tech, YING CHEN, Physical & Computational Sciences Directorate, Pacific Northwest National Laboratory, DIEGO TROYA, LOUIS A MADSEN, Department of Chemistry and Macromolecules Innovation Institute, Virginia Tech — Transport of water and ions through ionic polymer membranes depends on multi-scale membrane structure. This talk will focus on the nano-scale structure-transport relations of ionomer membranes. We will present studies on the temperature dependence of diffusion as a function of water uptake in a perfluorosulfonic acid (PFSA) membrane. Using NMR diffusometry and MD simulations, we are able to probe the activation energy of water diffusion \( E_a \), which arises from molecular scale interactions and reflects the nano-scale environment of a water molecule. By comparing \( E_a \) in the PFSA membrane to \( E_a \) in a free liquid environment, we are able to identify two structural primary features of ionomer membranes, nanoconfinement and nano-scale phase separation, that affect membrane transport. Nanoconfinement alters local energetics of water molecules and can prompt formation of more ordered water structures. Nano-scale phase separation creates a local environment for water molecules that is closer to that of pure water, and thus gives rise to \( E_a \) values that approach that of pure water. These findings shed light on the fundamental aspects of structure-transport interplay in ionomer membranes.

11:39AM B34.00003: Polymeric Ionic Liquid-Ligand Gels Exhibiting Transient Gel Behavior and Multivalent Ion Conductivity  SEAMUS JONES (Presenter), Chemical Engineering, University of California, Santa Barbara, NICOLE MICHENFELDER-SCHAUSER, Materials, University of California, Santa Barbara, GLENN H FREDRICKSON, RACHEL A SEGALMAN, Chemical Engineering, University of California, Santa Barbara — The conduction of metal ions through solid polymeric electrolytes relies on favorable but highly dynamic interactions between mobile metal cations and polymer-bound solvating functionalities. Metal-ligand interactions have shown promise as solvating functionalities in solid polymer electrolytes due to their ability to strongly solvate metal salts while simultaneously conducting mono and multivalent metal ions in the solid state. These interactions simultaneously act as reversible cross-links, enhancing the storage modulus of the material over short timescales. Controlled poly(methyl acrylate)s with imidazole chain ends are synthesized as model polymers to investigate metal-ligand bond lifetimes and design rules for solid polymer electrolytes. Materials with a controlled number of imidazole ligands per chain are used to generate dynamic star-like and network topologies which relax to a disordered melt through metal-ligand bond dissociation. The network-forming materials are further used to probe the kinetics of cation-ligand association when the identity and valency of the metal cation is varied. Scaling arguments based on oscillatory rheology and electrical impedance measurements are used to support a hopping-type mechanism of ion conduction in metal-ligand coordinating polymers.

11:51AM B34.00004: Hydroxide conducting block copolymers* [Invited] YOSSEF ELABD (Presenter), Texas A&M Univ — Hydroxide ion conducting block copolymers have the potential to possess the multiple orthogonal properties required for anion exchange membranes to enable long-lasting alkaline fuel cell performance, and therefore can accelerate the advancement of the alkaline fuel cell, a low-cost alternative to the well-adopted commercial proton exchange membrane fuel cell. In this work, an overview of hydroxide ion transport (a property that is proportional to fuel cell performance) in block copolymers will be presented and the subsequent impact of block copolymer morphology on ion transport (conductivity), where the careful design of block copolymer chemistry and chain architecture can accelerate hydroxide ion transport and subsequently alkaline fuel cell performance.

Simulation of Ion Transport through Percolated Aggregates in Precise Sulfophenylated Polyethylene Ionomers

BRYCE THURSTON (Presenter), MARK STEVENS, Center for Integrated Nanotechnologies, Sandia National Laboratories, BENJAMIN PAREN, KAREN WINEY, Materials Science & Engineering, University of Pennsylvania, AMALIE FRISCHKNECHT, Center for Integrated Nanotechnologies, Sandia National Laboratories — Ionomers present an attractive potential alternative to standard electrolytes in Li ion batteries due to their capacity to function as single-ion conductors. When the spacing between adjacent pendant groups is precisely controlled, ionic groups within ionomers have been shown to self-assemble to form aggregates with well-ordered morphologies. The structure of these aggregates can have a significant impact upon ion conductivity. In order to gain greater understanding at the microscopic level, we perform fully atomistic molecular simulations to probe the assembled ionic aggregates of sulfophenylated polyethylene ionomers with a spacing of five carbon atoms between pendant groups (p5PhS), neutralized with a series of cations (Li, Na, and Cs). We find that the ionic aggregates form percolating clusters provided the polymers are neutralized with a sufficiently high fraction of cations. Li and Na aggregates take ribbon-like configurations, while Cs aggregates are more disordered. In each case the ions are able to slowly diffuse from sulfonate group to sulfonate group through the percolated aggregates, with larger ions exhibiting larger mean-squared displacements. Finally, structure factors computed from simulation agree reasonably well with experimental X-ray scattering data.

Mechanisms of Ion Transport in Block Copolymeric Polymerized Ionic Liquids

ZIDAN ZHANG (Presenter), University of Texas at Austin, JAKUB KRAJNIAK, KU Leuven, JORDAN R KEITH, VENKATRAGHAVAN GANESAN, University of Texas at Austin — We present the results of a multiscale simulation framework investigating the ion transport mechanisms in multicomponent polymerized ionic liquids. Three different classes of polymeric ionic liquid systems, viz., random copolymers, lamellae forming block copolymers and homopolymers are constructed at the coarse-grained scale, and their atomistic counterparts are derived by using a reverse mapping method. Using such a framework, we investigate the influence of morphology on ion transport properties of such polymerized ionic liquids. Our results for ion mobilities are in qualitative agreement with experimental observations. Further analysis of random copolymer and block copolymer systems reveal that the reduced ion mobilities in such systems arise from the influence of architecture and/or morphology on ion coordination and intramolecular hopping events.
Composition fluctuation in weakly heterogeneous dielectric medium containing ions*  

XIAN KONG (Presenter), KEVIN J HOU, JIAN QIN, Stanford Univ — Impacts of salt doping on morphological behavior of block polymers, though well-documented, remain poorly understood. Selective ion solvation has been identified as a driving force for ordering, and its effects studied using mean-field models. We present an analysis of the composition fluctuation that couples, through the heterogeneous dielectric profile, to the ionic solvation in the weakly heterogeneous regime. The free energy is mapped onto the Brazovskii form. The scattering peak is found to depend on salt-doping, as a result of the shift of the critical point and the pairwise Coulomb interaction. Phase diagrams are presented under different doping conditions, revealing the competition between selective solvation and fluctuation. The need of consistently parameterizing permittivity and dispersion interaction is discussed.

Permeation and copermeation behavior of methanol and acetate in cation exchange membranes*  

JUNG MIN KIM, BRYAN BECKINGHAM (Presenter), Auburn University — The permeation of solutes, molecules and ions, through hydrated polymer membranes is of critical importance for many applications. We utilize in situ ATR FTIR spectroscopy to quantify the multicomponent transport of molecules and polyatomic ions through ion exchange membranes. We examine the individual and co-permeation of methanol and acetate across commercially available membranes, Nafion 117, and synthesized polyether-based membranes of varied and tunable ion content and charge type. Membrane permeability and selectivity calculated from single component permeation experiments are compared to those calculated for solutes in multicomponent permeation experiments. In Nafion 117 and model cation exchange membranes we find distinct differences in transport behavior of the acetate anion while the behavior of methanol remains unchanged. We also find no difference in transport behavior for these solutes in uncharged polyether membranes. We attribute this emergent transport behavior of the acetate anion to specific solute-solute-membrane interactions which likely emerge from the electrostatic screening of interactions between the acetate anion and membrane-bound anions.

*The authors thank Auburn University Presidential Award for Interdisciplinary Research.
**1:15PM B34.00009: Percolated ionic aggregates in precise sulfophenylated polyethylene ionomers: Morphology and ion transport**

BENJAMIN PAREN (Presenter), University of Pennsylvania, BRYCE THURSTON, Sandia National Labs, JUSTIN G KENNEMUR, Florida State University, MARK STEVENS, AMALIE FRISCHKNECHT, Sandia National Labs, KAREN WINEY, University of Pennsylvania — We present a set of precise single-ion conducting ionomers that demonstrate decoupled transport of metal cations within self-assembled percolated aggregates in glassy polymer matrices. These precise ionomers consist of a polyethylene backbone with a sulfonated phenyl group pendant on every 5th carbon, that is fully neutralized by a counterion X (Li\(^+\), Na\(^+\), or Cs\(^+\)), p5PhSA-X. The morphologies of these ionomers are characterized with X-ray scattering, and the ion transport properties are characterized with electrical impedance spectroscopy. Both experiments are performed under vacuum, from room temperature up to 180°C. Atomistic molecular dynamics simulations elucidate that the structure of the aggregates in the ionomers is a percolated network. The characteristic length scales of these percolated aggregates as measured by X-ray scattering are ~2nm and independent of ion type. There is good agreement between simulations and experimental X-ray scattering data. The ionomers exhibit conductivity of \(10^{-7}\) to \(10^{-6}\) S/cm at 180°C and demonstrate Arrhenius behavior up to 180°C. This indicates that the ion transport is decoupled from the polymer backbone, which is consistent with a percolated aggregate within which ions travel.

**1:27PM B34.00010: Investigation of monomer segment distributions, chain conformations, and lithium salt solvation in self-assembled, tapered block polymer electrolytes**

PRIYANKA KETKAR (Presenter), Chemical and Biomolecular Engineering, University of Delaware, KUAN-HSUAN SHEN, LISA HALL, William G. Lowrie Department of Chemical and Biomolecular Engineering, The Ohio State University, THOMAS EPPS, Chemical and Biomolecular Engineering, University of Delaware — Tapered block polymers (TBPs) contain modified monomer segment distributions (e.g., gradient or random copolymer regions) at the chemical junction between two homogeneous blocks. Nanostructured polystyrene-\textit{block}-poly(oligo-oxoethylene methacrylate) (PS-\textit{b}-POEM) TBP electrolytes have exhibited improved ionic conductivities, shear moduli, and processabilities in comparison to their conventional block polymer analogues. In this work, we studied the microscopic characteristics of TBPs that impart these enhanced properties. The monomer segment distributions of lithium salt-doped normal-, inverse-, and non-tapered PS-\textit{b}-POEM TBPs were obtained \textit{via} X-ray reflectivity, and these distributions also were successfully modeled through coarse-grained molecular dynamics simulations that included strong ion solvation effects. This combined experimental-computational approach allowed the segregation strengths, chain conformations, and ion solvation energies of the salt-doped TBPs to be quantified as a function of taper sequence and salt concentration. By understanding how these polymer assembly and ion solvation behaviors affect ion transport, we can guide the rational design of higher-performance polymer electrolytes.
1:39PM B34.00011: Model single ion conducting polymer networks for understanding the impact of ion content, crosslink density, and side chain length on Li transport
CHRISTOPHER EVANS, University of Illinois at Urbana-Champaign, CHENGTIAN SHEN (Presenter), Chemistry, University of Illinois, Urbana-Champaign — Single ion conducting polymer networks were designed containing tethered anions of bis(trifluoromethane sulfonamide) (TFSI), an acrylic backbone, and ethylene oxide (EO) side chains and crosslinkers to develop fundamental structure property relationships. The crosslinking density was varied from 1-50 % mol of the starting monomers, while the crosslinker was an EO diacrylate with 11, 22, or 33 atoms between acrylate groups. The Li to EO ratio was set by the density of fixed TFSI sites and spanned 1:20 to 1:100, while the length of EO side chain on non-ionic monomers was 11 or 22 atoms is achieved. By systematically manipulating parameters, a 3 order of magnitude difference in ionic conductivity and a 70 C shift in Tg was observed indicating the importance of design in such networks. Conductivities approaching 10^{-5} S/cm are reported in dry, single ion conducting networks which is comparable to the state-of-the-art. Adding plasticizer further increases the conductivity. The observed structure-conductivity trends provide insight into the design of single ion conductors for a broad range of energy applications.

1:51PM B34.00012: Salt-tethered nanoparticles in solvent: A potential high conductivity, high lithium transference number electrolyte system* SANKET KADULKAR (Presenter), DELIA MILLIRON, THOMAS TRUSKETT, VENKATRAGHAVAN GANESAN, University of Texas at Austin — Improving the lithium transference number in electrolytes, while maintaining high ionic conductivity, is crucial for reliable and high-performing lithium-ion battery technologies. In this work, using computer simulations, we model a relatively new class of electrolyte system, reported in a recent work [Chem. Mater. 2013, 25, 6, 834-839], wherein nanoparticles cofunctionalized with polymeric ligands and tethered lithium salts, are dispersed in a solvent host. We employ a sequential combination of Molecular Dynamics and kinetic Monte Carlo simulations, to study ion transport in this system. Our results are qualitatively consistent with the experimental findings. Specifically, we explain the interesting dependence of ionic conductivity on nanoparticle composition and anion chemistry. Further, we predict significant improvement in conductivity with high dielectric constant solvents. These results suggest that such electrolyte systems can potentially exhibit high conductivity, along with high lithium transference number.

*Support for this research was provided by the National Science Foundation through the Center for Dynamics and Control of Materials: an NSF MRSEC under Cooperative Agreement No. DMR-1720595.
Cluster Cohesion Effects on Segmental Dynamics in Ionic Polymer Solutions: Molecular Dynamics Simulation Studies* CHATHURIKA KOSGALLANA (Presenter), Department of Chemistry, Clemson University, Clemson, SC, SIDATH I WIJESINGHE, Department of Chemistry, University of North Carolina at Chapel Hill, Chapel Hill, NC, MANJULA SENANAYAKE, SUPUN SAMINDRA KAMKANAM MOHOTTALALAGE, Department of Chemistry, Clemson University, Clemson, SC, Piotr Zolnierczuk, Oak Ridge National Laboratory, Oak Ridge, TN, Gary Grest, Sandia National Laboratories, Albuquerque, NM, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC — A small number of ionizable groups tethered to a polymer backbone restricts their macroscopic dynamics. Here, using molecular dynamic (MD) simulations, the dynamics of sulfonated polystyrene (PSS) in toluene solutions are studied as the ionic domains are perturbed by small amounts of ethanol. The static and dynamic structure factors, S(q) and S(q,t) were calculated. S(q) exhibits a characteristic ionic domain signature that is affected by ethanol content. S(q,t), analyzed by KWW resolved two dynamic regions. At low ethanol concentrations, segmental dynamics increase, followed by constrained motion with increased alcohol concentration. Initially, the ionic domains swell, enabling segmental motion. Higher ethanol concentrations collapse the PS segments restricting the motion. These MD results are in excellent agreement with our neutron spin echo data.

Session B35 DPOLY: Directed Self-Assembly of Copolymers in Confined Geometry II 507 - Du Yeol Ryu, Yonsei University - Tag(s): Focus

In-Situ TEM Visualization of Pressure-Induced Ordering of Nanostructured Block Copolymer Thin Films RONG-MING HO (Presenter), CHEN-JUNG HUNG, SHIH-YI LI, JHENG-WEI LIN, HSIAO-FANG WANG, AUM SAGAR, YI-CHIEN LEE, Natl Tsing Hua Univ, AN-CHANG SHI, McMaster University, APOSTOLOS AVGEROPOULOS, University of Ioannina, FAN-GANG TSENG, Natl Tsing Hua Univ, FU-RONG CHEN, City University of Hong Kong — Here, we aim to suggest a facile and effective method for controlled orientation of block copolymer (BCP) thin films driven by pressure-induced ordering during thermal annealing. A novel chip with a built-up metal wire-based micro heater was fabricated utilizing microelectromechanical system (MEMS) technique to in-situ investigate the morphological evolution of free-standing polystyrene-block-polydimethylsiloxane (PS-PDMS) star-block copolymer thin films for demonstration of the suggested pressure-induced ordering. Owing to the high vacuum (~10^{-4} Pa) environment, the low pressure could transfer the extremely selective surface to weakly selective surface for the PDMS and PS, giving the neutral air surface for the formation of span-thru perpendicular cylinders with high-degree lateral ordering, as directly visualized by TEM. We believe that this finding will bring the new opportunities for the designs of polymeric materials in practical applications.
11:27AM B35.00002: Uncovering Hidden Structure in Polymer Films with Soft X-ray Reflectivity  
DANIEL SUNDAY (Presenter), JACOB THELEN, National Institute of Standards and Technology, CHUN ZHOU, IME, University of Chicago, R. JOSEPH KLINE, National Institute of Standards and Technology, PAUL F NEALEY, IME, University of Chicago — Studies on lamellar forming block copolymers (BCPs) organized parallel to a substrate are important for understanding assembly in confined conditions and the impact of surface effects. These have typically been conducted using either hard X-rays or neutron reflectivity where the contrast mechanism makes it difficult to distinguish depth dependent structural variations. Using soft X-rays the optical constants of a material can be controlled by varying the energy near an atomic absorption edge. As you approach the edge, the real and imaginary components can change dramatically as a function of functional group type, concentration and orientation. Additionally, unlike hard X-rays or neutrons, the absorption is no longer negligible and shifting energies can significantly change the depth profile of the electromagnetic field, providing additional control over sensitivity as a function of film depth. This technique is applied to two BCP multilayers with different affinities for a surface. Both systems show variations in interface width as a function of substrate proximity, where a strong surface affinity resulted in an increase in the interface width and a weak affinity resulted in a decrease. This type of surface induced behavior has important implications for BCP lithography.

11:39AM B35.00003: Mapping Self-Assembled Ternary Polymer Blend Phase Behavior Using Gradient Composition Libraries*  
GREGORY DOERK (Presenter), Brookhaven National Laboratory, KRISTOF TOTH, Yale University, CHINEDUM OSUJI, University of Pennsylvania, KEVIN YAGER, Brookhaven National Laboratory — Blending block copolymers (BCPs) with homopolymers, other BCPs, or nanomaterials is a simple yet powerful way to tune self-assembled structure. However, mapping the composition-dependent phase behavior of polymer blends experimentally is a slow, laborious process resulting in coarse data sets. In response, we have developed a first-of-its-kind user tool that combines electrospray deposition with programmable motor control and gradient solution pumping to generate three-component compositionally graded thin film libraries on single substrates. We describe the creation of thin film libraries featuring blends of polystyrene-block-poly(methyl methacrylate) (PS-b-PMMA) BCPs with PS and PMMA homopolymers, and demonstrate how synchrotron small angle X-ray scattering (SAXS) may be used to rapidly characterize the self-assembled domain morphology, spacing, and grain size as functions of blend composition and film thickness. This pairing introduces a high-throughput platform for autonomous characterization that promises to accelerate the discovery, design, and optimization of functional soft matter blends.

*Research performed at the CFN and NSLS-II, U.S. DOE Office of Science Facilities at Brookhaven National Laboratory under Contract No. DE-SC0012704.
11:51AM B35.00004: Rapid and Tunable Structuring of Block Copolymer Films using Controlled Solvent Swelling*  ANDREW SELKIRK (Presenter), ANNA TRUBETSKAYA, MICHAEL MORRIS, PARVANEH MOKARIAN, Department of Chemistry, Trinity College, The University of Dublin — We have studied the effect of the film swelling ratio on the phase separation of polystyrene-\(b\)-polyvinylpyridine (PS-b-PVP) block copolymer (BCP) nanopatterns by precisely controlling solvent uptake into the film. Using a custom-built annealing chamber with an inbuilt reflectometer, swelling ratios of up to 10x were achieved in a controlled vapor environment using a variety of solvents. The swelling behaviour of two different PVP molecular systems were studied, one of low molecular weight (~35 kg/mol) and another of high molecular weight (~800 kg/mol). Our results suggest that above a maximum swelling threshold, the ordering of BCP nanopatterns becomes extremely sensitive to slight variations in temperature and vapor pressure. By precisely controlling such variations, we successfully synthesized a surprisingly varied range of BCP morphologies from these individual systems, including highly sensitive metastable phases. Additionally, in comparison to conventional solvent vapor annealing methods we found that such highly ordered structures could be achieved in a matter of minutes rather than hours. A diffusion model is proposed to explain the kinetic effect, and the route to a rapid self-assembly process in BCP films.

*Enterprise Ireland (CF-2017-0638-P), Science Foundation Ireland

12:03PM B35.00005: Rapid Vertical Ordering of Lamellar Block Copolymer Films by Dynamic Thermal Gradient Annealing for Ion Conduction Membranes  MANINDERJEET SINGH (Presenter), WENJIE WU, Univ of Houston, MONALI N BASUTKAR, Intel Corporation, JOSEPH WALTER STRZALKA, Argonne National Laboratory, ALAMGIR KARIM, Univ of Houston — To achieve the full technological potential of block copolymers (BCPs) for use as electrolytes, filtration membranes, or in nanolithography, rapid ordering of BCPs with vertically oriented nanostructures on unmodified substrates is desirable. In this work, we demonstrate the rapid ordering of lamellar BCPs (< 40 s) by utilizing the effect of thermal gradient based Cold Zone Annealing (CZA) technique. The evaporation fronts during film casting results in poorly ordered yet vertically oriented BCP morphology. We demonstrate that CZA, by driving in-plane defect annihilation in such vertically oriented as cast BCP nanostructures, resulted in perpendicularly oriented and well-ordered morphology on a variety of substrates, at short time scales. The kinetics of lamellar grain size (x) evolution was observed to be much faster in CZA (x \(\sim t^{0.26}\)) as compared to oven annealing (x \(\sim t^{0.15}\)). Subsequent post-annealing integration of Ionic liquid (IL) as a penetrating additive was shown to selectively swell well-ordered lamellar domain by 100%, having potential use for mechanically robust ion-conducting channels in BCP membranes and electrolytes. Such highly swollen and vertically ordered lamellar nanostructures are not obtained by \textit{a priori} addition of IL to BCP solutions before film casting.
Directed self-assembly of block copolymer thin film with vertical lamellae by applying filtered plasma and repeated shear stress  

JINWOO OH (Presenter), JEONG GON SON, Korea Institute of Science and Technology — Directed self-assembly (DSA) of block copolymer (BCP) is a promising technology for nanolithography for semiconductors and nanodevices. Although defect-free BCP lamellar structure with vertical orientation nanopattern is necessary for the wide range of applications of BCP self-assembly, the formation of defect-free BCP lamellar nanostructures with vertical orientation in a large area is still a difficult challenge. In this study, we proposed a new approach of filtered plasma treatment and repeated shear stress on BCP film for directionally aligned and perpendicularly oriented lamellar BCP nanostructure. Shear induced ordering of BCP nanopatterns has been restricted to BCP with spherical and cylindrical nanopatterns because of the interfacial energy difference at surfaces. We introduced filtered plasma on the surface of the BCP thin film to produce crosslinked layer having neutral surface energy, and elastomer film was placed on the surface and subjected to shear stress to create a vertically oriented lamellae. To improve the quality of the alignment of BCP structures, the shear stress was repeatedly applied and defects of the nanopatterns were greatly reduced. Various types of BCP can be aligned with this strategy, and it suggests the potential for application in nanolithography.

Nanotubes from 6-arm star-shaped (PMMA-b-PS)$_6$ thin films*  

SO YEONG PARK (Presenter), CHUNGRYONG CHOI, EUNSEOL KIM, JUNHO JANG, YESEONG SEO, JINKON KIM, Department of Chemical Engineering, Pohang Univ of Sci & Tech — Fabrication of nanotube arrays has attracted much attention because of potential applications such as photo catalytic and sensors. Although nanotubes have been formed from core-shell cylindrical morphology in a triblock terpolymer, an appropriate solvent annealing should be done. Here, we obtained nanotube array by changing the chain architecture of block copolymers from linear to star shape. We synthesized 6-arm star-shaped poly(methyl metacrylate)-block-polystyrene copolymer [(PMMA-b-PS)$_6$] having a fixed volume fraction of PMMA with 0.50. When the film thickness was $nL_0$ ($n$ is integer and $L_0$ is the lamellar domain spacing), nanotube arrays were obtained after thermal annealing. We also investigated the surface reconstruction depending on film thickness, annealing time, and substrate.

**12:39PM B35.00008: Nanostructure sizes and interfacial roughness in blends of linear and cyclic block copolymers**  
AMY D GOODSON, MAXWELL RICK, JESSIE E. TROXLER, HANK ASHBAUGH, JULIE ALBERT (Presenter), Tulane Univ — Cyclic block copolymers (BCPs) are predicted to assemble into nanostructured domains up to 40% smaller than their linear analogues while exhibiting superior thin film stability and assembly dynamics, properties that are desirable for nanolithography. However, synthesizing large quantities of high purity cyclic BCPs is challenging. Thus, we employ dissipative particle dynamic (DPD) simulation to probe the self-assembly behavior of cyclic/linear BCP blends with the aim of answering two questions: How much impact do linear impurities have on cyclic BCP nanostructure size? Can cyclic BCPs be used as structure-directing agents to shrink the domains of linear BCPs in majority-linear blends? Our simulations indicate that up to 10% linear impurity in a cyclic BCP product has a negligible impact on domain spacing and interfacial width, suggesting that costly post-synthesis purification of cyclic BCPs to remove linear impurities may be unnecessary. In majority-linear BCP blends, we find that domain spacing decreases in direct proportion to the amount of cyclic BCP in the blend. These findings provide guidance to experimentalists wishing to utilize cyclic BCPs in nanolithography applications.

**12:51PM B35.00009: Morphological Evolution of Poly(solketal methacrylate)-block-polystyrene in Thin Films**  
[Invited] THOMAS RUSSELL (Presenter), MINGQIU HU, DUK MAN YU, Univ of Mass - Amherst, DARREN SMITH, Chemistry, State University of New York, Buffalo, HYEYOUNG KIM, Univ of Mass - Amherst, JAVID RZAYEV, Chemistry, State University of New York, Buffalo — Driving the size scale of block copolymer (BCP) microdomains to the nanoscopic level poses numerous challenges in obtaining thin films with highly oriented, laterally aligned structures of large areas. Here, we used the morphological evolution of the lamellar microdomains in thin films of symmetric poly(solketal methacrylate-b-styrene) (PSM-b-PS) BCPs that are converted into poly(glycerol mono-methacrylate-b-styrene) (PGM-b-PS) BCPs by the use of a photoacid generator dissolved in the thin film. This simple hydrolysis, performed in the solid state, causes a marked increase in the segmental interaction parameter, converting a hydrophobic-hydrophobic BCP into a hydrophobic-hydrophilic BCP, wherein the segmental interaction parameter ($\chi$) increased from 0.035 to 0.438 at 25 °C. To orient the microdomains normal to the film surface a hydroxyl-terminated random copolymer (PSM-r-PS) where the fraction of the mers can be varied to tune the interfacial interactions with the substrate and where the (PSM-r-PS) is simultaneously transformed into PGM-r-PS along with the BCPs. The use of the photoacid generator alleviates the need to use toxic vapors and enables a transformation of the BCP in a gradient manner across the substrate that can be used to promote long-range lateral ordering. As the BCP period decreases, the film thickness also must be decreased. Consequently, the ability to use a fully hydrophobic significantly enhances the ability to prepare uniform thin films over large areas.

**1:27PM B35.00010: Ordering and Defectivity in Sub-10 nm Perpendicular Lamellar Block Copolymer Thin Films**

ALVIN CHANDRA (Presenter), RYUICHI NAKATANI, TAKUMI UCHIYAMA, YUTA NABAIE, TERUAKI HAYAKAWA, Tokyo Inst of Tech - Tokyo — The self-assembled nanostructures of block copolymers (BCP) can be used to meet industrial demand for cost-effective methods for forming sub-10 nm lithographic patterns. By applying perpendicular lamellar BCP structures onto thin films, line and space patterns required for lithography can be obtained. However, there remain challenges that must be resolved prior to high-volume manufacturing; the development of strongly-segregating BCPs capable of forming sub-10 nm features, controlling the microdomain orientation into perpendicular structures, and reducing the nanostructure defectivity. Our lab has developed a strongly-segregating BCP, poly(methacrylyl polyhedral oligomeric silsesquioxane)-block-poly(2,2,2-trifluoroethyl methacrylate) (PMAPOSS-b-PTFEMA), that forms sub-10 nm perpendicular lamellae on thin films with ease. To work towards achieving zero defectivity, we studied the growth of ordered structures in PMAPOSS-b-PTFEMA thin films using combinatorial atomic force microscopy (AFM), grazing-incidence small angle X-ray scattering (GI-SAXS), and cross-sectional scanning electron microscopy (CS-SEM).

**1:39PM B35.00011: Boundary-Directed Epitaxy of Block Copolymers**

ROBERT JACOBBERGER (Presenter), University of Wisconsin - Madison, VIKRAM THAPAR, Chonnam National University, GUANGPENG WU, Zhejiang University, TZU-HSUAN CHANG, National Taiwan University, VIVEK SARASWAT, AUSTIN J WAY, KATHERINE JINKINS, ZHENQIANG MA, University of Wisconsin - Madison, PAUL F NEALEY, University of Chicago, SU-MI HUR, Chonnam National University, SHISHENG XIONG, Fudan University, MICHAEL ARNOLD, University of Wisconsin - Madison — Historically, there have been two strategies—graphoepitaxy and chemoepitaxy—for directing the self-assembly of block copolymers (BCPs) into useful nanoscale patterns. We have recently discovered a third paradigm—termed “boundary-directed epitaxy”—in which templates consisting only of planar, low-resolution features are used to drive the formation of more complex BCP patterns with enhanced feature resolution. The templates are comprised of spatial boundaries separating regions on a surface with different composition, formed at the edges of isolated stripes on a background substrate. Vertical BCP lamellae are pinned by chemical contrast at each stripe/substrate boundary, align parallel to the boundaries, selectively form on the stripes (whereas horizontal lamellae form on the background substrate), and register to wide and incommensurate stripes to multiply the feature density. Isolated BCP line arrays with half-pitch of 6.4 nm are demonstrated on stripes wider than 80 nm. Boundary-directed epitaxy circumvents the need for topographic structures used in graphoepitaxy or ultra-narrow guiding features used in chemoepitaxy to direct assembly of sub-10 nm BCP features, and provides an attractive path towards nanofabrication beyond the resolution of conventional lithography.
Effect of chain architectures on the segregation degree of block copolymers*  
XIANWEN JI (Presenter), WEI-HUA LI, State Key Laboratory of Molecular Engineering of Polymers, Department of Macromolecular Science, Fudan Univ, Shanghai, China — The design of polymer architectures provides a possible route for lowering the domain spacing of block copolymers in the application of directed self-assembly (DSA). However, the change of segregation degree is always coupled with that of domain spacing. Therefore, we rescale the segregation degrees of different multiblock copolymers with reference to that of AB diblock using self-consistent field theory (SCFT), including [AB]_n linear multiblock, A_nB_n multi-arm star and A_d,nB_d,n dendron-like, such that their density profiles of the lamellar morphology are consistent. Then we compare the lamellar periods of these different copolymers under the condition of equivalent segregation degrees. We find that the star and dendron-like architectures can significantly lower the domain spacing relative to that of AB diblock, especially when the arm number or the generation number is large. Our work presents a simple scheme for quantitatively quantifying the reduction of domain spacing of a specific multiblock architecture relative to that of AB diblock and also provides a useful guide for the application of directed self-assembly.

Session B36 DCOMP DCMP: Room temperature superconductivity in superhydrides at extreme pressures 601/603 - Renata Wentzcovitch, Columbia Univ - Tag(s): Invited
**11:15AM B36.00001: Clathrate Superhydrides Under High Pressure: A Class of Extraordinarily Hot Conventional Superconductors** [Invited] YANMING MA (Presenter), Jilin Univ — Room-T superconductivity has been a century long-held dream of mankind and a focus of intensive research. In an effort to search for Room-T superconductors, we proposed the first-ever sodalite-like clathrate superhydride CaH$_6$ suffer at extreme pressures that shows a potential of high superconductivity and is not captured at ambient pressure. We recently found a general phenomenon on the common formation of clathrate structures at high pressure in rare earth (RE) superhydrides having three stoichiometries of REH$_6$, REH$_9$, and REH$_{10}$, some of which exhibit high-T superconductivity$^2$. Subsequent experiments synthesized the predicted clathrate YH$_6$, YH$_9$, and LaH$_{10}$ with the measured $T_c$ values at 224, 243, and 260 K, respectively, setting up $T_c$ records among known superconductors. These discoveries open up the door of achieving Room-T superconductors.

In the talk, I will give an overview on the current status of research progress on superconductive hydrides, and then discuss the design principle for achieving Room-T superhydrides. As an example, our recent prediction on clathrate superhydride in Li-Mg-H ternary system$^3$ with a predicted $T_c$ at ~400 K will be discussed.

**11:51AM B36.00002: Road to Hot Hydride Superconductors** [Invited] MUHTAR AHART (Presenter), RAVHI KUMAR, Department of Physics, Univ of Illinois - Chicago, MADDURY SOMAYAZULU, HPCAT, X-ray Science Division, Argonne National Laboratory, RUSSELL HEMLEY, Departement of Physics and Chemistry, Univ of Illinois - Chicago — The realization of superconductivity in dense hydrides in the vicinity of room temperature dates back to predictions of very high $T_c$ in atomic metallic hydrogen and subsequently in doped metallic hydrogen alloys and compounds. Density-functional based structure-search methods calculations combined with BCS-type models predicted a series of dense hydride high $T_c$ superconductors (e.g., CaH$_6$, H$_3$S) at megabar pressures (>100 GPa), followed by the still higher $T_c$ superhydrides (e.g., LaH$_x$, YH$_x$, with $x > 6$). Using a variety of x-ray diffraction and transport measurements, we confirmed our predictions of the stability of LaH$_{10}$ and its $T_c$ to 260 K near 200 GPa as well as superconductivity in other La-H phases, results that were subsequently confirmed independently. Additional studies have been carried out on high $T_c$ hydrides of Se, Ca, Se-S, and other ternary systems. The results are consistent with conventional superconductivity, though the mechanism is likely affected by strong quantum effects in these systems. These efforts highlight the novel physics of metallic hydrogen-like materials, the success of ‘materials by design’ using high pressures, and the possibility of superconductivity well above room temperature as recently predicted.

*Supported by NSF (DMR-1933622, DOE-NNSA (NA-0003858; DE-NA0001974), and DOE-BES (DE-AC02-06CH11357).
MIKHAIL EREMETS (Presenter), Max Planck Institute for Chemistry — Room-temperature superconductivity is becoming realistic given progress in conventional superconductivity: the critical temperature $T_c = 203\, \text{K}$ has been discovered in $\text{H}_3\text{S}$ under high pressures $\sim 150\, \text{GPa}[1]$. Even higher, nearly room temperature superconductivity has been recently found in superhydride $\text{LaH}_{10}[2, 3]$ with $T_c \sim 250\, \text{K}$, following the theoretical predictions[4-6]. In this hydride, lanthanum atom is located at the center of the cage of hydrogen $\text{H}_{24}$ and acts as electron donor contributing to electron pairing, while the hydrogen atoms form weak covalent bonds with each other within the cage. This structure is different from that of $\text{H}_3\text{S}$, in which each hydrogen atom is connected by a strong covalent bond to the two nearby sulfur atoms. We will discuss prospects for further increase of $T_c$ to room temperature, which naturally is expecting for hydrides at high pressures. We will present recent studies on YH$x$, CaH$x$ and other compounds that are considered as potential room-temperature superconductivitors. We will consider various directions to explore high-temperature conventional superconductivity at low and ambient pressures.

1:03PM B36.00004: Electronic Structure and Superconductivity in Binary and Ternary Hydrides Under Pressure* [Invited] EVA ZUREK (Presenter), State Univ of NY - Buffalo — First principles calculations are employed to interrogate the electronic structure and bonding in two structures types that a priori crystal structure prediction methods have found for many compressed alkaline earth and rare earth metal binary hydrides: the $I4/mmm$ symmetry tetrahydrides, and the $Im-3m$ symmetry hexahydrides. We explore the relationship between their structure and electronic structure, as well as their propensity for superconductivity. Moreover, the XtalOpt evolutionary algorithm is used to predict the structures of novel stable and metastable ternary hydrides that could potentially be synthesized in high pressure experiments, and their superconducting critical temperatures are estimated.

*We acknowledge the NSF (DMR-1827815) and the National Nuclear Security Administration, through the Capital-DOE Alliance Center under Cooperative Agreement No. DE-NA0003858, for financial support.

1:39PM B36.00005: Superconductivity in Yttrium and Thorium Polyhydrides: a Route to Industrial Applications [Invited] DMITRII SEMENOK (Presenter), Material Science, Skolkovo Institute of Science and Technology, IVAN A TROYAN, FSRC Crystallography and Photonics, Shubnikov Institute of Crystallography, XIAOLI HUANG, College of Physics, Jilin University, ARTEM OGANOV, Material Science, Skolkovo Institute of Science and Technology — Recent blast growth in hydride superconductivity (SC) has resulted in the achievement of near-room critical temperatures ($\text{ThH}_{10}$: 161 K [1], $\text{H}_3\text{S}$: 203 K [2], $\text{YH}_6$: 226 K [3a-b], $\text{LaH}_{10}$: 250 K [4]) in centimeter-sized mini DACs. The logical final step in this sequence is achieving the room-temperature superconductivity. This progress would not be possible without the development of modern DFT methods and algorithms for crystal structure prediction (e.g. USPEX, CALYPSO, AIRSS). Thanks to these methods, the results of numerical simulations of new superconductors in La-H, Y-H, Th-H, Ce-H systems have been experimentally confirmed in recent years. This is probably the first such great success of computational material science in the field of high-$T_C$ SC.

Here we will present the latest results in high-pressure chemistry of Y, Ba, Sr, Eu superhydrides and measurements of their transport properties with targeted focus on ternary systems and doping of already known SC materials. Perspectives of hydride electronics in DACs, light and magnetic sensors, topology for superconducting storage rings and SQIUDs on diamonds will be discussed.

Monday, March 2, 2020 11:15 AM - 2:15 PM
In my lecture I will concentrate on accelerator-based light sources (with a focus on DESY). Here we will see novel particle accelerators in the next 10-15 years: (a) ring facilities with a revolutionary electron lattice exceeding the brilliance of previous synchrotron radiation sources by one hundred, (b) linear accelerators for X-ray laser sources which will routinely enable real-time imaging of molecular structures and processes in the femtosecond range, and disruptive developments in plasma accelerators with completely new fields of application, especially in medical technology.

11:51 AM B37.00002: THE EUROPEAN SPALLATION SOURCE [Invited]  
JOHN WOMERSLEY (Presenter), ESS — I will present an update on the European Spallation Source. The ESS is Europe's next-generation neutron scattering facility, and is under construction in Lund, with the data management and software centre hosted in Copenhagen. It will be the world's most powerful accelerator driven neutron source offering capabilities an order of magnitude beyond what currently exists. It is being built by a partnership of 13 European nations and has a total cost of roughly 2 billion Euros. Civil construction is nearing completion and operation of the first accelerator components is now starting. The initial suite of user instruments has been defined and we are making significant progress towards bringing the first three online in 2023. I'll describe progress on the project, outline the technical challenges and some of the science opportunities that ESS will offer. I'll also give an update on the work being done to understand and prepare for the start of operation of the facility in the coming decade.
The ASU Compact XFEL Project — We are pursuing phased development of a very compact XFEL (CXFEL) based on inverse Compton scattering (ICS) from a nanopatterned electron beam. In Phase 1 a compact x-ray light source (CXLS) is currently in commissioning and will demonstrate stable generation of femtosecond hard x-rays with properties similar to undulator radiation (not yet an XFEL). Results from CXLS commissioning will be presented.

In addition to commissioning results, we are designing the Phase 2 CXFEL that converts the undulator-like x-ray emission to fully coherent x-ray laser properties. CXFEL depends on a novel method to produce transform-limited x-ray output in all dimensions, i.e., with all photons in a single degenerate quantum state. This method avoids the noise amplification of SASE by imprinting a well-defined coherent modulation on the electrons via diffraction in a thin crystal grating. We will present experimental results demonstrating the first steps in this method.

The spatial pattern in the diffracted electrons is converted to a temporal pattern using sophisticated electron optics that exchange the transverse and temporal phase space dimensions. The result is a nano-patterned electron beam that can be tuned for wide range of applications. The method allows for coherent control of the phase, frequency, bandwidth, pulse length and amplitude of the x-ray pulses, and enables a variety of multi-color experiments with precisely tunable femtosecond delays for pump-probe experiments, and perhaps even sub-cycle phase-locking of the multiple colors. The output will cover the photon energy range from 100 eV to 8 keV. The CXFEL pulse energy is expected to be tens of nJ due to its small size and low beam energy. For experiments that require higher pulse energies or harder photons, CXFEL presents an excellent seed source that can transfer its unique phase control to large XFELs.

*This work is supported by NSF awards 1935994 (Bio) and 1632780 (Physics).
As we push the frontier of particle physics to higher particle energies, conventional accelerator techniques are attaining their limits. The use of an ionized gas —or plasma— circumvents the most significant barrier of conventional techniques by increasing the energy gained per unit length by several orders of magnitude. One class of plasma accelerators, relevant for high energy physics and light source applications, consists in using a particle beam, «the driver», to excite a plasma wave, that can then accelerate the main particle beam. These beam-driven plasma accelerators have made considerable progress in the past few years, with groundbreaking results such as the high-efficiency acceleration of an electron beam [1], the multi-gigaelectronvolt acceleration of positrons [2], and proton-driven electron acceleration [3].

Here we report on progress made in plasma-based accelerators using particle beam drivers from conventional RF accelerators as well as from novel laser-driven accelerators. First, we will present results on the successful acceleration of positron beams in plasma-based accelerators, and discuss intrinsic limitations, from experimental measurements and from theory and simulations. Second, we will show the first proof-of-principle demonstration of a plasma-based accelerator powered by laser-accelerated electron beams, and will discuss new possibilities opened by these results, from the direct optical imaging of the accelerating structure to the generation of bright beams beyond the state of the art.

Finally, we will discuss the perspectives of the field and the key physics challenges for plasma accelerators that need to be tackled in the future.

*The work was supported by the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (Miniature beam-driven Plasma Accelerators project, Grant Agreement No. 715807).
Electron beams are vital tools for scientific discovery, providing unique probes, sources of radiation and opening windows into the realm of high energy physics. To achieve these feats, accelerator physicists aim to improve beam brightness, spatial and temporal coherence, and achieve higher energies on smaller scales. The use of THz radiation to manipulate and accelerate electron beams is dramatically changing what is possible with the next generation of accelerators. We aim to explore new accelerating structures designed to withstand high gradients, power them with the newest generation of THz sources and lay the foundation for THz accelerator technology. This research will provide answers to fundamental questions about the limits of accelerating gradients and improve understanding for the role of frequency, pulse length and stored energy in plasma breakdown. In this presentation, we will review recent results, report on high gradient tests with metallic structures, explore advanced manufacturing techniques for structures and discuss near-term applications for THz accelerator technology.

Monday, March 2, 2020 11:15 AM - 2:15 PM

Session B38 GSNP: Heineman/Faculty/Greene Prize Session

11:15AM B38.00001: The Hofstadter's butterfly: from playing with numbers to studying quantum materials (Dannie Heineman Prize for Mathematical Physics talk)* [Invited]
SVETLANA JITOMIRSKAYA (Presenter), University of California, Irvine — We discuss some results on the Harper’s operator - the model behind the Hofstadter's butterfly: metal-insulator transitions of two kinds, the Ten Martini problem, the proof of Thouless' conjecture from the early 80s: that Hausdorff dimension of the spectrum is bounded by 1/2 for all irrational fluxes, as well as the discovery of self-similar (reflective-)hierarchical structure of eigenfunctions throughout the localization regime.
Partially based on joint works with S. Becker and R. Han, I. Krasovsky, and W. Liu.

*NSF
Many people are familiar with the atomic force microscope, but fewer have experience using its capabilities to do more than image the topography of a sample, usually in air. In this talk, I'll present three different subfields of research that all involve the atomic force microscope. The “force curve” enables the measurement of mechanical properties, including Young’s modulus and adhesion. Normally, the tip is brought into contact with a surface, and the force required to push into the sample is measured. We have used the AFM to image natively adhered bacteria to surfaces in fluid and perform force curves on individual bacteria. We have also grown the biofilm on a cantilever and brought it into contact with different surfaces, to study the early stages of adhesion. Magnetic force microscopy (MFM) may be a familiar technique that can reveal the magnetic state of nanostructures. In rings of the correct size, there is a vortex state in which all moments lie circumferentially in plane, creating a closed-flux state that does not have any MFM contrast in a perfectly symmetric ring. It is challenging to experimentally control the clockwise or counterclockwise circulation of this vortex state with a uniform external applied field. Instead, we pass a current through a solid platinum AFM tip in order to create a local circular Oersted field to probe the magnetic behavior of rings and discs. Finally, I'll present our current efforts using Kelvin probe force microscopy (KPFM) to image real-time charge motion in organic semiconductors. All of this work was completed in my lab at Mount Holyoke College, where I have mentored 50 undergraduate women over the past thirteen years.
The properties of quantum materials are dominated by electronic correlations, which often lead to novel emergent phenomena and spontaneous symmetry breaking at low temperatures or material interfaces. The underlying correlations are encoded in the collective excitations out of the ground state, which are sometimes unfortunately hidden from most experimental techniques. One example is the collective modes that transform as a pseudovector, e.g. the $A_{2g}$ representation of the $D_{4h}$ and $D_{3d}$ groups. Here, we use polarization resolved Raman scattering to directly probe the collective modes with $A_{2g}$ symmetry in two examples. In the heavy fermion metal, URu$_2$Si$_2$, the $A_{2g}$ collective mode uniquely couples to the reflection symmetry breaking ground state in the low temperature phase -- a chirality density wave that was hidden from other spectroscopic tools in the past [1,2]. Whereas on the surface of the 3D topological insulator, due to the strong Rashba spin orbit coupling, the electrons acquire chiral spin textures that results in novel collective modes and composite particles. In the example of Bi$_2$Se$_3$, we observed an $A_{2g}$ mode as the collective spin excitation from the surface states [3], and circularly polarized photoluminescence from chiral excitons [4].

Delafossite oxides: natural, ultra-pure metal-insulator heterostructures

VERONIKA SUNKO (Presenter), Max Planck Institute For Chemical Physics of Solids — Delafossite oxides are layered compounds, which can be thought of as natural heterostructures of triangularly coordinated metallic sheets and transition metal oxide blocks. A fascinating range of electronic states can be found both in their bulk and on their surfaces, including extremely high conductivity in PtCoO$_2$ and PdCoO$_2$ [1], maximal Rashba-like spin-splitting on the transition metal terminated surfaces of PtCoO$_2$, PdCoO$_2$ and PdRhO$_2$ [2], Stoner ferromagnetism on the Pd-terminated surface of PdCoO$_2$ [3] and, perhaps most remarkably, an intertwined spin-charge response due to a Kondo coupling between metallic and Mott insulating layers in PdCrO$_2$ [4]. Our group has investigated these states experimentally with angle resolved photoemission, and theoretically with first principles calculations and model Hamiltonians, where applicable.

Concentrating on the metal/Mott insulator heterostructure and the Rashba-like surface states, I will show how the simplicity of the materials allows us to pinpoint to the underlying cause for the remarkable electronic behaviour, and in turn to use delafossites as model systems to understand complex phenomena.

Hybridizing Spin, Charge and Photon on a Quantum Chip

XIAO MI (Presenter), Google — As we witness the transition of quantum information science from the singular objective of quantum supremacy to the eclectic world of NISQ algorithms, the metrics for success have become rapidly more complex. The simultaneous need for long coherence times, fast gates, accurate readout and high connectivity has both highlighted the respective advantages of various quantum hardwares and accentuated their shortcomings. Hybrid device developments, where technologies across different qubit incarnations are combined to compensate for their inherent physical limitations, have enjoyed much success in recent years. In this lecture, I will review one such example where the technique of circuit quantum electrodynamics (cQED) was successfully grafted from superconducting qubits to semiconductor quantum-dot spin qubits. We will cover the physics and technical developments that have led to the first observations of strong-coupling between a single electron charge in gate-defined quantum dots and a microwave photon [1] and strong-coupling between a single electron spin and a single photon [2]. As time permits, applications of the hybrid device to valley physics in silicon will also be covered [3, 4].

11:15AM B39.00001: Many-body effective energy theory: photoemission at strong correlation [invited] STEFANO DI SABATINO (Presenter), Université Toulouse - Paul Sabatier — Photoemission is a powerful tool to obtain insight into the electronic structure and excitations in materials. From the theoretical point of view, Many-Body Perturbation Theory, within the so-called GW approximation to electron correlation, is the method of choice for calculations of photoemission spectra of many materials. However, GW suffers from some fundamental shortcomings, and, in particular, it does not capture strong correlation, unless one treats the system in a magnetically ordered phase. In this talk, we illustrate some of these problems and efforts to overcome them [1-3]. In particular, we focus on a many-body effective-energy theory (MEET) that gives many-body spectral functions in terms of reduced density matrices (RDMs) [4]. We show that simple approximations, which require the knowledge of the lowest n-body RDMs only, can provide accurate photoemission spectra in model systems in the weak as well as strong correlation regime. With the example of several transition metal oxides, we show that our method yields a qualitatively correct picture both in the antiferromagnetic and paramagnetic phases, contrary to mean-field methods, in which the paramagnet is a metal [4,5].

11:51AM B39.00002: Stochastic Many-Body Perturbation theory beyond the GW approximation VOJTECH VLCEK (Presenter), University of California, Santa Barbara — I will present new stochastic approaches for the computation of electronic excitations within the many-body perturbation theory. The new methods go beyond the popular $G_0W_0$ approximation and include non-local vertex corrections in the screened Coulomb interaction ($G_0W_0^{tc}$) as well as in the self-energy ($G_0W_0^{tc} \Gamma_X$). I will discuss a stochastic implementation in real-time and space which scales linearly with the number of electrons. I will demonstrate that the vertex corrections predominantly affect unoccupied states and that they are crucial for predicting of the corresponding quasiparticle energies.
**12:03PM B39.00003: Stochastic resolution of identity to second order Green's function: ground-state and quasi-particle properties.** WENJIE DOU (Presenter), University of California, Berkeley, TYLER TAKESHITA, Mercedes-Benz Research and Development North America, MING CHEN, University of California, Berkeley, ROI BAER, The Hebrew University of Jerusalem, DANIEL NEUHAUSER, University of California, Los Angeles, ERAN RABANI, University of California, Berkeley — We develop a stochastic resolution of identity approach to the real-time second-order Green's function (real-time sRI-GF2) theory, extending our recent work for imaginary-time Matsubara Green's function (J. Chem. Phys. 151, 044114 (2019)). The approach provides a framework to obtain the quasi-particle spectra across a wide range of frequencies as well as predict ionization potentials and electron affinities. To assess the accuracy of the real-time sRI-GF2, we study a series of molecules and compare our results to experiments and to a many-body perturbation approach based on the GW approximation, where we find that the real-time sRI-GF2 is as accurate as self-consistent GW. The stochastic formulation reduces the formal scaling to $O(N^3)$, where $N$ is the number of electrons. This is illustrated for a chain of hydrogen dimers, where we observe as lightly lower than cubic scaling for systems containing up to $N=1000$.

**12:15PM B39.00004: Effects of electron-hole interactions in single-particle excitations within the $GW$ approach** MENG WU (Presenter), ZHENG LU LI, STEVEN LOUIE, Department of Physics, University of California at Berkeley and Lawrence Berkeley National Laboratory — There are a number of schemes in the literature to do “self-consistent” $GW$ calculations at different levels going beyond the $G_0W_0$ approximation. For single-particle excitations (e.g., the quasiparticle bandgap in semiconductors), a straightforward self-consistent update of both the single-particle Green's function $G$ and the screened Coulomb interaction $W$ generally gives less satisfactory results than those from the $G_0W_0$ approach as compared to experiment, which is due to an under-screening introduced and accumulated in the treatment of dielectric screening at the random phase approximation (RPA) level, where electron-hole interactions are neglected. In this work, we investigate the importance of electron-hole interactions in modifying $W$ and hence the $GW$ self-energy, as well as in reshaping single-particle excitations at the $GW$ level. We present our theoretical formalism, along with first-principles results for several conventional semiconductors.

*This work was supported by the Theory of Materials Program and the C2SEPEM at LBNL funded by the U.S. DOE under Contract No. DE-AC02-05CH11231, and by the National Science Foundation. Computational resources have been provided by NERSC and XSEDE.*
12:27PM B39.00005: Core-Level Spectra for Disordered Systems from GW*  DOROTHEA GOLZE (Presenter), PATRICK RINKE, Department of Applied Physics, Aalto University — We apply our recently developed GW core-level method to predict highly accurate X-ray photoelectron spectra (XPS) of disordered carbon-based materials, which require model sizes of more than 100 atoms. GW has become the method of choice for the computation of valence excitations [1]. We recently showed that GW can be also used for core excitations, even though it requires computationally more accurate techniques for the frequency integration of the self-energy than for valence states [2]. In addition, partial self-consistent schemes and relativistic corrections are crucial. For a benchmark set of small molecules, we find that GW-computed absolute and relative core-level binding energies deviate only 0.3 and 0.2 eV from experiment, respectively. Core-level spectroscopy is one of the few techniques that can be used to characterize disordered materials, such as functionalized amorphous carbon, which shows potential as coating and electrode material. However, the experimental spectra are difficult to interpret. We show that our method provides reliable computational references to support the peak assignment in experimental XPS spectra of amorphous carbon.

12:39PM B39.00006: Core and valence electron excitations in SrTiO$_3$ and MgO: a first-principles study including many-body effects*  VIJAYA BEGUM (Presenter), MARKUS ERNST GRUNER, ROSSITZA PENTCHEVA, Universität Duisburg-Essen — Using density functional theory calculations combined with many-body perturbation theory we investigate the optical and XAS spectra of two paradigmatic oxides, SrTiO$_3$ and MgO. For both systems taking into account quasiparticle (GW) and in particular excitonic effects (Bethe-Salpeter equation) is decisive to obtain good agreement with experiment. For the cubic phase of SrTiO$_3$ [1], the theoretical optical spectrum shows a prominent excitonic peak at 6.58 eV which involves interband transition between O-2$p$ and Ti-$e_g$ states. The main effect of the tetragonal distortion below 105 K is observed around this peak due to splitting of the $e_g$ bands. The optical spectrum of MgO shows the best agreement with experiment using a hybrid exchange-correlation functional. Furthermore, the x-ray absorption spectra of the O and Mg K-edge are in good agreement with experiment. The analysis of the origin of the peaks in $k$-space indicates a strong hybridization of the respective unoccupied $p$ and $d$-states, whereas the real space visualization of the exciton wavefunction illustrates its localization and bound nature.

12:51PM B39.00007: Cumulant expansion of the exciton Green's function: A unified approach for many-body intrinsic, extrinsic, and interference effects in XAS\textsuperscript{*} JOSHUA KAS (Presenter), JOHN REHR, University of Washington, JOHN VINSON, NIST, Gaithersburg, MD — Recently, a real-time cumulant approach has been successful in describing many-body effects in x-ray photo-emission and absorption spectra in a variety of systems.\textsuperscript{1} While the results for XAS are promising, intrinsic and extrinsic effects are not treated on the same footing, with the intrinsic excitations calculated via real-time TDDFT, while extrinsic/interference effects are calculated in a frequency space approach. In addition, extrinsic and interference effects are based on a model of free electrons interacting with plasmons, most appropriate for the alkali metals. Here we present a unified approach which treats satellites in terms of the real-time density response to the sudden appearance of an exciton, which is in turn described by solutions of the Bethe-Salpeter equation at a specific energy. We apply the method to the K-edge XAS of SrTiO3 and analyze the energy dependence of extrinsic and interference effects.\textsuperscript{1,2}

1:03PM B39.00008: Computational characterization of the RIXS Raman-to-fluorescence crossover in BaFe\textsubscript{2}As\textsubscript{2} KEITH GILMORE (Presenter), JONATHAN PELLICIARI, Brookhaven National Laboratory, THORSTEN SCHMITT, Paul Scherrer Institute — Resonant inelastic X-ray scattering (RIXS) studies have significantly enhanced our understanding of correlated materials. However, experimental and computational efforts have largely focused on insulating materials. We recently collected RIXS data on metallic BaFe\textsubscript{2}As\textsubscript{2} at the Fe L\textsubscript{3} edge, which exhibits a Raman-to-fluorescence crossover as the absorption threshold is traversed. By combining core and valence level Bethe-Salpeter solvers, we evaluate the RIXS cross section of BaFe\textsubscript{2}As\textsubscript{2} from first principles. Our calculations capture the Raman-to-fluorescence crossover as well as the main loss features observed in the experiment. By \textit{i)} considering additionally the absorption and non-resonant emission spectra, \textit{ii)} invoking the threshold singularity theory of Nozières and Abrahams \textsuperscript{[1]}, \textit{iii)} recognizing the role of the intermediate state lifetime, and \textit{iv)} decomposing the orbital character of the intermediate and final excitonic states, we are able to quantitatively and qualitatively separate simpler band structure contributions from more complex many-body effects in the RIXS spectra of BaFe\textsubscript{2}As\textsubscript{2}. This analysis is applicable to other strongly correlated metals.

Electronic structure of 3d-transition metal dioxide clusters from GW calculations*  

MEISAM REZAEI (Presenter), SERDAR OGUT, Univ of Illinois - Chicago — Transition metal oxide clusters are not only scientifically interesting, but they are also challenging systems to model using first principles approaches due to strong electron correlations and their open-shell character. These challenges are particularly noteworthy when modeling their excited state properties. The GW approximation using atom-centered localized basis sets has recently emerged as a reliable method for studying excited state properties of confined systems. Here, we investigate various flavors of the GW method (one-shot, eigenvalue self-consistent) with different starting points when applied to quasiparticle spectra of 3d transition metal dioxide cluster anions ScO$_2^-$, TiO$_2^-$, VO$_2^-$, CrO$_2^-$, MnO$_2^-$, FeO$_2^-$, NiO$_2^-$, and CuO$_2^-$. We compare predictions from different levels of theory with each other and with experimental photoelectron spectra.

Importance of long-range correlations in transition metal compounds: First-principle studies using the the multitier GW+EDMFT approach*  

FREDRIK NILSSON (Presenter), Lund Univ/Lund Inst of Tech, FRANCESCO PETOCCHI, PHILIPP WERNER, Physics, University of Fribourg, FERDI ARYASETIAWAN, Lund Univ/Lund Inst of Tech — Transition metal compounds exhibit a wide range of intriguing properties, such as high temperature superconductivity and colossal magnetoresistance. The standard method to describe these materials is density functional theory + dynamical mean-field theory (DFT+DMFT), which can treat the strong onsite correlations between the 3d electrons to all orders but omits the long-range intersite correlations. In this talk I discuss the recently developed multitier combination of the GW-approximation and dynamical mean-field theory [1], a parameter-free ab-initio method which yields a fully self-consistent description of both long- and short-range correlations. A systematic study of the cubic perovskites Sr(V,Mo,Mn)O3 reveal that the long-range correlations, which are typically ignored for this class of materials, can have a profound influence on the interpretation of the spectra. Specifically spectral features previously interpreted as Hubbard bands are reinterpreted as plasmon satellites originating from long-range charge fluctuations.

1:39PM B39.00011: Dynamically Screened Excitons in Heteropolar Semiconductors: The Case of Halide Perovskites* MARINA FILIP (Presenter), Molecular Foundry, Lawrence Berkeley National Laboratory, JONAH HABER, Physics, University of California, Berkeley, JEFFREY B NEATON, Lawrence Berkeley National Lab — The interaction between photogenerated electron-hole pairs in semiconductors is screened by their dielectric environment. In heteropolar semiconductors, dielectric screening originates with both electrons and polar phonons. State of the art GW/BSE methods for prediction of excitons typically only include the static electronic contribution to the screening. However, prior studies report on the importance of dynamical lattice contributions to screening from polar phonons for excitons in halide perovskites [1,2]. Here, we develop an extension of the BSE approach to include both electronic and lattice contributions to the dielectric screening. We show that in heteropolar semiconductors, lattice effects can significantly reduce the electron-hole interaction, even when the exciton binding energy is much larger than the characteristic phonon frequency. We demonstrate the importance of dynamical lattice screening for excitons in halide perovskites, and generalize our findings by extending the Wannier model to include lattice polarization effects, clarifying the relevance of this effect for general classes of heteropolar semiconductors.

1:51PM B39.00012: GW calculations and ultraviolet photoelectron spectroscopy of gas phase ion pairs - a window into the electronic structures of ionic liquids JUHAN MATTHIAS KAHK (Presenter), Imperial College London, IVAR KUUSIK, VAMBOLA KISAND, Institute of Physics, University of Tartu, JOHANNES LISCHNER, Imperial College London — Room temperature ionic liquids have extremely low equilibrium vapor pressures, but in ultrahigh vacuum vapors consisting of neutral ion pairs can be detected. Spectroscopic measurements of these ion pairs, the fundamental building blocks of ionic liquids, can yield insights into the electronic structures of these unusual and technologically important materials. From a theoretical perspective, the description of these ion pairs is challenging due to the presence of long range charge transfer. For example, in density functional theory different exchange correlation functionals can produce qualitatively different ground state electronic structures. In this study, it is shown that the GW method yields a consistent description of the gas phase ion pairs that is only weakly dependent on the mean field starting point. The effect of different levels of self-consistency in the GW calculations is analyzed. Theoretical valence level photoelectron spectra are calculated, and it is found that G0W0 at a hybrid DFT starting point yields excellent quantitative agreement with experiment. In one instance, GW calculations highlighted the presence of a contaminant in the experimental spectrum that had not been previously recognized, and corroborated its assignment to a decomposition product.
Low-cost alternatives to the Bethe-Salpeter equation: a simple hybrid functional for excitonic effects in solids*  

JIUYU SUN (Presenter), CARSTEN A. ULLRICH, Univ of Missouri - Columbia — The Bethe-Salpeter equation (BSE) is the standard computational method for optical excitations in solids, including excitonic effects. We reduce the computational cost of the BSE by simplifying the dielectrically screened Coulomb interaction: instead of calculating the dielectric function from first principles, we replace it by a momentum-dependent model dielectric function or just by a single parameter. Combined with a semilocal exchange-correlation kernel, this defines a new hybrid functional for solids within generalized TDDFT. We perform a systematic assessment of these simplified approaches, and find that they yield optical absorption spectra and exciton binding energies of semiconductors and wide-gap insulators in close agreement with standard BSE. We also present applications to more complex systems.

11:15AM B40.00001: Accelerating Large-Scale GW Calculations on Hybrid GPU-CPU Systems

MAURO DEL BEN (Presenter), Lawrence Berkeley National Laboratory, CHARLENE YANG, National Energy Research Scientific Computing (NERSC), STEVEN LOUIE, Department of Physics, UC Berkeley, JACK RICHARD DESLIPPE, National Energy Research Scientific Computing (NERSC) — Large-scale GW calculations are state-of-the-art to accurately describe excited state phenomena in materials, which is critical for the design of novel new devices based on complex materials with applications in many fields. Application of the GW method to complex systems is often perceived as being limited due to high computational cost. Reduced time to solution can be achieved through novel methods, algorithms and optimal implementations on modern HPC systems. In particular accelerators such as GPU’s can speed-up by order of magnitudes conventional CPU-only implementations and additionally reduce the energy per flop consumption. However, porting a large scale HPC code to hybrid GPU-CPU systems and achieve best performance is non-trivial and faces several challenges. This talk showcases the various techniques used to accelerate the Material Science code BerkeleyGW on hybrid architectures targeting to accelerate large scale simulations with thousands of atoms. These techniques include the efficient use of accelerated libraries, pinned host memory, asynchronous memory transfer, streams, batched operations, shared memory, and the overlapping of MPI communication and GPU computation. We achieve good strong- and weak-scaling on thousands of GPUs, and a 16x improvement is obtained on FLOPs/Watt efficiency compared to the CPU-only implementation. We show in this way that GW calculations on systems made of thousands of atoms can be performed with excellent time to solutions, of the order of minutes, even running on a moderate number of hybrid nodes.

12:03PM B40.00003: Simulating realistic features of chemical and materials systems with massively parallel many-body perturbation theory calculations*  DEREK VIGIL-FOWLER (Presenter), National Renewable Energy Laboratory, JACOB CLARY, CHARLES MUSGRAVE, Department of Chemical and Biological Engineering, University of Colorado, Boulder, AARON M HOLDER, National Renewable Energy Laboratory — With experiments obtaining increasingly fine resolution in time, energy, and position, there is a growing need for high-fidelity calculations that can match this rapidly improving resolution. Many-body perturbation theory is one approach that has had significant successes in the accurate simulation of the optoelectronic properties of many materials classes and also of surface chemistry. These methods have traditionally been applied to comparatively simple materials with relatively small numbers of atoms and atom types in a simulation cell, but increasing computing power allows for calculations on systems with hundreds and evens thousands of atoms in a simulation cell. In this talk we will discuss our work on simulating the electrochemical oxygen reduction reaction (ORR) on a system of FeN\textsubscript{4}clusters in graphene using the many-body random phase approximation (RPA) and including the effects of zero-point energy, vibrational entropy, solvation, and applied bias. We will also discuss calculations using the many-body GW-Bethe Salpeter equation (GW-BSE) approach to calculate the optoelectronic properties of complex materials including double perovskites.

12:15PM B40.00004: Large temperature sensitivity of optical emission via synergy of Raman and photoluminescence effects in BaTiO\textsubscript{3}-based phosphor*  ARNAB DE (Presenter), RAJEEV RANJAN, Dept. of Materials Engineering, Indian Institute of Science — The growing interest in luminescence-based optical thermometry in recent years is motivated by the prospect of designing phosphor materials capable of exhibiting large temperature sensitivity of the emission spectrum. The prevalent material design strategies predominantly rely on ascertaining temperature sensitivity using fluorescence intensity ratio (FIR) of the Stark lines in the photoluminescence (PL) emission spectrum of rare-earth(s) doped materials. This approach has yielded temperature sensitivity in the range 0-5%. Here we propose a new strategy for achieving high temperature sensitivity by considering a twin combination of Raman and PL spectrum of the phosphor material, and by introducing Raman-PL-intensity ratio (RPIR) as a parameter for measuring relative temperature sensitivity($S_r$). The effectiveness of this concept is demonstrated on Eu/Er-doped BaTiO\textsubscript{3} wherein a large $S_r$ range (-3 % to +6 %) and large color tuning (red to green) was achieved by exploiting the mechanisms which resulted in a contrasting effect of temperature on Raman and the PL part of the total spectra.

HUBERTUS VAN DAM (Presenter), Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, EDOARDO APRA, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, RAYMOND BAIR, Computational Science, Argonne National Laboratory, JEFFERY S BOSCHEN, Chemistry, Iowa State University, ERIC J. BYLASKA, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, WIBE A DE JONG, Computational Chemistry, Materials and Climate Group, Lawrence Berkeley National Laboratory, THOMAS H DUNNING, Advanced Computing, Math & Data, Pacific Northwest National Laboratory, NIRANJAN GOVIND, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, ROBERT J HARRISON, Institute for Advance Computational Science, Stony Brook University, KRISTOPHER KEIPERT, Nvidia, KAROL KOWALSKI, Environmental Molecular Sciences Laboratory, Pacific Northwest National Laboratory, SRIRAM KRISHNAMOORTHY, SURAJ KUMAR, ERDAL MUTLU, BRUCE PALMER, AJAY PANYALA, High Performance Computing, Pacific Northwest National Laboratory, BO PENG, Computational Engineering, Pacific Northwest National Laboratory, RYAN M RICHARD, Chemical & Biological Sciences, Ames Laboratory, T P STRAATSMAN, Oak Ridge National Laboratory, EDWARD F VALEEV, Department of Chemistry, Virginia Tech, MARAT VALIEV, Biosystems Dynamics & Simulation, Pacific Northwest National Laboratory, DAVID B WILLIAMS-YOUNG, CHAO YANG, Scalable Solvers Group, Lawrence Berkeley National Laboratory, THERESA L WINDUS, Chemistry, Iowa State University
— NWChemEx is an ECP project for computational chemistry that builds on the success of NWChem. NWChem is an early co-design project started in 1992, to address distributed memory parallel computers. The code's modular design, the Global Arrays for distributed data handling, and code generation using the Tensor Contraction Engine, provided a platform for building scalable chemistry capabilities. Key capabilities of the code are MD, DFT methods, and coupled cluster. The science challenges targeted by the NWChemEx are accurate simulations of catalytic reactions and biomolecular complexes. Such calculations require next generation computers that are very different from those NWChem was designed for. Hence, NWChemEx re-engineered the concepts, models and implementations for future computers. We focus on overcoming the limitations of NWChem's design. This involves platform enhancements like execution schedule aware tensor frameworks, composable simulations, code generation for accelerator hardware, and exploiting emerging sparsity. The required changes in the key methods will be discussed.

12:39PM B40.00006: Accessible and collaborative web interface for HPC materials simulations TIMUR BAZHIROV (Presenter), Exabyte Inc. — High Performance Computing (HPC) predictive capabilities are of key importance to chemical and materials sciences and engineering, contributing to the goal of the Materials Genome Initiative for enhancing the rate of breakthroughs in complex materials chemistry and materials design. However, recent advances in theory, algorithms, and HPC hardware for materials and chemical sciences, especially aimed at the exascale, are yet to be widely available to the majority of scientifically and technically capable communities in the United States [1]. We outline the concept for the creation of a web-enabled infrastructure for predictive theory and modeling [2] able to facilitate access to, coordination and sharing of information and data produced by scalable codes adapted for exascale computing. In addition, we explain how our web-based infrastructure can help promote universal standards for data inputs and outputs in the multitude of codes and methodologies and discuss the use cases.

12:51PM B40.00007: Large-scale many-body perturbation theory calculations on leadership class facilities* MARCO GOVONI (Presenter), Argonne Natl Lab, HE MA, FRANCOIS GYGI, GIULIA GALLI, University of Chicago — Many-body perturbation theory (MBPT) has been shown to provide an accurate description of excited state properties for the simulation of spectroscopic signatures of materials and molecules. The advent of exascale computing offers the appealing opportunity to expand the applicability of MBPT methods to systems of unprecedented size and complexity, e.g. to thousands of electrons. We will discuss methodological advances implemented in the WEST code [http://west-code.org] for both GW and BSE calculations. We will present new functionalities enabled by the concurrent use of WEST and the Qbox code [http://qboxcode.org], with focus on interoperability paradigms. We will discuss the advantages of developing interoperable software, and we will present results for the calculation of spectroscopic properties of defective insulators and semiconductors hosting optically addressable spin-defects.

Electronic density and atomic forces in solids by plane-wave auxiliary-field quantum Monte Carlo

SIYUAN CHEN (Presenter), Department of Physics, College of William & Mary, MARIO MOTA, Division of Chemistry and Chemical Engineering, California Institute of Technology, FENGJIE MA, Department of Physics, Beijing Normal University, SHIWEI ZHANG, Center for Computational Quantum Physics, Flatiron Institute — We present accurate electronic densities for several prototypical solids, including the ionic crystal NaCl, covalent-bond semiconductor Si, and metallic Cu. These results are obtained using ab initio auxiliary-field quantum Monte Carlo (AFQMC) method working in a plane-wave basis with multiple-projector, norm-conserving pseudopotentials. AFQMC has been shown to be an excellent many-body total energy method. Computation of observables and correlation functions other than the ground-state energy requires back-propagation, which we have implemented in this work in the plane-wave basis AFQMC framework. Our (near-exact) results are used to benchmark several density functionals, which can be useful in constructing improved density functionals. Besides density, we have also implemented the calculation of atomic forces, which paves the way for geometry optimization in solids.

A pseudo-BCS wavefunction from density matrix decomposition - application in auxiliary-field quantum Monte Carlo

ZHI-YU XIAO (Presenter), Department of Physics, College of William & Mary, HAO SHI, SHIWEI ZHANG, CCQ, Flatiron Institute, Simons Foundation — We present a method to construct BCS-like (pseudo-BCS) wave functions from the one-body density matrix. The resulting many-body wave function reproduces the density matrix and has the form of a particle number-projected BCS wave function (or antisymmetrized germinal power), which can provide a better Ansätze in correlated fermion systems than a single Slater determinant or a linear combination of Slater determinants (for example from a truncated active space calculation). We apply the pseudo-BCS wave function to auxiliary-field quantum Monte Carlo (AFQMC) as a trial wave function. Using the two-dimensional Hubbard model as an example, we show that it leads to improved results as a constraint. Further, the pseudo-BCS wave function allows a fully self-consistent constraint via the density matrix.

*We acknowledge the support from Simons Foundation.
1:27PM B40.00010: Electronic band gaps from Quantum Monte Carlo methods*  YUBO YANG (Presenter), University of Illinois at Urbana-Champaign, VITALY GORELOV, Université Paris-Saclay, CARLO PIERLEONI, University of L’Aquila, DAVID CEPERLEY, University of Illinois at Urbana-Champaign, MARKUS HOLZMANN, Univ. Grenoble Alpes — We develop a method for calculating the fundamental electronic gap of semiconductors and insulators using grand canonical Quantum Monte Carlo simulations. We discuss the origin of the bias introduced by supercell calculations of finite size and show how to correct the leading and sub-leading finite size errors either based on observables accessible in the finite-sized simulations or from DFT calculations. Our procedure is applied to solid molecular hydrogen and compared to experiment for carbon and silicon crystals. arXiv: 1910.07531

1:39PM B40.00011: RuCl$_3$ electronic structure by quantum Monte Carlo*  ABDULGANI ANNABERDIYEV (Presenter), North Carolina State University, CODY MELTON, RAYMOND C CLAY, LUKE SHULENBURGER, Sandia National Laboratories, GUANGMING WANG, LUBOS MITAS, North Carolina State University — The alpha phase of RuCl$_3$ crystal consists of 2D stacked honeycomb layers coupled with van der Waals interactions. Both bulk and multi/single layers of bonded RuCl$_6$ octahedra have been produced and exhibit several promising electronic, magnetic and structural properties. The ground state is a magnetic insulator with several possible magnetic states that are energetically very close. Furthermore, the material allows for a formation of putative spin liquid phases and other unconventional magnetic states due to Ru spin-orbit coupling and favorable orbital occupations. We study these systems using fixed-node quantum Monte Carlo (QMC) with averaged spin-orbit as well as with recently developed fixed-phase spin-orbit QMC that is based on two-component spinors formalism. In particular, we attempt to understand the role of electron correlations as they affect the ground and excited states. We carry out calculations for the low-lying magnetic states vs non-magnetic state and attempt to reveal the impact of explicit spin-orbit effects on magnetic and electronic properties.

1:51PM B40.00012: Heavy-atom systems in quantum Monte Carlo: pseudopotentials and beyond*  GUANGMING WANG (Presenter), ABDULGANI ANNABERDIYEV, North Carolina State University, CODY MELTON, Sandia National Laboratories, MICHAEL BENNETT, Oak Ridge National Lab, LUKE SHULENBURGER, Sandia National Laboratories, LUBOS MITAS, North Carolina State University — We study the electronic structure of selected systems with heavy atoms such as Ru, Ir, Pb, Bi and I, using quantum Monte Carlo (QMC). This is motivated by expanding real space QMC to systems with strong spin-orbit interactions and significant correlation effects. Such studies require accurate effective core potentials (ECPs), the ability to obtain accurate spinors and the eventual inclusion of multi-reference expansions of trial wave functions. We start by assessing the accuracy of ECPs and their impact on the most basic quantities such as the lowest energy excitations and binding in atomic and molecular systems. Moreover, we try to assess the errors caused by averaged vs. explicit spin-orbit interaction using the recently developed two-component spinor fixed-phase QMC method. We study also the corresponding biases that stem from the fixed-node vs fixed-phase approximations. Furthermore, we try to explore the cases where spin-orbit and correlation are of the same magnitude and can impact important quantities such as band gaps and magnetic states in periodic materials.

2:03PM B40.00013: Mitigating the Sign Problem Through Basis Rotations*  RYAN LEVY (Presenter), BRYAN CLARK, University of Illinois at Urbana-Champaign — Quantum Monte Carlo simulations of quantum many body systems are plagued by the fermion sign problem. The cost of overcoming the sign problem (and its overall existence) is basis dependent. In this talk, we show how to use sign-free quantum Monte Carlo simulations to minimize the effect of the sign problem by optimizing over the choice of basis on large two-dimensional systems. This can be done despite the fact that the sign problem makes it difficult to even compute the average sign of such a simulation. We numerically illustrate these techniques by decreasing the ‘badness’ of the sign problem through single-particle basis rotations on one and two dimensional Hubbard systems.

Session B41 GMAG: Electron Transport in Magnetic Materials 707 - Kyung-Jin Lee, Korea Univ
11:15AM B41.00001: Transport spin polarization of Pt/ferromagnetic insulator bilayers*
MICHAEL OSOFSKY (Presenter), JOSEPH PRESTIGIACOMO, United States Naval Research Laboratory, PENG LI, YURI SUZUKI, Dept. of Applied Physics, Stanford University — It has been shown that the anomalous Hall effect can be observed in platinum films deposited on a ferromagnetic insulator which implies the existence of a magnetic proximity effect. One of the key features of ferromagnetic metals is a net spin polarization of the carriers at the Fermi energy which enable the functionality of spintronic devices. In this presentation we show that spin polarized carriers are indeed present in Pt films of various thicknesses that were deposited on magnesium aluminum ferrite (MAFO) using point contact Andreev scattering. The results were obtained by extracting conductance vs. voltage data from I-V curves taken through contacts formed by driving a sharpened superconducting Nb tip into the Pt/MAFO samples. The resulting spectra were then analysed using a modified BTK theory of supercurrent conversion at a normal/superconductor interface to obtain the values of the transport spin polarization.

11:27AM B41.00002: Strong transverse spin current generation in bulk ferromagnetic materials*
ROHIT NAIR (Presenter), KRITI GUPTA, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, ZHE YUAN, The Center for Advanced Quantum Studies and Department of Physics, Beijing Normal University, GERRIT BAUER, Institute for Materials Research & WPI AIMR & CSRN, Tohoku University, PAUL KELLY, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente — The intrinsic spin Hall effect (SHE) is widely studied in non-magnetic metals and semiconductors. Recent studies have reported the observation of an inverse SHE (ISHE) in 3d ferromagnetic alloys where the underlying spin currents that generate the ISHE are oriented along the magnetization direction of permalloy (Py) [1]. Subsequent studies report a non-trivial SHE in Py [2,3] where the spin-polarization is not oriented along the magnetization; its origin in a 3d magnetic alloy is not known. To shed some light on the intrinsic SHE in magnetic materials we calculate transverse spin currents as a function of concentration $x$ for fcc $\text{Fe}_x\text{Ni}_{1-x}$ alloys within a first-principles DFT-LDA scattering framework. For Py we find a spin Hall angle (SHA) of 4.8% compared to a value of 5% we calculate for platinum at room temperature [4]. We find a surprisingly large transverse spin current that is polarized along the same direction that could be useful in field-free switching applications.

11:39AM B41.00003: Electric current control of spin helicity in an itinerant helimagnet

NAN JIANG (Presenter), Univ of Tokyo, YOICHI NII, HIROKI ARISAWA, Tohoku University, EIJI SAITO, Univ of Tokyo, YOSHINORI ONOSE, Tohoku University — The mechanism of homochirality in biological objects and other materials has been attracting great attention. The longitudinal helical magnetic structure is the chiral magnetic object, in which the ordered direction of the magnetic moment spatially rotates in the plane perpendicular to the propagation vector and the sense of rotation denoted as helicity determines the chirality. The robust magnetic degree of freedom may provide a new concept of magnetic memory if it can be electrically controlled and detected. Here we show that the helicity can be controlled by the magnetic field and electric current, and probed by the second-harmonic resistivity, which is sensitive to the chiral symmetry breaking, in an itinerant longitudinal helimagnet MnP. While the helicity can be controlled by the electric field in insulating multiferroic helimagnets, we have achieved the helicity manipulation in the conducting helimagnet compatible with electric circuits. The controllability may pave a new route to the spintronics.

11:51AM B41.00004: Experimental tests of spin transport models in organic semiconductors*

HENNA POPLI (Presenter), JINGYING WANG, XIAOJIE LIU, EVAN LAFALCE, TANIYA HANSIKA TENNAHEWA, HANS MALISSA, VALY VARDENY, CHRISTOPH M BOEHME, Department of Physics and Astronomy, University of Utah — It has been a long-standing question whether spin-transport and charge-transport in organic materials occur via the same electronic processes [1, 2], i.e. via charge excitations such as polaron states. If so, then the spin current that is produced by spin-pumping through Ferromagnetic resonance (FMR) excitation in an inverse spin-Hall-effect (ISHE) experiment on a NiFe/Alq_3/Pt device [3] must be diminished under electron paramagnetic resonance (EPR) excitation of the charge carriers [4]. We have executed such experiments and do not observe such quenching, which shows that spin-transport is neither due to propagation of charge carriers nor due to spin-transfer between weakly coupled charge carriers. However, these observations are consistent with the idea of exchange mediated transport. We discuss the implications of our experimental results as well as various control experiments that have been done to scrutinize our results. [1] M. Groesbeck et al. (unpublished); [2] Z. Yue et al., Phys. Rev. B 92, 045405 (2015); [3] S.W. Jiang et al., Phys. Rev. Lett. 115, 086601 (2015); [4] D. R. McCamey et al., Nature Mat. 7, 723 (2008).

**12:03PM B41.00005: Magneto-transport in half metallic CrO$_2$ nanowires with spin texture**

LIJUAN QIAN (Presenter), WENZHE CHEN, GANG XIAO, Brown University — Magneto-transport in ferromagnetic metals (FM) is influenced by spin textures. In this work, we study the magneto-transport of spin textures in epitaxial half-metallic CrO$_2$ nanowires. We quantitatively define the spatial non-uniformity of spin textures as spin curvature. We design geometric notches along the edges of the 300nm-width wires to introduce the spin curvature. The magnitude of the spin curvature is controlled via both the depth of notches and the magnetic fields. Through micromagnetic simulations and magneto-transport measurements, we uncover an empirical relation between the spin curvature and the magnetoresistance. This provides a quantitative method to predict the magneto-transport behavior of any spin texture. The thermal effect is studied from 10K and 250K. Results show that the thermal magnons worsen the spin asymmetry and suppresses the spin curvature induced resistivity at temperatures much lower than the ferromagnetic ordering temperature $T_c$.

*The work was supported by King Abdullah University of Science and Technology (KAUST) under the Sensor Initiative.

**12:15PM B41.00006: Non-local voltage measurements with wide F/I/N tunnel contacts are strongly affected by generation of circular electric currents**

YAROSLAW BAZALIY (Presenter), University of South Carolina, REVAZ RAMAZASHVILI, Laboratoire de Physique Theorique, IRSAMC, Universite de Toulouse, CNRS — Electric spin injection is routinely tested by non-local voltage measurements in lateral spin-valves. The advantage of this method is the absence of electric current entering the part of the device where the detecting F/N contact is located. Ideally this leads to the independence of the measured Johnson-Silsbee voltage from the contact size and shape. However, it was predicted [1] that if the detecting contact is wide enough, then circular electric currents are excited in it, altering the non-local voltage and making it dependent on the device geometry. Calculations [1] were performed in the regime of highly transparent F/N boundary. At the same time, modern measurements often use low transparency F/I/N tunnel contacts, in which circular currents should be strongly suppressed. Thus it seems that tunnel contact measurements should conform to the classic Johnson-Silsbee formula. Here we show that while circular electric currents are indeed suppressed by the tunnel barrier, the voltage modifications persist, may be significant, and have to be accounted for in the data analysis.

Magnetotransport in amorphous cobalt silicon and amorphous cobalt germanium thin films

CHRISTOPHER FUCHS (Presenter), University of California, Berkeley and University of Wurzburg, DINAH SIMONE BOUMA, University of California, Berkeley and Lawrence Berkeley National Laboratory, ZHANGHUI CHEN, Lawrence Berkeley National Laboratory, FRANK BRUNI, ARNOUD EVERHARDT, PAUL CORBAE, University of California, Berkeley, NEAL REYNOLDS, University of California, Berkeley and Lawrence Berkeley National Laboratory, LIN-WANG WANG, Lawrence Berkeley National Laboratory, FRANCES HELLMAN, University of California, Berkeley and Lawrence Berkeley National Laboratory — The transition-metal group IV compounds iron germanium and iron silicon show ferromagnetic properties in amorphous Fe\(_x\)(Ge,Si\(_{1-x}\)) films [1], and the recently shown non-trivial topology in crystalline CoSi [2] suggests a study of amorphous cobalt silicon (a-Co\(_x\)Si\(_{1-x}\)) and cobalt germanium (a-Co\(_x\)Ge\(_{1-x}\)) might lead to advances in the field of topological materials. A comparative study of a-Co\(_x\)Si\(_{1-x}\) and a-Co\(_x\)Ge\(_{1-x}\) thin films has been performed for 0.4<x<0.7. At low temperatures, a-Co\(_x\)(Ge,Si\(_{1-x}\)) shows no magnetism for x<0.6 and weak ferromagnetism above x≈0.6, well over an order of magnitude smaller than in a-Fe\(_x\)(Ge,Si\(_{1-x}\)). While the Fe-based alloys show hole carriers, the Co-based alloys show electron carriers. Resistivity measurements show that \(\rho_{xx} \geq 150\mu\Omega\text{cm}\) and dependents mainly on the carrier concentration, which is characteristic for amorphous metals. Hall measurements probe whether the anomalous Hall effect stems from the intrinsic (Berry curvature) mechanism, equal to the integral over occupied energy states of the density of Berry curvature, which is the sum of the spin-orbit correlations of local orbital states [1].

Two transient time in the charge and spin current

SUNG PO CHAO (Presenter), NARASIMHA RAJU CHEBROLU, Physics, Natl Kaohsiung Normal Univ — Using magnetic tunnel junction formed by two leads made of ferromagnetic metals and a thin insulating barrier, we study its time depedent charge and spin current following a square voltage pulse. Magnetic fluctuations in the tunnel junction is modeled as magnons, and its influence on the tunneling is treated as a local bosonic mode described by the spinful Anderson-Holstein model. We compute the time dependent spin and charge current perturbatively with Lang-Frisov transformation to handle the strong local electron-magnon or electron phonon interaction at finite temperature. Two transient behaviors are seen in the charge and spin currents. Those two time scales due to different spin and charge responses within one junction could be useful for parallel computing within a single unit.

**12:51PM B41.00009: Sublattice Magnetization Driven Planar and Anomalous Hall Effect in β-W/Gdx(FeyCo1-y)1-x Heterostructures**

ANTHONY JOHNSON, EZANA NEGUSSE, DAN ANYUMBA, DEANDRE MCAMONT, RAMESH BUDHANI (Presenter), Morgan State Univ — The antiferromagnetic coupling between 4f and 3d spin sublattices in amorphous films of GdFeCo alloys is known to affect the temperature dependence of magnetization and magnetic anisotropy dramatically. Multilayers of these alloys also reveal non-trivial spin textures driven by dipolar and chiral exchange interactions. Here we present measurements of anomalous Hall (AH) and planar Hall (PH) voltages in β-W/Gdx(FeyCo1-y)1-x bilayer films across the sublattice magnetization compensation point and the temperature at which the magnetic anisotropy changes from in-plane to out-of-plane configuration. We observe a robust planar Hall Effect in these samples that tracks the behavior of magnetization measured with vibrating sample magnetometry. The magnetization switching fields extracted from the PH data allow calculations of anisotropy energy as a function of temperature and 4f/3d moment ratios in the films. The anomalous Hall data in the reversible and irreversible regimes of response are analyzed to extract the Berry phase and spin orbit torque contributions to Hall resistivity.

**1:03PM B41.00010: Chirality-induced Spin Selectivity in a Two-terminal Semiconductor Device**

TIANHAN LIU (Presenter), Physics, Florida State University, XIAOLEI WANG, HAILONG WANG, Institute of Semiconductors, Chinese Academy of Sciences, GANG SHI, FAN GAO, HONGLEI FENG, Institute of Physics, Chinese Academy of Sciences, HAOYUN DENG, LONGQIAN HU, ERIC LOCHNER, PEDRO SCHLOTTMANN, STEPHAN VON MOLNAR, Physics, Florida State University, YONGQING LI, Institute of Physics, Chinese Academy of Sciences, JIANHUA ZHAO, Institute of Semiconductors, Chinese Academy of Sciences, PENG XIONG, Physics, Florida State University — Electrical generation of spin polarization in semiconductors is of great interest for the device potential in spintronics. One such mechanism is chirality-induced spin selectivity (CISS), with which structural chirality leads to different electric conductivities for electrons of opposite spins. CISS has been widely reported for chiral molecule assemblies on metal surfaces. However, theoretical understanding of the microscopic mechanism and manifestation of CISS in specific device structures remain controversial. Here, we report direct evidence of CISS in two-terminal devices of heterojunctions of (Ga,Mn)As/AHPA-L molecules/Au. The (Ga,Mn)As layer acts as a spin analyzer for electrons injected from the Au electrode through the AHPA-L monolayer. The CISS of AHPA-L and spin injection into the (Ga,Mn)As are manifested as sharp changes in the junction conductance at the coercive fields of the (Ga,Mn)As. The observations provide a definitive signature of CISS-induced spin valve effect in a two-terminal device. Theoretical implications of the effect and its bias dependence will be discussed.

1:15PM B41.00011: Resistivity Minimum in Dilute Itinerant Magnets  ZHENTAO WANG, CRISTIAN BATISTA (Presenter), University of Tennessee, Knoxville — Resistivity minima are commonly seen in itinerant magnets and they are often attributed to the Kondo effect. However, recent experiments are revealing an increasing number of materials showing resistivity minima in absence of the Kondo singlet formation. In a previous work, we demonstrated that the Ruderman-Kittel-Kasuya-Yoshida (RKKY) interaction can produce a classical spin liquid state at finite temperature, whose resistivity increases with decreasing temperature. In this work, we investigate the robustness of the RKKY-induced resistivity upturn against site dilution. By series expansions and molecular dynamics simulation, we show that site dilution competes with thermal fluctuations and further stabilizes the upturn, which applies to both 2D and 3D dilute itinerant magnets. Under a magnetic field, the resistivity upturn is reduced due to suppression of the electron-spin scattering.

1:27PM B41.00012: Nonequilibrium noise measurements using hBN tunnel barriers  XUANHAN ZHAO (Presenter), LIYANG CHEN, PANPAN ZHOU, DOUGLAS NATELSON, Rice Univ — Spin-orbit coupling, a relativistic effect coupling the spin angular momentum of an electron with its orbital angular momentum, has shown its significance for potential “spintronic” device applications. Nonequilibrium noise (or “shot”) noise, which comprises the inherent fluctuations in the electrical current of system driven out of equilibrium, is predicted to be an outstanding experimental probe for underlying physics in the spin-orbit coupling, since predictions shows the tunneling shot noise will be modified in the presence of spin accumulation. Here we report initial nonequilibrium charge current noise measurements in a variety of tunnel junctions prepared using hBN as monolayer tunnel barriers and strong spin hall angle materials as electros. We will also report flicker noise found during low-frequency noise measurement in Au/hBN/Au tunneling structures due to the presence of thermally excited dynamic defects.

1:39PM B41.00013: Theory of nonlinear Hall effects: modified semiclassics from quantum kinetics*  CONG XIAO (Presenter), University of Texas at Austin, ZONGZHENG DU, Southern University of Science and Technology, QIAN NIU, University of Texas at Austin — We propose a modified Boltzmann nonlinear electric-transport framework which differs from the nonlinear generalization of the linear Boltzmann formalism by a contribution that has no counterpart in linear response. This contribution follows from the interband-coherence effect of dc electric-fields during scattering and is related to the interband Berry connection. As an application, we demonstrate it in the second-order nonlinear Hall effect of the tilted massive Dirac model. The intuitive Boltzmann constructions are confirmed by a quantum kinetic theory, which shows that arbitrary $n$th-order nonlinear dc response up to the first three leading contributions in the weak disorder potential is handled by the same few gauge-invariant semiclassical ingredients.

1:51PM B41.00014: Spin valves with exfoliated 2D materials: MoS$_2$ MARTA GALBIATI (Presenter), FLORIAN GODEL, AYMERIC VECCHIOLA, VICTOR ZATKO, CNRS/THALES, SERGIO TATAY, Instituto de Ciencia Molecular, University of Valencia, REGINA GALCERAN, CNRS/THALES, SAMUEL MAÑAS-VALERO, Instituto de Ciencia Molecular, University of Valencia, MAËLIS PIQUEMAL-BANCI, MARIE-BLANDINE MARTIN, CNRS/THALES, ALICIA FORMENT-ALIAGA, EUGENIO CORONADO, Instituto de Ciencia Molecular, University of Valencia, BRUNO DLUBAK, PIERRE SENEOR, CNRS/THALES — In the last years 2D materials have attracted a huge attention for spintronics thanks to the amazing properties that arise when thickness approaches the single layer level and thanks to the large number of functionalities that they offer. The recent introduction of 2D materials in magnetic tunnel junctions (2D-MTJs) offers very promising properties such as atomically defined interfaces, spin filtering, perpendicular anisotropy and spin-orbit torques modulation. Nevertheless, the difficult integration of exfoliated 2D materials in spintronic devices has limited so far their exploration and performances, maintaining experimental results still far from theoretical expectations [1]. Here, we will show successful fabrication of NiFe/MoS$_2$/Co MTJs thanks to an in-situ fabrication process leading to the highest results reported so far for MTJs based on TMDCs 2D family [2]. Moreover, we will further discuss a path to alleviate fundamental technological and physics issues encountered for the integration of 2D-MTJs [2,3].

B41.00015: Coherent Resonant Tunneling through Double Metallic Quantum-Well States YUAN LU (Presenter), Institut Jean Lamour, Nancy, France, BINGSHAN TAO, CAIHUA WAN, PING TANG, JIAFENG FENG, HONGXIANG WEI, XIAO WANG, STÉPHANE ANDRIEU, Institute of Physics, Chinese Academy of Sciences, Beijing, China, HONGXIN YANG, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, Ningbo, China, MAIRBEK CHSHIEV, SPINTEC, University of Grenoble, Grenoble, France, XAVIER DEVAUX, THOMAS HAUET, FRANCOIS MONTAIGNE, STEPHANE MANGIN, MICHEL HEHN, DANIEL LACOUR, Institut Jean Lamour, Nancy, France, XIUFENG HAN, Institute of Physics, Chinese Academy of Sciences, Beijing, China — Study of resonant tunneling through multi-metallic quantum well (QW) structure is not only important for the fundamental understanding of quantum transport, but also for the great potential to generate advanced functionalities of spintronic devices. However, it remains challenging to engineer such structure due to the short electron phase coherence length in metallic QW system. Here, we demonstrate the successful fabrication of double-QW structure in a single fully epitaxial MTJ heterostructure, where two Fe QW layers are sandwiched between three MgAlOx tunnel barriers. We show clear evidence of the coherent resonant tunneling through the discrete QW states in the two QWs. Compared to the single QW structure, the resonant tunneling in double-QW MTJ produces strong conductivity oscillations with much narrower peak width (about half) owing to the enhanced energy filtering effect. This study presents a comprehensive understanding of the resonant tunneling mechanism in MTJ with multiple QWs, which is essential for future development of new spintronic devices operating in the quantum tunneling regime.
11:15AM B42.00001: Electronic Relaxation Rates in Clean Metallic Ferromagnets  JAMES AMAREL (Presenter), DIETRICH BELITZ, Univ of Oregon, THEODORE KIRKPATRICK, Univ of Maryland — In clean metallic ferromagnets at asymptotically low temperature the magnon-exchange contribution to the single-particle and transport relaxation rates is exponentially suppressed due to the exchange gap [1]. The power-law prefactor of the exponential term is difficult to determine since the gap provides an energy scale in addition to the temperature. To answer this question we present an asymptotically exact evaluation of the Kubo formula. Our solution also clarifies the relation between the integral equation inherent in the Kubo formula and the Boltzmann equation.

11:27AM B42.00002: Latent state in time-resolved nonlinear magnon scattering in thin films  TAO QU (Presenter), ANEESH VENUGOPAL, JAMES M. ETHERIDGE, PAUL CROWELL, RANDALL H. VICTORA, University of Minnesota — The physics of nonlinear magnon scattering has been exploited in nonlinear microwave devices for wireless and satellite communication applications. The latent state, which is the time delay in the response to a microwave pulse, is required to be reduced for fast information communication. We have studied the latent state in time-resolved nonlinear magnon scattering in thin films, in both theory and experiment. The experiment is performed using phase-sensitive time-resolved heterodyne ferromagnetic resonance. The theory is a hybrid time-resolved model which uses an analytical equation of motion based on the Holstein-Primakoff transformation, and realistic micromagnetic simulation, in order to capture the magnon number change caused by the scattering. From the experiment, we find the latent state is a function of power, frequency, and material properties, which indicates the delay time scale is tunable by specific design. The origin of the latent state is the magnon redistribution, in that the uniform magnon mode (wavevector $k=0$) takes time to scatter into non-uniform magnon modes $k\neq0$, which is reflected in the time-resolved magnon number of these modes.

*We thank DARPA, XSEDE and the SMART center (funded by SRC and NIST) for support of this project.
11:39AM B42.00003: A semi-analytical approach for studying the dynamics of magnetic vortices with Dzyaloshinskii-Moriya interactions* CARLA QUISPE FLORES (Presenter), Colorado State University, KAREN LIVESEY, Physics, University of Colorado Colorado Springs, KRISTEN S. BUCHANAN, Physics, Colorado State University — The magnetic vortex provides a convenient system to investigate the effects of the Dzyaloshinskii-Moriya interactions (DMIs) on the dynamics of patterned magnetic structures in confined geometries. Here we introduce a Landau-Lifshitz based diagonalization (LLD) method to calculate the effects of the DMI on radial-type modes in circular disks. The LLD method is a semi-analytical approach which diagonalize the magnetostatic kernel, exchange and DMI contributions to extract the system eigenfrequencies and eigenmodes. Our calculations show that the DMI leads to a frequency shift that is comparable to what is observed for extended films, however, only the down-shifted mode is observed. The excitation amplitudes are enhanced near the core and the structure edges, and modes with even symmetry that would normally be suppressed for a spatially uniform excitation field are present.

*This work is supported by NSF DMR 1709525.

11:51AM B42.00004: Theory for the unconventional dynamics of ferrimagnets [Invited] SE KWON KIM (Presenter), Univ of Missouri - Columbia — Title: Theory for the unconventional dynamics of ferrimagnets

Ferrimagnets have recently emerged as versatile platforms for spintronics owing to their unique tunability of material parameters. In particular, they offer the independent control of the spin density and the magnetization, which are impossible to achieve in more conventional magnets such as ferromagnets and antiferromagnets and thereby offer unprecedented opportunity to discover novel spin physics and realize highly tunable spintronic devices. In this talk, we will discuss the recent theoretical progress on the ensuing novel dynamics of ferrimagnets. The topics will include the dynamics of topological solitons such as domain walls [1,2], skyrmions [3,4], and vortices [5] within the framework of the generalized Landau-Lifshitz-Gilbert-like equations for ferrimagnets. Also, the novel properties of ferrimagnetic magnons such as the tunable g-factors, which can change the sign as well as the magnitude, will be discussed. The talk will be concluded by providing a future outlook on ferrimagnetic spintronics and by discussing some fundamental questions that we are facing to understand the non-equilibrium properties of ferrimagnets [6].

**12:27PM B42.00005: Local spin current probe of the global electrodynamics of ultrathin magnetic heterostructure electrofoils**  
DAVID MAYES (Presenter), MAXWELL GROSSNICKLE, MARK I LOHMANN, JUNXUE LI, VIVEK AJI, JING SHI, University of California, Riverside, JUSTIN SONG, Nanyang Technological University, NATHANIEL GABOR, University of California, Riverside — Spin current - the flow of angular momentum mediated by electrons - is a unique probe of non-trivial phases in ultrathin magnetic heterostructures. Electron spin, however, is highly sensitive to nearby electric and magnetic fields; thus, it is important to characterize nonlocal effects in spintronic devices. The high spin-orbit coupling of platinum in conjunction with ferrimagnetic insulator Yttrium Iron Garnet (YIG) provides an optimal platform for evaluating spin current as a robust probe. Here, we demonstrate the first technique capable of imaging the electric field using spin current as a local probe in Pt/YIG magnetic heterostructures. An imaging laser produces a localized thermal gradient that generates an out-of-plane spin current. In the Pt layer, this spin current scatters electrons in-plane and away from the external magnetic field, producing moving charges which interact with the local electric flux to generate a global voltage that we image in space. Electrofoil Pt/YIG devices, made with airfoil-shaped cutouts, are used to study several subtle nonlocal geometric effects, all of which are well described by the Shockley-Ramo theorem.

**12:39PM B42.00006: On the Field Dependence of Spin-Lattice Relaxation**  
JOHAN VAN TOL (Presenter), National High Magnetic Field Lab, Florida State Univ — Spin Lattice Relaxation (T₁) and spin-spin electron spin relaxation processes (T₂) are of importance for a variety of applications, like quantum information processing, quantum memory, spin cooling, and dynamic nuclear polarization. We studied the temperature dependence of the relaxation in the high magnetic field regime for a variety of paramagnetic spin systems. High frequency pulsed electron spin resonance at various fields and frequencies in the 3-14 T range was used to measure directly in the time domain. The low-temperature direct single-phonon spin lattice relaxation is found to have a strong field dependence (B²-B⁴) in the high frequency/field regime. A comparison is made between transition metal impurities in crystals, donor-bound electrons in semiconductors, and other systems of interest to quantum information processing. In spite of their small spin-orbit coupling, organic radicals in frozen solutions also show a marked field dependence of T₁. This is of importance to dissolution- and solid state dynamical nuclear polarization (DNP) for NMR and MRI studies. The experimental results are compared with existing theoretical models.

*The National High Magnetic Field Laboratory is supported by the National Science Foundation through NSF/DMR-1644779 and the State of Florida.*
12:51PM B42.00007: Spin dynamics in the density functional: problems and perspectives
VLADIMIR ANTROPOV (Presenter), Ames Laboratory, Ames, IA, 50011 — We discuss general dynamics in the charge-current-magnetization density functional theory. Starting from dynamics of one electron wave function we analyze transformation to coupled dynamics of charge, magnetization and current one electron densities. Further we concentrate on a coupled dynamics of total spin and spin current densities. From a methodical point of view we show a connection with the phenomenological Landau-Lifshitz dynamics, effective interactions of Heisenberg model and discuss major assumptions and key adiabatic approximations behind it. Practical expressions for the interatomic interactions parameters of this coupled dynamics are shown also in a standard long wave approximation. Realistic applications of such ab-initio coupled dynamics have been performed for spin excitations and exchange interactions in 3d ferromagnetic metals where “spin current enhancement” of spin waves appears as a perturbation. Several opposite examples of strongly coupled and non adiabatic spin dynamics have been found in 122 family of iron pnictides.

1:03PM B42.00008: Nonclassical magnetization reversal by quantum spin torque of many-electron pulse: A time-dependent density matrix renormalization group study* MARKO PETROVIC (Presenter), PETR PLECHAC, Department of Mathematical Sciences, University of Delaware, ADRIAN FEIGUIN, Department of Physics, Northeastern University, BRANISLAV NIKOLIC, Department of Physics & Astronomy, University of Delaware — Using the time-dependent density matrix renormalization group (tDMRG) method, we study nonclassical effects in the spin-transfer torque (STT) exerted by the spin-polarized electron current on a one-dimensional quantum Heisenberg ferromagnetic chain. Unlike standard STT induced dynamics of magnetization viewed as a classical vector of fixed length, quantum STT allows for the establishment of quantum entanglement between spins. Magnetization reversal driven by quantum STT is nonclassical in the sense that no rotation from its initial state occurs. We extend the findings of Ref. [1], which dealt with single electron wave packets impinging onto many quantum spins. In contrast, the tDMRG method allows us to tackle a problem of many quantum electrons coupled to many quantum spins. The quantum local spins, initially oriented along the negative z-axis, undergo a reversal into the positive z-axis direction after interaction with the spin-up polarized current.

1:15PM B42.00009: Efficient Method for the Simulation of high-temperature Spin Dynamics* GRIGORII STARKOV (Presenter), Theoretical Physics 3, Ruhr Universitat Bochum, BORIS FINE, Skolkovo Institute of Science and Technology — The measurements of nuclear free induction decays (FIDs) can be used to extract microscopic information about solids such as the distances between nuclear spins or electronic spin susceptibility. At the same time, the first-principles calculation of solid FIDs, which is important for such an extraction, is a long-standing problem. We propose a new hybrid quantum-classical method for the first-principles calculation of solid FIDs, which is based on simulating a large quantum spin lattice by a small cluster of quantum spins coupled to an environment of interacting classical spins via a correlation-preserving scheme. The hybrid method is applied to the computation of FIDs in real materials, such as: CaF$_2$, $^{29}$Si-enriched crystalline silicon and fluorapatite. In all the cases, excellent agreement with the experiment is observed.

1:27PM B42.00010: Physical realization of complex dynamical pattern formation in magnetic spinwave active feedback rings* JUSTIN ANDERSON (Presenter), Colorado Sch of Mines, PRAVEEN JANANTHA, Physics, Colorado State University, DIEGO ALCALA, Colorado Sch of Mines, MINGZHONG WU, Physics, Colorado State University, LINCOLN CARR, Colorado Sch of Mines — We report the clean experimental realization of cubic-quintic complex Ginzburg-Landau physics in a single driven, damped system. Five numerically predicted categories of complex dynamical behavior and pattern formation are identified for bright and dark solitary waves propagating around an active magnetic thin film feedback ring: (1) periodic breathing; (2) recurrence; (3) spontaneous spatial shifting; (4) intermittency; and (5) interactions of multiple solitary waves. These non-transient, long lifetime behaviors are observed in microwave spinwave envelopes circulating within a dispersive, nonlinear Yttrium-Iron-Garnet wave guide operating in a ring geometry where net losses are directly compensated for via linear amplification on each round trip (~100 ns). The behaviors exhibit periods ranging from 10s to 1000s of round trip times (~ 1 ms) and are stable for 1000s of periods (~1 s). We find these dynamical behaviors span the experimentally accessible ranges of attractive cubic nonlinearity, dispersion, and external field strength that support the self-generation of backward volume spinwaves in a four-wave mixing regime.

1:39PM B42.00011: An efficient method of spin dynamics for long-range interacting systems*  
TAICHI HINOKIHARA (Presenter), Physics, Univ of Tokyo, MUNETAKA SASAKI, Engineering, Kanagawa university, SEIJI MIYASHITA, Physics, Univ of Tokyo — We developed an efficient method for dynamical simulation, TQMC+SCO, which is useful for classical spin systems with long-range interactions. The method incorporates the stochastic cutoff method (SCO), which is originally specialized for simulating equilibrium state, into the time quantified Monte Carlo (TQMC) method. By using TQMC+SCO, the computational time for the spin-update process is proportional to $O(\beta N \log N)$ no matter how complicated the lattice structure is. We analytically proved that TQMC+SCO gives the same time evolution of the magnetization distribution as the stochastic Landau-Lifshitz-Gilbert (s-LLG) equation. In addition, we simulated a magnetization reversal process and confirmed that the result obtained by TQMC+SCO is in good agreement with that obtained by s-LLG. In this presentation, we introduce TQMC+SCO and discuss why this method works. We also present several examples, where TQMC+SCO can be a strong tool.

1:51PM B42.00012: Mechanism for a chemical potential of nonequilibrium magnons in parametric parallel pumping*  
NAOYA ARAKAWA (Presenter), Toho Univ — I present a new theory of parametric parallel pumping for a ferrimagnet and demonstrate a mechanism by which a chemical potential of nonequilibrium magnons is generated [1]. In the parametric parallel pumping, two magnetic fields parallel to each other are used; one is static, and the other is time-periodic. By using this pumping, we can achieve a nonequilibrium state in which the magnon distribution function is approximated by the Bose distribution function with a finite chemical potential. However, its mechanism has been unclear. In this talk, I will discuss how nonequilibrium magnons in the parametric parallel pumping acquire a finite chemical potential [1].

*This work was supported by JSPS KAKENHI Grant Number JP19K14664.
Spin transport at metallic interfaces is an essential ingredient of various spintronic device concepts, such as giant magnetoresistance, spin-transfer torque, spin-orbit torque, spin Hall magnetoresistance, and spin pumping. Spin-orbit coupling plays an important role in many such devices. In particular, spin current is partially absorbed at the interface due to spin-orbit coupling. Here, we develop a general magnetoelectronic circuit theory and generalize the concept of spin mixing conductance accounting for various mechanisms responsible for spin-flip scattering. For the case when exchange interactions dominate, we give a simple expressions for the spin mixing conductance in terms of contributions responsible for spin memory loss, spin torque, and spin precession, where all contributions are amenable to ab initio treatment. We observe that in general there is no straightforward relation between the spin torque part and the spin memory loss part, where the latter is often expressed in terms of the spin loss parameter, δ.

Session B43 DCOMP DAMOP DCMP: Precision many-body physics II: Dynamics of 1D quantum systems 702 - Guy Cohen, Tel Aviv University - Tag(s): Focus

11:15AM B43.00001: Quantum Phase Transitions Go Dynamical [Invited] VICTOR GURARIE (Presenter), Department of Physics and Center for Theory of Quantum Matter, University of Colorado, Boulder — Just like a thermal partition function can be a nonanalytic function of temperature, the trace of the evolution operator of a quantum system can be a nonanalytic function of time, the phenomenon referred to as dynamical quantum phase transitions. These singularities which occur at certain points in time in the evolution of a quantum system are the subject of this talk. Interestingly, they can even appear in systems which do not undergo conventional thermal or quantum phase transitions, although precise criteria when they are expected to occur are not yet known. While there might be no obvious way to measure the trace of the evolution operator directly, it is possible to observe the “return probability”, the probability that a system which underwent a quantum quench and subsequently evolved for some time finds itself back in its original state. Sharing some similarity with the trace of the evolution operator, this probability can also be singular at certain times. In the context of quantum quench dynamics these singularities were already observed experimentally. Interpreting the trace of the evolution operator in terms of spectral form factors allows to further narrow down the class of quantum systems which could feature these singularities. In particular, they can be seen in integrable and many body localized systems which can have appropriate spectral form factors, although they are not limited to these types of systems. In the absence of a comprehensive theory of these singularities, their numerical study is often the only tool at our disposal to identify relevant systems where they may be present.
11:51AM B43.00002: Information measures for local quantum phase transitions: Lattice bosons in a one-dimensional harmonic trap  
YICHENG ZHANG (Presenter), Department of Physics, Pennsylvania State University, LEV VIDMAR, Department of Theoretical Physics, J. Stefan Institute, Slovenia, MARCOS RIGOL, Department of Physics, Pennsylvania State University — We study ground-state quantum entanglement in the 1D Bose-Hubbard model in the presence of a harmonic trap. We focus on two transitions that occur upon increasing the characteristic particle density: the formation of a Mott insulating domain with site occupation one at the center of the trap (lower transition), and the emergence of a superfluid domain at the center of the Mott insulating one (upper transition). These transitions generate discontinuities in derivatives of the total energy and have been characterized by local (nonextensive) order parameters, so we refer to them as local quantum phase transitions. We show that while a second derivative of the total energy is continuous with a kink at the lower transition, it is discontinuous at the upper transition. We also show that bipartite entanglement entropies are order parameters for those local quantum phase transitions. We use the density matrix renormalization group, and show that the transition points extracted from entanglement measures agree with the predictions of the local density approximation in the thermodynamic limit. We discuss how to determine the transition points from results in small systems, such as the ones realized in recent optical lattice experiments that measured the order-2 Renyi entanglement entropy.

12:03PM B43.00003: Low-energy physics in the critical phase of the bilinear-biquadratic spin-1 chain*  
MORITZ BINDER (Presenter), THOMAS BARTHEL, Duke University — We use an efficient density matrix renormalization group (DMRG) algorithm to compute precise dynamic structure factors for the bilinear-biquadratic spin-1 chain with Hamiltonian $H = \sum_i [\cos\theta (S_i \cdot S_{i+1}) + \sin\theta (S_i \cdot S_{i+1})^2]$. Here, we focus on explaining the physics in the extended critical phase ($\pi/4 \leq \theta < \pi/2$) of the model. The phase transition from the Haldane phase to the critical phase is marked by the SU(3)-symmetric ULS point ($\theta = \pi/4$), where the elementary excitations are spinons that can be obtained from the Bethe ansatz solution. As we move deeper into the critical phase, the spinon continua contract, and new striking features appear at higher energies. In the vicinity of the transition point from the critical to the ferromagnetic phase, a dispersion with a surprisingly simple functional form emerges, suggesting integrability of the model in the limit $\theta \to \pi/2^-$.

12:15PM B43.00004: Entanglement decomposition for the simulation of quantum many-body dynamics*

THOMAS BARTHEL (Presenter), Duke University — Nonequilibrium dynamics in quantum matter are at the frontier of current research. Efficient and precise simulation techniques are needed to improve our understanding of equilibration and thermalization, dynamical phase transitions, decoherence effects, quantum transport etc. A major obstacle is the growth of entanglement with time which generally implies an increased complexity of the quantum state. For instance, the computation costs of simulations based on tensor network states generally grow rapidly in time, limiting the maximum reachable times. I will show how this problem can be addressed through entanglement decomposition. We can follow the dynamics, starting from an initial state, until the entanglement has grown to a point where our simulation resources are exhausted. We then decompose the current state into lower entangled components and continue by simulating the evolution of these components, decomposing them again when needed. I will demonstrate a specific entanglement decomposition scheme for matrix product state simulations and discuss its efficiency for the study of dynamics in quantum magnets.

*Research supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award No. DE-SC0019449.

12:27PM B43.00005: Energy resolved many-body localization emulated with a superconducting quantum processor

CHEN CHENG (Presenter), Lanzhou University, QIUJIANG GUO, Zhejiang University, ZHENGHANG SUN, Chinese Academy of Sciences, RUBEM MONDAINI, Beijing Computational Science Research Center, HENG FAN, Chinese Academy of Sciences, HAOHUA WANG, Zhejiang University — Many-body localization (MBL) describes the regime where isolated matter in disorder environments is able to retain local quantum information at arbitrarily long times, evading thermal equilibrium that naturally occurs in generic quantum systems under their own dynamics. In most experimental studies, MBL has been investigated in various highly-controlled environments, ranging from ultracold atoms in optical lattices, trapped ions to, more recently, quantum processors implemented via superconducting qubits. In this work, taking advantages of the large degree of tunability of the latter platform and using up to 19 qubits, we report on an energy resolved MBL transition. Specifically, by preparing generic product states with different energies and monitoring the persistence of local information in real time dynamics, we are able, for the first time, to investigate the MBL transition at different energy densities, and show an energy resolved experimental MBL phase diagram. While controversies on the existence of many-body mobility edge still exist, due to the system finiteness amenable to classical computers, our investigation potentially opens a path to the final answer by direct quantum simulations.
**12:39PM B43.00006: Exact two-spinon contribution to the longitudinal dynamical structure factor of the anisotropic XXZ model with comparison to DMRG simulations**  
ANDREAS WEICHSELBAUM (Presenter), IGOR ZALIZNYAK, Brookhaven National Laboratory, ISAAC P. CASTILLO, UNAM, Mexico City, JEAN-SÉBASTIEN CAUX, University of Amsterdam, The Netherlands — Motivated by inelastic neutron scattering experiments on quasi-one dimensional XXZ systems such as Yb$_2$Pt$_2$Pb, an exact formula for the two-spinon contribution to the dynamical structure factor is developed based on the quantum group (QG) approach. The results provide a QG derivation of the Baxter formula for the T=0 ordered spin. They are consistent with sum rules, and in excellent agreement with Density Matrix Renormalization Group (DMRG) simulations.

*DOE Grant No. DE-SC0012704, and UNAM-DGAPA-PAPIIT-IN106219.

**12:51PM B43.00007: Nonequilibrium steady state of quantum impurities: A numerically-exact tensor-network approach**  
MATAN LOTEM, School of Physics and Astronomy, Tel Aviv University, FRAUKE SCHWARZ, Physics Department, Arnold Sommerfeld Center for Theoretical Physics, and Center for NanoScience, Ludwig-Maximilians-Universität, ANDREAS WEICHSELBAUM, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, JAN VON DELFT, Physics Department, Arnold Sommerfeld Center for Theoretical Physics, and Center for NanoScience, Ludwig-Maximilians-Universität, MOSHE GOLDSTEIN (Presenter), School of Physics and Astronomy, Tel Aviv University — The accurate description of the nonequilibrium steady state properties of qubits coupled to different environments, or "quantum impurities" (such as an interacting quantum dot, e.g., in the Kondo regime, under the application of a finite bias voltage) is a central open problem in condensed matter physics. In order to study such systems, we employ a novel approach where the impurity is coupled to a finite number of lead levels, which in turn are incoherently coupled to baths, resulting in a Lindblad master equation for the density operator of an effective 1D system describing the impurity and the finite leads. Numerically exact tensor-networks based methods are employed in order to target the Lindblad equation steady state. First, equilibrium NRG is used to find the relevant Hilbert subspace of the impurity and its vicinity. The full system is then evolved towards the steady state using a time dependent Matrix Product Density Operator algorithm. Our results show that the Lindblad dissipation, if appropriately tuned, can cut off the entanglement entropy growth, which otherwise is the limiting factor in tensor-networks methods, while at the same time giving rise to the correct infinite system steady state observables.
Anomalous transport and hydrodynamics in 1D quantum systems

ROMAIN VASSEUR (Presenter), UTKARSH AGRAWAL, Univ of Mass - Amherst, SARANG GOPALAKRISHNAN, Physics, CUNY, BRAYDEN WARE, Univ of Mass - Amherst — In this talk, I will explain how anomalous transport can emerge in one-dimensional quantum systems at finite temperature, due to hierarchies of quasiparticle excitations. I will describe how to attack this problem using a combination of analytical (generalized hydrodynamics) and numerical (matrix product operators) techniques.

This work was supported by the National Science Foundation under NSF Grant No. DMR-1653271 (S.G.), the US Department of Energy, Office of Science, Basic Energy Sciences, under Early Career Award No. DE-SC0019168 (U.A. and R.V.), and the Alfred P. Sloan Foundation through a Sloan Research Fellowship (R.V.).

Universal scrambling in gapless quantum spin chains

SHUNSUKE NAKAMURA, University of Tokyo, EIKI IYODA (Presenter), Tokai Univ, TETSUO DEGUCHI, Ochanomizu University, TAKAHIRO SAGAWA, University of Tokyo — Information scrambling, characterized by the out-of-time-ordered correlator (OTOC), has recently attracted much attention, because it sheds new light on chaotic dynamics on quantum many-body systems. As an important feature of OTOC, its decay rate has an upper bound, which is referred to as the chaotic bound. The scale invariance, which appears near the quantum critical region in condensed matter physics, is considered to be important for the fast decay of OTOC.

In this study, we focus on the one-dimensional spin-1/2 antiferromagnetic XXZ model and investigate the relationship between scrambling and the scale invariance. As an indicator of the scrambling, we adopt the averaged OTOC, which is related to the operator space entanglement entropy (OSEE). We numerically calculate time-dependence of the OSEE in the early-time region in the thermodynamic limit by using the infinite time-evolving block decimation method. Our numerical results suggest that the scale invariance leads to a universal behavior of the OTOC that is independent of the anisotropic parameter, which reflects the universality of the two-dimensional conformal field theory with the conformal charge c=1 at low temperatures.

1:27PM B43.00010: Asymmetry in Forward/Backward Transition Times in Multi-Particle System with Interactions*  
JAEOH SHIN (Presenter), ANATOLY BORIS KOLOMEISKY, Rice Univ — Transition time is a fundamentally important property of various non-equilibrium processes, including biological transport and diffusion through channels that reflect the underlying microscopic dynamics. For single particles moving in arbitrary free-energy landscapes, it is known that the forward and backward transition times are the same due to the microscopic reversibility. To understand how and in which condition the symmetry breaks down, here we investigate a non-equilibrium one-dimensional multi-particle system on the lattice with periodic boundary conditions where the particles interact only via hard-core exclusions. We found the asymmetry in forward/backward transition times for time-averaged situations when the transition events are analyzed from long-time trajectories. We developed a fully analytical theoretical analysis that can describe the observed results. The microscopic origin of these surprising observations is discussed.

1:39PM B43.00011: Entanglement and matrix elements of observables in interacting integrable systems*  
TYLER LEBLOND (Presenter), KRISHNANAND MALLAYYA, Pennsylvania State University, LEV VIDMAR, Jozef Stefan Institute, MARCOS RIGOL, Pennsylvania State University — We study the bipartite von Neumann entanglement entropy and matrix elements of local operators in the eigenstates of an interacting integrable Hamiltonian (the spin-1/2 XXZ chain), and contrast their behavior with that of quantum chaotic systems. Remarkably, our results suggest that the volume-law coefficient of the average entanglement entropy of eigenstates of the spin-1/2 XXZ chain (zero magnetization sector) is the same as, or very close to, the one for translationally invariant quadratic fermionic models. We also study matrix elements of local operators in the eigenstates of the spin-1/2 XXZ chain at the center of the spectrum. For the diagonal matrix elements, we show evidence that the support does not vanish with increasing system size, while the average eigenstate to eigenstate fluctuations vanish in a power law fashion. For the off-diagonal matrix elements, we show that their distribution is close to log-normal, and that their variance is a well-defined function of \( \omega = E_\alpha - E_\beta \) (\( \{ E_\alpha \} \) are the eigenenergies) proportional to \( 1/D \), where \( D \) is the Hilbert space dimension.

Nonequilibrium dynamics of static electron-phonon models from Monte Carlo simulations* MANUEL WEBER (Presenter), JAMES FREERICKS, Georgetown University — Electron-phonon interactions play an important role in the relaxation of strongly-correlated materials driven out of equilibrium. However, numerical simulation of microscopic models is often restricted to very small system sizes due to the unbound dimensions of the bosonic Hilbert space or requires approximative schemes (such as perturbation theory). In this talk, we present an exact Monte Carlo method to simulate the nonequilibrium dynamics of electron-phonon models in the adiabatic limit of zero phonon frequency. We show applications to the one-dimensional Holstein and Su-Schrieffer-Heeger models and probe the formation and destruction of the ordered Peierls phase as a function of initial temperature when the system experiences strong applied electric fields.

*This work is supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award DE-FG02-08ER46542.

Heating rates in periodically driven strongly interacting quantum many-body systems* KRISHNANAND MALLAYYA (Presenter), MARCOS RIGOL, Pennsylvania State University — We study heating rates in strongly interacting quantum lattice systems in the thermodynamic limit. Using a numerical linked cluster expansion, we calculate the energy as a function of the driving time and find a robust exponential regime. The heating rates are shown to be in excellent agreement with Fermi's golden rule. We discuss the relationship between heating rates and, within the eigenstate thermalization hypothesis, the smooth function that characterizes the off-diagonal matrix elements of the drive operator in the eigenbasis of the static Hamiltonian. We show that such a function, in nonintegrable and (remarkably) integrable Hamiltonians, can be probed experimentally by studying heating rates as functions of the drive frequency.

Session B44 DCOMP: Real-Space Methods for the Electronic Structure Problem II 704 - Amir Natan, Tel Aviv University - Tag(s): Focus
11:15AM B44.00001: Real space and real time electron dynamics simulations for attosecond physics in solids [Invited] SHUNSUKE SATO (Presenter), Center for Computational Sciences, University of Tsukuba, Japan — Real-space and real-time electron dynamics simulation based on the time-dependent density functional theory is a powerful tool to analyze complex and highly-nonlinear interactions of light with solids. To investigate laser-induced ultrafast electron dynamics in solids, we developed a numerical technique to simulate pump-probe experiments [1]. Recently, we applied the numerical pump-probe simulations for the attosecond transient absorption spectroscopy and studied the light-induced ultrafast electron dynamics in solids [2,3]: First, we investigated laser-induced electron dynamics in GaAs with the first-principles simulations. As a result, we found an important role of the light-induced intraband transition in transient optical properties of optically-driven semiconductors [2]. Then, we investigated ultrafast electron dynamics in Titanium, and the first-principles simulations provided microscopic insight into laser-induced electron-localization dynamics in transition metals [3].

11:51AM B44.00002: Speeding up real-space based first-principles methods for excited-states properties using interpolative separable density fitting* JAMES CHELIKOWSKY, WEIWEI GAO (Presenter), University of Texas at Austin — Density fitting methods are a class of algorithms that provide low-rank approximations for products of orbital pairs. However, most of its applications in first-principles codes are based on localized basis sets. A recently proposed interpolative separable density fitting (ISDF) method does not rely on predefined auxiliary basis and is formulated in real space representation. We employ the ISDF method to significantly reduce the cost of linear response time-dependent density functional theory (LR-TDDFT) and GW calculations. In our implementation, we exploit the symmetry property of a system to effectively reduce the number of auxiliary basis and thus the computational cost. Our benchmarks show the cost for constructing auxiliary basis and interpolation coefficients are negligible compared to the total computational cost. Compared to a conventional “brutal-force” approach, the cost for evaluating all kernel matrix elements in LR-TDDFT and GW calculations is reduced by up to three orders of magnitude. The accuracy of our implementation is benchmarked with the GW100 set.

*Our work is supported by a subaward from the Center for Computational Study of Excited-State Phenomena in Energy Materials at LBNL, which is funded by the U.S. DOE under Contract No. DE-AC02-05CH11231.
12:03PM B44.00003: Ab initio stochastic time-domain formulation of the Bethe-Salpeter equation*  
CHENCHEN SONG (Presenter), Physics, University of California, Berkeley, ROI BAER, Fritz Haber Center of Molecular Dynamics and Institute of Chemistry, The Hebrew University of Jerusalem, DANIEL NEUHAUSER, Chemistry and Biochemistry, University of California, Los Angeles, JEFFREY B NEATON, Physics, University of California, Berkeley, ERAN RABANI, Chemistry, University of California, Berkeley — We present a reduced scaling formulation of the Bethe-Salpeter equation (BSE) through a combination of a time-dependent approach and stochastic representations, which allows efficient *ab initio* calculations of optical absorption spectra for semiconductor nanoparticles. The linear response of the system to external fields is simulated by propagating quasiparticle orbital dynamics in real time, followed by Fourier transforming the dipole-dipole correlation function to obtain the absorption spectrum. The spatially dependent screening of the system is described within the random phase approximation (RPA) and combines several efficient stochastic techniques, including factorization with stochastic representations, and time-dependent Hartree propagation of stochastic occupied orbitals. The computational cost of the new BSE formulation is quadratic scaling with respect to system size, which is a significant improvement compared with the conventional symplectic eigenvalue representation of the BSE. We discuss preliminary results from the applications of the method to silicon and CdSe nanocrystals.

*This work is supported by the Department of Energy through the Computational Materials Science Center C2SEPEM at Berkeley Lab; computational resources provided by NERSC.

12:15PM B44.00004: Fast real-time time-dependent density functional theory calculations using higher-order finite element methods  
BIKASH KANUNGO (Presenter), VIKRAM GAVINI, Univ of Michigan - Ann Arbor — We present a computationally efficient approach to solve the time-dependent Kohn-Sham equations in real time using higher order finite-element spatial discretization, applicable to both pseudopotential and all-electron calculations. To this end, we develop an apriori mesh adaption technique, based on the semidiscrete (discrete in space but continuous in time) error estimate on the time-dependent Kohn-Sham orbitals, to construct an efficient finite-element discretization. Subsequently, we obtain the full-discrete error estimate to guide our choice of the time step. Importantly, for the all-electron case, we present an efficient mixed basis, termed as enriched finite element basis, that combines the efficiency of atomic-orbitals-type basis to capture the sharp variations of the electronic fields closer to the atoms along with the completeness and spatial-adaptivity of the finite element basis. We demonstrate significant savings afforded by our approach over the finite-difference and Gaussian basis based approaches, for pseudopotential and all-electron calculations, respectively. Additionally, we discuss schemes to accelerate the time-evolution by constructing dynamic subspace based approaches, informed by time-dependent perturbation theory.
12:27PM B44.00005: Recent Advances in the Development of the Octopus Code for GPUs
SEBASTIAN OHLMANN (Presenter), Max Planck Computing and Data Facility — Since the end of Moore's law, using state-of-the-art supercomputers has become more and more difficult because simulation codes need to expose more and more parallelism to benefit from larger machines. Moreover, supercomputers have become heterogeneous as the increase in CPU performance has slowed down: all of the first three exascale machines to be built in the US will heavily rely on GPUs to achieve their compute performance. Thus, simulation codes in all areas, also real-space DFT codes, will need to utilize GPUs efficiently in order to use these next-generation machines. In this contribution, we report on recent advances in the development of the real-space DFT code Octopus for GPUs. Those developments include porting more algorithms to GPUs, both for ground-state and time-dependent calculations, improving the data handling when copying data to and from the GPU and improving the overlap of communication with computation. We will show how these advances improve the speed of the code and its scalability and apply the code to some larger problem sizes on GPUs.

12:39PM B44.00006: Excitonic effects from real-time parameter-free hybrid functions
NICOLAS TANCOGNE-DEJEAN (Presenter), ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter — Hybrid functionals are known to provide excellent band-gap of semiconductors compared to local and semi-local functional. Because hybrid functionals can be constructed to include the long-range part of the screened Coulomb interaction, they contain the basic ingredients that can produce the bound excitons in optical spectra of semiconductors and insulators. So far, the construction of such parameter-free functional requires complex procedures such that optimally-tune parameters [], or fitting of the band-gap on GW calculations []. This hampers the predictive power of such a functional and anchors it to the realm of optical properties of materials at equilibrium.

Because real-time time-dependent density functional theory (TDDFT) does not rely on perturbation theory, it has the capability to study materials out of their equilibrium or perturbed by strong fields. It is therefore of tremendous importance to find hybrid functionals that do not require auxiliary calculations to adjust parameters, in order to bring their predictive power to nonlinear and out-of-equilibrium optical properties.

**12:51PM B44.00007: Ab-initio photo-ionization dynamics without continuum states**

UMBERTO DE GIOVANNINI (Presenter), Max Planck Inst Structure & Dynamics of Matter — Photo-ionization underpins a range of spectroscopies central to the study of structural and dynamical properties of matter in the gas and solid phases. In solid state physics angular resolved photoelectron spectroscopy (ARPES) and time-resolved (tr) ARPES are the most prominent techniques. Leveraging the flexibility offered by real-space methods we developed a technique, based on the real-time formulation of time-dependent density functional theory (TDDFT), to simulate ARPES and tr-ARPES ab-initio without explicit reference to continuum states [1]. I will present the theory, the algorithm involved in the implementation and some of the most representative applications and predictions.

**1:03PM B44.00008: Efficient electromagnetic potential calculations within ground state and time dependent density functional theory.**

DOR GABAY (Presenter), Department of Physical Electronics, Tel Aviv University, ALI YILMAZ, Electrical and Computer Engineering, University of Texas at Austin, VITALIY LOMAKIN, Electrical and Computer Engineering, University of California at San-Diego, AMIR BOAG, AMIR NATAN, Department of Physical Electronics, Tel Aviv University — Electromagnetic potentials play a fundamental role in ground and excited state calculations of Density Functional Theory (DFT). One method for the calculation of such potentials is to directly solve their corresponding differential equations. In this work, the equivalent integral expressions of those potentials are evaluated within their spectral representation. Such integral expressions play a critical role in handling problems ranging from hybrid functionals to the calculation of retarded potentials within the time-dependent Kohn-Sham equation. The simplest of these are FFT procedures used to evaluate the static Poisson integral within ground-state calculations. We extend the use of these integral expressions to time-dependent retarded electromagnetic potentials in both the Lorenz and Coulomb gauges and demonstrate the efficiency of the approach. We use this method for the calculation of several electronic structures using a real-time real-space TDDFT approach. Finally, the various gauge-fixing conditions are compared to assure alignment in the limit of small magnetic fields and the advantages of the Lorenz gauge are outlined.

*This research was supported by the United States-Israel Binational Science Foundation (BSF), Jerusalem, Israel, under BSF grant numbers 2014426 & 2018182.*
1:15PM B44.00009: Real-space approach to the calculation for ionization potentials, exciton, and biexciton binding energies in quantum dots using explicitly-correlated electron-hole interaction kernel method*  PETER MCLAUGHLIN, NICOLE SPANEDDA, ARINDAM CHAKRABORTY (Presenter), Syracuse University — Inclusion of unoccupied states is the leading computational bottleneck for calculation of excited states for large chemical systems. In this work, we present the geminal-screened electron-hole interaction kernel (GSIK) method to address this problem. The GSIK is a real-space r12 method that avoids unoccupied orbitals for constructing the electron-hole interaction kernel by performing an infinite-order diagrammatic summation of particle-hole excitations and deriving a renormalized real-space electron-hole correlator operator. The GSIK method also bypasses the computational expensive AO-to-MO integral transformation by computing all integrals directly in the real-space numerically using permutation sampling Monte Carlo method. These two features allow GSIK method to be used for chemical systems where inclusion of a large number of unoccupied orbitals will be computationally prohibitive. In this work, the GISK method was applied to investigate exciton binding energies, biexciton binding energies, and ionization potentials for large semiconductor (Pb$_{140}$S$_{140}$, Pb$_{140}$Se$_{140}$, Cd$_{144}$Se$_{144}$) nanoparticles. The results from these calculations demonstrate the efficacy of the GSIK method for capturing electron-hole correlation in large clusters and nanoparticles.

1:27PM B44.00010: Recent developments in the Octopus code for strong light-matter coupling  MICAELOLIVEIRA (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — The Octopus code [1,2] is a finite-differences real-space code designed to fully take advantage of the flexibility and versatility of real-space grids and provide developers with a framework to easily implement and test new ideas and methods in the field of electronic excited states properties and dynamics, while ensuring optimal execution performance and parallelization.

In this talk I will give an overview of the recent advances in the Octopus code regarding several novel approaches in the field of strong light-matter interactions [3]. Such new methods are essential to correctly describe the coupling of light to chemical systems, quantum materials, or nanoplasmmonic systems, among others, when the electron-photon interaction has to be considered explicitly.

Monday, March 2, 2020 11:15 AM - 2:15 PM
11:15AM B45.00001: Sound Scattering and Plasticity in Amorphous materials* [Invited] ANNE TANGUY (Presenter), HAOMING LUO, PAUL DESMARCHELIER, ANTHONY GRAVOUIL, LaMCoS, INSァ Lyon, YAROSLAV BELTUKOV, Ioffe Institute, St Petersburg, FERNANDO LUND, universidad de chile, Santiago de chile — Plastic deformation in amorphous materials results from a succession of local irreversible rearrangements at the nanometric scale known as Transformation Zones. From a numerical point of view, these Transformation Zones are well described within the theory of Eshelby inclusions. In this talk, we will compare sound scattering in amorphous materials in the presence of inclusions. We first remind the signature of structural disorder on acoustic attenuation. We will then detail the role of heterogeneous elastic inclusions on sound attenuation and thermal transfers. Finally we will focus on the effect of Eshelby like inclusions on sound attenuation.

*We are thank to ECOS-chile for the financement C17E02, the 2018 Metchnikov fellowship of the French Embassy in Russia, and the french ministry of research for the PhD fellowship provided ED MEGA.
11:51AM B45.00002: Energy Dissipation in Amorphous Solids during Elastic Deformation*
JAN GRIESSER (Presenter), LARS PASTEWKA, Departement of Microsystems Engineering, University Freiburg — Excitation of atomic vibrational modes is an important mechanism for energy dissipation in friction phenomena. In crystalline materials, the vibrational modes can be represented as plane waves, i.e. the phonons. This is in general not possible in amorphous solids due to structural disorder, which gives rise to different types of vibrational modes. Energy dissipation is related to the lifetime of these vibrational modes. Here we use large-scale molecular dynamics simulations to investigate energy dissipation mechanisms in a model amorphous solid and compare it to a crystalline solid. While the lifetimes of phonons show universal scaling $\omega^{-2}$ in the limit of low frequencies $\omega$, vibrational modes in the amorphous system show different scaling that depends on the type of the vibrational mode. We also carry out cyclic deformation of the amorphous solid in the elastic regime. In this limit, energy dissipation can be traced back to non-affine deformation. We demonstrate that the energy dissipation can be predicted by knowledge of the lifetimes and the non-affine displacement field.

*The authors acknowledge support by the DFG (Grant PA 2023/2). Simulations were carried out on NEMO cluster in Freiburg (DFG grant INST 39/963-1 FUGG).

12:03PM B45.00003: Local excitations in re-heated ultrastable glasses  WENCHENG JI (Presenter), TOM W. J. DE GEUS, MARKO POPOVIĆ, EPFL, EDAN LERNER, University of Amsterdam, MATTHIEU WYART, EPFL — Quasilocalised modes are local excitations present at low frequency vibrational spectrum in glasses. We numerically study their frequency density $D_{\text{loc}}(\omega)$ evolution under thermal cycles at different temperatures $T$, starting from ultrastable glass configurations where these excitations are gapped. The latter are prepared by an algorithm where individual particles can "breathe", modelling the effect of the swap algorithm in a grand-canonical ensemble. We find that a quartic behavior $D_{\text{loc}}(\omega)=A_4 \omega^4$ always appears at any finite $T$. The prefactor $A_4$, which characterizes the number of quasilocalised modes, can increase by a factor of thousands with growing $T$ in our numerical observations. Moreover at small $T$, $A_4$ follows an Arrhenius behaviour: $A_4 \sim \exp(-E_a/T)$ where $E_a$ is atypical energy that depends on the magnitude of the gap initially present. We provide arguments for this dependence. Overall, our result support that true gaps never exists at finite temperature in finite dimensions, and suggest that in some equilibrated super-cooled liquids $A_4$ may decrease exponentially at low $T$. 
12:15PM B45.00004: Cluster-flip colloidal and atomistic algorithms with background potentials*  JARON KENT-DOBIAS (Presenter), JAMES PATARASP SETHNA, Cornell University — We introduce an extension to cluster algorithms of colloidal and atomistic models that naturally incorporates nonuniform background potentials. Simulations of these systems are important for studying the statistical mechanics of fluids and myriad liquid, solid, and glassy phase transitions. Nonuniform background potentials like gravitational or trapping fields are typically present in experiments and can reveal new features of the statistical mechanics at play due to, e.g., nonuniform chemical potential. This method takes existing cluster methods and incorporates background potentials without adding a rejection step by treating the orientation of the system as a dynamical degree of freedom. We assess its efficiency in several applications and explore connections with the celebrated swap Monte Carlo for glasses.

*NSF DMR-1719490

12:27PM B45.00005: Accelerated relaxation in amorphous materials under cyclic loading with alternating shear orientation*  NIKOLAI PRIEZJEV (Presenter), Wright State Univ — The effect of alternating shear orientation during cyclic loading on the relaxation dynamics in disordered solids is examined using molecular dynamics simulations. The model glass was initially prepared by rapid cooling from the liquid state and then subjected to cyclic shear along a single plane or periodically alternated in two or three dimensions. We showed that with increasing strain amplitude in the elastic range, the system is relocated to deeper energy minima. Remarkably, it was found that each additional alternation of the shear orientation in the deformation protocol brings the glass to lower energy states. The results of mechanical tests after more than a thousand shear cycles indicate that cyclic loading leads to the increase in strength and shear-modulus anisotropy.

12:39PM B45.00006: Mesoscale models of amorphous solids under cyclic shear: emergence and character of limit cycles.  KAREEM ABDELSHAFY (Presenter), Northeastern University, BOTOND TYUKODI, Physics, Brandeis University, DAMIEN VANDEMBROUCQ, PMMH, ESPCI Paris, CRAIG E MALONEY, Northeastern University — Amorphous solids (amorphous metallic alloys, glassy polymers, foams, emulsions, pastes, compressed granular packings, etc.) respond in complex ways to imposed shear. In steady shear, the response depends on preparation and shear may or may not localize upon yielding. In cyclic shear, if the amplitude of cycling remains below the yielding threshold, the system may either exhaust all plastic behavior and become purely elastic, or lock into a periodic orbit where plasticity is reversed after one or many cycles and the system returns to its previous configuration. These complex limit cycles have been observed in experiments and particle-based simulations. Here, we show that a simple mesoscale model which treats the material as a mosaic of yielding plaquettes is able to capture the complex limit cycles with orders of magnitude less computational time than particle-scale models. We use the mesoscale model to study the limit cycles at various strain amplitude.
Comparison of yielding behaviour in model network and atomic glasses

HIMANGSU BHAUMIK (Presenter), Theoretical Sciences Unit, Jawaharlal Nehru Centre For Advanced Scientific Research, Bangalore, India, GIUSEPPE FOFFI, Laboratoire de Physique des Solides, Universite Paris-Sud, France, SRIKANTH SASTRY, Theoretical Sciences Unit, Jawaharlal Nehru Centre For Advanced Scientific Research, Bangalore, India — Yielding in a model atomic glass (Kob-Andersen binary mixture) has been studied recently through athermal quasi-static shear deformations [1], revealing a sharp yielding transition accompanied by strain localisation [2]. We investigate the manner in which such a transition is manifested in a model network glass, the BKS model of silica [3]. Silica exhibits a fragile-to-strong cross over a function of temperature, and we investigate the manner in which yielding and the accompanying strain localisation differs in glasses prepared initially in the strong and fragile regimes. We find qualitative differences in the yielding behaviour, and in the details of structural changes accompanying yielding. We compare these results to the aforementioned atomic glass with comparable changes in the degree of annealing, and recent results regarding the effect of annealing in the yielding behaviour of glasses [4].

Molecular Dynamics Study on Mechanical and Rheological Properties of Bulk Metallic Glass around Glass Transition Temperature

JI WOONG YU (Presenter), Seoul Natl Univ, S. H. EBRAHIMNAZHAD RAHBARI, Korea Institute for Advanced Study, WON BO LEE, Seoul Natl Univ — Bulk Metallic Glasses (BMG) or amorphous alloys usually contain more than two kinds of atoms. These materials have been central in both material engineering and material physics ever since their first appearance in 1960s, and posses superior material properties (e.g. tensile yield stress). However, the mechanical properties of BMG are not well understood due to nonequilibrium nature of the glass transition, and dramatic slow-down of the dynamics around the glass transition temperature. Using large scale computational power, we investigated the mechanical properties of the celebrated Kob-Andersen mixture, a model BMG, using active microrheology in molecular dynamics (MD) simulations. Moreover, we systematically compared results of the active microrheology with those obtained from global shearing. With strong evidence, we conclude superiority of the either method.
1:15PM B45.00009: Computational generation of voids in a-Si and a-Si:H by cavitation at low density
ENRIQUE GUERRERO (Presenter), DAVID STRUBBE, University of California, Merced —
Hydrogenated amorphous Si (a-Si:H) has seen a renewed interest for its application in heterojunction with intrinsic thin-layer (HIT) solar cells. Known deficiencies in this material's photovoltaic properties are limited hole mobilities and the Staebler-Wronski effect, a light-induced degradation of efficiency which may be in part due to voids within the structure. Simulations of voids in a-Si typically involve atomic removal, but these methods require an a priori idea of the bonding structure near the void. Instead, we generate voids within a-Si and a-Si:H using a fast, unbiased approach: the Wooten-Winer-Weaire classical-potential Monte Carlo method where we vary the density and replace some Si-Si bonds with Si-H bonds. At low density, voids form (like cavitation in a liquid), maintaining 4-coordination but increasing bond angle deviation, reducing medium-range order, and altering local structure within 4 Å of the void. This work provides a set of void structures for further studies of their effects on degradation, hole mobility, two-level systems, thermal transport, and elastic properties. (ArXiv: 1907.01327)

1:27PM B45.00010: Molecular Dynamics Simulation of Amorphous Oxides
RUI ZHANG (Presenter), JUN JIANG, MAHER YAŻBACK, ALEC MISHKIN, HAI-PING CHENG, Physics, University of Florida — Amorphous oxides has been used as coating material of interferometers for gravitational wave detection. To optimize their performance, efforts have been devoted to determining diffusive behavior of amorphous pure Ta$_2$O$_5$ as well as Ta$_2$O$_5$ with various dopants by classical molecular dynamics (MD) simulations. Furthermore, empirical pair potentials aiming at reproducing elastic properties of GeO$_2$ and doped GeO$_2$ have been constructed. The new potentials are applied to examine the thermodynamic properties of such material. Also, the vibrational density of states and Raman spectra of amorphous oxides have been demonstrated using MD simulation.

*This work is supported by the NSF through grants PHY-1707870 and PHY-1404110.
We study two 2D systems known to support an open-packed Kagome phase[1]. Both systems have repulsive pair potentials, one designed by Piñeros, Baldea, and Truskett and another by Zhang, Stillinger, and Torquato[2-3]. Using the aperture cross-correlation function (ACCF), we identify structured fluctuations in the liquid phases approaching the Kagome-liquid transition[4]. These Kagome-like fluctuations may be distinguished from hexagonal ones by calculating the ACCF at two different wavevector magnitudes along the second diffraction ring. Fluctuations near a string-Kagome transition involve transient structures that are different for different potentials. We find congruencies in the sequence of phases along an isotherm for many different 2D systems of Hertzian, Lennard-Jones-Yukawa, Core-Corona, and Daoud–Cotton particle potentials. These similarities suggest a universal mechanism among the phase transitions of 2D systems supported by central repulsive potentials.

We thank the University of Chicago MRSEC, NSF Grant No. DMR-1420709, for funding this research.

Record Dynamics (RD) describes the ubiquitous relaxation phenomenology known as "aging" that ensues after a hard quench in terms of a log-Poisson process. According to RD, a nonequilibrium system after a quench relies on fluctuations that randomly generate a sequence of irreversible record-sized events (quakes or avalanches) that allow the system to escape ever-higher barriers of metastable states within a complex energy landscape. Only the activation over such barriers allows the system to relax while tumbling into the next meta-basin that is marginally more stable. Within this picture of RD, a clear distinction can be drawn between the coarsening dynamics of, say, an Ising ferromagnet and the aging of the spin glass, which are often put in the same category. To that end, we use Ising spin models that interpolate between the spin glass and ferromagnet by varying the admixture of anti-ferromagnetic bonds from 50% to zero. Indeed, the accumulation of record events grows logarithmically with time in the glassy regime, with a sharp transition at a specific admixture in the ferromagnetic regime where such activations saturate quickly. We show this effect both for the Edwards-Anderson model on a cubic lattice as well as the Sherrington-Kirkpatrick (mean-field) spin glass.
Many-body localization to spin glass phase transition in disordered spin-chain system

ZEYANG LI (Presenter), PAI PENG, Massachusetts Institute of Technology — Disorder in a strongly correlated spin-chain system can give rise to novel phases of matter, such as many-body localization (MBL) phases or spin-glass (SG) phases. The two phases share similar non-thermalizing properties due to the existence of extensive set of local integrals of motion (LIOMs), and the SG phases feature in other properties such as a SG order parameter as well as the doubly degenerate eigenstates.

We consider a disordered Heisenberg XXZ model with on-site random field and random anisotropy. By changing the relative strength between these two disorders, we numerically observe the phase transition from MBL to SG, using numerically constructed LIOMs. We also obtain a scaling property of this transition, which elucidates the phase diagram of this system in the thermodynamic limit.
Due to the exotic quantum phenomena of the frustrated quantum magnets, investigating the related ground states has caught a lot of attention. The two-dimensional Spin-1/2 triangular-lattice antiferromagnet (TLAF) is a typical example: the quantum fluctuations could interfere the spin states, such as the disordered liquid and glass phases, and keep them with the complicated interactions among the geometric frustration, low dimensionality, and small spin. \( \text{Ba}_3\text{CoSb}_2\text{O}_9 \) is the first spin-1/2 equilateral TLAF without the Dzyaloshinskii-Moriya interaction, and the magnetic \( \text{Co}^{2+} \) triangular layers are well separated by the non-magnetic clusters of the \( \text{Sb}_2\text{O}_9 \) bioctahedra and \( \text{Ba}^{2+} \) ions. The strong quantum effects were observed from a non-collinear 120° spin structure in zero magnetic field into a collinear up-up-down (uud) state in a finite range of applied magnetic field [1, 2]. Through the experimental and theoretical studies, we found that the Linear Spin-Wave + 1/S treatment was inadequate to explain our experimental observation and the interlayer interaction could not be ignored in the system [3, 4]. In order to study the interlayer interactions and magnetic moments dependence on the quantum effect, the work has been extended to the other TLAFs of the multi-layered perovskite compounds with \( S=1 \) and \( 5/2 \). Moreover, the non-magnetic \( B' \)-site ions of the \( \text{A}_m\text{BB}'_{m-1}\text{O}_{3m} \) were discussed.

11:51AM B46.00002: Effect of quenched disorder on an equilateral triangular lattice antiferromagnet Ba$_3$CoSb$_2$O$_9$* QING HUANG (Presenter), HAIDONG ZHOU, University of Tennessee, Knoxville, TAO HONG, Oak Ridge National Lab, EUN SANG CHOI, National High Magnetic Field Lab, JIE MA, Shanghai Jiao Tong University, LU LI, University of Michigan, COLE D MAUWS, University of Manitoba, CHRISTOPHER WIEBE, University of Winnipeg — Ba$_3$CoSb$_2$O$_9$ is one of few prototypical materials for the two-dimensional equilateral triangular lattice antiferromagnet. We present a systematic study on effect of quenched disorder on magnetic properties in the Sr doped single-crystalline sample of Ba$_{2.8}$Sr$_{0.2}$CoSb$_2$O$_9$ by means of DC and AC susceptibilities, specific heat and advanced neutron scattering. DC susceptibility in Ba$_{2.8}$Sr$_{0.2}$CoSb$_2$O$_9$ confirms an antiferromagnetic ordering below 2.8 K with an easy-plane anisotropy. AC susceptibility as a function of magnetic field measured at 0.02 K indicates a phase transition around 8 T. Evolution of the transition temperature as a function of field was determined by specific heat measurements in Ba$_{2.8}$Sr$_{0.2}$CoSb$_2$O$_9$. We will also discuss effect of side disorder on the magnetic structure in Ba$_{2.8}$Sr$_{0.2}$CoSb$_2$O$_9$ using the single-crystal neutron diffraction technique.

12:03PM B46.00003: Universal scaling of the heat capacity in a quantum spin liquid state of 1T-TaS$_2$ HINAKO MURAYAMA (Presenter), YUKI SATO, TOMOYA TANIGUCHI, RYO KURIHARA, HIROKI SUZUKI, XIANZHUO XING, WENKAI HUANG, SHIGERU KASAHARA, YUICHI KASAHARA, Physics, Kyoto University, ITAMAR KIMCHI, Physics, University of Colorado, MASARO YOSHIDA, CEMS, RIKEN, YOSHIHIRO IWASA, Applied Physics, the University of Tokyo, MARCIN KONCZYKOWSKI, Laboratoire des solides irradiées, L'École Polytechnique, YUJI MATSUDA, Physics, Kyoto University — To elucidate the nature of quantum spin liquid (QSL), it is important to understand the effect of randomness on QSL. Here, we have investigated the low energy excitations on pure, Se-substituted and electron-irradiated 1T-TaS$_2$, a QSL candidate material with spin-1/2 on a triangular lattice[1, 2], by measuring low-temperature thermal conductivity and heat capacity. Finite residual linear terms of thermal conductivity, $\kappa/T(T\to0)$, in pure 1T-TaS$_2$ indicates the presence of itinerant gapless excitations. The magnetic contribution of the heat capacity of 1T-TaS$_2$ and 1T-TaS$_{2-x}$Se$_x$ well obeys a universal scaling relation, consistent with a theory that assumes the presence of localized orphan spins forming random singlets[3]. These results capture a microscopic picture of the QSL, in which localized orphan spins induced by disorder are surrounded by itinerant spinon that forms Fermi surface. On the other hand, electron irradiation in 1T-TaS$_2$, which introduces strong quenched disorders in Ta-layers, changes the scaling function dramatically, suggesting a possible new state of spin liquid.

12:15PM B46.00004: Magnetic Excitations and Q-dependent magnon lifetime in Non-collinear Metallic Antiferromagnet CrB$_2$  
PYEONGJAE PARK (Presenter), KISOO PARK, TAEHUN KIM, Department of Physics and Astronomy, Seoul National University, YUSUKE KOUSAKA, JUN AKIMITSU, Research Institute for Interdisciplinary Science, Okayama University, TOBY G. PERRING, ISIS Pulsed Neutron and Muon Source, Rutherford Appleton Laboratory, MICHEL KENZELMANN, Paul Scherrer Institute, JE-GUEN PARK, Department of Physics and Astronomy, Seoul National University — Frustration and non-collinear magnetic ordering can introduce a wide variety of interesting physics; like a quantum spin liquid phase in insulators or topological band structures in metals, to name a few. Many studies have been made on the nature of magnetic excitations in non-collinear insulating magnets, while few experimental data exist for non-collinear metallic magnets. Using an inelastic neutron scattering technique, we report the magnetic excitation spectra of single crystal CrB$_2$; a metallic magnet in which magnetic moments of Cr on triangular lattice form incommensurate spiral magnetic order with the propagation vector $k = (0.285, 0.285, 0)$. Severely damped magnons are observed along with clear phonons which are as sharp as the instrumental resolution, yet most of them can be explained by Heisenberg Hamiltonian and a linear spin wave theory (LSWT). By excluding the effects of instrumental resolution, we mapped the intrinsic magnon linewidth $\Gamma(q, E)$ which shows some unusual behavior. We discuss the origin of the magnon decay by calculating 2-magnon density of states (DOS) and Stoner continuum DOS. Our work will be a rare comprehensive study on the spin dynamics of non-collinear metallic magnets; the 1st observation of 2-magnon effect in metallic magnets.

12:27PM B46.00005: Terahertz study of the frustrated triangular Ising magnet FeI$_2$*

ANAELLE LEGROS (Presenter), DIPANJAN CHAUDHURI, Johns Hopkins University, XIAOJIAN BAI, ZHILING DUN, MARTIN MOURIGAL, Georgia Institute of Technology, PETER ARMITAGE, Johns Hopkins University — 2D antiferromagnetic (AF) triangular lattices are of great interest due to their geometric frustration, which may lead to the absence of a long-range magnetic order at $T=0$. FeI$_2$ is part of the ferrous halides family, in which the Fe$^{2+}$ ions are distributed on hexagonal planes and spontaneously order in an AF phase below $T_N \sim 9$K [1]. Contrary to other ferrous halides, the spins in the ordered phase of FeI$_2$ form triangular AF sheets (instead of antiparallel ferromagnetic sheets), giving rise to a more complex magnetic structure. In this peculiar ground state, the spins (S=1) generate several types of magnetic excitations, including a mysterious two-magnon bound state that should be prevented by selection rules [2]. Moreover, when an external magnetic field is applied along the c-axis at $T<T_N$, successive magnetic transitions occur, including a phase without evidence of long-range order [3]. We present the results from in-field time-domain terahertz spectroscopy on FeI$_2$. These experiments give insight into the diverse magnetic excitations of this triangular AF lattice.

**12:39PM B46.00006: Synthesis and frustrated magnetism of the triangular lattice \( \text{ARESe}_2 \) single crystals**

JIE XING (Presenter), LIURUKARA D SANJEEWA, Oak Ridge National Laboratory, JUNGSOO KIM, GREGORY RANDALL STEWART, University of Florida, MAOHUA DU, FERNANDO REBOREDO, RADU CUSTELCEAN, ATHENA S. SEFAT, Oak Ridge National Laboratory — We have successfully synthesized \( \text{ARESe}_2 \) (\( A = \text{Alkali metal}, \ RE = \text{rare-earth} \)) single crystals by the salt flux. These crystals stabilize in either the trigonal (\( R-3m \)) or hexagonal (\( P6_3/mmc \)) crystal systems depending on the \( RE \), containing the ideal triangular \( RE^3+ \) layers. We have characterized them through magnetization and heat capacity down to 0.4 K. Antiferromagnetic interactions with large magnetic anisotropy is observed, while no long-range order is found indicating frustrated magnetism. Yb-based crystals present a two-peak feature in the heat capacity below 10 K, while the magnetic plateau is found at 4 T when the magnetic field is applied in the \( ab \) plane. The 112 system is found to be particularly interesting for the study of frustrated magnetism and its potential for quantum spin liquid behavior.

**12:51PM B46.00007: Measurement of a 1/2 magnetization plateau in a frustrated antiferromagnet**

SHANNON HALEY (Presenter), NIKOLA MAKSIMOVIC, University of California, Berkeley, ERAN MANIV, Lawrence Berkeley National Lab, DANIEL PARKER, University of California, Berkeley, JOHN SINGLETON, Los Alamos National Laboratory, JOEL MOORE, JAMES ANALYTIS, University of California, Berkeley — Frustrated magnetic systems lend themselves to a wealth of nontrivial behaviors. Among these are plateaus in magnetization with the application of an external field, resulting from quantum fluctuations stabilizing particular spin states. The existence of these plateaus at specific fractions of the saturated magnetization has been observed in a handful of systems with distinct physics. This talk will discuss our recent discovery of a \( \frac{1}{2} \) magnetization plateau in a frustrated antiferromagnet on a triangular lattice using fields up to 65T. This directly confirms recent theoretical predictions in frustrated magnets.

1:03PM B46.00008: Novel Excitations near Quantum Criticality in Geometrically Frustrated Antiferromagnet CsFeCl$_3$ [Invited] TAKATSUGU MASUDA (Presenter), SHOHEI HAYASHIDA, Institute for Solid State Physics, Univ of Tokyo, MASASHIGE MATSUMOTO, Shizuoka University, MASATO HAGIHALA, High Energy Accelerator Research Organization, NOBUYUKI KURITA, HIDEKAZU TANAKA, Tokyo Institute of Technology, SHINICHI ITOH, High Energy Accelerator Research Organization, TAO HONG, Oak Ridge National Laboratory, MINORU SODA, Ochanomizu University, YOSHIYA UWATOKO, Institute for Solid State Physics, Univ of Tokyo — The investigation of materials that exhibit quantum phase transition provides valuable insights into fundamental problems in physics. We present neutron scattering under pressure in a triangular-lattice antiferromagnet that has a quantum disorder in the low-pressure phase and a noncollinear structure in the high-pressure phase [1]. The neutron spectrum continuously evolves through critical pressure; a single mode in the disordered state becomes soft with the pressure and it splits into gapless and gapped modes in the ordered phase. Extended spin-wave theory reveals that the longitudinal and transverse fluctuations of spins are hybridized in the modes because of noncollinearity, and novel magnetic excitations are formed. We report a new hybridization of the phase and amplitude fluctuations of the order parameter near a quantum critical point in a spontaneously symmetry-broken state.

1:39PM B46.00009: Evidence of one-dimensional magnetic heat transport in the triangular-lattice antiferromagnet Cs$_2$CuCl$_4$* ERIK SCHULZE, STEVAN ARSENIJEVIC, LARS OPHERDEN, ALEXEY PONOMARYOV, JOACHIM WOSNITZA, Helmholtz-Zentrum Dresden-Rossendorf, TOSHIO ONO, Osaka Prefecture University, HIDEKAZU TANAKA, Tokyo Institute of Technology, SERGEI ZVYAGIN (Presenter), Helmholtz-Zentrum Dresden-Rossendorf — We report on low-temperature heat-transport properties of the spin-1/2 triangular-lattice antiferromagnet Cs$_2$CuCl$_4$. Broad maxima in the thermal conductivity along the three principal axes, observed at about 5 K, are interpreted in terms of the Debye model, including the phonon Umklapp scattering. For thermal transport along the $b$ axis, we found a pronounced field-dependent anomaly, close to the transition into the three-dimensional long-range-ordered state. No such anomalies were observed for the transport along the $a$ and $c$ directions. We argue that this anisotropic behavior is related to an additional heat-transport channel through magnetic excitations, that can best propagate along the direction of the largest exchange interaction. Our observations strongly support the quasi-1D spin-liquid scenario with spinons as elementary excitations, proposed for this frustrated antiferromagnet. Besides, peculiarities of the heat transport of Cs$_2$CuCl$_4$ in magnetic fields up to the saturation field and above are discussed.

*This work was supported by the Deutsche Forschungsgemeinschaft (DFG), through ZV 6/2-2, the excellence cluster ct.qmat (EXC2147, project-id 39085490), and SFB 1143, as well as by the HLD at HZDR, member of the European Magnetic Field Laboratory (EMFL).
1:51PM B46.00010: Torque equilibrium spin wave theory study of anisotropy and Dzyaloshinskii-Moriya interaction effects on the indirect K- edge RIXS spectrum of a triangular lattice antiferromagnet  TRINANJAN DATTA (Presenter), Chemistry and Physics, Augusta University, SHANJIAN JIN, LUO CHENG, DAO-XIN YAO, School of Physics, Sun Yat-Sen University — We apply the recently formulated torque equilibrium spin wave theory (TESWT) to compute the 1/S-order interacting K-edge bimagnon resonant inelastic x-ray scattering (RIXS) spectra of an anisotropic triangular lattice antiferromagnet with Dzyaloshinskii-Moriya (DM) interaction [1]. We extend the interacting torque equilibrium formalism, incorporating the effects of DM interaction, to appropriately account for the zero-point quantum fluctuation that manifests as the emergence of spin Casimir effect in a noncollinear spin spiral state. Using inelastic neutron scattering data from Cs₂CuCl₄ we fit the 1/S corrected TESWT dispersion to extract exchange and DM interaction parameters. We compare, and contrast the effects of spatial anisotropy and DM interaction on the RIXS spectra at various points across the magnetic Brillouin zone. We highlight the key features of the bi- and trimagnon RIXS spectrum at the roton like points whose behavior is quite different from an isotropic triangular lattice system [2]. Our calculation offers a practical example of how to calculate interacting RIXS spectra in a non-collinear quantum magnet using TESWT. [1] Jin et. al. Phys. Rev. B 100, 054410 (2019); [2] Luo et. al. Phys. Rev. B 92, 035109 (2015).

2:03PM B46.00011: A New Yb-based Spin-1/2 Triangular Lattice Magnet*  SHU GUO (Presenter), ROBERT J. CAVA, Princeton University — Very recently, two rare earth (R)-based triangular lattice (TL) materials, YbMgGaO₄ and NaYbO₂, are proposed to be quantum spin liquid candidate. From the structural point of view, the magnetic R atoms of these two compounds display a “ABCABC” stacking form in c axis. However, seldom research is focused on the “AA” cubic stacking R-based TL materials. Here, we present a cubic stacking Yb-based TL magnet. The centimeter-size single crystals of Yb-based TL magnet were grown by the flux method. In the crystal structure, the Yb-Yb separation (8.06 angstroms) between layers is larger than the in-plane Yb-Yb separation (5.63 angstroms). The absence of long-range ordering was confirmed by the magnetization (down to 1.8 K). Specific heat measured down to 0.3 K at zero field also confirmed the absence of long-range ordering. For applied field above 3 T, there is still no evidence of long-range magnetic ordering, but instead, a broad peak appears. This broad hump is associated with Schottky anomaly that shifts to higher temperatures at higher fields.

*This work was supported as part of the Institute for Quantum Matter, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Basic Energy Sciences under Award No. DESC0019331.

Session B47 GMAG: Interfaces, Coupling, and Ultra-Thin Materials
710/712 - Nathan Satchell, Univ of Leeds - Tag(s): Focus
XIAOQIAN CHEN, Lawrence Berkeley National Laboratory, JUSTIN WOODS, University of Kentucky, ROLAND KOCH, Lawrence Berkeley National Laboratory, BARRY W FARMER, University of Kentucky, CLAUDIO MAZZOLI, WEN HU, Brookhaven National Laboratory, RAJESH V CHOPDEKAR, Lawrence Berkeley National Laboratory, WAI-KWONG KWOK, Argonne National Laboratory, LANCE ERIC DE LONG, University of Kentucky, SUJOY ROY, Lawrence Berkeley National Laboratory, JEFFREY HASTINGS (Presenter), University of Kentucky — Artificial spin lattices (ASLs), including artificial spin ices, consist of patterned magnetic nanostructures that mimic Ising spins. Here we show that a permalloy, square ASL with a double edge dislocation exhibits an ordered antiferromagnetic ground state, unlike square ASLs with a single dislocation.¹ We demonstrate that soft x-rays resonantly scattered from this magnetic texture carry orbital angular momentum. Moreover, x-ray OAM from these samples can be modulated using and temperature and applied magnetic fields. X-ray beams carrying orbital angular momentum (OAM) have potential applications in nanoscale imaging, spectroscopy, and manipulation, but current means of generating x-ray OAM are difficult to modulate or reconfigure.² Scattering from ASLs may offer a potential path to flexible control of x-ray OAM.

11:27AM B47.00002: Enhancement of magnetoelectric coupling by insertion of Co atomic layer into Fe$_3$Si/BaTiO$_3$(001) interfaces identified by first-principles calculations

YASUNARI HAMAZAKI (Presenter), YOSHIHIRO GOHDA, Tokyo Inst of Tech - Yokohama — Magnetoelectric (ME) coupling of Ferromagnetic(FM)/ferroelectric(Fe) interfaces is stronger than those of single phase multiferroic materials. Especially, interface ME effect caused by bonding effect between interfacial atoms has been reported in many FM/FE interfaces and observed at room temperature. In this study, we examine interface ME coupling at Fe$_3$Si/Co/BaTiO$_3$ heterostructures by using first-principles calculations based on density functional theory to clarify the influence of atomic-layer insertion on the ME effect. D0$_3$-type Fe$_3$Si has only 0.1 % lattice mismatch with tetragonal BaTiO$_3$ (001), and it is considered as promising to emerge the interfacial ME effect. We construct several interface structures and compare the energy of each structure. Comparing the Fe$_3$Si/BaTiO$_3$ interface with the Fe$_3$Si/Co/BaTiO$_3$ interface, it is found that the interface ME effect is greatly increased when Co is inserted. We also clarify the differences in ferroelectric displacement and magnetic properties between Fe$_3$Si/BaTiO$_3$ and Fe$_3$Si/Co/BaTiO$_3$.

11:39AM B47.00003: Long-range exchange coupling in Co/Nb/Co trilayers

VICTOR GONZÁLEZ (Presenter), University of the Andes, NICOLAS M VARGAS, UC San Diego, S MERCONE, LSPM-CNRS UPR-3407, Université Paris, EDGAR J PATINO, University of the Andes, IVAN K. SCHULLER, UC San Diego, JUAN RAMIREZ, University of the Andes — Long-range interlayer exchange coupling (IEC) in multilayers has been a topic of extensive research, both experimental and theoretical. IEC can be induced by two ferromagnetic (FM) layers spaced by a thin non-magnetic (NM) material. In this work, we performed vector model Vibrating Sample Magnetometer (V-VSM), Magneto-optic Kerr effect and magnetoresistance (MR) measurements as a function of temperature from 1K up to room temperature. Interestingly, we observed an oscillatory behavior of the magnetic coercive field usually associated with IEC without fully antiferromagnetic compensation of the ferromagnetic layers at all temperatures. This may suggest an additional Long-range exchange coupling mechanism beyond the direct exchange.

*This is highly collaborative research. The Moke and preliminary VSM measurements were done at UCSD under DOE grant # DE FG02 87ER-45332, the experiments were designed and the work was analyzed by all authors. The authors also acknowledge support from Colciencias grant 120471250659. The V-VSM measurements were done at the facilities of University of Paris-VII with sponsorship from grants of the Île-de-France region.
Reduced exchange interactions in thin perpendicularly magnetized magnetic tunnel junction free layers and spin-transfer reversal mechanisms* [Invited]

JAMILEH BEIK MOHAMMADI (Presenter), Loyola University New Orleans, BARTEK KARDASZ, GEORG WOLF, Spin Memory Inc, YIZHANG CHEN, New York University, MUSTAFA PINARBASI, Spin Memory Inc, ANDREW KENT, New York University — Perpendicularly magnetized magnetic tunnel junctions (pMTJs) are being widely developed for spin-transfer torque magnetic random-access memories for data storage and embedded memories. The magnetic properties of the pMTJ free layer affect the dynamic properties of the free layer, such as the spin-torque switching efficiency and the switching speed, and therefore the device performance.

The magnetic exchange constant is one of the most important yet hard to measure properties of the free layer, as the layer is very thin and embedded in a pMTJ layer stack that includes a magnetic reference layer coupled to a synthetic antiferromagnet. The exchange constant sets the length scale for spatial variations of the magnetization. In perpendicularly magnetized tunnel junction devices, the exchange constant can also set the energy barrier for thermally activated reversal [1].

I will present the results of a systematic experimental study of the exchange constant of CoFeB free layers with perpendicular anisotropy. We have used vibrating sample magnetometry to determine the temperature dependence of the magnetic moment, and therefore the magnon population density [2] of the free layer. In particular, I will show that when a thin W insertion layer is introduced into a 2.3 nm thick CoFeB free layer to increase the perpendicular magnetic anisotropy of the layer, the exchange constant of the free layer is significantly reduced.

I will also present a micromagnetic study that shows that the spin-transfer reversal nucleates at the center of the element and completed by domain wall motion in elements larger than a critical size set by the exchange constant, magnetization and perpendicular magnetic anisotropy.

12:27PM B47.00005: Strain-driven spin-Hall antiferromagnetic memory for 180° switching*

ARUN PARTHASARATHY (Presenter), NIKHIL RANGARAJAN, Electrical and Computer Engineering, New York University, Brooklyn, NY 11201, SHALOO RAKHEJA, Holonyak Micro and Nanotechnology Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 — Antiferromagnets exhibit ultrafast spin dynamics with response times in the picosecond range, produce negligible stray fields, and are promising to design high-density nonvolatile memories. NiO is an antiferromagnetic insulator whose Néel order can be switched by 90° using electric current in the spin-Hall system NiO/Pt [1], or piezoelectric strain in Ni/NiO/PMN-PT [2]. Although these switching schemes allow storage of information, the 90° state is thermally metastable.

We propose 180° reversal of the Néel order by leveraging both piezoelectric strain and spin-Hall effect in PMN-PT/NiO/Pt system. The reversal is accomplished by first realizing strain-induced perpendicular reorientation, followed by an electric current pulse that provides the antidamping torque necessary to tip the Néel order to the reversed easy-axis orientation. The antiferromagnetic state is read via exchange-bias-coupled magnetic tunnel junction. Modeling shows that the strain-driven NiO memory can switch under 100 ps, while consuming < 300 aJ/bit switching energy.

12:39PM B47.00006: Inter-particle magnetic correlations and fluctuations in assemblies of Fe3O4 nanoparticles

KARINE CHESNEL (Presenter), JOHNATHON RACKHAM, COLBY WALKER, BRITTNI PRATT, DALTON GRINER, ROGER HARRISON, MARK TRANSTRUM, Brigham Young Univ - Provo — Magnetite (Fe3O4) nanoparticles (NPs) are increasingly used in biomedical applications such as drug & gene delivery, hyperthermia, or MRI. While the structural and magnetic properties of bulk Fe3O4 is well known [1], knowledge is still lacking about the spatio-temporal magnetic behavior of collections of Fe3O4 NPs. We here investigate the inter-particle magnetic correlations within the NP assembly throughout the superparamagnetic transition using x-ray resonant magnetic scattering (XRMS) [2]. By exploiting the light polarization, we extract the local inter-particle magnetic order. We show a dependence on particle size, suggesting an enhancement of magnetic couplings for bigger particles. [3] Additionally, we show a model based on NP chains, which we use to fit the XRMS data, suggesting ferromagnetic ordering at high external magnetic field, and the emergence of antiferromagnetic ordering near remanence. [4] Finally we investigate the slow dynamics of magnetic fluctuations between NPs by using photon correlation spectroscopy and show a drastic change through the superparamagnetic transition.

[1] Verwey, Nature 144, 327 (1939);
Magnetic nanoparticles are increasingly used in nanotechnologies and biomedical applications, such as drug targeting, MRI, and bio-separation. Magnetite (Fe3O4) nanoparticles stand to be effective in these roles due to the non-toxic nature of magnetite and its ease of manufacture. To be more effective in these applications, a greater understanding of the magnetic behavior of the individual magnetite nanoparticles is needed when a collection of them is used. This research seeks to discover the local magnetic ordering of ensembles of magnetite nanoparticles occurring at various stages of the magnetization process. To complete this study, we use resonant x-ray magnetic scattering, which provides information about the magnetic orders in the material. Here we discuss the modeling of the magnetic scattering data using a one-dimensional chain of nanoparticles with a mix of ferromagnetic, anti-ferromagnetic, and random order and the model's validation against empirical gaussian fits. The model utilizes twelve variable parameters and we used a Levenberg-Marquardt algorithm to find the best fit parameters. By fitting the model to the experimental data, we extracted information about the magnetic correlations in the nanoparticle assembly.
Coupling of ferroelastic and ferromagnetic order parameters in materials offers a means to achieve novel multiferroic applications. In this talk, we report strong coupling between the structural degree of freedom and spin state transition in the LaCoO$_3$ (LCO) thin films and heterostructures. Three major results will be present, 1) symmetry transition from a pseudocubic to a monoclinic structure happens in the LCO films as increasing the layer thickness, leading to the nonlinear behavior of magnetization vs. thickness; [1] 2) the observation of one-dimensional ferroelastic domains in LCO thin films that are intimately linked to magnetization. Unidirectional structural modulation is achieved by selective choice of substrate or growth plane, which produces broken in-plane rotational symmetry; [2] 3) the interfacial symmetry mismatch triggers the nonuniformed crystallographic parameters, thus the structural modification within a single LCO layer. The magnetization exhibits a reduced magnetization but an enhanced atomic density, whereas the film's interior (i.e., its film bulk) shows the opposite trend. This assertion is tested by systematic application of hydrostatic pressure during the polarized neutron reflectivity experiments. The magnetization can be controlled at a rate of −20.4% per GPa. [3] These results provide unique insights into mechanisms driving FM in strained LCO films while offering a tantalizing observation that tunable deformation of the CoO$_6$ octahedra in combination with the ferroelastic and ferromagnetic order parameters.

1:39PM B47.00009: "Boundary Conditions in Granular Magnetic Nanostructures with Dzyaloshinski-Moriya Interactions"* AHSAN ULLAH (Presenter), BALAMURUGAN BALASUBRAMANIAN, WENYONG ZHANG, DAVID SELLMYER, RALPH SKOMSKI, Department of Physics and Astronomy, NCMN, University of Nebraska - Lincoln 68588-0299, USA — Magnetic nanostructures such as compacted ensembles of metallic nanoparticles and melt-spun ribbons often but not always yield a topological Hall-effect contribution caused by the Berry phase of the conduction electrons. Among the experimental systems recently investigated in our group are MnSi, NiMnGa, NiMnIn, and Co-Si, The Berry-phase effect depends on the spin structure, which is strongly affected by real-structure feature such as easy-axis orientation and grain boundaries. Chemical inhomogeneities at grain boundaries yield $\nabla A$ terms in the materials equations (partial differential equations), where $A$ is the exchange stiffness. For sharp interfaces, this term corresponds to Erdmann-Weierstrass (EW) boundary conditions. In the presence of Dzyaloshinski-Moriya interactions ($D$), there are $\nabla D$ terms and modifications to the EW condition. The effect of the boundary conditions on spin structure and Berry phase is far-reaching and epitomized by the contrast between Bessel and modified Bessel functions in grains with cylindrical symmetry.

1:51PM B47.00010: The effect of x-ray illumination on magnetic domain memory in [Co/Pd] / IrMn multilayers* COLBY WALKER (Presenter), MASON L PARKES, Brigham Young Univ - Provo, DAVID J KEAVNEY, Advanced Photon Source, Argonne National Laboratory, ERIC FULLERTON, Center for Memory and Recording research, UCSD, KARINE CHESNEL, Brigham Young Univ - Provo — We are studying the effect that illumination by coherent x-rays may have on magnetic domain memory (MDM) in a [Co / Pd] / IrMn multilayers. MDM is the ability of the magnetic domains to retain their exact same domain topology upon field cycling. Earlier studies have suggested that under higher dose of x-ray illumination, the material may lose its existing MDM. To investigate this potential effect, we have used both x-ray resonant magnetic scattering (XRMS) along with magneto-transport measurements to track the exchange bias while the sample is illuminated with x-rays. Magneto-transport is here used to measure the hysteresis loop of our multilayers material from which we can measure the exchange bias and its possible alteration. A loss of exchange bias would indicate that the x-rays illumination dose may alter the strength of the exchange couplings and ultimately the amount of MDM. Knowing if a loss of exchange bias has occurred requires collecting magneto-transport data as well as XRMS data and correlating the observed changes under various dose of x-ray illumination.

Quantification of mixed Bloch/Néel character in a Co/Pd DMI multilayer thin film with Lorentz transmission electron microscopy.

JOSEPH GARLOW (Presenter), Brookhaven National Laboratory, SHAWN D. POLLARD, National University of Singapore, MARCO BELEGGIA, Technical University of Denmark, HYUNSOO YANG, National University of Singapore, YIMEI ZHU, Brookhaven National Laboratory — Chiral magnetic order stabilized by the Dzyaloshinskii-Moriya interaction holds promise for a range of spintronic device applications such as for magnetic-based memory and logic. Yet, direct methods for the quantification of their exact structure remains a challenge and is crucial towards understanding the fundamental physics associated with their ordering and manipulation. Here, we present an approach to quantify the mixed Bloch-Néel character of domain walls stabilized by the Dzyaloshinskii-Moriya interaction in Co/Pd multilayers. Analysis of the observed intensities under varied imaging conditions yield vital parameters that dictate their stability and properties, namely, the degree of mixed Bloch-Néel character \( \eta = 56^\circ \pm 5^\circ \), the domain wall width \( w = 10 \pm 2 \text{ nm} \), the strength of the Dzyaloshinskii-Moriya interaction \( D = 1.0 - 1.1 \text{ mJ/m}^2 \), and the exchange stiffness \( A = 23 - 30 \text{ pJ/m} \). This approach provides the necessary framework to quantify the magnetic structure for a broad array of topological spin systems using Lorentz phase microscopy.

Session B48 DCMP: Superconductivity in Low Dimensional Systems

High Ballroom 1A - Hongchao Xie, Univ of Michigan - Ann Arbor

11:15AM B48.00001: Quantum spin-liquid and chiral superconductivity in TaS\(_2^*\)

AMIT KANIGEL (Presenter), AMIT RIBAK, Technion - Israel Institute of Technology, RONI MAJLIN SKIFF, Tel Aviv University, MARK H FISCHER, Zurich University, JONATHAN RUHMAN, Bar Ilan University, YORAM DAGAN, Tel Aviv University — Van der Waals (vdW) materials offer unprecedented control of electronic properties via stacking of different types of two-dimensional materials. A fascinating frontier, largely unexplored, is the stacking of strongly correlated phases of matter. We study 4Hb-TaS\(_2\), which naturally realizes an alternating stacking of 1T-TaS\(_2\) and 1H-TaS\(_2\) structures. The former is a well-known Mott insulator, which has recently been proposed to host a gapless spin-liquid ground state. The latter is a superconductor known to also host a competing charge density wave state. This raises the question of how these two components affect each other when stacked together. We find a superconductor with a \( T_c \) of 2.7 K and anomalous properties, of which the most striking one is a signature of time-reversal-symmetry breaking, abruptly appearing at the superconducting transition. This observation is consistent with a chiral superconducting state.

11:27AM B48.00002: Blockade of vortex flow by thermal fluctuations in atomically thin clean-limit superconductors  
AVISHAI BENYAMINI (Presenter), Columbia Univ, DANTE KENNES, Institut fur Mathematische Physik, Technische Universitat Braunschweig, EVAN TELFORD, Columbia Univ, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ANDREW MILLIS, JAMES C HONE, CORY DEAN, ABHAY NARAYAN, Columbia Univ — Resistance in superconductors arises from the motion of vortices driven by flowing supercurrents or external electromagnetic fields and may be strongly affected by thermal or quantum fluctuations. The common expectation borne out in previous experiments is that as the temperature is lowered, vortex motion is suppressed, leading to a decreased resistance. A new generation of materials provides access to the previously inaccessible regime of clean-limit superconductivity in atomically thin superconducting layers. We show experimentally that for few-layer 2H-NbSe$_2$ the resistance below the superconducting transition temperature may be non-monotonic, passing through a minimum and then increasing again as temperature is decreased further. The effect exists over a wide range of current and magnetic fields but is most pronounced in monolayer devices at intermediate currents. Analytical and numerical calculations confirm that the findings can be understood in a two-fluid vortex model, in which a fraction of vortices flow in channels while the rest are pinned but thermally fluctuating in position, effectively controlling the mobility of the free vortices. The findings provide a new perspective on fundamental questions of vortex mobility and dissipation in superconductors.

11:39AM B48.00003: Supercurrent detection of topologically trivial zero-energy states in nanowire junctions*  
OLADUNJOYE AWOGA (Presenter), JORGE CAYAO, ANNICA M BLACK-SCHAFER, Department of Physics and Astronomy, Uppsala University — In this work we investigate phase-biased transport in SNS junctions based on nanowires, with strong Rashba spin-orbit coupling and magnetic field, strongly coupled to 2D conventional $s$-wave superconductors. We find that all the nanowire parameters are renormalized, in a manner dependent on the width of the superconductor. In particular, we show that the finite width of the superconductor induces a finite energy shift, or effective chemical potential, in the nanowire sectors coupled to the two superconductors, thus leading to a natural formation of a quantum dot at the junction. Remarkably, under these conditions, the junction supports the emergence of a pair of zero-energy states in the trivial phase, i.e. false Majorana fermion states. We demonstrate that this effect is highly tunable by the superconductor width, and suggest this as an explanation for the formation of trivial zero-energy states reported in recent experiments. Most importantly, we show that these zero-energy states produce a $\pi$-shift in the phase-biased supercurrent. This gives access to a simple tool for their unambiguous detection, thus ruling out any Majorana-like interpretation. See Phys. Rev. Lett. 123, 117001 (2019) for further details.

Quantum disoliton as a one-dimensional linear potential system

GEUNYONG KIM (Presenter), JINHO YANG, ILKYU YANG, Department of Physics, Pohang University of Science and Technology, DIRK WULFERDING, Institute for Condensed Matter Physics, TU Braunschweig, JINYOUNG YUN, Department of Physics, Pohang University of Science and Technology, ROMAN MOVSHOVICH, MPA-CMMS, Los Alamos National Laboratory, GILYOUNG CHO, KI-SEOK KIM, JEEHOON KIM, Department of Physics, Pohang University of Science and Technology — Disoliton as a bounded soliton system appeared initially in a swimming pool in the form of half vortex ring. Subsequently, it turns out to be a universal phenomenon at all length scales. Despite the discovery of several disoliton systems, their underlying physics such as nature of an interaction potential remains elusive due to the lack of a model system allowing controllability and repeatability. Here we report on a quantum disoliton (QDS) created as a U-shape quantum flux tube in a superconducting Nb film. A systematic control on a single QDS reveals the purported 1D linear potential, i.e. distance-independent force. The QDS will provide a novel platform for exploring 1D phase transition, quantum transport, and non-Abelian statistics.

Andreev bound states in hybrid full-shell Al/InAs nanowire devices

MARCO VALENTINI (Presenter), MATTHIAS BRAUNS, ANDREA HOFMANN, Institute of Science and Technology Austria, PETER KROGSTRUP, Center for Quantum Devices and Microsoft Quantum Lab–Copenhagen, GEORGIOS KATSAROS, Institute of Science and Technology Austria — Hybrid superconductor-semiconductor nanowire (NW) devices have attracted widespread interest as they can host Majorana zero modes (MZMs). While most of the previous experiments dealt with semiconductor NWs partially covered by a superconductor, a recent theory proposal [1] suggests to fully cover the semiconductor NWs with a superconductor. One of the main advantages of having a superconducting full-shell is that MZMs should arise at a very precise magnetic field, namely in the odd lobes of the Little-Parks effect. A first result [2] showed the presence of a zero bias peak (ZBP) in the first lobe, suggesting the presence of MZMs in such NWs. However, also Andreev bound states (ABS) could arise in such experiments. Hence, it is important to study them and especially their evolution in a magnetic field. Here, we present low temperature magnetotransport data using InAs NWs fully covered by Al [3]. We investigate ABS in the Little-Parks regime; we show that ABS can merge at zero bias in the first lobe, mimicking MZMs behaviour. Furthermore, we suggest how to discriminate ZBPs arising from MZMs and from ABS.

**12:15PM B48.00006: Gate-tunable superconductivity in layered β-MoTe$_2$**  
APOORV JINDAL  
(Presenter), Department of Physics, Columbia University, DANIEL A RHODES, Department of Mechanical Engineering, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, Tsukuba, Ibaraki 305-0044, Japan, CORY DEAN, Department of Physics, Columbia University, JAMES C HONE, Department of Mechanical Engineering, Columbia University, ABHAY PASUPATHY, Department of Physics, Columbia University — van der Waals heterostructures of mechanically-exfoliated crystalline materials are a platform to observe quantum phenomena in the low-disorder limit. Of special interest are materials with low carrier density, where the use of electrostatic doping and electric field tuning of bandstructure gives us easily accessible experimental tuning knobs. Twisted graphene and TMD superlattices, and monolayer WTe$_2$ are a couple of striking recent examples. In monolayer WTe$_2$, the use of gate potentials has been shown to tune between a topological insulator and a superconducting phase. In this talk, we describe transport measurements on a closely related material, β-MoTe$_2$. We show that β-MoTe$_2$ exhibits robust gate-tunable superconductivity in the few-layer limit. hBN encapsulated devices in the monolayer exhibit a superconducting critical temperature of ~ 6 K, a nearly hundred-fold enhancement over the bulk value. Using a dual-gated device structure, we also observe a strong dependence of superconducting properties on carrier density and displacement field. In this talk, we will fully characterize the layer, carrier density, displacement field, and magnetic field phase diagrams of this material.

**12:27PM B48.00007: Non-linear $I$/$V$ characteristics in two-dimensional superconductors: Berezinskii-Kosterlitz-Thouless physics vs inhomogeneity**  
LARA BENFATTO (Presenter), GIULIA VENDITTI, Univ of Rome La Sapienza, JOHAN BISCARAS, Sorbonne Universite, Paris, France, SIMON HURAND, NICOLAS BERGEAL, JEROME LESUEUR, ESPCI, Paris, France, ANJANA DOGRA, National Physical Laboratory, New Delhi, India, RAMESH BUDHANI, Morgan State University, Baltimore, USA, MINTU MONDAL, School of Physical Sciences, Kolkata, India, JOHN JESUDASAN, PRATAP RAYCHAUDHURI, TIFR, Mumbai, India, SERGIO CAPRARA, Univ of Rome La Sapienza — One of the hallmarks of the Berezinskii-Kosterlitz-Thouless (BKT) transition in two-dimensional superconductors is the universal jump of the superfluid density, that can be indirectly probed via the non-linear exponent of the current-voltage $I$/$V$ characteristics. Here, we compare the experimental measurements of $I$/$V$ characteristics in two cases, namely NbN thin films and SrTiO$_3$-based interfaces. While the former display a paradigmatic example of BKT-like non-linear effects, the latter do not seem to justify a BKT analysis. Rather, the observed $I$/$V$ characteristics can be well reproduced theoretically by modelling the effect of mesoscopic inhomogeneity of the superconducting state. Our results offer an alternative perspective on the spontaneous fragmentation of the superconducting background in confined two-dimensional systems.

Two-dimensional superconductivity and violation of Pauli paramagnetic limit in MBE-grown Al nanofilms*  

CHI-TE LIANG (Presenter), CHING-CHEN YEH, GUAN-MING SU, ANKIT KUMAR, BIYI WU, Physics, National Taiwan University, YEN-TING FAN, SHENG-DI LIN, Electronics Engineering, National Chiao-Tung University, LEE CHOW, Physics, University of Central Florida — We have performed low-temperature transport measurements on Al nanofilms on GaAs substrates prepared by molecular beam epitaxy (MBE) with as-grown thicknesses of 3 nm, 3.5 nm, and 4 nm. Such MBE-grown nanofilms all show the Berezinskii-Kosterlitz-Thouless transition, which is compelling evidence for two-dimensional superconductivity, with enhanced transition temperatures (≈2.3 K) compared to that of bulk Al (1.2 K). When the magnetic field is applied parallel to the plane of the Al nanofilms, we measure the upper critical magnetic field $H_{c\parallel}$ by the mid-points of resistive transitions at different temperatures $T$. In this way, we can estimate $H_{c\parallel}(T=0)$. It is found that $H_{c\parallel}(T=0)$ increases with decreasing film thickness. Interestingly, for the thinnest device, $H_{c\parallel}(T=0)$ exceeds the Pauli paramagnetic limit. Such experimental results can be ascribed to spin-orbit coupling effects on superconductivity, even though Al has a low atomic mass.

Superconducting Nanostructures Grown by He$^+$-Focused Ion Beam Induced Deposition (FIBID)  

ROSA CÓRDOBA, ICMOL, Universitat de València, PABLO ORÚS, ICMA, CSIC-University of Zaragoza (Spain), DOMINIQUE MAILLY, C2N, CNRS, GREGOR Hlawacek, HZDR, JOSE MARIA DE TERESA NOGUERAS (Presenter), ICMA, CSIC-University of Zaragoza (Spain) — W-C superconducting nanostructures have been grown by He$^+$-Focused Ion Beam Induced Deposition (He$^+$-FIBID), which allows superb lateral resolution as well as the capability for creating three-dimensional nanostructures. First, results on in-plane W-C superconducting nanowires grown by He$^+$-FIBID will be presented, where the long-range vortex transport has been investigated by means of non-local measurements; and we will compare them with previous research on in-plane nanostructures grown by Ga$^+$-FIBID [1]. Secondly, results on the growth and superconducting properties of out-of-plane nanotubes with well-controlled inner and outer diameter grown by He$^+$-FIBID will be shown [2]. Lastly, results on the growth and superconducting properties of nanohelices grown by He$^+$-FIBID with tailored dimensions will be presented. Here, remarkable vortex and phase-slip phenomena have been found and explained by the corresponding numerical simulations [3]. In summary, a better understanding of nanosuperconductivity is expected to occur in W-C nanostructures grown by the He$^+$-FIBID technique.

1:03PM B48.00010: Magnetotransport properties of layered quasi-one-dimensional superconductor Ta2PdS5† ENZE ZHANG (Presenter), Fudan Univ, JINHUA ZHI, Peking University, YICHAO ZOU, The University of Queensland, ZEFANG YE, LINFENG AI, JIACHENG SHI, CE HUANG, SHANSHAN LIU, Fudan Univ, NING KANG, HONGQI XU, Peking University, WEI WANG, LIANG HE, Nanjing University, JIN ZOU, The University of Queensland, JINYU LIU, Tulane University, ZHIQIANG MAO, The Pennsylvania State University, FAXIAN XIU, Fudan Univ — Ternary Ta2PdS5 is a newly discovered low-dimensional superconductor with typical quasi one-dimensional chain structure, which has attracted a great deal of research attention owing to its intriguing physical properties. Here we report the systematic study of magnetotransport properties of Ta2PdS5 nanowires exfoliated from its bulk material. The superconducting critical field of system shows strong anisotropic behavior and violation of the Pauli limit when the magnetic field is along the b-axis. I-V measurements show a series of multiple voltage steps in transition to normal state and systematic hysteresis between the up and down sweeps, indicating a typical quasi-one dimensional nature in its superconductivity. Surprisingly, the nanowire undergoes a superconductor-metal transition with increasing perpendicular magnetic field. Upon approaching the zero-temperature quantum critical point, the system uncovers the signature of the quantum Griffiths singularity state arising from enhanced quenched disorders, where the dynamical critical exponent becomes diverging rather than being constant.

1:15PM B48.00011: Superconductivity at the LaAlO3/SrTiO3 1D Zigzag Nanowires† YUN-YI PAI (Presenter), MEGAN BRIGGEMAN, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, Department of Materials Science and Engineering, University of Wisconsin at Madison, XIAOXING CHENG, Department of Materials Science and Engineering, Pennsylvania State University, MUQING YU, MENGCHEN HUANG, JIANAN LI, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin at Madison, LONG Q. CHEN, Department of Materials Science and Engineering, Pennsylvania State University, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — LaAlO3/SrTiO3 exhibits electron pairing far outside of the superconducting state [1]. The superconducting state of LaAlO3/SrTiO3 also exhibits an intrinsic 1D nature [2] which has been linked to ferroelastic domain structure in the SrTiO3. We further explore the role of ferroelastic domain patterns on superconductivity by creating a series of “zig-zag” nanowire structures. We find that straight nanowires are comparatively more resistive, both in their normal and superconducting state, than channels that have a zig-zag structure. We discuss possible interplay between the charge degree of freedom and the structural domains and employ state-of-the-art phase-field modeling to simulate the relevant domain morphologies.

1:27PM B48.00012: Frictional drag between two LaAlO$_3$/SrTiO$_3$ superconducting nanowires*  
YUHE TANG (Presenter), Department of Physics and Astronomy, University of Pittsburgh, JUNG-WOO LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, ANTHONY TYLAN-TYLER, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOOK LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, MICHELLE TOMCZYK, MENGCHEN HUANG, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — We report frictional drag measurements between two superconducting LaAlO$_3$/SrTiO$_3$ nanowires. In these experiments, current passing through one nanowire induces a voltage across a nearby electrically isolated nanowire. The frictional drag signal contains both symmetric and antisymmetric components. The antisymmetric component arises from the rectification of quantum shot noise in the drive wire due to asymmetries in the drag wire. The symmetric component is ascribed to rectification of thermal noise in the drive wire during superconducting-normal transition. The absence of symmetric drag resistance between a normal drag wire and a superconducting drive wire suggests a higher electron-hole asymmetry in the superconducting LaAlO$_3$/SrTiO$_3$ nanowire arising from the 1D nature of superconductivity at LaAlO$_3$/SrTiO$_3$ interface.

1:39PM B48.00013: Interface superconductivity in La$_{2-x}$Sr$_x$CuO$_4$ heterostructures*  
WENJIE GONG (Presenter), LARISSA LITTLE, JASON HOFFMAN, JENNIFER E. HOFFMAN, Harvard University — The lossless flow of current and the high, stable magnetic fields permitted by superconductor technology have led to advances in fields ranging from transportation to medical imaging. However, the low $T_c$ of conventional superconductors—often below 30 K—has limited their commercial applicability. Previous work has demonstrated high-$T_c$ superconductivity at interfaces between thin films of non-superconducting materials, such as between insulating and metallic La$_{2-x}$Sr$_x$CuO$_4$ [1]. Here, we aim to grow high-quality heterostructures of underdoped and overdoped La$_{2-x}$Sr$_x$CuO$_4$ on SrTiO$_3$ and LaSrAlO$_4$ with atomic layer-by-layer molecular beam epitaxy (MBE). We assess the samples grown with atomic force microscopy (AFM) and high-resolution x-ray diffraction (HRXRD). We then perform transport measurements on the La$_{2-x}$Sr$_x$CuO$_4$ heterostructures to examine the possible mechanisms behind $T_c$ enhancement at atomic interfaces.

B48.00014: Microscopic theory of in-plane critical field in two-dimensional Ising superconducting systems*  HONGCHAO LIU (Presenter), School of Physics, Peking University, HAIWEN LIU, Department of Physics, Beijing Normal University, DING ZHANG, Department of Physics, Tsinghua University, XINCHENG XIE, School of Physics, Peking University — We study the in-plane critical magnetic field of two-dimensional Ising superconducting systems, and propose the microscopic theory for these systems with or without inversion symmetry. Protected by certain specific spin-orbit interaction which polarizes the electron spin to the out-of-plane direction, the in-plane critical fields largely surpass the Pauli limit and show remarkable upturn in the zero temperature limit. The impurity scattering and Rashba spin-orbit coupling, treated on equal-footing in the microscopic framework, both weaken the critical field but in qualitatively different manners. The microscopic theory is consistent with recent experimental results in stanene and Pb superconducting ultra-thin films.

Session B49 DCMP: Superconductors: Complex Compounds, Borides, Organics, and Others  Mile High Ballroom 1B - Rongying Jin, Louisiana State University

11:15AM B49.00001: Plasmon-Polaron Superconductivity in Strontium Titanate*  ALEXANDER EDELMAN (Presenter), PETER B LITTLEWOOD, University of Chicago and Argonne National Laboratory — Strontium titanate (STO) is a bulk insulator that becomes a semiconducting superconductor at remarkably low carrier densities - below $10^{17}$ cm$^{-3}$ - with a characteristic superconducting dome as a function of doping which peaks at $T_c \sim 300$ mK, all in very close proximity to a ferroelectric quantum critical point. We investigate a scenario of superconductivity mediated by coupling to a strongly anti-adiabatic longitudinal optic phonon by extending a simple Engelsberg-Schrieffer theory of electron-phonon coupling to include the effects of electronic Coulomb interactions. For the carrier densities of interest, we find that the plasmon hybridizes strongly with LO mode with one of the resulting coupled modes inheriting the low energy scales of the softening ferroelectric mode. Working within the cumulant expansion, we calculate the spectral signatures of this unusual regime of coupling compare to experiment photoemssion[1] and tunneling[2] experiments, as well as the superconducting phase diagram including self-energy effects beyond one loop.

*Work at Argonne is supported by DOE Office of Science Basic Energy Sciences, Materials Science and Engineering under contract DE-AC02-06CH11357.
Recently the copper(II) benzenehexathiolate coordination polymer $[\text{Cu}_3(\text{C}_6\text{S}_6)_n]$ (Cu-BHT) attracts significant interests as the first superconductor in metal-organic frameworks (MOFs) with a superconducting transition temperature $T_c \sim 250$ mK. Since Cu-BHT has a perfect 2D Kagome structure formed by $S = 1/2$ spins of Cu$^{2+}$, unconventional superconductivity related to quantum fluctuations is expected. Although we have already reported that our magnetic penetration depth measurements suggest unconventional superconductivity in Cu-BHT, fundamental superconducting and normal state properties, such as dimensionality, magnetism, and the Fermi energy, which are important to elucidate the superconducting mechanism, are still unrevealed. In this study, therefore, we measured the angle-resolved upper critical field, magnetoresistance, electron spin resonance (ESR), and optical conductivity. By comparing the ratio of $T_c$ to the Fermi temperature with other unconventional superconductors, we revealed that Cu-BHT is possibly a member of strongly correlated electron systems.
11:39AM B49.00003: Exploring superconductivity using muon spin resonance in chiral noncentrosymmetric superconductors.* DANIEL MAYOH (Presenter), MATTHEW PEARCE, KATHRIN GOETZE, Physics Department, University of Warwick, Coventry, CV4 7AL, United Kingdom, ADRIAN HILLIER, ISIS facility, STFC Rutherford Appleton Laboratory, Harwell Science and Innovation Campus, Oxfordshire OX11 0QX, United Kingdom, GEETHA BALAKRISHNAN, MARTIN LEES, Physics Department, University of Warwick, Coventry, CV4 7AL, United Kingdom — Unconventional superconductivity remains one of the most interesting problems in condensed matter physics. For all superconductors, the topology of the electronic band structure, along with the underlying crystal structure, play vital roles in determining the superconducting properties of the material. Systems lacking a centre of inversion exhibit a nonuniform lattice potential, giving rise to a Rashba-type antisymmetric spin-orbit coupling which allows for an admixture of singlet and triplet pairs. This may give rise to exotic superconducting band structures and magnetoelectric effects such as upper critical fields that exceed the Pauli limit. The discovery of two noncentrosymmetric superconductors with chiral structures, TaRh$_2$B$_2$ and NbRh$_2$B$_2$ [1], has added a new twist to an already exciting area of superconductivity. Here we present our investigation into the superconducting order parameter using muon spin resonance techniques in TaRh$_2$B$_2$ and NbRh$_2$B$_2$ [2, 3].

11:51AM B49.00004: Magnetism and superconductivity in alkali metal doped 2,2'-bipyridine from near room temperature synthesis† DI PENG (Presenter), RENSHU WANG, XIAO-JIA CHEN, CEP, HPSTAR (Beijing) — Organic superconductors have long been the major players in the development of modern physical chemistry. So far, many cases of introducing charge into π-electron networks in organic superconductors with Meissner effect have been found. However, most of them lack pivotal zero resistance measurements because of the high synthesized temperature leading to the decomposition of organic materials and forming non-homogeneous phases. To avoid this tendency, a design principle for low temperature synthetic reaction process is indispensable.

We report a development method for doping alkali metals into organic materials and forming a homogeneous phase together with the experimental discoveries of superconductivity in sodium potassium alloy doped 2,2'-bipyridine. We successfully detected superconductivity from the observed Meissner effect and zero resistance effect. The work demonstrates that low temperature synthetic reaction process is of great significance for producing organic superconductors.

*National Key R&D Program of China (Grant No. 2018YFA0305900).
12:03PM B49.00005: Superconductivity in an organobismuth molecule*  RENSHU WANG (Presenter), LIUCHENG CHEN, XIAO-JIA CHEN, HPSTAR (Beijing), HUI YANG, MINGAN FU, JIA CHENG, XIAOLIN WU, YUN GAO, ZHONGBING HUANG, Hubei University — Recently, novel quantum phenomena such as topological insulators and superconductors were suggested in organobismuth compounds. However, evidence for superconductivity from the zero-resistivity state in any organometallic compound has not been achieved yet, though much effort has been made. Here, we report the experimental realization of superconductivity in a critical temperature of 3.6 K in potassium-doped tri-o-tolylbismuthine, with evidence of both the Meissner effect and the zero-resistivity state through dc and ac magnetic susceptibility and resistivity measurements. The superconducting phase and its composition are determined by combined studies of X-ray diffraction and theoretical calculations as well as Raman spectroscopy measurements. These findings enrich the applications of organometallic compounds in superconductivity and add a new electron-acceptor family of organic superconductors.

*National Key R&D Program of China, Grant No. 2018YFA0305900. National Natural Science Foundation of China, Grants No. 11574076, 11674087, and 91221103.

12:15PM B49.00006: Li$_{2x}$BC$_3$: a two dimensional MgB$_2$-like superconductor*  YUNDI QUAN (Presenter), WARREN PICKETT, University of California, Davis — Though most superconductors can be grouped into distinct structure classes, MgB$_2$ remains in a class of its own almost two decades after its discovery. Previous efforts to design superconductors in the same structure class as MgB$_2$ have been unsuccessful due to various complications. Recently, experimentalists are able to stabilize Li$_{2x}$BC$_3$ [1], a layered compound with Li sandwiched between alternating C-C and B-C honeycomb sheets similar to MgB$_2$. By carrying out linear response calculations, we find that at half occupation (i.e. x= 0.5), Li$_{2x}$BC$_3$ is a phonon mediated superconductor with a $T_c$ of around 45 K. Further increasing Li occupation (x) weakens electron-phonon coupling, thus lowering $T_c$. At occupation levels below 0.5, crystal structure of Li$_{2x}$BC$_3$ becomes dynamically unstable due to increased electron-phonon coupling. Electronic structure, Fermi surfaces and electron-phonon couplings etc of Li$_{2x}$BC$_3$ will be presented to help understand the origin of strong electron-phonon coupling.

12:27PM B49.00007: Inhomogeneity of superconductivity in a disordered charge density wave material Pd-intercalated ErTe$_3$ measured using scanning SQUID microscopy  YUSUKE IGUCHI (Presenter), JOSHUA A STRAQUADINE, JOHN ROBERT KIRTLEY, ANISHA SINGH, IAN FISHER, KATHRYN ANN MOLER, Department of Applied Physics, Stanford University — The rare-earth tri-tellurides RTe$_3$ (R=La-Pr, Sm, Gd-Tm) are quasi-2D metals that show unidirectional incommensurate charge density wave (CDW) states. Pd intercalation introduces significant disorder to the crystal lattice, suppressing the CDW formation and leading to a superconducting ground state. The material presents an opportunity to explore in detail the interplay between superconductivity (SC) and CDW formation in the presence of disorder. Here we study the spatial variance of the superfluid response as a function of Pd concentration in Pd$_x$ErTe$_3$ (0<x<0.06) by using a scanning SQUID microscope with sub-micron spatial resolution. We quantify the inhomogeneity of the emergent superconductivity as the CDW is progressively disordered by the Pd intercalation. Our results clarify how the superconducting state emerges from the disordered CDW.

12:39PM B49.00008: In-plane anisotropy of the c-axis magnetoresistance for BiCh$_2$-based superconductor  KAZUHISA HOSHI (Presenter), YOSHIKAZU MIZUGUCHI, YOSUKE GOTO, TATSUMA D. MATSUDA, Tokyo Metropolitan University, MOTOI KIMATA, Institute for Materials Research, Tohoku University — BiCh$_2$-based (Ch = S, Se) superconductor was discovered in 2012, the crystal structure is similar to that of high temperature superconductor, such as cuprate superconductor and iron-based superconductor. The pairing mechanisms of the superconductivity has not been completely understood. However, theoretical calculation, ARPES, and isotope effect suggest that unconventional superconductivity is essential for BiCh$_2$-based superconductor.

We have investigated the in-plane anisotropy measurement of the c-axis magnetoresistance for BiCh$_2$-based superconductor LaO$_{0.5}$F$_{0.5}$BiSSe single crystals. We observed the two-fold symmetry of the magnetoresistance in the $ab$-plane for LaO$_{0.5}$F$_{0.5}$BiSSe in superconducting states while the conducting plane possessed a tetragonal square plane with the four-fold symmetry. This results show that the BiCh$_2$-based superconductor may be nematic superconductor. Furthermore, more recently, we have investigated anisotropy measurement of the c-axis magnetoresistance for other BiCh$_2$-based superconductor NdO$_{0.7}$F$_{0.3}$BiS$_2$ single crystals. Two-fold symmetry was observed for NdO$_{0.7}$F$_{0.3}$BiS$_2$ above $T_c$, which is different behavior for LaO$_{0.5}$F$_{0.5}$BiSSe. We are going to report this latest result for the NdO$_{0.7}$F$_{0.3}$BiS$_2$ single crystals.
12:51PM B49.00009: Superconductivity at 262 K in Yttrium Superhydride at High Pressures*

ELLIOT M SNIDER, Department of Mechanical Engineering, University of Rochester, NATHAN M DASEN BROCK-GAMMON, Department of Physics, University of Rochester, RAYMOND MCBRIDE, Department of Mechanical Engineering, University of Rochester, RANGA DIAS (Presenter), Department of Physics and School of Engineering and Applied Sciences, University of Rochester — Superconductivity has been one of the most profound quantum phases in condensed matter physics. Efforts to identify and develop room temperature superconducting materials are an intensive area of research, motivated by both fundamental science and the prospects for applications. We report the synthesis and superconductivity in Yttrium superhydride with highest Tc of 262K at 183 GPa. The Tc is the highest ever recorded at this pressure. The superconductivity in Yttrium superhydride arises from clathrate based hydrogenic lattices. The electrical resistance measurements and magnetic field dependence transport measurement shows the clear indication of the observed superconductivity. Based on the Raman spectra, we suggest that YH6, is responsible observed superconductivity, which is in good agreement with recent theoretical studies. The hydrogen-rich materials are in the vicinity of achieving room temperature superconductivity.

*The NSF grant DMR-1809649 supported this research.

1:03PM B49.00010: Anisotropic energy gap in single crystals of isotropic superconductor SrPt$_3$P*

KYUIL CHO (Presenter), SERAFIM TEK NOWIJOYO, ELIZABETH KREN KEL, MAKARIY A TANATAR, RUSLAN PROZOROV, Ames Laboratory and Iowa state University, Ames, USA, NIKOLAI D ZHIGADLO, CrystMat Company, Zurich, Switzerland — Antiperovskie pnictide SrPt$_3$P shows the highest superconducting transition temperature, T$_c$, among the 5d element - based compounds, possibly with somewhat strong coupling, 2\(\Delta_0 / T_c\) ~5. While the material itself is quite isotropic, its energy gap structure and pairing state remain uncertain due to the lack of single crystals. Here we report directional measurements of electrical resistivity and London penetration depth in single crystals SrPt$_3$P. Surprisingly, our results show highly anisotropic nature of the superconducting energy gap.

*This work was supported by the US DOE, Office of Science, BES Materials Science and Engineering Division under contract # DE-AC02-07CH11358.
Non-centrosymmetric superconductors (NCSs) lack inversion center in their crystal structure, and consequently one of the typical symmetries for the formation of Cooper pairs. The absence of inversion symmetry strongly influences the Cooper pairing states possible in these materials. Here we report a muon spin rotation/relaxation (μSR) study of LaNiC$_2$ single crystals, a non-magnetic, NCS with weak electronic correlations and a superconducting transition temperature, $T_c \sim 2.7$ K. Previous zero-field μSR measurements on a pressed pellet of LaNiC$_2$ powder revealed the onset of spontaneous magnetic fields at $T_c$. This finding signifies time-reversal symmetry breaking (TRSB) in superconducting phase, which is compatible with a non-unitary triplet-pairing state. However, other kinds of experiments have provided evidence for conventional BCS $s$-wave pairing, point nodes in the gap function and even two-gap superconductivity. Our new μSR investigation of LaNiC$_2$ provides a fresh perspective on the nature of the superconducting pairing state, by yielding the temperature and magnetic field dependencies of the magnetic penetration depth and vortex core size in the mixed state and through a new test of TRSB.

*Acknowledged support from NSERC and JSPS KAKENHI with grant nos. JP15K05156 and JP15KK0149
1:27PM B49.00012: Superconductivity in Cu-doped TiSe$_2$: A first-principles calculation

OBINNA UZOH (Presenter), TAE-HO PARK, HAN-YONG Choi, Sungkyunkwan Univ — We present the superconducting properties of Cu-doped TiSe$_2$ materials based on first-principles calculations. Experimental study of Cu intercalated 1T-TiSe$_2$ under various copper doping concentrations ($x = 0.04$ – $0.10$) has been investigated extensively. Such study has shown that as doping concentrations increase charge density wave is steadily suppressed until about $x = 0.04$ where a dome-shaped superconductivity emerges with maximum $T_c$ of $4.15$ K at $x = 0.08$ [1]. In order to understand this observation theoretically, we perform first-principles calculations based on density functional theory and density functional perturbation theory incorporated with maximally localized Wannier functions. We calculate the electronic structures at various doping concentrations by modeling doping using virtual crystal approximation. Also, we estimate the superconducting $T_c$ by calculating the electron-phonon coupling and the Eliashberg spectral function. Further, we analyze all possible phonon modes in Cu$_x$TiSe$_2$ and ascertain dominant modes contributing to the superconductivity.

1:39PM B49.00013: Strain-stabilized superconductivity in RuO$_2$ JACOB RUF (Presenter), HANJONG PAIK, NATHANIEL SCHREIBER, HARI NAIR, LUDI MIAO, JASON KAWASAKI, JOCIENNE NELSON, BRENDAN FAETH, YONGHUN LEE, BERIT GOODGE, BETUL PAMUK, CRAIG FENNIE, LENA FITTING KOURKOUTIS, DARRELL SCHLOM, KYLE M SHEN, Cornell University — The rational control of superconductivity and the possibility of deterministically enhancing the superconducting transition temperature ($T_c$) by design, rather than by serendipity, has been an elusive and long sought-after goal in solid-state physics. Here, we report the first instance of transmuting a normal metal into a superconductor through the application of epitaxial strain. We demonstrate that synthesizing RuO$_2$ thin films on TiO$_2$(110) substrates stabilizes superconductivity under strain, having $T_c$s up to $2$ K; by contrast, RuO$_2$ thin films grown on TiO$_2$(101) substrates are non-superconducting down to the lowest measured temperatures ($T_c < 0.4$ K), consistent with the behavior of bulk RuO$_2$. Using a comprehensive combination of characterization techniques—including electrical transport, x-ray diffraction, scanning transmission electron microscopy, angle-resolved photoemission spectroscopy, and density functional theory—we reveal the primary electronic mechanism underlying this strain-stabilized superconductivity: the anisotropic strains redistribute the carriers amongst the manifold of 4$d$ states near the Fermi level ($E_F$), partially depopulating flat bands with $d_{||}$ orbital character, and thereby increase the density of states at $E_F$. 
1:51PM B49.00014: Physical Properties of New Alkaline Earth Tantalum Sulfides*
SHERMANE BENJAMIN (Presenter), MICHAEL SMITH, JOHN J NEUMEIER, Montana State University, Bozeman — Transition-metal sulfides serve as an interesting class of compounds for comparison to transition-metal oxides. They also often demonstrate properties such as metal-insulator transitions, superconductivity, and magnetism. In this work, single crystals of $\text{CaTa}_5\text{S}_{10}$, $\text{Sr}_3\text{Ta}_5\text{S}_{10}$ and $\text{BaTa}_{10}\text{S}_{10}$ samples were synthesized via chemical vapor deposition. $\text{CaTa}_5\text{S}_{10}$, $\text{Sr}_3\text{Ta}_5\text{S}_{10}$ and $\text{BaTa}_{10}\text{S}_{10}$ superconduct at $T_{\text{C, onset}} = 3.25$ K, 3.8 K and 2.8 K, respectively. The magnetic properties, specific heat, electrical resistivity, structural analysis, and compositional analysis will be discussed.

B49.00015: Coexistence of superconductivity and weak ferromagnetism in Rb-doped triphenylbismuthine and tri-$p$-tolylbismuthine* ZHONGBING HUANG (Presenter), Physics, Hubei University, REN-SHU WANG, JIA CHENG, Materials Science, Hubei University, MING-AN FU, HUI YANG, Physics, Hubei University, YUN GAO, Materials Science, Hubei University, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai — By using a two-step method - ultrasound treatment and low temperature annealing, we successfully synthesize Rb-doped triphenylbismuthine and tri-$p$-tolylbismuthine. The dc magnetic measurements show a coexistence of superconductivity at 4.0 K and weak ferromagnetism at 35 K in all synthesized samples, which is strongly supported by the resistivity measurements. The calculated electronic structure indicates that superconductivity is realized by transferring electron from rubidium to carbon atom, and the weak ferromagnetism is produced by nonparallel arrangement of magnetic moments on the phenyl rings. Our study provides a new platform for understanding the interplay between superconductivity and ferromagnetism.

*We acknowledge financial support from the National Natural Science Foundation of China under Grants Nos. 11674087 and 11574076.

Monday, March 2, 2020 11:15 AM - 2:03 PM

11:15AM B50.00001: Phase stabilization by electronic entropy in plutonium*  NEIL HARRISON (Presenter), JONATHAN B BETTS, MARK WARTENBE, FEDOR BALAKIREV, SCOTT RICHMOND, MARCELO JAIME, PAUL H TOBASH, Los Alamos Natl Lab — Plutonium metal undergoes an anomalously large 25% collapse in volume from its largest volume δ phase (δ-Pu) to its low temperature α phase, yet the underlying thermodynamic mechanism has largely remained a mystery. Here we use magnetostriction measurements to isolate a previously hidden yet substantial electronic contribution to the entropy of δ-Pu, which we show to be crucial for the stabilization of this phase. The entropy originates from two competing instabilities of the 5f-electron shell, which we show to drive the volume of Pu in opposing directions, depending on the temperature and volume. Using calorimetry measurements, we establish a robust thermodynamic connection between the two excitation energies, the atomic volume, and the previously reported excess entropy of δ-Pu at elevated temperatures.

*The work was performed under the Los Alamos National Laboratory LDRD program: project `20180025DR." Measurements were performed at the National High Magnetic Field Laboratory, which is supported by the National Science Foundation, Florida State and the Department of Energy. N. H. thanks John Wills, Jianxin Zhu, Angus Lawson, Jason Lashley, Albert Migliori, Boris Maiorov and John Joyce for insightful discussions.

11:27AM B50.00002: Physical Properties of 1-Dimensional 4f/5f-electron Heavy Fermion Materials*  ERIC BAUER (Presenter), T. ASABA, SEAN THOMAS, JOE D THOMPSON, PRISCILA ROSA, FILIP RONNING, Los Alamos Natl Lab — Quantum criticality has been an organizing principle to explain the behavior of many families of quantum materials including the high-temperature cuprate and iron-based superconductors and f-electron heavy fermion compounds. A central, unresolved issue is the effect on the dimensional character of the quantum fluctuations has on the properties of the system. Most work to date has focused on quantum criticality with two-dimensional (2-D) and three-dimensional (3-D) fluctuations. Strong quantum fluctuations are expected in quasi-1-D materials. Furthermore, these 1-D systems may be treated exactly by theoretical tools such as Density Matrix Renormalization Group, providing robust and accurate methods for accounting for the strong correlations in 1-D f-electron materials. In this talk, I will describe the thermodynamic and transport properties of several 4f and 5f quasi-1D heavy fermion materials.

Probing the local 4f-orbital symmetry in heavy fermion systems by linearly polarized angle-resolved core-level hard x-ray photoemission spectroscopy

AKIRA SEKIYAMA (Presenter), Hidenori Fujiwara, Satoru Hamamoto, Yuina Kanai-Nakata, Graduate School of Engineering Science, Osaka University, Shin Imada, Ritsumeikan University, Arata Tanaka, Hiroshima University, Kenji Tamasaku, Tetsuya Ishikawa, RIKEN SPring-8 Center — Ground-state (GS) orbital symmetry determined by the local effective crystalline electric fields (CEF) in strongly correlated electron systems play crucial roles in their functional properties such as superconductivity and multipolar ordering. We have found that the CEF-split GS 4f-orbital symmetry can be probed by linear dichroism (LD) in angle-resolved core d-level hard x-ray photoemission owing to the selection rules in the optical process [1]. We have applied this technique to Ce, Pr, and Yb-based heavy fermion systems, where the $\Gamma_7$ states with $J_z = \pm \frac{3}{2}$ and the $\Gamma_8$ states in the CEF-split GS 4f symmetry have been established for tetragonal YbRh$_2$Si$_2$ [2] and cubic YbB$_{12}$ [3]. Mutually different LDs reflecting the different orbital symmetry have been seen for cubic PrBe$_{13}$, PrB$_6$, and PrIr$_2$Zn$_{20}$ [4,5]. This technique has also revealed the CEF-split GS 4f wave functions for a pressure-induced superconductor CeCu$_2$Ge$_2$ [6].

Pressure effect on the chiral helimagnetic order in YbNi$_3$Al$_9$

YOSHIHIKO OTA (Presenter), Kazunori Umeo, Takumi Otaki, Yudai Arai, Taka Hiro Onimaru, Hiroshima Univ, Shota Nakamura, Shigeo Ohara, Nagoya Institute of Technology — YbNi$_3$Al$_9$ crystalizes in the trigonal ErNi$_3$Al$_9$-type structure with a space group of R32. This compound undergoes the chiral helimagnetic (CHM) order at $T_M = 3.4$ K. According to the chiral sine-Gordon model, the CHM order is realized by the competition between the Dzyaloshinskii-Moriya interactions and the ferromagnetic (FM) interactions, both of which work along the helical axis. By applying magnetic field perpendicular to the helical c-axis, the magnetic phase transition to the forced FM state manifests itself at $B_c = 0.1$ T in association with the divergence of the helical pitch.

In this work, we have studied pressure effect on the CHM order in YbNi$_3$Al$_9$ by measuring magnetization, electrical resistivity, and magnetoresistance under hydrostatic pressures. Both of $T_M$ for 0 T and $B_c$ for 0.3 K monotonically decrease by applying pressures up to 2.5 GPa in the ratios of $-0.22$ K / GPa and $-0.013$ T / GPa, respectively. By the application of pressures, the ordered moment increases and the Kondo scattering is suppressed, suggesting that the Ruderman-Kittel-Kasuya-Yosida interaction dominates the Kondo effect. Based on these results, we attribute the reduction in $T_M$ and $B_c$ to the destabilization of helical structures owing to the development of the FM correlations.
12:03PM B50.00005: Quadrupolar fluctuations of heavy-fermion metal YbRu$_2$Ge$_2$* MAI YE, Department of Physics and Astronomy, Rutgers University-New Brunswick, ELLIOTT W ROSENBERG, IAN FISHER, Department of Applied Physics, Stanford University, GIRSH BLUMBERG (Presenter), Department of Physics and Astronomy, Rutgers University-New Brunswick — Long-range order of electric quadrupole moments is one characteristic phenomenon in the family of multipolar Kondo systems. The heavy-fermion metal YbRu$_2$Ge$_2$ enters a ferro-quadrupolar (FQ) phase below $T_{FQ}$=10K, in which the $B_{1g}$-symmetry quadrupole moments at Yb$^{3+}$ sites order at zero wave vector [Proc. Natl. Acad. Sci. U.S.A. 116, 7232 (2019)]. This FQ phase is a realization of electronic nematic states since the electronic properties spontaneously break the four-fold rotational symmetry of the tetragonal crystal. We study the quadrupolar fluctuations of this compound by Raman scattering [Phys. Rev. B 99, 235104 (2019)]. The electronic Raman susceptibility in quadrupolar symmetry channels exhibit nearly Curie-law behavior, indicating weak exchange interactions between local quadrupoles. It is the relatively strong coupling between the quadrupole moments and the lattice strain fields in the $B_{1g}$ symmetry channel, analogous to cooperative Jahn-Teller effect, that enhances the vanishingly small Weiss temperature to the temperature of quadrupolar phase transition at $T_{FQ}$.

12:15PM B50.00006: Thermodynamic and transport properties of Kondo lattice YbCuAs$_2$ single crystals* EUNDEOK MUN (Presenter), DAVID EVANS, SYMPHONY HUANG, Physics, Simon Fraser Univ — YbCuAs$_2$ compound crystallizes into a tetragonal ZrCuSi$_2$-type structure. Magnetic susceptibility measurements for the YbCuAs$_2$ polycrystalline sample showed an antiferromagnetic phase transition below 4 K. However, the neutron powder diffraction measurements of this sample didn't show any additional Bragg peaks down to 1.5 K, indicating either there is no magnetic ordering down to 1.5 K or the ordered moment of Yb ions is smaller than the current experimental limit. We succeeded in growing single crystals of YbCuAs$_2$ by high temperature ternary melt. Thermodynamic and transport properties were investigated by measuring the magnetization, electrical resistivity, and specific heat. In this talk, I will present thermodynamic and transport properties of Kondo lattice YbCuAs$_2$ single crystals.

Dynamical Scaling of Charge Responses at a Kondo Destruction Quantum Critical Point*  STEFAN B. KIRCHNER (Presenter), Zhejiang University, HAOYU HU, ANG CAI, Rice University, ZUODONG YU, Zhejiang University, QIMIAO SI, Rice University — An overarching question on quantum criticality is whether and how it goes beyond the Landau framework of order-parameter fluctuations. In the studies of heavy fermion metals, the notion of Kondo destruction has been developed to address this issue [1]. Microscopically, it captures how the inter-local-moment singlet formation dynamically competes with the Kondo-singlet formation at the quantum critical point (QCP). An exciting recent surprise is that charge dynamics is also singular and shows omega/T scaling at the prototype antiferromagnetic QCP of YbRh2Si2 [2]. We study prototype models for Kondo destruction QCP, and find that both the charge and spin responses are singular and obey omega/T scaling [3,4]. The criticality of the charge dynamics originates from an f-electron delocalization-localization across the Kondo destruction QCP. Broader implications of our results are discussed, both for the beyond-Landau quantum criticality in general and for the exotic excitations and unconventional superconductivity of strongly correlated metals.

Itinerant Nature of Ce in CeCo5*  RENU CHOUDHARY (Presenter), DURGA PAUDYAL, Ames Lab — Due to the high uniaxial anisotropy and abundant nature of Ce, CeCo5 has attracted the attention of scientists for developing an excellent permanent magnet. Here, we discuss the itinerant nature of Ce in CeCo5 using density functional theory (DFT). Ce based intermetallic compounds show interesting magnetism because of the mixed-valence 4f state. The 3+ valence would have provided 1.0 µB/Ce 4f; however, in either case with and without employing on-site electron correlation parameter, we obtain 4f spin moment less than 1.0 µB/Ce 4f. Also, the 3d-5d hybridization in CeCo5 is strong enough to overlap 4f states below the Fermi level and form a 3d-5d-4f hybridization thereby indicating the itinerant nature of Ce 4f in CeCo5. This assessment allows us to consider CeCo5 as an itinerant magnetic material system suitable to treat by standard DFT. Further, the 4f spin moment of CeCo5 is partially canceled by the orbital counterpart and the Co moment is reduced by the stronger 3d-4f hybridization in the spin-down channel.

12:51PM B50.00009: The ground state and Fermi-surface nesting phenomenon in antiferromagnetic CeAuSb$_2$. JAEKYUNG JANG (Presenter), JOO YULL RHEE, Department of physics, Sungkyunkwan Univ — Recently, it was reported that, under an external magnetic field (≤ 3T) along the c-axis, the in-plane wave vector of the spin-density wave (SDW) is ($\eta$, $\eta$, ½) with $\eta \approx 0.136$ for CeAuSb$_2$ compound. To elucidate this SDW and the ground state we investigate the electronic structure of antiferromagnetic (AFM) CeAuSb$_2$ using the full-potential linearized-augmented-plane-wave method. The results of volume optimize calculations and total energy show that 1 x 1 x 2 unit cell construction with $\uparrow\uparrow\downarrow\downarrow\downarrow$ AFM configuration is the ground state, which are well matched with experiments. Fermi surface (FS) on the $ab$-plane exhibit FS nesting along the (110) direction. The nesting vector $q = (\zeta, \zeta, ½) (2\pi/a)$ with $\zeta \sim 1/7$, is very similar to the results of experiment. To confirm the relation between this FS nesting and SDW we will calculate the generalized susceptibility $\chi(q)$.

1:03PM B50.00010: Microscopic Nature of Magnetic Ground State in CeAuSb$_2$* GEORGE YUMNAM, YIYAO CHEN, Univ of Missouri - Columbia, YANG ZHAO, Department of Materials Sciences and Engineering, University of Maryland, College Park, MD, A. THAMIZHAEL, SUDESH K. DHAR, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, Mumbai, DEEPAK K SINGH (Presenter), Univ of Missouri - Columbia — The synergistic investigation of ground-state magnetic correlation in the single-crystal heavy-fermion compound CeAuSb$_2$ using detailed neutron scattering measurements and density functional calculations is presented. Unlike previous reports of single antiferromagnetic transition at $T_N = 6K$, three successive transitions with distinct critical exponents at $T_N = 5.3, 4.46, 3.76$ K, respectively, are detected in CeAuSb. The low-temperature ground-state magnetic correlation is described by the spin density wave order in the basal plane with the propagation wave vector (0.135, 0.135, 0.5). The spin density wave order arises due to the nesting of hole pockets in the Fermi surface, with parallel surfaces being separated by the experimentally found propagation vector. The comprehensive investigation of magnetic ground-state properties is expected to provide new insights in understanding the emerging quantum magnetism in this system, including the debated quantum critical state and magnetic field-induced metamagnetic transitions at low temperatures.

Electronic and Magnetic Properties of EuNi$_{2-x}$Sb$_2$ Structural Variants

WILLIAM NELSON (Presenter), Physics, NHMFL, Florida State University, ASHINI JAYASINGHE, Chemistry, Florida State University, DAVID E GRAF, NHMFL, Florida State University, SUSAN LATTURNER, Chemistry, Florida State University, RYAN BAUMBACH, Physics, NHMFL, Florida State University — XRD, magnetic susceptibility, magnetization, heat capacity, and resistivity results are reported for single crystals of two structural variants of EuNi$_{2-x}$Sb$_2$. While the CaBe$_2$Ge$_2$-type structure forms with a stoichiometric ratio, the ThCr$_2$Si$_2$-type structure exhibits a Ni site vacancy of 18%. Both systems show Curie-Weiss temperature dependence at elevated temperatures, indicating an antiferromagnetic exchange interaction between the Eu$^{2+}$ ions. At low temperatures, the different structural environments give rise to distinct ordering behavior. The CaBe$_2$Ge$_2$-variant first orders antiferromagnetically near $T_{N2}$=6.9K and then undergoes a first order transition at $T_3$=4.6K. The ThCr$_2$Si$_2$-variant orders antiferromagnetically at $T_{N1}$=5.6K. The 4f entropy recovered by the antiferromagnetic ordering is consistent with the predicted J=7/2 Hund's rule multiplet values for the ThCr$_2$Si$_2$-variant, while it is reduced for the CaBe$_2$Ge$_2$-variant. Thus, EuNi$_{2-x}$Sb$_2$ emerges as a useful system in which to study the impact of structural variation on electronic correlations.

Magnetically-enhanced lattice instability in EuRh$_2$Si$_2$ under pressure

ANJANA KRISHNADAS (Presenter), Okinawa Institute of Science and Technology, STEPHEN ARMSTRONG, California Institute of Technology, WENLI BI, University of Alabama at Birmingham, JIYONG ZHAO, ESEN ALP, Argonne National Laboratory, RIKI KOBAYASHI, MASATO HEDO, TAKAO NAKAMA, YOSHICHIKA ONUKI, University of The Ryukyus, THOMAS F ROSENBAUM, California Institute of Technology, YEJUN FENG, Okinawa Institute of Science and Technology — The family of ThCr$_2$Si$_2$ structured rare-earth Eu intermetallics exhibits the coexistence of three different instabilities: the competing Kondo and RKKY exchange interactions in heavy-fermion magnetic materials, as well as an isostructural collapse of the lattice particular to this type of tetragonal structure. Moreover, there is a valence instability in Eu that connects the lattice and magnetic instabilities, as the Eu$^{3+}$ magnetic moment can vanish with an atomic volume reduction to a non-magnetic Eu$^{2+}$ state. Here, in a series of ThCr$_2$Si$_2$ structured Eu antiferromagnets, we explore the subtle interaction and cooperation between these instabilities under pressure, using synchrotron-based Mossbauer spectroscopy and optical Raman scattering to track the evolution of the magnetism and the lattice, respectively. Exemplified by two end members of this series, we observe that magnetism disappears in EuRh$_2$Si$_2$ by 1 GPa, while it persists in EuGa$_4$ to beyond 36 GPa at $T = 4$ K. With the assistance of the magnetic instability, the structural instability in EuRh$_2$Si$_2$ demonstrates a pressure dependence of its phase line $dT_s/dP$ nearly 100 times higher than that in EuGa$_4$. This dramatic contrast in behavior with applied pressure illuminates a cooperative, magnetically-enhanced structural instability.
Magnetic fluctuations in the itinerant ferromagnet LaCrGe3 studied by 139La NMR

Khusboo Rana (Presenter), Division of Materials Sciences & Engineering, Ames Lab and Iowa State University, Hisashi Kotegawa, Graduate School of Science, Kobe University, Rahim R. Ullah, Jeffrey S. Harvey, Department of Physics, University of California Davis, Sergey L. Bud'ko, Paul C. Canfield, Division of Materials Sciences & Engineering, Ames Lab and Iowa State University, Hideki Tou, Graduate School of Science, Kobe University, Valentin Taufour, Department of Physics, University of California Davis, Yuji Furukawa, Division of Materials Sciences & Engineering, Ames Lab and Iowa State University — Recently much attention has been paid to itinerant ferromagnetic (FM) compounds because of the observations of unconventional superconductivity (SC) as well as the avoidance of FM quantum critical point (QCP) under application of pressure (p) and magnetic field (H). In this context, the itinerant ferromagnet LaCrGe3 (Curie temperature of TC=85 K) is very unique. It exhibits an avoided FM QCP under pressure through both a modulated antiferromagnetic phase as well as tricritical wing structure in its temperature-pressure-magnetic field (T−p−H) phase diagram. In order to characterize the static and dynamical magnetic properties of this peculiar material, we carried out 139La nuclear magnetic resonance (NMR) measurements. Here we present our analysis of the NMR data using self-consistent-renormalization theory and provide a comparison of this system in the generalized Rhodes-Wohlfarth plot with other similar itinerant ferromagnets.

Crystal field splitting and spin Hamiltonian of the quantum magnet YbCl3

Gabriele Sala, Matthew Stone, Binod Rai, Seunghwan Do, Andrew May, David Parker, Gabor Halasz, Pontus Laurell, Satoshi Okamoto, Oak Ridge National Laboratory, Nicholas Butch, National Institute of Standards and Technology, Yongqiang Cheng, G. Ehlers, Vasile O. Garlea, Qiang Zhang, Oak Ridge National Laboratory, Ganesh Pokharel, Hasitha Suriya Arachchige, David Mandrus, University of Tennessee, Mark D Lumsdon, Andy Christianson (Presenter), Oak Ridge National Laboratory — YbCl3 is a nearly ideal honeycomb lattice quantum magnet. Here we study YbCl3 with neutron scattering, magnetic susceptibility, and heat capacity measurements. We determine the crystal field Hamiltonian through simultaneous refinements of the inelastic neutron scattering and magnetization data. The ground state doublet of the crystal field Hamiltonian is well isolated and results in an effective spin-1/2 system with local easy plane anisotropy at low temperature. Cold neutron spectroscopy shows low energy spin waves peaked at 0.5 meV that can be understood through a Heisenberg model with a single nearest neighbor exchange interaction.
B50.00015: Quasi-1D Kondo chain in $\text{CeCo}_2\text{Ga}_8$  
YONGKANG LUO (Presenter), Huazhong University of Science & Technology — “Dimensions are critical”. This is because lower dimension means more phase space for long-wavelength fluctuations and a larger magnetic frustration parameter, the latter of which dictates the way that the system undergoes from a quantum ordered state to a disordered state: a conventional spin-density-wave (SDW) type quantum critical point (QCP) or an unconventional Kondo-destruction type QCP. Kondo destruction generically requires large spin fluctuations and thus favors lower dimension. In a limit where the Kondo coherence is realized in one dimension but fails in others, the Kondo lattice is reduced to a Kondo chain. Our recent study on the CeCo$_2$Ga$_8$ manifest that this compound is quasi-1D both electrically and magnetically, and most importantly, the Kondo scattering become coherent in c-axis but remains incoherent in both a- and b-axes. The anisotropy scattering mechanism and transport entropy are also investigated by thermopower and Nernst effect measurements.

Session B51 DCMP DMP: Graphene: Electronic Structure and Interactions Interactions: Moire, Correlations, and Topology  
Mile High Ballroom 1D - Onder Gul, Harvard University

11:15AM B51.00001: Ground State of Magic Angle Twisted Bilayer Graphene at Charge Neutrality II  
SHANG LIU (Presenter), Harvard University, NICK BULTINCK, University of California, Berkeley, ESLAM KHALAF, Harvard University, SHUBHAYU CHATTERJEE, University of California, Berkeley, ASHVIN VISHWANATH, Harvard University, MICHAEL ZALETEL, University of California, Berkeley — In magic angle twisted bilayer graphene (MATBG), interactions dominate over the kinetic energy, resulting in correlated insulating states and superconductivity whose origin remains a mystery. Here, using a combination of analytical arguments and numerical calculations we identify a family of candidate insulating ground states at charge neutrality and discuss how external perturbations such as the influence of the substrate or strain can alter the phase diagram.

Marginal Fermi liquid and dynamical symmetry breaking from Coulomb interaction in twisted bilayer graphene  JOSE GONZALEZ (Presenter), Instituto de Estructura de la Materia (CSIC), Spain, TOBIAS STAUBER, Instituto de Ciencia de Materiales de Madrid (CSIC), Spain — We investigate the effects of the strong Coulomb interaction near the magic angle of twisted bilayer graphene, focusing on the charge neutrality point and near half-filling of the highest valence band. In this latter instance, we predict the emergence of a marginal Fermi liquid, which can be traced back to the proximity to an extended van Hove singularity and the development of straight segments in the Fermi line. This leads to the linear scaling with energy of particle-hole excitations across the Fermi line, implying in turn the linear temperature dependence of the resistivity, logarithmic corrections to the heat capacity, and the consequent modification of the Wiedemann-Franz law. At the charge neutrality point, we show that the Coulomb interaction may be responsible for the opening of a gap through the condensation of particle-hole excitations about the Dirac nodes. We find in this case a direct competition between the dynamical breakdown of chiral symmetry (which prevails in the strong coupling regime) and the breakdown of time-reversal invariance (which has instead a stronger onset and leads to a Chern insulator phase at intermediate coupling).

Electrostatic gate-controlled fermi level dependent electronic band structure of graphene  RYAN MUZZIO (Presenter), Carnegie Mellon University, ALFRED JONES, Aarhus University, ROLAND KOCH, Advanced Light Source, DAVIDE CURCIO, DEEPNARAYAN BISWAS, JILL MIWA, PHILIP HOFMANN, Aarhus University, SIMRANJEET SINGH, Carnegie Mellon University, CHRIS JOZWIAK, ELI ROTENBERG, AARON BOSTWICK, Advanced Light Source, SØREN ULSTRUP, Aarhus University, JYOTI KATOCH, Carnegie Mellon University — The observation of electronic band structure in 2D material devices as they operate opens limitless opportunities to explore fundamental physics. The most robust technique to probe electronic structure is through angle-resolved photoemission spectroscopy (ARPES) and can now be used to investigate mesoscopic sized 2D materials and their heterostructures. Only being sensitive to filled states, ARPES measurements are restricted to states below the Fermi energy of the sample. Historically, chemical doping has been the preferred technique to manipulate the Fermi energy, but is difficult to control, introduces electronic states that are not intrinsic to the sample of interest, and can only be reversed through high-temperature annealing. Electrostatic doping, having none of these drawbacks, allows us to reversibly investigate the electron energy and momentum states of graphene far above the Dirac point. We will present our results on the electrostatic gate controlled electronic band structure of graphene using nanoARPES.
11:51AM B51.00004: Correlated states in magic angle twisted bilayer graphene under the optical conductivity scrutiny

*ELENA BASCONES (Presenter), MARÍA JOSÉ CALDERÓN, Instituto de Ciencia de Materiales de Madrid, ICMM-CSIC — Moiré systems displaying flat bands have emerged as novel platforms to study correlated electron physics. There is evidence of correlation induced effects at the charge neutrality point (CNP) of twisted bilayer graphene which could originate from spontaneous symmetry breaking. We will show how optical conductivity measurements allow to distinguish different symmetry breaking states and to follow the evolution of the band distortions with doping. In the specific case of a nematic order, which breaks the discrete rotational symmetry of the lattice, we find that the Dirac cones tend to be displaced, not only in momentum space but also in energy, inducing a finite density of states and Drude weight at the CNP. The nematic order is revealed in a dc conductivity anisotropy with its sign depending on the degree of relaxation, the doping and the nature of the symmetry breaking.

*We acknowledge funding from Spanish Ministerio de Ciencia, Innovación y Universidades under Grant No. PGC2018-097018-B-I00

12:03PM B51.00005: Correlated states and tunable topological bands in twisted monolayer-bilayer graphene heterostructures

HRYHORIY POLSHYN (Presenter), University of California, Santa Barbara, JIHING ZHU, Department of Physics, The University of Texas at Austin, MANISH KUMAR, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Materials Science, Japan, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin, ANDREA YOUNG, University of California, Santa Barbara — We experimentally investigate twisted van der Waals heterostructures of monolayer graphene rotated with respect to a bernal stacked graphene bilayer. We report transport measurements for devices with twist angles between 0.9 and 1.4°. The electric field allows efficient tuning of the width, isolation and the topology of the moiré bands in this system. By comparing magneto-resistance measurements to numerical simulations, we develop an understanding of the band structure. Finally, we observe correlated states at half- and quarter-fillings, which arise when narrow moire sublattice band is isolated by energy gaps from dispersive bands. We investigate the effects of in-plane and out-of-plane magnetic field on these states and discuss the implication for their spin- and valley- polarization.

12:15PM B51.00006: Hartree Fock study of insulating states in twisted bilayer graphene using hybrid Wannier basis

KASRA HEJAZI (Presenter), University of California, Santa Barbara, XIAO CHEN, University of Colorado Boulder, LEON BALENTS, University of California, Santa Barbara — In this work, the insulating behavior of twisted bilayer graphene and in particular the quantum anomalous Hall state has been studied; the effects of electron-electron interaction are taken into account by performing a Hartree-Fock analysis which is the standard approach for finding symmetry broken states. The model is truncated to the active relevant bands and the study is done using the basis of maximally localized Hybrid Wannier functions; this basis on the one hand respects important symmetries of the system, and on the other hand makes the interaction local at least in one direction. It also implies that the geometry of the system is that of a cylinder. Furthermore, by tuning the form/strength of the interaction, we are able to predict some other interesting phases which might potentially be found in the future.
12:27 PM B51.00007: Local electronic compressibility of magic angle twisted bilayer graphene* URI ZONDINER, ASAF ROZEN (Presenter), Weizmann Institute of Science, DANIEL RODAN, YUAN CAO, Massachusetts Inst of Tech-MIT, RAQUEL QUEIROZ, Weizmann Institute of Science, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Materials Science (NIMS), YUVAL OREG, Weizmann Institute of Science, FELIX VON OPPEN, Massachusetts Inst of Tech-MIT, ADY STERN, EREZ BERG, Weizmann Institute of Science, PABLO JARILLO-HERRERO, Massachusetts Inst of Tech-MIT, SHAHAL ILANI, Weizmann Institute of Science — Twisted bilayer graphene near the magic angle (MATBG) exhibits remarkably rich electron correlation physics, displaying insulating, magnetic, and superconducting phases. In this talk, we probe the local electronic compressibility of MATBG using a scanning single electron transistor. We find that when carriers are added into this system, they repeatedly refill the same bands, leading to a Dirac-like compressibility cascade near integer moiré fillings. Additionally, we present a clear compressibility asymmetry around the center of the conduction and valence bands, reflecting the evolution from low DOS at charge neutrality to high DOS at the band edges. A mean-field theory that includes this asymmetry reproduces the experimental results, and explains previous observations that were not yet fully understood. This cascade of Dirac revivals should thus serve as the starting point for understanding the unusual behavior in this system.

*We acknowledge support from the Helmsley Charitable Trust grant, the ISF (grant no. 712539), Sagol Weizmann-MIT Bridge program, and the ERC-Cog (See-1D-Qmatter, no. 647413)

12:39 PM B51.00008: Towards correlated electron states in trilayer-graphene Moiré band* KAN-TING TSAI (Presenter), XI ZHANG, University of Minnesota, ZIYAN ZHU, STEPHEN CARR, Harvard University, MITCHELL LUSKIN, University of Minnesota, PHILIP KIM, EFTHIMIOS KAXIRAS, Harvard University, KE WANG, University of Minnesota — The recent discovery of Moiré superconductivity in twisted-bilayer graphene (tBLG) and twisted-double bilayer-graphene (tDBG) systems [1][2][3] has generated a great amount of interest in the condensed matter community. Beyond this model system, this work focuses on studying a new Moiré platform based on the twisted trilayer-graphene. Preliminary magneto-transport measurements will be presented. Characterization of interlayer screening, band evolution with displacement field and Moiré periodicity will also be discussed.

*This research was supported by NSF DMREF 1922165 and the ARO MURI W911NF-14-0247.
12:51PM B51.00009: Band flattening in slightly twisted bilayers of Bravais networks
TOSHIKAZE KARIYADO (Presenter), Natl Inst for Materials Sci, ASHVIN VISHWANATH, Harvard University — Discovery of superconductivity in twisted bilayer graphene ignited the current intensive studies on stacked 2D materials with moire patterns, especially focusing on flat bands and associated correlated physics. Here, we demonstrate band flattening in twisted bilayers of generic but high symmetric 2D lattices, i.e., 2D Bravais networks [1]. We first show how symmetry of each network gives constraints on the effective potential governing low-energy physics in twisted bilayers. We further numerically demonstrate the band flattening due to the constrained potential using tight-binding models. From the generic theory, we can find an interesting possibility of anisotropic band flattening, in which quasi 1D band dispersion is generated from relatively isotropic original band dispersion. Rich physics is expected with the anisotropic band flattening, ranging from the valley dependent transport to the spin-orbital intertwined model in the strongly correlated limit.

1:03PM B51.00010: Twist disorder in twisted bilayer graphene
JUSTIN WILSON (Presenter), YIXING FU, Physics, Rutgers, SANKAR DAS SARMA, Physics, University of Maryland, JED PIXLEY, Physics, Rutgers — Recent experiments in twisted bilayer graphene have set off a flurry of work due to the observation of purportedly correlated phases at the so-called "magic-angle." The nearly pristine samples of graphene used in the experiment mainly have one significant source of disorder: the twist angle is not uniform throughout the sample. Current models in the literature are inadequate to fully capture this effect, so we introduce and study a new microscopic model in which the twist angle enters as a free parameter in real space. After benchmarking the results of the model with the continuum model, we simulate the effects of twist-angle disorder by constructing "patches" of uniform twist angle. We find that while the minibandwidth and gap are renormalized substantially, the Fermi velocity is not significantly altered. We discuss the implications of this for existing and ongoing experiments on twisted bilayer graphene.

1:15PM B51.00011: Higher-Order Topological Insulator in Twisted Bilayer Graphene
MOON JIP PARK (Presenter), Physics, KAIST, YOUNGKUK KIM, Sungkyunkwan University, GIL YOUNG CHO, Pohang University of Science and Technology, SUNGBIN LEE, Physics, KAIST — Higher-order topological insulators are newly proposed topological phases of matter, whose bulk topology manifests as localized modes at two-or higher-dimensional lower boundaries. In this work, we propose the twisted bilayer graphenes with large angles as higher-order topological insulators, hosting topological corner charges. At large commensurate angles, the intervalley scattering opens up the bulk gap and the corner states occur at half filling. Based on both first-principles calculations and analytic analysis, we show the striking results that the emergence of the corner states do not depend on the choice of the specific angles as long as the underlying symmetries are intact. Our results show that the twisted bilayer graphene can serve as a robust candidate material of two-dimensional higher-order topological insulator.

Topological flat bands without magic angles in massive twisted bilayer graphenes*

SRIVANI JAVAJI (Presenter), Department of Physics, University of Seoul, JIN-HUA SUN, Department of Physics, Ningbo University, JEIL JUNG, Department of Physics, University of Seoul — We show that in massive twisted bilayer graphenes, isolated nearly flat bands below a threshold bandwidth $W_c$ are expected for continuous small twist angles up to a critical $\theta_c$ depending on the flatness of the original bands and the interlayer coupling strength. The phase diagram of finite valley Chern numbers of the isolated moire bands expands with increasing difference between the sublattice selective interlayer tunneling parameters. The valley contrasting circular dichroism for interband optical transitions is constructive near 0° and destructive near 60° alignments and can be tuned through electric field and gate driven polarization of the mini-valleys. Combining massive Dirac materials with various intrinsic gaps, Fermi velocities, interlayer tunneling strengths suggest optimistic prospects of increasing $\theta_c$ and achieving correlated states with large $U/W$ effective interaction versus bandwidth ratios.

This work was partly performed at the Aspen Center for Physics, which is supported by National Science Foundation grant PHY-1607611.

Attractive electron-electron interactions from internal screening in magic angle twisted bilayer graphene

ZACHARY GOODWIN (Presenter), ARASH A MOSTOFI, JOHANNES LISCHNER, Imperial College London — Twisted bilayer graphene (tBLG) has emerged as a new platform for studying electron correlations. tBLG exhibits correlated insulating and superconducting states at twist angles close to the largest magic angle, with the phase diagram resembling that of cuprates, which suggests an unconventional mechanism for superconductivity. We have studied the effect of internal screening on electron-electron interactions and Hubbard parameters in undoped tBLG, within the random phase approximation (RPA) and constrained RPA (cRPA). Near the magic angle, the flattening of bands drastically increases the RPA dielectric constant of tBLG and the abrupt change in the band velocity as function of the band energy gives rise to attractive regions in the RPA screened interaction in real space, which could be intimately connected to the reported correlated-insulator and superconducting phases. The cRPA polarizability was used to parametrize a twist-angle-dependent Keldysh model which exhibits a dramatic enhancement with decreasing twist angle, and to calculate the extended Hubbard parameters of a downfolded Hamiltonian. We find that the extended Hubbard parameters depend sensitively on the twist angle and the on-site Hubbard $U$ is not simply a linear function of twist angle.
1:51PM B51.00014: Twistorics in bilayer graphene and other systems

SUJAY RAY (Presenter), Indian Institute of Science — The discovery of twisted bilayer graphene initiated the idea that a novel platform with unprecedented tunability can be garnered with a simple relative twist between two layers. For graphene systems, this technology has generated a versatile system where flat band, superconductivity and magnetism are intertwined. We present our work on the theory of Wannier pair in twisted bilayer graphene. For comparisons, we also study graphene on boron-nitride (GBN) possessing a different Moire pattern, and single-layer graphene (SLG) without a Moire pattern. We will also present novel properties emanating from similar bi-layer systems.

*The work is supported by the Science and Engineering Research Board (SERB) of the Department of Science & Technology (DST), Govt. of India for the Start Up Research Grant (Young Scientist), and also benefited from the financial support from the Infosys Science foundation under Young investigator Award.

BS1.00015: Symmetry breaking states at commensurate fillings of the Moire bands of the twisted bilayer graphene

YI ZHANG (Presenter), Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, KUN JIANG, ZIQIANG WANG, Department of Physics, Boston College, FUCHUN ZHANG, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences — We study the twisted bilayer graphene system with the continuous model together with the long-range Coulomb interaction. Within the Hartree Fock approximation, we are able to find some symmetry breaking ground states at commensurate fillings of the Moire bands, which will gap out the Dirac points at the reduced Brillouin Zone that are otherwise protected by the symmetry.

Monday, March 2, 2020 11:15 AM - 2:03 PM

Session B52 DCMP: Complex Oxide Films, Surfaces, and Interfaces I

High Ballroom 1E - Matthew Brahlek, Oak Ridge National Lab
**11:15AM B52.00001: Growth of the Transparent Correlated Metal SrVO$_3$**

LISHAI SHOHAM (Presenter), MARIA BASKIN, Andrew and Erna Viterbi Department of Electrical Engineering, Technion—Israel Institute of Technology, MYUNG-GEUN HAN, YIMEI ZHU, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, LIOR KORNBLUM, Andrew and Erna Viterbi Department of Electrical Engineering, Technion—Israel Institute of Technology —

The ongoing search for earth-abundant transparent conduction oxides (TCOs) has spread across a wide variety of research fields, highlighting the correlated metal SrVO$_3$ as a potential candidate. SrVO$_3$ displays high conductivity and transparency in the visible. Moreover, SrVO$_3$ is an attractive candidate for future electronics. A major hurdle for the synthesis of high quality SrVO$_3$ is to mitigate the formation of defects throughout the thin film. These defects can cause electron scattering and result in high resistivity and obscure some of the interesting physics. Film growth was done with molecular beam epitaxy (MBE), providing a scalable and industry-compatible fabrication process. In this work we present low defect SrVO$_3$ films with residual resistivity ratios exceeding 10 and room temperature resistivities in the order of 30 $\mu\Omega$ cm. Careful analysis of the structural and electronic properties of the SrVO$_3$ films paves the way towards further improvement of their quality and their implementation as TCO in optoelectronics and renewable energy devices.

*This work was funded by the Israeli Science Foundation (ISF Grant 375/17).*

**11:27AM B52.00002: Magnetic properties in strained PrVO$_3$ thin films**

WILFRID PRELLIER (Presenter), CRISMAT, CNRS — Transition metal oxides often having a perovskite structure form a wide and technologically important class of compounds. In these systems, ferroelectric, ferromagnetic, ferroelastic, or even orbital and charge orderings can develop and eventually coexist. These orderings can be tuned by external electric, magnetic, or stress field, and the cross-couplings between them enable important multifunctional properties, such as piezoelectricity, magneto-electricity, or magneto-elasticity. Here, a series of high quality epitaxial PrVO$_3$ (PVO) thin films were grown, by Pulsed Laser Deposition (PLD) technique, as a function of thickness on various substrates inducing different types of strains. Using a battery of techniques, I will show how the strains modify the magnetic properties and structural characteristics of the layers. At the end, I will propose a model based on dead layer to explain the data.

*Thanks to ANR, CNRS and Region Normandie*
Phase transformation by superoxygenation in cuprate and iridate thin films

CHAO C ZHANG (Presenter), HAO ZHANG, Department of Physics, University of Toronto, NICOLAS GAUQUELIN, SHAOBO CHENG, GIANLUIGI BOTTON, Canadian Centre for Electron Microscopy and Department of Materials Science and Engineering, McMaster University, CHRISTOPHER MCMAHON, DAVID GEOFFREY HAWTHORN, Department of Physics and Astronomy, University of Waterloo, PATRICK CLANCY, SAEHWAN CHUN, Department of Physics, University of Toronto, AMBROSE SEO, Department of Physics and Astronomy, University of Kentucky, YOUNG-JUNE KIM, JOHN Y.T. WEI, Department of Physics, University of Toronto — High-pressure O$_2$ has previously been used to hole-dope and stabilize high-oxidation phases of cuprates. We extend this superoxygenation technique to materials in thin film form since they are more reactive due to their large surface-to-volume ratio. YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) thin films grown by PLD are annealed in up to 700 atm O$_2$ and then characterized by TEM, XRD and XAS. The annealed films show phase conversion to Y$_2$Ba$_4$Cu$_7$O$_{15-\delta}$ and Y$_2$Ba$_4$Cu$_8$O$_{16}$, as well as regions well as regions of YBa$_2$Cu$_5$O$_{9-\delta}$ and YBa$_2$Cu$_6$O$_{10-\delta}$. Epitaxial thin films of Sr$_2$IrO$_4$ are subjected to extended high-pressure annealing and similarly characterized. The post-annealed films show up to 3 order-of-magnitude drop in room temperature resistivity and an evolution towards semi-metallic behaviour. Furthermore, as film thickness is reduced, the annealed films show a structural transformation towards a quasi-cubic phase. Our results demonstrate the potential of using superoxygenation to stabilize exotic phases of transition metal oxides not achievable in bulk form and to create novel materials by selectively transforming constituent layers in multilayer films. [1]

**11:51AM B52.00004: Coupling lattice instabilities across the interface in ultrathin oxide heterostructures**

THIERRY VAN THIEL (Presenter), Delft University of Technology, JENNIFER FOWLIE, University of Geneva, CARMINE AUTIERI, MagTop, NICOLA MANCA, MAKARS SISKINS, DMYTRO AFANASIEV, Delft University of Technology, STEFANO GARIGLIO, University of Geneva, ANDREA CAVIGLIA, Delft University of Technology — The resistivity of ultrathin SrIrO3 films grown epitaxially on SrTiO3 displays an anomaly at the temperature corresponding to the cubic-tetragonal transition of the substrate. We investigate its origin through synchrotron X-ray diffraction measurements, electronic transport and ab-initio calculations. The effect is ascribed to a redistribution of orthorhombic structural domains, driven by the cubic-tetragonal transition of SrTiO3. The compressive strain induced by the substrate is found to force the in-phase octahedral rotation axis of the film to lie in-plane, giving rise to a twofold degenerate domain structure that couples to SrTiO3 tetragonal domains. Transport measurements in van der Pauw devices reveal that a strong anisotropy of the longitudinal resistivity develops below the transition temperature. The strong structure-property relationships in the iridates makes these compounds particularly suitable for static and dynamic coupling at interfaces, providing a promising route towards realizing novel functionalities in oxide heterostructures.

**12:03PM B52.00005: Structure of SrRuO3 films on SrTiO3 (001) in the ultrathin limit**

PRAHALD SIWAKOTI (Presenter), MOHAMMAD SAGHAYEZHIAN, ZHEN WANG, Louisiana State University, Baton Rouge, YIMEI ZHU, Department of Energy Science and Technology, Brookhaven National Laboratory, E WARD PLUMMER, JIANDI ZHANG, Louisiana State University, Baton Rouge — The observation of unconventional anomalous Hall effect in SrRuO3 films on SrTiO3 has been suggested as the signature for the existence of topologically non-trivial magnetic structures driven by Dzyaloshinskii – Moriya (DM) interaction [1,2]. However, experimental evidence for RuO6 distortion, which should be directly correlated with DM interaction, is far from clear. We have carried out a study on the evolution of lattice structure and its relation to the magneto-transport properties of SrRuO3 films with thickness in the ultra-thin limit (< 10 unit-cells) utilizing in-situ Low Energy Electron Diffraction, ex-situ High Resolution Scanning Transmission Electron Microscopy and transport measurements. We discuss the lattice distortion effect on the Dzyaloshinskii – Moriya interaction in the system.

*Supported by U.S.NSF under Grant No. DMR1608865
Electronic and lattice coupling in thin films of Nd$_{1-x}$La$_x$NiO$_3$*  JENNIFER FOWLIE (Presenter), BERNAT MUNDET, Univ of Geneva, ALEXANDRU BOGDAN GEORGESCU, Flatiron Institute, CLARIBEL DOMINGUEZ ORDONEZ, Univ of Geneva, MARTA GIBERT, Univ of Zurich, JEAN-MARC TRISCONE, Univ of Geneva — The solid solution Nd$_{1-x}$La$_x$NiO$_3$ spans a range of materials properties. From NdNiO$_3$ (x = 0), a low temperature antiferromagnetic insulator with monoclinic symmetry to LaNiO$_3$ (x = 1) a metallic paramagnet with rhombohedral symmetry [1]. Using an intermittent sputtering technique, we grow high quality epitaxial thin films of this solid solution on various substrates and, in this way, achieve an analog control of the composition. We report here of an unexpected discontinuous electronic behaviour - an abrupt change from an insulating to a metallic groundstate - and establish a connection to the symmetries of the system. Our work sheds light on a little-explored area of the rare earth nickelate phase diagram.

*This work was supported by the Swiss National Science Foundation through Division II. The research leading to these results has received funding from the European Research Council under the European Union’s Seventh Framework Program (FP7/2007-2013)/ERC Grant Agreement 319286 (Q-MAC).
12:27PM B52.00007: Co valence transformation in isopolar LaCoO$_3$ / LaTiO$_3$ perovskite heterostructures via interfacial engineering* GEORGIOS ARAIZI-KANOUTAS (Presenter), Van der Waals-Zeeman Institute for Experimental Physics, Institute of Physics, University of Amsterdam, JAAP GEESSINCK, MESA+ Institute, Faculty of Science and Technology, University of Twente, NICOLAS GAUQUELIN, Electron Microscopy for Materials Science, University of Antwerp, STEEF SMIT, XANTHE VERBEEK, SHRAWAN MISHRA, Van der Waals-Zeeman Institute for Experimental Physics, Institute of Physics, University of Amsterdam, PETER BENCOK, Diamond Light Source Ltd, Diamond House, Harwell Science & Innovation Campus, CHRISTOPH SCHLUETER, PETRA III, DESY Photon Science, TIEN-LIN LEE, Diamond Light Source Ltd, Diamond House, Harwell Science & Innovation Campus, DILEEP KRISHNAN, JO VERBEECK, Electron Microscopy for Materials Science, University of Antwerp, GUUS RIJNDERS, GERTJAN KOSTER, MESA+ Institute, Faculty of Science and Technology, University of Twente, MARK GOLDEN, Van der Waals-Zeeman Institute for Experimental Physics, Institute of Physics, University of Amsterdam — Charge transfer up to a single electron per interfacial unit cell across the non-polar heterointerface consisting of the Mott insulator LaTiO$_3$ and the charge-transfer insulator LaCoO$_3$ was studied in multi-layered films grown by PLD, using element-specific soft X-ray absorption, magnetic dichroism, TEM and hard X-ray photoemission spectroscopies.

We provide robust evidence of systematic and controllable conversion of trivalent to divalent cobalt that occurs within an interfacial region of three unit cells in LaCoO$_3$ as a direct result of the ensuing Fermi energy mismatch, without the presence of dopants or structural modification, in agreement with the theoretical prediction. Through the excellent control of the growth process, the average Co valence is tuned at the nanoscale via a proper choice of the number of LaTiO$_3$ | LaCoO$_3$ interfaces and the thickness of LaCoO$_3$. Notably, the insertion of an ultrathin LaAlO$_3$ ‘break’ layer interrupts the charge transfer, highlighting its interfacial nature.

Besides the strong enhancement of the magnetic polarizability due to formation of divalent Co, this technologically-relevant guiding principle illustrates the efficacy of O2p-band alignment for property design in oxide heterointerfaces.

Long-range ordered domain walls in MBE-grown BiFeO$_3$ thin films and manipulation of their electrical properties

YONGJIAN TANG (Presenter), Department of Physics, Cornell University, ANTONIO B MEI, Department of Materials Science and Engineering, Cornell University, JÜRGEN SCHUBERT, Peter Grünberg Institute, SAHAR SAREMI, Department of Materials Science and Engineering, University of California, Berkeley, LUDI MIAO, Laboratory of Atomic and Solid State Physics, Cornell University, LANE WYATT MARTIN, Department of Materials Science and Engineering, University of California, Berkeley, DARRELL SCHLOM, DANIEL RALPH, Department of Materials Science and Engineering, Cornell University — Multiferroic BiFeO$_3$ thin films can allow electrical control of magnetism at room temperature and potentially magnetic control of electric polarization. We have investigated the use of adsorption-controlled molecular-beam epitaxy to grow BiFeO$_3$ thin films, as an alternative to the more commonly-used pulsed laser deposition or sputtering. We demonstrate unprecedentedly long-range domain periodicity of domain walls in commensurately strained BiFeO$_3$/SrRuO$_3$/DyScO$_3$(110)$_0$ epitaxial heterostructures. We observe two domain variants under piezoresponse force microscopy (PFM), which form alternating 140-nm-wide striped domains. Conductive AFM shows that the domain walls exhibit enhanced conductivity relative to the bulk and electrical rectification. For applications, ion irradiation can be used to reduce the through-film leakage without increasing the coercive field for ferroelectric switching. Doping with lanthanum is effective in reducing the strength of ferroelectric polarization, a necessary step to enable magnetic control of the polarization.

12:51PM B52.00009: Properties of the BiVO\(_4\) (010) surface in single crystals and epitaxially grown samples: A joint first-principles and experimental effort*  WENNIE WANG (Presenter), Pritzker School of Molecular Engineering, The University of Chicago, PATRICK STROHBEEN, Materials Science and Engineering, University of Wisconsin-Madison, DONGHO LEE, Department of Chemistry, University of Wisconsin-Madison, CHENYU ZHOU, Department of Chemical Engineering, Columbia University, JASON KAWASAKI, Materials Science and Engineering, University of Wisconsin-Madison, KYOUNG-SHIN CHOI, Department of Chemistry, University of Wisconsin-Madison, MINGZHAO LIU, Center for Functional Nanomaterials, Brookhaven National Laboratory, GIULIA GALLI, Pritzker School of Molecular Engineering, The University of Chicago — As a prototypical oxide for water photocatalysis, BiVO\(_4\) has many advantageous optoelectronic properties, including strong absorption in the visible and a favorable band alignment with water. However, its use as a photo-absorber is limited by its inefficient charge dynamics, especially at interfaces. Here, we present an integrated experimental and computational study aimed at an atomistic understanding of the surface morphology and electronic properties of BiVO\(_4\) as a function of oxygen vacancy concentration.

We carried out first-principles calculations with Quantum Espresso (www.quantum-espresso.org/) and XPS/UPS measurements to obtain work functions and band alignments with vacuum. We show that oxygen vacancies at the surface behave differently from their bulk counterpart, in terms of formation energy and transport of small polarons. We also compare single-crystalline and epitaxially-grown samples, with focus on the relation among oxygen vacancies, electronic structure, and growth techniques. Finally, based on a combined study of measured and STM microscopy images, we propose how varying surface termination may help tune the photoelectrochemical performance of BiVO\(_4\).

1:03PM B52.00010: Multi-level ionic conductivity in Ca-doped BiFeO\(_3\) thin films  JEONGHUN SUH (Presenter), JI SOO LIM, HEUNG-SIK PARK, CHAN-HO YANG, Department of Physics & Center for Lattice Defectronics, KAIST — Ca-doped bismuth ferrite is a promising material for studying collective ionic migration in solids [1]. We conduct impedance analysis with different magnitudes of AC voltage to understand the ionic conduction mechanism of this material. To suppress the electronic contribution to the conductivity, we annealed the sample in a reducing condition at elevated temperatures before the measurement. By using the mixed conductor equivalent circuit model [2], we obtain ionic conductivity, which shows a multi-level feature. This result shows consistency with the observation from electroforming experiments with DC voltages. This work provides useful insight into the ionic conduction mechanism in solids.
1:15PM B52.00011: Observation of anisotropic filamentary conduction pathways in Cadoped bismuth ferrite thin films  HEUNG-SIK PARK (Presenter), JI SOO LIM, JEONGHUN SUH, CHAN-HO YANG, Department of Physics & Center for Lattice Deflectronics, KAIST — Ionic migration is a key ingredient for applications such as oxide electrolytes and resistive switching memories. We investigate the evolution of the ionic conduction pathways based on optical contrast in an epitaxial Bi$_{0.7}$Ca$_{0.3}$FeO$_{3-\delta}$ thin film where oxygen vacancies are spontaneously produced.[1] We visualized electroforming processes in the hundreds-micron-scale material channels between coplanar electrodes with a constant electric bias at an elevated temperatures, systemically varying the channel orientation with respect to the crystal axis.[2] At the initial stage of electroforming, conducting filaments are created and propagate nearly along the crystal axes $<100>$, thereby making orthogonal self-similar networks. We also find that the filament-type ionic conduction is abruptly transformed to the bulk conduction around the time when the filament pathways connect both electrodes. These results offers useful insight into collective ionic migration in crystalline solids.

1:27PM B52.00012: Charge transport and distribution at the interfaces of SrTiO$_3$/LaAlO$_3$/SrTiO$_3$ (100) (STO/LAO/STO (100))  AKHILESH KUMAR SINGH, Inst of Physics Academia Sinica, C.P. SU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, T.C. WU, M.C. CHEN, M.Y. SONG, Inst of Physics Academia Sinica, Y.C. LAI, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, GUANG-YU GUO, Department of Physics, National Taiwan University, M.-W CHU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, WEI-LI LEE (Presenter), Inst of Physics Academia Sinica — The existence of a quasi-2-dimensional hole gas (q2DHG) in STO/LAO/STO (100) has been revealed by several groups. In this report, the STO(6-uc)/LAO(t-uc)/STO (100) samples with $t = 5$ and $3$ were grown using oxide MBE technique. From magneto-transport measurements at low temperatures and difference gate voltages ($V_g$), a clear signature for the existence of q2DHG was uncovered from rigorous two band model fittings to magneto-conductance data. At $T = 2K$ and $V_g = +100V$, the sheet density for q2DHG is as large as $1.47 \times 10^{13}$ per cm$^2$. Intriguingly, both the sheet densities for q2DEG and q2DHG increase with increasing positive $V_g$, which supports for a spatially separated electron-hole bilayer at the interfaces [1]. On the other hand, STEM-EELS measurements with atomic scale resolution across the interfaces were performed. The suppressed q2DHG in STO/LAO/STO (100) in the ultra-thin LAO limit can be attributed to the depolarization field within the LAO layer, arising from the strain-field interference across the two closely-spaced interfaces [2]. In principle, q2DHG can emerge by compensating the depolarization field, which is achievable either by increasing the LAO thickness or by electrical gating. [1] Singh et al., PRM 2, 114009 (2018). [2] Su et al., PRM 3, 075003 (2019).
1:39PM B52.00013: Observation of polar domains in a relaxor La-substituted BiFeO$_3$ thin film  YOUNGKI YEO (Presenter), YONG-JIN KIM, MUJIN YOU, CHAN-HO YANG, Department of Physics & Center for Lattice Defectronics, KAIST — Relaxor ferroelectrics have been widely studied because of their unique physical properties including high permittivity, high piezoelectric effects, etc. The existence of polar nanoregions (PNRs) is believed to be responsible for relaxor behaviors [1]. However, there is a lack of studies on PNRs linked to the flexoelectric effect. In this work, we report the direct observation of PNRs within tetragonal BiFeO$_3$ near morphotropic phase boundaries (MPBs) which are expected to involve large strain gradient. Heavily La-substituted BiFeO$_3$ thin films (BLFO) grown on LaAlO$_3$ (001) have been employed to explore the PNRs with the aid of an angle-resolved lateral piezoresponse force microscopy [2]. BLFO has been thought to be isotropic monoclinic energies [3]. the flexoelectric effect on tetragonal BLFO near MPBs stabilizes various monoclinic phases. The frequency-dependent dielectric anomalies and diffuse x-ray scattering have been confirmed to identify that our system shows the typical relaxor behaviors. Our findings will offer valuable information to study the role of the flexoelectric effect on the formation of PNRs.

1:51PM B52.00014: The linear electro-optical effect in thin oxide films*  ALEXANDER DEMKOV, ALI HAMZE (Presenter), WENTE LI, THERESE PAOLETTA, KURT D FREDRICKSON, University of Texas at Austin — The linear electro-optical (EO) effect, also known as the Pockels effect, has been the subject of increasing interest due to its potential for use in silicon photonic applications. As such, it is necessary to find materials that have a strong EO response in thin film form, which is essential for low power and small footprint devices. In this talk we will discuss general design rules for developing strong Pockels materials inferred from first principles theory. We will discuss the Pockels effect in BaTiO$_3$, strained SrTiO$_3$, LiB$_3$O$_5$ (LBO) and CsB$_3$O$_5$ (CBO) and use these materials as prototypical examples of where conventional wisdom breaks down. We analyze how the EO response is related to the optical phonon frequencies, Raman susceptibility and mode polarization and elucidate the underlying physical phenomena behind the large Pockels effect.

Guangyi Chen, Peking University
11:15AM B53.00001: Optical Phase Transitions in 1T'-MoTe$_2$ from Thin Film Strain Engineering AHMAD AZIZIMANESH (Presenter), TARA PENA, ARFAN SEWAKET, STEPHEN M WU, Electrical and Computer Engineering, University of Rochester — MoTe$_2$ has been shown to have the ability to undergo a semimetallic to semiconducting phase transition induced by strain. In this work, we explore this phase change in 1T'-MoTe$_2$ through static strain induced by thin film stress capping layers, analogous to the ones used in industrial strained silicon processes. The optically transparent stressor film is chosen to be e-beam evaporated Al$_2$O$_3$/MgF$_2$/Al$_2$O$_3$. This film carries a controlled amount of tensile thin film stress depending on MgF$_2$ film thickness. Al$_2$O$_3$ is used as both an adhesion layer to MoTe$_2$, and as a protective capping layer for the MgF$_2$ from the environment. Significant optical contrast change in the few layered MoTe$_2$ flakes is observed after stressor film deposition, which is confirmed to be a phase change with Raman spectroscopy. Al$_2$O$_3$ capped control samples eliminate the possibility that this effect originates from defect formation during device fabrication process. Increasing thin film stress, changes the phase of a larger number of layers from the top of each MoTe$_2$ flake, resulting in thinner flakes to show larger proportional contrast change. Stress is a well-known technique to induce a phase change in MoTe$_2$ and potentially other 2D materials, which may lead to interesting applications in 2D electronics and optics.

11:27AM B53.00002: Versatile multiscale envelope function formalism to study electron transport in lateral transition-metal dichalcogenide heterostructures SATHWIK BHARADWAJ (Presenter), Department of Physics, Worcester Polytechnic Institute, Worcester, MA, ASHWIN RAMASUBRAMANIAM, Department of Mechanical & Industrial Engineering, University of Massachusetts, Amherst, MA, L RAMDAS RAM-MOHAN, Department of Physics, Worcester Polytechnic Institute, Worcester, MA — Accurate determination of carrier transport properties is critical to design high-performance optoelectronic devices and quantum information platforms. Although, first-principles calculations effectively determine the atomistic potentials associated with heterointerfaces, defects, and impurities, they are ineffective for direct modeling of carrier transport properties at length scales relevant to device applications. Here, we develop a multiscale formalism to investigate electron transport in two-dimensional (2D) materials. We integrate $k.p$ perturbation theory, informed from ab-initio electronic structure calculations, with a novel non-asymptotic quantum scattering theory using the method of sources and absorbers [1]. Our approach fully accounts for the crucial contributions of evanescent solutions that arise in multi-band scattering across heterointerfaces. We apply this method to study electron transport in lateral transition-metal dichalcogenide heterostructures, and discuss the implication of interface patterns on enhancing the thermoelectric power factor of the system. This new formalism provides a versatile variational description, first-principles-informed modeling of electron transport in 2D materials.

11:39AM B53.00003: Characteristics of the localization of massless pseudospin-1 Dirac particles in 2D in a short-range correlated random one-dimensional potential* SEULONG KIM (Presenter), KIHONG KIM, Ajou Univ — We study theoretically the characteristics of Anderson localization of two-dimensional massless pseudospin-1 Dirac particles in a correlated random one-dimensional potential. These potentials include both scalar and vector potentials. Using the invariant imbedding method, we calculate the localization length in a numerically precise manner and derive the analytical expressions for the localization length in strong and weak disorder limits. We investigate the dependencies of the localization length on incident angle, disorder correlation length, disorder strength, energy and average potential for the cases with random scalar and/or vector potentials. Disorder correlations affect the scaling dependencies of the localization length on the disorder strength and the particle energy. We explain these dependencies and the crossovers between different scaling regimes using the analytical formulas.

11:51AM B53.00004: Strong two-body correlations in WS$_2$ – MoSe$_2$ Heterojunction Tunnel Diodes JEDEDIAH KISTNER-MORRIS (Presenter), TREVOR ARP, NATHANIEL GABOR, University of California, Riverside — Owing to the strong Coulomb interaction between electrons and holes, electron tunneling between individual layers of a van der Waals heterostructure may give rise to highly unusual phenomena not observed in conventional materials. Here we report on optoelectronic transport of encapsulated WS$_2$ – MoSe$_2$ tunneling heterojunctions, in which we observe anomalous photoconductance and strong rectification. Using Multi-Parameter Dynamic Photoresponse Microscopy, we generate $\sim 10^X$ photocurrent images of the heterostructure photoresponse as a function of source-drain voltage, gate voltage, and temperature. Alongside strong rectifying behavior, we observe an anomalous reduction in the interlayer conductance that is tunable with gate voltage and temperature. This behavior becomes significantly enhanced with optical illumination, allowing us to assess the interactions of electrons and holes at the heterostructure interface. Our measurements indicate that strong two-body correlations arise precisely at the onset to a reduction in tunneling conductance, which we speculate is a signature of the crossover from free electron to bound interlayer exciton state.
12:03PM B53.00005: Transfer-print of graphene, boron nitride and gold patterns onto polymeric materials  EVGENIYA LOCK (Presenter), United States Naval Research Laboratory, GABRIELLA GONZALEZ-PASCUAL, University of Puerto Rico, DANIEL CHOI, National Research Council, SANDRA VILLANUEVA RODRIGUEZ, University of Puerto Rico, RAY AUYEUNG, HEUNGSOO KIM, United States Naval Research Laboratory, KARTHIK SRIDHARA, Texas A&M university, BORIS FEYLGELESON, United States Naval Research Laboratory — Two dimensional (2-D) materials such as graphene, hexagonal boron nitride (h-BN), black phosphorene (BP), molybdenum disulfide (MoS₂) have intriguing electrical, optical and chemical properties, which may enable next generation flexible sensors and photodetectors fabrication. However, placement of 2D materials on polymers to produce large scale 2D material/polymer heterostructures and the following metal deposition remains challenging. In this work, we show a multistep approach towards realization of 2D heterostructures on flexible substrates using a dry transfer-print approach based on differential adhesion. First, plasma treatment of the polymeric materials was performed. Then, organic molecular linker layer was attached for increased polymer adhesion. Then, the polymers and the 2D materials were placed in a nanoimprinter at specified conditions (pressure, temperature and time) and mechanically separated after print. Similarly, gold patterns were transferred to polymers. Optical, chemical, electrical and structural characterization of the samples before and after print was performed. Based on our results, we believe that our 2D material transfer-print approach will allow for large scale fabrication of the next generation 2D/flexible hybrid electronics devices.

12:15PM B53.00006: A Novel Type of Water Desalination Technology Using MoS2-Based Thin Films for Selective Ion Transport.  GABRIEL MARCUS (Presenter), Wake Forest Univ — Molybdenum disulfide (MoS₂) is a widely studied transition metal dichalcogenide with a range of potential applications including next-generation electronics, hydrogen evolution, and catalysis. It can also be used as a thermoelectric, exploiting the Seebeck effect to generate an electric voltage in response to a temperature gradient. Additionally, lithium intercalated MoS₂ is known to undergo a transition from the 1T to 2H phase. Together, these two properties make this material suitable as a novel desalination technology that relies on selective ion transport. To assess MoS²'s capabilities for ion transport, two types of experiments were conducted. The first set of experiments investigated changes in electric potential resulting from dropwise contact of various salt solutions with an MoS₂ membrane. Droplet test data displayed abrupt changes in electric potential followed by an exponential decay representing ion movement over time. A second set of experiments measured ion concentration changes over time using an MoS₂ film in contact with separated DI water and salt solutions. Significant changes in solution ion osmolarities were recorded after a duration of one week. Results are promising for future development of a thermoelectric desalination device.
**12:27PM B53.00007: Substrate-Induced Dynamical Anti-Screening of Excitons in Quasi-2D Materials: Renormalization of Quasiparticle and Optical Excitations***

CHIN SHEN ONG (Presenter), FELIPE H. DA JORNADA, DIANA QIU, STEVEN LOUIE, University of California, Berkeley — It is now well established that screening from substrates can strongly reduce the many-electron interactions in quasi-2D insulating materials, and renormalize both the quasiparticle bandgap and exciton binding energy in such systems. However, for metallic substrates, the frequency dependence of screening plays a paramount role that is often ignored. Here, we show that the frequency dependence of metallic substrate screening can induce a strong anti-screening effect in the quasi-2D insulator and lead to anomalously non-hydrogenic exciton energy levels, i.e., there are dramatic additional changes that go beyond the q-dependent static screening of quasi-2D materials. A systematic first-principles study of renormalizations by a wide range of experimentally motivated substrates is carried out, and our calculated results provide conceptual and quantitative explanation of experiments.

**12:39PM B53.00008: Hydrodynamic Anomalous Transport in Interacting Noncentrosymmetric Metals***

RIKI TOSHIO (Presenter), Department of Physics, Kyoto University, KAZUAKI TAKASAN, Department of Physics, University of California, Berkeley, NORIO KAWAKAMI, Department of Physics, Kyoto University — In high-conductive metals with sufficiently strong momentum-conserving scattering, the electron momentum is regarded as a long-lived quantity, whose dynamics can be described by an emergent hydrodynamic theory. In this work, we propose a hydrodynamic theory for noncentrosymmetric metals, where a novel class of electron fluids is realized by lowering crystal symmetries and the resulting geometrical effects. Starting from the Boltzmann equation, we introduce the effects of the Berry curvature to electron hydrodynamics and formulate a *generalized Euler equation* for noncentrosymmetric metals. We show that this equation reveals a variety of novel anomalous nonlocal/nonlinear transport phenomena; *chiral vortical effect, quantum nonlinear Hall effect, thermal-gradient induced anomalous Hall effect, etc.*, whose transport coefficients are described by geometrical quantities such as *Berry curvature dipole* [1]. Furthermore, we give a symmetry classification of these coefficients and compare the results with existing hydrodynamic materials. In the presentation, we would like to discuss what phenomena are predicted to be observed in experiments in noncentrosymmetric materials, including bilayer-graphene and transition metal dichalcogenides.

12:51 PM B53.00009: Engineering the electronic, thermoelectric, and excitonic properties of 2D group-III nitrides through alloying \((Al_{1-x}Ga_xN, Ga_{1-x}In_xN, B_{1-x}Al_xN)\)\(^*\)  

DANIEL WINES (Presenter), FATIH ERSAN, CAN ATACA, Univ of Maryland-Baltimore County — Recently, two-dimensional (2D) group-III nitride semiconductors such as h-AlN, h-BN, h-GaN, and h-InN have attracted attention due to their exceptional electronic, optical and thermoelectric properties. It has also been demonstrated, theoretically and experimentally, that properties of 2D materials can be controlled by alloying. In this study we performed density functional theory (DFT) calculations to investigate 2D \(Al_{1-x}Ga_xN\), \(Ga_{1-x}In_xN\), and \(B_{1-x}Al_xN\) alloyed structures. We also calculated the thermoelectric properties of these structures using Boltzmann transport theory based on DFT and the optical properties using the GW method and the Bethe Salpeter equation (BSE). Fundamental band gaps were also calculated with quantum Monte Carlo (QMC) methods for benchmarking purposes. We find that by changing the alloying concentration, the band gap and exciton binding energies of each structure can be tuned accordingly, and for certain concentrations, a high thermoelectric performance is reported with strong dependence on the effective mass of the given alloyed monolayer. With the ability to control such properties by alloying 2D group-III nitrides, this work presents new novel possibilities to engineer the electronic, optical and thermoelectric properties of 2D materials.

1:03 PM B53.00010: Intrinsic gap and temperature collapse of the electric conductivity in bilayer graphene\(^*\)  

MOHAMMAD ZARENIA (Presenter), GIOVANNI VIGNALE, Univ of Missouri - Columbia — Recent experiments have reported signatures of electron-hole scattering in the electric conductivity of suspended bilayer graphene near charge neutrality. According to these experiments, plots of the electric conductivity as a function of \(\mu/k_B T\) (chemical potential scaled with temperature) obtained for different temperatures in the range of \(10K<T<50K\) collapse on a single curve independent of \(T\). This puzzling observation has been taken as an indication that the relevant scattering mechanism (besides electron-hole scattering) is not electron-impurity but electron-phonon scattering. Here we demonstrate that the collapse can be explained without invoking electron-phonon scattering by taking into account the fact that the suspended bilayer graphene is not a truly gapless system. In the presence of a small gap the intrinsic Coulomb resistivity acquires a temperature dependence that compensates for the temperature dependence of the impurity resistivity. Our theory produces excellent agreement with the observed conductivity collapse over the full reported range of temperatures, with a gap of 5 mev.

1:15PM B53.00011: Negative Differential Resistance in MoS\textsubscript{2} Esaki Diodes\textsuperscript{*} ADAM BRUCE (Presenter), YUN-PENG WANG, SHUANGLONG LIU, HAI-PING CHENG, University of Florida — Two dimensional MoS\textsubscript{2} is a semiconducting system valued for its potential application as a programmable material. In addition to its direct bandgap in a single layer, an external electric field allows for interlayer band-to-band tunneling in bilayer configuration, which raises the prospect of applications in nanocircuitry. Using a first principles approach via DFT+NEGF, we probe the electronic properties of MoS\textsubscript{2} p-i-n junctions. We show both the IV characteristics of our junctions as well as the corresponding partial density of states at biases of interest. By comparing the band alignment of the electrodes and the transmission of our junction, we establish a criterion for band to band tunneling. Finally, we discuss mitigating edge effects on electronic structure and the possible applications of our p-i-n junctions.

1:27PM B53.00012: Electrochemical intercalation of organometallic molecules in HfS\textsubscript{2}-based van der Waals material\textsuperscript{*} CHINEDU EKUMA (Presenter), Department of Physics, Lehigh University, Bethlehem, PA 18015, SINA NAJMAEI, ADAM A WILSON, ASHER LEFF, MADAN DUBEY, Sensors and Electronic Devices, U.S. Army Research Laboratory, Adelphi, MD 20783 — van der Waals (vdW) materials designed with atomic layers of 2D-based materials exhibit a broad set of novel properties that are highly desirable for enabling heterogeneous device concepts such as neuromorphic and quantum computing. Because of their flexible electronic structure, both carrier dynamics and charge injection are easily tunable with chemical or electrical doping. Using a combined computation and experiment, we demonstrate the feasibility of intercalating electronically active organometallic molecules of two of the family of metallocene: cobaltocene and chromocene into the vdW gap of HfS\textsubscript{2}-based prototype vdW materials. We achieve high tunability of the electronic and vibrational properties of the hybrid material. Our findings demonstrate a unique approach, leveraging the flexible structural properties of layered materials to create an organic/inorganic interface that tunes and tailor the properties of host materials for distinctive device applications.

Electronic States at Lateral Interfaces in Transition Metal Dichalcogenides

KAELYN FERRIS (Presenter), SERGIO E ULLOA, Physics & Astronomy, Ohio Univ —

Lateral heterostructures of two-dimensional crystals have received attention as defect free interfaces are increasingly grown in experiments. These interfaces show excitations unlike those at the original materials, suggesting the robustness of the interface. Tight binding and first principles calculations show that electronic states along the interface lie within the band gap of the bulk structure and provide a platform for possible use as high performance thermoelectric materials, spin-valley filters without the need for external gating, excitonic solar cells, and photocatalysis [1]. In this work, we explore the appearance of interfacial states in continuum models of such massive Dirac systems at low energy. We use k*p models to characterize lateral interfaces of various 2D materials and analyze the results of appropriate boundary conditions on various types of interfaces. This approach is able to describe midgap interface states that appear under mass or band inversion, as well as sign changes in effective curvature across the two materials. The states exhibit complex dispersion curves with strong spin-orbit effects, while being localized along the interface with different features in different materials.

Advanced atomistic models to accurately simulate graphitic nanostructures, bio-interfaces, and aromatic molecules*

KRISHAN KANHAIYA (Presenter), JORDAN WINETROUT, MICHEAL NATHANSON, HENDRIK HEINZ, University of Colorado, Boulder —

Graphene and carbon nanomaterials are used in biosensors, batteries, renewable composites, and functional materials. We introduce new atomistic models for the simulation of graphitic nanostructures, bio-interfaces, and aromatic molecules using common energy expressions (CHARMM, AMBER, CVFF, OPLS-AA, PCFF). The model contain virtual π-electrons in graphene/benzene ring that significantly increase the reliability of computed properties. Benchmarking of the new model shows improvements in the reproduction of cation-π interactions, π-π stacking, and electrolyte interfacial properties by ~10 fold. Two dummy electrons are attached to carbon atom to add the multipoles due to π-electrons in the aromatic rings. This leads to columbic interaction in accordance with experiment, which is missing in the old models. The models can accurately predict binding free energies, adsorption sites and biomolecular recognition, binding orientations, surface diffusion, and competitive adsorption of molecules. Details of the validation include agreement with experimental lattice parameters (<0.5% deviation), surface energy (<5% deviation), elastic constants (<15% deviation), hydration energy (10% deviation), water contact angles (<10% deviation) and cation-π interaction (<15% deviation).

*ARFL
Effects of hydrogen, oxygen, and hydroxyl adsorption on the electronic properties of transition metal dichalcogenides

GEORGIOS KOPIDAKIS (Presenter), DAPHNE DAVELOU, ARISTEA E MANIADAKI, IOANNIS N REMEDIAKIS, Univ of Crete — The unique properties of 2D transition metal dichalcogenides (TMDs) attract a lot of interest for optoelectronics, catalysis and energy related applications. Strain, environment, nanostructuring, affect TMD electronic properties and intensive efforts focus on their controlled modification. We present DFT calculations for the stability and electronic structure of semiconducting MX$_2$ (M=Mo, W and X=S, Se) monolayers and nanostructures with several concentrations of adsorbed hydrogen, oxygen, and hydroxyl and compare our results with pristine systems. The metallic character of the edge states [1] is preserved for all TMD nanoribbons examined, albeit Fermi level shifts that depend on the adsorbed atoms. Tuning electronic properties with strain [2] for improved TMD catalysts [3] is briefly discussed.

*We acknowledge support from the R.C. University of Crete (KA 10120).

Monday, March 2, 2020 11:15 AM - 2:03 PM

Session B54 DCMP: Fractional Excitations in the Quantum Hall Effect
Mile High Ballroom 2A
11:15AM B54.00001: Fermionic parity stability and interference measurements of non-Abelian e/4 and Abelian e/2 quasiparticle braiding at 7/2 and 5/2 filling factors* ROBERT WILLETT (Presenter), Nokia Bell Labs, KIRILL SHTENGEL, U.C. Riverside, CHETAN NAYAK, Microsoft, LOREN PFEIFFER, EDWIN CHUNG, K. W. BALDWIN, KENNETH WEST, Princeton University — The 5/2 state is expected to have Abelian charge e/2 quasiparticles and non-Abelian charge e/4 quasiparticles; past interference measurements are consistent with this [1]. Recent [2] interferometer experiments present 3 new findings: 1) at 5/2 four dominant resistance oscillation periods are observed at the expected values for the full complement of braids of non-Abelian e/4 and Abelian e/2: e/2 braiding e/2, e/4 braiding e/2, and modulated oscillations specifically attributable to non-Abelian e/4 braiding e/4, the even-odd effect. Parameters controlling expression of these oscillations are delineated. 2) at 7/2 this full complement of e/4 and e/2 braiding oscillations is also observed, but at different periods as expected for that filling factor. 3) most importantly, the oscillations attributable to non-Abelian e/4 even-odd effect are stable against fermionic parity fluctuations over long times (hours) near 5/2 and 7/2; this observed stability strengthens the case for using non-Abelian e/4 quasiparticles for topological quantum computation.

*P.U.: Moore Foundation - Grant GBMF4420, NSF - MRSEC Grant DMR 1420541 (E.C.).

11:27AM B54.00002: Non-Abelian braiding statistics via Aharonov–Bohm interferometry KIRILL SHTENGEL (Presenter), UC Riverside, ROBERT WILLETT, Nokia Bell Labs, CHETAN NAYAK, Microsoft Station Q, LOREN PFEIFFER, EDWIN CHUNG, Princeton University, MILTON PEABODY, Nokia Bell Labs, K. W. BALDWIN, KENNETH WEST, Princeton University — One of the most striking consequences of the non-Abelian braiding statistics in the ν=5/2 quantum Hall state has been the so-called even–odd effect theoretically predicted over a decade ago. While signatures consistent with the theoretical prediction have been seen in quantum Hall Fabry–Pérot interferometers, the key ingredient – controlling the number of quasiparticles inside the interferometer – remains a challenging experimental problem. Fortunately, signatures of the non-Abelian statistics can emerge in a simpler setting, namely in Aharonov–Bohm-type experiments where interference patterns are produced solely by changing the magnetic field. This nucleates new quasiparticles inside the interferometer, and if those include non-Abelian particles, the Aharonov–Bohm oscillations are expected to have distinct spectral features that would be absent otherwise. This talk will focus on the theoretical predictions and their comparison with the recent observations [1], arguing that the preponderance of experimental evidence unmistakably points towards the non-Abelian nature of ν=5/2 and 7/2 quantum Hall states and provides strong evidence of non-Abelian braiding.

11:39AM B54.00003: Contacts and Equilibration in the ν=5/2 Quantum Hall Effect* HAMED
ASASI (Presenter), MICHAEL C MULLIGAN, University of California, Riverside — The thermal Hall
conductance $K_T$ of the fractional quantum Hall state at $\nu=5/2$ has recently been measured to be
$K_T \approx 2.5(\pi^2 k_B^2 T/3h)[1]$. The half-integer value of this result provides strong evidence for the
presence of a Majorana edge mode and a corresponding quantum Hall state hosting quasiparticles with non-Abelian statistics. Whether this measurement points to the realization of the
PH-Pfaffian state or the anti-Pfaffian state has been the subject of debate [2][3]. Here we
consider various edge-state scenarios which may explain the measured thermal conductance,
paying close attention to the role of contacts and edge-state equilibration. Through a study of the
kinetic equations describing the low-temperature transport in the anti-Pfaffian and PH Pfaffian
dge states, we determine regimes of parameter space, controlling the interactions between the
different edge modes, that agree with experiment. We also discuss how point-contact tunneling
can distinguish various edge-state scenarios.

11:51AM B54.00004: Patterns in paired electron additions to fractional quantum Hall edge
states in large GaAs quantum dots* RAYMOND ASHOORI (Presenter), AHMET DEMIR, NEAL
EDWARD STALEY, SAMUEL ARONSON, SPENCER TOMARKEN, Massachusetts Institute of Technology
MIT, K. W. BALDWIN, KENNETH WEST, LOREN PFEIFFER, Electrical Engineering, Princeton University —
In vertical tunneling into a large and low disorder 2D GaAs quantum dot, we observe
electrons entering edge states and an unusual and unpredicted pair tunneling of electrons
into the dot’s quantum Hall edge states, with double-height capacitance peaks and a
coincident $h/2e$ periodicity in magnetic flux through the dot. Remarkably, results from
interferometry experiments[1] at similar Landau level filling fractions also show this $h/2e$
periodicity over the nearly the same filling factor range where it is observed in these dot
experiments. Thus, in increasing the magnetic field through the dot by one flux quantum,
we observe that 4 electrons are added to the edge (2 double height peaks). While we
observe such pairing everywhere in the filling factor range from $\nu = 2$ to $\nu = 5$, the $h/2e$
periodicity applies near filling factor 5/2. Away from 5/2, the double-height peaks are not
uniformly spaced in magnetic field but instead themselves group into pairs. Fourier
transforms of the data reveal different unusual periodicities other than $h/e$ and $h/2e$,
particularly in the tunneling rates for the peaks.

12:03PM B54.00005: Flux superperiods and periodicity transitions in quantum Hall interferometers*  
BERND ROSENOW (Presenter), Univ Leipzig, ADY STERN, Department of Condensed Matter Physics, Weizmann Institute of Science — For strongly screened Coulomb interactions, quantum Hall interferometers can operate in a novel regime: the intrinsic energy gap can be larger than the charging energy, and addition of flux quanta can occur without adding quasi-particles. We show that flux superperiods are possible, and reconcile their appearance with the Byers-Yang theorem. We explain that the observation of anyonic statistical phases is possible by tuning to the transition from a regime with constant chemical potential to a regime with constant particle density, where a flux superperiod changes to a periodicity with one flux quantum at a critical magnetic field strength.

12:15PM B54.00006: Probing the photon-assisted processes of anyons of charge e/3 and e/5 in the FQHE regime*  
CHRISTIAN GLATTLI (Presenter), IMEN TAKTAK, PREDEN ROULLEAU, CEA-Saclay — Recently, the microwave excitation of fractional edge channels at GHz frequency f have demonstrated time domain manipulation of e*=e/3 and e*=e/5 charged anyons in the FQHE regime [1]. The signature of anyons absorbing a single photon was observed a shot noise singularity when the applied voltage obeying the fractional Josephson relation e*V=hf. Going beyond these observations we analyze the amplitude of the microwave field propagating from the excited contact to a Quantum Point Contact. Using photon-assisted current, the microwave amplitude is shown to display interference when sweeping the frequency from 2 to 18GHz. We attribute these interference features to different propagation velocities of neutral and charged electron (or anyon) modes when several integer or fractional edge propagates in parallel. This study provide the necessary information to realize single anyon sources similar to Leviton [2] sources.

12:27PM B54.00007: Sublattice resolved spin wave transport through graphene fractional quantum Hall states as a probe of isospin order  
HAOXIN ZHOU (Presenter), HRYHORIY POLSHYN, Department of Physics, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, ANDREA YOUNG, Department of Physics, University of California, Santa Barbara — High quality graphene heterostructures host an array of fractional quantum Hall isospin ferromagnets with diverse spin and valley orders. While a variety of phase transitions have been observed, disentangling the isospin phase diagram of these states is hampered by the absence of direct probes of spin and valley order. I will describe nonlocal transport measurements based on launching spin waves from a gate defined lateral heterojunction, performed in ultra-clean Corbino geometry graphene devices. At high magnetic fields, we find that the spin-wave transport signal is detected in all FQH states between $\nu = 0$ and 1; however, between $\nu = 1$ and 2 only odd numerator FQH states show finite nonlocal transport, despite the identical ground state spin polarizations in odd- and even numerator states. The results reveal that the neutral spin-waves are both spin and sublattice polarized making them a sensitive probe of ground state sublattice structure. Armed with this understanding, we use nonlocal transport signal to a magnetic field tuned isospin phase transition, showing that the emergent even denominator state at $\nu = 1/2$ in monolayer graphene is indeed a multicomponent state featuring equal populations on each sublattice.

12:39PM B54.00008: Microscopic theory of fractional excitations in gapless bilayer quantum Hall states: semi-quantized quantum Hall states*  
OGUZ TURKER, TOBIAS MENG (Presenter), Tech Univ Dresden — Recent experiments in quantum Hall bilayer systems have revealed a new strongly correlated state: the semi-quantized quantum Hall state. This state arises in a bilayer quantum Hall system with strong interlayer-interactions, has a quantized Hall resistance and vanishing longitudinal resistance, while at the same time featuring a gapless sector that allows this state to exist for a continuum of filling factors. In this talk, I will explain what a semi-quantized quantum Hall state is, and use a coupled-wire construction to predict possible future experiments in the already existing experimental platforms.

Non-linear transport and noise measurements in reentrant integer quantum Hall states*  JIAN SUN (Presenter), JIASEN NIU, International Center for Quantum Materials, Peking University, PENGJIE WANG, Department of Physics, Princeton University, YANG LIU, International Center for Quantum Materials, Peking University, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, XI LIN, International Center for Quantum Materials, Peking University — Two-dimensional electron gas (2DEG) system in strong magnetic field is an ideal platform to explore interesting physics such as reentrant integer quantum Hall (RIQH) effect in second and higher Landau levels. We have carried out non-linear transport and noise measurements in ultra-high mobility GaAs/AlGaAs 2DEG to study RIQH states in Corbino-geometry samples. By increasing the DC bias gradually, we found the insulating phase of RIQH states disappeared, and the depinning trace can be divided into three regions according to different DC bias values. The narrow-band noise only appears in the middle region.

Edge Mode Engineering and Interferometry in the Quantum Hall Regime

RAJARSHI BHATTACHARYYA (Presenter), MORDEHAI HEIBLUM, DIANA MAHALU, VLADIMIR UMANSKY, Department of Condensed matter Physics, Weizmann Institute of Science — The interference of fractional charges is a much sought after goal in a variety of electronic interferometers. It has been shown before in an electronic Mach-Zehnder interferometer that neutral modes, topological or non-topological (via edge-reconstruction), cause dephasing in the fractional quantum Hall effect regime [1]. Recently interference of fractional charges has been observed in an electronic Fabry-Perot interferometer [2], though anionic statistics was not revealed. Here, we have adapted a novel route of engineering edge channels away from the physical boundary in order to minimize edge reconstruction. First, we show that these engineered edge channels, especially fractional ones, can have different edge structures (with a different thermal conductance) compared to ubiquitous edge channels that have the same electrical conductance. We then used a modified Mach-Zehnder interferometer to interfere such synthetic edge modes, with initial promising results.

1:15PM B54.00011: Paired Electron Additions to Fractional Quantum Hall Edge States in Large GaAs Quantum Dots*  SAMUEL ARONSON (Presenter), AHMET DEMIR, NEAL EDWARD STALEY, SPENCER TOMARKEN, Massachusetts Institute of Technology MIT, KENNETH WEST, K. W. BALDWIN, LOREN PFEIFFER, Electrical Engineering, Princeton University, RAYMOND ASHOORI, Massachusetts Institute of Technology MIT — We measure capacitance signals from additions of single electrons to a large (0.8 μm) 2D GaAs quantum dot and thereby determine the energies required to add electrons to the dot. The dot is sandwiched inside of a “tunnel capacitor” in which electrons can tunnel from the dot to a nearby capacitor electrode. We observe single electron capacitance peaks to edge states over a wide range of filling factors. As a function of magnetic flux through the dot, between filling factors ν = 1 and ν = 2, these edge state peaks are regularly spaced, with periodicity h/e. Surprisingly, over the range ν = 2 to ν = 5, the peaks have double-height, and the periodicity is halved to h/2e. The pairing cannot be explained in the Coulomb blockade picture, in which the two electrons in a pair would instead be separated by a charging energy, and models involving electron rearrangements fail because they predict a suppression of tunneling rates that we do not observe. Instead the sequence of successive paired tunneling events behaves in the same way as tunneling of electrons into superconducting quantum dots.

*Supported by the DOE Office of Science BES, FG02-08ER46514, and the Gordon and Betty Moore Foundation, GBMF2931. S. Aronson is supported by NSF Graduate Research Fellowship Program, Grant No. 1122374.

1:27PM B54.00012: Fabry-Perot interferometry of fractional quantum Hall edge states  JAMES NAKAMURA (Presenter), SAEED FALLAHI, HARSAD SAHASRABUDHE, SHUANG LIANG, GEOFF C GARDNER, MICHAEL MANFRA, Physics, Purdue University — Electronic interferometry has been proposed as an experimental probe of the braiding statistics and quasiparticle charge in quantum Hall states. Two significant challenges in Fabry-Perot interferometers are Coulomb charging effects and poor phase coherence. We have overcome these challenges using a novel GaAs/AlGaAs heterostructure which utilizes auxiliary GaAs screening wells in addition to the primary quantum well in order to screen and suppress Coulomb charging effects. This heterostructure design has enabled measurements of robust Aharonov-Bohm interfere at the ν = 1/3 fractional quantum Hall state. A recent theoretical work has predicted a shift in the interference pattern at ν = 1/3 when the magnetic field is varied from the center of the plateau. We present experimental measurements of Aharonov-Bohm interference across the 1/3 plateau. These results represent progress towards direct observation of anyonic braiding statistics.
1:39PM B54.00013: Phase Diagram of Majorana Island

JIE SHEN (Presenter), Delft University of Technology, GEORG WOLFGANG WINKLER, Microsoft Station Q, University of California Santa Barbara, FRANCESCO BORSOI, Delft University of Technology, SEBASTIAN HEEDT, Microsoft Quantum Lab Delft, VUKAN LEVAJAC, Delft University of Technology, SASA GAZIBEGOVIC, ROY OP HET VELD, Eindhoven University of Technology, JOON SUE LEE, MIHIR PENDHARKAR, CONNOR DEMPSEY, CHRIS PALMSTROM, University of California Santa Barbara, ERIK P.A.M. BAKKERS, Eindhoven University of Technology, BERNARD VAN HECK, LEO P. KOUWENHOVEN, Microsoft Quantum Lab Delft — Scalable topological qubit proposals based on semiconductor-superconductor systems are built on Majorana islands hosting pairs of Majorana zero modes. Here, by systematically measuring the periodicity of Coulomb blockade oscillations of InSb/Al island, we reconstruct the ground state parity of the island over large ranges of magnetic field and plunger gate voltage (Vpg). The resulting phase diagram can be divided into three regimes compared with numerical simulations. For negative Vpg, sub-gap states are absent due to strong proximity effect, so the 2e to 1e-periodic transition happens at high B-fields, indicating the poisoning of the superconducting state. For positive Vpg, the 2e-1e transition happens instead at a constant but small B-field. The reason is un-proximitized states quickly disperse below the charging energy due to the orbital effect of the magnetic field. The two regimes are separated by an intermediate regime where the 2e-1e transition field varies smoothly with Vpg, which is the most promising for locating a robust topological phase according to simulations. In this regime, we observe correlated oscillating peak spacing and heights. This complete phase diagram of Majorana island can lead to a guideline to set up a topological qubit in more complicated devices.

1:51PM B54.00014: Wigner Crystal Melting Phase Diagram of GaAs Two-dimensional Holes

MENG MA (Presenter), KEVIN VILLEGAS ROSALES, HAO DENG, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, MANSOUR SHAYEGAN, Princeton University — In a strongly interacting two-dimensional (2D) electron system, when the Coulomb energy dominates over the kinetic energy, the electrons tend to arrange periodically and form a so-called Wigner crystal (WC) ground state. In a GaAs 2D electron system, a magnetic-field-induced quantum WC forms at very low temperature and high magnetic field near filling factor $v = 1/5$ when the kinetic (Fermi) energy is quenched and the Coulomb energy dominates. In an GaAs 2D hole system, on the other hand, the WC phase forms near $v = 1/3$ because of the significant Landau level mixing caused by the large hole effective mass. Despite the fact that the 2D hole system has been a subject of intense interest for many years, a WC melting temperature vs filling factor phase diagram has been missing. In this work, we map out such phase diagram using a newly developed technique which probes the melting of the WC via its screening efficiency. The phase diagram shows rich features of the WC phases at low fillings and a clear reentrant behavior around $v = 1/3$.

*Supported by the DOE BES (DE-FG02-00-ER45841) for measurements, and the NSF (DMR 1709076, ECCS 1906253, and MRSEC DMR 1420541), and the Gordon and Betty Moore Foundation (GBMF4420) for sample fabrication and characterization.

Monday, March 2, 2020 11:15 AM - 2:15 PM
**Session B55 DCMP: Dirac and Weyl semimetals: Experiment** Mile High

**11:15AM B55.00001: Transport properties of topological semimetal candidate ReSbTe (Re = Sm, Nd, Pr)**

RABINDRA BASNET (Presenter), KRISHNA PANDEY, AARON WEGNER, JIN HU, Univ of Arkansas-Fayetteville — The breakthrough in the discovery of topological semimetals provides opportunities to explore the exotic properties of relativistic fermions in condensed matter. Recently, the nonsymmorphic compound ReSbTe (Re = rare earth) has attracted interested owing to its non-trivial topological electronic state. Here we present the magnetic transport properties of these topological semimetal candidates that uncovers it's electronic and magnetic properties. The coupling of magnetism and electronic properties, plus the variation of magnetism for different rare earth compound, make this material family a tunable platform for investigating topological fermion physics and for further exploration of electronic and spintronic science and applications.

*We acknowledge support from DoE award DE-SC0019467*

**11:27AM B55.00002: Anomalous Hall effect in epitaxial WTe$_2$/VTe$_2$ heterostructures**

JASON TRAN (Presenter), JUNXUE LI, JING SHI, PENG WEI, Department of Physics and Astronomy, University of California, Riverside — The Td (orthorhombic) phase of WTe$_2$, a transition metal dichalcogenide (TMD), is a type-II Weyl semimetal (WSM) when a few monolayer thick. Topological semimetals with broken time-reversal symmetry have recently garnered attention due to the ability to manipulate Weyl nodes, causing interesting electro-magnetic responses. Realizing a magnetic WSM in the thin film form, however, is challenging. In this talk, we present our studies on the magnetic properties of WTe$_2$/VTe$_2$ thin film heterostructures. Using molecular beam epitaxy, we grow WTe$_2$ in its Td phase confirmed by in situ reflection high energy electron diffraction. Ultra-smooth film showing atomic terraces and Raman spectroscopy confirm film quality. We perform systematic transport measurements on WTe$_2$/VTe$_2$ heterostructures with vanadium doping to form (W$_{1-x}$V$_x$)Te$_2$, varying x from 0% to 20%. V-doping also changes the Fermi level in WTe$_2$ and induces a carrier type change. An anomalous Hall effect (AHE) signal is observed, whose magnitude varies with the doping level, reaching a minimum near the charge compensation point. The sign of AHE does not change with carrier type. The origin of the AHE will be discussed.

*Acknowledgement: Spins and Heat in Nanoscale Electronic Systems (SHINES), the DOE-EFRC center under Award # SC0012670.*
Surface chiral metal in the bulk half-integer quantum Hall effect of BaMnSb$_2$* Jinyu Liu, Tulane Univ, Jabin Yu, Pennsylvania State University, Jinliang Ning, Tulane Univ, Leixin Miao, Lujin Min, Kleyser E Agueda Lopez, Yanglin Zhu, Hemian Yi, Timothy Pillsbury, Pennsylvania State University, Yubo Zhang, Tulane Univ, Yubu Wang, Pennsylvania State University, Jin Hu, University of Arkansas, Huiibo Cao, Oak Ridge National Laboratory, Fedor Balakirev, Franziska Weickert, Marcelo Jaime, Los Alamos National Laboratory, Kun Yang, National High Magnetic Field Laboratory, Jianwei Sun, Tulane Univ, Nasim Alem, Venkatraman Gopalan, Cui-Zu Chang, Nitin Samarth, Chaoxing Liu, Pennsylvania State University, Ross McDonald, Los Alamos National Laboratory, Zhiqiang Mao (Presenter), Pennsylvania State University

The study of Quantum Hall effect (QHE) in two-dimensional (2D) systems such as 2D electron gas and graphene has led to important breakthroughs in the development of many new concepts in modern physics. Although the QHE is not generally expected for bulk materials due to the band dispersion along the magnetic field direction, bulk QHE has been observed in a few materials such as Cd$_3$As$_2$ (1), ZrTe$_5$ (2) and EuMnBi$_2$ (3). In this talk, we report a unique bulk half-integer QHE observed in a layered Dirac semimetal BaMnSb$_2$.

In the extreme quantum limit, its quantum Hall state is accompanied by two-dimensional chiral metal at the surface, which represents a novel quantum liquid, never observed in any other bulk single crystal materials [4]. This finding establishes a promising experimental platform which not only provides access to 3D interacting topological states, but also offers opportunities to investigate the novel physics of 2D chiral metal.

11:51AM B55.00004: Towards Weyltronics: Realization of epitaxial NbP and TaP Weyl Semimetal thin films  AMILCAR BEDOYA PINTO (Presenter), AVANINDRA PANDEYA, DEFA LIU, HAKAN DENIZ, KAI CHANG, HENGXIN TAN, HYEON HAN, JAGANNATH JENA, ILYA KOSTANOVSKIY, STUART PARKIN, Max Planck Inst Microstructure — Weyl Semimetals (WSMs), a recently discovered topological state of matter, exhibit an electronic structure governed by linear band dispersions and degeneracy (Weyl) points leading to rich physical phenomena, which are yet to be exploited in thin film devices. While WSMs were established in the monopnictide compound family several years ago, the growth of thin films has remained a challenge. Here, we report the growth of epitaxial thin films of NbP and TaP by means of molecular beam epitaxy. Single crystalline films are grown on MgO (001) substrates using thin Nb (Ta) buffer layers, and are found to be tensile strained (1%) and with slightly P-rich stoichiometry with respect to the bulk crystals. The resulting electronic structure exhibits topological surface states characteristic of a P-terminated surface and linear dispersion bands in agreement with the calculated band structure, along with a Fermi-level shift of -0.2 eV with respect to the Weyl points. The growth of epitaxial thin films opens up the use of strain and controlled doping to access and tune the electronic structure of Weyl Semimetals on demand, paving the way for the rational design and fabrication of electronic devices ruled by topology.

12:03PM B55.00005: Experimental electronic structure of the switchable, topological, antiferromagnet CuMnAs  ANDREW LINN (Presenter), KYLE GORDON, PEIPEI HAO, BRYAN BERGGREN, University of Colorado, Boulder, SONKA REIMERS, University of Nottingham, NATHANIEL SPEISER, DUSHYANT NARAYAN, University of Colorado, Boulder, LIBOR SMEJKAL, Johannes Gutenberg-Universität Mainz, TOMAS JUNGWIRTH, PETER WADLEY, University of Nottingham, DANIEL STEPHEN DESSAU, University of Colorado, Boulder — Electrical switching and read out of the AFM Néel vector orientation in tetragonal CuMnAs has been experimentally demonstrated to be scalable to THz speeds, far exceeding speeds in state-of-the-art memory devices today. Additionally, CuMnAs is predicted to host two Dirac points protected by a nonsymorphic, glide mirror plane symmetry, which may or may not exist depending on the orientation of the Néel vector, offering the possibility of opening and closing a gap at the Dirac point at THz speeds. Until now, we lacked experimental confirmation of the predicted electronic band structure, but here we report the electronic structure of tetragonal CuMnAs experimentally measured with ARPES, which we compare to DFT. We performed experiments on the (001) surface of tetragonal CuMnAs thin films, measuring Fermi surfaces, kz dispersion, and high symmetry cuts.
12:15PM B55.00006: Temperature dependent infrared spectroscopy of PrAlSi* CATALIN MARTIN (Presenter), AASHISH POUDEL, IHOR SYDORYK, Ramapo College of NJ, Mahwah NJ, 07430, RODICA M MARTIN, Montclair State University, Montclair NJ, 07043, HALYNA HODOVANETS, HYUNSOO KIM, JOHNPIERRE PAGLIONE, Maryland Quantum Materials Center, Department of Physics, University of Maryland-College Park, College Park, Maryland 20742 — PrAlSi has been shown recently to provide a new platform for studying Weyl fermions and related effects, such as the anomalous Hall effect. In order to better understand the electronic and magnetic properties of its ground state, we performed temperature dependent optical reflectance measurements of single crystals of PrAlSi. The reflectance was measured between 80 cm\textsuperscript{-1} to 50,000 cm\textsuperscript{-1}, at temperatures between 300 K and 5 K. The Drude peak sharpens with decreasing temperature, consistent with metallic behavior and in good agreement with dc resistivity measurements. From Kramers-Kronig analysis, we obtained various optical functions and here we focus in particular on the evolution of the spectral weight with temperature and energy in PrAlSi.

*This work is supported by the National Science Foundation through grant No. 1625882.

12:27PM B55.00007: Planar Hall Effect in the Magnetic Weyl Semimetal Co\textsubscript{3}Sn\textsubscript{2}S\textsubscript{2}† SHAMA MONGA (Presenter), RADHE GOPAL, YOGESH SINGH, IISER Mohali — We have done the detailed magneto-transport study on single crystals of magnetic Weyl Semimetal Co\textsubscript{3}Sn\textsubscript{2}S\textsubscript{2}. Recently Liu et al. (Nat. Phys. 14, 1125 (2018)) have observed large anomalous Hall Effect and chiral anomaly in this material which has been suggested to be related to the large berry curvature between the Weyl points. Another effect that is expected to result from the topological band structure of magnetic Weyl materials is the Planar Hall Effect (PHE). We observed this intrinsic effect in single crystals of Co\textsubscript{3}Sn\textsubscript{2}S\textsubscript{2}. Crucially, the PHE is observed for temperatures T < 74 K which is much smaller than the ferromagnetic ordering temperature T\textsubscript{C} = 175 K indicating non-magnetic origin. Furthermore, we found the large anomalous Hall conductivity, which supports the Topological character of Co\textsubscript{3}Sn\textsubscript{2}S\textsubscript{2}. Additionally, we have probed PHE and anomalous Hall conductivity in this Weyl semimetal as a function of the location of the chemical potential with respect to the Weyl nodes.

†We acknowledge the use of the x-ray and SEM facilities at IISER Mohali. We thank Dr. Suvankar Chakraverty from INST, Mohali for the use of his PPMS for some of our measurements.
12:39PM B55.00008: Giant magneto-optical effect in the magnetic Weyl semimetal \(\text{Co}_3\text{Sn}_2\text{S}_2\)

YOSHIHIRO OKAMURA (Presenter), JO MURAMOTO, Univ of Tokyo, SUSUMU MINAMI, Kanazawa University, YOSHIHIRO KATO, YUKAKO FUJISHIRO, Univ of Tokyo, YOSHIO KANEKO, RIKEN CEMS, RYOMA KANEKO, KENTARO UEDA, Univ of Tokyo, VILMOS KOCSIS, RIKEN CEMS, NAOYA KANAZAWA, Univ of Tokyo, YASUJIRO TAGUCHI, RIKEN CEMS, TAKASHI KORETSUME, Tohoku University, RYOTARO ARITA, Univ of Tokyo, YOSHINORI TOKURA, RIKEN CEMS, YOUTAROU TAKAHASHI, Univ of Tokyo — The search for the topological materials has rapidly developed and novel phase of matter has been extensively proposed in recent years. In particular, the discovery of the Weyl semimetal (WSM), which has a pair of the Wey points with intense Berry curvature, is the important advance in this field. While the WSM shows various giant/functional electromagnetic phenomena such as the nonlinear optical effects and anomalous Hall effect (AHE), the direct evidence that the Weyl point plays the decisive role for those phenomena is still lacking. In this presentation, we will report the magneto-optical study on the recently discovered magnetic WSM \(\text{Co}_3\text{Sn}_2\text{S}_2\) with the giant AHE. The magneto-optical Kerr effect (MOKE) and first-principles calculations reveal that the optical Hall conductivity spectra are significantly dominated by the interband transition upon the nodal ring structures and the Weyl points. This observation demonstrates that those electronic structures play the decisive roles for the giant intrinsic AHE. We will also discuss the MOKE, which is exceptionally large compared with the conventional ferromagnetic metals.

12:51PM B55.00009: Extreme Electron-Phonon Coupling in a New Weyl Semimetal

VINCENT PLISSON (Presenter), KEN BURCH, FAZEL TAFTI, Boston College — Weyl semimetals are topological systems that have generated considerable interest due to their transport properties. One of the mechanisms that may play an important role in the manifestation of these transport properties is electron-phonon coupling. Previous optical experiments done on various Weyl semimetals have already shown phonon linewidths deviating from the usual model of anharmonic decay. Here we report on Raman measurements performed on a new Weyl semimetal. Careful analysis reveals the lifetime is consistent with electron-phonon coupling far in excess of the anharmonic decay channels.
Doping induced topological phase transition in WTe2*  

ANTONIO ROSSI (Presenter), GIACOMO RESTA, Physics, University of California, Davis, SENG HUAT LEE, RONALD REDWING, MRI, Penn State University, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, ALS, Lawrence Berkeley National Lab, SERGEY SAVRASOV, INNA VISHIK, Physics, University of California, Davis — WTe2 exhibits diverse phenomena including non-saturating magnetoresistance in its bulk with predicted type-II Weyl semimetal electronic structure, superconductivity under hydrostatic pressure, quantum spin hall insulator (QSHI) in its monolayer limit, and superconductivity in the gated monolayer. In many of these transformations, the tuning of the carrier density plays an important role. We report two non-monotonic changes in the electronic structure of WTe2 upon in-situ electron doping, realizing occupation near the chemical potential as a pathway for tuning structure and behavior of 2D materials. The first phase transition is understood in terms of the extra charge inducing a shear mode that triggers the recombination of the Weyl points, lifting the topological nature of the bands. This topological switching behavior is relevant for gate-controlled topological transistors or for producing lateral interfaces within a single material host via differential doping. The second phase transition is most consistent with a electrons in a 2D K-overlayer hybridizing with the WTe2 host, broadly relevant to understanding interactions with metallic contacts in devices constructed from 2D materials.

Electronic Correlations in Nodal-line Semimetals  

YINMING SHAO (Presenter), Columbia University, ALEXANDER N. RUDENKO, Wuhan University, JIN HU, University of Arkansas, ZHIYUAN SUN, Columbia University, YANGLIN ZHU, Pennsylvania State University, SEONGPHILL MOON, National High Magnetic Field Laboratory, ANDREW MILLIS, Columbia University, SHENGJUN YUAN, Wuhan University, ALEXANDER I. LICHTENSTEIN, University of Hamburg, DMITRY SMIRNOV, National High Magnetic Field Laboratory, ZHIQIANG MAO, Pennsylvania State University, MIKHAIL KATSNELSON, Radboud University, DMITRI BASOV, Columbia University — Dirac fermions with highly-dispersive linear bands are usually considered weakly correlated, due to relatively large bandwidths (W) compared to Coulomb interactions (U). With the discovery of nodal-line semimetals, the notion of Dirac point has been extended to lines and loops in the momentum space. The anisotropy associated with nodal-line structure gives rise to greatly reduced kinetic energy along the line. However, experimental evidence for anticipated enhanced correlations in nodal-line semimetals is sparse. Here we report on prominent correlation effects in a nodal-line semimetal compound ZrSiSe through a combination of optical spectroscopy and density-functional-theory calculations. We observed two fundamental spectroscopic hallmarks of electronic correlations: strong reduction (1/3) of the free carrier Drude weight and of the Fermi velocity compared to predictions of density functional band theory. The renormalization of Fermi velocity can be further controlled with external magnetic field. ZrSiSe therefore offers the rare opportunity to investigate correlation-driven physics in a Dirac system.
Correlated Dirac Semimetal State with Highly Mobile Electrons in Perovskite $\text{CaIrO}_3$

RINSUKE YAMADA (Presenter), University of Tokyo, JUN FUJIOKA, University of Tsukuba, MINORU KAWAMURA, SHIRO SAKAI, MOTOAKI HIRAYAMA, RIKEN Center for Emergent Matter Science, RYOTARO ARITA, TATSUYA OKAWA, University of Tokyo, DAISUKE HASHIZUME, MANABU HOSHINO, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science — The interplay between electron correlation and quantum topology of Dirac electrons have been a subject of great interest. The perovskite $\text{AlIrO}_3$ ($A=$Ca, Sr, Ba) is a candidate of Dirac semimetal with the sufficiently strong correlation on the verge of Mott transition[1]. Although the Dirac band dispersion has been observed by the angle resolved photoemission spectroscopy[2], the quantum transport originating from highly mobile Dirac fermions has been rarely observed in this class of strongly correlated topological semimetals.

In this study, we report the unique quantum transport phenomena of correlated Dirac electrons in perovskite $\text{CaIrO}_3$ with the Mott criticality[3]. We found that the electron mobility exceeds 60,000 cm$^2$/Vs and the giant magnetoresistance emerges in the quantum limit of the Dirac electrons. Combined with ab-initio calculations, we conclude that the interplay between electron correlation and spin-orbit interaction causes the remarkable proximity of Dirac node to the Fermi energy, yielding the highly mobile electrons. In the presentation, the origin of the giant magnetoresistance will also be discussed.

Unraveling the Topological Phase of ZrTe$_5$ via Magneto-infrared Spectroscopy*

YUXUAN JIANG (Presenter), Natl High Magnetic Field Lab, JINGYUE WANG, School of Physics, Peking University, TIANHAO ZHAO, ZHILING DUN, School of Physics, Georgia Institute of Technology, QING HUANG, Department of Physics and Astronomy, University of Tennessee, Knoxville, XIAOSONG WU, School of Physics, Peking University, MARTIN MOURIGAL, School of Physics, Georgia Institute of Technology, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, MYKHAYLO OZEROV, DMITRY SMIRNOV, Natl High Magnetic Field Lab, ZHIGANG JIANG, School of Physics, Georgia Institute of Technology — We have systematically studied the 3D band structure of ZrTe$_5$ up to its parabolic band components using magneto-infrared spectroscopy. By comparing the Landau level transitions in different magnetic field orientations, we find that the band velocities are highly anisotropic and the dominant contribution along the layer stacking direction is parabolic with a record-low band velocity. More interestingly, with such a low band velocity, we have both theoretically and experimentally demonstrated that the band inversion can lead to a second extremum (band gap), allowing for a direct probe of the material’s topological nature. Our work not only provides an alternative way to identify the band inversion in 3D layered topological materials, but also yields important implications for understanding the exotic behavior of ZrTe$_5$ as well as that in similar (layered) materials.

1:51PM B55.00014: Observation of fractional states in the three-dimensional quantum Hall regime of HfTe$_5$

STANISLAW GALESKI (Presenter), Chemical Physics of Solids, Max Planck Institute, WENLIANG ZHU, Institute of Physics and Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, SHASHANK HONNALI SUDHEENDRA, RAFAL WAWRZYNCZAK, NEETU LAMBA, ANASTASIOS MARKOU, CLAUDIA FELSER, Chemical Physics of Solids, Max Planck Institute, GENFU CHEN, Institute of Physics and Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, JOHANNES GOOTH, Chemical Physics of Solids, Max Planck Institute

Interacting electrons in two dimensions can bind magnetic flux lines to form composite quasiparticles with fractional electric charge. Existence of such states manifests itself by the occurrence of the Fractional Quantum Hall Effect (FQHE). Although similar composite quasiparticles have been predicted to occur in three dimensions, their experimental realization remained elusive. In this talk, we report the observation of fractional plateaus in the Hall conductivity of the bulk semimetal HfTe$_5$. The plateaus are accompanied by Shubnikov-de-Haas minima of the longitudinal electrical resistivity. The height of the Hall plateaus is given by twice the Fermi wave vector in the direction of the applied magnetic field and scales with integer and particular fractional multiples of the conductance quantum. Our findings are consistent with the 3D FQHE, suggesting the existence of quasiparticles with fractional electric charge in a 3D crystal.

2:03PM B55.00015: Fermi Surface Topology and Evidence of Non-trivial Berry Phase in the Flat-band Semimetal Pd$_3$Pb*

MOJAMMEL ALAM KHAN (Presenter), NIRMAL GHIMIRE, TERENCE BRETZ-SULLIVAN, ANAND BHATTACHARYA, J SAMUEL JIANG, Argonne Natl Lab, PO-HAO CHANG, George Mason University, JOHN SINGLETON, Los Alamos National Laboratory, JOHN MITCHELL, Argonne Natl Lab — We present a study of the Fermi surface of the putative triple point topological semimetal Pd$_3$Pb carried out by measuring Shubnikov-de Haas (SdH) oscillations in fields of up to 60 T. A multi-sheet Fermi surface has been reconstructed from the oscillation data and is largely in agreement with DFT calculations, albeit with a Fermi level shifted slightly (~30 meV) by small electron doping. A Berry-phase analysis of the SdH oscillations reveals a non-trivial phase for two bands along high symmetry directions, confirming the topological nature of Pd$_3$Pb. Importantly, the phase of the oscillation shows an angular dependence with respect to the direction of the applied magnetic field. With the signature of a topological phase transition to a trivial phase, this angular dependence may signify a unique identity of the evolution of triple point fermionic states under field.

Session B56 DCMP GMAG: Kagome and Triangular Lattice Magnetism

Mile High Ballroom 2C - Gyanendra Dhakal, Univ of Central Florida
11:15AM B56.00001: Valence bond phases of herbertsmithite and related copper kagome materials*  
MICHAEL NORMAN (Presenter), Materials Science Division, Argonne National Lab,  
NICHOLAS LAURITA, DAVID HSIEH, Department of Physics, California Institute of Technology — Recent evidence from magnetic torque, electron spin resonance, and second harmonic generation indicate that the prototypical quantum spin liquid candidate, herbertsmithite, has a symmetry lower than its x-ray refined trigonal space group. Here, we consider known and possible distortions of this mineral class, along with related copper kagome oxides and fluorides, relate these to possible valence bond patterns, and comment on their relevance to the physics of these interesting materials.

*Work by MRN is supported by the US DOE, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. NJL acknowledges support from the Institute for Quantum Information and Matter Postdoctoral Fellowship.

11:27AM B56.00002: Evidence for a parity broken monoclinic ground state in the S = 1/2 Kagome antiferromagnet Herbertsmithite  
NICHOLAS LAURITA (Presenter), ALON RON, Institute for Quantum Information and Matter, California Institute of Technology, JEONG WOO HAN, JONGSEOK LEE, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, ALLEN SCHEIE, Institute for Quantum Matter, Johns Hopkins University, JOHN P SHECKELTON, REBECCA SMAHA, WEI HE, JIAJIA WEN, YOUNG SANG LEE, Department of Applied Physics, Stanford University, MICHAEL NORMAN, Materials Science Division, Argonne National Laboratory, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology — Nearest neighbor interacting S = ½ spins on the ideal Kagomé lattice have been predicted to form a variety of novel quantum entangled states, including quantum spin-liquid (SL) and valence bond solid phases. However, in real materials, the presence of additional perturbative spin interactions may greatly expand the variety of entangled states, which recent theoretical analyses have shown are identifiable through the spontaneous loss of particular discrete point group symmetries. Here we comprehensively resolve the ground state point group symmetries of the prototypical Kagomé SL candidate ZnCu$_3$(OH)$_6$Cl$_2$ (Herbertsmithite) using a combination of optical ellipsometry and wavelength-dependent multi-harmonic optical polarimetry. We uncover a subtle parity breaking monoclinic structural distortion well above the nearest neighbor exchange energy scale. Surprisingly, the parity-breaking order parameter is dramatically enhanced upon cooling and closely tracks the build-up of nearest neighbor spin correlations, suggesting that it is energetically favored by the SL state. The refined low temperature symmetry group greatly restricts the number of viable ground states, and, in the perturbative limit, points toward the formation of a nematic SL ground state, a SL analogue of a liquid crystal.
**11:39AM B56.00003: Magnetism on ideal triangular lattices in NaBaYb(BO$_3$)$_2$**  
ALIREZA GHASEMI (Presenter), Johns Hopkins University, SHU GUO, ROBERT J. CAVA, Chemistry, Princeton University, COLLIN LESLIE BROHOLM, Johns Hopkins University — In the search for compounds that have a stable spin liquid phase, the triangular lattice of Yb is of interest. Frustration combined with the quantum spin-orbital degree of freedom of Yb provides potentially favorable conditions for a quantum spin liquid. Here we study NaBaYb(BO$_3$)$_2$, which has two different triangular layers of Yb; one sandwiched between two layers of Na, the other between two layers of Ba. Here we discuss, the low-temperature heat capacity and susceptibility of this compound. Our high-field heat capacity data and susceptibility data indicate Yb$^{3+}$ has a Kramers doublet ground state. From lower field data where the Schottky anomaly moves to lower T, we infer the energy scale of inter-site interactions is similar to that of magnetic dipole interactions. While we find a small anomaly in the zero-field heat capacity at 0.41(2)K, most of the Rln2 magnetic entropy is retained to the lowest T=0.1 K accessed here [1].

**11:51AM B56.00004: Magnetic and charge susceptibilities in the half-filled triangular lattice Hubbard model**  
SHAOZHI LI (Presenter), EMANUEL GULL, Univ of Michigan - Ann Arbor — The spin spectra of a triangular system have been studied extensively using the Heisenberg model. But for a correlated metallic triangular system, where the Heisenberg model is not valid, the spin properties are unknown. In this talk, I present momentum-dependent magnetic and charge susceptibilities of the half-filled two-dimensional triangular Hubbard model in the metallic, Mott insulating, and crossover regions of parameter space, using the dual fermion approach. In the insulating state, I find strong spin fluctuations at the K point at low energy corresponding to the 120° antiferromagnetic order. The spin spectra of the insulating state are consistent with the inelastic neutron spectra of the triangular compound Ba$_8$CoNb$_6$O$_{24}$. I also find that the spin fluctuations at the K point persist into the metallic phase and move to higher energy. These results are in agreement with the studies of spin-lattice relaxation times in k-(ET)$_2$Cu$_2$(CN)$_3$. Finally, I present charge susceptibilities in different areas of parameter space, which should correspond to momentum-resolved electron-loss spectroscopy measurements on triangular compounds.

12:03PM B56.00005: Topological flat bands in the 3d transition metal-based kagome lattices*  MIN GU KANG (Presenter), Massachusetts Institute of Technology MIT, SHIANG FANG, Department of Physics, Harvard University, LINDA YE, HOI CHUN PO, Massachusetts Institute of Technology MIT, JONATHAN DENLINGER, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Laboratory, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University, JOSEPH G CHECKELSKY, RICCARDO COMIN, Massachusetts Institute of Technology MIT — Electronic flat bands in momentum space, arising from strong localization of electrons in real space, are an ideal stage to realize strong correlation phenomena as highlighted by the recent example of twisted-bilayer graphene. In certain lattice systems, electronic flat bands with nontrivial topology may naturally arise from the combination of geometrical frustration, spin-orbit coupling, and reduced dimensionality, while their experimental realization has been elusive so far. Here, we report the observation of topological flat bands in series of 3d transition metal-based kagome compounds. Using angle-resolved photoemission spectroscopy, we directly show how the dispersion of the flat bands is strongly quenched along all three momentum directions. Spin-orbit coupling opens a large gap at the quadratic band touching point between the Dirac and flat bands, endowing a nonzero $\mathbb{Z}_2$ topological invariant to the flat band. Our observation opens a promising route to engineer novel emergent phases at the crossroad between strong correlated and topological materials.

*This work was supported by the STC Center for Integrated Quantum Materials, NSF Grant No.DMR-1231319, Gordon and Betty Moore Foundation EPIQS Initiative, Grant No. GBMF3848, and ARO Grant No.W911NF-16-1-0034.

12:15PM B56.00006: Localized states of the topological flat bands in the 3d transition metal kagome compound*  SHIANG FANG (Presenter), Department of Physics and Astronomy, Rutgers University, MIN GU KANG, LINDA YE, HOI CHUN PO, Department of Physics, Massachusetts Institute of Technology, JONATHAN DENLINGER, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, E. O. Lawrence Berkeley National Laboratory, JOSEPH G CHECKELSKY, RICCARDO COMIN, Department of Physics, Massachusetts Institute of Technology, EFTHIMIOS KAXIRAS, Harvard University — The kagome lattice can host both Dirac electrons and the flat band in the spectrum. With spin-orbit coupling, the flat band will acquire non-trivial topology. On the other hand, when the kinetic energy scale is quenched as with a flat band, the electron interactions could facilitate the formation of correlated phases. Hence, the kagome lattice system has the potential to open a door to study the interplay between topology and electron correlations. In synthesized kagome compounds, additional degrees of freedom such as the orbitals further enrich the physics. To elucidate the nature of the electronic structure, we perform the ab initio density functional theory calculations. We focus on the 3d transition metal kagome compound with topological flat bands, observed experimentally by angle-resolved photoemission spectroscopy. The effective Hamiltonians of these topological flat bands are investigated with the derivations of Wannier states. The implications of topological obstructions and crystalline symmetries are discussed. These localized Wannier functions with intricate spin and orbital texture in the real space reveal their origin from the frustrated kagome structure.

*This work was supported by STC CIQM, NSF Grant No. DMR-1231319.
**12:27PM B56.00007: Colossal transverse response from non-centrosymmetric kagome ferromagnets**

TOMOYA ASABA (Presenter), SEAN THOMAS, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory — The interest of the anomalous Hall effect (AHE) and anomalous Nernst effect (ANE) has been renewed since the discoveries of large values of the AHE and ANE due to topologically nontrivial origins, and their potential application to spintronics and efficient energy conversion. Good examples are kagome magnets Mn3Sn and Co2MnGa. Among topological materials, in particular, uranium compounds are one of the best candidates to find large responses of AHE and ANE due to the correlated, flat f-band feature and large spin-orbit coupling that is the key ingredient for topology. However, the study of AHE and ANE for uranium compounds has been very sparse with only a few superconducting exceptions. Here, we will present the giant transverse response from uranium kagome ferromagnets. Our results shed light on the potential of uranium compounds as new spintronic and energy-conversion materials.

**12:39PM B56.00008: Wigner solid of charge transfer excitons in Yin-Yang Kagome lattice**

GURJYOT SETHI (Presenter), Materials Science and Engineering, University of Utah, CONGJUN WU, University of California, San Diego, FENG LIU, Materials Science and Engineering, University of Utah — We demonstrate that photo absorption between two enantiomorphic topological flat bands, as hosted in a Yin-Yang Kagome lattice, provides a perfect platform for the realization of excitonic Wigner crystallization. By solving the Bethe Salpeter equation in Tamm Dancoff approximation within a tight-binding framework, we study the flat-band excitons in terms of their binding energy and dispersion. We show that they are charge-transfer excitons, characterized by a constant binding energy (dispersion-less) in momentum space and highly localized electron-hole pair distribution function in real space. By virtue of electronic and excitonic flat bands our results are indicative of excitonic Wigner crystallization. This would be the first-time realization of Wigner solid of charge-transfer excitons in a lattice model. Our findings open the door to further investigation of photo excitation and many-body physics of correlated electrons in multiple flat bands.

*This work was supported by U.S. DOE-BES (Grant No. DE-FG02-04ER46148)
12:51PM B56.00009: Three-colored quantum scars in the kagome quantum antiferromagnet*  Hitesh Chanrai (Presenter), Physics, Florida State University, Arijeet Pal, University College London — Non-equilibrium properties of quantum materials present many intriguing properties, among them athermal behavior, which violates the eigenstate thermalization hypothesis. Such behavior has primarily been observed in disordered systems. More recently, experimental and theoretical evidence for athermal eigenstates, known as "quantum scars", has emerged in non-integrable disorder-free models in one dimension with constrained dynamics. In this work we investigate quantum scar eigenstates and the associated dynamical properties for the two dimensional kagome antiferromagnet. The model we study was previously shown to harbor a special exactly solvable point with three-color ground states, which involves only nearest neighbor XXZ interactions [H. J. Changlani et al. Phys. Rev. Lett. 120, 117202 (2018)]. In particular, we demonstrate the occurrence of low entanglement states spread throughout the middle of the spectrum and show quantum revivals for appropriately chosen initial states. We also present natural generalizations of our ideas to higher dimensions.

*We acknowledge start-up funds from Florida State University and the National High Magnetic Field Laboratory which is supported by the National Science Foundation through NSF/DMR-1644779 and the state of Florida.

1:03PM B56.00010: A new quantum spin liquid candidate with Co-based triangular lattice  Ruidan Zhong (Presenter), Shu Guo, Princeton University, Guangyong Xu, Zhijun Xu, National Institute of Standards and Technology, Robert J. Cava, Princeton University — Currently under active study in condensed matter physics, both theoretically and experimentally, are quantum spin liquid (QSL) states. However, the existing QSL candidates all have their intrinsic disadvantages, and solid evidence for quantum fluctuations is scarce. Here, we report a previously unreported compound, Na2BaCo(PO4)2, a geometrically frustrated system with effective spin-1/2 local moments for Co2+ ions on an isotropic two-dimensional (2D) triangular lattice. Magnetic susceptibility and neutron scattering experiments show no magnetic ordering down to 0.05 K. Thermodynamic measurements show that there is a tremendous amount of magnetic entropy present below 1 K in zero magnetic field. The presence of localized low-energy spin fluctuations is revealed by inelastic neutron measurements. At low applied fields, these spin excitations are confined to low energy and contribute to the anomalously large specific heat. In larger applied fields, the system reverts to normal behavior as evident by both neutron and thermodynamic results. Our experimental characterization thus reveals that this material is an excellent candidate for the experimental realization of a QSL state.
1:15PM B56.0001

**SU(4) antiferromagnetism on the triangular lattice**

Anna Kesselman (Presenter), Kavli Institute for Theoretical Physics, University of California, Santa Barbara, Lucile Savary, Laboratoire de physique, École Normale Supérieure de Lyon, Leon Balents, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — In systems with many local degrees of freedom, high-symmetry points in the phase diagram can provide an important starting point for the investigation of their properties throughout the phase diagram. In systems with both spin and orbital (or valley) degrees of freedom, such as twisted multilayer graphene or transition metal dichalcogenides, such a starting point gives rise to SU(4)-symmetric models. Here we consider SU(4)-symmetric “spin” models, corresponding to Mott phases at half-filling, i.e. the six-dimensional representation of SU(4). In particular, we study the SU(4) antiferromagnetic “Heisenberg” model on the triangular lattice, both in the classical limit and in the quantum regime. Carrying out a numerical study using the density matrix renormalization group (DMRG), we argue that the ground state is non-magnetic. We then carry out a dimer expansion of the SU(4) spin model. An exact diagonalization study of the effective dimer model suggests that the ground state breaks translation invariance, forming a valence bond solid (VBS) with a 12-site unit cell. Finally, we consider the effect of SU(4)-symmetry breaking interactions due to Hund’s coupling, and argue for a possible phase transition between a VBS and a magnetically ordered state.

1:27PM B56.0001

**Stability of chiral spin liquid phase of the triangular lattice Hubbard model with hopping anisotropy**

Aaron Szasz (Presenter), Perimeter Institute for Theoretical Physics, Johannes Motruk, Lawrence Berkeley National Laboratory — In our previous work (arXiv:1808.00463), we showed using density matrix renormalization group (DMRG) simulations on infinite cylinders that the triangular lattice Hubbard model hosts a chiral spin liquid phase at intermediate interaction strength. However, the model we studied featured isotropic hopping, whereas real triangular lattice spin liquid candidate materials, such as $\kappa$-(BEDT-TTF)$_2$Cu$_2$(CN)$_3$, are not precisely isotropic. To better connect to experimental results in such spin liquid candidates, in this work we investigate the stability of the chiral spin liquid against anisotropy in the hopping and show that the phase survives, providing further support for the applicability of our findings to experiments.
1:39PM B56.00013: Dynamical DMRG study of spin excitation dynamics in triangular lattice spin-1/2 antiferromagnet  SHIGETOSHI SOTA (Presenter), TOMONORI SHIRAKAWA, SEIJI YUNOKI, RIKEN, TAKAMI TOHYAMA, Tokyo University of Science — Recently, the theoretical understanding of the ground state of frustrated two-dimensional spin-1/2 antiferromagnetic Heisenberg models has been dramatically progressed. In contrast, much less has been understood for the spin excitation dynamics. For example, it is well established by now that 120 degree Néel order appears in the ground state of the triangular lattice spin-1/2 antiferromagnetic Heisenberg model. However, the spin excitation dynamics is still under active debate. In fact, the spin excitations observed by recent neutron scattering for Ba$_3$CoSb$_2$O$_9$, modeled by the triangular lattice spin-1/2 antiferromagnetic Heisenberg model, cannot be explained by the linear spin wave theory. By using the dynamical DMRG method, here we investigate the spin excitation dynamics of the triangular lattice spin-1/2 antiferromagnetic Heisenberg model. We find that our results are in good agreement with the experimental results for Ba$_3$CoSb$_2$O$_9$, implying that the quantum fluctuations beyond the linear spin wave theory play an important role on the spin excitations dynamics of Ba$_3$CoSb$_2$O$_9$.

1:51PM B56.00014: Spin properties of triangular-lattice rare-earth compounds K$_2$CsYb(PO$_4$)$_2$ and K$_2$CsEr(PO$_4$)$_2$  LUWEI GE (Presenter), Physics, Georgia Institute of Technology, QING HUANG, Physics, University of Tennessee, Knoxville, ZHILING DUN, Physics, Georgia Institute of Technology, HAI DONG ZHOU, Physics, University of Tennessee, Knoxville, MARTIN MOURIGAL, Physics, Georgia Institute of Technology — On the way to discover frustrated magnetic materials that realize unconventional phases of matter such as spin liquids, recent attention has been devoted to triangular-lattice materials comprising lanthanoid atoms. Here we report our detailed study of two such rare-earth-based compounds K$_2$CsYb(PO$_4$)$_2$ and K$_2$CsEr(PO$_4$)$_2$, where the magnetic ions form equilateral triangular lattices and where site mixing/distortion effects are absent. In spite of the limited size of the single crystals that we could obtain, we conducted detailed thermomagnetic and inelastic neutron scattering (INS) studies unravelling the spin dynamics and crystal electric field effects in these systems. Our results indicate that exchange interactions are weak and magnetic excitations essentially accounted for by weakly coupled paramagnetic anisotropic effective spin degrees of freedom. We hope our research will benefit future efforts in this exciting line of research.

*The work at Georgia Institute of Technology was supported by NSF-DMR-1750186. The work at University of Tennessee, Knoxville was supported by NSF-DMR-1350002.
Imaging antiferromagnetic domains of $\text{PdCrO}_2$

(Presenter), Lawrence Berkeley National Laboratory, ARIELLE LITTLE, University of California, Berkeley, RITIKA DUSAD, Lawrence Berkeley National Laboratory, ELINA ZHAKINA, PHILIPPA MCGUINNESS, VERONIKA SUNKO, SEUNGYUN KHIM, CLIFFORD W. HICKS, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, JOSEPH ORENSTEIN, University of California, Berkeley — The layered antiferromagnet $\text{PdCrO}_2$ is an exceptionally pure system, providing an ideal platform for studying how magnetic frustration is relieved in a triangular lattice. Here we spatially resolve the antiferromagnetic domains of $\text{PdCrO}_2$ using a novel temperature-modulated birefringence imaging setup. The material undergoes a weakly first-order transition at the Néel temperature (38 K), forming three distinct types of antiferromagnetic domains that are oriented at 120 degrees from one other. The domain structure is observed to reorient after each cooling cycle (upon heating to sufficiently high temperatures), indicating that the domain walls are highly mobile under external perturbations. The effect of strain on the domain population and the phase transition will also be discussed.

Monday, March 2, 2020 11:15 AM - 2:03 PM

Session B57 DMP DCOMP: 2D Semiconductors: Optical Spectroscopy

Manipulating the potential landscape of 2D materials through external dielectric screening [Invited] ARCHANA RAJA (Presenter), Molecular Foundry, Lawrence Berkeley National Laboratory — Atomically thin, quasi two-dimensional (2D) materials like semimetallic graphene and semiconducting transition metal dichalcogenide (TMDC) monolayers have been shown to have extraordinary optoelectronic properties, along with the possibility to tailor physical phenomena by assembling individual layers into novel heterostructures. The interaction between charge carriers in these 2D materials is strongly influenced by the local environment. By tuning the external dielectric screening, the band gap and exciton energies in 2D TMDCs can be modified to create lateral heterojunctions without modifying the material itself [1]. Using a combination of optical and angle-resolved photoemission spectroscopies with microscopic spatial resolution, we show that the band structure rigidly shifts in response to the change in local dielectric screening [2]. Furthermore, this environmental sensitivity can lead to a new type of disorder that leads to spatially inhomogeneous band gap and exciton energies as a consequence of spatial variations in the external dielectric screening rather than any material imperfections [3].

Nano-optical cavity imaging and control of interlayer exciton emission in WSe$_2$/MoSe$_2$ heterostructures

MOLLY A MAY (Presenter), Physics, Chemistry, and JILA, University of Colorado, Boulder, CHENFENG DU, Physics, University of Washington, TAO JIANG, KIYOUNG-DOUG PARK, Physics, Chemistry, and JILA, University of Colorado, Boulder, XIAODONG XU, Physics, University of Washington, MARKUS B. RASCHKE, MARKUS B. RASCHKE, Physics, Chemistry, and JILA, University of Colorado, Boulder — Long lived interlayer excitons in transition metal dichalcogenide heterobilayers hold promise for applications from high temperature exciton condensates to nano-lasers with extended spatial coherence and other 2D optoelectronic devices. However, fundamental properties of interlayer excitons, their relaxation processes, and the mechanism for their formation through interlayer charge tunneling are still poorly understood. Furthermore, new methods for control of interlayer exciton emission and the associated nonradiative decay pathways are desired to establish high temperature exciton condensation and coherent emission. Here, we use a configurable nano-optical cavity based on a plasmonic scanning probe tip to quantify the interlayer exciton lifetime of (39 +/- 8) ps and charge transfer rate of (80 +/- 20) fs at room temperature. Further, using tip-sample force perturbation with deep sub-nm precision, we actively control interlayer exciton formation and tune the competition between nonradiative charge transfer and Purcell enhancement. We discuss the extension of this tip nano-cavity approach to low and variable temperature modalities for nano-spectroscopy, imaging, and control from dark excitons to localized states.

Exciton valley depolarization in two-dimensional MoSe$_2$ and WSe$_2$

MIN YANG (Presenter), DINH VAN TUAN, Department of Electrical and Computer Engineering, University of Rochester, HANAN DERY, Department of Electrical and Computer Engineering & Department of Physics and Astronomy, University of Rochester — The valley degree of freedom is a sought-after quantum number in monolayer transition-metal dichalcogenides. Similar to the spins of electrons and holes, the valley degree of freedom is not a conserved quantity and excitons lose their original helicity over time. Valley depolarization of excitons in monolayer transition-metal dichalcogenides due to long-range electron-hole exchange typically takes a few ps at low temperatures. Exceptions to this behavior are monolayers MoSe$_2$ and MoTe$_2$ wherein the depolarization is much faster. We elucidate the enigmatic anomaly of these materials, finding that it originates from Rashba-induced coupling of the dark and bright exciton branches next to their degeneracy point. When photoexcited excitons scatter during their energy relaxation between states next to the degeneracy region, they reach the light cone after losing the initial helicity. The valley depolarization is not as fast in monolayers WSe$_2$, WS$_2$ and likely MoS$_2$ wherein the Rashba-induced coupling is negligible.

*This work is supported by the Department of Energy, Basic Energy Sciences, under Contract No. DE-SC0014349.
12:15PM B57.00004: Deciphering the rich photoluminescence spectrum of monolayer WSe$_2$. HANAN DERY (Presenter), University of Rochester — High-quality monolayer WSe$_2$ samples when gated and encapsulated by hBN exhibit unprecedented rich photoluminescence spectrum. In this talk, I will summarize what we (think we) already understand, identifying the signatures of dark and indirect excitons as well as of dark trions, along with their zone-center and zone-edge phonon replicas. I will then focus on the signatures of many-body interactions, proposing novel electron-assisted optical transitions of dark excitons and the brightening of these excitons when they are coupled to collective charge or spin excitations (plasmons and magnons). I will explain why these many-body interactions have the right conditions to manifest in the photoluminescence spectra of electron-doped tungsten-based monolayers.

12:27PM B57.00005: Candidates for the origin of many-body spectral features in monolayer WSe$_2$. DINH VAN TUAN (Presenter), HANAN DERY, University of Rochester — The combination of strong Coulomb interaction, spin and valley degrees of freedom give rise to multiple optical peaks in the spectrum of WSe$_2$. While the physics of many peaks has been identified, the origin of a strong low-energy peak in highly electron-doped WSe$_2$ remains elusive since its first observation in 2013 [1]. In this talk, we show possible explanations for the origin of this optical transition including the interaction of excitons with intervalley plasmons [2,3,4], or magnons induced by resident electrons. We explain why the proposed mechanisms are suitable for the peak to emerge in the spectrum of electron-doped WSe$_2$ while being absent in hole-doped regime or in the whole spectrum of MoSe$_2$ monolayer [5].

12:39PM B57.00006: Saddle-point Excitons and Their Extraordinary Light Absorption in Two-Dimensional beta-phase Group-IV Monochalcogenides*  
NANNAN LUO (Presenter), CHONG WANG, ZEYU JIANG, YONG XU, XIAOLONG ZOU, DUAN WENHUI, Tsinghua University — In two-dimensional (2D) materials, saddle-points in the electronic structure give rise to diverging density of states, which leads to intriguing physical phenomena useful for applications, including magnetism, superconductivity, charge density wave, as well as enhanced optical absorption. Using first-principles calculations, we show monolayer beta-phase of group-IV monochalcogenides are a new class of 2D materials that possess saddle-points. Due to the existence of saddle-points, a remarkable absorption peak within the fundamental gap is found in these materials. The properties of saddle-point excitons can be effectively tuned by both the strain and thickness of these materials. Importantly, the strong optical absorbance induced by saddle-point exciton absorptions and the appropriate band gap give ideal power conversion efficiencies as large as 1.11% for monolayer beta-SnSe, significantly higher than reported high-performance ultrathin solar cells using transition metal dichalcogenides. These results not only open new avenues for exploring novel many-body physics, but also suggest beta-phase MXs could be promising candidates for future optoelectronic devices.

12:51PM B57.00007: Temperature dependent valley polarization in WS\(_2\) heterostructures*  
GEORGE KIOSEOGLOU (Presenter), Univ of Crete and IESL/FORTH, IOANNIS PARADISANOS, IESL/FORTH, KATHLEEN M MCCREARY, Naval Research Lab, AUBREY T. HANBICKI, LPS, LEONIDAS MOUCHLIADIS, IESL/FORTH, DAVOUD ADINEHLOO, VASILI PEREBEINOS, University of Buffalo, BEREND THOMAS JONKER, Naval Research Lab, EMMANUEL STRATAKIS, IESL/FORTH — The absence of degeneracy in the valley indices of monolayer-TMDs serves as an essential property for the development of valleytronic devices. One criterion for the realization of such a device is to attain high polarization at RT. We examine vertical WS\(_2\) heterostructures and show that the material type used, significantly influences the valley polarization of WS\(_2\). The interaction between WS\(_2\) and graphene has a strong effect on the T-dependent depolarization, with a polarization of 24% at RT under near-resonant excitation. This contrasts with hBN- encapsulated WS\(_2\), which exhibits a RT polarization of 11%. The low depolarization rate in WS\(_2\)/Graphene is attributed to a) rapid charge and energy transfer processes of the scattered excitons, b) absence of thermal dissociation of trions and thermally assisted dark-to-bright transitions and c) partial suppression of the T-dependent bandgap renormalization. Significant variations in the polarization are also observed at 4K. We propose that intervalley hole scattering in the VB proximity between the K and Γ points of WS\(_2\) is sensitive to the immediate environment, leading to the observed variations.

Tunable Spontaneous Valley Coherence in Atomically Thin Semiconductors

MANDAR SOHONI (Presenter), MURALIDHAR NALABOTHULA, Physics, Indian Institute of Technology, Bombay, PANKAJ JHA, Applied Physics and Material Science, Califormnia Institute of Technology, TONY LOW, Electrical & Computer Engineering, University of Minnesota, ANSHUMAN KUMAR, Physics, Indian Institute of Technology, Bombay — An interesting feature of monolayer transition metal dichalcogenides (TMDCs) is the existence of two degenerate, but disparate, band extrema valleys in k space with different optical selection rules. In order to manipulate this “valley degree of freedom”, we should be able to control, and manipulate the coherence between the two valleys.

In this work we study the spontaneous valley coherence generated in a van der Waals heterostructure created by combining a TMDC with other two dimensional (2D) materials. First, we discuss general results on exploring the parameter space of the optical conductivity tensor of such a system to get the highest values of valley coherence and coherence times. Second, we analyze the spontaneously generated valley coherence for “hybrid” (a mixture of interlayer and intralayer) excitons in a system involving an anisotropic photonic metasurface and a TMDC heterostructure. We study the dependence of the coherence on external tuning knobs such as an electric field, and interlayer coupling in the heterostructure. Our analysis should help the community in designing heterostructures for maximum valley coherence, and help solidify the foundation of the valley degree of freedom as a qubit.

Valley-selective optical Stark shift of exciton-polaritons in a monolayer semiconductor

TREVOR LAMOUNTAIN (Presenter), JOVAN NELSON, ERIK J LENFERINK, AKSHAY MURTHY, VINAYAK D. DRAVID, NATHANIEL PATRICK STERN, Northwestern University — Light provides a high-speed coherent medium for measurement and manipulation of electronic quantum states. Exploiting the optical selection rules of transition metal dicalchogenide monolayers (TMDs), the optical Stark effect allows for valley-selective control of energy levels using sub-resonant optical pulses. Recent discoveries have revealed that microcavity exciton-polaritons in TMDs preserve valley features while also incorporating many of the favorable properties of light. Here, we use polarization-dependent transient reflectance to demonstrate that the optical Stark effect can also be used for valley-selective manipulation of energy levels in WS2 exciton-polaritons. In the reflectance spectra we observe a simultaneous shift of both polariton branches when pump and probe are co-polarized, and no appreciable shift when they are cross-polarized. We find excellent agreement between measured data and a Lorentz oscillator model over a wide range of experimental parameters. The extracted polariton shift confirms the expected linear power dependence of the optical Stark effect. The polarization-dependent Stark shift of TMD exciton-polaritons provides a new tool for state control in coherent valleytronics.

1:27PM B57.00010: Anisotropic Optical Properties and Vibrational Characteristics of 2D Silicon Telluride Nanoplates* JIYANG CHEN (Presenter), ROMAKANTA BHATTARAI, XIAO SHEN, Univ of Memphis, JINGBIAO CUI, The University of North Texas, THANG HOANG, Univ of Memphis — The p-type semiconductor silicon telluride (Si2Te3) has a unique layered crystal structure with hexagonal closed-packed Te sublattices and Si-Si dimers occupying octahedral intercalation sites. The orientation of the silicon dimers leads to unique optical and electronic properties. Here, we report a combined experimental and computational study of the optical properties of individual Si2Te3 nanoplates (NPs). 2D Si2Te3 NPs with thickness of tens to hundreds of nanometers and diameter of tens of micrometers are synthesized by the chemical vapor deposition technique. Polarized reflection measurements at different temperatures show a 90-degree periodic change in the absorption coefficient, which indicates an anisotropic orientation of the Si-Si dimers and is in agreement with the theoretical calculation of the dielectric constants. Polarized and spatial Raman mapping measurements of single Si2Te3 NPs at different temperatures reveal various vibrational modes, which are in agreement with the Density Functional Theory calculation.

1:39PM B57.00011: Anomalous photovoltaic effect in van der Waals heterointerface TOSHIYA IDEUE (Presenter), TAKATOSHI AKAMATSU, The University of Tokyo, LING ZHOU, Nanjing University, SOTA KITAMURA, MASARU ONGA, YUJI NAKAGAWA, The University of Tokyo, JOSEPH LAURIENZO, Case Western Reserve University, JUNWEI HUANG, Nanjing University, TAKAHIRO MORIMOTO, The University of Tokyo, HONGTAO YUAN, Nanjing University, YOSHIHIRO IWASA, The University of Tokyo — Van der Waals interfaces are unique platforms for novel properties and functionalities. In addition to being building blocks for functionalized devices such as p-n junctions or tunneling junctions, symmetry of the van der Waal interface has recently been attracting much attention, represented by Moiré physics in twisted interfaces [1-3] and pseudo landau level formation in graphene/black phosphorus heterostructures [4]. In this talk, I will focus on the effect of symmetry on the photovoltaic effect in van der Waals interface. The anomalous photovoltaic effect, which indicates the emergence of photo-induced spontaneous current without semiconductor p-n junction nor bias voltage, is observed at the symmetry engineered interface. A potential microscopic mechanism of the anomalous photovoltaic effect will be also discussed.

1:51PM B57.00012: Deep-Learning-Based Image Segmentation Integrated with Optical Microscopy for Automatically Searching for Two-Dimensional Materials*  
SATORU MASUBUCHI (Presenter), EISUKE WATANABE, YUTA SEO, IIS, Univ of Tokyo, SHOTA OKAZAKI, TAKAO SASAGAWA, Tokyo Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, Japan, TOMOKI MACHIDA, IIS, Univ of Tokyo — Deep-learning algorithms enable precise image recognition based on high-dimensional hierarchical image features. Here, we report the development and implementation of a deep-learning-based image segmentation algorithm in an autonomous robotic system to search for two-dimensional (2D) materials. We trained the neural network based on Mask-RCNN on annotated optical microscope images of 2D materials (graphene, hBN, MoS2, and WTe2). The inference algorithm is run on a 1024 × 1024 px optical microscope images for 200 ms, enabling the real-time detection of 2D materials. The detection process is robust against changes in the microscopy conditions, such as illumination and color balance, which obviates the parameter-tuning process required for conventional rule-based detection algorithms. Integrating the algorithm with a motorized optical microscope enables the automated searching and cataloging of 2D materials. This development will allow researchers to utilize unlimited amounts of 2D materials simply by exfoliating and running the automated searching process.

B57.00013: Chiral phonon replicas of dark excitonic states in monolayer WSe2  
ERFU LIU (Presenter), JEREMIAH VAN BAREN, University of California, Riverside, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, YIA-CHUNG CHANG, Research Center for Applied Sciences, Academia Sinica, Taipei 11529, Taiwan, CHUN HUNG LUI, University of California, Riverside — We observe a set of replica luminescent peaks below the dark excitonic states (including excitons and trions) in monolayer WSe2. The replica redshift energies match the energies of the zone-center and zone-corner optical phonons. The phonon replicas exhibit parallel gate dependence and same g-factors as the dark excitonic states, but follow the valley selection rules of the bright excitonic states. Our results and symmetry analysis show that a K-valley dark excitonic state can decay into a left-handed chiral phonon and a right-handed photon, whereas a K'-valley dark excitonic state can decay into a right-handed chiral phonon and a left-handed photon. Such valley selection rules of chiral phonon replicas can be utilized to identify the valleys of the dark excitonic states and explore their chiral interactions with phonons.

3B - Adam Wasserman, Purdue Univ - Tag(s): Focus
11:15AM B58.00001: On the Constrained Search-Coordinate Scaling Formulations in DFT

[Invited] MEL LEVY (Presenter), Chemistry and Quantum Theory, Tulane University — First, a review of the early history of DFT is given, including anecdotes, and the constrained-search formulation is presented within the context of this history. Then it is shown how this formulation leads to the derivation of key constraints for approximating density functionals. These constraints include those that involve the coordinate scaling of the total density, and of the individual up and down spin densities, where the use of spin-free wavefunctions for the derivations has very recently proven to be effective.

The utility of expressing the total energies of ground-states and excited states as simple sums of augmented orbital energies shall also be discussed. Then several open problems in DFT shall be presented.

11:51AM B58.00002: Essential difference between the machine learning and artificial Kohn-Sham potentials

RYO NAGAI (Presenter), Department of Physics, The University of Tokyo, KIERON BURKE, Departments of Physics and Astronomy and of Chemistry, University of California, Irvine, RYOSUKE AKASHI, OSAMU SUGINO, Department of Physics, The University of Tokyo — The Kohn-Sham density functional theory is widely used to predict physical or chemical properties of various materials with its practical accuracy and computational cost. Its accuracy depends on the exchange-correlation functional. Although there exist many approximations for the functional, its entire structure is yet elusive since the reference databases and physical conditions available are limited. On the other hand, we develop another strategy; the functional structure is represented with a flexible neural network and its parameters are trained with machine-learning algorithms[1]. The NN-based functional becomes transferable enough by training with the density, which contains abundant information in the 3D space.

Here, we analyze the properties of the machine-learning density functionals. We investigate essential differences between the machine-learned functionals and artificial functionals by comparing their performance using accurate densities and ones from artificial functionals as the training data.

12:03PM B58.00003: Machine learning accurate exchange and correlation functionals of the electronic density*  SEBASTIAN DICK (Presenter), MARIVI FERNANDEZ SERRA, State Univ of NY - Stony Brook — Density Functional Theory (DFT) is the standard formalism to study the electronic structure of matter at the atomic scale. The balance between accuracy and computational cost that DFT-based simulations provide allows researchers to understand the structural and dynamical properties of increasingly large and complex systems at the quantum mechanical level. In Kohn-Sham DFT, this balance depends on the choice of exchange and correlation functional, which only exists in approximate form. Here we propose a framework to create highly accurate density functionals by using supervised machine learning, termed NeuralXC. These machine-learned functionals are designed to lift the accuracy of local and semilocal functionals to that provided by more accurate methods while maintaining their efficiency. We show that the functionals learn a meaningful representation of the physical information contained in the training data, making them transferable across systems. We further demonstrate how a functional optimized for water can reproduce experimental results when used in molecular dynamics simulations.

12:15PM B58.00004: Constrained Machine Learning de-orbitalization of meta-GGA exchange-correlation functionals*  KANUN POKHAREL (Presenter), JAMES FURNESS, JIANWEI SUN, Tulane Univ — Meta-generalized-gradient-approximation (mGGA) exchange-correlation functionals commonly take the orbital kinetic energy density $\tau(r)$ as an ingredient in their construction [1]. Such $\tau(r)$ dependent functionals have shown impressive performance for diverse problems, but orbital dependence of $\tau(r)$ complicates the exchange-correlation potential and increases computational cost. Recently, Rodriguez et.al. constructed a mGGA with laplacian $\nabla^2 n$ without significantly degrading accuracy [2]. This suggests an intriguing but unclear relationship between $\tau(r)$ and $\nabla^2 n$. We exploit this relationship using machine learning combined with exact constraints to explore how neural-network models can de-orbitalize functionals and model fundamental components of Kohn-Sham density functional theory.

**12:27PM B58.00005: Semiclassical Approximation to Sums of Eigenvalues with Application to DFT**

PAVEL OKUN (Presenter), KIERON BURKE, University of California, Irvine — I present a new mathematical framework developed by Kieron Burke and Michael V. Berry for estimating the sum of the lowest N eigenenergies of a one-dimensional potential. I apply this method to several model one-dimensional systems (harmonic oscillator, Poschl-Teller well, quartic oscillator, linear well, and exponential well). This new method gives the sum of the energies as a semiclassical series, which can be shown to reproduce the DFT gradient expansion for slowly varying densities, and also produces a correction to the gradient expansion for finite systems with a discrete spectrum. Explicit corrections to the gradient expansion of the kinetic energy are derived which in simple cases greatly improve accuracy. All work is done assuming a system of non-interacting identical fermions. This research is funded by the NSF (CHE 1856165).

*NSF Grant:CHE 1856165

**12:39PM B58.00006: Progress in the Development of Advanced Temperature-Dependent Free-Energy Density Functionals Beyond the Generalized Gradient Approximation**

DEYAN MIHAYLOV (Presenter), BRENDA MCLELLAN, VALENTIN V KARASIEV, SUXING HU, Laboratory for Laser Energetics, University of Rochester — Recently, it has been shown that explicit dependence on temperature in the exchange-correlation (XC) free-energy density functional is important in density functional theory studies of warm dense matter [1]. As a first approximation, in the attempt to include thermal effects into XC, the finite-T KSDT local spin-density approximation functional was constructed by the analytical parametrization of the XC free energy of the homogeneous electron gas. Consequently, the non-empirical KDT16 [2] generalized gradient approximation (GGA) functional, which captures nonhomogeneity effects and shows better agreement with experiments, has been constructed. Here, we present recent progress in going beyond the GGA by developing finite-T extensions to the PBE0 and SCAN-L (the de-orbitalized version of SCAN) XC functionals. We present preliminary results for optical reflectivity of shocked CH and warm dense He.

Symmetry-Breaking Polymorphous Descriptions for Correlated Materials without Interelectronic $U^*$

YUBO ZHANG, JAMES FURNESS, RUIQI ZHANG, Tulane Univ, ZHI WANG, ALEX ZUNGER, university of colorado, JIANWEI SUN (Presenter), Tulane Univ — Correlated materials with open-shell $d$- and $f$-ions having degenerate band edge states show a rich variety of interesting properties. The textbook view for the electronic structure of these materials is that mean-field approaches are inappropriate, as the interelectronic interaction $U$ is required to open a band gap between the occupied and unoccupied degenerate states while retaining symmetry. We show that the mean-field band theory can lift such degeneracies when nontrivial unit cell representations (polymorphous networks) are allowed to break symmetry, in conjunction with a recently developed non-empirical exchange and correlation density functional without an on-site interelectronic interaction $U$. We rationalize how density functional theory (DFT) in the polymorphous representation achieves band gap opening in correlated materials through a separate mechanism to the Mott-Hubbard approach. We show the method predicts magnetic moments and gaps for four classical $3d$ transition-metal monoxides in both the antiferromagnetic and paramagnetic phases, offering a highly-efficient alternative to symmetry-conserving approaches for studying a range of functionalities in open $d$- and $f$-shell complex materials.

A step in the direction of resolving the paradox of Perdew-Zunger self-interaction correction*

RAJENDRA ZOPE (Presenter), YOH YAMAMOTO, CARLOS DIAZ, TUNNA BARUAH, University of Texas at El Paso, JUAN PERALTA, KOBLAR ALAN JACKSON, Central Michigan University, BISWAJIT SANTRA, JOHN P. PERDEW, Temple University — Self-interaction (SI) error, which results when exchange-correlation contributions to the total energy are approximated,limits the reliability of many density functional approximations. The Perdew-Zunger SI correction (PZSIC), when applied in conjunction with the local spin density approximation (LSDA), improves the description of many properties, but overall, this improvement is limited. Here we propose a modification to PZSIC that uses an iso-orbital indicator to identify regions where local SI corrections should be applied. Using this local-scaling SIC (LSIC) approach with LSDA, we analyze predictions for a wide range of properties including, for atoms, total energies, ionization potentials, and electron affinities, and for molecules, atomization energies, dissociation energy curves, reaction energies, and reaction barrier heights. LSIC preserves the results of PZSIC-LSDA for properties where it is successful and provides dramatic improvements for many of the other properties studied. Atomization energies calculated using LSIC are better than those of the Perdew, Burke, and Ernzerhof (PBE) generalized gradient approximation (GGA). LSIC also restores the uniform gas limit for the exchange energy that is lost in PZSIC-LSDA.

*U.S. DOE under grants DE-SC0018331 and DE-SC0006818.
1:15PM B58.00009: Kohn-Sham effective potentials from FLOSIC using Ryabinkin-Kohut-Staroverov method*  
CARLOS DIAZ (Presenter), LUIS BASURTO, RAJENDRA ZOPE, University of Texas, El Paso — Density functional or beyond methods are often used in combination with photoelectron spectroscopy to obtain physical insights about the electronic structure of molecules and solids. The Kohn-Sham eigenvalues are not electron removal energies except for the highest occupied one, but they often, though not always, provide good approximations to electron binding energies (EBEs). Eigenvalues of the range separated hybrid functionals using tuned separation parameter generally provide good approximations to EBEs due to mitigation of self-interaction (SI) errors. We adapt and implement the Ryabinkin-Kohut-Staroverov method to obtain effective local potentials from the self-interaction corrected Fermi-Lowdin orbitals and density in the FLOSIC code. The density of states and HOMO-LUMO gaps obtained using this approach show much closer agreement with experimental values compared to those obtained with a range of DFA or functionals.

*DE-SC0018331

1:27PM B58.00010: Performance of scaled self-interaction correction to semilocal functionals*  
PUSKAR BHATTARAI (Presenter), CHANDRA SHAHI, KAMAL WAGLE, BISWAJIT SANTRA, JOHN P. PERDEW, Temple Univ — Most semilocal functionals suffer from self-interaction error (SIE). Perdew and Zunger (PZ)\(^1\) applied self-interaction correction (SIC) to each delocalized Kohn-Sham orbital by subtracting the SIE from each occupied orbital. The Fermi-Lowdin orbital self-interaction correction (FLOSIC) uses size-extensive localized Fermi-Lowdin orbitals that improve the results for the properties like barrier heights that involves strong SIE, as in stretched bonds. However, it worsens the equilibrium properties such as atomization energies, as FLOSIC applied to a functional violates the exact constraints and the appropriate norms that the semilocal approximations satisfy\(^2\). Here, we apply a scaled PZ SIC to LSDA, PBE, and SCAN and calculated different properties such as electron affinity, ionization potential, barrier height, atomization energy, and bond length of some representative test sets. We find that the scaled SIC works well for both the equilibrium properties and for the features that involve stretched bonds or noded densities.

Session B59 DMP: Skyrmions and Topological Magnonics Mile High Ballroom 3C
11:15AM B59.00001: THz spectroscopy of topological magnon candidate CoTiO$_3$*  EVAN JASPER (Presenter), Ohio State Univ - Columbus, TIMOTHY DELAZZER, KATE ROSS, Colorado State University, ROLANDO VALDES AGUILAR, Ohio State Univ - Columbus — Recent advancements in topological band theory have predicted the existence of topologically-protected magnon excitations [1] with potential spintronic applications. CoTiO$_3$ is an Ilmenite-structure antiferromagnet with a Néel temperature of 38 K and magnon energies in the THz range. Previous work has also identified CoTiO$_3$ as a candidate to host topological magnons [2]. We follow up on that research by measuring the THz transmission and reflectivity of both single crystal and pressed powder samples of CoTiO$_3$ and we report the results including a large absorptions near 1 and 1.6 THz. We propose that the modes broaden with decreasing temperature or a new absorption appears below the Néel temperature with energy coinciding with a zone-center magnon excitation. We will discuss these possibilities together with the details of the THz polarization response.

*Funding at OSU for this research was provided by the Center for Emergent Materials: an NSF MRSEC under award number DMR-1420451, and at CSU by the CIFAR Quantum Materials program.

11:27AM B59.00002: Three-dimensional topological magnon systems*  HIROKI KONDO (Presenter), YUTAKA AKAGI, HOSHO KATSURA, Univ of Tokyo — Recently, magnonic analogs of spin Hall insulators in two dimensions have been proposed theoretically [1]. In our previous work, we defined a $Z_2$ topological invariant for them and proposed the first model of a magnonic analog of a spin Hall insulator without spin conservation [2]. Building on this previous work, in this study, we propose a concept of three-dimensional (3D) topological magnon systems characterized by a set of $Z_2$ topological invariants [3]. They can be thought of as magnonic analogs of 3D topological insulators. One of the models proposed is a bosonic counterpart of the Fu-Kane-Mele model, which is found to exhibit three distinct phases analogous to strong topological, weak topological, and trivial insulator phases. We also discuss a possible realization of the thermal Hall effect of surface Dirac magnons in the presence of a magnetic field.

*JSPS Grant-in-Aid for Scientific Research on Innovative Areas: No. JP18H04478 (H.Katsura) and No. 18H04220 (Y.A.)
11:39AM B59.00003: Chiral Magmonic Edge States in Ferromagnetic Skyrmion Crystals Controlled by Magnetic Fields  SEBASTIAN A DIAZ (Presenter), University of Basel, TOMOKI HIROSAWA, University of Tokyo, JELENA KLINOVJA, DANIEL LOSS, University of Basel — We show that an external magnetic field can drive a topological phase transition in the spin wave spectrum of a ferromagnetic skyrmion crystal. The topological phase transition is signaled by the closing of a low-energy bulk magnon gap at a critical field. In the topological phase, below the critical field, two topologically protected chiral magmonic edge states lie within this gap, but they unravel in the trivial phase, above the critical field. Remarkably, the topological phase transition involves an inversion of two magnon bands that at the Γ point correspond to the breathing and anticlockwise modes of the skyrmions in the crystal. Our findings suggest that an external magnetic field could be used as a knob to switch on and off magnon spin currents carried by topologically protected chiral magmonic edge states.

11:51AM B59.00004: Magnetic field control of topological magnon-polaron bands in two-dimensional ferromagnets*  PENGTAO SHEN (Presenter), SE KWON KIM, Univ of Missouri - Columbia — We theoretically study magnon-phonon hybrid excitations in a square lattice ferromagnet subjected to a magnetic field by varying the field direction. The bulk bands of hybrid excitations, which are referred to as magnon-polarons, are investigated by considering all three phonon modes: vertical phonon, transverse phonon, and longitudinal phonon. We show that the topological properties of three hybridizations are different in terms of the Berry curvature and the Chern numbers. We also find that the topological properties of the bands can be controlled by changing the direction of the magnetic field, exhibiting one or more topological phase transitions. The dependence of thermal Hall conductivity as a function of magnetic field direction is proposed as an experiment probe of our theoretical results. This work is posted on arXiv:1910.08603.

*This work is supported by the University of Missouri. S.K.K. acknowledges Young Investigator Grant (YIG) from Korean-American Scientists and Engineers Association (KSEA).

12:03PM B59.00005: Magnonic Su-Schiffer-Heeger Model in Honeycomb Ferromagnets  YUHANG LI (Presenter), RAN CHENG, University of California, Riverside — We study a collinear honeycomb ferromagnet with variable nearest-neighbor exchange interactions in the presence of the next nearest-neighbor Dzyaloshinskii-Moriya interaction. By examining the band topology and the associated chiral edge states, we find that varying the nearest-neighbor exchange interactions can induce topological phase transitions between trivial insulators with vanishing Chern number \( C=0 \) and magnon Hall insulators with \( C=1 \). Such a phase transition from topological trivial phase into a topological nontrivial one can be characterized by a sharp increase of the thermal Hall conductivity, which is attributed to the emerge of the topologically protected chiral edge states of magnons. Moreover, the magnon Hall state is robust against magnon-photon interactions. Possible materials realization is also discussed.
12:15PM B59.00006: Nonsymmorphic-symmetry-protected topological magnons in three-dimensional Kitaev materials  YONG-BAEK KIM (Presenter), WONJUNE CHOI, Univ of Toronto, TOMONARI MIZOGUCHI, Physics, University of Tsukuba — Topological phases in magnetic materials offer novel tunability of topological properties through varying the underlying magnetism. We show that field-induced canted zig-zag order of three-dimensional hyperhoneycomb Kitaev materials has gapless topological magnons protected by nonsymmorphic magnetic space group symmetries. The non-Hermitian nature of the bosonic magnons leads to unique topological protection that is different from their fermionic counterparts. We investigate how such topological magnons can be controlled by varying the strength of the spin-exchange interactions.

12:27PM B59.00007: Quantum field theory of topological spin dynamics*  PREDRAG NIKOLIC (Presenter), George Mason Univ — Topological magnetic materials are promising hosts for novel strongly correlated states. I will present a unifying quantum field theory of a wide range of such materials, which captures their universal and topological dynamics. All topological features arise from the continuum-limit gauge fields that one can calculate starting with a microscopic lattice model. Non-collinear incommensurate magnets are shaped by non-Abelian vector gauge fields, including the Dzyaloshinskii-Moriya interaction. Chiral spin couplings related to topological defects give rise to rank-2 antisymmetric tensor gauge fields. The spin-orbit coupling of mobile electrons is similarly described by non-Abelian gauge fields, including rank-2 tensors related to the 3D Berry flux. All gauge fluxes are generally exchanged between electrons and local moments through Kondo-type interactions. I will discuss applications of this theory to (i) spin-wave dynamics in the presence of Weyl electrons, (ii) instabilities of Weyl semimetals, (iii) fluctuations and temperature-dependence of the anomalous/topological Hall effect, and (iv) topological phase transitions involving monopoles and hedgehogs (which can fractionalize electrons).

12:39PM B59.00008: Polarization-resolved Raman spectroscopy of α-RuCl3 and evidence of room-temperature two-dimensional magnetic scattering  ANGELA HIGHT WALKER
(Presenter), THUC MAI, AMBER MCCREARY, National Institute of Standards and Technology, PAULA LAMPEN-KELLEY, Material Science and Technology Division, Oak Ridge National Lab, NICHOLAS BUTCH, National Institute of Standards and Technology, JEFFREY SIMPSON, Department of Physics, Towson University, JIAQIANG YAN, Material Science and Technology Division, Oak Ridge National Lab, STEPHEN E NAGLER, Neutron Scattering Division, Oak Ridge National Lab, DAVID MANDRUS, Material Science and Technology Division, Oak Ridge National Lab, ROLANDO VALDES AGUILAR, Department of Physics, The Ohio State University — Polarization-resolved Raman spectroscopy was performed and analyzed from large, high-quality, monodomain single crystal of α-RuCl3, a proximate Kitaev quantum spin liquid. Spectra were collected with laser polarizations parallel and perpendicular to the honeycomb plane. Pairs of nearly degenerate phonons were discovered and show either a fourfold or twofold polarization angle dependence in their Raman intensity, thereby providing evidence to definitively assign the bulk crystal point group as C2h. The low-frequency continuum that is often attributed to scattering from pairs of Majorana fermions was also examined and found to disappear when the laser excitation and scattered photon polarizations were perpendicular to the honeycomb plane. This disappearance, along with the behavior of the phonon spectrum in the same polarization configuration, strongly suggests that the scattering continuum is two-dimensional. We argue that this scattering continuum originates from the Kitaev magnetic interactions that survive up to room temperature, a scale larger than the bare Kitaev exchange energy of approximately 50 K. DOI: 10.1103/PhysRevB.100.134419

12:51PM B59.00009: Dimension transcendence and anomalous charge transport in magnets with moving multiple-Q spin textures† YING SU (Presenter), Los Alamos National Laboratory, SATORU HAYAMI, Department of Physics, Hokkaido University, SHIZENG LIN, Los Alamos National Laboratory — Multiple-Q spin textures, such as magnetic bubble and skyrmion lattices, have been observed in a large family of magnets. These spin textures can be driven into motion by external stimuli and affects the electronic states. Here we show that to describe correctly the electronic dynamics, the momentum space needs to be transcended to higher dimensions by including the ancillary dimensions associated with phason modes of the translational motion of the spin textures. The electronic states have non-trivial topology characterized by the first and second Chern numbers in the high dimensional hybrid momentum space. This gives rise to an anomalous electric charge transport due to the motion of spin textures. By deforming the spin textures, a nonlinear response associated with the second Chern number can be induced. The charge transport is derived from the semi-classical equation of motion of electrons that depends on the Berry curvature in the hybrid momentum space. Our results suggest that the motion of multiple-Q spin textures has significant effects on the electronic dynamics and provides a new platform to explore high dimensional topological physics.

1:03PM B59.00010: Thermal-transport properties of chiral antiferromagnet CsCuCl$_3$

MASATOSHI AKAZAWA (Presenter), MASAAKI SHIMOZAWA, MINORU YAMASHITA, ISSP, Univ. of Tokyo, YUSUKE KOUSAKA, Department of Physics and Electronics, Osaka Prefecture University, JUN AKIMITSU, RIIS, Okayama Univ., NAOTO TSUCHIYA, KATSUYA INOUE, Department of Chemistry, Hiroshima Univ., JULIEN ZACCARO, ISABELLE GAUTIER-LUNEAU, CNRS, Institut NEEL, DOMINIQUE LUNEAU, Universite de Lyon — Recently, topological effects related to a Berry curvature dipole has been extensively studied in metals without inversion symmetry. On the other hand, these topological effects on charge-neutral bosonic excitations have yet to be clarified. To investigate this issue, we measured the longitudinal and transverse thermal conductivity of the chiral antiferromagnet CsCuCl$_3$, a high-quality homochiral single crystal of which becomes available very recently. We find a large enhancement of the longitudinal thermal conductivity in the ordered phase. This result suggests a large spin thermal conduction that could not be observed clearly in multi-domain crystals. We further find a sizable thermal Hall effect with a non-linear heater dependence even at zero magnetic field. We will discuss a possible origin for this non-linear thermal Hall effect.

1:15PM B59.00011: Intrinsic Quantized Anomalous Hall Effect in a Moiré Heterostructure, Part II: Temperature Dependence and Current Switching*

MAREC SERLIN (Presenter), CHARLES TSCHIRHART, HRYHORIY POLSHYN, YUXUAN ZHANG, JIACHENG ZHU, Physics, University of California, Santa Barbara, MARTIN E HUBER, Physics, University of Colorado, Denver, LEON BALENTS, Physics, University of California, Santa Barbara, KENJI WATANABE, TAKASHI TANIGUCHI, Physics, NIMS, ANDREA YOUNG, Physics, University of California, Santa Barbara — This is the second of three talks describing the observation and characterization of a ferromagnetic moiré heterostructure based on twisted bilayer graphene aligned to hexagonal boron nitride. I will compare the qualitative and quantitative features of this observed quantum anomalous Hall state to traditional systems engineered from thin film (Bi,Sb)$_2$Te$_3$ topological insulators. In particular, we find that the measured electronic energy gap of ~30K is several times higher than the Curie temperature, consistent with a lack of disorder associated with magnetic dopants. In this system, the quantization arises from spontaneous ferromagnetic polarization into a single spin and valley moiré subband, which is topological despite the lack of spin orbit coupling. I will also discuss the observation of current induced switching, which allows the magnetic state of the heterostructure to be controllably reversed with currents as small as a few nanoamperes.

* I would like to thank the MURI Program, AFOSR, Sloan Foundation, and the ARO for their generous support of this work.
We report the observation of a quantized anomalous Hall effect in a moiré heterostructure consisting of twisted bilayer graphene aligned to an encapsulating hBN substrate. The effect occurs at a density of 3 electrons per superlattice unit cell, where we observe magnetic hysteresis and a Hall resistance quantized to within 0.1% of the resistance quantum at temperatures as high as 3K. In this first of 3 talks, I will describe the fabrication procedure for our device as well as basic transport characterization measurements. I will introduce the phenomenology of twisted bilayer graphene and present evidence for hBN alignment as manifested in the hierarchy of symmetry-breaking gaps and anomalous magnetoresistance.

*I would like to thank the MURI program, Sloan foundation, AFOSR, and ARO for their generous support of this work.

This is the third of three talks describing the observation and characterization of a ferromagnetic moiré heterostructure based on twisted bilayer graphene aligned to hexagonal boron nitride. In this segment I will present scanning probe magnetometry data acquired using a nanoSQUID-on-tip microscope, which provides ~150 nm spatial resolution and a field sensitivity of ~10 nT/rtHz. We study the distribution of magnetic domains within the device as a function of density, magnetic field training, and DC current. Our data allow us to constrain the magnitude of the orbital magnetic moment of the electrons in the QAH state. Comparison with simultaneously acquired transport data allows us to precisely correlate single domain dynamics with discrete jumps in the observed anomalous Hall signal.

*I would like to thank the MURI program, Sloan foundation, AFOSR, and ARO for their generous support of this work. I would also like to thank the NSF GRFP and the Hertz foundation for their generous support of my graduate studies.
1:51PM B59.00014: The RKKY Interaction in Graphene Proximity Coupled to an Antiferromagnetic Insulator* JIA-JI ZHU (Presenter), JIN YANG, School of Science, Chongqing University of Posts and Telecommunications — We study theoretically the long-range Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction mediated by itinerant electrons of graphene between magnetic moments induced by proximity effect of an antiferromagnetic insulator. The antiferromagnetic insulators provides both broken time-reversal symmetry and spin-orbit coupling [1]. We find more spin-spin interaction terms which had not reported previously in other spin-orbit systems[2]. The additional terms could induce a spatially inhomogeneous spin order. We also find a rich texture of the total RKKY range function. With the Fermi energy residing in the band gap induced by the spin-orbit coupling, the RKKY interaction degenerates to the Bloembergen-Rowland (BR) interaction. The BR interaction is a short range exponentially-decay interaction mediated by virtual excitations. We show a possible transformation of anomalous Hall effect to quantum anomalous Hall effect while the RKKY interaction degenerating to the BR interaction.

B59.00015: Non-Spin-Wave type of Magnetic Excitations in a Well-characterized Nearest-Neighbor Triangular Antiferromagnet WEI BAO (Presenter), Physics, City University of Hong Kong —

The $S = \frac{3}{2}$ Mn$^{4+}$ ions of La$_2$Ca$_2$MnO$_7$ forms perfect triangular lattice in the ABC stacking. Therefore when the 120° antiferromagnetic order forms on the triangular lattice, interlayer magnetic interaction cancel out exactly. The two-dimensional long-range antiferromagnetic order develops below 2.8K, evidenced by the perfect Warren magnetic peak profile as well as in heat capacity and magnetic susceptibility data, substantially lower than the Weiss temperature of 25K. High temperature susceptibility data fitting to the Rushbrooke-Wood formulus yields a nearest-neighbor exchange constant which is identical to that derived from the low-energy stiffness of magnetic excitations, validating the nearest-neighbor magnetic interaction in plane. Different from magnetic excitation spectra previously reported in neutron scattering studies using samples with 3-dimensional long-rang 120° antiferromagnetic order, in our sample of 2-dimensional 120° antiferromagnetic order, the Spin-Wave spectrum definitely fails to describe our observed spectra. There are conflicting theories as to what kind of magnetic excitation beyond the Spin-Wave theory should be at the moment, ranging from the fractionalization of spin at the low dimensions to the mode-mode coupling decay of the spin-wave modes.

Session B60 DMP: Topological Materials: Weyl, Dirac, Chiral, and Other Semimetals Mile High Ballroom 4A - Gavin Osterhoudt, Boston College - Tag(s): Focus
We have shown that Kramers-Weyl fermions are a universal topological electronic property of all non-magnetic chiral crystals with spin-orbit coupling and are guaranteed by structural chirality, lattice translation and time-reversal symmetry. We determined that all point-like nodal degeneracies in non-magnetic chiral crystals with relevant spin-orbit coupling carry non-trivial Chern numbers. Kramers–Weyl materials can exhibit a monopole-like electron spin texture and topologically non-trivial bulk Fermi surfaces over an unusually large energy window [G. Chang et al. Nature Materials 17, 978-985 (2018)]. Among all the materials, we predicted the RhSi family to exhibit the ideal topological band structures, displaying the largest possible momentum separation of compensative chiral fermions, the largest proposed topologically nontrivial energy window, and the longest possible Fermi arcs on its surface [G. Chang et al. PRL 119, 206401 (2017)]. We present the theory of exotic nonlinear optical responses of topological chiral crystals, including quantized photogalvanic effect in RhSi and robust photocurrents from Fermi arc surface states [G. Chang et al. PRL 119, 206401 (2017) and arXiv:1906.03207 (2019)]. We also discuss the experimental discovery of RhSi as topological chiral crystals [D. S. Sanchez et al. Nature 567, 500-505 (2019)] and additional experiments that our discovery has enabled. (This work is in collaboration with D. S. Sanchez, I. Belopolski, T. A. Cochran, B. J. Wieder, F. Schindler, J. Yin, S. S. Zhang, S. Huang, B. Singh, T. Chang, A. Bansil, T. Neupert, S.-Y. Xu, H. Lin, and M. Zahid Hasan)

11:51AM B60.00002: Unconventional Topological Fermions in Orthorhombic RhSi*  SHIRIN MOZAFFARI (Presenter), National High Magnetic Field Laboratory, NIRAJ ARYAL, Florida State University, RICO SCHOENEMANN, National High Magnetic Field Laboratory, KUAN-WEN CHEN, Florida State University, GREGORY MCCANDLESS, JULIA CHAN, University of Texas at Dallas, EFSTRATIOS MANOUSAKIS, Florida State University, LUIS BALICAS, National High Magnetic Field Laboratory — Topological semimetals with different types of band crossings, distinct from conventional Dirac and Weyl nodes, can give rise to novel fermionic excitations that may not have analogues in high-energy physics. Exotic multifold topological excitations have been predicted theoretically and observed in a family of transition metal silicides (e.g. β-RhSi). These compounds adopt the cubic FeSi structure type (space group No. 198), for which the calculations predict Chern numbers > 1 at specific high symmetry points within their Brillouin zone.

Through Density Functional Theory (DFT) calculations, we report that such multi degenerate fermions also exist in α-RhSi, which adopts an orthorhombic structure type (space group No. 62). Group symmetry analysis combined with DFT calculations indicate the coexistence of multiple types of multifold Dirac fermions at or near high symmetry points. Measurements of the angular dependence of the de Haas–van Alphen effect, indicate a Fermi surface whose topography is in reasonable agreement with the DFT calculations. We observe a pronounced anomaly in the magnetic torque of α-RhSi suggesting the possibility of topological phase-transitions.

12:03PM B60.00003: Ultrasound Studies of the Magnetic Weyl Semimetal Co₃Sn₂S  RUI XUE (Presenter), CANDICE KINSLER-FEDON, BRIANNA MUSICO, University of Tennessee, Knoxville, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, VEERLE M KEPPENS, DAVID MANDRUS, University of Tennessee, Knoxville — Co₃S₂Sn₂ is a magnetic Weyl semimetal that crystallizes in a shandite structure with the Co atoms forming a kagome lattice. It orders ferromagnetically at about 174 K with easy axis perpendicular to the kagome plane. Co₃S₂Sn₂ displays a giant anomalous Hall effect as well as other transport anomalies characteristic of Weyl semimetals. Here we present Resonant Ultrasound (RUS) measurements on single crystals of Co₃S₂Sn₂ as a function of temperature and magnetic field. RUS measures the mechanical resonances of the crystals and is highly sensitive to phase transitions and other thermodynamic irregularities in the sample.
Prototypical topological Weyl and Dirac semimetals are 3D crystal structures and are typically grown in the form of bulk. Discovering and engineering topological semimetals from the family of 2D TMDs could open the way for exploitation of their topological properties by fabricating thin epitaxial films and devices on suitable substrates. In this work, we show that using molecular beam epitaxy, single and few layers of HfTe$_2$[1] and ZrTe$_2$[2] can be grown epitaxially on AlN and InAs substrates. By combining ARPES and DFT calculations we provide evidence that they are type-I and type-II Dirac semimetals, respectively, with the Dirac point located at the Fermi energy. Dirac cones are maintained down to the single-layer, suggesting that they could be considered as the electronic analogues of graphene. Moreover, we report the first direct observation at room temperature of the orthorhombic Weyl semimetal phase of MoTe$_2$[3]. DFT calculations predict eight type-II Weyl nodes which are located just below the Fermi level, making them accessible to electronic transport, thus creating prospect for practical applications.

The Kagome lattice is hexagonal and composed of corner sharing triangles. Materials with layered Kagome lattice allow the interplay of topological properties and interactions in flat bands, and can give rise to spin liquids, skyrmions and other novel phases. There is broad interest in realizing high-quality topological semimetal materials such as Mn$_3$X (Sn, Ge and others) [1], FeSn [2] and Co$_3$Sn$_2$S$_2$ [3], in layered Kagome structure. Both angle-resolved photoemission spectroscopy (ARPES) and transport measurement indicate they are topologically nontrivial. Until now, most measurements are performed on bulk samples which can be a limitation for both physics and application. By using molecular beam epitaxy and sputtering, we synthesized Kagome structured FeSn and Mn$_3$Ge films. Both in-situ and ex-situ characterizations indicate these films are highly crystalline and c-axis oriented. Highly ordered atomic layers are captured by scanning transmission electron microscopy. Anomalous Nernst effect has been measured which can be related to non-vanishing Berry curvature.

AHMAD IKHWAN US SALEHEEN (Presenter), RAMAKANTA CHAPAI, LINGYI XING, DONGLIANG GONG, ROSHAN NEPAL, DAVID P YOUNG, RONGYING JIN, Louisiana State University, Baton Rouge — We have investigated the magnetotransport properties of the transition metal trichalcogenide TaSe$_3$, which is a Dirac semimetal candidate. While the electrical resistivity exhibits metallic behavior at zero field, a magnetic field (H)-induced upturn is observed at low temperatures for $H > 4$ T, applied perpendicular to the current direction. The extremely large, non-saturating transverse magnetoresistance (MR) reaches $\sim 7000\%$ for $H = 14$ T at 1.9 K. For $H > 6$ T, Shubnikov-de Haas (SdH) oscillations are observed with frequencies $F_\alpha \approx 98$ T and $F_\beta \approx 186$ T. By constructing the Landau fan diagram for each oscillation, we calculated the Berry phase to be 1.1 $\pi$ and 0.2 $\pi$ for $F_\alpha$ and $F_\beta$, respectively. The underlying physics will be discussed.

*This work is supported by the U. S. Department of Energy under EPSCoR grant no DE-SC0012432 with additional support from the Louisiana Board of Regents.

ROBERT KEALHOFER (Presenter), JAMES ANALYTIS, University of California, Berkeley — Topological Weyl and Dirac semimetals have excited much research interest in the last few years. Much of the study of these materials has focused on the existence of exotic signatures of topology, such as Fermi arc surface states, nonlocal transport, and observations of boundary effects such as the quantum Hall effect. One feature shared by many of these materials is a low carrier density. Landau quantization in low carrier density topological semimetals in moderate magnetic fields produces large changes in the band structure of these materials, allowing the formation of tunable, strongly interacting correlated states. We present thermal and thermodynamic signatures of these strong correlations in the prototypical Weyl semimetal TaAs.

1:03PM B60.00008: A non-linear Hall effect at zero field in a chiral nonmagnetic compound
KOHEI MATSUURA (Presenter), MINGWEI QIU, YUTA MIZUKAMI, KENICHIRO HASHIMOTO, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, The University of Tokyo, TEPPEI UENO, TAKESHI TAKAHASHI, Department of Physics, Okayama University, KAYA KOBAYASHI, Research Institute for Interdisciplinary Science, Okayama University, MASATOSHI AKAZAWA, SAKURAKO FUJII, JUN GOUCHI, MINORU YAMASHITA, YOSHIYA UWATOKO, Institute for Solid State Physics, The University of Tokyo, MASAAKI SHIMOZAWA, Department of Materials Engineering Science, Osaka University — The Hall effect arising from the Berry curvature is one of the most important topological phenomena. In the linear response regime, such a Hall effect appears only in the time-reversal symmetry breaking condition; this is well-known as an anomalous Hall effect. By contrast, the recent studies have proposed that in the nonlinear response regime, a Hall voltage can be observed due to the Berry curvature even in time-reversal invariant systems. These works demonstrate that the new-type of Hall effect is a powerful probe for investigating Berry physics in the nonmagnetic topological materials. However, experimental studies on this nonlinear Hall effect are still lacking.
Here, we report the observation of nonlinear Hall effect in a chiral nonmagnetic compound. We find that an electric current induces a nonlinear Hall voltage under time-reversal invariant conditions. The sign of the voltage at 4.2 K depends strongly on the direction of the chirality of crystal structure, which is consistent with the theoretical calculations. Furthermore, this nonlinear Hall effect becomes smaller at higher temperatures but is still observable even at room temperature.

1:15PM B60.00009: Topology Classification using Chiral Symmetry: Chiral Zak Phase and Spin Correlations
JINGWEI JIANG (Presenter), STEVEN LOUIE, Physics, University of California, Berkeley — Topology classification theory has been broadly applied to explain and gain deeper insight of many physical phenomena. On the other hand, the power of this theory for one-dimensional (1D) systems has not been as widely used. Quasi 1D graphene nanoribbons (GNRs) can now be synthesized with atomic precision via bottom-up molecular precursor techniques and are discovered to possess nontrivial topological properties, as predicted by Cao, Zhao and Louie under a $Z_2$ classification using time reversal and spatial symmetries. However, the use of these symmetries constrains the classification to nonmagnetic materials with symmetric unit cell. Here we develop another approach to use only chiral symmetry (based on chiral Zak phase) to classify 1D materials, which gives an $Z$ classification. Using bulk-edge correspondence, we connect the chiral Zak phase with an edge-index that predicts the characters of topology-induced states at junctions of two 1D materials belonging to different classes. Moreover, using the GNRs as an example, we investigate the spin-spin correlations between topologically protected junction states via first-principles calculations.

1:27PM B60.00010: Anisotropic thermoelectric properties of topological semimetal \textit{YbMnSb}_2 single crystal  
YU PAN, CHENGUANG FU, FENGREN FAN, YANGKUN HE, CLAUDIA FELSER (Presenter), Max-Planck Institute for Chemical Physics of Solids — Topological materials can be a suitable platform for the study of thermoelectric transport properties due to the high mobility and exotic transport behaviors. Some topological materials are also good thermoelectric materials, for example, Bi$_2$Te$_3$ alloys. In this work, we report the thermoelectric properties of topological semimetal \textit{YbMnSb}_2 single crystal. Although being a semimetal, \textit{YbMnSb}_2 still show promising Seebeck coefficient due to the much larger contribution of valence band than the conduction band. Large anisotropy is found in resistivity and thermal conductivity, while Seebeck is almost isotropic. Furthermore, we investigate the thermoelectric transport properties under magnetic field, wherein a maximum enhancement of the thermoelectric figure of merit ($zT$) reached 200\% at 100 K under 9 T. With further reduction of the thermal conductivity by alloying, microstructure engineering et al., we expect better thermoelectric performance. The present work can be instructive for the search of other new high-performing thermoelectric materials.

1:39PM B60.00011: STM/STS of Few-Layer Topological Semimetal \textit{NiTe}_2 at 78 K*  
STEPHANIE LOUGH (Presenter), Physics & Nanoscience Technology Center, University of Central Florida, DUY LE, Physics and Renewable Energy and Chemical Transformations Cluster, University of Central Florida, BRANDON BLUE, JESSE E THOMPSON, Physics & Nanoscience Technology Center, University of Central Florida, TALAT RAHMAN, Physics and Renewable Energy and Chemical Transformations Cluster, University of Central Florida, MASA ISHIGAMI, Physics & Nanoscience Technology Center, University of Central Florida — \textit{NiTe}_2 is a semimetal which has garnered interest due to recent observation of topological states and Dirac nodes near the Fermi level ($E_F$). Here, Au-assisted exfoliation of bulk \textit{NiTe}_2 is performed to generate a few-layer \textit{NiTe}_2 surface to better understand the evolution of the band structure as a function of film thickness. Scanning tunneling microscopy and spectroscopy measurements are performed at 78 K to probe the local density of electronic states (LDOS) at the surface and around defects. Multiple peaks in the LDOS are observed near $E_F$ and are compared to those obtained computationally from density functional theory (DFT) to reveal the nature of these features in the electronic structure.

* D.L. and T.S.R. are supported in part by U.S. Department of Energy Grant DE-FG02-07ER46354.
1:51PM B60.00012: Topological light meets topological semimetal  ZHURUN JI (Presenter), WENJING LIU, University of Pennsylvania, SERGIY KRYLYUK, National Institute of Standards and Technology, XIAOPENG FAN, ZHIFENG ZHANG, University of Pennsylvania, ANLIAN PAN, Hunan University, LIANG FENG, University of Pennsylvania, ALBERT DAVYDOV, National Institute of Standards and Technology, RITESH AGARWAL, University of Pennsylvania — A Weyl semimetal carries topological charges at the Weyl nodes; a light beam can also carry a topological charge, when it has an orbital angular momentum (OAM) from spatial phase and/or polarization gradients. Recently there has been a lot of interest in understanding how the spin angular momentum (SAM) of light interacts with materials to induce photocurrents (circular photogalvanic effect, CPGE), but not many studies have focused on photocurrents generated by the OAM of light. Here we report a unique orbital photogalvanic effect (OPGE) in a type-II Weyl semimetal WTe$_2$, featured by a photocurrent winding around the axis of OAM-carrying beams, whose intensity is directly proportional to the topological winding number of the light field, and can be attributed to a discretized dynamical Hall effect. In addition to obtaining new microscopic insights into light-matter interactions with topological light, these measurements show promise for fabricating on-chip photodetectors on Weyl semimetals capable of detecting OAM modes, which can be useful for building the next-generation, high-capacity optoelectronic circuits.

2:03PM B60.00013: Quenching of Relaxation Pathway In Weyl Semimetal TaAs  JIAYUN LIU (Presenter), LIANG CHENG, DAMING ZHAO, XIAOXUAN CHEN, Division of Physics and Applied Physics, Nanyang Technological University, Singapore, ZHILIN LI, XIAOLONG CHEN, Institute of Physics, Chinese Academy of Sciences, HANDONG SUN, EE MIN CHIA, Division of Physics and Applied Physics, Nanyang Technological University, Singapore — Following the topological classification of materials, Weyl semimetal has been predicted theoretically and has since been experimentally confirmed. Experimental investigation on Weyl semimetal shows promise in the field of optoelectronics due to its wide spectral response from visible to near infrared regime. However, the transient dynamics of Weyl semimetal has not been clearly established. In this work, we studied the ultrafast response of tantalum arsenide (TaAs) in the optical regime through transient reflection spectroscopy with varying pump fluence. We noted two relaxation pathways for the hot injected electrons in TaAs by the pump pulse. We identified the origin of these two relaxation pathways through pump fluence dependent study. We noticed that depending on the energy of the probing wavelength, one of the relaxation pathways is quenched. The understanding of this quenching mechanism provides a reliable way to study the transient dynamics in Weyl semimetal.

Session B61 DMP DCMP DCOMP: Fe-Based Superconductors - Mayorana / Topological Mile High Ballroom 4B - Yanwei Ma - Tag(s): Focus
Majorana fermions can be realized as quasiparticle excitations in a topological superconductor, whose non-Abelian statistics provide a route to developing robust qubits. In this context, there has been a recent surge of interest in the iron-based superconductor, FeSe$_{0.5}$Te$_{0.5}$. Theoretical calculations have shown that FeSe$_{0.5}$Te$_{0.5}$ may have an inverted band structure which may lead to topological surface states, which can in turn host Majorana modes under certain conditions in the superconducting phase. Furthermore, recent STM studies have demonstrated the existence of zero-bias bound states inside vortex cores which have been interpreted as signatures of Majorana modes. While most recent studies have focused on Majorana bound states, more generally, akin to elementary particles, Majorana fermions can propagate and display linear dispersion. These excitations have not yet been directly observed, and can also be used for quantum information processing. This talk is focused on our recent work in realizing dispersing Majorana modes. I will describe the conditions under which such states can be realized in condensed matter systems and what their signatures are. Finally, I will describe our scanning tunneling experiments of domain walls in the superconductor FeSe$_{0.45}$Te$_{0.55}$, which might potentially be first realization of dispersing Majorana states in 1D.
11:51AM B61.00002: Longer-range exchange interaction in iron-based superconductors: First-principles studies* WEIGUO YIN (Presenter), Brookhaven National Laboratory — The nature of strong electronic correlations in iron-based superconductors (FeSCs) was shown to be kin to manganites where localized spins and itinerant electrons coexist and are coupled by Hund’s rule interaction, leading to fierce competition between superexchange antiferromagnetism and orbital-degenerate double-exchange ferromagnetism [1,2]. This implies that in a low-energy spin-only description of FeSCs where the itinerant-electron degree of freedom were integrated out, the effective exchange interactions would have been long ranged. The spin dynamics in FeSCs has been interpreted by using such spin-only Heisenberg models with exchange couplings extended to the third nearest neighbors, i.e., the J1-J2-J3 model. Here, we use first-principles calculations on the K2Fe4Se5 and KFeAgTe2 insulators to demonstrate the importance of J4 the effective exchange between the fourth nearest neighbors. We further reveal that the band gap of K2Fe4Se5 or KFeAgTe2 is not of Mott type but the gap of Hund's metal. Our findings shed a new light on the understanding of FeSCs and the puzzling strong magnetic fluctuations in FeSe in particular. [1] PRL 105, 107004 (2010); [2] PRB 86, 081106(R) (2012).

12:03PM B61.00003: Quasiparticle self-consistent GW analysis in iron-based superconductors KATSUHIRO SUZUKI (Presenter), Division of Materials and Manufacturing Science, Graduate School of Engineering, Osaka University, TAISHI OGURA, Department of Physics, Ritsumeikan University, HIROFUMI SAKAKIBARA, TAKAO KOTANI, Department of Applied Mathematics and Physics, Tottori University, HIROAKI IKEDA, Department of Physics, Ritsumeikan University — Since the early theoretical study of iron-based superconductors, the density functional theory (DFT) has given great contributions to understand material properties, e.g. magnetic/orbital structure, pairing mechanism of superconductivity, etc. However, the LDA/GGA exchange-correlation potential in conventional DFT calculations is insufficient to describe the electronic state observed experimentally, such as in the angular resolved photoemission spectroscopy (ARPES) and de Hass van Alphen (dHvA) measurement [1-3]. In this study, we calculated the electronic band structure of iron-based superconductors with the quasiparticle self-consistent GW (QSGW) method. We found that the QSGW can improve the LDA/GGA band structure and Fermi surface in most cases. We will summarize the result and discuss the superconducting gap in the obtained QSGW band structure. [1] A. A. Kordyuk et al., Phys. Rev. B 83 134513 (2011). [2] K. Okazaki et al., Science 337 1314 (2012). [3] T. Terashima et al., J. Phys. Soc. Jpn. 79 053702 (2010).
12:15PM B61.00004: Search for evidence of quantum anomalous vortices in Iron-based Topological Superconductor Fe$_{1+y}$Te$_{1−x}$Se$_x$  LU LI (Presenter), LU CHEN, ZIJI XIANG, COLIN TINSMAN, Univ of Michigan - Ann Arbor, GENDA GU, Brookhaven National Laboratory — Topological superconductivity makes it possible for fault-tolerant quantum computations. Fe-based superconductors are a rich material family of intermetallic compounds for high-temperature superconductivity. The interplay between these two exciting fields creates an emergent new field, marked by recent discoveries of the superconducting Dirac surface state and Majorana bound states at the vortex cores in iron-based superconductors Fe$_{1+y}$Te$_{1−x}$Se$_x$. However, the direct electronic transport consequence is not clear out of these topological superconducting states. We are left wondering how to operate these novel excitations. We solve the problem by thermally drive ordinary superconducting vortices around these Majorana zero modes and search for a transverse electrical response. This scheme is the Nernst effect in the superconducting state. A finite Nernst signal is observed at zero fields in the superconducting states of Fe$_{1+y}$Te$_{1−x}$Se$_x$. This anomalous Nernst signal shows field-symmetric dependence on the external magnetic field. Our experiments provide the first evidence of broken time-reversal symmetry in topological superconductors and point to a new method to engage Majorana zero mode excitations in transport properties.

12:27PM B61.00005: The Triplet Resonating Valence Bond State and Superconductivity in Hund's Metals: I Concept and Symmetries*  PIERS COLEMAN (Presenter), YASHAR KOMIJANI, ELIO KOENIG, Rutgers University, New Brunswick — A central idea in strongly correlated systems is that doping a Mott insulator leads to a superconductor by transforming the resonating valence bonds (RVBs) into spin-singlet Cooper pairs. Here, we argue that a spin-triplet RVB (tRVB) state, driven by spatially, or orbitally anisotropic ferromagnetic interactions can provide the parent state for triplet superconductivity. One of the new features of the concept, is that triplet RVB bonds can resonate into the interior of an atom, where they are supported as Hund’s coupled triplet states between orbitals at the same site. Remarkably though, simple symmetry arguments due to P. W. Anderson, mean that such a process can only develop coherence with triplet pairs on the Fermi surface, if the there are two symmetry related atoms per unit cell, leading to a state that has staggered structure of onsite pair correlations that can be detected using Josephson tunneling. A natural candidate for this physics are the iron based superconductors, as will be described in the two following talks [1].

12:39PM B61.00006: Title: The Triplet Resonating Valence Bond State and Superconductivity in Hund's Metals: II Mean-field theory*  
PIERS COLEMAN, YASHAR KOMIJANI (Presenter), ELIO KOENIG, Rutgers University, New Brunswick — Triplet resonating valence bond (tRVB) states are entangled states that are produced in anisotropic magnetic environments [1], just like how singlet RVB states arise in frustated antiferromagnetic systems. A single Iron atom in a cubic environment contains miniature triplet states resonating between various t2g orbitals of the d-shell due to the large Hund's coupling. I will discuss how this can be used to derive a local inter-orbital triplet pairing applicable to Iron-based superconductors [2]. While the order parameter contains significant inter-band pairing, the projection on the Fermi surface appears as an odd-parity intra-band triplet pairing which enjoys a weak-coupling instability and gaps out the entire Fermi surface. In analogy with the RVB theory, a Gutzwiller projected variational mean-field is suggested for the ground state. Furthermore, we augment our mean-field theory using a Kotliar-Liu slave-boson approach to include the effect of intra- and inter-orbital interactions. 
Experimental signatures of the proposed triplet superconductor are discussed in the next talk.

*This work was supported by DOE Basic Energy Sciences grant DE-FG02-99ER45790.

PIERS COLEMAN, YASHAR KOMIJANI, ELIO KOENIG (Presenter), Rutgers University, New Brunswick — Based on the triplet Resonating Valence Bond concept introduced in the previous two talks, I will discuss the prospects and signatures of this theory in the context of iron based superconductors. I will explicitly concentrate on the spin-triplet, orbital antisymmetric pairing state as derived in part II and on four experimental techniques of fundamental interest: (1) nuclear magnetic resonance, (2) neutron scattering, (3) tunneling spectroscopy, (4) scanning Josephson tunneling microscopy.

First, I will demonstrate that this pairing state develops an anisotropic, partial suppression of the Knight shift and discuss existing experimental data on single crystals. Second and third, I will demonstrate that the relative sign between triplet d-vectors of electron and hole pockets crucially affects finite frequency spin-susceptibility and local density of states. I will discuss the consequences thereof for key experimental observables, i.e. a sharp subgap spin-resonance and characteristic quasi-particle interference patterns, that previously were interpreted as evidence for $s_\pm$ pairing. Finally, I describe experimental signatures of the staggered order parameter in scanning Josephson microscopy.

1:03PM B61.00008: Unconventional superconductivity and Hund's induced electron correlations: a Cooperative mechanism* LAURA FANFARILLO (Presenter), University of Florida, ANGELO VALLI, Institute for Solid State Physics, Vienna University of Technology, MASSIMO CAPONE, SISSA — The phenomenology of iron-based superconductors shows that the normal state is a bad metal characterized by orbital-selective correlations induced by the Hund's exchange coupling, suggesting an important role of the electron-electron interactions. On the other hand theories based on the exchange of bosons (e.g. spin fluctuations) describe correctly a variety of phenomena pointing towards a more standard pairing mechanism.

To overcome this dychotomy we study how a multiorbital superconducting pairing driven by a generic weak-coupling boson exchange is affected by the presence of correlations. The key novelty of the study is the inclusion of the dynamical properties that make a Hund's metal substantially different with respect to both a weakly interacting metal and to an ordinary correlated metal with a large effective mass renormalization. We unveil the crucial role of the redistribution of spectral weight of the Hund's metal to promote superconductivity and to enhance the orbital-selective character of the gap functions.

1:15PM B61.00009: Hund-enhanced electronic compressibility in LiFeP, LiFeAs and NaFeAs tuned by chemical substitution* PABLO VILLAR ARRIBI (Presenter), Argonne Natl Lab, LUCA DE MEDICI, ESPCI ParisTech — We study the electronic structure of LiFeP, LiFeAs and NaFeAs in their paramagnetic metallic phase including dynamical electronic correlations within a density functional theory + slave-spin mean-field framework. Our results show that the three compounds are next to the crossover between a normal and a Hund's metal, where a region of enhanced electronic compressibility that may be relevant for superconductivity is present in this type of systems. While LiFeP and LiFeAs lie in the normal metallic regime, with LiFeAs in the vicinity of the crossover, NaFeAs is in the Hund's metal regime, which explains the different behavior observed in these materials. Our findings correlate positively with the experimental trends for doping- and pressure-dependence of superconductivity in these compounds, as well as the predicted mass renormalizations and Sommerfeld coefficients.

1:27PM B61.00010: Modified pairing structure due to momentum-dependent correlations in iron-based superconductors* SHINIBALI BHATTACHARYYA (Presenter), PETER HIRSCHFELD, University of Florida, THOMAS MAIER, Oak Ridge National Laboratory, DOUGLAS J SCALAPINO, University of California, Santa Barbara — We discuss the influence of momentum-dependent correlation effects arising from particle-hole interactions on the superconducting gap structure of iron-based superconductors. Within the Eliashberg formalism, we obtain a modified linearized gap equation arising from the spin-fluctuation interaction in the weak-coupling regime which includes self-consistent renormalizations of quasiparticle weights. The modification of the particle-particle interaction vertex by particle-hole processes modifies the superconducting gap structure, i.e. momentum-dependent enhancement or suppression of gap amplitude compared to traditional spin-fluctuation pairing calculations. We obtain good agreement with experimentally observed anisotropic gap structures in LiFeAs, indicating that inclusion of non-local correlation effects in the existing weak-coupling theories can account for observed signatures of the correlated iron-based superconductors.

1:39PM B61.00011: Systematic derivation of ab initio effective Hamiltonians for iron-based superconductors* TAKAHIRO MISAWA (Presenter), KOTA IDO, YUICHI MOTOYAMA, KAZUYOSHI YOSHIMI, University of Tokyo, Institute for Solid State Physics — Iron-based superconductors have attracted much attentions since its discovery at 2008. Owing to huge amount of studies, more than a dozen iron-based superconductors including related compounds have been found. In this study, combining the first-principles calculations and accurate numerical methods for treating quantum lattice models [1], we systematically obtain and analyze first-principle effective Hamiltonians of more than 20 iron-based superconductor and the related compounds. We perform the band calculation using Quantum ESPRESSO [2], derive the ab initio effective Hamiltonians using RESPACK [3], and analyze the Hamiltonians using mVMC [4]. As a result, we show the materials dependence of the microscopic parameters/physical quantities, and their relations with the superconducting transition temperatures.

Topological bands in Fe(Se,Te)*  

TAMAGHNA HAZRA (Presenter), Physics, Ohio State University, HIMANSHU LOHANI, AMIT RIBAK, YUVAL NITZAV, Physics, Technion - Israel Institute of Technology, HUIXIA FU, BINGHAI YAN, Condensed Matter Physics, Weizmann Institute of Science, MOHIT RANDERIA, Physics, Ohio State University, AMIT KANIGEL, Physics, Technion - Israel Institute of Technology — Bulk FeSe$_{0.45}$Te$_{0.55}$ has recently emerged as a promising candidate to host topological superconductivity on its surface, with experimental signatures for a Dirac surface state and Majorana bound states in vortex cores. However, ARPES measurements of the bulk band structure show essentially no $k_z$ dispersion, in apparent contradiction with DFT predictions for the significant $k_z$ dispersion that drives the band inversion.

We reconcile the observed lack of dispersion with the predicted band inversion using a tight binding model with strongly renormalized inter-layer hopping and reasonable values of spin-orbit coupling. We use symmetry arguments to identify a sharp signature of bulk band inversion in the photon energy dependence of the ARPES matrix elements. We test our prediction for the change in orbital character of the band using ARPES data with a wide range of photon energies covering several Brillouin zones along $k_z$. We thus provide direct evidence for the non-trivial topology of the bulk bands in Fe(Se,Te), where the band inversion occurs in a nearly flat band due to an interplay of strong correlations and topology.

Session B62 DMP: Nanostructures and Metamaterials II  

Mile High Ballroom 4C - Hou-Tong Chen, Los Alamos Natl Lab - Tag(s): Focus
11:15AM B62.00001: Nonlinear Optical Metasurfaces* [Invited] IGAL BRENER (Presenter), Center for Integrated Nanotechnologies, Sandia National Laboratories — Nonlinear optics is a decades-old, well-established discipline that normally relies on macroscopic media and propagation lengths that are much longer than the wavelength. Recent progress in artificially structured materials has enabled a resurgence of this field into new directions and phenomena. Examples are increased efficiencies using materials that were not useful for bulk nonlinear optics and complete relaxation of phase matching conditions. In this talk I will cover some of these new developments in nonlinear optical metasurfaces and hybrid nonlinear metasurfaces that include semiconductor quantum wells.

11:51AM B62.00002: Microwave hybrid resonance with an electromagnetic metasurface XIAONAN ZHANG (Presenter), PING SHENG, Hong Kong University of Science and Technology — Hybrid resonances were discovered in acoustics a few years ago. Here we demonstrate through full waveform simulations the realization of microwave hybrid resonance by using a simple H-fractal metallic metasurface, with unit cell's lateral dimension much subwavelength in size. With an extremely thin back cavity, the resonances of the metallic structure at different frequencies can be hybridized to generate a new mode near the anti-resonance frequency. The oscillator strength and dissipation power of the hybrid resonance can be easily tuned, with total absorption occurring when the surface impedance matches that of vacuum. Similar to the acoustic case, the local fields are found to be much larger than the incident wave amplitude while the surface averaged fields are comparable to the incident fields. The total thickness of the surface is less than the peak absorption wavelength by two orders of magnitude. And we also found this microwave hybrid resonance by using the metallic metasurface and its complementary structure, which is hard to achieve in acoustics.
12:03PM B62.00003: Regular sloshing modes in irregular cavity using metabathymetry
ADAM ANGLART (Presenter), Physique et Mecanique des Milieux Heterogènes (PMMH), AGNES MAUREL, Institut Langevin, ESPCI, PHILIPPE PETITJEANS, Physique et Mecanique des Milieux Heterogènes (PMMH), VINCENT PAGNEUX, Laboratoire d'Acoustique de l'Université du Maine — We demonstrate experimentally and numerically that metamaterials can be used to control water wave propagation and resonance properties of a closed cavity. The anisotropic medium, designed using coordinate transformation theory [1] and the homogenization of fully three-dimensional linear water wave problem [2], consists of a bathymetry with a layered structure at a subwavelength scale. Three cavities with bending angles of 15°, 30° and 45° are tested and compared to a reference case with flat bathymetry. Fourier Transform Profilometry [3] as well as Confocal Displacement Sensors are used for space-time resolved measurements of a water surface deformation. Experimental data show the capability of water-wave metamaterials to provide a robust anisotropic medium for wave propagation.

12:15PM B62.00004: Measurement of asymmetrical water waves wake due to an anisotropic bathymetry
LEO-PAUL EUVE, PHILIPPE PETITJEANS (Presenter), AGNES MAUREL, ESPCI Paris, VINCENT PAGNEUX, LAUM, Univ. du Maine, France — Metamaterials have the surprising property of modifying the wave propagation, and more precisely in our investigation, the waves forming the wakes. One example of wakes in metamaterials is the study of Luo et al [1] describing different behavior for the Cerenkov radiation in a photonic crystal. In our case, we consider ship wakes. This domain have received considerable attention over the last decade, even though this specific field of water waves has been studied for almost a century and a half, if we refered to the Lord Kelvin studies.

We show, experimentaly, that ship wakes can become highly asymmetrical when they propagate on an anisotropic metamaterial. In our study, the metamaterial is obtained with a periodic stratified bathymetry which varies at a subwavelength order. More precisely, vertical plates are placed in parallel on the bottom of a water tank, as in [2,3]. The experimental results can be numerically reproduced using a theory based on an anisotropic dispersion relation [3].

12:27PM B62.00005: High-index nanostructures and layered materials for light scattering control

VIKTORIIA BABICHEVA (Presenter), Electrical and Computer Engineering, University of New Mexico — Planar optical elements with efficient light control at the nanoscale can be designed based on transdimensional photonic lattices that operate in the translational regime between two and three dimensions. Such transdimensional lattices include 3D-engineered nanoantennas supporting multipole Mie resonances and arranged in the 2D arrays to harness collective effects in the nanostructure [1]. Optical antennas made out of van der Waals material with naturally-occurring hyperbolic dispersion is a promising alternative to plasmonic and high-refractive-index dielectric structures in the practical realization of nanoscale photonic elements. The antenna made out of hexagonal boron nitride (hBN) possesses different multipole resonances enabled by the supporting high-k modes and their reflection from the antenna boundaries. The full range of the resonances is demonstrated for the hBN cuboid antenna, a decrease of reflection from the array, and highly directional resonant scattering from antennas pairs. We show that transdimensional lattices consisting of resonant hBN antennas in the engineered periodic arrays have great potential to serve as functional elements in ultra-thin optical components and photonic devices. 12:39PM B62.00006: Towards perfect absorption via block copolymer designed metasurfaces

CIAN CUMMINS (Presenter), QUENTIN FLAMANT, ALEXANDRE BARON, Centre de Recherche Paul Pascal, University of Bordeaux, GEORGES HADZIOANNOU, GUILLAUME FLEURY, University of Bordeaux, VIRGINIE PONSINET, Centre de Recherche Paul Pascal, University of Bordeaux — Engineering light-matter nanoscale interactions has diverse applications for advancing optical nanodevices, sensors, and energy harvesting. An emerging route to realise perfect absorption is based on artificial ultrathin nanosurfaces, known as “metasurfaces”.1 We describe a versatile metasurface fabrication strategy based upon gold (Au) selective deposition in block copolymer (BCP) templates towards perfect absorption. Since BCPs can be patterned over large wafer scale areas (i.e. 300 mm) and are industry compatible, they offer a viable path towards realising nanophotonic devices.2 Here, we describe a Au−Al₂O₃−Au stack layer for perfect absorption at visible frequencies using BCP templating. Our approach opens up a flexible methodology to precisely tune Au nanostructure height, e.g. 5-30 nm and resulting absorption wavelength range. The ability to tailor Au features precisely is extremely appealing and surpasses various wet chemical approaches that cannot be processed in thin film form. We will present key experimental parameters guided by numerical simulations to show the effect of Au height and stack architecture on absorption properties.

12:51PM B62.00007: Femtosecond Polarization Pulse Shaping by Dielectric Metasurfaces

LU CHEN (Presenter), WENQI ZHU, National Institute of Standards and Technology, JUNYEOB SONG, Electrical and Computer Engineering, Virginia Tech, JARED H STRAIT, CHENG ZHANG, National Institute of Standards and Technology, WEI ZHOU, Electrical and Computer Engineering, Virginia Tech, HENRI J LEZEC, AMIT AGRAWAL, National Institute of Standards and Technology — Metasurfaces are ultra-thin, planar optical elements that have been successfully employed for a variety of spatial-domain wavefront manipulations[1]. Recently, the time-domain shaping of a large bandwidth, near-infrared femtosecond pulse was demonstrated using dielectric metasurfaces. Simultaneous and independent control of the phase and amplitude of frequency components of a pulse enables finely tailored pulse-shaping operations, including splitting, compression, chirping and higher-order distortion[2]. Here, we further exploit dielectric metasurfaces to control the temporal polarization state within a single pulse. Such an approach expands the versatility of the already fruitful metasurfaces, revealing new possibilities in the field of ultrafast science and technology.

1:03PM B62.00008: Broadband Linear-to-Circular Polarization Conversion Enabled by Birefringent Off-Resonance Reflective Metasurfaces

DONGFANG LI (Presenter), CHUN-CHIEH CHANG, Los Alamos National Laboratory, ZHEXIN ZHAO, Stanford University, ANTOINETTE TAYLOR, Los Alamos National Laboratory, SHANHUI FAN, Stanford University, HOU-TONG CHEN, Los Alamos National Laboratory — Circularly polarized light in the terahertz (THz) regime is essential for a variety of scientific research and technological applications. However, it is challenging to achieve broadband circular polarization at these long wavelengths due to the dispersion of common birefringent materials. Here we propose and demonstrate the broadband linear-to-circular polarization conversion with up to 80% fractional bandwidth and near-unity power conversion efficiency based on the coupled-mode theory using reflective birefringent metasurfaces [1]. The arbitrary rotation of a linear polarization can also be achieved by leveraging the design parameters of the unit cell. This novel design approach can be further expanded to the mid-infrared and visible regimes by simply scaling the size of the structure. The realization of the polarization converter and rotator may significantly enrich the polarization-based optical probe of matter, including circular dichroism spectroscopy at THz regime and studies of the rising quantum materials.

1:15PM B62.00009: Constructing broadband multifunctional wave plates with stereo-metastructures*  
SIJIA SUN, XIANG XIONG (Presenter), YAJUN GAO, RUWEN PENG, MU WANG, 
Nanjing Univ — Polarization is one of the most important properties of light. Over the past few years, the development of metamaterials offers different approaches to manipulate the polarization state. Most designs are based on resonantly coupling. Due to the high losses and strong dispersion, their working frequency ranges are usually narrow. The multifunction design is another approach to integrating the element. Realizing different functionalities with one element can miniaturize the element. However, due to the uncontrollable electro-magnetic coupling between different parts, the multifunctional metastructures is difficult. Here we demonstrated two 3D broadband multifunctional wave plates. Simulated and experimental results indicate that half wave plate and quarter wave plate functions can be realized separately at lower and higher frequency with one metastructure. Moreover, coding and display depending on polarization were also proposed. Our work provides a new idea for design of highly compact metastructure and shows prospects for applications in display technology.

1:27PM B62.00010: Optical properties of plasmonic metasurface with sub-nm gaps - Refractive index variation originating from electron transports -  
TAKASHI TAKEUCHI (Presenter), MASASHI NODA, KAZUHIRO YABANA, Univ of Tsukuba — Plasmonic metasurfaces consisting of two-dimensionally arrayed metallic nano-objects on a plane have drawn attention in terms of its exotic optical characteristics. Although investigations of metasurfaces conducted to date have focused on structures with sub-wavelength spatial scale, recent experimental studies have demonstrated those with much smaller size in which the gap distances between the nano-objects reach to sub-nm length where quantum mechanical effects becomes important. In our presentation, we theoretically and numerically investigate the plasmonic metasurface with sub-nm gaps in terms of the refractive index variation due to quantum mechanical effects. To take into account quantum mechanical effects in the analysis, we employ time-dependent density functional theory(TDDFT) treating the constituent nano-particles by a jellium model. Furthermore, to distinguish the importance of the quantum mechanical effects, another simulation based on conventional classical electromagnetism is also employed and compared with the TDDFT. SALMON(https://salmon-tddft.jp/) developed by our group has been used for those numerical calculations. We will show that drastic change of the refractive index starts around gap distances 0.2 nm where electron transports take an important place.
1:39PM B62.00011: Dynamic Switching between Surface Wave and Plane Wave with MEMS-based Metasurface* CHUNXU CHEN (Presenter), XIAOGUANG ZHAO, Boston Univ, KELSON KAJ, IAN HAMMOCK, University of California, San Diego, KE WU, Boston Univ, RICHARD AVERITT, University of California, San Diego, XIN ZHANG, Boston Univ — We present polarization-insensitive dynamic surface wave (SW) switching at terahertz frequencies utilizing a MEMS-based metasurface. Our MEMS-based metasurface consists of a micro-cantilever array, enabling dynamic tuning between a plane wave (PW) and a SW for normal incidence of terahertz radiation. Through individual control of the driving voltages on the cantilever unit cells, we achieve nearly 2π phase modulation with minimal reflection amplitude modulation. Coupled mode theory (CMT) is employed to design the metasurface device and agrees with full-wave electromagnetic simulations. Our demonstration paves the road for terahertz multifunctional metasurface devices for spatial light modulation, dynamic beam steering, focusing, and beam coupling.

*Research supported by National Science Foundation under Grant No. ECCS-1810252.

1:51PM B62.00012: Dynamically-tunable metastructures based on phase transition of vanadium dioxide RUWEN PENG (Presenter), F. Z. SHU, J. N. WANG, Nanjing University, China, YONGMIN LIU, Northeastern University, Boston, USA, MU WANG, Nanjing University, China — Tunable nanophotonic materials and devices are drawing intense attention with great promise for practical applications. In this work, we have experimentally demonstrated several dynamically-tunable metastructured devices based on phase transition of vanadium dioxide, which include dynamic plasmonic color generators, dynamically switchable polarizers, and dynamically tunable bowtie nanoantennas. First, we have fabricated periodic arrays of silver-nanodisks on a vanadium dioxide film to realize different colors, relying on the excitation of localized and propagating surface plasmons. Based on insulator-metal transition of vanadium dioxide, the plasmonic colors can be actively tuned by varying temperature. Second, we have demonstrated a system consisting of anisotropic plasmonic nanostructures with vanadium dioxide that exhibits distinct reflections subjected to different linearly polarized incidence at room temperature and in the heated state. Third, we have made the dynamically tunable bowtie nanoantennas integrated on a vanadium dioxide thin film. The investigations here can be applied in dynamic digital displays, optical data storage, and imaging sensors. References: 1) Adv. Opt. Mater.(2018) 6, 1700939; 2) Phys. Rev. Appl. (2018) 9, 034009; 3) Opt. Lett. (2019) 44, 2752.
Metasurfaces have enabled unprecedented control of the phase, amplitude, and polarization of optical wavefronts, providing new opportunities in areas such as negative refraction and optical cloaking. The fabrication of optical metasurfaces still requires complex processing techniques that include additive or subtractive methods. Here we electrically create metasurfaces in VO$_2$ thin film by using a resist layer with periodic boomerang-shaped orifices to strictly confine the metallic VO$_2$ antennas induced by ionic liquid gating within the insulating VO$_2$ matrix. The non-volatile insulator-to-metal transition in VO$_2$ is due to a tiny reduction of oxygen content of the VO$_2$ under ionic liquid gating. Such optical plasmonic metasurfaces, with metallic VO$_2$ feature sizes ranging from 100 to 500 nm, allow the complete phase control ($-\pi$ to $\pi$) and orthorhombic polarization switching of light in the mid infrared range. Our result represents a new paradigm for the fabrication and manipulation of optical metamaterials.

*We acknowledge partial funding from the EU H2020 program “Phase Change Switch”.

Monday, March 2, 2020 11:15 AM - 2:15 PM
Electronic Structure of Tetragonal CH$_3$NH$_3$PbI$_3$ * JEEHONG PARK (Presenter), DONGHEE KANG, JAEHYUN YANG, YOUNG WOO CHOI, Institute of Physics and Applied Physics, Yonsei University, SOONSANG HUH, Center for Correlated Electron Systems, Institute for Basic Science, HYOUNG JOON CHOI, Institute of Physics and Applied Physics, Yonsei University, CHANGYOUNG KIM, Center for Correlated Electron Systems, Institute for Basic Science, HYUNBOK LEE, Department of Physics, Kangwon National University, YEONJIN YI, Institute of Physics and Applied Physics, Yonsei University — Organic-inorganic halide perovskites (OIHP) have been highlighted in optoelectronics research area for the last decade. OIHPs exhibit long carrier diffusion length ($\lambda$) despite of its moderate-to-low mobility ($\mu$). In case of CH$_3$NH$_3$PbI$_3$, the highest value of reported $\lambda$ reaches beyond $\mu$m while the $\mu$ is about only <100cm$^2$s$^{-1}$V$^{-1}$. Several underlying mechanisms have been proposed in order to account for the unusual transport property. One of them is the suppression of charge-carrier recombination by formation of spin-polarized indirect bandgap due to the Rashba effect. However, experimental evidence of such effect is lacking so far and there are ongoing debates regarding its presence and effectiveness. In this presentation, we present our unprecedented high-quality ARPES results measured on single crystal CH$_3$NH$_3$PbI$_3$ (001) surface. We also show circular dichroism ARPES (CD-ARPES) from which we can exploit the information about spin-polarization of electronic structure and discuss the compatibility of the Rashba scenario. We believe our work provides important experimental evidence of one of the most debatable issues in OIHPs.

*This study was supproted by the NRF of Korea [NRF-2018R1D1A1B07051050, 2018R1A6A1A03025582 and 2017R1A5A1014862 (SRC program: vdWMRC center)]

Wavelength Dependent Photostability of Perovskite Thin Films * BEN ECKER (Presenter), KE WANG, YONGLI GAO, University of Rochester — In the ten years since their first reported use in a photovoltaic device, hybrid organic-inorganic perovskite solar cell's power conversion efficiencies have surpassed 25% and further research efforts have continued to improve their scalability and long-term operational stability. One stability that has to be thoroughly investigated is the long term photostability of the perovskite materials. Here we will present our recent in-situ wavelength-dependent photostability investigation on bare perovskite thin films. Pristine co-evaporated CH$_3$NH$_3$PbI$_3$ thin films were initially grown on pyrolytic graphite surfaces, and they were then illuminated for prolonged durations to approximately 1 sun (1mW/mm$^2$) of either blue (408 nms) or red (650 nms) laser light. The films were maintained under constant vacuum conditions, and x-ray photoemission spectroscopy measurements were taken after each exposure. The dichotomy of the behavior of the films while under either the red or blue light, is suggestive of a wavelength dependence to the degradation mechanisms.

11:39AM B63.00003: Excitonic behavior in hybrid halide perovskite for optoelectronic applications  
HYE RI JUNG (Presenter), WILLIAM JO, EWHA Woman's Univ — Organic-inorganic lead halide perovskites, \( \text{CH}_3\text{NH}_3\text{PbX}_3 \) (\( \text{X} = \text{Cl}, \text{Br}, \text{I} \)), have gained great attentions for their attractive optoelectronic properties and excellent performances in various optoelectronic devices. To resolve the remained issues and advance the optoelectronic application devices, understanding intrinsic properties of this material is significant. In particular, free carrier and excitonic behaviors play a crucial role to support the charge transport process which aids the advanced device design. We verified structural properties using temperature dependence photoluminescence and transmission spectra. Under 160 K as orthorhombic phase, unusual excitonic behaviors were found near band edge. We also determined surface potential distribution with and without external light source using Kelvin probe force microscopy. We described electronic band structures of halide perovskite effected by photovoltage. Since the large band gap energy about 3 eV, different photovoltages characteristics were displayed depending on the wavelength of the light source, and it is affected by the defect states on the band edges and the bound excitons on the band edge. Those results suggest that the identified perovskite structure and excitonic properties will apply to many optoelectronic devices.

11:51AM B63.00004: Recombination Dynamics of Chlorine Doped Hybrid Perovskite Single Crystals*  
LA MOYNE MIX (Presenter), MIN-CHEOL LEE, KENNETH O'NEAL, NICHOLAS SIRICA, JEREMY TISDALE, WANYI NIE, ROHIT P PRASANKUMAR, DZMITRY YAROTSKI, Los Alamos National Laboratory — Controlling the photo excited properties and behavior of hybrid perovskites by halide doping has the potential to impact a wide range of emerging technologies, including solar cells and radiation detectors. Crystalline samples of methyl ammonium lead bromide (MAPbBr) were substituted with varying levels of Cl at the c site and probed with transient reflectivity spectroscopy. MAPbBr perovskites exhibit an increase in transient reflectivity following photoexcitation, with electron-phonon relaxation on a few picosecond timescale and a triple exponential recombination dynamic which is not complete after 1.5 nanoseconds. The recombination dynamics strongly depend on pump fluences, while the electron-phonon relaxation remains unchanged. We also observed that the doping level affected the electron-phonon coupling within the conduction band, becoming stronger with increased percentage of Cl.

12:03PM B63.00005: Ultrafast Carrier Dynamics of Dual Emissions from Methylammonium Lead Iodide Perovskites*  MARIA MUNOZ (Presenter), Florida International University, MICHAEL TITZE, Sandia National Laboratories, FEI CHENGBIN, Department of Physics, University of Miami, XUEWEN WANG, Florida International University, HE WANG, Department of Physics, University of Miami, HEBIN LI, Florida International University — Hybrid lead iodide perovskites have been attractive for its optical properties for many applications in different fields. One of the most promising applications is as a material for future generation of solar cells. The understanding of the photoexcitation dynamics is very important for improving their performance in solar cells and other applications. We implemented optical two-dimensional coherent spectroscopy to study the carrier dynamics and coupling of dual emissions in Methylammonium Lead Iodide film at 115 K. The sample was prepared by spin-coating perovskite precursor onto a glass substrate and successive annealing at 100 °C. From the 2D spectra we observed an ultrafast redistribution of the photoexcited carriers into the two emission resonances. The dynamics of carrier relaxation into the high energy and low energy resonance are different. The high-energy resonance is a short-lived transient state. The low-energy resonance has a longer lifetime and interacts with coherent phonons.

12:15PM B63.00006: Third-order optical nonlinearities of lead halide perovskite single crystals*  KEIICHI OHARA (Presenter), TAKUMI YAMADA, HIROKAZU TAHARA, TOMOKO AHAREN, HIDEKI HIRONI, Kyoto Univ, HIDEKATSU SUZUURA, Hokkaido Univ, YOSHIHIKO KANEMITSU, Kyoto Univ — Lead halide perovskite semiconductors, MAPbX$_3$ (MA = CH$_3$NH$_3$, X = I, Br, and Cl), have attracted much attention as a new class of photonic device materials because of their excellent optoelectronic properties. Recently, we found unique nonlinear optical responses such as large optical modulation [1] and efficient higher-order harmonic generation [2] in MAPbX$_3$ perovskites. However, the origin of large nonlinear optical responses remains unclear. In this work, we determined the third-order nonlinear optical coefficients of the wide-gap semiconductor MAPbCl$_3$ single crystals by using the Z-scan method. We measured the excitation wavelength and polarization dependences of these coefficients. It is found that the absolute values of coefficients depended on the crystal orientation of perovskite single crystals. These excitation wavelength dependences can be quantitatively explained by a two-band model including the exciton effect and Kane’s kp theory. The Kane energy and the exciton reduced mass of MAPbCl$_3$ were determined [3].

12:27PM B63.00007: Fine Features of Free and Bound Excitons in the Photoluminescence of Single Crystal MAPbI$_3$*  MATTHEW SHEFFIELD (Presenter), YUE YAO, ISAAC P BROWN HEFT, HESHAN HEWA WALPITAGE, University of Utah, YE LIU, ZHENYI NI, JINSONG HUANG, University of North Carolina at Chapel Hill, YAN LI, University of Utah — Understanding the photoluminescence (PL) characteristics and exciton properties of hybrid organic-inorganic perovskites (HOIPs) plays a key role in optimizing their performance in optoelectronic devices. In particular, PL is an important technique for the investigation of carrier-phonon interactions and quantification of defects in a system. However, these properties are inaccessible when important signatures are masked by the wide inhomogeneous broadening seen in polycrystalline films, which are commonly used in devices. Here, we study PL on high quality MAPbI$_3$ single crystals in the orthorhombic phase. The high crystalline quality and well controlled defect density allow us to obtain PL spectra with narrow features and reveal new ones that were not resolvable before. Temperature dependence and excitation intensity dependence data clearly show features of the free exciton and several bound excitons, with consistent energy levels verified among several samples. Assignment of each peak will be discussed, as well as exciton binding energy and exciton-phonon couplings. These newly resolved fine features on high quality single crystals will allow further in-depth studies of the intrinsic photophysics and defect properties related to growth conditions in HOIPs.

12:39PM B63.00008: Spintronic Terahertz Emission by Ultrafast Spin-Charge Current Conversion in Reduced Dimensional Organic-Inorganic Hybrid Perovskites*  
KANKAN CONG, Advanced Photon Source, Argonne National Laboratory, ERIC VETTER (Presenter), Physics, North Carolina State University, YAN LIANG, Department of Chemistry, University of North Carolina at Chapel Hill, YI LI, Department of Physics, Oakland University, QI ZHANG, Advanced Photon Source, Argonne National Laboratory, YUZAN XIONG, Department of Physics, Oakland University, HONGWEI QU, Department of Electronic and Computer Engineering, Oakland University, RICHARD D SCHALLER, Advanced Photon Source, Argonne National Laboratory, AXEL HOFFMANN, Materials Science Division, Argonne National Laboratory, ALEXANDER F KEMPER, Physics, North Carolina State University, WEI YOU, Department of Chemistry, University of North Carolina at Chapel Hill, HAIDAN WEN, Advanced Photon Source, Argonne National Laboratory, WEI ZHANG, Department of Physics, Oakland University, DALI SUN, Physics, North Carolina State University — Reduced Dimensional Hybrid Metal Halides (RD-HMHs) are a new class of synthetic semiconductor prepared via low-temperature solution processing with a wide array of possible chemical and structural arrangements enabled by the versatility of their molecular cations. RD-HMHs have already been shown to possess remarkable photovoltaic, excitonic, and optoelectronic properties, but their rich spintronic functionalities have yet to be utilized. We report the successful observation of the inverse Rashba-Edelstein Effect (IREE) in a 2D HMH (BA)$_2$(MA)$_{n-1}$Pb$_n$I$_{3n+1}$ driven by spin pumping from an adjacent ferromagnetic Ni$_{81}$Fe$_{19}$ layer using femtosecond laser pulses. We observed spin-dependent THz radiation at room temperature. The phase of the THz field can be controlled by means of an external magnetic field. Circular polarization dependence of the THz radiation confirms the helicity-dependent directional THz radiation and reveals the Rashba states in the RD-HMH materials. This work opens the door for next generation, low-cost THz emitters with tunable functionalities.

12:51PM B63.00009: Utrafast Spectroscopy Studies in Chiral Hybrid Perovskites*  
YAXIN ZHAI (Presenter), MATTHEW C BEARD, National Renewable Energy Laboratory — An organic–inorganic hybrid perovskite incorporating chiral organic molecules has been demonstrated as a new class of chiral semiconductors. Here we report our recent studies on the optical and spin properties in FAPbBr$_3$ nanoparticles with different ratio of chiral ligands by using the broadband ultrafast spectroscopy.

1:03PM B63.00010: Exciton decoherence probed by magneto-photoluminescence in halide perovskite bulk single crystals* LIANG TAN (Presenter), Lawrence Berkeley National Laboratory, ALYSSA KOSTADINOV, EFRAT LIFSHITZ, Solid State Institute, Technion — Understanding the physics behind the high performance of lead halide perovskite compounds is an urgent objective of photovoltaics research. Due to the existence of large spin-orbit interactions, the investigation of spin properties in these materials has emerged as the primary consideration for using halide perovskites as building blocks in spin-electronic devices. Herein we report on a combined theoretical and experimental effort to probe spin dynamics in halide perovskites using magneto-optical measurements. We perform magneto-photoluminescence measurements of MAPbBr$_3$ high quality single crystals, observing luminescence intensity suppression and recovery at magnetic fields corresponding to cyclotron frequencies where triplet exciton thermalization is in competition with exciton spin precession into the singlet exciton state. Theoretical modeling of exciton dynamics provides evidence for the existence of an Overhauser effect, arising from spin exchange between the excitonic and nuclear spin systems.

1:15PM B63.00011: Investigating the Optical and Electrical Properties of Two-dimensional Organic-inorganic Hybrid Perovskite Multiple Quantum Wells via Electroabsorption Spectroscopy Studies* [Invited] LUISA WHITTAKER-BROOKS (Presenter), University of Utah — Despite the tremendous progress observed in the development of high-efficient 3D organic-inorganic halide perovskites (OIHPs) with power conversion efficiencies (PCEs) above 24%, there is still a significant challenge for the field related to addressing their poor stability towards extrinsic (i.e., moisture and oxygen) and intrinsic factors (ion migration, water intake, thermal instability). To ameliorate these notorious pitfalls that deleteriously affect PCEs and the long-term stability of OIHP solar cells, the photovoltaics field has shifted towards developing and understanding the properties of 2D OIHPs as the organic cation spacers comprising these layered systems do provide superb environmental stability to the structure. However, this increase in stability is often accompanied by a decrease in PCEs. Hence, the task posed by the field deals with increasing the PCEs of 2D OIHPs without compromising their stability. In this talk, I will discuss the role of excitons/free carries, sample heterogeneity, orientation, and bias stress effects on the photovoltaic performance of OIHPs. I will then discuss the exciton dynamics of 2D OIHPs and how phase and quantum well purity may affect exciton transitions and binding energies.

Visible and near-infrared emission properties of melt-grown Dy doped CsPbCl$_3$ perovskite crystals*  

SAMUEL UBA (Presenter), UWE HOMMERICH, ALIX ALLEN, Hampton University — Doping of lead halides perovskites with rare-earth metals ions has become of significant current interest for possible applications in optoelectronics. In this research, we studied the material preparation and the visible to near IR optical properties of Dy$^{3+}$ doped CsPbCl$_3$. The crystal was synthesized from purified starting materials and melt-grown by vertical Bridgman technique. Visible emission studies under resonant-intra-4f excitation at ~450nm revealed bright yellow emission centered at 575nm arising from the $^4F_{9/2}$ to $^4H_{13/2}$ transition of Dy$^{3+}$ ions. Additional emission bands arising from the $^4F_{9/2}$ excited states were centered at 485nm, 664nm and 752nm. The decay time of the $^4F_{9/2}$ level was non-exponential with an average lifetime of ~320 µs. Near-infrared emission studies were performed using a 808 nm diode lasers and revealed several IR bands located at 1.14 µm ($^6H_{7/2}$+$^6F_{9/2}$ ->$^6H_{15/2}$), 1.33 µm($^6H_{9/2}$+$^6F_{11/2}$ ->$^6H_{15/2}$), 1.55 µm ($^6F_{5/2}$ ->$^6H_{11/2}$), and ~1.7 µm ($^6H_{11/2}$ ->$^6H_{15/2}$) arising from lower excited states of Dy$^{3+}$ ions. More details of the emission spectra and dynamics of Dy:CsPbCl$_3$ as well as a comparison to Dy:KPbCl$_2$ will be presented at the conference.

Improvement of luminescence properties of surface-passivated mixed-halide perovskites with CdSe/ZnS quantum dots  

IL-WOOK CHO (Presenter), MEE-YI RYU, Kangwon National University — CdSe/ZnS core-shell quantum dots (QDs) have been employed to enhance the optical properties of perovskite (PS). We investigated the luminescence properties of surface-passivated mixed halide perovskite (CH$_3$NH$_3$PbI$_2$Br) using photoluminescence (PL) and time-resolved PL spectroscopy. The integrated PL intensity and PL decay time of the QD/PS hybrid structure increased compared to those of the bare PS films, owing to charge transfer (CT) from the CdSe/ZnS QDs to the PS and reduced charge traps. The CT efficiency increased from ~7 to 63% for the QD/PS hybrid structure when the core diameter of the QDs decreased from 6.5 to 2.7 nm, respectively, which can be explained by the enhancement in the CT rate due to the control of energy level alignment of QDs. A shorter radiative lifetime was obtained in the QD/PS hybrid structures as compared to the bare PS film, which is attributed to the screening effects of the Rashba splitting and internal electric field due to the CT. These results allow us to understand fundamental mechanisms such as CT from QDs to PS as a function of the size of the QDs.

Session B64 DMP: Nickelate, Ferrite, and Cobaltate-Based Heterostructures: Metal-Insulator Transition, Magnetism, and Orbital Ordering  

Mile High Ballroom 4E - Divine Kumah, North Carolina State University - Tag(s): Focus
Effect of ordered oxygen vacancies on the electronic and magnetic structure of perovskite-derived LaNiO$_{3-\delta}$ nickelate  

YONGJIN SHIN (Presenter), JAMES RONDINELLI, Northwestern University — Rare-earth nickelates perovskites (RNiO$_3$, with R=rare earth) exhibit a plethora of electronic and magnetic phase transitions owing to the orbital structure of its trivalent Ni cations. Unlike other RNiO$_3$ compounds, LaNiO$_3$ is the only compound lacking a thermal metal-insulator transition. Nonetheless, oxygen-deficient LaNiO$_{3-\delta}$ exhibits interesting electronic/magnetic transitions with varying oxygen content $\delta$ owing to the reducibility of Ni$^{3+}$. Specifically, the metal-semiconductor-insulator transition occurs concurrently with paramagnetic (PM)-ferromagnetic (FM)-antiferromagnetic (AFM) transition in bulk materials as $\delta$ varies [1]. Here, we explain the LaNiO$_{3-\delta}$ phase transitions and their dependencies upon (ordered) oxygen vacancy formation using first-principles calculations. We find oxygen vacancies form along the (110)$_{pc}$ direction and transform NiO$_6$ octahedra to NiO$_4$ square planar units. The resultant NiO$_4$ unit is electronically and magnetically inactive, and this with the change in NiO$_6$ connectivity governs the phase transitions. We conclude with model interpretations of the transient states reported for LaNiO$_{2.5}$ and LaNiO$_3$, and their connection to experimental observations.

Length Scales and Symmetries in The Physics of Correlated Perovskite Oxides*  

ALEXANDRU BOGDAN GEORGESCU (Presenter), Center for Computational Quantum Physics, Flatiron Institute, CLARIBEL DOMINGUEZ ORDONEZ, JENNIFER FOWLIE, BERNAT MUNDET, University of Geneva, YAJUN ZHANG, ALAIN MERCY, University of Liège, SARA CATALANO, University of Geneva, DUNCAN T.L. ALEXANDER, École Polytechnique Fédérale de Lausanne, PHILIPPE R GHOSEZ, University of Liège, ANTOINE GEORGES, ANDREW MILLIS, Center for Computational Quantum Physics, Flatiron Institute, MARTA GIBERT, University of Zurich, JEAN-MARC TRISCOME, University of Geneva — An essential aspect in the study of correlated materials is the interplay of structural motifs and electronic degrees of freedom. This talk will describe how to design an oxide heterostructure composed of two different nickelates in order to provide insight into the length and energy scales involved in the metal insulator transition, as well as the resulting roles of the different structural motifs [1]. Then, I will explain how different aspects of the symmetry of the system can affect the interplay of correlations and kinetic energy. Specific results will be presented for heterostructures composed of different rare earth nickelate materials, and possible generalizations to other materials will be presented.
