In the past few years, work on lead chalcogenide alloys of PbSe, and PbTe has shown interesting tunability of electronic properties. PbTe-based materials have shown enhanced phonon scattering driven by a near ferroelectric phase transition mediated by strain or alloying. The thermal properties of such materials are of interest for thermoelectric applications. We consider a low-dimensionality heterostructure, the nanowire, which generally has a lower thermal conductivity compared to bulk. We consider a computationally efficient shell model to find the phonon dispersion of bulk, and approximate the nanowire phonon dispersion. Phonon transport is modeled with an energy deviational Monte Carlo formulation of the Boltzmann transport equation. We further consider layered alloys, with three different transition types between layers: abrupt, linear, and exponential. The considered phonon scattering mechanisms are phonon-phonon, boundary, defect, interface, alloy, and strain. We will report on the further tunability of thermal conductivity by manipulating nanowire heterostructures of these lead chalcogenide alloys.

**H71.00259: Imaging Nematic Transitions in Iron-Pnictide Superconductors with a Quantum Gas**  
FAN YANG, STEPHEN TAYLOR (Presenter), STEPHEN D EDKINS, JOHANNA PALMSTROM, IAN FISHER, BENJAMIN L LEV, Stanford Univ — The SQCRAMscope is a recently realized Scanning Quantum CRyogenic Atom Microscope that utilizes an atomic Bose-Einstein condensate to measure magnetic fields emanating from solid-state samples. Here, we combine the SQCRAMscope with an in situ microscope that measures optical birefringence near the surface of a sample to study iron-pnictide superconductors, where the relationship between electronic and structural symmetry-breaking resulting in a nematic phase is under debate. We conduct simultaneous and spatially resolved measurements of both bulk and surface manifestations of nematicity via transport and structural deformation channels, respectively. By performing the first local measurement of emergent resistivity anisotropy in iron pnictides, we observe a spatially inhomogeneous increase in the temperature at which optical birefringence appears near the surface over that at which anisotropic local transport appears within the bulk. This is consistent with the existence of a higher-temperature surface nematic transition, albeit one that emerges inhomogeneously. More broadly, these measurements demonstrate the SQCRAMscope's ability to reveal important insights into the physics of complex quantum materials.

*Supported in part by ONR and DOE.

**H71.00260: Monte-Carlo simulations of a random-field Ising-O(3) model**  
NATHANIEL PAGE (Presenter), THOMAS VOJTA, Missouri Univ of Sci & Tech — Many of the iron-based superconducting compounds undergo a structural phase transition and stabilize a stripe-like spin-order at low temperatures. We investigate the relation between the structural and magnetic phase transitions in these materials and study the effects of random strain commonly found in the samples. To do so, the magnetic properties of these materials are modeled via quasi-two dimensional Ising-O(3) model which describes both spin and nematic (stripe) degrees of freedom. Random strain is included via a random field term coupling to the nematic variables. We perform large-scale Monte Carlo simulations of this model to determine the phase diagram and characterize the phase transitions.

**H71.00261: Abstract Withdrawn**
H71.00262: Specific Heat Study in Iron Based Superconductors: A Theoretical Three-Orbital Model Analysis. MADHAVI AHALAWAT (Presenter), AJAY SINGH, Department of Physics, Indian Institute of Roorkee, India — The present work deals with the study of specific heat in superconducting state of iron based superconductors. In these materials, five 3d orbitals due to iron, Hund's coupling and electron correlations coexist and dominate electronic properties of these systems. Therefore, we have attempted the theoretical analysis based on three orbitals per site tight-binding model Hamiltonian containing hopping between orbitals, Hund's coupling and intra and inter orbital Coulomb interaction. We have employed Green's function technique within BCS mean field approximation to calculate the expressions of superconducting energy gap parameter and quasiparticle energies and used these results to calculate specific heat jump as a function of temperature and various parameters of the model Hamiltonian. Then we compared the results with the recent specific heat data and other relevant data of iron based superconductors.

H71.00263: Contribution of substrate phonon to the superconductivity of 1 unit-layer FeSe on SrTiO$_3$ HOYEON JEON (Presenter), MINJUN LEE, Seoul National University, Seoul, Korea, JIN MO BOK, HAN-YONG CHOI, Sungkyunkwan University, Suwon, Korea, YUNKYU BANG, Pohang University of Science and Technology, Pohang, Korea, JUNGPIIL SEO, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Daegu, Korea, JUNGSEOK CHAE, Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul, Korea, YOUNG KUK, Daegu Gyeongbuk Institute of Science and Technology (DGIST), Daegu, Korea — A single unit-layer (1 UL) FeSe grown on SrTiO$_3$ is one of Fe-based superconductors and has a high superconducting transition temperature compared to bulk FeSe of which Tc is near 8K. To investigate interface effect, especially phonons of substrate, we used scanning tunneling microscope (STM) and measured local electron density of states (DOS) of 1 UL FeSe on SrTiO$_3$. Our results show that the spectral features depend on the phonon dispersions of FeSe as well as that of SrTiO$_3$. Phonon density of states and electron-phonon coupling constant were calculated according to Eliashberg theory.
H71.00264: S* Superconductivity in Electron-Doped Iron Selenide by Exchange of Hidden Spin Fluctuations* JOSE RODRIGUEZ (Presenter), Physics and Astronomy, California State University Los Angeles — The observation of spin resonances around the corner of the unfolded Brillouin zone in intercalated iron-selenide high-$T_c$ superconductors is consistent with the presence of low-energy hidden spin fluctuations in these materials. We develop an Eliashberg theory based on the exchange of hidden spin fluctuations by electrons in the principal $3d_{xz}$ and $3d_{yz}$ orbitals of the iron atom. At half filling, and in the absence of interactions, an electron-type Fermi surface exists at the center of the unfolded Brillouin zone and a hole-type Fermi surface exists at the corner of the unfolded Brillouin zone. As the interaction strength grows strong, Eliashberg theory predicts a Lifshitz transition to electron/hole Fermi surface pockets at the corner of the folded Brillouin zone. They are extremely faint because of wavefunction renormalization. The Eliashberg theory also predicts a rigid shift of the renormalized band structure upon electron doping, resulting in small but faint hole Fermi surface pockets, and in larger electron Fermi surface pockets. Last, the Eliashberg theory predicts an instability to S-wave Cooper pairing that alternates in sign between the electron-type and the hole-type Fermi surface pockets.

H71.00265: Giant enhancement of critical current density at high field in superconducting (Li,Fe)OHFeSe films by Mn doping* DONG LI (Presenter), JIE YUAN, PEIPEI SHEN, Institute of Physics, Chinese Academy of Sciences, CHUANGYING XI, High Magnetic Field Laboratory, Chinese Academy of Science, JINPENG TIAN, SHUNLI NI, JINGSONG ZHANG, ZHONGXU WEI, WEI HU, ZIAN LI, LI YU, Institute of Physics, Chinese Academy of Sciences, JUN MIAO, School of Materials Science and Engineering, University of Science and Technology Beijing, FANG ZHOU, Institute of Physics, Chinese Academy of Sciences, LI PI, High Magnetic Field Laboratory, Chinese Academy of Science, KUI JIN, XIAOLI DONG, ZHONGXIAN ZHAO, Institute of Physics, Chinese Academy of Sciences — Critical current density ($J_c$) is one of the major limiting factors for high-field applications of iron-based superconductors. Here, we report that Mn ions are successfully incorporated into nontoxic superconducting (Li,Fe)OHFeSe films. Remarkably, the $J_c$ is significantly enhanced from 0.03 to 0.32 MA cm$^{-2}$ under 33 T, and the vortex pinning force density monotonically increases up to 106 GN m$^{-3}$, which is the highest record so far among all iron-based superconductors. Our results demonstrate that Mn incorporation is an effective method to optimize the performance of (Li,Fe)OHFeSe films, offering a promising candidate for high-field applications.

Results of Point-Contact Spectroscopy Measurements of the Energy Gap of Phosphorus-doped Iron Pnictides BaFe$_2$(As$_{1-x}$P$_x$)$_2$* BRET CONTI (Presenter), KEERAN O RAMANATHAN, ERIK CAULEY, University of the Sciences, CHENGLIN ZHANG, YU SONG, GUOTAI TAN, PENGCHENG DAI, Rice University, ROBERTO RAMOS, University of the Sciences — The study of multi-band superconductivity has gained momentum over the past few years, especially with the advent of iron-based superconductors where multiple energy gaps have been observed. The observed energy gaps which are anisotropic largely depend on the way that the crystal has been grown and how contact is made to access tunneling directions. Soft point contacts to the crystals studied were carefully made using silver paint. We report the results of four-wire tunneling spectroscopy measurements of the energy gap of phosphorus-doped iron pnictides BaFe$_2$(As$_{1-x}$P$_x$)$_2$ where $x = 0.204$, 0.304, 0.25, 0.39, 0.43 and 0.69. The differential conductance $dI/dV$ of these samples exhibit broad peaks and shoulders with $\Delta_1 = 2$-5 meV, and $\Delta_2 = 7$-10 meV. Some of these results were reproducible over similar samples, correspond well with existing data from literature while other features appear new. We report temperature-dependent features that we are in the process of analyzing. These measurements were performed fully by undergraduates.

**H71.00267: Quantum phase transition between the quantum anomalous Hall liquid and insulator states**

CHANG LIU (Presenter), YUNBO OU, YANG FENG, GAOYUAN JIANG, WEIXIONG WU, SHAORUI LI, ZIJIA CHENG, KE HE, XUCUN MA, QIKUN XUE, YAYU WANG, Tsinghua University — The quantum anomalous Hall (QAH) effect has been discovered in magnetically doped topological insulator (TI) thin films in zero magnetic field. A fundamental question concerning the QAH effect is whether it is merely a zero-magnetic-field quantum Hall (QH) effect, or if it can host unique quantum phases and phase transitions that are unavailable elsewhere. Here we perform transport studies on more than 80 QAH samples with different level of disorders. We discover two novel quantum phases, namely the QAH liquid and anomalous Hall (AH) insulator, and the quantum phase transition between them driven by magnetic field. Surprisingly, a universal quantum resistance h/e² is observed at the coercive field of QAH liquid samples in the low disorder limit. We propose that the transmission between chiral edge states, tunable by disorder and magnetic field, is the key for unraveling the peculiar quantum transport phenomena in magnetic TIs.

**H71.00268: High throughput screening of magnetic thermoelectric materials based on anomalous Nernst effect by first-principles study**

HIKARU SAWAHATA (Presenter), NAOYA YAMAGUCHI, SUSUMU MINAMI, FUMIYUKI ISHII, Kanazawa Univ — The thermoelectric conversion based on the anomalous Nernst effect (ANE) has attracted attention because the ANE realizes the high-density integration more easily compared to that based on the Seebeck effect. This effect is induced by the anomalous Hall conductivity (AHC), and if the AHC changes drastically as a function of the Fermi level, we expect the large ANE [1]. In this study, we implemented the method of computing AHC in metallic systems efficiently [2] to OpenMX code, and we performed high-throughput screening, searching for two-dimensional ferromagnetic materials which have the large Nernst coefficient by the first-principles calculation.

**H71.00269: The evolution of magnetism in intrinsic magnetic insulator material**

*MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n*  
FUCONG FEI (Presenter), Nanjing University — Magnetic topological insulators (MTIs) are promising platforms for the observation of quantum anomalous Hall effect (QAHE), which is a long-expected dissipationless quantum transport phenomenon without applying external magnetic field. The recent progress on intrinsic MTI materials shed new light on the observation of higher temperature of QAHE. Here we grow the high-quality single crystals of three promising intrinsic MTI candidates MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ ($n = 0, 1, 2$). By magnetic measurement, we discover that the all three compounds show anti-ferromagnetic (AFM) behavior, while the magnetic transition temperature decreases when increasing the value $n$. Meanwhile, by transport measurement, anomalous Hall effect can be observed in all three samples and the behaviors are correspondingly consistent with the magnetic measurements. The AFM coupling becomes weaker since the critical magnetic field for anti-ferromagnetism to ferromagnetism transition becomes lower when increasing $n$, and net ferromagnetic moment retains in $n = 1$ and 2 under low temperature. We believe that the tunable magnetic and transport properties by controlling the component ratio in MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ provide an ideal platform to investigate the high-temperature QAH phase and the related physics.

**H71.00270: Topological Electronic Structure and Its Temperature Evolution in Antiferromagnetic Topological Insulator MnBi$_2$Te$_4**

YUJIE CHEN (Presenter), Tsinghua University, LIXUAN XU, ShanghaiTech University, JIAHENG LI, Tsinghua University, YIWEI LI, University of Oxford, HONGYUAN WANG, ShanghaiTech University, CHAOFAN ZHANG, National University of Defense Technology, HAO LI, YANG WU, Tsinghua University, AIJI LIANG, CHENG CHEN, ShanghaiTech University, SUNGWON JUNG, CEPHISE CACHO, Diamond Light Source, YUANHAO MAO, National University of Defense Technology, SHUAI LIU, MEIXIAO WANG, YANFENG GUO, ShanghaiTech University, YONG XU, Tsinghua University, ZHONGKAI LIU, ShanghaiTech University, LEXIAN YANG, YULIN CHEN, Tsinghua University — The intrinsic magnetic topological insulator MnBi$_2$Te$_4$ exhibits rich topological effects such as quantum anomalous Hall effect and axion electrodynamics. Here, by combining the use of synchrotron and laser light sources, we carry out comprehensive and high-resolution angle-resolved photoemission spectroscopy studies on MnBi$_2$Te$_4$ and clearly identify its topological electronic structure. In contrast to theoretical predictions and previous studies, we observe topological surface states with diminished gap forming a characteristic Dirac cone. We argue that the topological surface states are mediated by multidomains of different magnetization orientations. In addition, the temperature evolution of the energy bands clearly reveals their interplay with the magnetic phase transition by showing interesting differences between the bulk and surface states, respectively. The investigation of the detailed electronic structure of MnBi$_2$Te$_4$ and its temperature evolution provides important insight into not only the exotic properties of MnBi$_2$Te$_4$, but also the generic understanding of the interplay between magnetism and topological electronic structure in magnetic topological quantum materials.
**H71.00271: Multifold Weyl nodes in a nonsymmorphic garnet compound**

HYO-SUN JIN (Presenter), KWAN-WOO LEE, Division of Display and Semiconductor Physics, Korea University — In condensed matters, now, many systems show linear band crossings of 4-fold Dirac nodes or 2-fold Weyl nodes, which have been sought for a long time in high energy physics. Recently, multifold nodes, which have no high energy counterpart, have been also proposed, e.g., 3-, 6-, and even 8-fold Weyl nodes. However, except triple-node points, no experimental realization has been successful yet. In this presentation, we will introduce an interesting real system with various exotic Weyl nodes, lying not far away from the Fermi energy.

Using first principles calculations, we will address a nonsymmorphic ferrimagnetic garnet insulator with the \textit{Ia-3d} space group (No.230). In the absence of spin-orbit coupling (SOC), this system shows various magnetic multifold Weyl nodes, in particular, of 4- and 6-folds. These nodes with nonzero Chern numbers are due to a combination of several crystalline symmetries including inversion and glide reflection symmetries. Furthermore, we will discuss on the topological nature of the unconventional Weyl nodes by an effective Hamiltonian analysis.

**H71.00272: Decoupling of electronic thermal conductivity and electrical conductivity in the magnetic nodal semimetal CeAlGe**

FEI HAN (Presenter), QUYNH NGUYEN, THANH NGUYEN, RICARDO PABLO PEDRO, ANUJ APTE, NINA ANDREJEVIC, MINGDA LI, Massachusetts Institute of Technology MIT — Wiedemann-Franz (WF) law is a robust empirical law stating that the ratio between the electronic thermal conductivity and electrical conductivity is related by a universal Lorenz number. For conventional materials, this law is strictly obeyed even when the electronic thermal conductivity and electrical conductivity are suppressed by magnetic fields. In the magnetic nodal semimetal CeAlGe, we observed a decoupling of electronic thermal conductivity and electrical conductivity.

CeAlGe possesses a ferrimagnetic ordering in the ab plane below 4.5 K. The magnetic field applied along the c axis diminishes the ferrimagnetic ordering and induces a ferromagnetic ordering along the c axis. At a certain temperature, the positive magnetoresistance (MR) originating from the enhanced electron cyclotron motion and the negative MR originating from the spin reorientation compensates completely, which makes the MR is zero at this temperature. However, at this temperature, the thermal conductivity does not keep a constant as expected by the WF law. In contrast, we found the magnetic field suppressed the thermal conductivity to the largest extent at this temperature. This indicates a new mechanism dominating the relationship between the electronic thermal conductivity and electrical conductivity.
**H71.00273: Magneto-transport properties of antiferromagnetic Weyl semimetal CuMnSb**

VIPIN NAGPAL (Presenter), SATYABRATA PATNAIK, School of Physical Sciences, Jawaharlal Nehru University-New Delhi — The electrical resistivity and magneto-transport properties of reported magnetic Weyl semimetal CuMnSb is studied. CuMnSb with an antiferromagnetic transition at 60K is synthesized using solid state reaction technique and crystallizes in cubic lattice structure with space group F-43m (216). No abrupt change in resistivity is observed below the transition under the application of 5T field. A highest non-saturating MR of 4% is observed at 5K and 6T. It is analyzed that MR in CuMnSb arises from the contribution of linear field $B$ dependence as well as the parabolic $B^2$ term.

*V. Nagpal acknowledge UGC NET-JRF, UGC New Delhi for financial support. S. Patnaik thanks funding support of SERB, DST-FIST and DST-PURSE programs of Government of India.

**H71.00274: Molecular beam epitaxy growth of (MnSb$_2$Te$_4$)(Sb$_2$Te$_3$)$_n$ SL/QL sequences**

IDO LEVY (Presenter), HAIMING DENG, STEVEN ALSHEIMER, LIA KRUSIN-ELBAUM, MARIA C TAMARGO, The City College of New York — Recent predicted intrinsic magnetic topological materials in the MB$_2$T$_4$-family (where M = V, Mn, Ni or Eu, B = Bi or Sb, T = Te, Se, or S) show a great promise for realizing intrinsic axion insulators and quantum anomalous Hall (QAH) insulators. These materials modify the B$_2$T$_3$ crystal structure forming septuple layers (SL) in the form of T-B-T-M-T-B-T. Not all of the listed magnetic TI candidates have been yet explored, and thus far out-of-plane surface magnetization was only found in MnBi$_2$Te$_4$ and MnSb$_2$Te$_4$. Both materials are antiferromagnetic (AFM) in the bulk and not suitable for QAH unless they have odd number of SLs. Recent studies in MnBi$_2$Te$_4$ have shown that separating SLs with Bi$_2$Te$_3$ quintuple layers (QL) turns an AFM into a ferromagnet (FM). Here we show that through layer-by-layer growth using molecular beam epitaxy (MBE) we can control the SL/QL sequence. We describe the conditions for which MnSb$_2$Te$_4$/Sb$_2$Te$_3$ sequence is ferromagnetic with $T_c$ higher than that in the Bi-based SL/QL sequence, as witnessed by large anomalous Hall signal with coercive field $\sim$0.1 T at 2 K. The structural (TEM and HR-XRD) characterization and the optimization of the SL/QL sequence will be presented.

*This work was supported by NSF Grant Nos. DMR-1420634 and HRD-1547830.
H71.00275: First-principles theory of Cr-vacancy in BaZrO$_3$ as a solid-state qubit candidate

JAEWOOK LEE (Presenter), HOSUNG SEO, Ajou Univ — Recently, remarkable advances have been made in the development of solid-state quantum bits (qubits), which are the basic hardware units of quantum information processing. One of the leading solid-state qubit platforms is the nitrogen-vacancy (NV) center in diamond. Furthermore, a significant interest has been emerging in the literature to develop such defect-based qubits in diverse wide-gap semiconductors for broadening the scope of the solid-state quantum information. In this study, we explore a Cr-O vacancy complex in BaZrO$_3$ as a potential solid-state qubit candidate. We use first-principles density functional theory to examine the stability and the electronic and spin properties of the Cr-O vacancy pair in BaZrO$_3$. To investigate the stability of the defect in various charge states, we calculate the defect formation energy of Cr-vacancy in BaZrO$_3$. In addition, we use HSE06 hybrid functionals to accurately calculate the defect level diagram and the zero-phonon line of the Cr-O vacancy. In the poster, we also discuss the recent progress and challenges in computational design of new defect qubits in complex wide-gap materials.

H71.00276: Magnetic-field and tunable-barrier effects on charge transport in DNA heterostructures

YONG JOE (Presenter), ALAA ALSAID, IBTISAM ABU ALKHAYR, Ball State University — The tunable barrier and magnetic field effects are studied in the electron transport of the double-stranded DNA molecular electronic structure. Our theoretical approach involves the application of the two-dimensional tight-binding Schrödinger equation to calculate transmission and electric current through the nearest-neighbors of twenty base-pairs’ DNA. A combination of G-C and A-T base-pairs of DNA, which can be considered as a barrier and a well, forms a superlattice in semiconductor heterostructures and exhibits a miniband whose width depends on the strength of the barriers and energy level of the wells. We also incorporate a variation of magnetic field flux density into the hopping integrals as a phase factor and observe Aharonov-Bohm (AB) oscillations in the transmission. It is shown that for non-zero magnetic flux, the transmission zero leaves the real-energy axis and moves up into the complex-energy plane. We also point out that both the hydrogen bonds between the base pair and the coupling between leads and DNA with flux variations play a role to determine the periodicity of AB oscillations in the transmission.
**H71.00277: Non-Hermitian Thermal Emitters using Metal-Semiconductor Hybrid Resonators**

CHLOE F DOIRON, GURURAJ NAÎK (Presenter), Rice Univ — Thermal emitters always have absorption losses and hence are open systems. Open systems are non-Hermitian and are best described by non-Hermitian physics. Here, we develop a non-Hermitian description of resonant thermal emitters and thereby take advantage of absorption loss in the system. Further, the non-Hermitian description provides new design tools such as symmetry, phase, and topology to control the properties of the thermal emission. We demonstrate such a thermal emitter using coupled plasmonic and photonic resonators. A lossless silicon photonic resonator is coupled to a lossy tungsten plasmonic resonator via a spacer. As the spacer thickness is increased, the thermal emission from the device held at 1000 K exhibits a transition from PT-symmetric to symmetry-broken phase through an exceptional point. The thermal emission from the device breaks the trade-off between emission brightness and spectral selectivity and simultaneously achieves both. Further, we show that the internal phase of resonators is a powerful tool to control the thermal emission from this device. Overall, this work is an unorthodox approach towards designing not only thermal but also other nanophotonic light sources.

**H71.00278: The effect of van der Waals force on two-dimensional SiC/GeC heterostructures**

SAFIA ABDULLAH R ALHARBI, MING YU (Presenter), Univ of Louisville — The effect of van der Waals interaction on two-dimensional (2D) SiC/GeC heterostructures has been studied based on the density functional theory. The van der Waals interaction is considered by employing the semi-empirical correction scheme of Grimme [1], which is used in optimizing the equilibrium interlayer distance and binding energy between 2D monolayers. We found that for the layered SiC/GeC heterostructure with the C-Ge (Si-C) species order, the cohesive energy as a function of interlayer distance is about 0.03 eV per unit cell lower than that with the C-C (Si-Ge) species order, for both AA and AB stacking. Further findings show that the interlayer electrostatic forces mainly stabilize the equilibrium distance for the C-Ge (Si-C) species ordering, and vdW interactions only make the system attain a lower cohesive energy. On the other hand, vdW forces stabilize the interlayer distance for the C-C (Si-Ge) species order. These preliminary results suggest that interlayer electrostatic forces may play a role in ionic-like multilayer heterostructures.

*We acknowledge the finding support by Arts and Sciences Research and Creative Activities Grant at University of Louisville.
H71.00279: Experimental studies of nonlinear optics of self-assembled hyperbolic metamaterials  
WILL KORZI (Presenter), JONATHON CARTELLI, BRYAN AUGSTEIN, KENT HESS, Department of Physics, Astronomy, and Geosciences, Towson University, NAVEEN KADASALA, STEPHEN BLAMA, MARY SAJINI DEVADAS, Department of Chemistry, Towson University, VERA N SMOLYANINOVA, Department of Physics, Astronomy, and Geosciences, Towson University, IGOR I SMOLYANINOV, Saltenna LLC and University of Maryland — Sub-wavelength confinement of light in nonlinear hyperbolic metamaterials due to formation of spatial solitons has attracted much recent theoretical attention because of its seemingly counter-intuitive behavior. In order to achieve self-focusing in a hyperbolic wire medium, a nonlinear self-defocusing Kerr medium must be used as a dielectric host. It was demonstrated that this behavior finds natural explanation in terms of analogue gravity in effective “optical spacetime”, which can be used to describe nonlinear optics of a hyperbolic wire medium. In this work we will report first experimental observation of this effect using iron-cobalt ferrofluid-based self-assembled hyperbolic metamaterials subjected to external magnetic field.

H71.00280: Enhancing the Light Emission of Colloidal Quantum Dots with Dual-band Absorbers Based on Metasurfaces  
DONGFANG LI (Presenter), CHUN-CHIEH CHANG, AJAY SINGH, JENNIFER A HOLLINGSWORTH, HOU-TONG CHEN, Los Alamos National Laboratory — Quantum dots (QDs) are essential light emitters with great tunability of spectrum and find important technological applications in various areas, including light-emitting devices, photovoltaics, and bioimaging. The recent advance of metamaterials has enabled the direct control of the light emission properties with patterned ultrathin metallic films, ranging from enhanced light emission and modified fluorescence spectrum to well-defined polarization and unidirectional radiation. However, the outcoupling efficiency of two-dimensional (2D) QD-based optoelectronic devices is still limited. Here we propose and demonstrate the enhancement of the light emission of QD-based 2D optoelectronic devices at around telecom wavelengths by employing dual-band perfect absorbers based on plasmonic metasurfaces. The two resonant peaks of the absorber simultaneously match the absorption and radiation wavelengths of non-blinking “giant” QDs at the telecom regime, thus enhancing the excitation pump meanwhile maintaining the efficient outcoupling of the light emission. These findings will not only benefit technological applications of QD-based optoelectronic devices but also offer better understanding of the fundamental physical mechanisms of light-matter interactions.
**H71.00281: High-Yield Production of Nanoplatelet Bi$_2$Te$_3$ via Supercritical Ball Milling in Carbon Dioxide**

MOHAMED ATWA (Presenter), Okinawa Institute of Science and Technology, TESSUI NAKAGAWA, Department of Chemistry, University of the Ryukyus, MAKOTO SCHREIBER, YOSHINORI OKADA, Okinawa Institute of Science and Technology — Nanoplatelet Bi$_2$Te$_3$ is highly desired as a starting powder for the consolidation of bulk nanostructured thermoelectric legs, as low-dimensional Bi$_2$Te$_3$ has long been expected to result in a higher Seebeck coefficient and lower thermal conductivity, leading to an unprecedented enhancement in the thermoelectric figure of merit (zT) in this material. The production of few-layer Bi$_2$Te$_3$ nanoplatelets has thus far mainly been limited to low-yield hydrothermal synthesis techniques. Studies have suggested that Bi$_2$Te$_3$ degrades in the presence of water, making such hydrothermal techniques inherently non-ideal for the production of high thermoelectric performance Bi$_2$Te$_3$ nanoplatelets. In this study, we show that gram-yield quantities of few-layer Bi$_2$Te$_3$ nanoplatelets are preferentially exfoliated along the basal plane using a novel, “all-dry” supercritical carbon dioxide (scCO$_2$) ball milling technique. We will discuss advantages of our method in terms of the size, morphology, and crystallinity of the resulting nanoplatelets are compared against conventional ball milling techniques.

**H71.00282: Tuning structural and electronic properties of α-Te tubular nanostructures by uniaxial strain**

YANRONG GUO, JINJIN WANG, SONGYOU WANG, Optical Science and Engineering, Fudan University, Shanghai 200433, China, YU JIA, School of Physics and Engineering, Zhengzhou University, Zhengzhou 450001, China, WAN-SHENG SU (Presenter), National Taiwan Science Education Center, Taipei 11165, Taiwan — Tellurene, a new member of two-dimensional family materials, shows outstanding photoelectric characteristics. Here, a first-principles calculation is employed to explore the effect of uniaxial strains on the electronic properties for α-Te tubular nanostructures with various tube sizes. Under compressive and tensile strains of 10%, the atomic structures of α-Te tubular nanostructures have not been destroyed, demonstrating they have good flexibility. Interestingly, we found armchair (5,5) α-Te tubular nanostructures experience an intriguing semiconductor–metal transition at a certain strain, while other α-Te tubular nanostructures are semiconductor with modulable band gap. The electronic properties of α-Te tubular nanostructures under strain modulation can help to understand the properties of new nanomaterials comprehensively, paving the way for future optoelectronic applications.

*W.-S. Su would like to thank the Ministry of Science and Technology for financially supporting this research under Contract No. MOST-108-2112-M-979-001. Support from the National Centers for Theoretical Sciences and High-performance Computing of Taiwan in providing significant computing resources to facilitate this research is also gratefully acknowledged.*
H71.00283: Thermal drift induced artifacts in AFM atomic lattice images*  DONGHYEON MOON (Presenter), BO RAM JEON, SUENNE KIM, Hanyang Univ — Two-dimensional materials are emerging as next-generation ultra-thin semiconductor device materials. The electronic band structure of these materials is strongly perturbed by mechanical strain. Therefore, many studies on the strain engineering of two-dimensional materials have been conducted recently. The aim of these studies is to control the electronic and optical properties of two-dimensional materials. To determine the effect of strain, it is necessary to investigate the atomic lattice structure accurately. Various scanning force microscopy (SFM) techniques have been used to observe these two-dimensional crystal lattices. In this study, we show that artifacts due to thermal drift in AFM measurements can impede accurate structural interpretation related to strain. In other words, distorted images can lead to incorrect scientific conclusions on the critical strain issues in these atomically thin two-dimensional materials.

H71.00284: Phonon dispersion curves for three new MoS$_2$ type monolayers.*  FERNANDO MAGANA (Presenter), GERARDO-JORGE VAZQUEZ FONSECA, ERICK GARCES GARCIA, Univ Nacl Autonoma de Mexico — Using ab initio calculations based on density functional theory, we obtained new structures for MoS$_2$ type monolayers: NbS$_2$, MoP$_2$ and NbP$_2$, not previously reported in the literature. These proposed structures were relaxed to their minimum energy configuration. Then, we calculated the phonon dispersion curves for each one of them. We exhibit the differences with respect of MoS$_2$. The Quantum-Espresso package [1] was used with norm conserving pseudo potentials.

*We thank Dirección General de Asuntos del Personal Académico de la Universidad Nacional Autónoma de México, partial financial support by Grant IN-111807 and we also thank Miztli Super-Computing center the technical assistance.
We present a theoretical study of second harmonic generation (SHG) in structured metamaterials; particularly, an array of cross-shaped vacuum inclusions within a silver host. We calculate the nonlinear susceptibility tensor, for a large number of geometrical configurations for the inclusions. We demonstrate that both, the SHG intensity and the resonance peaks are highly sensitive to even subtle changes in the geometry that break the centrosymmetry of the array of inclusions. We presented the results for calculation of non linear susceptibility of second order for a metamaterial composed by silver host and cross-shaped inclusions of vaccum. The dielectric functions of both materials are known. The intensity in nonlinear susceptibility tensor depends on the variation in the symmetry of the metamaterial. We present the three non-zero components of that tensor, calculated by Haydock Recursive Method.

Recent studies have hinted at the importance of dynamic interactions between electronic states and the lattice in organic-inorganic 2D perovskites (2DPs). It is thus critical to understand the interplay between structure and properties during light excitation and in operating devices. Here, we investigate these effects by exploring the 2DPs phase space in terms of both layer thickness and interlayer organic spacer rigidity. We reveal the relation between structural and photophysical properties in 2DPs by correlating structural and optoelectronic spectroscopy at the sub-micron scale and under magnetic field, with support from theory. Our work demonstrates that during photoexcitation strongly bound excitons are generated and their characteristics (mass, size, energy) can be modulated not only by the thickness of the 2D perovskites layers as in classic quantum-wells but also through structural distortions such as perovskite octahedra tilting induced by the organic spacer or crystal edge termination.[1] Similar effects are linked to local compositional changes or artificial interfaces, resulting in giant enhancement of photoemission at the 2DP and WS

H71.00287: Investigation of Spectral Diffusion due to Static and Dynamic Disorder in Perovskite Thin Films*  GEOFFREY DIEDERICH, ADAM HALAOUI (Presenter), AMANI H ALFAIFI, Univ of Denver, SEAN SHAHEEN, Electrical, Computer and Energy Engineering, University of Colorado Boulder, MARK SIEMENS, Univ of Denver — Multidimensional coherent spectroscopy (MDCS) is an ultrafast spectroscopy technique that spreads coherent information across multiple dimensions, resolving features that might overlap in one-dimensional measurements. Both coherent and incoherent transport, broadening mechanisms, and spectral diffusion can be separated and clearly measured with MDCS. Additionally, the phase sensitivity of MDCS measurements allows visualization of the full complex signal field. These attributes make MDCS ideal for studying complex material systems like perovskites thin films where cation mixing, ion migration, and inhomogeneous grain conditions can make spectra difficult to interpret.

Here, we present MDCS spectra from thin films of a mixed-cation perovskite at low temperature. The spectra show inhomogeneously broadened free and defect-bound excitons with a homogeneous dephasing time on the order of 1 ps. The excitons undergo spectral diffusion and relaxation on a much more rapid timescale than has been measured in GaAs quantum wells, increasing the resonance linewidth by a factor of ~3 over one picosecond.

*We acknowledge the financial support of the National Science Foundation

H71.00288: The evolution of ultrafast carrier dynamics in-situ perovskite optoelectronic devices  KANISHKA KOBBEKADUWA, PHYSICS, Clemson University, SHREETU SHRESTHA, LANL, PAN P ADHIKARI, EXIAN LIU, PHYSICS, Clemson University, WANYI NIE, LANL, JIANBO GAO (Presenter), PHYSICS, Clemson University — Although significant progresses have been made toward to optoelectronics application including solar cells, large color gamut LEDs, photodetectors, and X-ray detectors, the fundamental understanding of ultrafast carrier dynamics of organic-inorganic perovskite materials remains unclear. The ultrafast dynamics, which reveals some novel physical phenomena such as hot carrier cooling, phonon bottle-neck effect, and many-body problem was widely studied by ultrafast optical spectroscopies, which include pump-probe transient absorption (transmission, reflection, time-resolved THz, optical Kerr effect, and the most popular time-resolved photoluminescence(TRPL). However, it remains a challenge to study the perovskite optoelectronic devices in-situ in an ultrafast fashion.

In this talk, we use an ultrafast photocurrent spectroscopy with sub-25 picosecond time resolution to reveal the evolution of ultrafast carrier dynamics from sub-25 ps to microsecond in-situ perovskite solar cells and photoconductors. We address the basic questions of carrier photogeneration, recombination, transport, trapping, in addition to directly extracting carrier mobility, lifetime, and the property of trap states such as density, energy level, and capture cross-section.

H71.00291: Pentacene Thin Film Growth* BRADLEY LOCKHART (Presenter), Physics and Astronomy, Ohio Northern University, JESSICA BICKEL, Physics, Cleveland State University — Pentacene is a common organic semiconductor with a relatively high conductivity that increases when crystallized. In this experiment pentacene was studied by depositing it on highly ordered pyrolytic graphite (HOPG) using a thermal evaporator and characterizing it with scanning tunneling microscopy (STM). The daily pressure inside the evaporation chamber had small day-to-day variations, between 1 and 7x10^-5 torr, which caused significant variations in growth rates. We subsequently developed a method to measure the growth rate immediately before the deposition by opening the shutter of the thermal evaporator to a specific angle so that the growth rate could be measured with a quartz crystal monitor without depositing any material on the HOPG substrate. Examining the resulting depositions with STM, we find several images showing the deposited pentacene either forming into clumps, or into seemingly more ordered track-like patterns. These images were analyzed to find the dimensions of these structures and compared to previously gathered pentacene data from other groups.

H71.00292: Characterizing the Crystal Formation and Interdiffusion Mechanisms of PLA/PS/dSMMA Thin Films* SURAJ DHULIPALLA (Presenter), MUKIL SHANMUGAN, DORIS YANG, XIANGHAO ZUO, MIRIAM RAFAILOVICH, Stony Brook University — Polylactic Acid (PLA) thin films have emerged as an eco-friendly alternative for nonbiodegradable polymers in industrial coatings. As such, our investigation characterized the interfacial diffusion and crystal formation in thin films (PLA, polystyrene (PS), and deuterated styrene methyl methacrylate (dSMMA) blends) on different substrates. AFM data showed that larger molecular weight PS additives increased crystal size and roughness of PLA-PS annealed samples. In bilayer samples, we found a 32% roughness decrease in PS/dSMMA on PLA compared to PLA on PS/dSMMA samples. SIMS data showed that dSMMA was nearly absent in the PS layer and interfacial thickness increased with dSMMA concentration. Previous studies proved dSMMA's compatibilizing property in bulk[1]; we prove dSMMA retains this property under confinement without compromising crystallinity. This study shows that substrates influence the roughness and crystallinity of PLA thin films and that dSMMA is an effective compatibilizer of PLA and PS thin films which is a promising sign for future use in bioelectronics.

H71.00293: Quasi-static C-V Characterization of Traps in Sputtered Bismuth Selenide FET*
PROTYUSH SAHU (Presenter), JUNYANG CHEN, JIANPING WANG, University of Minnesota — Bismuth Selenide based devices have gained a lot of attention due to the highly conducting, spin-polarized, topologically protected surface states [1]. They have found a lot of promise in spintronics. Previous works have shown the existence of high charge to spin conversion in sputtered, polycrystalline Bi$_x$Se$_{1-x}$ [2-4]. This is attributed to the quantum confinement effect in the individual grains of the film. Characterizations have revealed non-idealities from this material due to charge trapping. In this work, we characterize charge traps in FET devices by quasi-static Capacitance-Voltage measurement. The experimental C-V curve shows a hysteretic behavior which is attributed to oxide and interfacial traps. We use the known charge trapping model to calculate the trap densities for different devices. To further understand the physics of random defects, we simulated the electric field in the FET device by 2D finite difference time domain technique (computational electrodynamics) to analyze the E-field uniformity near a defect edge and along the Bi$_x$Se$_{1-x}$/SiO$_2$ interface.

*This work was supported by ASCENT, a SRC program.

H71.00294: Investigation of phonon-mediated relaxation within the topological insulator Bismuth Tellurium*
CHAO-HONG LIN (Presenter), MENG-CHING LEE, JIN-WEI LI, TSUN-I CHEN, CHAO-KUEI LEE, Sun Yat-sen University — In this work, using double pulses excitation technique, the energy coupling ratio from excitation laser to coherent phonons of topological insulator bismuth tellurium(Bi$_2$Te$_3$) thin film was characterized. First of all, by analyzing excitation intensity dependent heating temperature of the thin film from the transmission pump probe results, the coherent phonon generation and the energy coupling from laser to phonons were confirmed. The coupling ratio was accordingly estimated and with decreasing nature as increasing temporal spacing between double pulses. Furthermore, the frequency and intensity of the phonon mode were investigated as well. Beside identification of the relaxation characteristic, we also find evidence of phonon-mediated relaxation of the energy density at the Bi$_2$Te$_3$ surface.

H71.00295: Weak antilocalization in hexagonal Ca$TX$ ($T$ = Cu or Ag, $X$ = Sb or Bi) single crystal

SOUVIK SASMAL (Presenter), Condensed matter physics and Material science, Tata Institute of Fundamental Research, RAJIB MONDAL, Condensed matter physics, UGC-DAE Consortium for Scientific Research, RUTA KULKARNI, Condensed matter physics and Material science, Tata Institute of Fundamental Research, BAHADUR SINGH, Department of Physics, Northeastern University, A. THAMIZHA VEL, Condensed matter physics and Material science, Tata Institute of Fundamental Research — The hexagonal ABC-type topological semimetals Ca$TX$ ($T$ = Cu or Ag, $X$ = Sb or Bi) are currently drawing intense interest due to their intriguing properties. Specifically, the first-principles calculations have revealed that CaAgBi is a topological Dirac semimetal where the Dirac points are located on the rotational axis slightly above the Fermi level and are protected by $C_{6v}$ point-group symmetry [1].

We have grown the single crystals of these topological semimetals. We find that although ABC-type materials crystallize in the hexagonal structure, they adopt different space-groups depending on the $T$ (Cu/Ag) atom. The electrical resistivity shows metallic behaviour following Bloch-Gruneisen relation whereas the Hall resistivity measurements reveal a semimetallic nature with predominantly $p$ type charge carriers. The transverse magnetoresistance measurements reveal the weak antilocalization (WAL) behaviour for fields below 5 T and temperatures less than 100 K. The angular dependence of the magnetoconductance measurements show that CaCuSb and CaAgSb host topologically protected bulk and surface states. We find that WAL is specific to these type of topological semimetals single crystals.

H71.00296: Electronic transport properties of doped Bi$_2$X$_3$ (X = Se, Te) single crystals Shailja Sharma, C.S. Yadav School of Basic Sciences, Indian Institute of Technology Mandi-175005 (H.P.) India

SHAILJA SHARMA, CHADR YADAV (Presenter), School of Basic Sciences, Indian Institute of Technology Mandi — The observation of anomalous Hall effect and the occurrence of superconductivity in doped 3D topological insulators, are some of the very interesting phenomenon in these systems [1-3]. We have investigated the magneto-transport properties of Bi$_2$Se$_3$ and Bi$_2$Te$_3$ single crystals to explore the effect of intercalation and substitution of Fe, Ag, Au, Pt, Pd etc. on the electronic state of the systems. Magnetoresistance of the magnetically doped Bi$_2$Se$_3$ was found to follows Kohler’s rule, suggesting the single scattering rate at all the points on the Fermi surface. Hall effect measurements suggest the consistence doping of charge carriers in the system upon intercalation. Our findings on the weak antilocalization and weak localization cusps in the magnetoresistance and their evolution with dopant concentration bring out the effect of charge transfer or magnetic elements on the topological surface states of these compounds [4].

H71.00297: Tunable anomalous Hall effect in Dirac semimetal Cd$_3$As$_2$ nanowire SHUO WANG (Presenter), BENCHUAN LIN, Southern University of Science and Technology, YING LI, Peking University, DAPENG YU, Southern University of Science and Technology, ZHI-MIN LIAO, Peking University — Recent years, the combination of topology and physics has led to the rapid development of topological physics. Dirac semimetal Cd$_3$As$_2$, with a pair of symmetry-protected three-dimenisonal Dirac cones, has drawn a lot of attention. Here, we report the experimental observation of tunable anomalous Hall effect in Cd$_3$As$_2$ nanowire. The anomalous Hall signal maximizes near the Dirac point under an applied magnetic field. As the gate voltage is tuned away from the Dirac point, the anomalous Hall signal decreases and eventually disappears. Based on the detailed analysis of the anomalous signal with gate voltage, temperature and magnetic field direction, the observed anomalous Hall effect is attributed to the Berry curvature originated from the Weyl node.
H71.00298: Thermodynamic properties of non-trivial topological semimetal CaSn$_3$  
K A M HASAN SIDDIQUEE (Presenter), RIFFAT MUNIR, CHARUNI DISSANAYAKE, University of Central Florida, XINZHE HU, SWAPNIL YADAV, YASUMASA TAKANO, University of Florida, EUN SANG CHOI, Florida State University, TALAT RAHMAN, DUY LE, YASUYUKI NAKAJIMA, University of Central Florida — Topological semimetals, a group of gapless electronic phases with topologically stable energy band crossing, give pathways to observe new quantum phenomena. We will report torque magnetometry and heat capacity measurements on CaSn$_3$, which is theoretically proposed to be a non-trivial topological semimetal. We will present a detailed study of band structure for CaSn$_3$ single crystals via torque magnetometry in high magnetic fields up to 35T. We will also present the thermodynamics properties of this material.

H71.00299: Growth and transport measurements of nanowires of cubic B20 topological semimetals  
NITISH MATHUR (Presenter), ANDREW JACOB DERUITER, Department of Chemistry, 1101 University Avenue, Madison, WI-53706, University of Wisconsin Madison, ANASTASHIA GEORGE, Department of Chemistry, Durango, CO 81301, Fort Lewis College, MINGLIANG TIAN, High Magnetic Field Laboratory, Chinese Academy of Science, Hefei, Anhui 230026, China, SONG JIN, Department of Chemistry, 1101 University Avenue, Madison, WI-53706, University of Wisconsin Madison — Since the discovery of topological insulators and semimetals, topological materials are key research frontiers in the field of condensed matter physics. One of the examples of the topological material is a Weyl semimetal where two non-degenerate bands cross at a node in a momentum space and acquires a quantized topological charge known as the Chern number. Among them, cubic B20 material systems (such as CoSi, RhSi, AlPt) are found to possess unconventional chiral fermions with higher Chern number and long fermi arcs due to multiple point degeneracies at high symmetry Brillouin points. We have synthesized single-crystal cubic B20 topological semimetal nanowires (NWs) of CoSi and CrGe via chemical vapor deposition (CVD). We conducted magnetotransport measurements with different configuration of applied magnetic field (in-plane/out-of-plane) and current direction to connect quantum topological properties to electronic band structures. We are also performing physical property measurements under high magnetic field. These NW systems can act as the perfect prototypes to understand the impact of surface states and bulk Landau levels on the transport behaviors in finite size topological semimetals.
H71.00300: Measurements of cyclotron resonance of the interfacial states in strong-spin orbit coupled 2D electron gases proximitized with aluminum.*

PRASHANT CHAUHAN, Johns Hopkins University, CANDICE THOMAS, TYLER LINDEMAN, Department of Physics and Astronomy and Microsoft Quantum Purdue, Purdue University, West Lafayette, Indiana 47907 USA, GEOFF C GARDNER, SERGEI GRONIN, Microsoft Quantum Purdue, Purdue University, West Lafayette, Indiana 47907, USA, JAN GUKELBERGER, Quantum Architecture and Computation Group, Microsoft Research, Redmond, Washington 98052, USA, ROMAN LUTCHYN, Station Q, Microsoft Research, Santa Barbara, California 93106-6105, USA, MICHAEL MANFRA, Department of Physics and Astronomy and Microsoft Quantum Purdue, Purdue University, West Lafayette, Indiana 47907 USA, PETER ARMITAGE (Presenter), Johns Hopkins University — The two dimensional electron gas (2DEG) in InAs proximitized by aluminum (Al) is a promising platform for topological qubits based on Majorana zero modes. However, there are still substantial uncertainties associated with the nature of the electronic states at the interfaces of these system. In this work we have investigated a range of In$_{1-x}$Ga$_x$As heterostructures with Al overlayers using high precision time-domain THz spectroscopy. In magnetic field a prominent cyclotron resonance is observed that can be associated with the response of the interfacial states. Measurements of the THz range complex Faraday rotation allow the extraction of the sign and magnitude of the effective mass, density of charge carriers, and scattering times. We compare the results of measurements with numerical calculations.

H71.00301: Pressure-induced superconductivity and topological phase transitions in the topological nodal-line semimetal SrAs$_3$

ERJIAN CHENG (Presenter), SHIYAN LI, Fudan Univ — Topological nodal-line semimetals (TNLSMs) are materials whose conduction and valence bands cross each other, meeting a topologically-protected closed loop rather than discrete points in the Brillouin zone. TNLSMs have several anticipated properties, such as drumhead-like nearly flat surface states, the possibility of realizing high-temperature superconductivity and so on. Recently, SrAs$_3$ has been theoretically proposed and then experimentally confirmed to be a TNLSM. Here, we report high-pressure experiments on SrAs$_3$, identifying a Lifshitz transition below 1 GPa and a superconducting transition accompanied by a structural phase transition above 20 GPa. A topological crystalline insulator (TCI) state is revealed by means of density functional theory calculations on the emergent high-pressure phase. As the counterpart of topological insulators, TCIs possess metallic boundary states protected by crystal symmetry, rather than time reversal. In consideration of topological surface states and helical spin texture observed in the high-pressure state of SrAs$_3$, the superconducting state may be induced in the surface states, and is most likely topologically nontrivial, making pressurized SrAs$_3$ a strong candidate for topological superconductor.

Effect of Mn/Fe ratio on the Magnetic and Magnetocaloric Properties of Hexagonal Mn$_{2-x}$Fe$_{1+x}$Ge ($0 \leq x \leq 1$) Heusler Alloys*

ANIL ARYAL (Presenter), IGOR DUBENKO, Southern Illinois University Carbondale, JOSE LUIS SÁNCHEZ LLAMAZARES, JONATHAN ZAMORA, Instituto Potosino de Investigación Científica y Tecnológica A.C., Mexico, CESAR FIDEL SÁNCHEZ-VALDÉS, División Multidisciplinaria, Universidad Autónoma de Ciudad Juárez (UACJ), Mexico, DIPANJAN MAZUMDAR, SAIKAT TALAPATRA, Southern Illinois University Carbondale, SHANE STADLER, Department of Physics & Astronomy, Louisiana State University, Baton Rouge, USA, NAUSHAD ALI, Southern Illinois University Carbondale — In this work, we synthesized bulk Mn$_{2-x}$Fe$_{1+x}$Ge ($0 \leq x \leq 1$) by arc melting and Mn$_2$FeGe melt-spun ribbons by rapid solidification using the melt-spinning technique and investigated their structural, magnetic, and magnetocaloric properties. Room temperature X-ray diffraction analyses show that Mn$_2$FeGe crystallizes into the hexagonal DO$_{19}$ crystal structure with a small trace of a secondary phase. Mn$_2$FeGe was found to be ferrimagnetic (FIM) with saturation magnetization ($M_S$) values of ~1.7 µB/f.u. at ground state which is consistent with the value 2.0 µB/f.u. predicted by the Slater-Pauling rule. Substitution of Fe for Mn in bulk Mn$_{2-x}$Fe$_{1+x}$Ge resulted in a change of the magnetic ground state from FIM to ferromagnetic (FM) with a maximum $M_S$ value of 5.1 µB/f.u. for $x = 1.0$. A tunable Curie temperature ($T_C$) in a wide range of about 200 K, including the near room temperature ones, was found in Mn$_{2-x}$Fe$_{1+x}$Ge which may be important for practical applications. Maximum magnetic entropy changes of -3.1 Jkg$^{-1}$K$^{-1}$ (at $\mu_0\Delta H = 5$ T) was found at room temperature with a refrigerant capacity of 325 Jkg$^{-1}$ for $x = 0.4$.

*The support from U.S. DOE, BES Award # DE-FG02-06ER46291 (SIUC) & DE-FG02-13ER46946 (LSU), NSF CAREER grant (ECCS, Award # 1846829), Conacyt, LINAN, IPICYT and DMCU-UACJ is acknowledged.

Characterization of ferrimagnetic and spin wave resonance for frequency selective limiting of iron garnet epitaxial films

SCOOTER JOHNSON (Presenter), HANS HAUCKE, CLIFFORD M KROWNE, SANGHOON SHIN, SYED B QADRI, United States Naval Research Laboratory — High-frequency devices, such as frequency selective limiters utilize magnetic materials such as yttrium iron garnet (YIG). The requirement of low loss to enable low-power limiting requires the material to be of high-quality single crystal. Unfortunately, the low magneto-crystalline anisotropy in YIG requires a bias magnet to generate the necessary field and frequency conditions for spin wave generation at higher frequency operation. Alternatively, the bismuth-substituted rare earth iron garnet (Bi-RIG) (BiGdLu)$_3$(Fe$_{1-x}$Ga$_x$)$_5$O$_{12}$ [1] has been found to show low loss (FMR linewidth ~50 Oe) with high anisotropy field (~2300 Oe), thus possibly avoiding the need for external bias [2]. In this study, we characterize and compare the magnetic properties and power dependences of single-crystal YIG and Bi-RIG grown using liquid phase epitaxy using a vibrating sample magnetometer and a coplanar waveguide configuration to assess dc and microwave magnetic properties for potential use in microwave device integration.

H71.00306: Antiferromagnetic characteristics in Sr- and Ba-doped phenanthrene superconductors LEI GAO (Presenter), Beijing Computational Science Res Ctr, GUO-HUA ZHONG, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, HAI-QING LIN, Beijing Computational Science Res Ctr — It’s very important to clarify the competition between magnetism and superconductivity in alkaline earth metals doped phenanthrene. To achieve this, we have recently studied the crystal structures of Mg-, Ca-, Sr- and Ba- doped phenanthrene and found the most stable ones, which have the lowest energy by first-principles calculations. The result shows that only the most stable Sr\textsubscript{1.5}phenanthrene and Ba\textsubscript{1.5}phenanthrene show the weak AFM behavior and the others are non-magnetic. The Sr and Ba atoms intercalate the intralayer region and stay close to benzene-ring. By calculating the different charge density we found that the most stable Sr\textsubscript{1.5}phenanthrene and Ba\textsubscript{1.5}phenanthrene structures have charge redistribution and C atoms have gained electrons obviously. From the spin-charge density, we see inequitable phenanthrene molecules have opposite spin polarizations. The density of states (DOS) of the two structures shows that spin-up and spin-down electrons have the unsymmetrical distribution. Combining these results we conclude that the spin polarization of electrons transferring from metal atoms to C-2p orbitals atoms causes the local AFM behavior. This indicates that superconducting Sr\textsubscript{1.5}phenanthrene and Ba\textsubscript{1.5}phenanthrene are near the AFM ground state.

H71.00307: Magnetism in the honeycomb layers of Na\textsubscript{2}Ni\textsubscript{2}TeO\textsubscript{6} with chiral layers of Na\textsuperscript{*} NATHAN EPISCOPO (Presenter), KINLEY WANGMO, University of Texas, El Paso, NARAYAN POUDEL, KRZYSZTOF GOFRYK, Idaho National Laboratory, PO-HAO CHANG, RAJENDRA ZOPE, University of Texas, El Paso, RYAN KLEIN, National Renewable Energy Laboratory, CRAIG BROWN, NCNR, NIST, THOMAS HEITMANN, MURR, HARIKRISHNAN S NAIR, University of Texas, El Paso — Low dimensional magnetic lattices offer the possibility of realizing flatbands in the magnon spectrum which can then lead to dissipation-less spin transport and associated magnon Hall effect. One could expect to find a magnon insulator, similar to a topological insulator. In the present work we present a rather less-studied honeycomb material Na\textsubscript{2}Ni\textsubscript{2}TeO\textsubscript{6} where our preliminary density functional theory calculations of magnetic structure shows departures from reported structures. Our samples of Na\textsubscript{2}Ni\textsubscript{2}TeO\textsubscript{6} confirmed hexagonal \textit{P}6\textsubscript{3}/mcm space group with refined lattice parameters, a=5.2023(1)Å and c=11.1552(8)Å. The bulk magnetism for the present sample is characterized using magnetic susceptibility and specific heat, both of which confirm a phase transition at 28 K. Application of 8 T magnetic field only slightly polarizes the transition. We obtain a Curie-Weiss temperature of -9.7(2)K and effective paramagnetic moment of 2.24(4)\textit{m}_B/\textit{Ni}. This matches well with the spin-only moment of Ni\textsuperscript{2+}. Elastic and inelastic neutron scattering experiments are currently underway and reveal a rather flat spin wave excitation at 5 meV. Combining neutron diffraction with the DFT results, we would arrive at an accurate estimation of the exchange constants for Na\textsubscript{2}Ni\textsubscript{2}TeO\textsubscript{6}.

H71.00308: Magnetism of stacked multilayered graphene nanostructures in carbon microspheres

ARMEN KOCHARIAN (Presenter), ARAM MANUKYAN, HARUTYUN GYULASARYAN, Physics Department, Russian-Armenian (Slavonic) University, Yerevan, EDUARD SHAROYAN, Institute of Physical Research, NAS of Armenia, Laboratory of Solid State Physics, Ashtarak, PAUL OYALA, Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, OSCAR BERNAL, LUIS VALENCIA, CAL State University, Los Angeles — Morphology, structure and magnetic properties of synthesized by pyrolysis (using as precursors metal free phthalocyanine and polyethylene) samples with different concentration of nitrogen in multilayered graphene nanostructures with zigzag edges in carbon microspheres was investigated by XRD, XPS, Raman, HRTEM microscopy, magnetometry, EPR measurements. Studied magnetic characteristics depend on temperature, magnetic field and concentration of nitrogen impurity centers. Prepared sample at Tpyr=700 K demonstrates strong paramagnetism, ferromagnetism and temperature-independent diamagnetism with susceptibility $\chi^{Dia}=-10^{-6}$ emu/gOe at T=300K. Saturation magnetization vs temperature behavior with maximum magnetization $M_s$ saturation at 20 K closely resembles a spin glass behavior. The itinerant ferromagnetism of $\pi$-electrons in narrow impurity bands is interpreted using temperature dependence of spin correlations at zigzag edges in nanographenes. A magnetic hysteresis is also observed under variation of temperature at 100<T<300 K where magnetization displays diamagnetic character.

H71.00309: Screening and Design of Novel 2D Ferromagnetic Materials with High Curie Temperature above Room Temperature

ZHOU JIANG (Presenter), PENG WANG, XUE JIANG, JIJUN ZHAO, Physics, Dalian University of Technology — Two-dimensional (2D) intrinsic ferromagnets with high Curie temperature ($T_C$) are desirable for spintronic applications. Using systematic first-principles calculations, we investigate the electronic and magnetic properties of 22 monolayer 2D materials with layered bulk phases. From these candidates, we screen out five ferromagnetic monolayer materials belonging to three types of structures: type i (ScCl, YCl, LaCl), type ii (LaBr$_2$), and type iii (CrSBr). Type i is a kind of metallic ferromagnetic material, whereas LaBr$_2$ and CrSBr of type ii and iii are small-bandgap ferromagnetic semiconductors with $T_C$ near room temperature. Moreover, the ferromagnetic CrSBr monolayer possesses a large magnetic moment of $\sim 3 \mu_B$ per Cr atom, originating from its distorted octahedron coordination. The robust ferromagnetism of the CrSBr monolayer is ascribed to the halogen-mediated (Cr-Br-Cr) and chalcogen-mediated (Cr-S-Cr) superexchange interactions; then, an isoelectronic substitution strategy is proposed to tailor the magnetic coupling strength. Hence, monolayer structures of CrSI, CrSCI, and CrSeBr with notably enhanced Curie temperature up to 500 K as well as favorable formation energy are designed.

H71.00310: Griffiths-like phase in a Mn-Intercalated Dichalcogenide  PAUL SHAND
(Presenter), PAUL WHITE, Physics, Univ of Northern Iowa, EMILIA MOROSAN, Physics, Rice University — Static and dynamic magnetic measurements have been performed on polycrystalline Mn$_{0.23}$TaS$_2$. The measurements indicate the presence of a Griffiths-like phase preceding the paramagnetic to ferromagnetic transition at 57 K. The transition temperature in the clean limit, i.e., for single-crystalline Mn$_{0.25}$TaS$_2$, is known to be 80 K. dc magnetization measurements on Mn$_{0.23}$TaS$_2$ indicate a magnetic field-dependent downturn in the inverse susceptibility as a function of temperature below 105 K, a key indicator of the existence of a Griffiths phase. The magnetization also exhibited power law behavior as a function of both temperature and field in this regime. The power-law exponent for $M(H)$ varied with temperature in the Griffiths regime until the critical region was approached. At this point, a modified Arrott plot was necessary to describe the data, giving critical exponents close to the theoretical values for 3D Heisenberg magnets. The second-order ac susceptibility exhibited frequency-dependent peaks in the Griffiths region, which strongly suggests the formation of ordered clusters. The dc magnetization also exhibited logarithmic time decay. The evidence points to a robust Griffiths phase in Mn$_{0.23}$TaS$_2$.

H71.00311: X-ray absorption and magnetic circular dichroism studies of spin-orbital magnetism in the three-dimensional Kitaev honeycomb γ-Li$_2$IrO$_3$  ANNA SOPER (Presenter), KEWEI ZHOU, NICHOLAS BREZNAY, Harvey Mudd College, DANIEL HASKEL, YONGSEONG CHOI, Argonne National Lab, PHILIP MOLL, Ecole polytechnique federale de Lausanne, ALEJANDRO RUIZ, University of California, San Diego, JAMES ANALYTIS, University of California, Berkeley — Transition metal oxides are an exiting platform for exploring novel states of quantum matter. The choice of transition metal and its crystalline structure determine the magnitude of spin orbit coupling and electronic correlations, parameters that can be carefully tuned to create Mott insulators, topological insulators, superconductors and spin liquids. The 5d transition metal oxide lithium iridate γ-Li$_2$IrO$_3$, a Mott insulator and Kitaev spin liquid candidate, displays particularly strong spin orbit coupling, several honeycomb crystal structures, and magnetic ground states that can be tuned with applied pressure and magnetic fields; however, there are still open questions about its electronic structure. X-ray absorption spectroscopy was used to probe the γ-Li$_2$IrO$_3$ valence states and measure spin orbit coupling and crystal field splitting energy scales. In addition, X-ray Magnetic Circular Dichroism measurements were used to extract the spin and orbital content of the iridium magnetic moment. Evidence from these experiments will help to build a more accurate picture of the electronic states driving magnetism in this material.
H71.00312: Deviation from nonmagnetic \( J = 0 \) state in a pentavalent columnar iridate

\( \text{Sr}_3\text{NaIrO}_6 \)

ABHISEK BANDYOPADHYAY (Presenter), SUGATA RAY, School of Materials Science, Indian Association for the Cultivation of Science — Strong spin-orbit coupling (SOC) leads to the exotic properties in otherwise banal pool of 'paramagnetic' heavy ion oxides. The 5\( d^4 \) iridates eventually stirred up a controversy about the origin of magnetism in them. A nonmagnetic \( J = 0 \) ground state should be realized ideally for a pentavalent \( d^4 \) iridate in the \( jj \) coupling limit, which has never been achieved in any of the reported \( d^4 \) Ir oxides to date. Briefly introducing the previously handled (by our group) such \( 5d^4 \) cases with different Ir environments, we here pay serious focus on \( \text{Sr}_3\text{NaIrO}_6 \), a 5\( dt_2g^4 \) columnar iridate having well separated \( \text{Ir}^{5+} \) centers, which is expected to have a singlet \( J = 0 \) ground state with no net magnetic moment under strong SOC. However, stabilization of such state at moderate SOC is exceptionally fragile to minute external perturbation and enhanced magnetic responses appear. Moreover, the magnetic interaction between these developed magnetic moments becomes another important point. We, in this work, using detailed magnetic and thermodynamic measurements, refute any chance of nonmagnetic ground state in \( \text{Sr}_3\text{NaIrO}_6 \) compound. Instead, our experimental observations reveal the existence of quantum spin-orbital liquid state down to 40 mK atleast with sufficiently large magnetic moments on individual \( \text{Ir}^{5+} \).

H71.00313: Quantum spin liquid state in three dimensional metal-organic frameworks

CHARUNI DISSANAYAKE (Presenter), K A M HASAN SIDDIQUEE, RIFFATH MUNIR, Physics, University of Central Florida, WESLEY NEWSOME, FERNANDO URIBE-ROMO, Chemistry, University of Central Florida, XINZHE HU, SWAPNIL YADAV, YASUMASA TAKANO, Physics, University of Florida, EUN SANG CHOI, Florida State University, YASUYUKI NAKAJIMA, Physics, University of Central Florida — Quantum spin liquid (QSL) is a massive superposition state of spins, or highly entangled quantum matter in which electrons’ spins fluctuate and remain liquid-like, even at absolute zero temperature. Thus, they preserve spin-rotational symmetry but inhibit long range magnetic-ordering [1]. This novel state of matter attracted much attention in recent years due to the possibility of hosting fractionalized excitations, artificial gauge fields and exotic forms of superconductivity [2]. Here we attempt to uncover the QSL character of the hyperhoneycomb metal-organic framework (MOF) of \([\text{(C}_2\text{H}_5)_3\text{NH}]_2\text{Cu}_2(\text{C}_2\text{O}_4)_3\). We reveal the absence of magnetic transition in high magnetic fields up to 35T and magnetic anisotropy via torque magnetometry. Further, we will discuss the exotic nature of the spin liquid ground state and unusual excitations evidenced by the thermodynamic studies performed on candidate QSL \([\text{(C}_2\text{H}_5)_3\text{NH}]_2\text{Cu}_2(\text{C}_2\text{O}_4)_3\) down to 1.8K.

H71.00314: Structural Determination of Frustrated Double Perovskites $\text{Ba}_2\text{EuMoO}_6$ and $\text{Ba}_2\text{PrMoO}_6$°  JEREMY CARLO (Presenter), NICHOLAS LA MANNA, Villanova Univ — Geometric magnetic frustration occurs when magnetic order is inhibited by the arrangement of magnetic ions. In some materials with antiferromagnetic interactions, the moments are arranged in such a way that only certain interactions can be satisfied at once, and are said to be magnetically frustrated.

Double perovskites of composition $A_2BB'O_6$, with 'rock-salt' order of magnetic B' ions, potentially exhibit frustration. Double perovskites are of particular interest due to their chemical versatility, enabling the synthesis of compounds with divergent chemical and magnetic properties, providing great potential to yield new insights into frustration physics.

We have studied the structure of two double perovskites, $\text{Ba}_2\text{EuMoO}_6$ and $\text{Ba}_2\text{PrMoO}_6$, using X-ray diffraction. After encountering difficulties evidenced by peak splitting, a sample of $\text{Ba}_2\text{YMoO}_6$ was synthesized in order to test and refine the synthesis process. The Pr sample showed evidence of structural distortion while the Eu shows promise for future refinement.

H71.00315: Design and Synthesis of Novel Quantum Magnets  ERIC SEEWALD (Presenter), Department of Physics and Department of Chemistry, Duke University, LALIT YADAV, SACHITH DISSANAYAKE, RABINDRANATH BAG, Department of Physics, Duke University, SARA HARAVIFARD, Department of Physics and Department of Mechanical Engineering & Materials Science, Duke University — Due to recent advances in the field of topological quantum spin liquids, there is an increasing demand for high quality single crystals of frustrated magnets that host such exotic behavior. Here we present our recent results of such efforts. Solid-state reactions are used to synthesize polycrystalline samples of quasi-2D and 3D frustrated quantum magnets, whose purity is confirmed by powder x-ray diffraction analysis. With a pure polycrystalline sample, the optical floating zone and chemical vapor transport techniques are used to produce high quality large single crystal samples. We use an array of thermal and magnetic measurements as well as single crystal x-ray diffraction to characterize the samples, before performing advanced neutron and synchrotron x-ray scattering experiments at national user facilities.
Longitudinal spin fluctuations in complex ordered states with a Landau-Ising model

HARRY KEEN (Presenter), ANDREAS HERMANN, Univ of Edinburgh — Classical local-moment models, like the Heisenberg and Ising models, are often used in combination with ab initio calculations to predict the magnetic properties of real materials. These can often perform poorly for metals, where fluctuations in the magnitude of the moment are important. Modelling longitudinal spin fluctuations phenomenologically: by allowing spin magnitudes to vary constrained by a Landau-like on-site potential, has been applied frequently by other authors and tends to improve agreement with experiment.

We study a simple model of scalar spins with such an on-site potential, where the energy scale of the fluctuations is characterised by a single parameter: the rigidity of the magnetic moment. We explore the implications of these fluctuations on collinear magnetic states with Monte Carlo simulations. This is particularly challenging for the Metropolis algorithm, so we discuss the numerical implementation of an alternative method, the Heat-bath algorithm. We study a variety of ordered states on a stacked triangular lattice, including frustrated and modulated phases. The influence of fluctuations on the nature of these phases is discussed in depth, and we uncover interesting behaviour which is sensitively dependent on the configuration of interaction parameters.

Sign reversal of anomalous Hall effect in polycrystalline ultrathin Mn$_3$Pt films

JOYNARAYAN MUKHERJEE (Presenter), SATYAKI SASMAL, KARTHIK RAMAN, TIFR Centre for Interdisciplinary Sciences — The kagome structure of noncolinear antiferromagnet (NC-AFM) gives rise to finite Berry curvature which consequences many novel phenomena such as anomalous Hall effect (AHE), magneto optical Kerr effect and topological Hall effect$^1$. Although AHE has been reported in epitaxial thin films of NC-AFM, Mn$_3$Pt$^2$, here we present the sign reversal of AHE in polycrystalline Mn$_3$Pt films varying the thickness of the film and measurement temperature. Polycrystalline Mn$_3$Pt films of thickness 5-25 nm have been grown on SiO$_2$ substrate using co-sputtering technique. X-ray diffraction reveals the phase purity of our samples. Electrical transport has been carried out in Hall bar geometry prepared by optical lithography and Ar ion etching. We observe negative Hall resistivity ($\rho_{\text{AH}}$) at 300 K which changes sign ~ 10 K. In addition to that, we also observe nearly linear positive magnetoresistance (MR) at high temperature regime (300 to 15 K). Similar to the $\rho_{\text{AH}}$, MR becomes negative at the same temperature. We attribute this sign reversal due to the rotation of Mn moments confirmed from the temperature dependent of magnetization data$^3$.

H71.00318: Magnetic anisotropy in the rare-earth honeycomb lattice YbCl₃*  HUIBO CAO
(Presenter), ERXI FENG, Oak Ridge National Lab, JIE XING, University of California Los Angeles, YAN WU, YAOHUA LIU, Oak Ridge National Lab, EVE EMMANOUILIDOU, CHAOWEI HU, TIANCI SONG, NI NI, University of California Los Angeles — The Kitaev quantum spin liquid (KQSL) is an exact solvable exotic state with bond-directional interactions in a honeycomb lattice [1]. Its potential applications in quantum information field attract a lot of attention. So far only a few KQSL candidates are available, such as honeycomb lattices α-RuCl₃ and Na₂IrO₃ with strong spin-orbital coupling 4d (Ru) and 5d (Ir) elements [2-4]. All these lattices show the long-range zig-zag magnetic order at low temperature instead of KQSL states. Recently we found a new Kitaev candidate, the rare-earth honeycomb lattice YbCl₃ with an effective spin-1/2, which presents a short-range magnetic order around 1.2 K and another kink at 0.6 K [7]. We investigated the magnetic ground state and magnetic anisotropy of YbCl₃ using unpolarized/polarized neutron diffraction techniques, which will be the focus of the presentation.

*The research was supported by the U.S. DOE, Office of Science, Early Career Research Program Award KC0402010 and used the DOE User Facility operated by the ORNL.
H71.00319: Phase transitions in novel Li-containing honeycombs, Li$_8$Cr$_2$(Te/Sb)$_2$O$_{12}$

HECTOR MANDUJANO (Presenter), SANDRA GONZALEZ, University of Texas, El Paso, NARAYAN POUDEL, KRZYSZTOF GOFRYK, Idaho National Laboratory, STUART CALDER, Oak Ridge National Laboratory, HARIKRISHNAN S NAIR, University of Texas, El Paso — Honeycomb frameworks of Li$_8$M$_2$(Te/Sb)$_2$O$_{12}$ ($M$ = transition metal), present interesting magnetic phenomena related to frustrated two-dimensional lattices of spins. In the present work, polycrystalline Li$_8$Cr$_2$(Te/Sb)$_2$O$_{12}$ were synthesized by standard solid-state route. Powder X ray diffraction patterns were recorded to check the phase formation and purity. C$_2$/m space group was confirmed using Rietveld analysis and lattice parameters are determined to be $a$=5.141Å, $b$=8.884Å, $c$=5.143Å, $\beta$=109.5Å for Li$_8$Cr$_2$Sb$_2$O$_{12}$, and $a$=5.128Å, $b$=8.850 Å, $c$=5.151Å, $\beta$=109.8Å for Li$_8$Cr$_2$Te$_2$O$_{12}$, presenting diminished unit cell sizes compared to that of Li$_8$Co$_2$Te$_2$O$_{12}$ are $a$=5.226Å, $b$=8.892Å, $c$=5.160Å, $\beta$=110.9Å. In the case of Li$_8$Cr$_2$Sb$_2$O$_{12}$ a magnetic phase transition is present at 7.4 K as determined from the derivative, $dCp/dT$. A similar transition is found in Li$_8$Co$_2$Te$_2$O$_{12}$ at 9.5 K. Neutron diffraction is underway for comprehending cationic ordering, crystal, and magnetic structure of Li$_8$Cr$_2$(Te/Sb)$_2$O$_{12}$ as well as its mixed occupancy of the 4g Wyckoff position in the C$_2$/m space group. Our experimental results will highlight the magnetism of the honeycomb layers of Cr and the ionic diffusion of inter-layer Lithium and will be of interest to magnetism as well as battery research.

*University of Texas at El Paso
The compound Cu$_9$O$_2$(SeO$_3$)$_4$Cl$_6$ is a new multiferroic material. Comprehensive studies on single and polycrystalline samples have revealed an anomaly at $T_N = 37$ K associated with long-range antiferromagnetic order. However, no signature of this phase transition is observed with the $H || b$-axis, indicating anisotropic magnetic properties. The magnetic structure derived from neutron scattering shows half of the Cu(5) ions carrying no moments. An anomaly in the dielectric constant near $T_E = 267$ K is identified with no measurable spontaneous polarization below $T_E$, suggesting an antiferroelectric order. A step-like anomaly seen in $c(T)$ at $T_E$ hints at weak spin-lattice coupling. High-resolution synchrotron x-ray diffraction experiments elucidate a local structural distortion at $T_E$.

H71.00321: Characterization of GaTa₄Se₈ single crystal with Jeff=3/2 ground state magnetic molecular*  
CHOONGJAE WON, Center for Complex Phase Materials, Max Planck POSTECH/Korea Research Initiative, SEUNGHWAN DO (Presenter), Oak Ridge National Lab, JAE-YOU KIM, JAE-HOON PARK, Pohang University of Science and Technology, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University — The geometrical spin frustration in the tetramer of lacunar spinel is a good subject for exploring the quantum spin liquid. In tantalum lacunar spinel, GaTa₄Se₈, there are molecular $J_{\text{eff}} = 3/2$ ground state and curious non-magnetic state with Jahn-Teller distortion [1]. Recently, we successfully grown the high quality of GaTa₄Se₈ single crystal, and studied by characterization of physical properties and inelastic neutron scattering. Temperature dependence of those characterization shows the difference between structure transition with orbital ordering, and indicates that gapped excitation already exists at higher temperature than orbital ordering temperature $T_S \sim 53 \text{K}$.

H71.00322: First-principles study of the Ir-Ir dimerization effect on the magnetic phase diagram of honeycomb iridates  
KEVIN LUCHT (Presenter), Univ of Illinois - Chicago — Honeycomb lattice iridates have been a promising candidate for the realization of the Kitaev spin model. However, the addition of off-diagonal and Heisenberg interactions result in magnetic ordering at low temperatures, causing the quantum spin liquid (QSL) phase to remain elusive. The application of hydrostatic pressure to the system has shown the loss of magnetic ordering, and although indicative of a spin liquid phase, has been shown to be caused by dimerization between iridium ions. Using ab initio calculations, we intend to identify the pressure region in beta-Li₂IrO₃ and alpha-Na₂IrO₃ where the symmetry lowers in the systems, marking the onset of dimerization. Subsequently, using exact diagonalization (ED) and cluster mean field theory (CMFT) on a periodic cluster, we will identify the ground state of the dimerized system and explore its phase diagram and spin correlations.
H71.00323: Crystal structure and magnetic behavior of NdAlGe.* CHETAN DHITAL (Presenter), Kennesaw State Univ, RAMAKANTA CHAPAI, SUNIL KARNA, QIANG ZHANG, Physics, Louisiana State University, YAN WU, Oak Ridge National Laboratory, RONGYING JIN, Physics, Louisiana State University, HUIBO CAO, Oak Ridge National Laboratory, DAVID P YOUNG, JOHN DITUSA, Physics, Louisiana State University — Rare earth compounds are known to exhibit varieties of exciting electronic and magnetic properties arising from complex interplay of conducting charges, usually derived from s- or p-like bands and more localized f-electrons. Added variety of interesting states comes from differences in lattice symmetry, spin-orbit interactions, crystalline electric fields, and the related magneto-crystalline anisotropy. A recent addition to such exciting properties is the theoretical prediction and experimental verification magnetic Weyl fermion state in RAlGe (R=Rare earth) family of compounds. Previous investigations of this class of compounds were limited to R=La, Ce and Pr. In this work, we extend this line of inquiry to isostructural NdAlGe to explore how these electronic and magnetic properties vary as the size of the rare earth element and consequently the position of the f-electron states with respect to the Fermi level is varied. I will present the crystal structure and magnetic behavior of NdAlGe.

H71.00324: Raman Spectroscopy of layered magnetic systems MAINAK PALIT (Presenter), ANUDEEPA GHOSH, SUBHADEEP DATTA, Indian Association for the Cultivation of Science — Metal phosphorus trichalcogenides (MPX₃) have emerged as an exciting class of layered magnetic 2D materials for future spintronics. Retaining long range magnetic ordering even in the exfoliated few layers is the hallmark of 2D magnetism. Raman spectroscopy can be an effective probe to identify low-energy phonon modes and possible spin-phonon coupling in reduced dimension from bulk crystal. In this study, temperature dependent Raman Spectra of exfoliated iron phosphorous trichalcogenides (FePS₃) flakes reveal a distinct shift of the large wave number phonon peaks towards higher wavenumber as temperature decreases. A clear deviation from standard anharmonic behavior below characteristic Néel temperature (T_N) is also observed. Other low wave number symmetry modes exhibit temperature dependent non-anharmonic self-energy as a function of layer thickness below T_N, related to the strong spin-lattice interaction due to short-range magnetic order. Energies and symmetries of the observed Raman-active modes are in agreement with DFT calculations. Below T_N low wave number broad mode in the paramagnetic state(T>T_N) splits into multiple distinct modes and evolve further into a possible magnon mode. We believe these results will pave way for possible spintronic applications exploiting magnons.
H71.00325: Quantum magnetization reversal studied in S/F/S Josephson $\phi_0$ junction

GWANG-HEE KIM (Presenter), Sejong Univ — We study quantum tunneling of magnetization in the presence of the bias current and the magnetic field along the general direction in the Josephson $\phi_0$ junction. With account taken of the influence of the superconductivity on the ferromagnet in the kelvin or subkelvin range, we present the analytic formulas of the tunneling rate in the uniaxial and nonuniaxial symmetries, and find that the tunneling exponents depend on three parameters related to the current and the magnetic field. We demonstrate that the current is equivalent to the effect of the magnetic field along the easy axis and the tunneling rate can be shifted by the bias current in the presence of such an external magnetic field. These features are expected to be observable with existing experimental techniques.

H71.00326: Slowed relaxation of the magnetism through dilution into paramagnetic mediums

IAN MOSELEY (Presenter), JOSEPH ZADROZNY, Colorado State University — Single molecule magnets (SMMs) represent the smallest magnetic domains (a single molecule) and as such have potential applications in information storage, quantum computing, and spintronics. Extending the lifetime of the magnetic relaxation is critical to applications of these molecules. Dilution of SMMs is a common strategy employed to extend magnetic relaxation and is typically carried out by dilution into a solvent or cocrystallization with an isostructural diamagnetic species. Herein, we report the first known example of extended magnetic relaxation through dilution into a paramagnetic medium. Using the canonical SMM $[\text{PPh}_4]^2(\text{Co(SPh})_4)$, dilutions into the isostructural paramagnets $[\text{PPh}_4]^2(\text{M(SPh})_4)$ (where $M = \text{Ni, Fe, and Mn}$) were made by cocrystallization. We show that across a range of concentrations, both Fe and Ni perform like the diamagnetic Zn congener, whereas the Mn dilution results in an accelerated relaxation. Dipolar interactions between spin centers are considered and we hypothesize that the observed relaxation enhancement can be attributed to low temperature magnetism of the paramagnetic diluents.

*Magnetization experiments were performed at the CSU Central Instrument Facility, which is supported by an NIH-SIG award (1S10OD021814-01) and the CSU-CORES Program.
H71.00327: Charge Transfer in Single-Molecule Magnetic Complexes

[\text{Mn}_{12}\text{O}_{12}(\text{O}_2\text{CR})_{16}(\text{H}_2\text{O})_4]^* 

DMITRY SKACHKOV, JIA CHEN, GEORGE CHRISTOU, XIAOGUANG ZHANG, SAMUEL TRICKEY, HAI-PING CHENG (Presenter), University of Florida — Single-molecule magnetic (SMM) complexes [\text{Mn}_{12}\text{O}_{12}(\text{O}_2\text{CR})_{16}(\text{H}_2\text{O})_4], with R=-H, -\text{CH}_3, -\text{CHCl}_2, -\text{C}_6\text{H}_5, have twelve Mn atoms in the core, eight of them are in 3+ charge state and located at peripheral ring of the molecule, while the four remaining Mn atoms in the center of the molecule are in 4+ charge state. When the SMM molecule is receiving the additional electron by excitation, this electron is localizing on one of the peripheral Mn atom, and the charge state of this atom is changing from Mn$^{3+}$ to Mn$^{2+}$, what is confirmed by experiment measuring the Mn-O bond lengths [Inorg. Chem. 2017, 56, 10706]. In order to develop the SMM with high catalytic activity, it is very important to know the energy barrier for electron transfer from Mn$^{2+}$ atom to another Mn$^{3+}$ atom located on diametral site of the molecule, in order to stimulate oxidation reaction. We calculated the minimum energy pathway for electron transfer in tunneling regime calculating the energy barrier for electron motion by plotting the profile of electrostatic potential along possible pathways. In the talk we will discuss the pathways for electron transfer in SMM for different ligands.

*US Department of Energy Basic Energy Sciences Energy Frontier Research Centers under Grant No. DE-SC0019330

H71.00328: WITHDRAWN ABSTRACT —

H71.00329: Electron Spin Resonance of Heisenberg Spin Chains of Four Ti Atoms

SOO-HYON PHARK (Presenter), Center for Quantum Nanoscience, Institute for Basic Science, KAI YANG, IBM Almaden Research Center, TANER ESAT, ANDREAS HEINRICH, Center for Quantum Nanoscience, Institute for Basic Science, CHRISTOPHER LUTZ, IBM Almaden Research Center — Heisenberg spin chain (HSC) is a one-dimensional circular array of spins, where the nearest neighbors are exchange-coupled. Quantum transitions between the energy eigenstates of such spin chains are well understood by the creation and annihilation of spin wave quanta. Using a low temperature (1.1K) scanning tunneling microscope (STM), we composed two circular spin chains of four hydrogenated Ti atoms, spin-$1/2$ atomic species, on MgO surface by atom manipulation techniques. The nearest neighbor couplings are antiferromagnetic and tuned to be 6 and 25 GHz by interatomic distance control. We performed electron spin resonance (ESR) combined with the STM on the spin chains. The measured ESR spectra show a remarkable consistency with the quantum transition probabilities calculated from the Heisenberg spin Hamiltonian, which identifies the energy eigenstates of the spin chains. We discuss the experimental data by employing the spin wave theories. This work suggests that our Ti spin chains deserve an ideal exchange-coupled quantum spin system. In addition, this work demonstrates an experimental approach plausible to creation and control of quantum phenomena in artificial spin structures.
H71.00330: Thermal spin-transfer torque driven by Chirality Induced Spin Selectivity effect in layered chiral hybrid perovskite*  KYUNGHOON KIM, ERIC VETTER, North Carolina State University, LIANG YAN, WEI YOU, University of North Carolina at Chapel Hill, DALI SUN, JUN LIU (Presenter), North Carolina State University — Thermal spin-transfer torque (STT), the transfer of the spin current mediated by heat current, provides a new way to control the orientation of nanomagnets. The recent discovery of the Chiral-Induced Spin Selectivity (CISS) effect offers an opportunity to create spin current in chiral materials without the need of ferromagnet elements, e.g., chiral (left- or right-handed) molecules. In the presence of electron transport mediated by heat current, the chiral materials would produce a spin current via CISS effect, of which the spin polarization determined by handedness of the material. Here we study the CISS effect in solution-processed, 2D-layered, hybrid perovskite materials incorporating chiral molecule ligands, sensed by the thermal STT signal using ultrafast Time-Resolved Magneto-Optical Kerr Effect (TR-MOKE) technique. The chirality-dependent precession of the magnetization in the ferromagnet layer on top of layered chiral hybrid perovskites were observed which is attributed to the CISS effect. Our work opens a new route for the use of layered chiral hybrid perovskite materials for novel STT devices. K.K., E.V., and L.Y. contributed to this work equally.

*We acknowledge funding from NC State-Nagoya Research Collaboration grant and the NSF award 1933324 and 1933297.

H71.00331: Electronic structure and magnetism of monolayer Janus transition metal dihalides*  CHASE HANSON (Presenter), ANTIA S. BOTANA, Arizona State Univ — Based on first-principles calculations, the evolution of the electronic and magnetic properties of transition metal Janus dihalides MXY (M= V, Mn, Fe, Co, Ni; X, Y = Cl, Br, I) is analyzed at the monolayer limit. A variety of magnetic ground states is obtained as a result of the competition between direct exchange and superexchange. We show how structural symmetry-breaking plays a crucial role in the magnetic and electronic properties of 2D magnetic materials.

*NASA Space Grant
H71.00332: Spinon-magnon interaction in an antiferromagnet with alternating antiferromagnetic and ferromagnetic quantum spin chains  
HEDA ZHANG (Presenter), Michigan State Univ, ZHIYING ZHAO, Fujian Institute of Research on the Structure of Matter, Chinese Academy of Science, VASILE O GARLEA, TAO HONG, Oak Ridge National Lab, Neutron Scattering Division, DOMINIQUE M GAUTREAU, AMARTYAJYOTI SAHA, University of Minnesota, Department of Chemical Engineering and Materials Science, S D MAHANTI, Michigan State Univ, TURAN BIROL, University of Minnesota, Department of Chemical Engineering and Materials Science, XIANGLIN KE, Michigan State Univ

— The concepts of quasiparticles and collective modes have been successfully applied to describe low-energy excitations in physics. In conventional magnets low-energy excitations are carried by spin waves, represented by massless bosons called magnons with $S = 1$. However, in one-dimensional antiferromagnetic quantum spin ($S = 1/2$) systems, quantum fluctuations destroy LRO in the ground state and magnons do not exist. Instead, the low-energy excitations are known as spinons, with $S = 1/2$. Although both magnons and two-spinon continuum have been observed in several quasi-one-dimensional antiferromagnets, magnons and spinons do not coexist in the same energy range. Here, we report the observation of coexistence of magnon and spinon excitations in Cu$_2$(OH)$_3$Br, a quantum antiferromagnet consisting of nearly decoupled, alternating ferromagnetic and antiferromagnetic $S=1/2$ chains. Importantly, the excitation spectra of both the magnetic chains emerge in close energy range and cross over each other, enabling strong spinon-magnon interaction.

H71.00333: Synthesis of Amorphous Soft Magnet using the IR image furnace  
DEOK YOUNG LEE (Presenter), Agency for Defense Development, DAEHWAN PARK, JUN HAN LEE, YOON SEOK OH, Department of Physics, Ulsan National Institute of Science and Technology — Study of soft magnets has been an important research topic because of their various applications such as transformers, magnetic shielding, transducers, and large variety of apparatus. Amorphous soft magnets are conventionally synthesized by using melt-spinning method, in which molten metal is cast onto a fast-rotating copper wheel and could be cooled down with $10^5$-$10^6$ K/sec to form highly amorphous state. However, constitutionally, the melt-spinning method yields potential contamination from the copper wheel. An improved synthesis method is required to get highly pure and ultimate soft magnet. In order to avoid the potential copper contamination, we have synthesized soft magnet using the IR image furnace. The IR image furnace focuses high-power infrared light from two or four lamps in the middle of two ceramic rods with two or four mirrors and develops floating molten zone, where provides a crucible free environment. By control of lamp power, travelling speed, rotation speed of rods, and gas conditions, the amorphous alloy could be synthesized without copper contamination. Here we present morphology, chemical, and magnetic properties of amorphous soft magnet synthesized by the IR image furnace.
Synthesis and structural and magnetic properties of Sr$_{1-y}$Pr$_y$Fe$_{12-x}$Co$_x$O$_{19}$ nanocomposites prepared via auto combustion technique  

MRIDUL BHATTARAI (Presenter), JIBA NATH DAHAL, Department of Physics, Truman State University — Sr$_{1-y}$Pr$_y$Fe$_{12-x}$Co$_x$O$_{19}$ (x = 0.0 - 1.5 and y = 0.1 - 0.3) polycrystalline samples were prepared via auto combustion method and analyzed with respect to their structural and magnetic characteristics. The possibility of simultaneous substitution of Fe$^{3+}$ by Co$^{2+}$ was verified for low substitution degrees. At higher substitution of Co$^{2+}$, a secondary soft magnetic phase CoFe$_2$O$_4$ is observed. The room temperature magnetic parameters derived from hysteresis loops showed that the saturation magnetization of Sr$_{1-y}$Pr$_y$Fe$_{12-x}$Co$_x$O$_{19}$ increased with the increase in cobalt content, and a concomitant reduction in coercivity values is controlled by substituting Pr$^{3+}$ for Sr$^{2+}$. Mr value increases with increasing Co$^{2+}$ content indicating the presence of an exchange coupling between magnetic hard and soft phases of the composite. The highest magnetization 61.17emu/g and coercivity Hc 3.98 kOe is observed in y = 0.1, x = 1 content. The coercivity observed is about 11% higher than pure SrFe$_{12}$O$_{19}$. Therefore, the substitution of Pr$^{3+}$ and Co$^{2+}$ in SrFe$_{12}$O$_{19}$ can bring magnetization and coercivity enhancement, which is useful for the high-temperature magnetic application.

Permanent magnet properties of Fe$_5$C$_2$ from first principles*  
LI YIN (Presenter), DAVID PARKER, Oak Ridge National Lab — Iron carbides, such as Fe$_3$C, Fe$_2$C and the Hagg carbide Fe$_5$C$_2$ are commonly produced in steel-making and in fact often play an important role in strengthening such steel. Here we study the permanent magnet properties of Fe$_5$C$_2$ from first principles, focusing on the magnetization and magnetic anisotropy – two indispensable components of a permanent magnet material. We find a substantial magnetization exceeding 1.5 T, along with a significant magnetic anisotropy exceeding 1 MJ/m$^3$ (here defined as the energetic difference between the magnetically easiest and hardest directions). While the anisotropy for an intermediate direction is much smaller, likely precluding the use of Fe$_5$C$_2$ for permanent magnet applications, the 1 MJ/m$^3$ anisotropy value is rather significant for a material containing only relatively light elements such as Fe and C. It is in fact more than half again as large as the value for hcp Co. We discuss the implications of these results for permanent magnet applications.

*This research was supported by the Critical Materials Institute, an Energy Innovation Hub funded by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Advanced Manufacturing Office.
**H71.00336: Detection of magnetic domain wall of YIG with scanning diamond NV center probe**

YUTA KAINUMA (Presenter), RUI WANG, KUNITAKA HAYASHI, KENICHI NAKASHITA, TOSHU AN, School of Materials science, Japan Advanced Institute of Science and Technology (JAIST) — Probing and imaging of the magnetic domain structure at the nanoscale are important to understand the basic physics of the magnetic interaction, and for the application in the spintronics field. The nitrogen-vacancy (NV) center; spin state of a defect structure in diamond, is attracting much attention for its novel spin sensing ability at nanoscale and room temperature conditions. We developed a scanning NV center spin sensing probe combined with atomic force microscopy (AFM) based on quartz tuning-fork resonator. Electron spin resonance (ESR) signal from the apex of the NV center probe can be detected optically (optically detected magnetic resonance, ODMR) via confocal microscope setup. A diamond probe (φ 4 µm, length 10 µm) hosting an ensemble of NV centers is glued at the end of the AFM probe enabling simultaneous measurements of the ESR and topographic images of the sample. Magnetic insulator of yttrium iron garnet (YIG) was used for the magnetic film sample that shows magnetic domain wall structures with a micrometer scale under zero external magnetic field. The stray magnetic field from magnetic domain walls was measured with the scanning NV center probe.

**H71.00337: A Low-Cost Vibrating Sample Magnetometry Based on Audio Components**

BABU SANKHI (Presenter), EMRAH TURGUT, Oklahoma State University-Stillwater — Measurement of magnetization is an important characterization step for magnetic materials to understand their fundamental properties and to utilize in industrial applications[1]. In this project, we construct a cheap and versatile vibration sample magnetometer (VSM) using the sound card. We tested our VSM for the hysteresis loops of three distinct magnetic samples: bulk Nickel piece, perm-alloy thin film with an easy- plane anisotropy, and Co/Pt multilayer with perpendicular magnetic anisotropy. The magnetizations of corresponding loops are analyzed at different frequencies and, the noises are also measured and compared for two methods. Although sound card performance is not very good for the frequencies below 20 Hz due to the cut-off frequency, its sensitivity is approximately 7 times better than that of lock-in amplifier at higher frequencies up to 60 Hz. The measured sensitivity of our sound card based VSM is of the order of emu, which is better than the sensitivities obtained in the previous similar experiments [2] at room temperature.

H71.00338: Resolution Increase and Faster Phase Identification for Electron Magnetic Imaging  MD MAZHARUL ISLAM (Presenter), EMRAH TURGUT, NATHANIEL BERRY, Oklahoma State University-Stillwater — A detailed imaging of magnetic skyrmion arrangement allows us to understand the interactions in them and their dynamics, which can pave the way to the low power spintronics device [1]. Lorentz Transmission Electron Microscopy is an effective way for imaging the internal magnetic properties of a material [2]. The phase shift of the electron beam has a relationship with the magnetization distribution of the nanostructure that is based on Aharonov-Bohm Effect. Here, we are using several methods to get the electron phase shift caused by the complex magnetization distribution. We then reconstructed the magnetization using a model based iterative algorithm [3]. For getting an accurate magnetization distribution, cost function minimization analysis was done. We then compared the accuracy of the reconstructed magnetization from the electron phase shift from different forward process. Here, our methods reduce the artifacts that are usually seen in magnetization reconstruction process.

H71.00339: Emerging Widefield Magnetic Microscopy Applications with Nitrogen-Vacancy centers in Diamond  PAULI KEHAYIAS (Presenter), TZU-MING LU, ANDREW M MOUCHE, Sandia National Laboratories — We will discuss using magnetically-sensitive nitrogen-vacancy (NV) color centers in diamond for widefield magnetic microscopy, a technique which offers sub-micron spatial resolution, high magnetic moment sensitivity, and parallel magnetic readout in ambient conditions. NV magnetic imaging is being used to study superconductivity, current flow in 2D materials, magnetic domain structures, and other condensed-matter physics applications. With the objective of exploiting the NV magnetic imaging advantages in a wider array of scientific problems, we will report on our recent progress using NV imaging for applications relating to synthetic micromagnets, magnetic materials, hardware security, and electronics fabrication.

Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the DOE's National Nuclear Security Administration under contract DE-NA0003525.

H71.00340: Tabletop EUV magnetic linear dichroism spectroscopy on thin-film antiferromagnetic chromium across the 3p absorption edge  PETER JOHNSEN, CHRISTIAN GENTRY, SINEAD RYAN (Presenter), MARGARET MURNANE, HENRY KAPTEYN, Department of Physics and JILA, University of Colorado, Boulder — We present the magnetic linear dichroism (MLD) reflection spectra measured on antiferromagnetic Chromium by use of a tabletop high harmonic generation (HHG) source across the 3p absorption edge. The spectra were obtained by rotating the field-cooled direction of the magnetization 90 degrees relative to the incident polarization angle. Furthermore, we investigate the effect as a function of both film thickness and angle of incidence.
**H71.00341: Tunneling Magneto Resistor Nano-columns**

DEREJE SEIFU (Presenter), Morgan State Univ — Nanowires inside carbon nanotubes (CNTs), nano-columns, and thin films of ferromagnet/insulator/ferromagnet (FM/I/FM) tunneling magnetoresistance (TMR) were synthesized using magnetron DC/RF sputtering [1]. Nanowires were synthesized inside CNTs using glancing angle deposition. The magnetic properties of nanowires, nano-columns and planar nano-metric thin films of FM/I/FM showed similarities including two-fold magnetic symmetry. Nanowires of Fe/MgO/Fe showed enhanced magnetic properties in particular a high increase in coercive field, 754% higher compared to planar thin films of Fe/MgO/Fe [1]. This could be due to shape anisotropy in nanowires, which play an important role in coherence. TMR of nano-columns and nano-metric thin films of FM/topological/FM are other examples studied. TMR is a macroscopic phenomenon that can only be explained by quantum mechanics, where electrical resistance varies when an external magnetic field is applied parallel to the tri-layer system.

*The corresponding author D.S acknowledges the support of ARL-W911NF-19-2-0222.

**H71.00342: Magneto Restrictive Sensor**

DEREJE SEIFU (Presenter), Morgan State Univ, ASHA J HALL, VTD, ARL — Magneto restrictive based sensors can be used for diagnosis and prognosis of cracks and creep in vital parts of several mechanical systems. One material studied extensively for this application is Tb$_{0.3}$Dy$_{0.7}$Fe$_2$ (TFD). We studied the structural and magnetic properties of micro-particles of TFD embedded inside reinforced carbon fiber polymer (RCFP) using VSM, TMM and MFM. Results show enhanced magnetic properties for TFM when embedded inside RCFP and a two-fold magnetic symmetry. To get a deeper understanding of the structural and magnetic properties of TFD, thin films were synthesized using magnetron DC/RF sputtering. Study of surface magnetism of films processed at a substrate temperature of 250 °C using MOKE revealed a four-fold magnetism. Results from magnetic and structural measurements will be presented.

**H71.00343: Structural, interface, and device properties of some Bi2Se3-based spintronic heterostructures.**

YUB RAJ SAPKOTA (Presenter), DUSTON WETZEL, DIPANJAN MAZUMDAR, Physics, Southern Illinois University Carbondale — Incorporating Topological Insulators in spintronic heterostructures and devices have gained interest due to several recent observations of greater spin-orbit torque compared to heavy metals. However, strong tunnel magnetoresistance (TMR) behavior has not been established with TIs compared to standard spintronics interfaces such as CoFeB-MgO. In this work, we have systematically investigated the structural, interface properties of prototypical a TI material (Bi2Se3) with normal Ferromagnets such as Co. Bilayer (Bi2Se3/Co) and TMR heterostructures (Co/Bi2Se3/Co) was fabricated using magnetron sputtering and their structure and interface investigated using X-ray diffraction and X-ray reflectivity method. Systematic thickness and substrate dependence studies with different growth and post-deposition annealing conditions have been carried out. We show that a sharp Bi2Se3/Co interface is possible, but annealing may lead to significant interdiffusion. Shadow mask techniques were incorporated to define micron-sized TMR devices. Detailed transport and magnetotransport and current-voltage characteristics will be discussed.

*NSF CAREER grant (ECCS: Award#1846829)

**H71.00344: Magnetic and Electronic Materials towards Realization of a FET based on Spin-Orbit Torques**

PHILLIP DANG (Presenter), ZEXUAN ZHANG, JOSEPH CASAMENTO, XIANG LI, JASHAN SINGHAL, DARRELL SCHLOM, DANIEL RALPH, HUILI XING, DEBDEEP JENA, Cornell University — The spin-orbit torque field effect transistor (SOTFET) is a recently proposed device that combines the spin-orbit-torque mechanism for writing magnetic memories with semiconductor transistors that are ubiquitous in logic. The SOTFET utilizes a magnetoelectric multiferroic to couple a SOT-controlled ferromagnet to the semiconducting channel. Therefore, this magnetic device may access the orders-of-magnitude on/off ratio of transistors, giving it the potential to combine memory and logic. It's realization, however, relies on the delicate interplay between topological insulating, ferro/ferrimagnetic, multiferroic, and semiconducting materials. In this talk, we discuss the material parameters and candidates that show promise for integration into a SOTFET and give an overview of the material advances towards realizing the device.

*The research was partially supported by the National Science Foundation under Grant Nos. E2CDA 1740286 and NewLAW EFRI 1741694 and partially supported by the Semiconductor Research Corporation as nCORE task 2758. P.D.’s support by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1650441 is acknowledged.
**H71.00345: Large Unidirectional Magnetoresistance in Topological Insulator/Ferromagnet Bilayers**

DUSTON WETZEL (Presenter), YUB RAJ SAPKOTA, DIPANJAN MAZUMDAR, Physics, Southern Illinois University Carbondale —

Strong spin-orbit coupling in topological insulators (TI) is expected to induce strong spin-orbit torque on proximal magnetic moments. This has motivated significant recent interest in topological insulator/ferromagnet (TI/FM) systems, with potential applications in spintronic memory and sensor technologies. We have thus carried out magnetotransport measurements on Bi$_2$Se$_3$/Co bilayers. Using standard four-probe methods, low-field, in-plane longitudinal and transverse (planar Hall) magnetoresistance (MR) has been measured, at room temperature, as well as angular-dependent MR at various field strengths. When current is passed predominantly through the Co layer, we observe typical AMR behavior. However, by promoting higher current near the TI/FM interface (verified by a two probe resistance value between that of Co and Bi$_2$Se$_3$), we observe unidirectional magnetoresistance orders of magnitude higher than Co alone, as well as an unusual cos(φ) angular dependence. The effects of current, sample angle, and sample thickness, along with comparison with standard Co/heavy metal systems will be discussed.

*NSF CAREER grant (ECCS: Award#1846829)

**H71.00346: Fabrication and characterization of CuO-doped Ni-Co-Zn ferrite composites for RF applications.**

POONAM LATHIYA (Presenter), JING WANG, Univ of South Florida — With the recent advancements related to imminent rollout of 5G and IoT technologies, there is a growing demand for soft magnetic materials for different applications such as antennas, circulators, inductors, interference suppressors and wireless power transfer etc. Ni-Co-Zn ferrites exhibit excellent soft magnetic properties such as high resistivity, high permeability and low magnetic loss for RF applications. To meet the performance specifications for aforementioned applications, Ni-Co-Zn sheets with a high permeability and low magnetic loss is desired. In this work, we present a novel method to prepare thin Ni-Co-Zn ferrite sheets with high permeability and low magnetic loss for RF antenna applications. Ni-Co-Zn ferrite powders were prepared by solid state synthesis. Different CuO wt% were doped in Ni-Co-Zn samples. Toroidal samples made from powders under different level of hydraulic force were sintered in air. Enhancement in the resonance frequency was achieved by doping of copper oxide (0 to 10 wt%) in Ni-Co-Zn ferrite. The permeability decreases from 7 (0 wt%) to 5.3 (10 wt%) along with increase in resonance frequency from 300 to 530 MHz. Magnetic loss of 0.04 achieved at 530 MHz frequency. Ni-Co-Zn sheets were prepared with same optimized conditions for RF antennas.
H71.00347: Effect of Demagnetization Method on Remnance Magnetization States in Metallic Ferromagnets  JENNIFER FREEDBERG (Presenter), E. DAN DAHLBERG, University of Minnesota — Parametric plots of the remagnetization versus demagnetization remnances, commonly called Henkel plots, were constructed for four metallic ferromagnets. These were compared to Wohlfarth's simple model for noninteracting particles [1]. Three different paths to a net zero magnetization state (AC and two types of DC demagnetization) were explored for all the samples and in addition two of the samples were thermally demagnetized. These results present a useful comparison between metallic and particulate ferromagnetic systems, and how fundamental differences in their magnetization processes affect subsequent measurements. While adherence of our data to Wohlfarth's model was poor for several paths to zero magnetization, many similarities between our data and models including magnetic interactions were found [2, 3].

*This work was funded by NSF grant DMR 1609782

H71.00348: Classical mechanism for the anomalous enhancement of Hall resistivity during magnetization reversal  CHRISTOPHER ARD (Presenter), HUA CHEN, OLIVIER PINAUD, Colorado State University — Certain bulk or synthetic ferromagnetic conductors with broken inversion symmetry show a characteristic hump in the hysteresis curve of the Hall resistivity, which is commonly ascribed to the topological Hall effect due to the formation of skyrmion lattice in finite fields. Here we argue that the hump could also be due to classical mechanisms associated with transport in random media. By modeling a 2D inhomogeneous ferromagnetic conductor using a random resistor network model, we are able to show that an anomalous enhancement of the Hall resistivity can arise before the ferromagnet is fully switched by a perpendicular magnetic field. The qualitative behavior is further analyzed by solving the diffusion equation with correlated disorder perturbatively.
H71.00349: Ferromagnetic Resonance Studies of MnZn Ferrites/Polymer Composite Materials. PAUL COUTURE (Presenter), ROBERT CAMLEY, KAREN LIVESEY, ZBIGNIEW J CELINSKI, University of Colorado, Colorado Springs — We characterize MnZn ferrite particles embedded in a polymer for use in low frequency EMF emissions shielding. The ferrites particles are approximately 1.2 µm in diameter and embedded in PVC resin in various concentrations: 10% - 70% by weight. The composite undergoes an extrusion process which creates a 0.6 mm thick slab and orders some of the particles along the extrusion direction. This creates an easy axis along the extrusion direction with an associated anisotropy. We characterized the ferromagnetic resonance absorption peaks with broad-band FMR, 1-30 GHz, and cavity based FMR systems. Comparing the results to the expected FMR peaks for measurements along the easy and hard axes, and normal to the slab, using the Landau-Lifshitz-Gilbert equation provides some interesting irregularities. Samples with high ferrite concentrations, Kittel's equation for thin film resonance can be used to describe the FMR frequency vs. field dependence. For low ferrite concentrations the resonance conditions have to be modified to account for an effective thickness beyond the normal filling factor correction associated with presence of a matrix. These results indicate the effective demagnetizing factors, determined by the spatial extend of the RF fields, can describe the observed FMR absorption.

H71.00351: Evolution of Skyrmion state from Helical state in Mn$_x$TaS$_2$*  RABILUL ISLAM (Presenter), Electrical & Computer Engineering, University of Waterloo, PENG LI, Institute of Quantum Computing, University of Waterloo, MARIJAN BEG, HANS FANGOHR, Faculty of Engineering and Physical Sciences, University of Southampton, GUOXING MIAO, Electrical & Computer Engineering, University of Waterloo — Skyrmion-based memory and logic devices are promising to overcome the limitations of the conventional data storage and information processing devices. However, the number of materials hosting magnetic skyrmions is very limited. Therefore, the discovery of new materials is an important avenue of research. In this work, we explore whether the skyrmion state can be an equilibrium state in Mn$_x$TaS$_2$ (MTD) as well as how does the skyrmion state emerges from the helical order with its helical length of 95 nm. By applying an external magnetic field, we were able to modulate the helical period and eventually obtain the skyrmion state. Our findings demonstrate the existence of the skyrmion state in MTD magnetic materials as well as the evolution path. 3D view of magnetic moments gives a picture of the Bloch-type skyrmion. Moreover, we measure the magnetoresistance as a function of the applied field for MTD materials. In the in-plane field dependence of magnetoresistance and magnetization, we saw the clear corresponding jumps when the skyrmion is formed.

H71.00352: Nonmagnetic Zinc substitution on Cobalt Ferrites and measurement of their Structural, Dielectric and Magnetic Properties  TAMANNA MARIAM (Presenter), Univ of Toledo, KAZI HANIUM MARIA, Department of Physics, University of Dhaka, Dhaka, Bangladesh, NAZRUL ISLAM KHAN, Materials Science Division, Bangladesh Atomic energy Centre, Dhaka, Bangladesh, SHAMIMA CHOUDHURY, Department of Physics, University of Dhaka, Dhaka, Bangladesh — A series of Co$_{1-x}$Zn$_x$Fe$_2$O$_4$ ferrites with (x=0.0,0.1,0.2,0.3,0.4,0.5) compositions were synthesized by standard double sintering ceramic technique. Substituting nonmagnetic Zn in place of Co influenced the structural, dielectric and magnetic properties of the samples. The X-Ray diffraction pattern confirmed the single-phase cubic spinel structure. The lattice parameters were found to increase with Zn substitution. The grain size of the samples was reduced by enhancing the Zn concentration. The dielectric constant of the sample is found to decrease with increase in frequency exhibiting normal dielectric behavior. The variation of the resistivity versus temperature was also studied and the dielectric constant of the system has a variation quite similar to that of the resistivity. Saturation magnetization and coercivity were estimated with variation of Zn content by VSM measurement. These effects are due to facilitation of demagnetization by substitution of the non-magnetic Zn ions. Permeability was found to decrease with increasing in Zn content, which showed proportionality behavior with grain size. Low coercivity, moderate saturation magnetization and high anisotropy constant has made Cobalt Ferrite a good candidate to contribute in multiferroic materials and in storage devices
**H71.00353: Room-temperature ferromagnetism in oxidized-graphenic nanoplatelets induced by topographic defects**

JOHN PRIAS (Presenter), Doctoral Program in Physical Sciences, IIS and EITP, University of Quindío, KATHERINE GROSS, Department of Physics, University of Valle, HERNANDO ARIZA, Interdisciplinary Institute of sciences, University of Quindío, PEDRO PRIETO, University of Valle, CINZIA DI GIORGIO, FABRIZIO BOBBA, ANNAMARIA CUCOLO, Department of Physics, University of Salerno — Pyrolytic oxidized-graphenic nanoplatelets (OGNP) obtained from bamboo pyroligneous acid (BPA) by varying the density of extended defects, show room-temperature ferromagnetism. Topographic defects, created during the fabrication process, arise from a natural formation of clusters; such clusters drastically distort the graphitic basal plane, giving rise to abrupt surface curvatures. Topographic defects were found to be sources of the magnetic signal, as evidenced by bulk magnetization and MFM measurements. Increased defect density, which is tuned by carbonization temperature, results in enhanced magnetization.

*We would like to thank the Interdisciplinary Institute of Sciences, Doctoral Program in Physical Sciences and EITP at Universidad del Quindío and the Center of Excellence for Novel Materials (CENM) at Universidad del Valle, Cali for the financial support.

**H71.00354: Self-regulating magnetic hyperthermia (SrMH) of Ni$_x$Cu$_{1-x}$ nanoparticles**

BIANCA PAOLA MENESES BRASSEA (Presenter), MOHAMED F. SANAD, DAWN S. BLAZER, Physics, University of Texas at El Paso, SHIRIN POURMIRI, Physics and Astronomy, University of Delaware, AHMED A. EL-GENDY, Physics, University of Texas at El Paso — Ni$_x$Cu$_{1-x}$ ($x=0.2-0.5$) nanoparticles have been synthesized by reducing Ni and Cu from metal precursors using sol-gel route followed by annealing at different temperatures for controlled self-regulating magnetic hyperthermia applications (SrMH). SEM, TEM, and XRD reveal spherical 20-50 nm nanoparticles with FCC cubic structure for different compositions of Ni$_x$Cu$_{1-x}$. The magnetic properties exhibited ferromagnetic behavior with saturation magnetization ($M_s$) ranging from 8-20 emu/g at 300 K and Curie temperature ranging from 42-25 °C within the limit of the therapeutic temperature range of 42-46 °C. The feasibility of hyperthermia has been performed under the therapeutic limits of alternating magnetic field and frequency. The samples exhibited heating rate and a significant dissipated heating power or measured as specific absorption rate (SAR) ranging from 0.1-1.6 °C/min and 20-100 W/g, respectively. Results reveal nanoparticles' feasibility for self-regulating hyperthermia.

*AAE acknowledge the startup and rising stars funds by UTEP and UT-system respectively. Also, the research reported in this paper was partially supported by the National Institute of General Medical Sciences of the National Institutes of Health under linked award numbers RL5GM118969, TL4GM118971, and UL1GM118970.
H71.00355: Functionalized superparamagnetic Fe@Au Core/shell nanoparticles and their feasibility for magnetic hyperthermia*  BIANCA PAOLA MENESES BRASSEA (Presenter), MOHAMED F. SANAD, DAWN S. BLAZER, Physics, University of Texas at El Paso, SHIRIN POURMIRI, Physics and Astronomy, University of Delaware, AHMED A. EL-GENDY, Physics, University of Texas at El Paso — Superparamagnetic Fe@Au core/shell nanoparticles have been synthesized at ambient condition at different ratios of Fe:Au precursors using one-step wet chemistry method and functionalized with tween. SEM, TEM, and XRD reveal spherical FCC Fe core nanoparticles coated with Au shells. The particles sizes average 61, 71, 83 nm at Fe:Au precursor's ratio of 1:1, 2:1, 3:2 respectively. VSM reveals superparamagnetic behavior at 300 K. The saturation magnetization ($M_S$) of the samples amounts 79, 165 and 89 emu/g for 61, 71 and 83 nm respectively. Feasibility for hyperthermia treatment of cancer have been tested under applied magnetic fields and frequencies, heating power known as specific absorption rate (SAR) has been recorded. SAR dependence of magnetic field and frequency yields 35, 50, 25 W/g at therapeutic range of 400 Oe and 304 kHz for samples with $M_S$ of 79, 165 and 89 emu/g respectively. The samples show feasibility for future in vitro/in vivo studies for tumor cells.

*AAE acknowledge the startup and rising stars funds by UTEP and UT-system respectively. Also, the research reported in this paper was partially supported by the National Institute of General Medical Sciences of the National Institutes of Health under linked award numbers RL5GM118969, TL4GM118971, and UL1GM118970.

H71.00356: The evolution of electronic and magnetic states for transition-metal rings embedded in carbon nanotubes*  JOSEPH WARD (Presenter), RITHVI RAVICHANDRAN, JASON HARALDSEN, Univ of North Florida — We investigate the electronic and magnetic states for various sizes of transition metal rings that have been substituted into carbon nanotubes. Using density functional theory, we examine the electronic density of states, magnetic moment, and total energy for various transition metal atoms and magnetic configurations. After determining the structural and magnetic ground states, we show how the introduction of these metal atoms affect the electronic states and determine the ground state magnetic configuration with a variation of transition metal atom and onsite potential. Future work will look into the use of these magnetic systems in a device application setting as we work towards possible spintronic applications.

*This project is supported, in part, by the Institute for Materials Science at Los Alamos National Laboratory.
H71.00357: Effect of Structural Disorder on the Magnetic Properties of Melt-Spun Co$_{3+x}$V alloys

ONUR TOSUN (Presenter), Physics and Astronomy, University of Delaware, INCI RUZYBAYEV, Kinsley School of Engineering, Sciences and Technology, York College of Pennsylvania, FRANK M ABEL, Physics and Astronomy, University of Delaware, BALAMURUGAN BALASUBRAMANIAN, RALPH SKOMSKI, DAVID SELLMYER, Physics and Astronomy, University of Nebraska, Lincoln, GEORGE C HADJIPANAYIS, Physics and Astronomy, University of Delaware — We have investigated the structural and magnetic properties of melt-spun Co$_{3+x}$V alloys for x = 0, 0.2, 0.4 and 0.6 in order to study the effect of structural disorder on the magnetic properties of Co-V alloys. Bulk Co$_3$V exists in two phases: An ordered hexagonal (Al$_3$Pu-type) low-temperature phase (LTP) and a cubic $L1_2$ (Cu$_3$Au)-type high-temperature phase (HTP) [1, 2]. Both the LTP and HTP are paramagnetic down to 4.2 K. The as-spun samples have the HTP structure. However, when they are annealed at 1173 K, they transform into the LTP. Magnetic data suggest that the as-made ribbons are ferromagnetic with ordering temperatures of 10, 20, 30 and 75 K for x = 0, 0.2, 0.4 and 0.6, respectively. This behavior is attributed to a slight destruction of perfect order in the HTP and which can lead to an increase in the Co-Co exchange interaction. The magnetic properties of annealed samples are currently being measured and the results will be presented and discussed at the meeting.

*This research is supported by US Department of Energy (DOE) with grant number DE-FG02-04ER46152 and DE-FG02-90ER45413.

H71.00358: Structural and Magnetic Properties of Iodide-Mediated Synthesized L1$_2$ FePt$_3$ Nanoparticles

VIMAL DEEPCHAND (Presenter), Univ of Delaware, VASILEIOS TZITZIOS, Department of Chemical Engineering, Khalifa University of Science and Technology, Petroleum Institute, GEORGE C HADJIPANAYIS, Univ of Delaware — Halide ion-mediated synthesis of L1$_0$ FePt has previously been used to form magnetically hard L1$_0$-FePt phase without the need of any post-annealing or 3$^{rd}$ element addition [1,2]. In this work, we chemically synthesized L1$_2$ FePt$_3$ by the co-reduction of iron and platinum-based precursors in the presence of elemental iodine. Thermomagnetic data showed that the magnetic properties depend strongly on the degree of atomic ordering. The as-made structure showed the L1$_2$ phase but with a low degree of ordering. Magnetic measurements showed that the ordering temperature of the as-made sample is at 380 K. The chemical ordering increased to 0.71 when the samples were annealed at 700°C for 30 minutes. The annealed samples showed a different ordering temperature of 251 K. Our data agreed with those reported by Margeat et al [3]. Room temperature hysteresis loops showed that the coercivity of our samples increased with annealing temperatures, up to 0.23 kOe for samples annealed at 700°C. Thermomagnetic measurements from 50 K to 380 K also provide evidence of a phase transformation in the L1$_2$ FePt$_3$ nanoparticles, which we believe to be the transition from the AFM state to a FM state.

*DOE-FG02-90ER45413
Effect of Surfactants on the Shape of Iron Oxide Nanoparticles Synthesized by Thermal Decomposition

H71.00359

SHIRIN POURMIRI (Presenter), Physics and Astronomy, University of Delaware, VASILEIOS TZITZIOS, Institute of Nanoscience and Nanotechnology, NCSR “Demokritos, GEORGE C HADJIPANAYIS, Physics and Astronomy, University of Delaware — Superparamagnetic iron oxide nanoparticles are one of the most promising materials for biomedical applications. However, despite the large number of researches done on spherical nanoparticles, there is much less work on the effect of particle shape of these nanoparticles on their magnetic properties and biomedical applications. In this work, iron oxide nanoparticles were synthesized using thermal decomposition of iron acetylacetonate in the presence of a mixture of oleyl amine and oleic acid. The XRD measurements show that the nanoparticles have a pure Fe3O4 phase. TEM images show that by changing the ratio of oleic acid to oleyl amine from 0.6 to 1, 1.1 and 1.3 the nanoparticle’s shapes change from spheres to cubes, octopods and rods, respectively; when the ratio is increased to more than 1.3, the nanoparticles start to form spherical shape again. The size of each of these shapes can be precisely controlled by adjusting the time and temperature of the reaction. Magnetic properties and hyperthermia measurements of these samples will be presented and discussed in the meeting.

Characterization of NiFe/SiO2 multilayers for on-wafer inductors operating at radio and low GHz frequencies

H71.00360

SARA GOLDMAN (Presenter), Physics, UCCS — Magnetic layers surrounding copper core inductors are studied for use in circuits operating at radio and low GHz frequency ranges in order to address performance issues and quality losses normally observed in miniaturized inductors. Coating an inductor core in a magnetic material has the potential to increase the inductance proportional to the magnetic permeability of the coating. The objective of this research is to identify and construct an appropriate magnetic coating to improve the inductance and quality (Q-factor) of inductors. Permalloy (Py) was selected for these experiments due to its high relative permeability. Py layers, from 10nm to 1μm thick, were grown on silicon wafers using magnetron sputtering. These layers were characterized with SQUID magnetometer and broad-band FMR system. A specific issue we address is that inductor coatings have the potential to decrease the Q-factor due to eddy currents during high frequency operation. A method to reduce eddy current losses is to reduce layer thickness. Therefore, in addition to individual Py layers, multilayer coatings are developed: depositing 5 to 50 identical layers of Py (for total thickness from 150nm to 1.5μm) separated with 5nm layers of SiO2. Such structures are suitable for high frequency inductor operations.
H71.00361: Mn$_2$FeSi: Experimental realization of an antiferromagnetic inverse-Heusler alloy

DIPANJAN MAZUMDAR (Presenter), ANIL ARYAL, SAID A BAKKAR, HASSANA SAMASSEKOU, SUDIP PANDEY, IGOR DUBENKO, Physics, Southern Illinois University Carbondale, SHANE STADLER, Physics and Astronomy, Louisiana State University, NAUSHAD ALI, Physics, Southern Illinois University Carbondale — Search for low-moment magnetic materials with high spin-polarization is important for future spintronics applications. In this work, we have conducted detailed and varied materials growth and characterization along with complementary first-principles calculations to investigate the structure and magnetism of Mn$_2$FeSi, which is a prospective inverse-Heusler material identified by prior calculations. We show that Mn$_2$FeSi adopts a cubic structure that is in very good agreement with theoretical estimates while the magnetic and resistivity measurements show behavior consistent with antiferromagnetism which can be tuned to a very low-moment state under appropriate growth conditions. Supporting first-principles calculations show that compensated antiferromagnetic states are energetically feasible. Our work provides new evidence that the magnetic properties of Manganese-based inverse-Heuslers can be useful to explore new applications in the area of spintronics.

*NSF CAREER grant (ECCS 1846829); NSF DMREF grant No. 1235396; U. S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award No. DE-FG02-06ER46291 and DE-FG02-13ER46946

H71.00362: Emergent Topological Hall Effect in La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrIrO$_3$ Heterostructures

YAO LI (Presenter), Nanjing University, LUNYONG ZHANG, Max Planck Institute for Chemical Physics of Solids, QINGHUA ZHANG, Institute of Physics, Chinese Academy of Sciences, CHEN LI, Nanjing University, TIEYING YANG, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, YU DENG, Nanjing University, LIN GU, Institute of Physics, Chinese Academy of Sciences, DI WU, Nanjing University — Novel magnetic and electric phenomena could emerge in perovskite oxide heterostructures due to multiple and complex coupling at the hetero-interface. Here, we report that an emergent giant topological Hall effect (THE) can be induced in ferromagnetic La$_{0.7}$Sr$_{0.3}$MnO$_3$ thin films in a wide temperature range up to 200 K by constructing La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrIrO$_3$ epitaxial heterostructures. The observed THE indicates a non-coplanar spin texture, which also leads to strongly pinched field dependent magnetization (MH) loops in the out-of-plane direction. This THE and pinched MH loops are not observed in La$_{0.7}$Sr$_{0.3}$MnO$_3$ single layer films or La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrTiO$_3$/SrIrO$_3$ trilayer heterostructures, indicating the relevance of the La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrIrO$_3$ interface, where Dzyaloshinskii-Moriya interaction due to strong spin-orbital coupling in SrIrO$_3$ may play a crucial role. This work demonstrates the feasibility of using SrIrO$_3$ to modify magnetic and transport characteristics by interfacing with other correlated oxides, which might be useful to novel spintronic applications.
**H71.00363: Novel Magnon Transport Properties in Magnetic Oxides by Mesoscopic Boltzmann Approach**

YANXIA WANG, WEI WANG, YUHENG LI, JIANWEI ZHANG (Presenter), School of Physics Science and Engineering, Tongji University — The coherent transport properties of magnon in ferromagnetic insulator (FI) demand precise physical understanding of magnon scattering and relaxation processes. In this presentation, we invent a general magnon Boltzmann equation from full quantum magnon Hamiltonian[1]. By including N-process magnon-scattering due to dipole-dipole interaction, we demonstrated a novel collective decay dynamics of magnon group, which showed hydrodynamics transport properties of magnon. To conduct N-process scattering, a new spatial dependent magnon interaction field \( \lambda \) was introduced, which was describing collective local field in magnon. We also found N-process scattering is the physical origin that why coherence magnons can transfer to thermal magnons in FI relaxation process. Furthermore, our results showed magnon current can be manipulated by varying of anisotropy in magnetic oxides, especially in strong anisotropic energy materials, such as NiFe2O4 or CoFe2O4. In this framework, we also provide the methods to manipulate magnon transport by applying gradient magnetic field and gradient T field.

**H71.00364: Two-dimensional magnetic monopole gas in an oxide heterostructure**

LUDI MIAO (Presenter), YONGHUN LEE, ANTONIO B MEI, MICHAEL J LAWLER, KYLE M SHEN, Cornell University — Magnetic monopoles have been proposed as emergent quasiparticles in magnetically frustrated pyrochlore spin ice compounds, such as R2Ti2O7 (RTO) (R = Ho, Dy). To date, all experimental investigations have been limited to the behaviour of large ensembles comprised of equal numbers of monopoles and antimonopoles in macroscopic bulk. Therefore, fundamental questions about the existence, properties, and dynamics of single, isolated monopoles, as well as the new phases of matter that these monopoles may form, remain unanswered or inaccessible. To address these issues, we propose the formation of a two-dimensional magnetic monopole gas (2DMG) with a net magnetic charge and whose monopole density can be controlled by an external field, at the interface between a spin ice and an isostructural antiferromagnetic (AFM) pyrochlore iridate (e.g. R2Ir2O7 (RIO)). Our proposal is based on a series of Monte Carlo simulations of the thermodynamic and transport properties, which also demonstrate the robustness of the 2DMG against long-range dipolar interactions. This proposed 2DMG should enable entirely new classes of experiments and devices which can be performed on magnetic monopoles, akin to two-dimensional electron gases in semiconductor heterostructures.
H71.00365: Magnetic Properties of MBE Grown La$_{1/3}$Y$_{1/3}$Sr$_{1/3}$MnO$_3$ thin films and Superlattices* THOMAS PEKAREK (Presenter), CAITLIN KENGLE, JAMES PAYNE, DAKOTA BROWN, MAITRI WARUSAWITHANA, Univ of North Florida — We have investigated the magnetic properties of thin films related to the standard CMR system La$_{2/3}$Sr$_{1/3}$MnO$_3$ where Y substituted for 50% of the La atoms. These La$_{1/3}$Y$_{1/3}$Sr$_{1/3}$MnO$_3$ films were grown as a random alloy where La, Y, and Sr atoms randomly occupied the A-site or as a superlattice where each unit-cell-thick layer stacked along the crystallographic (001) direction contained only one of the atoms La, Y, and Sr occupying the A-site. One key magnetic feature of La$_{2/3}$Sr$_{1/3}$MnO$_3$ is a prominent ferromagnetic transition near 350 K. We find the substitution of La with Y suppresses this ferromagnetic transition in both the random alloy and the superlattice samples. In the superlattice sample we find a magnetic transition that is coincident with a metal-to-insulator transition observed in electronic transport. In the random alloy sample, we see a similar magnetic transition but at lower temperatures, where we find the sample is too insulating to measure electronic transport. We will compare our measurements on these La$_{1/3}$Y$_{1/3}$Sr$_{1/3}$MnO$_3$ samples with CMR thin films of La$_{2/3}$Sr$_{1/3}$MnO$_3$.

*T.M.P. acknowledges support from the UNF Terry Presidential Professorship and the National Science Foundation Grant DMR-1626332. Some of the samples studied were grown at NSF funded PARADIM (DMR-1539918).

H71.00366: WITHDRAWN ABSTRACT —

H71.00367: Spin dynamics in a chain with three-spin interactions in a transverse magnetic field OSIEL BONFIM (Presenter), Physics, University of Portland, B BOECHAT, J. FLORENCIO, Physics, Fluminense Federal University — The quantum dynamics of a spin chain with three-spin interactions in the presence of a transverse magnetic field is investigated. We use both direct diagonalization and the method of recurrence relations to obtain the time-dependent correlation function and its corresponding frequency-dependent spectral density function. Although our calculations are done with chains up to 14 spins with periodic boundary conditions, the results are easily extended for infinite-size chains. We present the calculations for the behavior of these quantities as a function of the transverse magnetic field in the high-temperature limit.

H71.00368: Magnetic Properties and de Gennes Scaling of Quaternary Intermetallic Compounds WONCHOON LEE (Presenter), Physics, Sookmyung Women's Univ. — The interplay between antiferromagnetism and superconductivity has been studied for the quaternary intermetallic superconductor R$_{1-x}$R'$_x$Ni$_2$B$_2$C systems from the isothermal magnetization curves and temperature dependent magnetization measurements to determine the crystalline field effect such as low energy levels of singlet $\Gamma_4$ and excited $\Gamma_1$ and $\Gamma_5$ in theoretical group analysis of the energy scheme. In addition, by using the R$^{+3}$ ions Hund's rule, we have qualitative agreement between the de Gennes $T_N$ scaling behavior and crystalline electric effect scheme.
H71.00369: Reliable Electrical Switching of Tri-State Antiferromagnetic Néel Order in α-Fe₂O₃ Epitaxial Films* YANG CHENG (Presenter), SISHENG YU, MENGLIN ZHU, JINWOO HWANG, FENGYUAN YANG, Ohio State Univ - Columbus — Ability to manipulate antiferromagnetic (AF) moments is a key requirement for the emerging field of antiferromagnetic spintronics. Electrical switching of bi-state AF moments has been demonstrated in metallic AFs, CuMnAs and Mn₂Au. Recently, current-induced “saw-tooth” shaped Hall resistance was reported in Pt/NiO bilayers, while its mechanism is under debate. Here, we report the first demonstration of convincing, non-decaying, step-like electrical switching of tri-state Néel order in Pt/α-Fe₂O₃ bilayers. Our experimental data shows the switching behavior of α-Fe₂O₃ Néel order among three stable states, which can be detected by the change of Hall resistance $\Delta R_{xy}$ through spin Hall anomalous Hall effect (SH-AHE). We also show that the observed “saw-tooth” Hall resistance is due to an artifact of Pt, not AF switching, while the signature of AF switching is step-like Hall signals. Together with the Monte-Carlo simulations, we reveal the clear mechanism of AF Néel order switching and explain why only the first current pulse switches the Néel order. This demonstration of electrical control of magnetic moments in AF insulator (AFI) films will greatly expand the scope of AF spintronics by leveraging the large family of AFIs.

H71.00370: Large magnetic anisotropy in hexagonal Fe₂MnSn alloy* YUNG HUH (Presenter), BISHNU DAHAL, ABDULLAH AL MARUF, Physics, South Dakota State University, SAM PROPHET, PAVEL LUKASHEV, Physics, University of Northern Iowa, PARASHU R. KHAREL, Physics, South Dakota State University — We performed combined theoretical and experimental studies of electronic, magnetic, and structural properties of Fe₂MnSn Heusler alloy. The density functional theory (DFT) calculations of bulk and thin-film Fe₂MnSn Heusler alloys predict that this compound crystallizes in energetically close hexagonal D0₁₉ and cubic L₂₁ phases due to their very similar equilibrium energies, which agrees well with the experimental results. Both the cubic and hexagonal phases are ferromagnetic with high $T_c$ of 325 K and 475 K, respectively. The high-field magnetizations measured at 100 K are 3.3 $\mu_B$/f.u. and 4.3 $\mu_B$/f.u) for the cubic and hexagonal phases, respectively. These values are smaller than the predicted values (6.0 $\mu_B$/f.u. for the cubic and 6.5 for the hexagonal phases) by the DFT calculations. The hexagonal phase shows high value of magnetic anisotropy of 5.1 Merg/cm³ at 100 K. The cubic phase has an energy gap in the minority-spin conduction band that vanishes in the hexagonal phase.

H71.00371: Study of magnetization dynamics in magnetic insulators for magnonic applications*  
RODRIGO VICTOR (Presenter), LUIZ SAMPAIO, FLAVIO GARCIA, Centro Brasileiro de Pesquisas Físicas —  
Electronics devices are based on semiconductors transistors, and their improvement is mostly due to reducing its size, which is reaching its limit. To overcome this problem magnonics have appeared as an alternative solution for electronics, with advantages such as lower energy cost, faster information exchange and lower heating due to the absence of Joule effect. Magnetic insulators, more specifically $Y_3Fe_5O_{12}$ (YIG), appear as a promising material for this application because it has low Gilbert damping and low coercivity, among other properties. In this work, YIG thin films were reproducibly grown on $Gd_3Ga_5O_{12}$ with 111 oriented substrates by magnetron sputtering furthermore an ex situ annealing with oxygen flow was performed. A systematic study of the magnetic dynamics using ferromagnetic resonance was carried out to optimize the growth conditions of YIG, seeking the lowest value of Gilbert damping aiming towards magnonic applications. After the optimization, non-magnetic metallic materials (bismuth-doped copper, which produces a giant spin Hall effect and Pt) were deposited on YIG to evaluate the applicability for the spin current generated by spin pumping and spin Hall effect via inverse spin Hall effect.  

*The authors thank Brazilian agencies CNPq and CAPES for financial support.
Heusler material via femtosecond laser excitation  CHRISTIAN GENTRY (Presenter), PHOEBE M TENG DIN, ADAM Z BLON SKY, DMITRIY ZUSIN, MICHAEL GERRITY, Physics and JILA, CU Boulder, LUKAS HELLBRUCK, MOR ITZ HOF HERR, University of Kaiserslautern, JUSTIN SHAW, Quantum Electromagnetics Division, National Institute of Standards and Technology, YAROSLAV KVASHNIN, ERNA DELCZE G-CZIRJAK, Physics and Astronomy, University Uppsala, MONIKA ARORA, HANS NEM BACH, TOM SILVA, Quantum Electromagnetics Division, National Institute of Standards and Technology, BENJAMIN STADTMULLER, University of Kaiserslautern, STEFAN MATHI AS, Physikalisches Institut, Georg-August-Universitat Gottingen, MARTIN AESCHLIMANN, University of Kaiserslautern, HENRY KAPTEYN, Physics and JILA, CU Boulder, DANNY THONIG, Physics and Astronomy, University Uppsala, KONSTANTINOS KOUMPOURAS, Engineering Sciences and Mathematics, Lulea University, OLLE ERIKSSON, Physics and Astronomy, University Uppsala, MARGARET MURNANE, Physics and JILA, CU Boulder — Heusler compounds are exciting materials for future spintronics applications because they display a wide range of tunable electronic and magnetic interactions such as metallicty, superconductivity, and giant magnetoresistance. We use a femtosecond light pulse to directly transfer spin polarization from one element to another in a half-metallic Heusler material, Co$_2$MnGe. This spin transfer initiates as soon as light is incident on the material, showing that we can transfer angular momentum between neighboring atomic sites on timescales less than 10 fs. The observation is made possible by the ability of ultrafast high harmonic pulses to simultaneously and independently probe the magnetic state at two atomic sites, Co and Mn, during laser excitation. We find that the magnetization of Co is enhanced by the laser pulse, while that of Mn rapidly quenches. By comparing our measurements to density functional theory, we show that the optical excitation *directly* transfers spin from one magnetic sub-lattice to another, via preferred spin-polarized excitation pathways. The enhancement of ferromagnetic order demonstrates direct manipulation of spins via light, thus providing a path towards spintronic devices such as switches that can operate on few femtosecond or faster timescales.
H71.00373: Finding Structural Phase Transitions in Barlowite and Claringbullite
ALYSSA HENDERSON, LIANYANG DONG, Florida State University, SANANDA BISWAS, Institut für Theoretische Physik Goethe Universität Frankfurt am Main, HANNAH REVELL (Presenter), YAN XIN, National High Magnetic Field Laboratory, JOHN A SCHLUETER, Division of Material Research, National Science Foundation, ROSER VALENTI, Institut für Theoretische Physik Goethe Universität Frankfurt am Main, THEO SIEGRIST, National High Magnetic Field Laboratory — Barlowite (Cu₄(OH)₆FBr) and claringbullite (Cu₄(OH)₆FCl) are minerals related to the quantum spin liquid candidate herbertsmithite ZnCu₃(OH)₆Cl₂, the popular S = ½ antiferromagnet with a geometrically perfect kagome lattice. The kagome lattices of claringbullite and barlowite are stacked perfectly on top of one another, separated by planes consisting of Cu²⁺ and halide ions, and show promise as QSL candidates. Both materials have a hexagonal crystal structure with P6₃/mmc symmetry and undergo temperature-dependent phase transitions to Pnma symmetry. Previously we examined the barlowite transitions at 276 K, but the claringbullite transition occurs much lower. To pinpoint the transition, equipment had to be modeled and aligned.

H71.00374: Hanle effect in vertical Ohmic spin valves
YAROSLAW BAZALIY (Presenter), University of South Carolina — Hanle effect measurements in lateral spin valves provide valuable information on spin lifetimes and diffusion lengths in the transport channel. However, their interpretation is made difficult by the fact that current distribution near the injector substantially deviates from the assumptions of a simple 1D model. These difficulties can be partially alleviated by using the "three terminal" measurement method. A logical continuation of this line of thought is the usage of a “current perpendicular to plane” (vertical) F/N/F spin valve, where electric current distribution is strictly uniform. Additional advantage of the vertical valve is a better experimental control of the normal spacer thickness. The complication is the presence of two F/N interfaces, both contributing to the total voltage drop. Here we derive theoretical expressions for the valve magnetoresistance due to Hanle effect experienced by spins in the normal spacer. We assume diffusive regime, transparent boundaries with Ohmic conductivity, and allow for the back-action of spin accumulation in N on the injection process. Magnetoresistance is calculated for arbitrary angle between the magnetizations of the F-layers and any thickness of the N-spacer.
**H71.00375: Deterministic spin-orbit torque switching with a perpendicularly non-uniform magnet**  
SEYED ARMIN RAZAVI (Presenter), HAO WU, KANG-LUNG WANG, University of California, Los Angeles — Spin-orbit torque (SOT) switching of magnetization is a promising emerging technology for non-volatile memory and logic applications. However, deterministic switching of perpendicular magnetization with SOTs requires breaking of inversion-symmetry [1], usually provided by an external magnetic field, which is not suitable for practical applications. We experimentally realize deterministic SOT switching without any external magnetic fields by using a ferromagnet with non-uniform properties in the perpendicular direction (CoFe/CoFeB bilayer). In this structure, a heavy metal acts as the source of SOTs and all the layers have uniform thicknesses. We discuss the role of Dzyaloshinskii-Moriya interaction (DMI) as a possible cause of inversion-symmetry breaking. This method of symmetry breaking for SOT switching can be readily employed in current industrial processes and can pave the way for the practical application of SOT-based technology.

**H71.00376: Effect of interfacial intermixing on spin-orbit torque in Co/Pt bilayers**

GIOVANNI BAEZ FLORES (Presenter), KIRILL BELASHCHENKO, University of Nebraska - Lincoln — Using the first-principles non-equilibrium Green’s function technique [1] with supercell disorder averaging, we study the influence of interfacial intermixing on the spin-orbit torque in Co/Pt (111) bilayers. The interlayer distances are optimized, several models of intermixing are considered, and atomic potentials in the intermixed layers are obtained using the coherent potential approximation. The magnitude and thickness dependence of the damping-like torque are similar to earlier results for the Co/Pt (001) interface [1,2] and rather insensitive to intermixing. In contrast, the field-like torque, which is small in the case of an ideal interface, is dramatically enhanced by intermixing.

*This work was supported by NSF DMR-1609776.
H71.00377: Giant magnetoelectric effect in Pt/Co/Ta ultrathin films with perpendicular magnetic anisotropy on Pb(Mg$_{1/3}$Nb$_{2/3}$)$_{0.7}$Ti$_{0.3}$O$_3$ ferroelectric substrate  

AITIAN CHEN (Presenter), King Abdullah Univ of Sci & Tech (KAUST), HAOLIANG HUANG, University of Science and Technology of China, YAN WEN, SENFU ZHANG, JÜRGEN KOSEL, King Abdullah Univ of Sci & Tech (KAUST), YALIN LU, University of Science and Technology of China, XIXIANG ZHANG, King Abdullah Univ of Sci & Tech (KAUST) — Perpendicular magnetic anisotropy (PMA) is important for increasing the information storage density in the perpendicular magnetic recording media, and electric-field control of PMA is drawing much attraction due to its potential to lower energy consumption. Multiferroic heterostructures, hybrid ferromagnetic and ferroelectric, enable electric-field control of magnetism via strain-mediated magnetoelectric coupling, though most studies have focused on how to control ferromagnetic films with in-plane magnetization. Here, we deposited Pt/Co/Ta ultrathin films with PMA on PMN-PT ferroelectric substrate and investigate the effect of electric-field-induced piezostrain on its PMA. Through measuring anomalous Hall effect (AHE) under in situ electric fields, we observed a remarkable modulation of AHE curves by electric fields and achieved a giant converse magnetoelectric coefficient (approximately $-2.1 \times 10^{-6}$ s m$^{-1}$), which is comparable with the largest value in the multiferroic heterostructures with in-plane magnetization. Furthermore, the in situ polar Kerr image measurements with electric fields confirmed this giant magnetoelectric effect in PMN-PT/Pt/Co/Ta multiferroic heterostructure. These results pave a way to realize future energy-efficient PMA magnetoelectric and spintronic devices.

H71.00378: Magnetic field noise caused by surface paramagnetic impurities on nitrogen vacancy center diamonds*  

PHILIP CHROSTOSKI, Physics and Astronomy, University of Missouri - St. Louis, DEBORAH SANTAMORE (Presenter), Delaware State Univ — Noise is a detrimental issue for nitrogen vacancy (NV) center diamond sensing devices. The magnetic field noise is caused by both surface and bulk impurities. Here, we study the noise due to the interactions between the NV center electron spin and the surface impurity electron spins that are dissolved in a thin water layer on hydrogen (H-), oxygen (O-), or fluorine (F-) terminated surfaces. We apply the Langevin method to spin fluctuation theory to calculate and analyze the surface noise spectral density. Impurity hopping among the available sites determines the impurity relaxation time that controls the contribution of the noise either from the spin flip-flops noise only or additional spin precession noise. Our results show that O-terminated surface give a much lower surface noise than H- and F-terminated surfaces. This is because only spin flip-flop noise are present for O-terminated surface due to oxygen's picosecond electron spin-lattice relaxation time while both spin flip-flop noise and spin precession noise are present for H- and F-terminated surfaces. Comparing to the previous work on bulk impurity noise, we find that the surface impurities are indeed a greater source of magnetic field noise than the bulk impurities.

*This work is supported by NSF DMR-No.1505641.
H71.00379: Room temperature gate tunable spin-to-charge conversion in LaCrO₃/SrTiO₃ heterostructures

SHIJIA YANG (Presenter), North Carolina State University — The emergence of novel spintronics studies focuses on the generation, transmission, and control of a pure spin current through spin-orbit effects. The emergence of novel electronic and magnetic phenomena at the interfaces between polar and non-polar crystalline transition metal complex oxides such as high mobility two-dimensional electron gases (2DEG) provides an ideal platform for the design of spin-to-charge (StC) convertors. At these interfaces, an interface-driven spin-orbit coupling mechanism - the Rashba effect - shows great promise due to its unprecedented StC interconversion efficiency, called inverse Rashba-Edelstein effect (IREE). We report a new type of 2DEG formed at the interface between antiferromagnetic LaCrO₃ and insulating SrTiO₃ heterostructure with StC conversion efficiency. The measured IREE length is up to 0.3 nm which can be modulated by a gate voltage. The frequency and field orientation dependence of IREE response are both consistent with the spin pumping model, from which the spin relaxation time (~30ps) is derived. Our findings launch a new class of oxide-based 2DEGs for future spin orbitronic applications.

*Device preparation was partially supported by ECCS-1933297 and NC State-Nagoya Collaboration Grant. Sample growth was supported by NSF DMR-1751455.

H71.00380: Data-driven study of magnetic interactions of transition-metal based 2D materials

AYANA GHOSH (Presenter), Univ of Connecticut - Storrs, SHIZENG LIN, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — Engineering magnetic interactions are critical to control magnetic behavior for device applications. Depending on the presence or absence of inversion symmetries, the magnetic interactions stabilize several exciting magnetic behaviors such as formation of chiral helimagnets, skyrmions, and even quantum spin liquid. Various exchange interactions and magnetic anisotropy within crystal lattices can be estimated using DFT-based simulations approaches, based on which an effective spin only Hamiltonian can be constructed. This multi-scale modeling allows one to predict magnetic properties for real materials. Here, we propose to use a data-driven approach to screen for suitable candidates exhibiting magnetic skyrmions, followed by evaluating their exchange interactions in transition-metal based 2D magnetic materials. This curated dataset of 2D magnetic materials and computed magnetic interactions can then be used to develop a combined protocol to search for similar compounds in a variety of materials space followed by constructing predictive machine learning models to understand magnetic behavior of such systems.

*This work was carried out under the auspices of the U.S. DOE NNSA under Contract No. 89233218CNA000001, and was supported by the LANL LDRD Program.
H71.00381: Study of Tunneling Magnetoresistance (TMR) in Twisted CrBr$_3$ Bilayers

ZHUANGEN FU (Presenter), PIUMI SAMARAWICKRAMA, JIFA TIAN, Univ of Wyoming — The recent discovery of two-dimensional (2D) magnetic materials (such as CrI$_3$ and Cr$_2$Ge$_2$Te$_6$) has opened new opportunities for novel electronics and spintronics [1][2]. By controlling the stacking angle between two monolayers, the twisted 2D bilayers have shown novel quantum states, such as unconventional superconductivity and ferromagnetism [3][4]. However, whether the magnetic ground states of twisted 2D magnetic bilayers can be tuned by the twisting angle is still an open question. In this work, we fabricated $h$-BN/Graphene/twisted CrBr$_3$ bilayer/Graphene/$h$-BN devices using a dry-transfer technique with the twisting angle well controlled. The tunneling magnetoresistances of the twisted CrBr$_3$ devices with different twisting angles will be measured at different temperatures and magnetic fields. We are aiming to establish a phase diagram of the magnetic ground states in the twisted CrBr$_3$ bilayers as a function of the twisting angle. Our study may pave a new way for manipulating magnetic orders in 2D magnetic materials and offer new opportunities in designing 2D material-based spin devices.

H71.00382: First-principles calculations for high-temperature ferromagnetic semiconductor (In,Fe)Sb

HIKARI SHINYA (Presenter), Tohoku University, TETSUYA FUKUSHIMA, The University of Tokyo, AKIRA MASAGO, KAZUNORI SATO, Osaka University, HIROSHI KATAYAMA-YOSHIDA, The University of Tokyo — Fe-doped semiconductors have been attracting much attention due to fascinating properties. In fact, Fe-doped InSb not only exhibits the high Curie temperature but can also be $n$-type doping [1]. Our previous calculations reveal that, (In,Fe)Sb has complex magnetic properties [2]. In the isoelectronic (In,Fe)Sb case, the Fe atoms show strong antiferromagnetic interactions due to the superexchange mechanism. We have demonstrated that by modulating the chemical potentials corresponding to $n$- or $p$-type doping, the magnetic property can be changed drastically from antiferromagnetism to ferromagnetism. This transition can be well understood in terms of the Alexander-Anderson-Moriya mechanism. However, we have obtained high Curie temperature in only $p$-type (In,Fe)Sb case. We suspect that there are the other ferromagnetic mechanisms in addition to the magnetic transition and spinodal nano-decomposition in (In,Fe)Sb. In this study, we have clarified the origin of high Curie temperature by the density functional theory calculations.

H71.00383: All-electron calculations of crystalline and amorphous phases in magnetic phase change materials by KKR Green's function method  
TETSUYA FUKUSHIMA (Presenter), The University of Tokyo, KAZUNORI SATO, Osaka University, HIROSHI KATAYAMA-YOSHIDA, The University of Tokyo, RUDOLF ZELLER, PETER DEDERICHS, Forschungszentrum Juelich — We perform large-scale density functional theory (DFT) calculations for crystalline and amorphous phases in magnetic phase change materials by all-electron full-potential screened Korringa-Kohn-Rostoker (KKR) Green's function method. Here, we choose transition metals doped Ge\textsubscript{2}Sb\textsubscript{2}Te\textsubscript{5} (GST) systems as the typical cases. We consider large unit cells containing 1000 sites for the crystalline phase and 1365 sites for the amorphous phase to model the configurational and structural disorders in the magnetic phase change materials. Such large-scale DFT calculations are performed using the program KKRnano, where a massively parallel linear scaling all-electron algorithm is implemented. We investigate the electronic structures and distance dependent magnetic exchange coupling constants in the crystalline and amorphous phases. It is found, in the crystalline phase, that ferromagnetic states are favorable in the cases of V and Cr doping, due to the double exchange mechanism, whereas antiferromagnetic superexchange interactions appear to be dominant for Fe- and Mn-doped GST. In particular, the Cr doped GST shows strong ferromagnetic interaction and high Curie temperature for both the crystalline and amorphous phases.

H71.00384: Interfacial Spin Conductance Behavior in Topologically Non-trivial Heterostructures*  
STEPHEN HOFER (Presenter), Physics, Southern Illinois University Carbondale, TRINANJAN DATTA, Chemistry and Physics, Augusta University, DIPANJAN MAZUMDAR, Physics, Southern Illinois University Carbondale — Spintronics is a paradigm that utilizes spin angular momentum as the fundamental logical bit for computing. Spin current is the means by which these bits can be altered to read and write digital information. Toward this end, topological magnon excitation offers a potentially alternative avenue to produce highly efficient topologically mediated spin currents in a device. Topological magnon excitations are hosted in 2D honeycomb topological magnon insulators (TMI) such as CrI\textsubscript{3}. We investigate the behavior of interfacial spin conductance at the boundary of TMIs, normal metals, and topologically trivial ferro- and anti-ferromagnets. The ensuing transport implications of the underlying topological heterostructure is discussed within the context of thermally driven spin conductivity.

*NSF CAREER grant (ECCS: Award#1846829).

H71.00385: WITHDRAWN ABSTRACT
H71.00386: Growth and characterization of magnetic van der Waals films  ALEXANDER BISHOP (Presenter), TIANCONG ZHU, DANTE J O’HARA, JAY A GUPTA, ROLAND KAWAKAMI, Ohio State Univ - Columbus — In the recent past, magnetic, two-dimensional (2D), van der Waals (vdW) systems have become an exciting class of materials to study. On their own, these materials can give insights to low-dimensional spin behavior, but they also have the potential to be integrated into vdW heterostructures. Both areas are rich in scientific novelty and potential spintronics applications. Here we present the synthesis and characterization of 2D vdW magnets 1T-MnSe$_2$ and MnBi$_2$Se$_4$. The materials were grown by molecular beam epitaxy (MBE) and studied with various techniques including X-ray diffraction (XRD), spin-polarized scanning tunneling microscopy (SPSTM), and superconducting quantum interference device (SQUID). The XRD measurements show that highly crystalline MnBi$_2$Se$_4$ films can be grown consistently and SQUID measurements indicate a layered antiferromagnetic structure. This material also exhibits ferromagnetism in the monolayer limit with a Curie temperature near 10K. Monolayer 1T-MnSe$_2$ exhibits room-temperature ferromagnetism when analyzed with SQUID measurements. The magnetic signal from this material was also directly observed using SPSTM with a chromium tip.

H71.00387: Magnetic phase transition of monolayer RuCl$_3$ induced by optical and electrostatic unipolar doping*  WEIWEI GAO (Presenter), University of Texas at Austin, YINGZHEN TIAN, ERIK HENRIKSEN, Washington University in St. Louis, JAMES CHELIKOWSKY, University of Texas at Austin, LI YANG, Washington University in St. Louis — RuCl$_3$ is a layered material showing signatures of a quantum spin liquid and strong magnetic frustration. Based on first-principles calculations, we predict that electrostatic doping with either electrons or holes and optical doping can both cause a phase transition of free-standing monolayer RuCl$_3$ from the spin-liquid phase to stable ferromagnetic ordering with a moderate carrier/e-h density, achievable with current experimental techniques. Increasing the electron-hole pair density by optical doping can further enhance ferromagnetism and also increases the Curie temperature significantly. The mechanisms for driving the magnetic phase transition of monolayer RuCl$_3$ are discussed based on orbital magnetism and itinerant magnetism. Our prediction of optically driving 2D ferromagnetism offers the possibility of non-contact tunability for exploring new physics and spintronic applications.

**H71.00388: Probing Chirality Induced Spin Selectivity in Chiral 2D Hybrid Perovskites Using Spin Hall Magnetoresistance**

ERIC VETTER (Presenter), Physics, North Carolina State University, YAN LIANG, Department of Chemistry, University of North Carolina at Chapel Hill, YUZAN XIONG, Department of Physics, Oakland University, SHULEI ZHANG, ZHIZHI ZHANG, Materials Science Division, Argonne National Laboratory, YI LI, Department of Physics, Oakland University, HONGWEI QU, Department of Electronic and Computer Engineering, Oakland University, VALENTYN NOVOSAD, AXEL HOFFMANN, Materials Science Division, Argonne National Laboratory, WEI YOU, Department of Chemistry, University of North Carolina at Chapel Hill, WEI ZHANG, Department of Physics, Oakland University, DALI SUN, Physics, North Carolina State University — The emergence of the Chirality Induced Spin Selectivity (CISS) effect, where electron transport through chiral materials is spin filtered, offers many new and exciting opportunities for the field of spintronics. However, many questions surrounding the exact nature of this physical phenomenon still remain. Here, we employ spin Hall magnetoresistance (SHMR) measurements and use pure spin currents for probing the effective magnetic fields native to the chiral two-dimensional hybrid perovskites as predicted by the CISS effect. Chiral 2D perovskites are spin coated on top of Pt Hall bars on a Si/SiO$_2$ substrate and the Pt resistance is measured using lock-in detection to separate the first and second harmonic dependencies as a function of magnetic field, field angle, and temperature. We find significant SHMR signals despite the lack of any ferromagnetic material, as well as exotic hysteretic behaviors that we attribute to a CISS-induced SHMR. This work helps to elucidate the mechanism of CISS and paves the way for the use of chiral hybrid perovskites for novel spintronic devices.

**H71.00389: First-principles evaluation of four-fold symmetric component of anisotropic magnetoresistance in 3d transition metal alloys**

YOHEI KOTA (Presenter), National Institute of Technology, Fukushima College — Anisotropic magnetoresistance (AMR) is a conventional magnetotransport phenomenon, and its origin is understood based on the Campbell-Fert-Jaoul model. Recent experimental studies of AMR reported that the four-fold symmetric component of the electrical resistivity is not so small compared to the two-fold symmetric component in several material films. Theoretically, Kokado and Tsunoda proposed that the four-fold symmetric component of AMR is attributed to the degradation of the crystalline symmetry due to tetragonal distortion [1], whereas Yahagi, Miura, and Sakuma proposed that the four-fold symmetric component arises from the higher order contribution of spin-orbit interaction [2]. The both proposed mechanisms are possible, however, it is unclear which mechanism is more important to generate the four-fold symmetric component of AMR in a realistic material system. In this study, we simulate the magnetization angle dependence of the electrical resistivity in ferromagnets using first-principles calculations. We present the comparison of the two- and four-fold symmetric component of AMR in cubic and tetragonally distorted crystals.

H71.00390: Strain effects on the magnetotransport properties of transition metals*
RAFAEL GONZALEZ-HERNANDEZ (Presenter), JORGE AMELL, ALVARO GONZALEZ-GARCIA, WILLIAM LOPEZ-PEREZ, Departament of Physics, Universidad del Norte, Colombia., JAIRO SINOVA, Department of Physics, Johannes Gutenberg-Universität Mainz — The Anomalous Hall Effect (AHE) is a phenomenon which consists of an extra anomalous transverse voltage developing when current is passed through ferromagnetic material in a magnetic field. In this work, we studied the dependence of strain and magnetization effect on the intrinsic anomalous Hall conductivity (AHC) in 3d metal Fe-bcc, Co-fcc, Co-hcp, and FeCo structure. For the Fe-bcc case, the AHC shows a slightly decreasing with the increase of pressure, being this associate to the magnetization dependence with the lattice constant. However, the AHC for lattices constants above 2.95Å shows a downturn around 70%, even when the magnetization has increased. This decreasing seems to be related to a transition of d-states occupations above this lattice constant. The computation of the anomalous Hall conductivity was carried out using ab-initio calculations (included the effect of spin-orbit interaction for the ferromagnetic state) and the Wannier interpolation technique for the application of the Kubo-Greenwood formula.

*The authors gratefully acknowledge the computing time granted on the supercomputer Mogon at Johannes Gutenberg University Mainz (hpc.uni-mainz.de) and the support of the Alexander Von Humboldt Foundation.

H71.00391: Topological magnons in the checkerboard lattice*  ANTONIO PIRES (Presenter), Univ Fed de Minas Gerais — In analogy with topological insulators in electronic systems, one has the topological magnon insulators which are characterized by the existence of edge states modes in the presence of a gap. In these systems one has a transverse heat current mediated by magnons in response to thermal gradient, or a transverse spin current in response to a magnetic field gradient. Here we study topological magnon effects in a generalized ferromagnetic checkerboard lattice, also known as planar pyrochlore, with Dzyaloshinskii-Moryia interaction (DMI). The DMI breaks the inverse symmetry of the lattice, generates a magnetic flux and leads to non zero Chern numbers. We calculate the Berry curvature, the spin Hall conductivity, the spin Nerst coefficient and the Hall thermal conductivity as a function of temperature. We also analyze the effect of an applied magnetic fiels. Our study complements work done in the honeycomb, kagome, Lieb and pyrochlore lattices.

**H71.00392: Hopfion Dynamics in Chiral Magnets**  
ZULFIDIN KHODZHAEV (Presenter), EMRAH TURGUT, Oklahoma State University-Stillwater — Resonant spin dynamics of topological spin textures are hugely correlated with their topological nature and can be employed to understand nature, which attracts interest in condensed matter physics and memory and storage technology [1]. Among topological spin textures, skyrmions and vortices have been heavily studied, but hopfions have been paid little attention thus far. In this study, we present a numerical resonant study of spin dynamics of a three-dimensional topological spin texture hopfion in a B20 chiral magnet. Recent studies proposed to use interfaces with strong perpendicular magnetic anisotropy adjacent to a B20 FeGe nanodisk to stabilize hopfions [2]. In our study, using micromagnetic simulations, we first identified the ground state spin configurations of a hopfion, effects of anisotropies, geometric confinements and demagnetizing fields. Then, we calculated the resonance frequencies and spin-wave modes of spin precession dynamics. Our work helps to guide experimental studies to identify 3-dimensional topological spin texture of hopfions in chiral magnets in a functioning device, where imaging is not possible.

**H71.00393: Transportation of Topological Spin Textures at Material Boundaries**  
JEFFREY MICHEL (Presenter), Department of Physics and Astronomy, Stony Brook University, EMRAH TURGUT, Department of Physics, Oklahoma State University — We examine the dynamics of topological spin textures, magnetic skyrmions and skyrmionium, at the boundaries where material properties vary. Using skyrmions or skyrmionium as information storage, e.g. race track memory, requires a basis of knowledge on how these topological spin structures react to changes in material parameters. Using micromagnetic simulations, we investigated the dependence of radius and Hall angle due to: exchange stiffness, magnetic saturation, Dzyaloshinskii-Moriya Interaction, damping constant, anisotropy, and non-adiabaticity of spin transfer torque. There is also a comparison made between the feasibility of skyrmionium as an alternative to skyrmions as a method of storing and transportation information.

**H71.00394: Helimagnetism and Soliton Lattice in a Chiral Magnet**  
CHENHUI ZHANG (Presenter), JUNWEI ZHANG, PENG LI, YE YUAN, SENFU ZHANG, YAN WEN, DONGXING ZHENG, XIXIANG ZHANG, King Abdullah Univ of Sci & Tech (KAUST) — Herein, we report the observation of helimagnetism and soliton lattice in a chiral magnet. Below the Curie temperature, the in-plane field-dependent magnetization shows an abrupt increase as well as a narrow hysteresis just before saturation, which indicates a metamagnetic transition from soliton lattice to ferromagnetic state. Using Lorenz microscopy, we observed sinusoidal magnetic patterns in real space below the Curie temperature. In thin film samples, we also observed abrupt and hysteretic magnetoresistance jumps when sweeping the magnetic field.
H71.00395: A nonintrusive reduced order modelling of magnetic skyrmions  
MUHAMMET ANNAORAZOV (Presenter), SHADY AHMED, OMER SAN, EMRAH TURGUT, Oklahoma State University—Stillwater — We show that a nonintrusive reduced order modeling framework can predict the magnetic field dependent internal structures of magnetic skyrmions[1] and their density in thin films. After we train the framework using results of micromagnetic simulations, in which we vary the anisotropy, asymmetric exchange energy, and the external magnetic field, we were able to predict the ground state spin configurations for given anisotropy, asymmetric exchange energy, and external magnetic field. Besides, we implement PC[2] (principal component) manifold to interpolate multidimensional data more accurately compared to other methods. We then confirm these spin configurations by calculating micromagnetically[3] and found XX percent accuracy and XX orders of magnitude reduction in the simulation time. Our data-driven approach accelerates identifying the spin texture by eliminating the need of re-calculation of micromagnetic simulations for every material parameter in a functioning device.

H71.00396: Observation of skyrmion-like magnetism in multiferroic BiMnO3* 
ZONG-HENG YANG (Presenter), HUNG-CHENG WU, TING-WEI KUO, D. CHANDRA SEKHAR KAKARLA, Department of Physics, National Sun Yat-sen University, Kaohsiung 804, Taiwan, LIANGZI DENG, CHING (PAUL) W CHU, Texas Center for Superconductivity, University of Houston, Texas, 77204, USA, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, Kaohsiung 804, Taiwan — Polycrystalline sample BiMnO3 was synthesized at high-pressure and temperature and characterized by X-ray diffraction. In our previous reports [1, 2], the multiple magnetic anomalous transitions have been investigated under a hydrostatic pressure up to 11.9 kbar, where the interesting magnetic H-T phase diagrams were also established. In this study, we revisit the pressure effect on the magnetic properties in BiMnO3, particularly in low magnetic field region. Interestingly, a pressure induced skyrmion-like A phase was observed in low magnetic field. The striking and unexpected observation of skyrmion-like phase in BiMnO3 will be discussed.

Transport in a Spintronic Device Using a Magnetic Skyrmion Lattice

DAVID KING (Presenter), JINKE TANG, Physics and Astronomy, University of Wyoming, JOHN ACKERMAN, Chemical Engineering, University of Wyoming — Magnetic skyrmions are a topologically protected state in certain magnetic systems. Their topological properties make skyrmions stable and thus a possible basis for memory or energy storage spintronic devices. We present results for a transport device that uses a skyrmion lattice in the magnetic insulator Cu$_2$OSeO$_3$ as a precursor to an energy storage device. Data from the transport device and its fabrication are presented. The transport data are then used to test the underlying elasticity theory for the skyrmion lattice.

Effect of viscosity on propagation of MHD waves in astrophysical plasma

ALEMAYEHU CHERKOS (Presenter), Addis Ababa Univ — We determine the general dispersion relation for the propagation of magnetohydrodynamic (MHD) waves in an astrophysical plasma by considering the effect of viscosity with an anisotropic pressure tensor. Basic MHD equations have been derived and linearized by the method of perturbation to develop the general form of the dispersion relation equation. Our result indicates that an astrophysical plasma with an anisotropic pressure tensor is stable in the presence of viscosity and a strong magnetic field at considerable wavelength.

Unification of Gravity and Electromagnetism

MOHAMMED EL-LAKANY (Presenter), Physics, Faculty of Science, Cairo University — Gravity and electromagnetism are two sides of the same coin, which is the clue of this unification. Gravity and electromagnetism are represented by two mathematical structures, symmetric and antisymmetric respectively. Einstein gravitational field equation is the symmetric mathematical structure. Electrodynamics Lagrangian is three parts, for electromagnetic field, Dirac field and interaction term. The definition of canonical energy momentum tensor was used for each term in Electrodynamics Lagrangian to construct the antisymmetric mathematical structure; symmetric and antisymmetric gravitational field equations are two sides of the same Lagrangian.
H71.00401: Adding a Dynamic to Gravitation Reveals How Extra Gravity Halos are Projected from Galactic Cores*  JOHN HUENEFELD (Presenter), APS — It is unfortunate that the term *dark matter was used* to describe the extra gravity observed in galaxy clusters. The name presupposes a material answer, but the only thing *actually* observed is an Extra Gravity Halo (EGH). The mysterious source of this extra gravity remains unresolved. Or does it?

A new theory, sets GR in motion, predicting an ongoing space-time contraction within a gravitational field. Unlike Hubble expansion, this contraction field is non linear with distance from the source and projects more strongly with the increasing amount of concentrated matter generating the field. No assumed additional mass is needed to boost the orbital velocity of stars around a galactic core. The contraction field augments the acceleration of gravity to achieve galaxy rotation curves consistent with observation.

Dark matter is not a particle. EGHs are the result of relativity, and are an integral part of gravitation. The contraction field acts to scale up gravity. The scale factor, which falls easily from the math, has exactly the right mathematical shape to replicate assumed dark matter distributions. Not only do these contraction fields explain galaxy rotation curves, they also explain the Bullet Cluster, and Ultra Diffuse galaxies which have either a very strong EGH or none at all.

H71.00402: Excess Surface Energy and Attraction of Matter: A New Vision to explain the Origin of Gravitation  PRITAM MANDAL (Presenter), Durgapur Women's College — This talk presents a model based on minimization of excess surface energy to better explain the origin of gravitation, which is more intuitive and coherent with other fundamental principles of the working of the physical world. Here’s a picture to imagine: If a big ball of liquid (say water or mercury) is broken into many pieces, and kept on a frictionless plane in vacuum (say in an enclosed glass-jar), the smaller balls would tend to merge back into a single ball (initial state). An observer watching the phenomena from outside the glass-jar would explain the phenomena in terms of some mysterious force (e.g. gravitation), but the merging of the smaller balls in this ideal experimental set-up is merely an outcome of the tendency of the universe to minimize free energy. Surface tension explains this phenomenon satisfactorily. For same reason, metallic surfaces touching in the vacuum can stick to each other and fuse, known as the cold welding. This model has the potential to lead us to the grand unification of the fundamental laws of nature. In our model, the concept of space-time curvature is replaced by the curved meniscus of “fluid” energy-field around a mass.

We strongly suggest designing a suitable experimental set-up to test the validity of the model.
H71.00403: Statistical Analysis of Low States in VY Scl Stars  KYLEE FORD (Presenter), FREDERICK A RINGWALD, California State University, Fresno — The first detailed statistics of the light curves of a class of cataclysmic variable binary star systems, known as the VY Sculptoris stars, was compiled. These light curves are time-series observations of these stars’ apparent magnitudes in visible light. These observations were made by the American Association of Variable Star Observers and were made available publicly on a server funded by the National Science Foundation. In every star in this sample, the presence of low states that define the VY Scl stars was confirmed. The VY Scl stars typically spend most of their time in a high state, and irregularly drop by between 0.4 and 7.6 magnitudes into low states. We have compiled tables of the depths and durations of the low states of each system. We discuss these statistics in the context of the explanation that the low states may be caused by concentrations of magnetism on the secondary star, namely starspots.

H71.00404: Sea water intrusion in coastal aquifers and sustainable solution to control the intrusion  LIBIA HAZRA (Presenter), N. SRINIVAS, CH. RAMAKRISHNA, Gandhi Institute of Technology and Management — Groundwater in coastal regions is often prone to degradation in quality due to sea water intrusion. Sea level rise, coastal geomorphology, the amplitude and frequency of water waves, the depth of water near the coast, changing precipitation regimes and changing groundwater recharge rates may all influence the incidence of saltwater intrusion. A systematic study has been carried out to evaluate salt water intrusion in the coastal aquifers of Visakhapatnam city, Andhra Pradesh, India. The study areas are alongside of the sea (Bay of Bengal) shore. Water samples from bore wells were analyzed to determine the physico-chemical parameters of groundwater. Presence of bromide in all samples and Cl/Br ratio confirms the seawater intrusion near seashore samples. This condition is attributed to anthropogenic activities of the respective area and also the influence of climate conditions over Bay of Bengal. We seek sustainable solution to control the intrusion and implement protective measures such as conservation of ground water resources along with coastal management practices i.e. green belt development and strengthening of bunds along the coastal areas.
We will report results for single crystals of Sm$_6$T$_4$Al$_{43}$ (T=Mo,W) that were synthesized using a molten Al flux. Powder X-Ray diffraction measurements show that both compounds crystallize in the hexagonal Ho$_6$Mo$_4$Al$_{43}$ structure with lattice constants near $a = 10.97$ Å and $c = 17.67$ Å, as reported previously [1]. As for other compounds in this structure, the electrical transport data exhibit a weak temperature dependence due to significant disorder scattering, likely associated with atomic site interchange. The temperature dependent magnetic susceptibility and heat capacity further show that ferromagnetic ordering emerges from a weakly paramagnetic state near $T_C = 15$ and 16 for the Mo and W variants, respectively. We will discuss these results in the context of other Sm-based intermetallics, where the $f$-state and the associated magnetism is strongly influenced by van Vleck physics.

H71.00406: Au nanoparticle’s plasmonic nearfield induced photoluminescence enhancement of fluorophores  HASNA ALALI (Presenter), Western Michigan Univ — Gold nanoparticles in fused quartz substrates were synthesized with ion implantation using the Western Michigan University's particle accelerator lab. Localized Surface Plasmon Resonance with respect to ion fluence ($1 \times 10^{16}$ to $9 \times 10^{16}$ atoms/ cm$^2$) at fixed ion beam energy (70 keV) was studied. Rutherford Backscattering Spectrometry and UV/Vis techniques were used to quantify Au concentration and detect the formed nanoparticles respectively within the substrate. The investigation of enhanced electric fields of embedded nanoparticles with incident electromagnetic wave were used to amplify the photoluminescence intensity of dye and various perovskites nanocomposites. Steady state time resolved photoluminescence spectroscopy were used to investigate the emission enhancement and the energy transfer between the fluorophore and the metal nanoparticle. It was observed that the photoluminescence enhancement of perovskites in the vicinity of Au nanoparticles had a direct relationship with the ion implanted fluence. The photoluminescence intensity was quenched for C515 dye indicating the energy transfer from molecule to the Au nanoparticle. The photoluminescence enhancement was obtained for the lead halide perovskites and the maximum relative enhancement of $\sim 29$ times was obtained in CsPbI$_3$. 
H71.00407: Discovery of Faraday's law of self-induction*  JUNHO JEONG (Presenter), Dong-A University — Maxwell mathematically proved electromagnetic wave emission via his wave equations, and Hertz proved it experimentally. However, Hertz experimented on Henry's self-induction instead of mutual-induction. An oscillating electric dipole p(t) = Q(t)r with charge Q(t) emits electric dipole radiation because of the external energy, and Faraday's law shows the relationship between the two charges. Here, we have first discovered the existence of a new Faraday's law of self-induction, which only requires charge Q(t) and that an electromagnetic wave is a method of emitting the received external energy for Q(t) to return to the stable state according to Lenz's law. Second, when the inapplicability of relativistic electromagnetism to the Lorentz force was analysed based on the above facts, we additionally discovered that observers in different inertial systems could physically distinguish charges generating electric fields from those generating magnetic fields because the physical phenomena between the perspectives of mass and charge differ.

*I wish to thank SBN Science Ltd. for supporting funding.

H71.00408: Advances and possibilities of the Materials Innovation Platform with examples from Spin-ARPES  DANIEL BEATON (Presenter), M. LUNDWALL, T. WEILL, ScientaOmicron, Inc — The quest for device applications based on quantum materials, such as topological insulators or superconductors, requires strict control of the environments these materials are exposed to during production and while under investigation. It is therefore most straightforward to gather all parts of the experiment, from sample growth to analysis, in one connected UHV system - creating a so-called Materials Innovation Platform (MIP). This approach has proven to be extraordinarily valuable in recent years.

In this presentation, I will focus on a combination of MBE/ARPES, and also coupled spin detection. The advantages of this set-up will be explored, as well as highlighting some of the very recent electronic band structure research performed with such a system. Two specific examples will be reviewed: Yang et al.[1] investigation of the impact of photogenerated carriers on the superconducting transition temperature; and advances high efficiency spin-ARPES. The work by Yang et al. was enabled by the in-situ growth and analysis possibility and clearly demonstrates the possibility of making energy-efficient quantum optoelectronics devices. Future possibilities of Spin-ARPES and laser-ARPES in combination with MIP set-up will also be discussed.

**H71.00409: Probing Dark Matter Halos with Ultra-Faint Dwarf Galaxies: A Spectroscopic Analysis of Leo V**

SYDNEY JENKINS (Presenter), University of Chicago, TING LI, Carnegie Observatories, JOSHUA A FRIEMAN, University of Chicago — The nature of dark matter presents one of the most significant problems in astrophysics. Ultra-faint dwarf (UFD) galaxies may play a key role in solving this mystery, as they are the most dark-matter dominated systems known and they allow us to probe dark matter halos down to the scale of tens of parsecs. However, many UFDs have few known member stars, making it difficult to provide robust measurements of the galaxies’ key features. We are currently locating new members and providing refined, consistent measurements of physical parameters for 15 UFDs using publicly archived spectroscopic data from the Very Large Telescope. We present a representative analysis of Leo V, a UFD with twelve known non-variable member stars. We identify three new likely members in addition to five new plausible members that require further follow-up, and perform a comparative analysis of seven previously discovered members. Using our catalogue of member stars, we perform a search for binary stars within the galaxy and investigate the possibility that Leo V is tidally disrupted. Our analysis of Leo V and other UFDs will enhance our understanding of these enigmatic stellar populations and contribute to future dark matter studies.

**H71.00410: Casimir Energy For Perfect Electric Conductors Using the A-Phi Formulation**

CARLOS SALAZAR-LAZARO (Presenter), University of Illinois at Urbana-Champaign — Previous work by Reid, et.al. [1] calculated the Casimir energy for conducting geometries using the method of moments applied to the impedance matrix given by Electric Field Integral Equation (EFIE). His results were later extended by Atkins [2] by making use of the Argument Principle applied to the EFIE and transforming the calculation of the Casimir energy to one that used the Augmented EFIE (AEFIE) as its impedance matrix. We will use the same approach as Atkins but instead of using the AEFIE, we will propose using the A-Phi [3] formulation impedance matrix in order to calculate the Casimir energy for 2-D conducting geometries.

H71.00411: Tricritical physics in two-dimensional p-wave superfluids near resonance

FAN YANG (Presenter), FEI ZHOU, University of British Columbia — We study the effect of quantum fluctuations on the stability of two-dimensional \((p+ip)\)-wave superfluids near resonance. The system is a Bardeen-Cooper-Schrieffer superfluid on one side of the resonance and a Bose-Einstein condensate on the other side. When the quantum fluctuations are strong, the interactions between Cooper pairs or bosonic molecules are substantially renormalized. As a result, the interactions between bosonic fields can become attractive at low energy and destabilize the superfluid phase even if the mean-field interactions are repulsive. We find that in the strong coupling limit, there exists a finite region near resonance where the superfluids are unstable and the system undergoes a first order phase transition at its boundary. The size of this region scales as \(\exp(-c/g^2)\), where \(g\) is the \(p\)-wave interaction constant and \(c\) is a numerical factor. Using a simple renormalization group analysis, we identify the tri-critical points which separate the continuous phase transition from the first order phase transition.

H71.00412: Electron correlation Time-Dependent Density-Functional Theory for Higher Harmonic generation in solids

DIDARUL ALAM (Presenter), NASEEM UD DIN, SHIMA GHOLAM MIRZAEMOGHADAR, TAO JIANG, MICHAEL CHINI, VOLODYMYR TURKOWSKI, Univ of Central Florida — We present details of our Time-Dependent Density-Functional Theory (TDDFT) approach, which takes into account the effects of electron-electron correlations, to analyze high-order harmonic (HH) spectra in solids. The used TDDFT exchange-correlation kernel was obtained from the charge susceptibility for the effective Hubbard model for the system calculated by using Dynamical Mean-Field Theory. The corresponding system of the TDDFT equations for polarizations and state occupancies is a generalization of the semiconductor Bloch equations on the case of locally-interacting electrons. To establish the signs of the correlation effects in the HH spectrum, we solved the equations analytically in the limit of weak external laser-pulse perturbation and numerically for various field strengths in the case of one of the most studied system – ZnO. It was found that correlation effects significantly affect the HH spectrum, most notably by shifting the spectral weight to higher harmonics. We discuss possible extensions of the theory on the case of non-local electron-electron interactions.

*This work is supported in part by NSF Grant No. DMR-1809181
H71.00413: Hot electron noise in semiconductors from first principles* PEISHI CHENG (Presenter), ALEXANDER CHOI, AUSTIN MINNICH, Caltech — First principles calculations of the properties such as mobility in semiconductors are now routine owing to advances in the ab-initio treatment of the electron-phonon interaction. However, fluctuational properties like the spectral noise power of current fluctuations, which can be calculated from the same ab-initio inputs, are experimentally accessible but yet to be reported. Here, we report an ab initio calculation of the spectral noise power in GaAs using a Boltzmann-Green's function method. This approach expresses the noise spectral power using the current autocorrelation function computed from solutions of the Boltzmann transport equation with first principles electron-phonon interactions as input. The physical insights yielded by this description of fluctuational properties will help guide the design of semiconductor devices operating closer to the standard quantum limit of noise.

H71.00414: Consecutive Study Of Back Contact Barrier Height and CdS Layer Thickness And Their Effect On CdTe Solar Cell Efficiency* PATRICK MILAN (Presenter), MATTHEW MELFI, YUNIS YILMAZ, SADE SAMPSON, MEHMET ALPER SAHINER, PROF WEINING WANG, Seton Hall Univ — Favored for its low cost and relatively high efficiency (22.1% in 2016), Cadmium Telluride (CdTe) solar cells are popular among the thin film generation because they still have room for improvement. CdTe solar cells have a high electron affinity (about 4.5 eV) and as a result when metal contacts are used, a good ohmic contact is not created, and a Schottky barrier is formed at the back-contact junction. This barrier impedes current flow and lowers cell performance. The thickness ratio of Cadmium Sulfide (CdS) to CdTe is also important as increasing or decreasing the thickness of the [n-type] CdS layer will affect the production and recombination rate of charge carriers.

In this work, we show our studies on the effect of the back-contact barrier height and CdS layer thickness on the performance of CdTe solar cells. Using the turning point technique and a corresponding formula, we were able to obtain the barrier height at the back-contact junction of cells with different back-contact materials. We have also fabricated four CdTe samples using a pulsed-laser deposition process, each with a different CdS layer thickness, and have determined their efficiencies. Our results show us that barrier height and CdS layer thickness do have a direct effect on solar cell performance.

*NASA-NJSGC
H71.00415: Non-volatile nanosecond phase change in BiFeO$_3$ thin films induced by pulse laser

YI-DE LIOU, Natl Cheng Kung Univ, HAILI SONG, East China Normal University, WEN-YEN TZENG, National Chiao Tung Univ, RONG HUANG, East China Normal University, CHIH-WEI LUO, National Chiao Tung Univ, YI-CHUN CHEN, JAN-CHI YANG, YU CHEN LIU (Presenter), Natl Cheng Kung Univ — Nowadays, increasing technology interest has focused on the optical control of non-volatile functional units based on ferroic materials, especially those with ultrafast tunabilities. Despite the fact that various light sources can be used to alter the ferroelectricity and magnetization of ferromagnets via means of light, this usually requires low-temperature or high-energy flux to fulfill significant changes. In this work, we reveal nanosecond non-volatile phase alteration in multiferroic BiFeO$_3$ (BFO) thin films.

This approach utilizes the delicate combination of thermal effect and strain pulse triggered by pulsed laser illumination. Taking advantage of the low phase transition barrier in the mixed phase BFO, we successfully demonstrate an effective optical approach to alter the phase distribution and corresponding ferroic properties in BFO. The application of single laser pulse results in the preferred phase transition from mixed phase to tetragonal phase. The fast phase change is attributed to the martensitic phase transformation induced by laser pulse, as evidenced by HAADF-STEM. We further show that the changes results from laser illumination are reversible, demonstrating new pathways to control the ferroic systems in ultrafast time scale through optical stimulus.

H71.00416: Investigation of self-heating phenomena in high-electron mobility transistors (HEMTs) using millisecond-resolution Y-factor method*

ALEXANDER CHOI (Presenter), AUSTIN MINNICH, Caltech — Low noise microwave amplifiers are critical components in measurement systems with applications ranging from qubit readout in quantum computing to the detection of fast radio bursts in RF astronomy. Recent work has suggested that the noise floor in high electron mobility transistors (HEMTs), presently around a factor of 5 above the quantum limit, is in part set by the thermal noise from the gate metal corresponding to a temperature exceeding the cryostat temperature. This temperature differential originates from high thermal resistance associated with phonon blackbody radiation at cryogenic temperatures. In this talk, we report on experiments designed to examine self-heating phenomena in HEMTs at cryogenic temperatures using liquid helium cooling and a custom noise figure analyzer that measures noise temperature with millisecond resolution. Our results confirm that self-heating at cryogenic temperatures is key mechanism in setting the noise floor of transistor amplifiers. These findings help to identify a path for transistor microwave amplifiers operating closer to the standard quantum limit of noise.

**H71.00417: Design of Polyelectrolyte-based Materials using Molecular Modeling**

THOMAS OWEIDA (Presenter), IBRAHIM AHMAD, YAROSLAVA YINGLING, North Carolina State University —
Polyelectrolyte block copolymers have shown promise as carriers for drug and gene delivery due to their ability to self-assemble into a variety of responsive morphologies with tailored properties. Dissipative Particle Dynamics (DPD) is a computationally inexpensive, coarse-grained simulation technique that has previously been used to predict the resulting morphologies of polyelectrolyte block copolymers. However, the design space of these materials is still largely unexplored with the influence of most design parameters being poorly understood. This study utilizes DPD and machine learning methods to investigate a multi-dimensional, morphological phase diagram for polyelectrolyte block copolymers. A machine learning method, support vector machine (SVM), is trained and tested on DPD simulation data to handle the high dimension of features influencing the polyelectrolyte block copolymer morphology. The results are the development of a comprehensive and detailed morphological phase diagrams for block copolymer properties versus environmental conditions that can be used as a robust predictive tool. These results provide the fundamental basis for synthesizing polyelectrolyte block copolymers for materials with novel, desirable properties.

**H71.00418: Jammed solids held together with pins: structure and dynamics**

LIAM PACKER, BRIAN JENIKE, ARI LILOIA (Presenter), AMY GRAVES, Physics, Swarthmore College, SEAN RIDOUT, Physics, University of Pennsylvania — Currently, much is known about idealized grains like soft discs in the vicinity of the "Point J" threshold for jamming. However, an important unanswered question concerns the role that a scaffolding in the form of fixed particles, or "pins", plays in the structure and dynamics of a jammed solid. We model pins as tiny fixed particles organized in lattice shapes such as square, triangular, honeycomb, or randomly distributed lattices. We find a number of interesting results: While at low pin densities the jamming threshold, φj, does what one expects - decreases linearly with pin density and independently of pin geometry - this is not true in general. Instead, the behavior of φj with pin density depends on the type of lattice, and whether the particles are bi- or polydisperse. The distribution of contact forces is very different from the familiar gaussian shape in the absence of pins. The linear elastic response is significantly affected by pins, both in terms of the magnitudes of bulk and shear moduli and the Zener ratio, showing that pins can break the isotropy of jammed states.

H71.00419: Adsorption of Binary Gas Mixtures on Graphite*  
G.M DINUKA GALLABA  
(Presenter), ALDO DANTE MIGONE, Department of Physics, Southern Illinois University Carbondale — Determining how a binary gas mixture approaches equilibrium in the presence of a sorbent can have important implications for applications adsorption to gas separation. To understand the behavior of binary gas mixtures we are studying how adsorption equilibrium is reached on a well characterized planar sorbent, exfoliated graphite. We have conducted a series of adsorption measurements of methane and nitrogen mixtures on exfoliated graphite at low temperatures. We will present results for different initial mixture compositions and different temperatures. We will present results on the how the pressure approaches equilibrium, and, on the composition of the mixture at equilibrium for the different conditions explored.

*This work is supported through grant NSF DMR 1807094

H71.00420: Solving the Green's function as a single eigenstate in a boundary value problem  
JOSE HERNANDEZ (Presenter), LI GE, Physics and Astronomy, CUNY College of Staten Island — It is well known that the Green’s function of an operator $L(x)$ in a boundary value problem can be expressed as a bilinear expansion using the eigenstates of $L(x)$. Here we introduce an auxiliary eigenvalue problem, from which the Green’s function is uniquely determined by a single eigenstate. This approach is easy to implement numerically, and it becomes very helpful when the eigenstates of $L(x)$ are badly conditioned, for example, when $L(x)$ is non-Hermitian and at an exceptional point. We illustrate this approach in one-dimensional and two-dimensional Helmholtz equations, with a focus on non-Hermitian systems that are due to their openness as well as non-Hermitian potentials.

Session J01 DAMOP: Quantum Computing, Communication, and Information in AMO Systems 103 - Ruichao Ma, Purdue Univ

2:30PM J01.00001: Robust and high-fidelity quantum entangling gate with neutral Rydberg atoms*  
XIAO-FENG SHI (Presenter), Xidian University — In this talk, I will show some theoretical proposals of quantum entangling gate with neutral Rydberg atoms that have high intrinsic fidelity and are robust against dephasing from the atomic motion. With off-resonant transitions between ground and Rydberg states, it is possible to induce input-state-dependent phase to the two-qubit state, so that entanglement can be created with only one pulse efficiently. This talk also presents schemes for partially suppressing the motional dephasing of the transition between ground and Rydberg states for neutral atoms.

2:42PM J01.00002: Towards Trapping Electrons in Paul Traps for Quantum Computing  
JINEN GUO (Presenter), CLEMENS MATTHIESEN, HARTMUT HAEFFNER, University of California, Berkeley — Trapped-electron qubits provide an interesting alternative to trapped ions in quantum information processing. The operations on trapped electron systems can be all-electronic, making it easier to scale up, and the light mass of electrons enables faster two-qubit gates. In order to evaluate the feasibility of a trapped electron quantum computer, we simulate the electron dynamics inside Paul traps with a drive frequency of 1.5 GHz. From the simulations, we determine the trap depth and explore the validity of pseudopotential approximation. In addition to the electron dynamics in the trapping potential, we also explore how to deterministically eject electrons from the trapping potential towards a particle detector.

2:54PM J01.00003: Controlling entanglement sudden death in two coupled atoms interacting off-resonance with a radiation field*  
GEHAD SADIEK (Presenter), Applied Physics and Astronomy, University of Sharjah, WIAM AL-DRESS, Physics and Astronomy, King Saud University — We study a system of two coupled two-level atoms (qubits) interacting, at non-zero detuning, with a single mode radiation field. This system is of special interest in the field of quantum information processing (QIP) and can be realized in electron spin states in quantum dots or Rydberg atoms in optical cavities and superconducting qubits in linear resonators. We utilize our exact analytical solution for the time evolution of the system to show how entanglement sudden death (ESD), which represents a major threat to QIP, can be efficiently controlled by tuning atom-atom coupling and non-zero detuning. We demonstrate that while one of these two system parameters may not separately affect the ESD, combining the two can be very effective in reducing, eliminating or creating ESD depending crucially on the system initial state. A synchronization between the population inversion collapse-revival pattern and the entanglement dynamics is observed at all system parameter combinations. The variation of the radiation field intensity shows a clear impact on the duration of the ESD at any combination of the other system parameters.

3:06PM J01.00004: Realizing the Hayden-Preskill Protocol with Coupled Dicke Models*
YANTING CHENG (Presenter), CHANG LIU, Tsinghua University, JINKANG GUO, Department of Physics, Peking University, YU CHEN, Department of Physics, Capital Normal University, PENGFEI ZHANG, Institute for Quantum Information and Matter, California Institute of Technology, HUI ZHAI, Tsinghua University — Hayden and Preskill proposed a thought experiment that Bob can recover the information Alice throws into a black hole if he has a quantum computer entangled with the black hole, and Yoshida and Kitaev recently proposed a concrete decoding scheme. Here we propose to realize this decoding protocol in a physical system of two Dicke models, with two cavity fields prepared in a thermofield double state. We show that the Yoshida-Kitaev protocol allows us to read out the initial spin information after it is scrambled into the cavity. We show that the readout efficiency reaches a maximum when the model parameter is tuned to the regime where the system is the most chaotic, characterized by the shortest scrambling time in the out-of-time-ordered correlation function. Our proposal opens up the possibility of discussing this profound thought experiment in a realistic setting.

3:18PM J01.00005: High-fidelity ground state preparation of single neutral atom in an optical tweezer* XIWANG LUO (Presenter), University of Texas at Dallas, MARK G RAIZEN, University of Texas at Austin, CHUANWEI ZHANG, University of Texas at Dallas — Arrays of neutral-atom qubits in optical tweezers are a promising platform for quantum computation. Despite experimental progress, a major roadblock for realizing neutral atom quantum computation is the qubit initialization. Here we propose that supersymmetry—a theoretical framework developed in particle physics—can be used for ultra-high fidelity initialization of neutral-atom qubits. We show that a single atom can be deterministically prepared in the vibrational ground state of an optical tweezer by adiabatically extracting all excited atoms to a supersymmetric auxiliary tweezer with the post-selection measurement of its atomic number. The scheme works for both bosonic and fermionic atom qubits trapped in realistic Gaussian optical tweezers and may pave the way for realizing large scale quantum computation, simulation and information processing with neutral atoms.

3:30PM J01.00006: A simple embedding scheme for quantum computer simulations of molecules
CHRISTINA DANIEL (Presenter), MANUEL WEBER, Georgetown University, DOMINIKA ZGID, University of Michigan, JAMES FREERICKS, Georgetown University — Current era noisy intermediate-scale quantum computers are limited in what they can accurately simulate. One of the most successful applications to date has been the variational quantum eigensolver, which uses the quantum computer to create a trial wavefunction and then employs a simple circuit to measure the expectation value of different pieces of the Hamiltonian. A classical computer is employed to accumulate all of the results and determine the energy; it also is employed to optimize the trial wavefunction, if desired. In this work, we focus on the question of whether one can easily improve the accuracy of this calculation via an embedding strategy. We take a classical Hartree-Fock (or similar) approximation for a large system and correct its energy using the correlation energy derived from the smaller quantum computer calculation. We illustrate this concept with calculations performed on some simple molecules.

*We acknowledge support from the National Science Foundation under grant number NSF-CHE-1836497.

3:42PM J01.00007: Memory-enhanced quantum communication using diamond quantum networks
CHRISTIAN NGUYEN (Presenter), MIHIR K BHASKAR, RALF RIEDINGER, BARTHOLOMEUS J MACHIELSE, DAVID LEVONIAN, ERIK KNALL, HONGKUN PARK, Harvard University, DIRK R. ENGLUND, Massachusetts Institute of Technology, MARKO LONCAR, DENIS D SUKACHEV, MIKHAIL LUKIN, Harvard University — The ability to communicate quantum information over long distances is of central importance in quantum science and engineering. For example, it enables secure quantum key distribution (QKD) relying on fundamental principles that prohibit the “cloning” of unknown quantum states. While QKD is being successfully deployed, its range is currently limited by photon losses and cannot be extended using straightforward measure-and-repeat strategies without compromising its unconditional security. Quantum repeaters, which utilize intermediate quantum memory nodes and error correction techniques, can extend the range of quantum channels. However, their implementation remains an outstanding challenge, requiring a combination of efficient and high-fidelity quantum memories, gate operations, and measurements. Here, we present our approach towards building a quantum repeater using silicon-vacancy color centers (a solid-state quantum memory) integrated into diamond nanophotonic cavities.

**3:54PM J01.00008: Continuous protection of a quantum state from inhomogeneous dephasing**

RAN FINKELSTEIN (Presenter), OHR LAHAD, OMRI DAVIDSON, EILON POEM, OFER FIRSTENBERG, Weizmann Institute of Science — Room-temperature atomic vapors are known for their simplicity and their potential scaling-up in applications. In spite of these benefits, laser-cooled atoms have evolved to be the prevalent systems for studying strong and coherent light-matter interactions, as the latter are unhindered by Doppler broadening. Here we present several methods to overcome the effective decrease of both atom-photon cross-section [1] and coherence time in vapors, and in fact in any inhomogeneously broadened atom-like system. The mechanism we study can be understood as the counteraction of the inhomogeneous dephasing of two coupled states, where one state has enhanced sensitivity to the source of dephasing. A far-detuned dressing field admixes a fraction \( \frac{\Omega^2}{\Delta^2} \) of this "sensor" state into the "protected" state, yielding a velocity-insensitive state and line-narrowing in two-color transitions [2]. Finally, we apply this method to extend the lifetime of collective excitations stored in a thermal atomic vapor. This method is continuous, in contrast to pulsed echo-based techniques.

**4:06PM J01.00009: Correlation spectroscopy as a tool for comparing optical clocks**

MAY KIM (Presenter), ETHAN R. CLEMENTS, KAIFENG CUI, AARON HANKIN, SAMUEL M BREWER, JWO-SY CHEN, DAVID B HUME, DAVID LEIBRANDT, National Institute of Standards and Technology Boulder — Highly accurate optical clocks are quantum sensors with fractional frequency uncertainty below one part in \( 10^{18} \) [1]. Comparisons between such clocks can lead to a better understanding of fundamental physics and potentially replace cesium microwave clocks to redefine the SI second. However, noise from the local oscillator often limits the measurement stability of these comparisons, requiring long averaging times to reduce statistical uncertainty. One way to overcome this limitation is by performing correlation spectroscopy in which a Ramsey pulse sequence derived from the same probe laser is applied to the clocks synchronously. The coherent differential frequency measurements between atomic systems permit interrogation times beyond the laser coherence time, which leads to a reduction in the quantum projection noise limit. As a result, the frequency comparison instability is significantly lower than is possible for incoherent comparisons using the same local oscillator. We demonstrate this technique using two Al+ quantum-logic clocks separated in space by a few meters.

*This work was supported by the Defense Advanced Research Projects Agency, the National Institute of Standards and Technology, and the Office of Naval Research.*
Correlation Spectroscopy Between Two $^{27}$Al$^+$ Quantum-Logic Clocks

ETHAN CLEMENTS (Presenter), MAY KIM, KAIFENG CUI, AARON HANKIN, SAMUEL M BREWER, JWOSY CHEN, DAVID LEIBRANDT, DAVID B HUME, National Institute of Standards and Technology Boulder — Correlation spectroscopy is a technique for performing coherent differential frequency measurements between two atomic clocks with an interrogation time beyond the coherence time of the local oscillator. This technique was initially demonstrated for two co-trapped ions [1-3]. Here, we present a demonstration of correlation spectroscopy between two independent $^{27}$Al$^+$ optical atomic clocks separated by a few meters. We discuss limitations caused by differential noise sources and techniques that can be used to mitigate these effects. Correlation spectroscopy allows us to extend the interrogation time to 8 seconds, beyond the capability of cavity stabilized lasers and approaching the lifetime limit of the Al$^+$ atomic transition. From this increase in the interrogation time we obtain a fractional measurement instability below $4 \times 10^{-16}$ at 1 s, a factor of $\sim 10$ improvement from previous Al$^+$ clock comparisons.

This work was supported by the Defense Advanced Research Projects Agency, the National Institute of Standards and Technology, and the Office of Naval Research.

Conversion of position correlation into polarization entanglement

CHITHRABHANU PERUMANGATT (Presenter), ALEXANDER LOHRMANN, ALEXANDER LING, Centre for Quantum Technologies — Photons entangled in polarization have been a prime tool for experiments in fundamental quantum physics. To generate polarization entanglement from spontaneous parametric down conversion (SPDC), it is necessary to impose coherent superposition of two pump-decay paths. There is a variety of techniques by which this coherent superposition can be achieved. Examples of previous entangled photon-pair sources have utilized momentum correlation, indistinguishable pump decay in two separate crystals, or two distinguishable pump beams. We present a method to convert position correlation of photon-pairs into polarization entanglement. This is achieved by individually manipulating the polarization state of photons generated in different parts of a non-linear medium and putting them in coherent superposition. This concept is experimentally demonstrated using photon-pairs produced by SPDC. The method was used to implement a compact source producing an observed photon-pair rate of 120,000/s/mW with an entanglement fidelity of 0.99. This method can be extended to any photon-pair generation process with initial position correlation.

This research is supported by National Research Foundation, and the Singapore Ministry of Education Research Centres of Excellence program.
4:42PM J01.00012: Toward quantum-logic spectroscopy of single molecular ions in a cryogenic ion trap* DALTON CHAFFEE (Presenter), ALEJANDRA L COLLOPY, DIETRICH LEIBFRIED, DAVID LEIBRANDT, CHIN-WEN CHOU, Time and Frequency Division, NIST, Boulder — Quantum state control of trapped and cooled atomic ions is an established technique with applications including precision metrology and quantum computing. Molecules provide even richer physics, but their additional degrees of freedom make such control more challenging. In our group, quantum-logic spectroscopy (QLS) of a single CaH⁺ ion has enabled preparation and coherent manipulation of pure molecular quantum states [1]. However, the currently used loading scheme is applicable only to certain hydrides, and background gas collisions and black-body radiation in the room-temperature apparatus eventually limit measurement precision and fidelity of quantum control. Here, we present progress of the design and construction of a cryogenic ion trap apparatus for more versatile loading of molecular ions and better control of their states. Molecules will be injected from an interchangeable gas source, ionized in a strong laser field, and co-trapped with an atomic ion for QLS. This device will be used to perform precision spectroscopy of molecules relevant for, e.g., tests of fundamental physics.

*This work was supported by the Army Research Office and the National Science Foundation.

4:54PM J01.00013: Towards quantum logic spectroscopy of multi-ion arrays* KAIFENG CUI (Presenter), KEVIN T BOYCE, DAVID LEIBRANDT, DAVID B HUME, PML, National Institute of Standards and Technology Boulder — We describe a new approach for precision spectroscopy of trapped ions using quantum logic. Our approach adapts method developed in the context of quantum information processing to non-destructive detection of the ¹S₀-³P₀ clock transition in ²⁷Al⁺. A state-dependent force is employed on the spectroscopy ion(s) to modulate the qubit state of the detection ion(s), similar to the techniques employed for high-fidelity quantum gates[1,2] and sensitive force detection experiments [3,4]. This method does not require ground state cooling and would enable scaling to large numbers of spectroscopy ions to improve ion clock stability.

*This work was supported by Argonne National Laboratory, the Defense Advanced Research Projects Agency, the National Institute of Standards and Technology, and the Office of Naval Research.
5:06PM J01.00014: Direct characteristic-function tomography of quantum states of the trapped-ion motional oscillator*  CHRISTA FLÜHMANN (Presenter), Institute for Quantum Electronics, ETH Zurich — Quantum state reconstruction is an important element enabling diagnosis and improvement of quantum control. As larger states come under experimental control the number of measurements required to perform state reconstruction becomes crucial. Here, significant gains can be found by choosing the appropriate basis in which to make measurements. In this talk I will present recent experiments analyzing direct phase-space tomography of the motion of a single trapped Ca$^+$ ion. The method, which is based on ion internal state rotations combined with state-dependent shifts of the oscillator, is used to reconstruct displaced squeezed oscillator states as well as a three-component superposition thereof. Such states have applications in quantum information, quantum sensing and fundamental studies. We find reductions in measurement times of a factor 20 compared to methods we used previously, which we anticipate to improve future ion motion state preparation and control.

*We acknowledge support from the Swiss National Science Foundation through the National Centre of Competence in Research for Quantum Science and Technology (QSIT) grant 51NF40-160591, and from the Swiss National Science Foundation under grant number 200020_165555/1.

5:18PM J01.00015: High dimensional entanglement between a photon and a multiplexed atomic quantum memory  CHANG LI (Presenter), YUKAI WU, WEI CHANG, SHENG ZHANG, LUMING DUAN, Center for Quantum Information, Tsinghua University — Multiplexed quantum memories and high-dimensional entanglement can improve the performance of quantum repeaters by promoting the entanglement generation rate and the quantum communication channel capacity. Here, we experimentally generate a high-dimensional entanglement between a photon and a collective spin wave excitation stored in the multiplexed atomic quantum memory. We verify the entanglement dimension by the quantum witness and the entanglement of formation. Then we use the high-dimensional entangled state to test the violation of Bell-type inequality. Our work provides a prominent method to generate multidimensional entanglement between the flying photonic qubits and the atomic quantum interfaces, a key step toward quantum networks.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

Session J02 DQI DAMOP: Advances in AMO Quantum Information and Technologies 105 - Alejandra Collopy, National Institute of Standards and Technology Boulder
2:30PM J02.00001: Rydberg physics for quantum computing in arrays of neutral atom qubits  JONATHAN KING (Presenter), ALEXANDER PAPAGEORGE, SABRINA HONG, REMY NOTERMANS, BRIAN LESTER, STANIMIR KONDOV, KRISH KOTRU, MICKEY MCDONALD, ROBIN COXE, PRASAHNT SIVARAJAH, BENJAMIN BLOOM, Atom Computing, Inc — Ultracold neutral atoms have recently emerged as a scalable quantum computing platform. Their long coherence times and parallel coherent control portend the realization of high-fidelity quantum operations on large arrays of qubits. Interactions between neutral atoms in Rydberg states provide a means to 2-qubit and multi-qubit gates. Understanding the energy level structure of Rydberg atoms and their interactions are a necessary prerequisite to designing gate schemes. To this end we discuss Rydberg interactions for quantum computing with trapped single atoms, including simulations of the full Hilbert space relevant to 2-qubit gates.

2:42PM J02.00002: Robustness and sensitivity to imperfections in the dynamics of general observables within near-term quantum simulators*  PABLO POGGI (Presenter), University of New Mexico, NATHAN LYSNE, KEVIN KUPER, POUL STERNDORFF JESSEN, University of Arizona, IVAN DEUTSCH, University of New Mexico — We analyze the robustness of analog quantum simulators in the presence of weak perturbations. To this end, we focus on the dynamics of expectation values for generic observables and study the error arising from the imperfect operation of the device. We show that the properties of the error depend crucially on the observable considered as output of the simulator and we demostrate how even a low-fidelity quantum simulation is still able to reproduce the dynamics of other observables with a small relative error. To explain this, we define the observable purity, which characterizes the magnitude of the support of the observable in Hilbert space, and analytically show that these imperfect devices are able to reproduce the dynamics of low-purity observables (such as collective operators like the magnetization in a spin system) accurately, while the error in the expectation value of high-purity observables (such as projectors onto pure states) are much larger on average. We demonstrate our findings in a state-of-the-art 16-dimensional quantum simulator where, without assuming any particular error model, we observe this predicted behavior. This shows that these features are generic for a highly accurate device where we expect imperfections to be small.

*Support from NSF is acknowledged
A central goal for modern quantum information science is to demonstrate computational speedup for experimentally feasible architectures in the noisy intermediate-scale regime. In a previous work, we studied this problem in the context of simulating boson sampling by noninteracting bosonic atoms on a one-dimensional lattice [1]. We extend these results to include Bose-Hubbard-type interactions. In the presence of weak interactions, we show that the output-sampling distribution is close to that of a free-boson sampler in the total variational distance. We calculate the scaling of the interaction-strength such that this total variational distance is bounded by a constant, demonstrating a regime where the sampling complexity is equivalent to that of the corresponding boson sampler. We close with some outlook for the possibility of applying worst-to-average-case reduction tools to extend these results beyond the perturbative regime.

*Google Quantum Algorithms Focused Award.

Strong and precisely controlled interactions between quantum objects are essential for emerging technologies such as quantum information processing, simulation, and sensing. A well-established paradigm for coupling otherwise weakly interacting quantum objects is to use auxiliary quantum particles, typically bosons, to mediate interactions, for example photon-mediated interactions between atoms or superconducting qubits, and phonon-mediated interactions between trapped ions. General methods for amplifying these interactions through parametric driving of the boson channel have been proposed for a variety of quantum platforms, but an experimental demonstration has yet to be realized. Here we experimentally demonstrate the amplification of a boson-mediated interaction between two trapped-ion qubits by parametrically modulating the confining potential of the trap. The stronger interaction enables a 3.3-fold reduction in the time required to implement an entangling gate between the two qubits. Our method can be applied wherever parametric modulation of the boson channel is possible, enabling its use in a variety of quantum platforms to explore new parameter regimes and for enhanced quantum information processing.

*We acknowledge funding from the NIST Quantum Information Program
3:18PM J02.00005: TDDFT potential inversion applied to spin systems on noisy quantum computers*  JAMES BROWN (Presenter), JUN YANG, JAMES D WHITFIELD, Dartmouth Coll — One route to numerically propagating quantum systems is time-dependent density functional theory (TDDFT). We recently introduced a newly developed solver[arXiv:1904.10958] for the scalar time-dependent Kohn-Sham potential using a grid-like basis of Sinc functions. In this talk, we discuss the application of this method to describing interacting spin systems (which can be implemented readily on quantum computers) as a non-interacting Kohn-Sham system. The method's robustness when used in conjunction with current noisy quantum devices is discussed.

*This work was primarily supported by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, under the Quantum Computing Application Teams program (Award 1979657). 3:30PM J02.00006: Electric field in a two-dimensional time-multiplexed photonic quantum walk  HAMIDREZA CHALABI (Presenter), SABYASACHI BARIK, SUNIL MITTAL, THOMAS E. MURPHY, MOHAMMAD HAFEZI, EDO WAKS, University of Maryland, College Park — It is of fundamental importance to control the evolution of a photonic quantum walk for conducting various quantum simulations. However, due to the lack of charge, photons are indifferent to applied electric fields, which limits our ability to control photonic quantum walks. One approach to mimic the effect of electric fields is through the use of synthetic gauge fields. In this presentation, we show the creation of a uniform effective electric field using a linearly time-varying gauge field in a time-multiplexed two-dimensional quantum walk. In this platform, varied lengths of optical fibers create time delays and the gauge fields are implemented through phase modulations. We demonstrate that the generated electric field leads to Bloch oscillations that enable revival of the quantum walker state. By measuring the probability of the revival, we show good agreement between the observed values and the theoretically predicted results. We also demonstrate the possibility of waveguiding quantum walkers by applying an inhomogeneous electric field.
Experimental few-copy multipartite entanglement detection  

VALERIA SAGGIO (Presenter), Univ of Vienna, ALEKSANDRA DIMIĆ, University of Belgrade, CHIARA GREGANTI, VitreaLab GmbH, LEE ARTHUR ROZEMA, PHILIP WALThER, BORivoJE DAKiC, Univ of Vienna — The reliable verification of quantum entanglement is an essential task to scale up quantum technologies. Although progressively more efficient techniques have been developed, most of these focus solely on minimizing the number of measurement settings. Recently, a single-shot probabilistic method was proposed [1], wherein it was shown that even a single detection event can be sufficient to verify if a state exhibits entanglement. In our work [2] we extend this theoretical approach by showing that any entanglement witness can be translated into this probabilistic framework. To prove our findings, we report the experimental entanglement verification in a photonic six-qubit cluster state. We find that the presence of entanglement can be certified with at least 99.74% by using only 20 copies of the state, and that genuine six-qubit entanglement is verified with at least 99% confidence by using 112 copies of state. This novel method entails a significant reduction of resources, promising a great impact in future experiments where an efficient and resource saving approach will be essential for entanglement verification problems in multi-qubit states.

Deterministic Logic Gates for Photonic Qubits* 

MIKKEL HEUCK (Presenter), Massachusetts Institute of Technology MIT, KURT JACOBS, Computational and Information Sciences Directorate, U. S. Army Research Laboratory, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — Quantum logic gates operating on qubits encoded in photons are highly desirable for processing quantum information as it is being transmitted through quantum networks. However, the difficulty of enabling sufficiently strong interactions between photons has hindered their experimental realization. Additionally, the multi-mode nature of finite-duration photon wave packets limits the gate fidelity if photons interact while travelling. We propose a method that converts travelling continuous-mode photons into quasi-single mode fields by absorbing them into cavities. This is enabled by strong classical control fields that perform the necessary re-distribution of photon frequency-modes. Letting the photons interact while occupying modes of a cavity with high quality factor and low mode-volume achieves a large interaction strength and simultaneously avoids gate fidelity degradations. We consider nonlinear interactions due to \( \chi^{(2)} \), \( \chi^{(3)} \), and atom-like emitters. Our numerical results show that high-fidelity gates are possible with near-term improvements in nanofabrication.

4:06PM J02.00009: Accelerating quantum optics experiments using statistical learning*
Cristian Cortes (Presenter), Sushovit Adhikari, Xuedan Ma, Stephen K Gray, Argonne Natl Lab — Quantum optics experiments, involving the measurement of low-probability photon events, are known to be extremely time-consuming. In this talk, we present a new methodology for accelerating such experiments using simple statistical learning techniques such as Bayesian maximum a posteriori estimation based on few-shot data. We show it is possible to reconstruct time dependent data using a small number of detected photons, allowing for fast estimates in under a minute, and providing a one-to-two order of magnitude speed up in data acquisition time. We test our approach using real experimental data to retrieve the $G^2(\tau)$ time trace for thermal light emitted by a Neon light source as well as anti-bunched light emitted by a quantum dot driven with periodic laser pulses. We also show, through numerical simulations, that our approach can be used to accelerate sub-diffraction image reconstruction based on $G^2(\tau)$ coincidence measurements. The proposed methodology has the potential to impact the scientific discovery process across a multitude of domains.

4:30PM J02.00011: Heralding High Fidelity Entanglement Between Imperfect Artificial Atoms*  
HYEONGRAK CHOI (Presenter), DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — Color centers in diamond have emerged as excellent candidates for quantum networks. However, despite their stable optical properties, residual spectral dephasing and diffusion still limit the achievable fidelity of heralded entanglement. Here, we address this problem through a new single-photon entanglement protocol that uses detuned optical coupling to spin-dependent optical transitions. Our calculations include entanglement distillation and are compared to other leading entanglement protocols. Estimates based on present-day technology indicate that this protocol enables entanglement fidelity in excess of 99% for leading diamond color centers.

*The authors acknowledge the support from the Air Force Office of Scientific Research MURI (FA9550-14-1-0052), the Army Research Laboratory (ARL) Center for Distributed Quantum Information (CDQI), the Defense Advanced Research Projects Agency (DARPA) DRINQS (HR001118S0024) and the National Science Foundation (NSF) RAISE TAQS (CHE1839155) and EFRI ACQUIRE (EFMA-1838911).

4:42PM J02.00012: A Dielectric Antenna for Quantum Emitter Interfaces*  
LINSEN LI (Presenter), HYEONGRAK CHOI, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — Color centers in diamond have shown long spin coherence time and stable optical properties as a promising system for large scale quantum information processing. Collecting single photons from emitters with high efficiency can significantly boost the entanglement generation rate of remote quantum memories. Here, we propose a method to design a dielectric antenna for low numerical aperture optics systematically. Our simulation results show that the design is robust in the presence of fabrication imperfection. The dielectric antenna design enables efficient interfaces to closely packed arrays of quantum memories for multiplexed quantum repeaters, arrayed quantum sensors, and modular quantum computers.

4:54PM JO2.00013: Sub-kilohertz optical homogeneous linewidth in transparent Er$^{3+}$:Y$_2$O$_3$ ceramics*  RIKUTO FUKUMORI (Presenter), YIZHONG HUANG, University of Chicago, JUN YANG, HAITAO ZHANG, Corning Inc., TIAN ZHONG, University of Chicago — Global quantum networks require quantum memories with long coherence times to act as quantum repeaters connected by optical fibers. Erbium doped solid-state systems are good candidates for such memories, as they exhibit long coherence lifetimes and an optical transition in the low-loss telecom band. We measure an optical homogeneous linewidth of 580 Hz in transparent Er$^{3+}$:Y$_2$O$_3$ ceramics at millikelvin temperatures, the narrowest so far in rare-earth doped ceramics, and suppressed spectral diffusion at 300 Hz/decade. Temperature, field, and time dependence studies of homogeneous linewidth reveal the limiting dephasing mechanisms as tunneling two-level systems and superhyperfine interactions between the electronic spins of erbium and nuclear spins of yttrium. These spectroscopic results put Er$^{3+}$:Y$_2$O$_3$ ceramics as a promising candidate for telecommunication quantum memories.

*We acknowledge funding support from the National Science Foundation EAGER award No 1843044, Funder Id: http://dx.doi.org/10.13039/100000001

5:06PM JO2.00014: Cavity nano-optics with configurable interaction: room temperature strong coupling of single emitter  MOLLY A. MAY, University of Colorado, Boulder, DAVID FIALKOW, University of Maryland, Baltimore County, TONG WU, Institute d'Optique, CRNS, University of Bordeaux, KYOUNG-DUCK PARK, University of Colorado, Boulder, HAIXU LENG, JARON KROPP, THEODOSIA GOUGOUSI, University of Maryland, Baltimore County, PHILIPPE LALANNE, Institute d'Optique, CRNS, University of Bordeaux, MATTHEW A PELTON, University of Maryland, Baltimore County, MARKUS B. RASCHKE (Presenter), University of Colorado, Boulder — Quantum state control of two-level emitters is fundamental for many information processing, metrology, and sensing applications. However, quantum-coherent photonic control of solid-state emitters has traditionally been limited to cryogenic environments, which are not compatible with implementation in scalable, broadly distributed technologies. In contrast, plasmonic nanocavities with deep sub-wavelength mode volumes have recently emerged as a path towards room temperature quantum state hybridization and control. Here we establish plasmonic tip-enhanced strong coupling (TESC) with a configurable nano-tip cavity to modulate and control the cavity-emitter interaction with sub-nanometer precision, quantify coupling strength exceeding ~160 meV, at mode volumes of $< 10^{-6} \lambda^3$, augmented by theoretical modeling. Based on this work, we provide a perspective for nano-cavity optics as a promising tool for room temperature control of quantum coherent interactions that could spark new innovations in fields from quantum information and quantum sensing to quantum chemistry and molecular opto-mechanics.
5:18PM J02.00015: A cavity enhanced spin-photon interface for NV centers in a quantum network*  MATTHEW WEAVER (Presenter), MAXIMILIAN RUF, MATTEO PASINI, Delft University of Technology, MARTIN ESCHEN, TNO, RONALD HANSON, Delft University of Technology — Fast entanglement generation between remote nodes is the foundation for quantum networks. Experiments with Nitrogen Vacancy (NV) centers in bulk diamond have made promising progress towards such a network, because of their long spin coherence, narrow optical transitions and accessible nuclear spin memories. However, these demonstrations are currently limited by low emission into the zero phonon line and low collection efficiency. To boost emission and collection, we construct a tunable Fabry-Pérot cavity around NV centers in a diamond membrane. We verify the good optical properties of NV centers in membranes and observe the characteristic lifetime reduction from Purcell enhancement of the zero phonon line. These measurements progress towards an NV node for networks with two orders of magnitude faster entanglement rates.

Session J03 GSCCM: Materials in Extremes: Novel Materials and Phenomena at Extreme Conditions 107 - Elissaios Stavrou, Lawrence Livermore Natl Lab -

Tag(s): Focus

2:30PM J03.00001: Novel experimental approaches toward metastable materials discovery under pressure [Invited]  JAMES WALSH (Presenter), Univ of Mass - Amherst — High pressure is a powerful synthetic tool that enables the discovery of novel materials with unprecedented bonding, crystal structure, and bulk properties. We are developing experimental methods that provide chemists with access to regions of high-pressure phase space that are currently difficult to explore. Examples include methods to target specific elemental compositions in ternary systems where competing binary phases are a complication, or techniques to kinetically stabilize high-pressure phases that do not survive traditional decompression routes. Our work is underpinned by state-of-the-art DFT packages that allow us to explore systems in search of candidate high-pressure phases and determine their formation conditions before even stepping into the lab. I will present recent results that highlight the growing synergy between cutting-edge computational methods and novel experimental approaches.
3:06PM J03.00002: New materials under extreme environments*  WENDY MAO (Presenter), Stanford Univ — The application of extreme environments (including variable pressure, temperature and irradiation) can induce dramatic changes in materials and give us a much broader field to discover new phases and explore novel phenomena. Improving our understanding of the modifications that occur can also provide guidance for designing improved materials with desirable properties that can be utilized for energy-related applications. I will presenting some examples which demonstrate the range of new materials that can be formed and properties which can be altered under extreme environments. In particular, I will focus on experimental work using high pressure as promising variable for tuning materials behavior.

*This work was supported by the Department of Energy (DOE) through the Stanford Institute for Materials & Energy Sciences DE-AC02-76SF00515.

3:18PM J03.00003: Detection of High-Pressure Electride Phases with X-ray Diffraction: A First Principles Analysis*  RAFI ULLAH (Presenter), STANIMIR BONEV, Lawrence Livermore Natl Lab — The direct experimental detection of high pressure electride phases of matter is a challenging problem. It was suggested that the interstitial localization of valence electrons - a signature of the electride phase - could be detected in the x-ray diffraction experiments. We have used first-principles calculations to quantify detectable changes in the x-ray scattering patterns of high pressure electrides. A comparison of the electron localization function and the first principles charge density to corroborate the nature and extent of interstitial electron localization will be discussed as well.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. The funding through LDRD Grant No. 17-ERD-025 is thankfully acknowledged. IM No. LLNL-ABS-795462.
**3:30PM J03.00004: High-pressure chemistry of transition metal polynitrides**

MAXIM BYKOV (Presenter), Howard University, STELLA CHARITON, Center for Advanced Radiation Sources, University of Chicago, ELENA BYKOVA, Geophysical Laboratory, Carnegie Institution of Washington, MOHAMMAD MAHMOOD, Howard University, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington, LEONID DUBROVINSKY, Bayerisches Geoinstitut, University of Bayreuth — The high-pressure chemistry of nitrogen and nitrogen-rich compounds have been in a focus of many studies in the recent years due to both fundamental and practical interest and due to the improvement of high-pressure synthetic and characterization techniques. Poly-nitrogen compounds are usually considered as potential high energy density materials (HEDM) due to the remarkable difference in the average bond energy between the single N–N bond, the double N≡N bond, and the triple N=N bond. Numerous polynitrogen compounds with various nitrogen polymeric networks were theoretically predicted, but there are only a very few experimental attempts to obtain such compounds.

In the present work we have systematically studied reactions between 5d transition metals and nitrogen at pressures up to 130 GPa in laser-heated diamond anvil cells. All 5d metals except Au react with nitrogen at these conditions resulting in the formation of polynitrides with various types of polynitrogen species. Here we will discuss current progress in high-pressure chemistry of nitrogen, methodological challenges and novel approaches to the high-pressure synthesis.

*Research was sponsored by the Army Research Office and was accomplished under the Cooperative Agreement Number W911NF-19-2-0172.

**3:42PM J03.00005: Formation of XeN$_4$ at high pressure-high temperature conditions**

MADDDURY SOMAYAZULU (Presenter), X-ray Science Division, Argonne Natl Lab, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution for Science, YUE MENG, JESSE SMITH, X-ray Science Division, Argonne Natl Lab, WATKINS B ERIK, DANA DATTELBAUM, M Division, Los Alamos National Laboratory, RUSSELL J HEMLEY, Department of Physics and Chemistry, University of Illinois at Chicago — Mixtures of xenon and nitrogen have been observed to form a cubic, van der Waals compound Xe(N$_2$)$_2$ at pressures above 2 GPa in concurrence with the study reported to pressures above 150 GPa [1,2]. The existence of the z phase of nitrogen [3] and hcp xenon [4] could be inferred from x-ray diffraction. The sample becomes opaque above 170 GPa and could be laser heated quite easily. In contrast to what is reported for pure N$_2$ [5], a new phase forms when the sample was laser heated above 2800 K and above 160 GPa. This phase is identified to be monoclinic and has distinctive Raman signatures that can be ascribed to the existence of N$_4$ units which are linear and double bonded. This is at variance to the theoretical prediction of cubic XeN$_6$ [6]. We will report the details of the spectroscopy (Raman and FTIR) as well as synchrotron powder diffraction analysis of this potentially energetic nitride of xenon.

3:54PM J03.00006: High Magnetic Field Probe of Hydride Superconductors*  FEDOR BALAKIREV (Presenter), DAN SUN, JONATHAN B BETTS, Los Alamos Natl Lab, SHIRIN MOZAFFARI, LUIS BALICAS, National High Magnetic Field Laboratory, MARI EINAGA, KATSUYA SHIMIZU, Osaka University, VASILY S MINKOV, PANPAN KONG, DMITRY KNYZAEV, ALEXANDER DROZDOV, MIKHAIL EREMETS, Max-Planck-Institut fur Chemie — High magnetic fields have proven to be an invaluable tool for exploring properties of novel superconductors. A combination of miniature diamond anvil cells and pulse magnets allows us to controllably tune and probe the superconducting order and the vortex matter in several recently discovered hydride superconductors at the extremes of pressure-field parameter envelope. Because of the larger superconducting energy scale, magnetic fields of the order of 100 T are required to establish key superconducting properties, including Cooper pair coherence length, the strength of the electron-phonon coupling, the role of the spin-orbit coupling, and the dominant mechanism breaking the Copper pairs. We find that the orbital effect suppresses superconductivity over the entire temperature range, while pronounced deviations from the Werthamer, Helfand, and Hohenberg theory predictions are observed at lower temperatures.

*The work at NHMFL was supported by the National Science foundation under cooperative Grant Nos. DMR-1157490 and DMR-1644779, the U.S. DOE, and the State of Florida, and DoE-BES DE-SC0002613.

4:06PM J03.00007: High-pressure studies of magnetism on EuAFe$_4$As$_4$ (A=Rb, Cs) via synchrotron Mössbauer spectroscopy*  WENLI BI (Presenter), Univ of Alabama - Birmingham, PHILIPP MATERNE, JIYONG ZHAO, ESEN E. ALP, JIN-KE BAO, Argonne National Laboratory, YI LIU, GUANG-HAN CAO, Zhejiang University — EuAFe$_4$As$_4$ (A=Rb, Cs) is a recent addition to the iron-based superconductors. EuAFe$_4$As$_4$ exhibits peculiar properties with coexistence of superconductivity ($T_C \sim 35$ K) and ferromagnetism from local moment in divalent Eu ($T_m \sim 15$ K) [1–4]. The application of pressure suppresses superconductivity and enhance magnetic ordering temperature [5,6] with a crossover of $T_C$ and $T_m$ around 7 GPa [5]. We have investigated the magnetic and valence state in Eu ions via synchrotron Mössbauer spectroscopy in $^{151}$Eu in diamond anvil cell. The detailed changes of Eu’s magnetism and local magnetic phase diagram will be discussed.

*The Experiments were carried out at beamline 3ID of the Advanced Photon Source, Argonne National Laboratory. Use of the Advanced Photon Source was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.
4:18PM J03.00008: Understanding EuD₄TEA and its Use as Impact or Radiation Sensors in Extreme Environments  JOHN MILLER (Presenter), WILLIAM A. HOLLERMAN, Physics, University of Louisiana at Lafayette, KARILI TOLGA, Chemistry, University of Louisiana at Lafayette, ALYSSA V. BIENVENU, Chemistry, Pennsylvania State University — If humans desire to leave the safety of Earth and explore extreme environments, cost effective and low mass health monitoring sensors will be essential to monitor impacts or incident ionizing radiation as they travel. To ensure the safety of the astronauts, a luminescent material-based sensor might be used to provide reliable in-situ impact detection or radiation monitoring for space vehicles. An extensive research program has been completed to date where many luminescent materials have been irradiated with protons and electrons. Results have generally shown that charged particle irradiation reduces the intensity of emitted luminescence by producing quenching centers. Related research has also shown that some of the same materials will emit copious light in the form of triboluminescence when crushed or struck. This paper investigates the effects of impacts or radiation on europium tetrakis dibenzoylmethide triethylammonium (EuD₄TEA). Special emphasis will be placed on our work to better understand the structure and composition of EuD₄TEA. This research can be used to help determine if luminescent materials can be used as an impact or radiation sensor in extreme environments like space.

4:30PM J03.00009: “Persistent” Insulator: Avoidance of Metallization at Megabar Pressures in Strongly Spin-Orbit-Coupled Sr₂IrO₄  ZHAORONG YANG (Presenter), CHUNHUA CHEN, YONGHUI ZHOU, High Magnetic Field Laboratory, Chinese Academy of Sciences, Hefei 230031, China, GANG CAO, Department of Physics, University of Colorado at Boulder — Here we report a rare insulating state that persists up to at least 185 GPa in the antiferromagnetic iridate Sr₂IrO₄, which is the archetype of a spin-orbit-driven Jₑₛₛ = 1/2 insulators. This study shows the electrical resistance of single-crystal Sr₂IrO₄ decreases initially with pressure, then reaches a minimum in the range, 32 - 38 GPa, and is followed by a rapid rise to fully recover the insulating state (~10⁷ W) with further pressure increases up to 185 GPa. The onset of the rapid increase in resistance is accompanied by a structural phase transition from the native tetragonal I₄₁/aₐcd phase to an orthorhombic Pbca phase (with much reduced symmetry) at 40.6 GPa, according to our synchrotron x-ray diffraction and Raman scattering data. This close correlation explains the existence of the rare insulating state at megabar pressures: the pressure-induced, severe structural distortions prevent expected metallization, despite a 26% volume compression in Sr₂IrO₄ at the highest pressure accessed in this experiment. It is striking that the high electrical resistance remains essentially unchanged with a tripling of very high pressure range from 61 GPa to 185 GPa.

4:42PM J03.00010: Pressure-Induced novel properties in Several Topological Materials.  XIANGANG WAN (Presenter), Nanjing Univ — Topological materials, exemplified by the topological insulators and nodal semimetals, showcase intriguing physical properties which could not emerge had electrons been classical particles. Recently the effect of high pressure on these materials has also attracted much attention. We will discuss our results in several topological materials.
4:54PM J03.00011: Hydrostatic pressure effect on several superconductors: 1T- & 2H-Ta(S,Se)₂ and (Ba, Sr)Bi₃  BOSEN WANG (Presenter), JINGUANG CHENG, Chinese Academy of Sciences, Institute of Physics, YUPING SUN, High Magnetic Field Laboratory, Chinese Academy of Sciences, Hefei, YOSHIYA UWATOKO, Institute for Solid State Physics, University of Tokyo — Under high hydrostatic pressure in Cubic Anvil Pressure Apparatus, we revealed the universal phase diagram of superconductivity and charge density wave (CDW) for 1T- and 2H-Ta(S,Se)₂ by electrical transport and ac susceptibility. For 1T-, CDWs and SC coexists in narrow pressure windows and superconducting transition temperature (T_c) increases monotonously, clarifying that the superconducting cooper-pairing is associated with CDW instability [1, 2]. For 2H-, CDWs and SC coexists in a real space and T_c tends to saturation at critical pressures. Possible physical mechanisms are proposed. Besides, we firstly reported pressured-induced crossover from Type-II to Type-I superconductivity in spin-orbit-coupled SCs (Ba, Sr)Bi₃ [3].

J03.00012: High-pressure synthesis and pressure-induced spin, charge and lattice transitions of PbCoO₃  YOUWEN LONG (Presenter), Chinese Academy of Sciences — By using a peculiar high-pressure and high-temperature method, we for the first time prepared PbCoO₃ [1]. It crystallizes into an A-site and B-site ordered quadruple perovskite structure with space group of Pn-3. The charge combination is confirmed to be Pb²⁺Pb⁴⁺₃Co²⁺₂Co³⁺₃O₁₂, where the Co²⁺ is high spin while the Co³⁺ is low spin. Although only Co²⁺ is magnetic, the compound experiences two antiferromagnetic transitions. More interestingly, when external pressure is applied, the high spin Co²⁺ gradually changes to low spin with pressure up to 15 GPa. Between 15 and 30 GPa, the intermetallic charge transfer occurs between Pb⁴⁺ and Co²⁺. The accumulated charge-transfer effect triggers a metal-insulator transition as well as a first-order structural phase transition toward a Tetra.-I phase at ~20 GPa near room temperature. On further compression over 30 GPa, the charge transfer completes, leading to another first-order structural transformation toward a Tetra.-II phase and the reentrant electrical insulating behavior.

J03.00013: Computational prediction of correlated iron compounds at high pressure and experimental synthesis  DUCK YOUNG KIM (Presenter), HPSTAR (Beijing) — Iron is one of key elements in our contemporary technology and the backbone element of the Earth. Study on pure iron and iron-compounds in extreme conditions is important and finding new iron compounds is particularly of our interest. In this talk, I will present recent progress in finding new iron compounds at high pressure. Computationally we used ab initio structure searching strategies to predict the compositions and crystal structures based on density functional theory, which were successfully synthesized by experiments [1,2]. Dynamic mean field theory provides more precise description for the electronic structure of the predicted compounds by revealing metal-insulator transition, and spin transition induced by pressure [3, 4]. I will also discuss possible implications for geoscience of these studies [5].

Session J04 DCP DCOMP DBIO DSOFT: Water Dynamics in Different Environments: Experiment and Theory IV. Bulk Water and Solute Hydration 109 - Radha Boya, Univ of Manchester - Tag(s): Focus
2:30PM J04.00001: Systematic optimization of atomistic water models for molecular simulation using liquid/vapor surface tension data* [Invited] LEE-PING WANG (Presenter), YUDONG QIU, University of California, Davis, TERESA HEAD-GORDON, University of California, Berkeley, PAUL S NERENBERG, California State University, Los Angeles — The heat of vaporization is one of the most important experimental properties that is used to train the parameters of empirical potentials (force fields) commonly used to simulate molecular liquids. We investigated whether experimental surface tension measurements, which are less sensitive to quantum and self-polarization corrections, could replace the commonly used heat of vaporization data. To test this hypothesis we implemented new functionality into the automated ForceBalance optimization procedure for using surface tension data, and parameterized revised three-point and four-point rigid, fixed charge water models named TIP3P-ST and TIP4P-ST. The TIP3P-ST model reproduces the correct temperature of maximum density of water for the first time, but also leads to over-structuring of the liquid and less accurate transport properties. The TIP4P-ST model is highly accurate for a broad range of thermodynamic and kinetic properties, with similar performance compared to other recently developed four-point models. The results show surface tension to be a useful fitting property in general, especially when self-polarization corrections or nuclear quantum corrections for heat of vaporization are not readily available for molecular liquids of interest.

3:06PM J04.00002: Kosmotrope and Chaotrope Salts Influence on Water Structural Relaxation and hydrogen Bond Dynamics Investigated by Coherent Quasielastic Neutron Scattering ANTONIO FARAONE (Presenter), Center for Neutron Research, National Institute of Standards and Technology, ERKAN SENSES, Department of Chemical and Biological Engineering, Koc University, EUGENE MAMONTOV, Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory — Salts can either increase or decrease the viscosity when dissolved in water. This phenomenon has been traditionally interpreted within the classification of the solutes as kosmotropes (structure makers) and chaotropes (structure breakers), with reference to their hypothesized property of enhancing or weakening the hydrogen bond network. However, at the molecular level the distinction is less clear as both kosmotropes and chaotropes affect the structure of the surrounding water molecules. Using coherent quasielastic neutron scattering, we have investigated the dynamics of NaCl/D O and KCl/D O, NaCl being a kosmotrope and KCl being a chaotrope, respectively. By probing the dynamics of these systems at the structure factor peak, we measured how different salts affect the structural relaxation of water. At the same time, by collecting data at the second peak in the deuterium intermolecular partial structure factor, the hydrogen bond dynamics was probed. Whereas the hydrogen bonding dynamics is largely unchanged by the presence of the salts, NaCl and KCl affect the structural relaxation differently: the former slows down the dynamics whereas the latter mostly leaves the relaxation unchanged.
3:18PM J04.00003: The SCAN330 dataset of first-principles molecular dynamics simulations of water*  MICHAEL D LACOUNT (Presenter), FRANCOIS GYGI, University of California, Davis — We present the SCAN330 dataset of first-principles molecular dynamics simulations of liquid water [1] obtained using the Qbox code [2] and the SCAN meta-GGA density functional [3] at a temperature of 330 K. The dataset consists of 16 independent simulations with a cumulative duration of 696 ps. Structural properties, polarizability, infrared and Raman spectra are compared with experiment and with previous results of PBE simulations carried out at 400 K, showing a substantial improvement in all computed properties. The availability of multiple independent trajectories provides a measure of the uncertainty associated with computed spectra. All simulation data and trajectories are available at http://quantum-simulation.org and provide uncorrelated configurations for use in further investigations of the electronic structure of water.

*Supported by the Midwest Integrated Center for Computational Materials (MICCoM), as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences.

3:30PM J04.00004: Sensitizing Hydration Shells of Ions by Analyzing Water Dynamics Using High Sensitive Dielectric Spectroscopy*  DJAMILA LOU (Presenter), LUAN DOAN, HENRY J. KESTING, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — A variety of measurement techniques have provided evidence that ions and other solute molecules affect the structure and dynamics of water directly surrounding them. Most experiments use infrared spectroscopy to study the vibrational relaxation of hydration shells, which observe intramolecular vibrations. In response, we have employed a highly sensitive, high-resolution, frequency domain, MHz to THz dielectric spectrometer that is sensitive to intermolecular dynamics. We have confirmed that water dynamics over this range are best described by three Debye relaxation processes with three-time constants of 8.56, 1.1ps and 179fs. Our argument is also supported by studies of dielectric relaxation of aqueous salt solutions, which produce the same three-time constants but amplitudes that vary with solute concentration. The amplitude of each process provides information about the structure of hydration shells. While the amplitude of the first process is related to the structure of the first hydration layer, the amplitude of the second and the third are linked to the second and/or the third hydration layers. Our results shed light on the dynamics of hydration shells around solute molecules in a biologically relevant environment.

*Supported by AFOSR (FA9550-18-1-0263) and NSF (CHE-1665157).
Spatio-temporal analysis of water molecules around DNA employing extended MHz-THz spectroscopy and MD simulations

ABHISHEK K SINGH (Presenter), LUAN DOAN, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — The molecular motion of water molecules within hydration shells around DNA strongly influences its functionality. However, the structure and dynamics of water molecules in their hydration shells are still controversially discussed among the research community. The understanding developed in this regard so far, is mostly due to computational/simulation studies, with far lesser experimental investigations. Here we present a temperature-dependent study for dynamics of water molecules around salmon testes DNA, employing extended megahertz-terahertz dielectric spectroscopic technique and Fourier transform infrared spectroscopy supported by MD simulations. We have observed that water molecules are heterogeneously distributed around DNA and they can be classified as “tightly” and “loosely” bound water molecules with the relaxation times of ~500 ps and ~70 ps, respectively. We are able to locate the successive hydration layers with respect to the DNA molecule. FTIR analysis of hydrogen bond fluctuations indicates that the DNA behaves like a “chaotropoc” solute and reduces the structural order of water molecules with respect to the bulk water.

*Air Force Office of Scientific Research under award number FA9550-18-1-0263 and National Science Foundation (CHE-1665157).
The solvation of molecules in water is pivotal for a myriad of molecular phenomena and is of crucial importance to understand diverse issues such as chemical reactivity and biomolecular function. It has been shown that laser techniques in the infrared (IR) and Terahertz (THz) frequency ranges offer fundamental insights into hydration from small solutes to proteins. In bulk liquid, motions of water molecules lead to ultrafast fluctuations at femto- to pico-second time scales. Underlying molecular processes range from diffusional motions spanning nanoseconds, rattling modes of anions and cations within their solvation shells on a ps time scale, the breaking and reformation of hydrogen bonds, and includes sub-100 fs librational motions. Here we report unprecedented non-linear THz experiments on water molecules in the liquid phase. This novel finding indicate that inducing anisotropy in bulk liquids is feasible.

Strong orbital interactions of the Zundel cation $\text{H}_5\text{O}_2^+$ with hydration shell water

MARIA EKIMOVA, CARLO KLEINE, JAN LUDWIG, Max Born Inst, MIGUEL OCHMANN, Institute for Nanostructure and Solid State Physics, University of Hamburg, THOMAS A. GUSTAFSSON, Department of Physics, Stockholm University, EVE KOZARI, EHUD PINES, Department of Chemistry, Ben Gurion University of the Negev, NILS HUSE, Institute for Nanostructure and Solid State Physics, University of Hamburg, PHILIPPE WERNET, Department of Physics and Astronomy, Uppsala University, MICHAEL ODELIUS, Department of Physics, Stockholm University, ERIK T. J. NIBBERING (Presenter), Max Born Inst

We use O K-edge X-ray absorption spectroscopy in transmission to determine the electronic structure and hydrogen bond characteristics of the Zundel cation $\text{H}_5\text{O}_2^+$ in solution. $\text{H}_5\text{O}_2^+$ plays a key role in water-mediated proton transport in bulk water, hydrogen fuel cells and transmembrane proteins. For this, we elucidate spectroscopic signatures of O 1s core excitations to O-H $\sigma^*$ anti-bonding orbitals of hydrated protons. By a dedicated and previously established sample preparation procedure, we can systematically tune the hydration degree of the protons, starting from the Zundel cation solvated by acetonitrile, and exchange solvation layers with water, thus altering the hydrogen bond characteristics of $\text{H}_5\text{O}_2^+$. The significant decrease of pre- and main-edge combined with a major increase of the post-edge transition cross sections point at strong interactions of the first hydration shell water molecules with the Zundel cation. With our flatjet system for x-ray absorption spectroscopy in transmission, now successfully operating for the polar acetonitrile solvent, and in combination with previously obtained laboratory infrared spectroscopic data, we can establish a systematic structural approach to hydrated proton structures in solution.
Molten hydrate clathrates as a new class of macromolecular fluids.*

CARLOS LOPEZ-BUENO (Presenter), CIQUS, Quimica-Fisica, University of Santiago de Compostela, CARLOS HERREROS-LUCAS, CIQUS, Quimica-Inorganica, University of Santiago de Compostela, MARIUS BITTERMANN, Van't Hoff Institute for Molecular Sciences, University of Amsterdam, ALFREDO AMIGO, Fisica-Aplicada, University of Santiago de Compostela, SANDER WOUTERSEN, Van't Hoff Institute for Molecular Sciences, University of Amsterdam, MARIA DEL CARMEN GIMÉNEZ-LÓPEZ, CIQUS, Quimica-Inorganica, University of Santiago de Compostela, FRANCISCO RIVADULLA, CIQUS, Quimica-Fisica, University of Santiago de Compostela — Despite water being the most prominent liquid and a common reaction media of biological processes, the effect of hydrophobic solutes on its properties is not completely understood. For instance, apolar chains of tetrabutyl ammonium salts promote the formation of clathrate hydrates at low temperatures or high pressures. Here we demonstrate the formation of a supramolecular liquid in ≈1.4-2.2m aqueous solutions of tetrabutyl ammonium bromide. Temperature and composition dependent compressibility, FTIR, thermal conductivity and heat capacity suggest that most of water molecules are locally ordered in a liquid clathrate-like structure. This completely rearranges the tetrahedral H-bond network characteristic of bulk water and affects dramatically to its thermodynamic and transport properties. Our results suggest a new way to design macromolecular solvents with different properties than its constituents.

A New Model for the Structure and Dynamics of the Hydrated Proton in Liquid Acetonitrile and Water

EVE KOZARI, MARK SIGALOV, DINA PINES, Ben-Gurion University of the Negev, BENJAMIN PHILIPP FINGERHUT, Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, EHUD PINES (Presenter), Ben-Gurion University of the Negev — A new proton-solvation and -transport model in aqueous solutions is proposed based on our combined NMR and IR experiments and theoretical quantum-classical-molecular-dynamics findings. The H$_7^{+}$O$_3$ solvate is at the center of the emerging model of the aqueous proton transport which is based on measurements made on protonated water solvates in liquid acetonitrile up to water-cluster size of at least 12 water molecules. The existence of structurally well-defined protonated water clusters in these solutions is unequivocally verified by NMR and FTIR spectroscopies of the hydrated proton. In contrast to the gas-phase where the H$_7^{+}$O$_3$ unit is symmetric, the core H$_7^{+}$O$_3$ unit in polar liquids is characterized by a chain of 3 water molecules with asymmetrically distorted oxygen-oxygen distances due the fluctuating solvent environment which does not allow a complete isotropic solvation of the proton. Such solvent-field-induced asymmetric distortion favors a Zundel-type, dimeric active proton solvation structure within the protonated water trimer unit. The dimeric solvation structure determines the (ultrafast) IR vibrational response of the genuine proton transfer mode in the ~ 1200 cm$^{-1}$ region putting the model in harmony with recent fs-resolved 2D-IR experiments.
5:06PM J04.00010: Determination of Ion–Water Correlated Motions in Aqueous Salt Solutions*  YUYA SHINOHARA (Presenter), Oak Ridge National Lab, RAY MATSUMOTO, MATTHEW THOMPSON, Vanderbilt University, WOJCIECH DMOWSKI, CHAE WOO RYU, University of Tennessee, Knoxville, TAKUYA IWASHITA, Oita University, DAISUKE ISHIKAWA, JASRI/SPring-8, ALFRED BARON, RIKEN SPring-8 Center, PETER THOMAS CUMMINGS, Vanderbilt University, TAKESHI EGAMI, University of Tennessee, Knoxville — We report on the real-space correlated motion of water molecules and ions in an aqueous salt solution. The Van Hove functions of aqueous salt solution were determined by high-resolution inelastic X-ray scattering (IXS) spectra and molecular dynamics simulation. (Pseudo-) Partial Van Hove function was determined to identify the element-specific correlated motions. Our results depict the distance-dependent correlated dynamics in the picosecond time-scale and identify the changes in the anion–water correlations. It is found that the anion–water correlations show a two-step relaxation. The fast term depends on the anion type, while the slow term is hardly dependent on the anion type. This result indicates that the process governing the molecular/ionic connectivity between the water molecules and the anions is almost independent of the type of anions.

High-energy X-ray diffraction work and MD simulation work were supported as part of the Fluid Interface Reactions, Structures and Transport Center, an Energy Frontier Research Center funded by the U.S. DOE, Office of Science, Office of Basic Energy Sciences.

5:18PM J04.00011: Lysozyme Solution-State Tertiary Structure Measured in Protic and Aprotic Ionic Liquid Aqueous Mixtures  IAN REYES (Presenter), JOSE L BANUELOS, University of Texas, El Paso —

Aqueous protic ionic liquid (PIL) mixtures are interesting solvent media for the stabilization of proteins over wide temperature ranges, which may help develop long term protein storage methods or high temperature catalysis applications. The stabilization and shift in the thermodynamics of hen egg white lysozyme (HWL) was previously demonstrated using differential scanning calorimetry (DSC). Understanding the relation between structure and function of HWL in PIL-based media will help design improved bioprotective solvents. The tertiary structure of HWL in mixtures of PIL ethylammonium nitrate (EAN), water, and an imidazolium-based aprotic ionic liquid (APIL) were measured using small-angle x-ray scattering (SAXS) over temperatures of 25-75 °C. APIL was introduced to confirm reports that APILs destabilize proteins, and to understand the role of aqueous solvation on all the dissolved species. A structural transition of HWL was observed between 50 and 55 °C. Results from models which delineate contributions due to protein unfolding from changes due to irreversible aggregation will be presented and compared with DSC results. The impact of water content on overall miscibility was studied using light scattering methods and the resulting protein structures will be discussed.

2:30PM J05.00001: Quantum cavities and Floquet materials engineering from first principles QEDFT* [Invited] ANGEL RUBIO (Presenter), Max Planck Inst Structure & Dynamics of Matter
— An appealing and challenging route towards engineering materials with specific properties is to find ways of designing or selectively manipulate materials, especially at the quantum level. We will provide an overview of how well-established concepts in the fields of quantum chemistry and materials have to be adapted when the quantum nature of light becomes important. We will pursue the question whether it is possible to create these new states of materials as groundstates of the system. To this end we will show how the emerging (vacuum) dressed states resembles Floquet states in driven systems. A particular appeal of light dressing is the possibility to engineer symmetry breaking which can lead to novel properties of materials, e.g. coupling to circularly polarized photons leads to local breaking of time-reversal symmetry enabling the control over a large variety of materials properties (e.g. topology). We show that the new quantum electrodynamics density-functional formalism (QEDFT) can account for those effects. We illustrate the realisation of those ideas in molecular complexes and 2D materials.

3:06PM J05.00002: Investigating New Reactivities Enabled by Polariton Photochemistry*
ARKAJIT MANDAL, PENGFEI HUO (Presenter), University of Rochester — We perform quantum dynamics simulations to investigate new chemical reactivities enabled by cavity quantum electrodynamics. With quantum dynamics simulations, we demonstrate that the selectivity of a model photo-isomerization reaction can be controlled by tuning the photon frequency of the cavity mode or the light-matter coupling strength, providing new ways to manipulate chemical reactions via light-matter interaction. We further investigate collective quantum effects enabled by coupling quantized radiation mode to multiple molecules. Our results suggest that in the resonance case, a photon is recycled among molecules to enable multiple excited state reactions, thus effectively functioning as a catalyst. In the non-resonance case, molecules emit and absorb virtual photons to initiate excited state reactions through fundamental quantum electrodynamics processes. These results from quantum dynamics simulations reveal basic principles of polariton photochemistry as well as promising reactivities that take advantage of intrinsic quantum behaviors of photons.

3:18PM J05.00003: Polariton Mediated Charge Transfer Reaction through Cavity-Quantum Electrodynamics*  ARKAJIT MANDAL (Presenter), PENGFEI HUO, University of Rochester — We study the polariton mediated electron transfer in a three-state model molecular system that describes the the photoinduced charge transfer process from an optically bright donor to an optically dark acceptor. With direct quantum dynamical simulations and analytical rate expressions, we demonstrate that coupling the molecular system to the quantized radiation field in an optical cavity can significantly enhance or suppress the photoinduced charge transfer process. Moreover, we also assess the accuracy of commonly used approximations in the field of polariton photochemistry such as the rotating wave approximation and the effect of ignoring the dipole self-energy term. We find that both terms are equally important to accurately describe the charge transfer process, especially in the ultra-strong coupling regime.

*National Science Foundation (NSF) “Enabling Quantum Leap in Chemistry” program under a Grant number CHE-1836546

3:30PM J05.00004: Polaronic effects on exciton-polaritons in two-dimensional metal-halide perovskite microcavities [Invited]  CARLOS SILVA (Presenter), Georgia Inst of Tech — While polarons --- charges bound to a lattice deformation induced by electron-phonon coupling --- are primary photoexcitations at room temperature in bulk metal-halide hybrid organic-inorganic perovskites (HOIP), excitons --- Coulomb-bound electron-hole pairs --- are the stable quasi-particles in their two-dimensional (2D) analogues. Here we address the fundamental question: are polaronic effects consequential for excitons in 2D-HIOPs? Based on our recent work, we argue that polaronic effects are manifested intrinsically in the exciton spectral structure, which is comprised of multiple non-degenerate resonances with constant inter-peak energy spacing. We highlight our own measurements of population and dephasing dynamics that point to the apparently deterministic role of polaronic effects in excitonic properties. We contend that an interplay of long-range and short-range exciton-lattice couplings give rise to exciton polarons, a character that fundamentally establishes their effective mass and radius, and consequently, their quantum dynamics. Finally, we consider how the exciton spectral struture and dynamics controls exciton-polaron properties in Fabry-Perot microcavities.
A variational approach for the dynamics of triplet harvesting in the polariton regime.* LUIS ANGEL MARTINEZ MARTINEZ (Presenter), University of California, San Diego, ELAD EIZNER, STEPHANE KENA-COHEN, Department of Engineering Physics, Ecole Polytechnique de Montreal, JOEL YUEN-ZHOU, University of California, San Diego — The recent interest on the manipulation of chemical processes within confined electromagnetic environments has opened up new directions on theoretical efforts to understand the emergent dynamics of organic molecules embedded in the former. Density-matrix, wave-packet propagation, and Langevin-based approaches, among other methodologies, have been developed to get insight on the interplay between the vibrational, electronic and photonic degrees of freedom in the dynamics of these hybrid light-matter (polariton) setups. Hereby, we extent the methodology toolbox to treat these systems by presenting a variational approach applicable to different regimes of vibronic and light-matter couplings for organic molecules. We use this method to understand the influence of coupling of molecular aggregates to photon fields on triplet harvesting. Furthermore, we elaborate on the role of the the so-called dark states, on generic electronic transitions featured by organic molecules, under the strong light-matter coupling regime.

Modifying reverse intersystem crossing with cavity polaritons* FRANCESCA FASSIOLI OLSEN (Presenter), COURTNEY DELPO, BRYAN J KUDISCH, KYU HYUNG PARK, Princeton University, DANIELE FAUSTI, University of Trieste, GREG SCHOLES, Princeton University — Strong light-matter coupling gives rise to a superposition of light and matter states called polaritons. In the molecular setting, strong light-matter coupling is usually achieved when a large number of molecules is coupled to the same mode of an optical cavity. In this case, the energy structure is normally described as consisting of two distinct polaritonic states together with a large set of intermediate molecular dark states, that due to their purely molecular nature are believed to exhibit dynamics that resemble those of the bare molecular states. In this work we investigate the nature of these intermediate states and how their dynamics and optical response deviate from those of molecules outside the cavity. We apply our framework to simulate linear and non-linear optical responses of an experimentally studied system, namely 4CzIPN, to gain insight into how these intermediate states are involved in and modify intersystem crossing and reverse intersystem crossing under the strong light matter coupling regime.

4:30PM J05.00007: Multiscale Molecular Dynamics Simulations of Polaritonic Chemistry*
[Invited] GERRIT GROENHOF (Presenter), Department of Chemistry and NanoScience Center, University of Jyvaskyla, JOHANNES FEIST, Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center, Universidad Autónoma de Madrid, JUSSI TOPPARI, Department of Physics and NanoScience Center, University of Jyvaskyla — When photoactive molecules interact strongly with confined light modes in optical cavities new hybrid light-matter states form, the polaritons. These polaritons are coherent superpositions of excitations of the molecules and of the cavity mode. Because light-matter hybridization can change the potential energy surface with respect to the bare molecules, polaritons are considered a promising paradigm for controlling photochemical reactions. To gain insight into the effects of strong coupling on the reactivity of molecules, we have extended the Tavis-Jaynes-Cummings model into an all-atom hybrid quantum chemistry / molecular mechanics approach, capable of simulating thousands of molecules inside cavities. After presenting our model, we will discuss recent simulations that illustrate how the dynamics and reactivity of large ensembles of molecules are affected by their strong interaction with the confined light modes of the cavity.

5:06PM J05.00008: Polariton assisted down-conversion of photons via nonadiabatic molecular dynamics: a molecular dynamical Casimir effect* JUAN PEREZ-SANCHEZ (Presenter), JOEL YUEN-ZHOU, University of California, San Diego — Recently it has been possible to reach new regimes in which the light-matter interaction energy is comparable to electronic or vibrational energies using optical microcavities or nanostructures, giving rise to new hybrid light-matter states called polaritons. Most recent works focus on using strong light-matter coupling to change molecular processes such as photodissociation and charge and energy transfer. Here, we focus on a less addressed complementary question: can the emergent molecular dynamics be harnessed for photonic applications? We calculate the quantum dynamics of the photoisomerization of a single molecule embedded in an optical microcavity. We found that for specific cavity frequencies and sufficiently strong couplings, molecular photoexcitation into an electronic excited state can be followed by the spontaneous emission of two photons of a lower frequency via the cavity after isomerization, thus offering a new mechanism for photonic down-conversion using molecular polaritons. We show how this mechanism occurs when the light-matter coupling is strong enough so the nuclear dynamics cannot be considered to be adiabatic with respect to the electronic and photonic degrees of freedom.

5:18PM J05.00009: Cavity controlled inverse harmonic generation  DAVIS DAVE WELAKUH  (Presenter), MARY-LEENA MARTINE TCHENKOUE DJOUOM, MICHAEL RUGGENTHALER, HEIKO APPEL, ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter — Interaction between quantized light and matter lies at the heart of a broad range of applications, such as frequency down-conversion in ultrastrong cavity QED [1]. Frequency down-conversion schemes are often treated with few-level approximations of the matter subsystem. In the present work, we consider the case of a semiconductor quantum ring described in real space coupled to more than one mode and investigate a down-conversion process. We show that the down-converted photons have unique features such as non-classicality and entanglement. In addition, we show shortcomings of few-level approximations and mean-field theory. An interesting outcome for down-conversion is that ultrastrong coupling is more efficient than just increasing the incoming field strength.

Session J06 DLS: Ultrafast Dynamics and Control of Quantum Materials 113 - Tag(s): Focus

2:30PM J06.00001: Terahertz through X-ray Control and Measurement of Quantum Material Dynamics [Invited]  KEITH NELSON (Presenter), Chemistry, MIT — This is for an APS-DLS FOCUS SESSION. The focus session is "Ultrafast Dynamics and Control of Quantum Materials"

This invited talk is to be given by Prof. Keith Nelson of MIT, who is a leader in the field of dynamics in complex materials.
3:06PM J06.00002: Magnetic symmetry breaking driven by photoinduced piezomagnetism*
ANKIT DISA (Presenter), MICHAEL FECHNER, BIAOLONG LIU, TOBIA NOVA, MICHAEL FOERST, Max Planck Institute for the Structure and Dynamics of Matter, PAOLO G. RADAELLI, Department of Physics, University of Oxford, ANDREA CAVALI, Max Planck Institute for the Structure and Dynamics of Matter — Symmetries govern the macroscopic behavior of solids and dictate how their properties can be controlled by external fields. Resonantly driving optical phonons offers the possibility to coherently manipulate symmetry and induce new functional properties away from equilibrium. Here, we demonstrate magnetic symmetry breaking by light leading to an induced ferrimagnetic phase in the classical antiferromagnet CoF$_2$. We utilize high-intensity terahertz pulses to simultaneously excite degenerate in-plane phonon modes and observe the resulting magnetization dynamics by optical Faraday rotation and circular dichroism. We find that the excitation generates a net c-axis magnetization on the picosecond time scale, evidencing an ultrafast magnetic phase transition. First-principles calculations show that the effect is driven by a novel photoinduced piezomagnetic effect, in which anharmonic phonon dynamics uncompensate the equilibrium antiferromagnetic order via a site-selective modulation of the crystal field. This rare example of photoinduced symmetry breaking provides a new mechanism for magnetic control, which could also be used for manipulating spins at heterointerfaces and engineering magnetoelectric phenomena by light.

3:18PM J06.00003: Distinguishing Intrinsic from Extrinsic Effects in Time-resolved Photoemission*
PATRICK KIRCHMANN (Presenter), SIMES, SLAC - Natl Accelerator Lab, HEIKE PFAU, Lawrence Berkeley National Laboratory, JONATHAN A SOBOTA, SIMES, SLAC - Natl Accelerator Lab, HADAS SOIFER, School of Physics and Astronomy, Tel Aviv University, NICOLAS GAUTHIER, SIMES, SLAC - Natl Accelerator Lab, KEJUN XU, HONGYU XIONG, SHUJIE TANG, Geballe Laboratory for Advanced Materials, Stanford University, COSTEL R. ROTUNDU, ZHIXUN SHEN, SIMES, SLAC - Natl Accelerator Lab — Time- and angle-resolved photoemission is becoming established as a powerful tool for the study of nonequilibrium electron dynamics in quantum materials. With the proliferation of this technique it is important to develop a robust understanding of the method itself. I will discuss how electron dynamics that are intrinsic to the sample can be distinguished from generic electron dynamics that are extrinsic. This includes apparent binding energy shifts due to surface photovoltage, and shifts and broadening due to pump-induced vacuum space charge.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
3:30PM J06.00004: Tuning time and energy resolutions in time- and angle-resolved photoemission spectroscopy*  ALEXANDRE GAUTHIER (Presenter), Geballe Laboratory for Advanced Materials, Stanford University, JONATHAN A SOBOTA, NICOLAS GAUTHIER, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, KEJUN XU, Geballe Laboratory for Advanced Materials, Stanford University, HEIKE PFAU, Lawrence Berkeley National Laboratory, COSTEL R. ROTUNDU, ZHIXUN SHEN, PATRICK KIRCHMANN, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — Time- and angle-resolved photoemission is a powerful probe of nonequilibrium band structures. Time and energy resolution are two important parameters which determine the range of possible measurements. We demonstrate tunable time and energy resolutions by adjusting the thickness of nonlinear BaB\textsubscript{2}O\textsubscript{4} crystals commonly used to generate 6 eV pulses from a 1.5 eV fundamental. We tune the time resolution between 58 and 103 fs and obtain corresponding energy resolutions of 55 to 27 meV, maintaining a time-bandwidth product under 150% of the Fourier limit. Calculations clarify the interactions between laser bandwidth and nonlinear crystal thickness which contribute to determining experimental resolutions.

3:42PM J06.00005: Time-resolved ARPES study on Ta\textsubscript{2}NiSe\textsubscript{5}  TAKESHI L. SUZUKI (Presenter), Univ of Tokyo-Kashiwanoha, YASUSHI SHINOHARA, School of Engineering, Univ. of Tokyo, YANGFAN LU, Dept. of Science, Univ of Tokyo, MARI WATANABE, JIADI XU, Univ of Tokyo-Kashiwanoha, KENICHI L. ISHIKAWA, School of Engineering, Univ. of Tokyo, HIDE TAKAGI, Dept. of Science, Univ of Tokyo, MINORU NOHARA, Research Institute for Interdisciplinary Science, Okayama University, NAOYUKI KATAYAMA, HIROSHI SAWA, Department of Applied Physics, Nagoya University, MASAMI FUJISAWA, TERUTO KANAI, NOBUHISA ISHII, JIRO ITATANI, Univ of Tokyo-Kashiwanoha, TAKASHI MIZOKAWA, School of Advanced Science and Engineering, Waseda University, SHIK SHIN, KOZO OKAZAKI, Univ of Tokyo-Kashiwanoha — Ta\textsubscript{2}NiSe\textsubscript{5} has been long proposed as an excitonic insulator, in which remarkable band flattening below the structural transition temperature at 328 K, as a result of the strong Coulomb attractive interactions between the conduction and valence bands. Recently, photo-excitation has been intensively used to explore non-equilibrium phases. Our previous result also confirms that Ta\textsubscript{2}NiSe\textsubscript{5} is an excitonic insulator from the characteristic dynamical behavior [1]. In this work, we have used time-resolved ARPES (TARPES) to investigate the photo-excited non-equilibrium phases in Ta\textsubscript{2}NiSe\textsubscript{5}. We have discovered that intense photo-excitation induce a transient semimetallic state, which could not be realized under equilibrium. In order to gain insight on the mechanism of this phase transition, we have pursued the TARPES measurements with better signal-to-noise ratio enabled by use of the higher repetition rate laser system. We have observed oscillating behaviors corresponding to the coherent phonons in the ARPES intensity maps, which allowed us to identify which phonon mode is relevant to the metallization.
3:54PM J06.00006: Light-driven ultrafast phonomagnetism* DMYTRO AFANASIEV, JORRIT HORTENSIIUS (Presenter), Delft University of Technology, BORIS IVANOV, National Academy of Sciences and Ministry of Education and Science, ALIREZA SASANI, ERIC BOUSQUET, University of Liège, YAROSLAV M. BLANTER, Delft University of Technology, ROSTISLAV MIKHAYLOVSKIY, Lancaster University, ALEXEY KIMEL, Radboud University Nijmegen, ANDREA CAVIGLIA, Delft University of Technology — Over the past few decades, ultrashort pulses of light have been widely employed to control the behavior of matter in its different phases. This is a particularly interesting challenge in magnetism, where the speed, dissipation and routes for ultimately fast switching of the spin orientation often lead to proposals for novel approaches in information processing and data recording. [1] In this work we control the magnetic state by resonantly pumping optical phonons, low-energy elementary vibrations of the crystalline lattice. We demonstrate that by exciting the crystal lattice of the prototypical antiferromagnetic DyFeO$_3$, it can be driven within picoseconds into a transient metastable magnetic state. The state is characterized by a change in the strength of magnetic anisotropy along different crystal axes. This is experimentally seen as a long-lived shift in the frequency of the spin precession driven along the corresponding axes. For sufficiently strong excitation, this promotes an instability of the initial magnetic structure and launches a spin reorientation transition within a few picoseconds.

*This work was partially supported by the EU through the European Research Council, grant No. 677458 (AlterMateria)

4:06PM J06.00007: Absence of amplitude mode softening of intermediate states in the charge density wave material 1T-TaSe$_2$ WENJING YOU (Presenter), XUN SHI, YINGCHAO ZHANG, YIGUI ZHONG, ZHENSHENG TAO, University of Colorado, Boulder, MICHAEL BAUER, KAI ROSSNAGEL, Kiel University, HENRY KAPTEYN, MARGARET MURNANE, University of Colorado, Boulder — Recently, we uncovered new long-lived metastable charge density wave (CDW) states in 1T-TaSe$_2$ that are launched by an ultrafast laser pulse [1]. Moreover, the transitions from CDW to metastable to normal phases exhibit second order phase transition behaviors with continuously tunable order parameters, although it is a first order transition under thermal-equilibrium conditions. Ultrafast light-induced phase transitions thus extend the phase diagram of strongly-coupled materials, allowing us to access new states which are unreachable by chemical doping or by varying the temperature. In order to further understand the nature of these new metastable intermediate states, a second weak pump pulse is applied to probe their properties. Surprisingly, the CDW amplitude mode frequency of all intermediate states (between the CDW and normal states) is the same as that of CDW state - and vanishes only when the material reaches the normal state. This abrupt change of phonon mode frequency, reveals an exotic interatomic potential that may be intrinsic to the first-order nature of the phase transition in equilibrium. Our results provide new insight in understanding the formation and nature of ultrafast laser- induced metastable states.

4:18PM J06.00008: Universal dynamics of order parameter fluctuations in pump-probe experiments  
PAVEL DOLGIREV (Presenter), MARIOS MICHAEL, Harvard University, ALFRED ZONG, NUH GEDIK, Physics, MIT, EUGENE DEMLER, Harvard University — Upon excitation by a laser pulse, broken-symmetry phases of a wide variety of solids demonstrate similar order parameter dynamics characterized by a dramatic slowing down of relaxation for stronger pump fluences. Motivated by this recurrent phenomenology, we develop a simple non-perturbative effective model of dynamics of collective bosonic excitations in pump-probe experiments. We find that as the system recovers after photoexcitation, it shows universal prethermalized dynamics manifesting a power-law, as opposed to exponential, relaxation, explaining the slowing down of the recovery process. For strong quenches, long-wavelength over-populated transverse modes dominate the long-time dynamics; their distribution function exhibits universal scaling in time and space, whose universal exponents can be computed analytically. Our model offers a unifying description of order parameter fluctuations in a regime far from equilibrium, and our predictions can be tested with available time-resolved techniques.

4:30PM J06.00009: Ultrafast nonlinear excitation of collective modes in iron pnictides by intense terahertz pulses  
CHIRAG VASWANI (Presenter), DIN HERATH MUDIYANSELAGE, Iowa State University, JONG-HOON KANG, University of Wisconsin - Madison, MARTIN MOOTZ, University of Alabama at Birmingham, XU YANG, Iowa State University, ILIAS PERAKIS, University of Alabama at Birmingham, CHANG-BEOM EOM, University of Wisconsin - Madison, JIGANG WANG, Iowa State University — Nonlinear terahertz (THz) spectroscopy has been a promising tool for the study of collective excitations in superconductors, as demonstrated by the observation of Higgs mode and Leggett mode in BCS superconductors with phonon-assisted pairing. The nonlinear nature of the excitation is essential as these modes arise from exotic symmetries and do not linearly couple to the electromagnetic field. Unconventional superconductors with strong inter-band pairing channels and multiple spin/charge fluctuations are expected to host new and rich collective excitations which have not yet been explored. Here we report the observation of collective modes in iron pnictides excited by intense THz pulses. The modes diminishes at both high temperatures and field strengths when there is strong quenching of the superconducting coherence. Our results clearly show out of equilibrium driving of multiband superconducting systems can induce nonlinear couplings between collective excitations of order parameters, leading to the formation of novel phase.
**4:42PM J06.00010: Experimental observation of phonon- and band-specific electron-phonon coupling in a topological semi-metal**

NICOLAS GAUTHIER (Presenter), Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, HADAS SOIFER, School of Physics and Astronomy, Tel Aviv University, ALEXANDRE GAUTHIER, Geballe Laboratory for Advanced Materials, Stanford University, EDBERT JARVIS SIE, AARON LINDENBERG, PATRICK KIRCHMANN, ZHIXUN SHEN, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — Light excitation of quantum materials can drive phase transitions such as insulator-to-metal transitions or the melting of magnetic orders. It can also lead to ultrafast topological phase transitions, as it was demonstrated recently in the topological semi-metal WTe$_2$ using ultrafast electron diffraction [1]. The photoinduced transition in this system occurs when a shear phonon mode is driven sufficiently strongly to recover the inversion symmetry of the lattice. In this context we studied the electron dynamics of WTe$_2$ using time- and angle-resolved photoemission spectroscopy. We report the observation of band oscillations at four different frequencies that are due to $A_{1g}$ coherent phonon modes and include the shear mode causing the photoinduced topological transition. By isolating the effect of each phonon on the different electronic bands, we reveal the complexity of electron-phonon coupling in the electronic band structure.

**4:54PM J06.00011: Light-induced coherent modulation of the electrons and lattice in a charge density wave material**

XUN SHI (Presenter), WENJING YOU, YINGCHAO ZHANG, ZHESHENG TAO, YIGUI ZHONG, University of Colorado, Boulder, XIANXIN WU, RONNY THOMALE, University of Wurzburg, FAIROJA CHEENICODE KABEER, PABLO MALDONADO, PETER OPPENEER, Uppsala University, MICHAEL BAUER, KAI ROSSNAGEL, University of Kiel, HENRY KAPTEYN, MARGARET MURNANE, University of Colorado, Boulder — Ultrashort light pulses can selectively excite charges, spins and phonons in materials, providing a powerful approach for manipulating their properties. In this work, we use time- and angle-resolved photoemission spectroscopy to show that a femtosecond laser pulse can coherently modulate the electrons and lattice in the charge density wave (CDW) material $1T$-TaSe$_2$ [1, 2]. These intertwined electron-phonon dynamics are launched by displacive excitation of the CDW amplitude mode, and provide unique opportunities to capture mode-specific electron-phonon couplings, interatomic potentials, and hidden phases that are inaccessible using equilibrium excitation. Surprisingly, we observe a coherent modulation of the electron temperature/occupation at the amplitude mode frequency, that is synchronized to the modulation of the Ta $5d$ band (CDW order). Then, as we increase the laser fluence to drive the material into a metastable state mediated by mode-selective electron-phonon coupling, this oscillation exhibits a phase change of $\pi$, indicating a competition between different interactions. This approach can be extended to other complex materials, to steer strongly-coupled quantum materials towards a desired state using light.

5:06PM J06.00012: Towards a Many Body Theory for Fourier Transform Inelastic X-Ray Scattering Experiments in Correlated Materials*  RYAN NESSELRODT (Presenter), JAMES FREERICKS, Georgetown University — In recent years new ultrafast x-ray sources have enabled the probing of materials at previously inaccessible time and length scales, allowing for new insights into phonon populations and dynamics far from equilibrium through direct time domain measurements. As these experiments improve, classical descriptions of phonons, particularly in correlated materials, will be pushed to their limits. With this in mind we seek to develop a fully quantum mechanical, many-body theory for ultrafast pump-probe scattering experiments that accounts for electron-phonon coupling and electronic correlations that can inform and inspire experiments. A new theory could help us gain better insight into exotic nonequilibrium states in correlated materials, superconductivity, as well as lead to a better understanding of charge and heat transport under normal operating conditions in current and new devices.

*This work was supported by the Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering, under contract No. de-sc0019126.

5:18PM J06.00013: Ultrafast Nonlinear Optical Spectroscopy of the Charge Density Wave in 1T-TaS2  XIANGPENG LUO (Presenter), WENCAN JIN, Univ of Michigan - Ann Arbor, SANG-WOOK CHEONG, Physics & Astronomy, Rutgers University, LIUYAN ZHAO, Univ of Michigan - Ann Arbor — Nonlinear optics has recently emerged as an appealing symmetry-sensitive probe for revealing and investigating exotic quantum phases of matter, in addition to its more traditional application in determining crystalline structures. Here, we report using temperature-dependent and time-resolved nonlinear optical techniques to study the 1T polytype of TaS$_2$, an intensively-studied prototypical system hosting the charge density wave (CDW) order. We show that an enhancement of broken mirror symmetry is identified across the nearly commensurate to commensurate CDW transition by rotation anisotropy second harmonic generation (RA SHG). We then report the ultrafast responses of commensurate CDW to optical excitations, using both time-resolved reflectivity and time-resolved RA SHG. The excitation fluence dependence of the commensurate CDW phase will further be discussed.
2:30PM J07.00001: Design and Fabrication of Impedance Matched Parametric Amplifiers for Quantum Applications*  
JOEL GREBEL (Presenter), AUDREY BIENFAIT, HUNG-SHEN CHANG, MING-HAN CHOU, CHRISTOPHER R CONNER, Pritzker School of Molecular Engineering, University of Chicago, ETIENNE DUMUR, Argonne National Laboratory, GREGORY PEAIRS, Department of Physics, University of California, Santa Barbara, RHYS G POVEY, YOUPENG ZHONG, Pritzker School of Molecular Engineering, University of Chicago, ANDREW CLELAND, Pritzker School of Molecular Engineering, University of Chicago, Argonne National Laboratory — Josephson parametric amplifiers (JPAs) are an important resource for the single-shot readout of superconducting qubits. Being able to amplify signals at the quantum limit, with noise approaching 1/2-photon for phase-independent gain [1], enables high fidelity measurements of single as well as multiplexed qubits. We will describe the circuit designs and fabrication process for on-chip impedance matched lumped-element JPAs ([2], [3]) operated in both three-wave and four-wave mixing modes. We will present data on the devices’ gain, saturation power, and bandwidth. Key improvements from the previous year’s design will be discussed as well as practical advice for ensuring reliable performance in the cryogenic environment.

2:42PM J07.00002: Josephson Array Mode Parametric Amplifier*  
VOLODYMYR SIVAK (Presenter), SHYAM SHANKAR, GANGQIANG LIU, Yale University, JOSE AUMENTADO, National Institute of Standards and Technology, MICHEL H. DEVORET, Yale University — We introduce a novel near-quantum-limited amplifier with a large tunable bandwidth and high dynamic range – the Josephson Array Mode Parametric Amplifier (JAMPA). The signal and idler modes involved in the amplification process are realized by the array modes of a chain of 1000 flux tunable, Josephson-junction-based, nonlinear elements. The frequency spacing between array modes is comparable to the flux tunability of the modes, ensuring that any desired frequency can be occupied by a resonant mode, which can further be pumped to produce high gain. We experimentally demonstrate that the device can be operated as a nearly quantum-limited parametric amplifier with 20dB of gain at almost any frequency within (4−12)GHz band. On average, it has a 3dB bandwidth of 11MHz and input 1dB compression power of −108dBm, which can go as high as −93dBm. We envision the application of such a device to the time- and frequency-multiplexed readout of multiple qubits, as well as to the generation of continuous-variable cluster states.

2:54PM J07.00003: Frequency Tunable Josephson Traveling Wave Parametric Amplifier with Nondegenerate Pump Phase Matching  Kaidaong Peng (Presenter), Mahdi Naghloo, Kevin O’Brien, Massachusetts Institute of Technology MIT — Resonantly phase-matched Josephson traveling wave parametric amplifiers (JTWPs) with gigahertz of bandwidth and near-quantum limited noise performance are now widely used in superconducting quantum computing experiments. For such conventional single-pump JTWPs, resonators are critical to cancel phase mismatch from both the normal group velocity dispersion and the nonlinear phase modulations. However, these resonators make up half of the device footprint, require high fabrication uniformity, and fix the device operating frequency. Here we develop a resonator-free, dual-pump JTWPA with a reduced footprint, wider bandwidth, but comparable gain, dynamic range, and noise performance. In contrast to the resonant phase matching technique, our dual-pump scheme generates a linear phase mismatch which naturally compensates the nonlinear phase mismatch. In addition to their larger fabrication tolerance, these dual-pump JTWPs have dynamically reconfigurable frequency bands controlled by the frequency detuning of the two pumps. These devices will open up new possibilities for tunable amplification, both phase sensitive and preserving, applicable to cQED and higher-frequency cosmological applications.

3:06PM J07.00004: Minimal manifestation of Kerr-mediated frequency combs in superconducting circuits*  Pinlei Lu (Presenter), Department of Physics and Astronomy, University of Pittsburgh, Saeed Khan, Department of Electrical Engineering, Princeton University, Tzu-Chiao Chien, Xi Cao, Department of Physics and Astronomy, University of Pittsburgh, Hakan Türeci, Department of Electrical Engineering, Princeton University, Michael Jonathan Hatridge, Department of Physics and Astronomy, University of Pittsburgh — In this presentation, we present an experimental realization of a coherently driven, Kerr-mediated, microwave frequency comb. Our device consists of two superconducting modes: a mode with modest Kerr-nonlinearity strongly coupled to a second, linear mode. We explore the phase space of the two-mode system, including the transition from a stable regime to a region where the system settles into limit cycle dynamics exhibiting a frequency comb [1]. Temporal correlation function measurements reveal it is highly coherent, with a phase coherence as 30 μs, significantly exceeding the bare mode decay times of 15 ns. Additionally, in contrast to standard optical comb devices the comb’s coherence is strongly influenced by quantum fluctuations due to the intrinsic Kerr nonlinearity of the system. This result is further supported by excellent agreement of comb coherence and dynamics measurements with a microscopic quantum theory of the two-mode system. The combination of strong and engineerable interactions in our system makes it a promising platform for engineering spectrally broader and denser microwave frequency combs, and also a good testbed for studying complex quantum nonlinear dynamics.

3:18PM J07.00005: Impedance-matched Josephson parametric amplifier using open stubs as shunt capacitance*  YOSHIRO URADE (Presenter), KUN ZUO, RIKEN, KUNIHIRO INOMATA, National Institute of Advanced Industrial Science and Technology, ZHIRONG LIN, Shanghai Institute of Microsystem and Information Technology, TSUYOSHI YAMAMOTO, NEC Corporation, YASUNOBU NAKAMURA, RIKEN — Broadband Josephson parametric amplifiers (JPAs) are essential devices for frequency-multiplexed readout of integrated superconducting qubits towards large-scale quantum computers. Lumped capacitors such as parallel-plate capacitors are often used for such broadband JPAs to bring LC resonance with Josephson inductances to the GHz frequency region. Fabricating insulating layers of the parallel-plate capacitors makes fabrication process complex and causes additional dielectric losses.

In this presentation, we show that open stubs (open-circuited transmission lines connected at one end) can be used as shunt capacitances for JPA resonators. Such distributed elements are implemented by planar structures and thus have advantages over parallel-plate capacitors in terms of fabrication simplicity and dielectric loss. Using the open-stub structure, we experimentally demonstrate a broadband flux-driven JPA device based on impedance-matching technique, which operates at around 10 GHz with an instantaneous bandwidth of 300 MHz and saturation input power of -110 dBm.

3:30PM J07.00006: Four-port directional parametric amplifier*  VIDUL JOSHI (Presenter), GANGQIANG LIU, ANDREW LINGENFELTER, SHYAM SHANKAR, MICHEL H. DEVORET, Yale University — Quantum limited parametric amplifiers based on Josephson junctions are important for measurement of superconducting qubits. Traditionally, these are reflection amplifiers which need external non-reciprocal elements to separate the input from the output. It is possible however, to make multi-mode circuits and drive multiple parametric processes together to achieve non-reciprocity. Three-mode devices based on these techniques that have been made so far have either lacked output matching or provide unity reverse gain, thus relying on perfectly well matched and thermalized output lines. Adding a fourth mode can solve these issues and can help us build a fully directional parametric amplifier. We present the design and experimental progress towards realizing such a four-mode device which under appropriate drive conditions would act like an amplifier which has appreciable forward gain, has perfect isolation, is input- and output-matched and has an auxiliary port which acts as the cold load.

*Work supported by: ARO, ONR, AFOSR, and YINQE
3:42PM J07.00007: Pump-power-efficient 3-wave mixing Josephson parametric amplifier*  
WEI DAI (Presenter), VOLOYMDYR SIVAK, GANGQIANG LIU, SHYAM SHANKAR, MICHEL H. DEVORET,  
Yale University — Josephson Parametric Amplifiers (JPAs) are commonly used in superconducting  
quantum information processing. In linear amplification regime, a JPA typically requires pump  
that is orders of magnitude stronger than its output power. Larger signal power handling of a JPA  
would require application of even stronger pump. However, maximum pump power delivered to  
a JPA, which is proportional to power dissipated in attenuators, is limited by cooling power of  
dilution fridges. To address this limitation, we apply on-chip impedance engineering to enable  
strong coupling of the off-resonance pump to a 3-wave-mixing JPA. Compared to similar JPAs with  
a capacitively coupled pump port or mutual-inductively coupled flux-pumping, this design  
requires at least an order of magnitude less pump power, while achieving theoretically quantum-  
limited amplification with state-of-the-art dynamic range. Preliminary experimental results will be  
shown.

3:54PM J07.00008: Optimizing Josephson-Ring-Modulator-based Josephson Parametric  
Amplifiers via full Hamiltonian control*  
CHENXU LIU (Presenter), TZU-CHIAO CHIEN, MICHAEL  
JONATHAN HATRIDGE, DAVID PEKKER, Department of Physics and Astronomy, Univ of Pittsburgh — A  
Josephson Parametric Amplifier (JPA) with a large saturation power is an essential  
ingredient to achieve efficient quantum sensing and qubit readout in superconducting  
quantum computing circuits. In a previous work, we showed that the saturation power of  
JPAs is not limited by pump depletion, but instead by the strong nonlinearity of Josephson  
junctions, the nonlinear circuit elements that enables amplification in JPAs [1]. Here, we  
present a systematic study of the nonlinearities in JPAs, we show which nonlinearities  
limit the saturation power, and present a strategy for optimizing the circuit parameters  
for achieving the best possible JPA. For concreteness, we focus on JPAs that are  
constructed around a Josephson Ring Modulator (JRM). We show that by tuning the  
external and shunt inductors, we should be able to take the best experimentally available  
JPAs and improve their saturation power by ~ 15dB. Finally, we argue that our methods  
and qualitative results are applicable to a broad range of JPAs with few-Josephson  
junctions like SNAILs.  
*We acknowledge support from the ARO, LPS, and PQI
4:06PM J07.00009: Dependence of Kerr nonlinearity on junction array size in Josephson parametric amplifiers*  GANGQIANG LIU (Presenter), VOLODYMYR SIVAK, SHYAM SHANKAR, LUIGI FRUNZIO, MICHEL H. DEVORET, Yale University — Josephson parametric amplifiers have become indispensable components of superconducting quantum computing devices. However, their gain saturation power, which is limited by Kerr nonlinearity of Josephson junctions, is still too low for large scale readout. One way to suppress the Kerr nonlinearity, therefore improving the gain saturation power, is to replace the single Josephson element with an array of such elements. We investigate the dependence of Kerr nonlinearity on the array size under realistic fabrication constraints. We find the suppression of Kerr nonlinearity is sub-linear in array size for amplifiers with tens to hundreds Josephson element. We believe such a weak dependence accounts for the fact that arraying has not yet brought significant improvement of the dynamic range in Josephson parametric amplifiers.

4:18PM J07.00010: A quantum state router based on parametrically driven photon exchange*  CHAO ZHOU (Presenter), PINLEI LU, Univ of Pittsburgh, MATTHIEU PRAQUIN, École Normale Supérieure (Paris), XI CAO, RYAN KAUFMAN, ROGER MONG, DAVID PEKKER, MICHAEL JONATHAN HATRIDGE, Univ of Pittsburgh — Precisely controlled couplings between qubits are a vital part of all quantum information processing. For superconducting qubits, most efforts seek to implement a “surface code” architecture, which only couples nearest-neighbor qubits. However, longer range couplings are very desirable as they reduce the overhead of interactions between distant qubits. We present a design that can realize long range couplings between qubits through a modular quantum router. The design contains a 3D superconducting waveguide ‘trunk’ of microwave modes and a Superconducting Nonlinear Asymmetric Inductive eElement (SNAIL) to generate parametric photon exchange couplings between each pair of modes. We couple individual modules via a communication cavity deliberately detuned from a corresponding waveguide mode, with resulting (weaker) parametric couplings directly from module to module. Quantum information is exchanged between modules by driving the SNAIL at the difference of the communication modes’ frequencies. We will present a theory treatment of our router’s performance, as well as experimental results from our realization in an aluminum waveguide prototype.

*This work is supported by the ARO, LPS, NSF and the Kauffman foundation.
4:30PM J07.00011: Superconducting Parametric Cavities as an “Optical” Quantum Computation Platform  JIMMY SHIH-CHUN HUNG (Presenter), CHUNG WAI SANDBO CHANG, A.M. VADIRAJ, IBRAHIM NSANZINEZA, C.M. WILSON, Institute for Quantum Computing and Electrical and Computer Engineering, University of Waterloo — Quantum information may be encoded into systems of discrete variables (DV) or continuous variables (CV). CV quantum computation has typically been studied at optical frequencies using linear quantum optics to realize Gaussian operations. To achieve universal computation, however, non-Gaussian resources such as the photon number measurements or the cubic phase state are necessary. In superconducting circuits, DV quantum computation is dominant. Here, we propose and study the superconducting parametric cavity for optical quantum computation using microwave photons. At optical frequencies, the qumodes are often separated spatial modes. Here we use the orthogonal frequency modes of the cavity. Gaussian operations between the modes are achieved via standard parametric interactions. In addition, the recent realization of three-photon spontaneous parametric downconversion in this system provides access to both a non-Gaussian gate and resource state, which provides a path to universality. We will present preliminary results towards the development of the parametric cavity for optical quantum computation starting with demonstrations of simple algorithms. One such algorithm is a quantum machine learning algorithm called Quantum Kitchen Sinks.

4:42PM J07.00012: In-cavity parametric amplification for qubit readout in 3D circuit QED architecture*  ZHIXIN WANG (Presenter), VOLODYMYR SIVAK, SHANTANU O MUNDHADA, SHYAM SHANKAR, MICHEL H. DEVORET, Yale University — High-efficiency qubit readout is essential for implementing quantum feedback and remote entanglement schemes as well as studying the basic physics related to quantum measurement processes. In circuit quantum electrodynamics (QED) systems, one typically reads out superconducting qubits by monitoring the qubit-state-dependent phase shift of a microwave tone, which is first amplified by a quantum-limited parametric amplifier before being processed by classical electronics. In this configuration, readout efficiency is mainly limited by the loss between the readout microwave resonator and the parametric amplifier. The optimized arrangement is therefore to place the latter inside the former. Here we introduce a design that uses two coupled transmon artificial atoms housed in a 3D readout cavity/waveguide to perform quantum-limited amplification within the circuit QED module. Compatible with 3D cold cavity attenuators, this layout minimizes the qubit dephasing induced by residual thermal photons and can potentially achieve the single-shot readout for qubits with long coherence times. Preliminary results will be presented.

4:54PM J07.00013: Amplification with an array of lumped Josephson Parametric Converters*  
OLIVIA LANES (Presenter), TZU-CHIAO CHIEN, CHENXU LIU, Univ of Pittsburgh, ANJA METELMANN, Physics, Freie University of Berlin, DAVID PEKKER, MICHAEL JONATHAN HATRIDGE, Univ of Pittsburgh — Josephson Parametric Amplifiers, although nearly quantum-limited, suffer from lack of directionality, low saturation powers, and a fixed gain-bandwidth product. We have recently shown that when extremely strong, carefully imbalanced gain and conversion processes (GCI) are combined between a pair of modes, we produce an amplifier that has broadband, bi-directional gain in transmission and is matched at both ports. This latter feature opens the possibility of chaining GCI amplifiers together in series. We have realized an amplifier series array by chaining two Josephson Parametric Converters (JPCs) together in such a way that signal ports form the chain’s input and output and the two idlers are matched in frequency and capacitively coupled. The signal modes have deliberately different frequencies so that all parametric processes may be individually controlled. As the dynamic range of JPCs typically fall faster than linearly with gain, we can distribute gain unequally among the array elements to enhance the array’s overall saturation power. We will also use our array as a platform for studying new combinations of parametric couplings, with a particular focus on pump schemes which provide directional amplification.

5:06PM J07.00014: Experimental violation of the standard quantum limit for parametric amplification of broadband signals*  
MICHAEL RENGER (Presenter), KIRILL FEDOROV, STEFAN POGORZALEK, QI-MING CHEN, YUKI NOJIRI, MATTI PARTANEN, ACHIM MARX, FRANK DEPPE, RUDOLF GROSS, Walther-Meißner-Institut & Technische Universität München, Germany — Phase-preserving amplification of weak signals is a crucial part of many protocols in microwave quantum information processing, such as quantum teleportation, remote state preparation, or dispersive qubit readout. Flux-driven Josephson parametric amplifiers (JPAs) allow amplification close to the standard quantum limit (SQL), implying a fundamental bound of 1/2 for the maximal quantum efficiency $\eta$ for amplification of narrowband input signals. We demonstrate that the SQL does not hold for broadband input signals and experimentally find $\eta = 70\%$ with an amplification chain consisting of a JPA and a cryogenic HEMT amplifier. We show that $\eta$ can reach 100% and experimentally is limited by the Poissonian fluctuations in the JPA pump line. This result can be exploited for multiple applications such as high-efficiency parity measurements of superconducting qubits.

5:18PM J07.00015: Nonreciprocal amplification via Hamiltonian Engineering* TZU-CHIAO CHIEN (Presenter), CHENXU LIU, PINLEI LU, OLIVIA LANES, XI CAO, RYAN KAUFMAN, DAVID PEKKER, MICHAEL JONATHAN HATRIDGE, Univ of Pittsburgh — In superconducting quantum information processing, we realize high fidelity measurements by using quantum-limited parametric processes. However, cavity-based amplifiers have limited bandwidth, saturation power, and operate in reflection, and so must be operated with external lossy microwave commercial components such as circulators. Many of these limitations can be circumvented by combining multiple parametric processes in a few-mode device. By combining multiple instances of imbalanced gain and conversion processes between three modes[1], we can realize an amplifier with non-reciprocal, transmission-only amplification, matched ports, and large, gain-independent bandwidth. We have realized this scheme in a Lumped, single-ended version of the Josephson Parametric Converter (LJPC) whose inductance is dominated by the central Josephson Ring Modulator. We avoid the use of hybrids by integrating the LJPC and superconducting bandpass filters on a single chip. The resulting device is small, relatively simple to fabricate and thus an excellent candidate for direct integration into superconducting quantum computers.

2:30PM J08.00001: Simulating quantum systems on quantum computers* SEAN A FISCHER, C STEPHEN HELLBERG, MARCO LANZAGORTA-SALDANA, DANIEL GUNLYCKE (Presenter), United States Naval Research Laboratory — In this presentation, we discuss a new mapping method—called symmetry configuration mapping (SCM)—that uses the symmetry of the physical system to isolate different parts of the computational space. As well as providing robustness against state leakage, this new approach allows the computation to be separated into a set of smaller independent calculations involving fewer quantum logic gate operations and fewer qubits. For a fluorine molecule, the numbers of quantum logic gate operations and qubits are reduced by factors of 3 and 4, respectively. These reductions have allowed us to solve for the full many-body ground state on the IBM Q “Poughkeepsie” quantum computer. As long as quantum computing resources remain limited, similar target-customized mappings are expected to be employed in quantum computing across all areas of application.

*This work has been supported by the U.S. Naval Research Laboratory through Base and Naval Innovative Science & Engineering (NISE) programs.
2:42PM J08.00002: Studying many-body localization on a universal quantum computer
SONIKA JOHRI (Presenter), Intel Corp - Santa Clara, DAIWEI ZHU, NHUNG NGUYEN, CINTHIA
ALDERETE, KEVIN LANDSMAN, NORBERT M LINKE, CHRISTOPHER ROY MONROE, Physics, University
of Maryland, ANNE MATSUURA, Intel Corp - Santa Clara — An interacting disordered system may
exhibit localized or thermal behavior depending on the ratio of the disorder to interaction
strength. The study of this phenomena has been proposed as an application of near-term
quantum computers. However, it is known that most diagnostics of localization such as many-
body level statistics and the failure of the eigenstate thermalization hypothesis do not survive
coupling to a bath. One robust diagnostic theoretically known to survive introduction of noise are
the spectral functions of local operators [1]. Signatures of localization in this diagnostic include a
discrete spectrum and a gap at low frequencies. Here, we design an algorithm to compute the
spectrum on a universal quantum computer using Trotterized time-evolution. Further, we
implement the technique on a three-qubit trapped ion system and find that we can clearly
discern the vanishing of the low-frequency response as the disorder increases. Thus, we show
that for near-term quantum computers, spectral functions of local operators provide a robust
and scalable diagnostic for distinguishing between localized and thermal phases.

2:54PM J08.00003: Towards material design applications in a quantum computer
PANAGIOTIS BARKOUTSOS (Presenter), IBM Research - Zurich, FOTIOS GKRITSIS, King's College London,
IGOR SOKOLOV, PAULINE JEANNE OLLITRAULT, STEFANWOERNER, IVANO TAVERNELLI, IBM
Research - Zurich — Developing new materials for specific applications is an active field of research
for both material science and quantum chemistry communities. The number of atomic
compositions of molecular structures scales combinatorically with the size of the molecules,
limiting the efficiency of classical algorithms. On the other hand, quantum computers can provide
an efficient solution to the sampling of the chemical compound space. In this talk we propose a
quantum algorithm with favorable scaling in resource requirements, allowing for the solution of
the material design problem in currently available noisy quantum processors. The proposed
scheme divides the problem into a classical optimization and a quantum search problem within a
hybrid quantum classical algorithm. We demonstrate both in simulations (with and without
noise) and in IBMQ quantum hardware the efficiency of our scheme and highlight the results in a
few test cases. These preliminary results can serve as a basis for the development of further
material design quantum algorithms for near term quantum computers.
3:06PM J08.00004: Simulating quantum field theory in the light-front formulation*
MICHAEL KRESHCHUK (Presenter), WILLIAM KIRBY, GARY R GOLDSTEIN, PIERRE-HUGUES BEAUCHEMIN, PETER LOVE, Tufts Univ — We explore the possibility of simulating relativistic field theories in the light-front (LF) formulation and argue that such a framework has numerous advantages as compared to both lattice and second-quantized equal-time approaches. These include a small number of physical degrees of freedom leading to reduced resource requirements, efficient encoding with model-independent asymptotics, and sparse Hamiltonians. Many quantities of physical interest are naturally defined in the LF, resulting in simple measurements.

The LF formulation allows one to trace the connection between relativistic field theories and quantum chemistry, allowing one to use numerous techniques developed in the last decade. It also provides a promising application for NISQ devices, since for certain calculations one may need of an order of hundred qubits. As an example, we provide a detailed algorithm for calculating analogues of QCD parton distribution functions in a simple 1+1-dimensional model. We also discuss the generalization to QCD, and provide estimates.

3:18PM J08.00005: Simulating Dynamic Material Properties on Near-Term Quantum Computers*
LINDSAY BASSMAN (Presenter), KUANG LIU, YIFAN GENG, DANIEL SHEBIB, ARAVIND KRISHNAMOORTHY, Univ of Southern California, SHOGO FUKUSHIMA, FUYUKI SHIMOJO, Kumamoto University, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Univ of Southern California — Dynamic simulation of controllable electronic properties of materials offers insight into how to harness such tunability for use in myriad technologies. Recent successes have been achieved in computing static properties of small molecules on currently available quantum computers, however, simulating dynamical properties still remains a challenge. In this work, we demonstrate successful simulation of time-dependent magnetization in a simplified model of an atomically-thin two-dimensional material on IBM’s Q16 Melbourne quantum processor and Rigetti’s Aspen quantum processor. Near overlap between experimental results from the quantum computer and those theoretically derived from simulated noisy qubits indicates there is a good understanding of the largest sources of error currently faced on available quantum computers. This early proof-of-concept gives hope that near-future quantum computers, capable of simulating larger systems, may soon be able to give insights into the dynamic control of tunable electronic properties in material.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607.
3:30PM J08.00006: Robust Preparation of Many-body Ground States in Jaynes-Cummings Lattices

KANG CAI, PRABIN PARAJULI, Physics, University of California, Merced, CHEE WEI WONG, Electrical and Computer Engineering, University of California, Los Angeles, GUILU LONG, Physics, Tsinghua University, LIN TIAN (Presenter), Physics, University of California, Merced — Strongly-correlated polaritons in Jaynes-Cummings (JC) lattices can exhibit novel quantum phase transitions at integer fillings. However, it is often challenging to prepare such states with high fidelity, especially near the quantum critical points with a vanishing energy gap. Here we study the robust preparation of the many-body ground states of polaritons in a finite-sized JC lattice by combining the techniques of quantum state engineering and adiabatic evolution. In the deep Mott-insulating or deep superfluid regimes, the many-body ground states can be generated with high fidelity by applying quantum-engineered pulse sequences to the JC lattice. Using these states as the initial state and tuning the system parameters adiabatically, the many-body ground states in the intermediate regime can be reached. Our numerical result shows that the fidelity of the generated states can be significantly improved by employing a nonlinear ramping scheme during the adiabatic evolution. We derive the optimal nonlinear index analytically, which agrees well with the numerical result. This study gives insights into the preparation of many-body states in artificial quantum systems, such as quantum simulators.

3:42PM J08.00007: Quantum Algorithm for Simulating a Driven Dissipative 3-site Hubbard Ring

BRIAN ROST (Presenter), LORENZO DEL RE, Georgetown University, MICHAEL C JOHNSON, Arizona State University, ALEXANDER F KEMPER, North Carolina State University, JAMES FREERICKS, Georgetown University — Much research has been done concerning the simulation of closed quantum systems on near term quantum computers. Considerably less focus has been given to the simulation of open quantum systems, despite their importance as realistic models of real world systems. We consider the simulation of a three site Hubbard model driven by an electric field, connected to a Fermionic bath. This is the simplest model capable of stabilizing a non-zero steady state current with the added benefit that the fermionic bath admits an analytic solution in the non-interacting limit. We simulate this model classically using a master equation approach and provide an implementation for simulating it on a quantum computer. Even this simple model shows rich steady state behavior and offers a promising approach for simulating a variety of time dependent, driven, dissipative, open quantum systems.

*This work was funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0019469. In addition, BR received supplemental support from the National Science Foundation under Award DMR-1747426 and JKF received supplemental support from the McDevitt bequest at Georgetown.
Simulation of quantum Hamiltonians is one of the most promising applications proposed for which quantum hardware may provide significant advances over classical methods. However, significant limitations on near-term hardware size and fidelity pose a significant challenge for implementing known methods for realistic applications in chemistry and material science. Finding realistic systems for which near-term hardware can produce a useful simulation remains an open question. In this work we demonstrate that downfolding Hamiltonians, a process by which real materials are mapped on to model Hamiltonians, can yield a Hamiltonian form and size that is suitable for simulation on near-term quantum hardware. We apply this approach to several example materials and show how to implement it on realistic hardware using generalized swap networks.

4:18PM J08.00010: Quantum Computation of the Ground and Excited State Energies Using Quantum Imaginary Time Evolution and Quantum Lanczos Methods*  KUBRA YETER AYDENIZ (Presenter), RAPHAEL POOSER, Oak Ridge National Lab, GEORGE SIOPSIS, University of Tennessee, Knoxville — Various methods have been developed for quantum computation of the ground and excited states of physical systems, but many of them require either large numbers of ancilla or high dimensional optimization. The quantum imaginary time evolution (QITE) and quantum Lanczos (QLanczos) methods proposed in [1] eschew the aforementioned issues. In this study, we demonstrate the application of these algorithms on a nontrivial quantum computation, using the deuteron binding energy as an example. With the correct choice of initial and final states we showed that the number of time steps in QITE and QLanczos can be reduced significantly, which commensurately simplifies the required quantum circuit and improves compatibility with NISQ devices. We performed these calculations on cloud-accessible IBMQ quantum computers, and with the application of readout error mitigation and Richardson error extrapolation, we obtained ground and approximate excited state energies within 3% of the theory. These results show promise for using the algorithms in future field theory, scattering, and chemistry calculations.

4:30PM J08.00011: Driven-dissipative quantum mechanics on a lattice: Describing a fermionic reservoir with the master equation*  LORENZO DEL RE (Presenter), BRIAN ROST, Georgetown University, ALEXANDER F KEMPER, North Carolina State University, JAMES FREERICKS, Georgetown University — The possibility of simulating dissipative processes with digital circuits and quantum simulators, and using dissipation as a resource for state preparation, have created a renewed interest on the driven-dissipative many body problem. Here, I address a tight binding model of electrons driven out-of-equilibrium by an electric field, where the system can exchange energy and number of particles with a fermionic reservoir. The problem is solved using the master equation formalism. I use the exact solution for the noninteracting driven-dissipative system to benchmark the accuracy of the results obtained with the master-equation, showing a very good quantitative agreement. Furthermore, to create a better link with the simulation of open quantum systems, I provide with the time dependent Kraus map that pumps the system to the non-equilibrium steady state. Generalizations of such a method to broken symmetry phases (like CDW) and their simulation on quantum computers are discussed too.

4:42PM J08.00012: Quantum synchronization on the IBM Q system  MARTIN KOPPENHOEFER (Presenter), CHRISTOPH BRUDER, ALEXANDRE ROULET, Department of Physics, University of Basel — We report the first experimental demonstration of quantum synchronization. This is achieved by performing a digital simulation of a spin-1 limit-cycle oscillator on the quantum processors of the IBM Q system. Applying an external signal to the oscillator, we verify typical features of quantum synchronization and demonstrate an interference-based quantum synchronization blockade. Our results show that state-of-the-art noisy intermediate-scale quantum processors are powerful enough to implement realistic open quantum systems. Finally, we discuss limitations of current quantum hardware and define requirements necessary to investigate more complex problems.

4:54PM J08.00013: Quantum Digital Cooling+ STEFANO POLLA (Presenter), YAROSLAV HERASYMENKO, THOMAS O'BRIEN, Lorentz Institute — We introduce a new method for digital preparation of ground states of a simulated Hamiltonians, inspired by cooling in nature and adapted to leverage the capabilities of digital quantum hardware. The cold bath is simulated by a single ancillary qubit, which is reset periodically and coupled to the system non-perturbatively. Studying this cooling method on a 1-qubit system toy model allows us to optimize two cooling protocols based on weak-coupling and strong-coupling approaches. Extending these, we develop two scalable protocols for larger systems. The LogSweep protocol extends the weak-coupling approach by sweeping energies to resonantly match any targeted transition, demonstrating preparation of an approximate ground state for ferromagnetic and critical Ising chain, with error that can be made polynomially small in time. The BangBang protocol extends the strong-coupling approach, and exploits a heuristics for local Hamiltonians to approximately match transition energies, allowing rapid cooling to an approximation of the ground state, which makes this protocol appealing for near-term simulation applications.

5:06PM J08.00014: Resource-Efficient Quantum Algorithm for Protein Folding IVANO TAVERNELLI (Presenter), ANTON ROBERT, PANAGIOTIS BARKOUTSOS, STEFAN WOERNER, IBM Research - Zurich — Due to the central role of proteins’ 3D structures in chemistry, biology and medicine applications (e.g., in drug discovery), protein folding has been intensively studied for over half a century. Although classical algorithms provide practical solutions for the conformation space sampling of small proteins, they cannot tackle the intrinsic NP-hard complexity of the problem, even reduced to its simplest Hydrophobic-Polar model. While fault-tolerant quantum computers are still beyond reach for state-of-the-art quantum technologies, there is evidence that quantum algorithms can be successfully used on Noisy Intermediate-Scale Quantum (NISQ) computers to accelerate energy optimization in frustrated systems. In this talk, I will present a folding algorithm that requires resources (number of qubits and gate operations) that scale polynomially with the number of amino acids (AA). In particular, we propose a robust and versatile optimisation scheme to simulate the folding of the 10 AA Angiotensin peptide on 22 qubits and a 7 AA neuropeptide model using 9 qubits on an IBM Q 20-qubit quantum computer.
5:18PM J08.00015: Digital quantum simulation of quantum vibrational dynamics and control*  ALICIA MAGANN (Presenter), Princeton University, MATTHEW D GRACE, Sandia National Laboratories, California, HERSCHEL A RABITZ, Princeton University, MOHAN SAROVAR, Sandia National Laboratories, California — Quantum computers are expected to offer speed-ups for solving certain scientific problems. One example is digital quantum simulation, where sequences of quantum gates can be used to simulate the dynamics of quantum systems in polynomial time. This could have applications in simulations of quantum optimal control, which aim to identify shaped fields to drive a quantum system towards a designated control objective. In this talk, I will explore how digital quantum simulation could be used to make quantum optimal control simulations more tractable. I will introduce a framework that utilizes a quantum computer to simulate the field-induced dynamics of a quantum system in combination with classical optimization to update the field. As a demonstration of this framework, a quantum vibrational control problem will be considered.

Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525. Session J09 DQI: Open Quantum Systems II 106 - Peter Groszkowski, University of Chicago

2:30PM J09.00001: Master equation approach to study Non-Markovian dynamics of open quantum systems  YUSUI CHEN (Presenter), New York Inst of Tech — A full understanding of the decoherence dynamics of an open quantum system is of crucial importance for quantum information theory and quantum computing. In the last two decades, most theoretical and experimental research is replied on the Born-Markov approximation, a no-memory and quasi-static process. The associated Lindblad master equation has the great success in explaining some phenomena, e.g. the long-time limit steady state, quantum-classical transition. However, the recently achieved strong coupling between system and environment in many experiments breaks the Born-Markov approximation and forces one to study the decoherence in a strong non-Markovian and non-equilibrium regime. The major difficulty is raised up by lack of the technique to deal with the large number of degrees of freedom of the colored noisy environment. Starting from stochastic Schrödinger equations, we demonstrate a systematical method to derive the exact time convolution-less master equation for various open quantum systems, e.g. qubit systems, multi-level systems, and harmonic oscillator systems. Our methods can also be extended to the optomechanical systems and other non-linear coupling systems.
2:42PM J09.00002: Markovian Entanglement Dynamics under Locally Scrambled Quantum Evolution  
WEI-TING KUO (Presenter), AHMED AKHTAR, DANIEL AROVAS, YIZHUANG YOU, University of California, San Diego — We study the time evolution of quantum entanglement for a specific class of quantum dynamics, namely the locally scrambled quantum dynamics, where each step of the unitary evolution is drawn from a random ensemble that is invariant under on-site basis transformations. In this case, the average entanglement entropy follows Markovian dynamics that the entanglement property of the future state can be predicted solely based on the entanglement properties of the current state and the unitary operator at each step. We introduce the entanglement feature formulation to concisely organize the entanglement entropies over all subsystems into a many-body wave function, which allows us to describe the entanglement dynamics using an imaginary-time Schrodinger equation, such that various tools developed in quantum many-body physics can be applied. In addition to Haar random circuits and Brownian circuits, we also study a new type of circuit — fractional swap circuit in which the two local qudits are partially exchanged and partially staying on the same site. We further investigate the bipartite operator mutual information and tripartite operator mutual information of the fractional swap circuit and compare with different CFT results.

2:54PM J09.00003: Critical Properties of the Measurement-Induced Transition in Random Quantum Circuits*  
AIDAN ZABALO (Presenter), Rutgers University, New Brunswick, MICHAEL GULLANS, Princeton University, JUSTIN WILSON, Rutgers University, New Brunswick, SARANG GOPALAKRISHNAN, CUNY College of Staten Island, CUNY Graduate Center, DAVID HUSE, Princeton University, Institute for Advanced Study, JED PIXLEY, Rutgers University, New Brunswick — A transition was observed in random quantum circuits with local projective measurements where the entanglement entropy (EE) goes from volume law to area law scaling as the measurement rate, \( p \), is increased above a critical value, \( p_c \). Attempts to extract the critical properties through finite size scaling of the EE has proven difficult due to the logarithmic divergence at criticality. We study the tripartite mutual information (TMI) as an alternative diagnostic of the transition that is finite at criticality while maintaining a volume law for \( p<p_c \) and vanishing for \( p>p_c \). Our intuition for the Haar random circuit is guided by results on stabilizer circuits which can be simulated at much larger sizes. We find that the TMI has weaker finite size effects when compared to other quantities. Our numerics of the Haar random circuit suggests \( p_c=0.17 \) and the critical exponent \( \nu=1.3 \) for Renyi indices \( n\geq1 \), which are smaller than previously reported results. We also find a strong Renyi index dependence of the coefficient of the logarithmic divergence \( \alpha(n)=1.0(1)/n+0.7(1) \).

3:06PM J09.00004: Boundary Theory of a Deformed AKLT Model on the Square Lattice  JOHN MARTYN (Presenter), University of Maryland, College Park, KOHTARO KATO, ANGELO LUCIA, Institute for Quantum Information and Matter, California Institute of Technology — The 1D AKLT model is a paradigm of antiferromagnetism initially devised as a modification to the Heisenberg model, and its ground state is a quintessential example of symmetry protected topological order. On a 2D lattice, the AKLT model is particularly interesting because it also exhibits symmetry protected topological order, and can act as a resource for universal quantum computation. In contrast to the 1D case, the existence of the spectral gap in 2D, which guarantees the robustness of the model, remains an open problem despite extensive analyses. Recently, it has been shown that one can deduce this spectral gap by analyzing its boundary theory via a tensor network representation of the ground state. In this work, we present a method to calculate the boundary state of the 2D AKLT model in terms of a classical loop model, where loops, vertices, and crossings are each given a weight. We use numerical techniques to sample configurations of loops and subsequently evaluate the boundary state and boundary Hamiltonian on a square lattice. As a result, we evidence a spectral gap, and also indicate the presence of several different phases by varying the weights of the model.

3:18PM J09.00005: Basic construction of a tensor network library*  THOMAS BAKER (Presenter), ALEXANDRE FOLEY, AGUSTIN DI PAOLO, MARTIN P THOMPSON, Département de Physique, Université de Sherbrooke — We present a template tensor network code written in the programming language julia. The code is simple, short, and is also is efficient, competing in speed with some implementations in lower-level languages. The code can provide an efficient means to learn tensor networks as it is well documented for users of all levels, and the code can be used to check other libraries in development. A large number of algorithms have been implemented. Given time, new algorithms developed while creating this library will be discussed.

*T.E.B. graciously thanks funding provided by the postdoctoral fellowship from Institut quantique and Institut Transdisciplinaire d'Information Quantique (INTRIQ). This research was undertaken in part to funding from the Canada First Research Excellence Fund (CFREF).

3:30PM J09.00006: Tree tensor network study of out-of-time-order correlators on a sparse graph  CHRISTOPHER WHITE (Presenter), BRIAN SWINGLE, University of Maryland, College Park — The SYK model, which consists of Majorana fermions with random few-fermion all-to-all interactions, is a paradigmatic model of a "fast scrambler". Recent work (Bentsen, Gu, and Lucas: PNAS 116, 6689) argued that all-to-all connectivity is not necessary: rather, interactions on a sparse connectivity graph are sufficient. Because many such graphs are locally treelike, they are amenable to treatment with tree tensor networks. In this talk I will describes a study of out-of-time-order correlators using tree tensor networks; I will also comment on some methodological subtleties.
3:42PM J09.00007: Sparsity of the stabilizer projector decomposition of a density matrix and robustness of magic*  
YIFEI HUANG (Presenter), PETER LOVE, Tufts Univ — We extend the stabilizer rank of state vectors to mixed states and define the rank(minimal $l_0$ norm) for stabilizer projector decomposition of a density matrix and show its advantage over the rank of Pauli decomposition. Both improvements on the scaling over standard orthonomal basis(computational basis for state vector and Pauli basis for density matrix) come from the fact that stabilizer states form a densely overcomplete basis. In comparison with Monte Carlo simulation that scales with Robustness of Magic(minimal $l_1$ norm), we analyse the strong simulation cost of noisy Clifford+T circuits with respect to the rank. Using results from compressed sensing, we explore the sparsity condition where the minimal $l_0$ and $l_1$ norm are reached at the same decomposition.

3:54PM J09.00008: Single T gate in a Clifford circuit drives transition to universal entanglement spectrum statistics  
SHIYU ZHOU (Presenter), Boston Univ, ZHICHENG YANG, University of Maryland, ALIOSCIA HAMMA, University of Massachusetts Boston, CLAUDIO CHAMON, Boston Univ — Clifford circuits are insufficient for universal quantum computation or creating t-designs with t bigger than 4. While the entanglement entropy is not a telltale of this insufficiency, the entanglement spectrum is: the entanglement levels are Poisson-distributed for circuits restricted to the Clifford gate-set, while the levels follow Wigner-Dyson statistics when universal gates are used. In this paper we show, using finite-size scaling analysis of different measures of level spacing statistics, that in the thermodynamic limit, inserting a single T gate in the middle of a random Clifford circuit is sufficient to alter the entanglement spectrum from a Poisson to a Wigner-Dyson distribution.

4:06PM J09.00009: Recurrences in nonlinear few-body entanglement dynamics  
ALEXANDER KIRAL (Presenter), ARJENDU KISHORE PATTANAYAK, Carleton College — We study quantum tunneling for an initially pure coherent spin state in a many-body spin system. This manifests as dynamics which transforms it into a non-classical (in our case highly entangled) state that later recoheres. We develop a metric to determine the existence of tunneling as well as spectral techniques to predict rates of tunneling for an initial coherent state. We discover that the locations of tunneling reflect phase space structures that come from symmetries of the Hamiltonian. This can be visualized through the Husimi representation of stationary states which allows us to connect to other dynamical variables such as periodicity, entanglement, and chaos.
4:18PM J09.00010: Entanglement spectrum and entropy in non-Hermitian systems*  PO-YAO CHANG (Presenter), Department of Physics, National Tsing Hua University, JHIH-SHIH YOU, IFW Dresden, XUEDA WEN, Department of Physics, Massachusetts Institute of Technology, SHINSEI RYU, University of Chicago — In this talk, we study both the entanglement spectrum and the entanglement entropy by use of a biothogonal basis in non-Hermitian free fermion systems. We show the entanglement spectrum can characterize topological features in the non-Hermitian Su-Schrieffer-Heeger model with parity and time reversal symmetry. In addition, we find the entanglement entropy at the critical point of this model has a logarithmic scaling with corresponding central charge $c=-2$, which can be described by the non-unitary conformal field theory.

4:30PM J09.00011: GPU-accelerated simulations of realistic quantum systems with a focus on Quantum Information and Computation.*  ALEKSANDER LASEK (Presenter), HUGO V LEPAGE, CRISPIN H.W. BARNES, DAVID R M ARVIDSSON SHUKUR, Univ of Cambridge — In this talk we present our method of numerically simulating realistic quantum systems. With recent increases in GPU processing power, we are able to simulate two-particle 2D systems on thousands of spatial sites in a reasonable time. Even though today's quantum computers can manipulate multiple qubits, the long-term fidelity of many-qubit operations is still poor. Numerical simulations of quantum computers can help guide experiments towards better fidelities. We focus on simulating physical qubits, which leads to a better understanding of where the errors that are observed in quantum computers and experiments come from. We describe the techniques used to make our calculations possible, as well as present simulation results of realistic quantum experiments, including performing an entangling operation on two electron-spin qubits, controlling a charge qubit, and sound driven single electron transfer between quantum rails.

4:42PM J09.00012: Unified Quantum Parallel Computing Theory and Discrete Time Crystals
CHENG-HSIAO WU (Presenter), Missouri Univ of Sci & Tech —
Quantum computing from general-purpose and birth-and-death biological types of computing, executed by a man-made quantum processor, to atom-as-processor type are formulated in a four-computational-state cellular automata architecture. When a chain of entangled atoms are employed as a computing machine in cellular automata, the computation results are the discrete time crystals with subharmonics value limited between $\frac{1}{2}$ and $\frac{1}{4}$. The four orthogonal states of each atom in the entangled environment requires that the transition rules for the four computational states be of equal probability and cyclic. Superposition of two transition rules in one cellular automaton is shown to exist and the quantum computing irreversibility will be presented.

4:54PM J09.00013: Error rates in interacting Kitaev chains at finite temperature
JOHN STENGER (Presenter), ROGER MONG, DAVID PEKKER, Univ of Pittsburgh — As proposed by Alexey Kitaev, a topological one-dimensional superconducting wire hosts Majorana zero modes, which could be used to store and process quantum information in a topologically protected manner. At finite temperatures (or quasi-particle densities), Kitaev's model remains topologically protected because it is integrable. However, in the presence of interactions and finite temperature, topological protection is lifted. We investigate how error rates depend on interactions and temperature using TEBD and perturbation theory. These results are significant to experimental efforts to build a Majorana zero mode qubit.

5:06PM J09.00014: Time dependent variational principle with ancillary global Krylov subspace
MINGRU YANG (Presenter), STEVEN ROBERT WHITE, University of California, Irvine — We propose an improved scheme to do the time dependent variational principle (TDVP) in finite matrix product states (MPS) for two-dimensional systems or one-dimensional systems with long range interactions. We present a method to represent the time-evolving state in a MPS with its bond dimension increased by state-averaging with global Krylov vectors. We show that the projection error is significantly reduced so that precise time evolution can still be obtained even if a larger time step is used.

2:30PM J10.00001: Surface Structure of α-Quartz(0001)  KRISTEN BURSON (Presenter), Physics Department, Hamilton College, GEORG H. SIMON, Fritz-Haber Institute of the Max Planck Society, CLARE M. MUNROE, Physics Department, Hamilton College, MARKUS HEYDE, H J FREUND, Fritz-Haber Institute of the Max Planck Society — Crystalline silica (SiO₂) surfaces play an important role in nature and technology, and are often used as substrates in scientific studies. Despite its importance, the atomic surface structure of quartz still remains poorly understood, especially on the experimental side. Here we present a real space structure study of α-quartz(0001) surfaces prepared at high temperature in air. The preparation approach is highly reproducible and leads to well-defined, flat, and clean terraces in ambient conditions. Using high-resolution atomic force microscopy (AFM), we observed a large scale surface termination with a reconstruction periodicity of 5 nm, consistent with previous literature [1,2]. By characterizing the samples with AFM in humid air, dry nitrogen, and water we establish insight into surface morphology and reconstruction. Using the enhanced resolution capabilities of atomic force microscopy in liquid water, we address the real space atomic scale structure of this surface and find that the lattice dimensions agree with the bulk crystal lattice constants for α-quartz.

*KMB thanks the Alexander von Humboldt foundation.

2:42PM J10.00002: Nonlinearity-induced frequency mixing in AFM: novel contrast imaging with machine learning  GREG HAUGSTAD (Presenter), Characterization Facility, University of Minnesota, ANDREW AVERY, Unilever Research, STEPHAN HUBIG, RACHEL RAHN, Ecolab, ALON MCCORMICK, Dept. of Chem. Eng. and Mat. Sci., University of Minnesota, BING LUO, HAN SEUNG LEE, Characterization Facility, University of Minnesota — On complex thin films pertinent to lubrication and superhydrophilicity, dynamic AFM methods were used to sense both the elastic and viscous response to an AFM tip. A novel strategy in "multifrequency" AFM -- vibrating the AFM microcantilever (to which the tip is attached) at two tones near the fundamental flexural resonance - - generates dozens of intermodulation tones of response due to nonlinear tip-sample interaction (a well-known concept in electrical engineering usually in the context of AC signal distortion). This method1 both expands contrast mechanisms -- with images of amplitude and phase at each mixing tone via 40 FPGA lock-in amplifiers -- and the ability to reconstruct the distance dependence of conservative and dissipative response at each image pixel via a 40-term discrete Fourier transform of tip motion. This reconstruction is an unprecedented capability in "force spectroscopy" (probing distance dependent interactions). Machine learning, to cluster force-spectroscopic fingerprints and thereby generate higher signal-to-noise images, is further discussed.

2:54PM J10.00003: Light Scattering and Localization by Dislocation Scattering Sites*  
FARBOD SHAFIEI (Presenter), University of Texas at Austin, TOMMASO ORZALI, ALEXEY VERT, SEMATECH, MOHAMMAD-ALI MIRI, CUNY, PY HUNG, MAN HOI WONG, SEMATECH, ANDREA ALU, CUNY, GENNADI BERSUKER, The Aerospace Corporation, MICHAEL C DOWNER, University of Texas at Austin — Lattice mismatch between epitaxially grown crystalline thin film over substrate introduce variety of subsurface defects including threading dislocations. Dislocations defects behave as an acceptor traps for electron and thus acting as Coulomb scattering sites. Multi-scattering and localization of the light from these atomic defects scattering sites was collected by a 50 nm aperture fiber based scanning probe microscope. The localized light appears as few to multiple hundreds of nm optical hotspots based on dislocation density of the film. The smaller hotspots correlated to higher defects density as the multi-scattering light is confined in smaller area. The optical collection was done in second harmonic regime to avoid the dominating surface reflection of fundamental light. We used this approach to introduces a noninvasive tabletop technique capable of optically detecting dislocation atomic defects in III-V materials thin films. New diagnosis and supporting simulation would be shown.

*Welch Foundation

3:06PM J10.00004: Native and induced surface charge-transfer doping of MoTe$_2$  
GHEORGHE STAN (Presenter), National Institute of Standards and Technology, CRISTIAN CIOBANU, SRI RANGA JAI LIKITH, Department of Mechanical Engineering and Materials Science Program, Colorado School of Mines, ASHA RANI, SIYUAN ZHANG, CHRISTINA HACKER, SERGIY KRYLYUK, ALBERT DAVYDOV, National Institute of Standards and Technology — In this work, the surface charge transfer doping (SCTD) of air-exposed MoTe$_2$ surfaces was investigated by means of Kelvin probe force microscopy (KPFM). The induced changes in the surface potential of MoTe$_2$ due to air adsorbates were detailed as a function of the thickness of exfoliated MoTe$_2$ flakes all the way down to a single atomic layer. It was found that the SCTD driven by adsorbates can be easily adjusted through thermal annealing and, in this way, have an effective modulation on the surface potential of MoTe$_2$. Furthermore, the SCTD was controlled locally at the nanoscale by using the probe of an electrostatic force microscope as a floating gate. Following either thermal annealing or contact electrification, the air-exposed MoTe$_2$ surfaces exhibited slow reversal processes of re-adsorption with the restoration of the original positively charged doping. The KPFM measurements were paired with X-ray photoelectron spectroscopy measurements and density functional theory calculations to assess the contribution of physisorbed molecules to the observed variations in the measured surface potential. The study emphasizes that, as a reversible and controllable nanoscale physisorption, the SCTD can add significant progress to the paradigm of emerging 2D-TMDC electronics.
3:18PM J10.00005: A traveling salesperson and sparse sampling boost to quasiparticle interference mapping*  JENS OPPLIGER, FABIAN NATTERER (Presenter), Department of Physics, University of Zurich — The serial nature of STM investigations render complex measurement tasks, such as QPI mapping, impractical. Conventionally, QPI is carried out by recording hundreds of thousands of point-spectra that capture LDOS modulations from which scattering-space is calculated via Fourier-transform. Yet, despite the efforts required, QPI is mapped extensively because it provides insight into band-structure details when measurement conditions prohibit the use of ARPES. However, in view of the large number of data-points, it is surprising that QPI patterns contain only little information. This motivates our use of compressed sensing (CS) to fundamentally speed-up QPI mapping [1]. From only a fraction of the usual LDOS measurements, we reliably recover the full QPI pattern. Since CS depends on incoherent measurements, we sparsely sample LDOS at randomly selected locations using constant and varying probability density. The STM tip is moved between LDOS measurements according to a traveling salesperson to achieve an overall 5-50 faster QPI throughput.

*Funding from the Swiss National Science Foundation under project number PP00P2_176866 is appreciated.

3:30PM J10.00006: Controlled Manipulation of Molecules: A New Pathway to Catalysis Research  OMUR DAGDEVIREN (Presenter), CHAO ZHOU, Yale University, MILICA TODOROVIC, Aalto University, ERIC ALTMAN, UDO DIETMAR SCHWARZ, Yale University — With the continued development of scanning probe microscopy techniques, the manipulation of single molecules has become possible. Thereby, the manipulation path can be chosen at will and energy barriers can be quantified, as can the energy landscape around the molecule [1]. The molecules were either pushed, pulled, jumped to the tip, or did not move depending on the chemical surrounding of the molecule and the chemical identity of the tip. To preserve the accuracy of recovered tip-sample interaction, we used oscillation amplitudes significantly larger than the decay length of the tip-sample interaction potential [1-3]. For further insight, we compared measured energy landscapes and manipulation outcomes with computational results obtained using a search protocol [4]. References: [1] O. E. Dagdeviren et al., Nanotechnology 27 (2016). [2] O.E. Dagdeviren et al., Phy. Rev. App. 9 (2018). [3] O. E. Dagdeviren et al., Rev. of Scien. Ins. 90 (2019). [4] M. Todorovic et al. npj Comp Mat. 5 (2019).
3:42PM J10.00007: Optimal Bayesian experimental design for everyday measurements*
ROBERT MCMICHAEL (Presenter), National Institute of Standards and Technology, SERGEY DUSHENKO, KAPILDEB AMBAL, University of Maryland and National Institute of Standards and Technology — This talk gives an overview of software that increases speed and precision of routine measurements. In experiments where one would traditionally fit data to extract parameters, the 'optbayesexpt' package recommends measurement settings “on the fly” based on analysis of accumulating data. The algorithm uses optimal Bayesian experimental design to predict settings with the best chance of reducing parameter uncertainty. In simulations and in tests, we demonstrate order-of-magnitude speedup in measurements of Lorentzian peaks and significant speedup of exponential decay measurements relative to measure-then-fit strategies. The package, written in Python, includes a server script that communicates with instrument control software in any popular instrument control language. Demonstrations include magnetic resonance spectra of NV centers in diamond, and simulations include calibration of π-pulses for spin control. See the manual at https://pages.nist.gov/optbayesexpt/ and software at https://github.com/usnistgov/optbayesexpt.

3:54PM J10.00008: Defect Identification and Statistics Toolbox (DIST): A Tool for Automating Defect Analysis and Statistics Generation*
ALANA GUDINAS (Presenter), SHAWNA HOLLEN, Univ of New Hampshire, JASON P MOSCATELLO, Textron Systems, Wilmington, MA — Widely available scanning tunneling microscopy (STM) image analysis software do not automate the process of identifying and analyzing atomic defects in images. We present the Defect Identification and Statistics Toolbox (DIST) as a solution for automated defect analysis, based in MATLAB. DIST provides a graphical user interface for interactive image processing and background noise reduction to aid in defect identification. In DIST, topographical contour plots are generated in the image to isolate defects based on their brightness compared to the background. DIST implements an ant colony optimization (ACO) algorithm [1] to compare the shapes of individual defects defined by the contour plots. DIST also automatically compiles and outputs statistics of identified defects, such as apparent height, line profiles, and area. The novel automation techniques in DIST allow users to quickly and accurately analyze hundreds of defects at a time without relying on the user to manually identify each one.

4:06PM J10.00009: Learning hidden structure of nanoscale spectroscopies with metric analysis* [Invited] PETRO MAKSYMOVYCH (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Lab — Scanning probe microscopy is routinely faced with analysis of heterogeneous datasets, largely without having reference analytical models. Ordered parts of probed materials, such as regular lattice structures or coherent scattering can often be effectively captured with integral transforms to reveal the atomic and electronic structure, sometimes with unprecedented resolution. However, the problem of capturing inhomogeneities and furthermore understanding of their physical significance demands further attention. Here we will demonstrate how an appropriately chosen metric, combined with analysis of its variability enables effective characterization of key and often hidden structures within hyperspectral datasets. We applied such methodology to three representative cases with remarkably strong inhomogeneity in the nanoscale properties — variability of superconducting gap and electronic structure in unconventional superconductors FeSe and Ba$_2$FeAs$_2$, measurement of individual defects in these systems and structural phase transitions in dipolar solids. In each case, metric analysis has revealed a wide-range of sometimes unexpected properties, such as log-normal distribution in tunneling spectroscopy and sub-surface location of atomic-scale defects, while also providing a robust approach to understand spectral weight transfer and spectral signatures of electronic defects and to detect phase transitions in dielectric solids from their hysteretic response to applied fields. Future extension of these methodologies to combine elements of machine and deep learning will also be discussed.

*We gratefully acknowledge materials and microscopy teams at Oak Ridge National Laboratory for their contribution in materials synthesis and nanoscale measurements. Support provided by U.S. DOE, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. Microscopy was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

Tuesday, March 3, 2020 2:30 PM - 4:54 PM

Session J15 DFD DSOFT: Active Colloids II 210/212 - Quentin Brosseau, University of Pennsylvania
Floor- or ceiling-sliding for chemically active, gyrotactic, sedimenting Janus particles

SAYAN DAS, Theory of Inhomogeneous Condensed Matter, Max Planck Institute for Intelligent Systems, Stuttgart, Germany, ZOHREH JALILVAND, Department of Chemical Engineering, City College of the City University of New York, MIHAIL POPESCU (Presenter), Theory of Inhomogeneous Condensed Matter, Max Planck Institute for Intelligent Systems, Stuttgart, Germany, WILLIAM E. USPAL, Department of Mechanical Engineering, University of Hawai'i at Manoa, SIEGFRIED DIETRICH, ILONA KRETZSCHMAR, Theory of Inhomogeneous Condensed Matter, Max Planck Institute for Intelligent Systems, Stuttgart, Germany — Chemically active particles achieve force- and torque-free motility via catalytic chemical reactions promoted on parts of their surface. These lead to inhomogeneity in the chemical composition of the solution (“chemical field”) and hydrodynamic flow of the solution. By means of coupling distortions of these fields back to its motion, a chemically active particle experiences effective interactions with boundaries; this can lead to the occurrence of, e.g., states of steady "sliding" along a wall.

The often employed Janus spherical particles are density mismatched with the solution and, additionally, gyrotactic ("bottom-heavy"); the latter promotes alignment of the axis orthogonal to a horizontal wall. It is thus unclear under which conditions sliding states for such particles may occur. Here we study this issue theoretically for model gyrotactic, self-phoretic Janus spheres near horizontal planar walls which are either below (“floor”) or above (“ceiling”) the particle. We construct "state diagrams" as a function of the sedimentation velocity and gyrotactic response of the particle. These show that in certain cases sliding states may emerge simultaneously at both the ceiling and the floor. The predictions are critically compared with experimental results.

Effects of Colloid Interactions on Active–Passive Collective Behavior

IAN MADDEN (Presenter), Northwestern University, LINLIN WANG, JULIANE SIMMCHEN, Technische Universität Dresden, ERIK LUIJTEN, Northwestern University — Active colloidal matter can exhibit different phases, such as flocking, rafting, and spinning, in response to changes in active particle properties (Soft Matter 14, 6969–6973 (2018)). The links between these phenomena and the catalytic, hydrodynamic, electrostatic, and phoretic properties of the colloids are disputed, in part because it is difficult to separate the impact of each force in experiment. Whereas current models can capture some aspects of a system's collective behavior, oversimplification can lead to incorrectly attributing a particular behavior to a specific interaction (The European Physical Journal E 41, 145–169 (2018)). Using experimentally informed models, we employ lattice-Boltzmann and molecular dynamics simulations to deconvolute these interactions and make direct connections between particle properties and observed collective phenomena.
RICARD ALERT (Presenter), Princeton University, JIE ZHANG, University of California, Santa Barbara, JING YAN, Yale University, NED WINGREEN, Princeton University, STEVE GRANICK, Ulsan National Institute of Science and Technology — At thermodynamic equilibrium, phase separation arises from attractive interparticle interactions. However, self-propelled particles can phase separate even if they have purely repulsive interactions. This phenomenon, called motility-induced phase separation (MIPS), has become a landmark of active matter physics. The conventional mechanism of MIPS is the decrease of particle speed due to repulsive interactions in high-density regions, which leads to further accumulation of particles. In this talk, I will demonstrate a new mechanism of MIPS, which instead of relying on a slowdown of particle motion with density, is based on interaction torques that reorient particles toward high-density regions. We show that such torques take place in suspensions of Janus colloids driven by an electric field. From the electrostatic interactions between the particles, we derive hydrodynamic equations that show how MIPS arises from orientational interactions in this system. Furthermore, we predict that, in contrast to the repulsion-based MIPS scenario, the phase diagram of torque-based MIPS exhibits reentrance, with the system reentering the uniform phase at high self-propulsion speed.

CHONG SHEN (Presenter), LANFANG LI, ZHIYU JIANG, JAMES F GILCHRIST, H DANIEL OU-YANG, Lehigh Univ — Active Brownian particles (ABPs), colloidal particles driven into persistent motions by external fields, can serve as a model for understanding the non-thermal behavior of biological systems. Non-thermal fluctuations of an ABP are expected to behave differently from thermal Brownian motions in distinctive manners, e.g., exhibiting different diffusivities, effective temperatures, and fluctuation power spectral densities. While the non-thermal fluctuations can be separated from the thermal ones in their power spectral densities, it is non-trivial to decouple the non-thermal from thermal changes in a fluctuation histogram, because the experimentally measured fluctuation histogram is a convolution of the two fluctuations. We hypothesize that the non-thermal fluctuation could be extracted from the overall noise histogram by standard deconvolution algorithms when thermal fluctuations can be determined independently. This presentation reports an experimental study using a model ABP in a quadratic potential well to test the hypothesis and its limitations.
3:42PM J15.00005: Transport phenomena and Green-Kubo relations in active media:
Theory* JEFFREY EPSTEIN (Presenter), KRANTHI MANDADAPU, University of California, Berkeley — We derive Green-Kubo relations for the several viscosity terms that appear in a constitutive theory of viscous active fluids with and without an internal spin degree of freedom, starting from an Onsager regression hypothesis on the non-equilibrium steady state. In particular, we focus on the connection between time-reversal symmetry breaking and the emergence of the non-dissipative component of viscosity known as odd viscosity. Our results allow measurement of this odd viscosity in molecular dynamics simulations (for details see the corresponding Simulation talk). Time permitting, extensions of our results to liquid crystals will be discussed, with possible relevance to the modeling of active fluids such as suspensions or colonies of bacteria.

3:54PM J15.00006: Transport phenomena and Green-Kubo relations in active media:
Simulation CORY HARGUS (Presenter), University of California, Berkeley, KATHERINE KLYMKO, CCSE, Lawrence Berkeley National Laboratory, JEFFREY EPSTEIN, KRANTHI MANDADAPU, University of California, Berkeley — We compute the viscous transport coefficients of an active fluid composed of chirally rotated dumbbells with molecular dynamics simulations. We use recently obtained Green-Kubo relations to calculate the emergent viscous transport coefficients (for details see accompanying Theory talk), and find that odd viscosity arises due to the breaking of time-reversal symmetry at the level of stress correlations. We demonstrate agreement between viscosity coefficients obtained from Green-Kubo relations and non-equilibrium molecular dynamics simulations with imposed shear. This verifies the Green-Kubo relations derived using the application of Onsager’s regression hypothesis to non-equilibrium steady states of active systems, and provides an impetus for developing the theory of non-equilibrium thermodynamics of active media.

Nonlinear dynamics of chemically active microdrops grants an insight into interfacial chemistry

MATVEY MOROZOV (Presenter), LAURENCE RONGY, FABIAN BRAU, Universite libre de Bruxelles — Active emulsions are complex physicochemical systems that may provide a model for biological phenomena such as RNA polymerase clusters. Theoretical understanding of the physical chemistry of active emulsions is key for reliable modeling of these systems. We consider the simplest "building block" of an active emulsion: a microdroplet undergoing gradual micellar solubilization in the bulk of surfactant solution. In experiments, dissolving droplets may spontaneously induce a flow in the surrounding fluid. Our model links the features of the flow around the drop with the characteristics of nonlinear surfactant sorption kinetics and nonlinear chemical reaction at the droplet interface. We show that continuous assembly of micelles may act as a cleaning mechanism preventing the formation of a continuous monolayer of surfactant monomers even when bulk surfactant concentration exceeds CMC. Our asymptotics reveals that the Marangoni flow velocity depends heavily on the reaction rate and micelle size, while numerical simulations indicate that nonlinear kinetics of micelles production allows for multistability of flow regimes.

Revisiting the equation of state of active Brownian particles

STEWART MALLORY (Presenter), Caltech, AHMAD OMAR, University of California, Berkeley, JOHN F BRADY, Caltech — One of the unique feature of active systems is that they are able to phase separate without the presence of attractive interparticle interactions. Determining quantitatively the phase boundary for these fundamentally out-of-equilibrium systems is an on-going challenge within the community. The mechanically defined active pressure plays a central role in many of the recently proposed coexistence criteria. Using a combination of large-scale simulation and analytical theory, we reveal previously unknown features of this equation of state. Recognizing these features is essential when attempting to assess coexistence criteria by comparing the predicted phase diagram to simulation data. Upon using this refined equation of state, the predicted phase boundaries are qualitatively altered in comparison to previously work.

4:30PM J15.00009: Three-body problem for Brownian particles at different temperatures*  
MICHAEL WANG (Presenter), ALEXANDER Y GROSBERG, New York Univ NYU — A mixture of Brownian particles at different temperatures has been a useful model for studying out-of-equilibrium systems of many components with differing levels of activity (e.g. phase separation of mixtures of passive and active particles). This model was previously studied analytically up to the second virial coefficients using pair distributions in the dilute limit. We are interested whether or not the two-particle results can be extended to understand the three-particle distributions. By considering the solvable case of pairwise quadratic interactions, we show that, unlike the two-particle distribution, the three-particle distribution takes on an interesting form that is not in general Boltzmann-like with an effective temperature. We summarize some of our results here and briefly discuss an interesting connection with the Newtonian three-body problem.

4:42PM J15.00010: Microscopic Origins of the Swim Pressure and the Anomalous Surface Tension of Active Matter  
AHMAD OMAR (Presenter), University of California, Berkeley, ZHEN-GANG WANG, JOHN F BRADY, California Institute of Technology — The unique pressure exerted by active particles -- the "swim" pressure -- has proven to be a useful quantity in explaining many of the seemingly confounding behaviors of active particles. However, its use has also resulted in some puzzling findings including an extremely negative surface tension between phase separated active particles. Here, we demonstrate that this contradiction stems from the fact that the swim pressure is not a true pressure. At a boundary or interface, the reduction in particle swimming generates a net active force density despite no external fields or forcing -- it is an entirely self-generated body force. The pressure at the boundary, which was previously identified as the swim pressure, is in fact an elevated (relative to the bulk) value of the traditional particle pressure that is generated by this interfacial force density. Recognizing this unique mechanism for stress generation allows us to define a much more physically plausible surface tension. We clarify the utility of the swim pressure as an "equivalent pressure" (analogous to those defined from electrostatic and gravitational body forces) and the conditions in which this concept can be appropriately applied.

Session J16 DQI: Quantum Annealing and Optimization I  
201 - Rolando Somma, Los Alamos National Laboratory - Tag(s): Focus
2:30PM J16.00001: Toward integration of Kerr-nonlinear parametric oscillators for adiabatic quantum computation with Lechner-Hauke-Zoller scheme  TARO KANAO (Presenter), HAYATO GOTO, Toshiba Corp — Adiabatic quantum computation with networks of Kerr-nonlinear parametric oscillators (KPOs) has been proposed, which can solve combinatorial optimization problems (or Ising problems) by using quantum bifurcation [1, 2]. KPO networks integrated in two-dimensional plane can deal with all-to-all connected Ising problems by utilizing Lechner-Hauke-Zoller (LHZ) scheme [3], where KPOs are coupled by local four-body interactions [4, 5]. In the previous studies, however, the number of effective KPOs is limited within three. In this study, we investigate LHZ-scheme KPO networks with larger number of KPOs. Based on numerical simulations, we confirm that the LHZ scheme works for a wide range of the amplitude of the four-body interactions. Besides, we propose a method to improve the LHZ-scheme KPO networks, which is important for the case of larger number of KPOs.

2:42PM J16.00002: Long range coupling through a chain of RF-SQUIDs for superconducting flux qubit quantum annealers* ANTONIO JAVIER MARTINEZ (Presenter), DANIEL M TENNANT, XI DAI, DENIS MELANSON, ALI YURTALAN, SALIL BEDKIHAL, EDWARD TANG, University of Waterloo, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, RABINDRA DAS, DAVID K KIM, JONILYN YODER, STEVEN WEBER, ANDREW JAMES KERMAN, MIT Lincoln Laboratory, SERGEY NOVIKOV, STEVEN M DISSELER, JAMES I BASHAM, JEFFREY GROVER, Northrop Grumman Corporation, EVGENY MOZGUNOV, DANIEL A LIDAR, University of Southern California, ADRIAN LUPASCU, University of Waterloo — Increasing the degree of coupling in a quantum annealer can improve its computational power; however, each physical connection to a superconducting flux qubit increases its area and hence its susceptibility to noise. The coupler tree architecture is a proposed solution which allows increasing coupling degree without increasing qubit area. We report on a subgraph of the coupler tree consisting of 2 capacitively shunted flux qubits connected by 7 RF-SQUIDs. We experimentally demonstrate propagation of a magnetic flux signal through the chain, visible as a frequency step in the persistent current readouts attached to each qubit and coupler. Anticrossing spectroscopy is explored to confirm the quantum character of the coupling. Results are in agreement with full quantum circuit simulations. Prospects for measurement of entanglement and noise are discussed.

2:54PM J16.00003: Finding optimized anneal paths in capacitively shunted flux qubits

MOSTAFA KHEZRI (Presenter), Univ of Southern California, JEFFERY GROVER, Northrop Grumman, DANIEL A LIDAR, Univ of Southern California — Quantum annealers require accurate control and optimization of system parameters to reduce noise levels and ultimately demonstrate a computational advantage over classical algorithms. This requires a careful characterization of the system and its behavior in response to control biases.

In this work we study a capacitively shunted flux qubit (CSFQ), and use spectroscopy and dispersive readout to extract system parameters and model the qubit.

We confirm the multi-level structure of the circuit model of the CSFQ by annealing the qubit through small gaps and observing quantum signatures of level crossing between different eigenenergies.

We then use our model to mitigate the effect of noise by finding optimized anneal paths that minimize the transition width between the flux qubit's left and right wells.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) through the Army Research Office (ARO) Contract No. W911NF-17-C-0050.

3:06PM J16.00004: Quantum annealing with spin lock technique

HIDEAKI HAKOSHIMA (Presenter), YUICHIRO MATSUZAKI, YUYA SEKI, SHIRO KAWABATA, National Institute of Advanced Industrial Science and Technology (AIST) — Quantum annealing (QA) and adiabatic quantum computation (AQC) are attractive ways to tackle combinatorial optimization problems. However, the standard QA and AQC require strong interactions between qubits, and the coupling strength should be comparable with the resonant frequency of the qubits to solve practically useful problems. Such requirement prevents many systems from performing QA and AQC experimentally. Here, we propose an alternative way to implement a spin-lock based QA, which effectively tunes the qubit frequency by a continuous drive. Under the rotating-wave approximation, we show that our method is equivalent to the standard QA and AQC, and moreover we can analyze the deviation of the rotating-wave approximation systematically. Our method can be implemented by many systems such as superconducting transmon qubits, superconducting capacitive shunted flux qubits, and Si quantum-dots-based spin qubits. Since these systems have an advantage in scalability, our results pave the way to implement the practical QA and AQC.

3:18PM J16.00005: Assessing the potential of Rydberg atoms for adiabatic quantum computing of an NP-hard problem* BERTRAND MARCHAND (Presenter), FABRICE SERRET, THOMAS AYRAL, Atos Quantum Lab — When practically confronted with an NP-hard combinatorial optimization problem, the first question many computer scientists ask is whether a good approximation algorithm exists (i.e a tractable algorithm with provable guarantees on solution quality). We argue that the quality and potential of NISQ quantum annealers should therefore be assessed through the approximation ratio that they achieve on specific NP-hard problems. We put this methodology to practice for a platform consisting of neutral atoms trapped in optical arrays [1], which may be used to tackle an NP-hard problem called UD-MIS [2]. We present numerical estimates of the approximation ratio achieved by this approach under realistic noise conditions, on a class of experimentally-implementable random graphs. These results are then compared with the performances achieved by classical PTASs (Polynomial-Time Approximation Schemes) on the same problem.

*This work was supported by Atos and the European Union’s Horizon 2020 research and innovation program under grant agreement No. 817482 PasQuanS.

3:30PM J16.00006: A theoretical analysis of the power of pausing* HUO CHEN (Presenter), DANIEL A LIDAR, Univ of Southern California — Recent experimental results have shown that adding a pause during quantum annealing can significantly improve the success probability for certain hard optimization problems. An optimal pausing position, where the maximum performance improvement compared to the unpaused case is achieved, has also been observed. In this work, we present a theoretical analysis that explains these observations. We identify the key features of examples known empirically to benefit from pausing. Using these features as building blocks, we then construct a toy model with a simple analytic structure. Using this model, we derive, in an open quantum system setting, a set of sufficient conditions for which an optimal pausing position exists.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.
Quantum computation using Kerr-nonlinear parametric oscillators

HAYATO GOTO (Presenter), Toshiba Corp — In the past few years, the author and others have proposed quantum computation using Kerr-nonlinear parametric oscillators (KPOs). This approach opens new possibilities for adiabatic quantum computation [1-3], universal quantum computation [4,5], and physical implementations of qubits [6]. Since this idea is based on quantum bifurcations of KPOs [1], we refer to this kind of quantum computer as Quantum bifurcation Machine (QbM) [7]. Here we review the QbM with its recent progress.

Effectiveness of quantum annealing pause and partial gauges on embedded degree-bounded minimum spanning tree problems

SHON GRABBE (Presenter), NASA Ames Research Center, ZOE GONZALEZ IZQUIERDO, University of Southern California, STUART HADFIELD, JEFFREY MARSHALL, ZHIHUI WANG, ELEANOR RIEFFEL, NICHOLAS CRAMER, NASA Ames Research Center — Robust communication networks are essential to the growing use of small Unmanned Aerial Systems (sUAS) technologies. This work focused on evaluating the potential for harnessing quantum annealing to optimize communication routing in UAS communication networks subject to constraints. To support experimentation on early hardware, we consider as a surrogate problem finding the minimum degree-bounded spanning tree within a communication graph. While finding the minimum spanning tree is computationally tractable, with bounds on the degree the problem becomes NP hard. We provide a mapping of the degree-bounded minimum spanning tree problem to a Quantum Unconstrained Binary Optimization problem, and report on results demonstrating the effectiveness of an annealing pause on these embedded problem instances. Lastly, we demonstrate the effectiveness of partial gauge transformation for situations where asymmetric parameter ranges make standard gauge transformation infeasible.

*We are grateful for support from NASA Ames Research Center, from the AFRL Information Directorate under grant F4HBKC4162G001, and from the Office of the Director of National Intelligence (ODNI) and the Intelligence Advanced Research Projects Activity (IARPA), via IAA 145483.
4:30PM J16.00009: Quantum annealing with boundary canceling schedules* HUMBERTO MUNOZ-BAUZA (Presenter), LORENZO CAMPOS VENUTI, DANIEL A LIDAR, Univ of Southern California — The boundary cancellation theorem (BCT) for open systems bounds the distance between the final equilibrium state and the evolved state of an ergodic dissipative Liouvillian, where the scaling with anneal time depends on the number of vanishing derivatives of the annealing schedule at the end of the evolution. We test the thermal scaling of small gadgets up to 8 qubits on the D-Wave quantum annealer by controlling the vanishing derivatives of the schedule during the thermalization phase. While the theoretical BCT bounds are not accessible experimentally, we find that such schedules improve thermal scaling during the anneal and consequentially enhance the ground state probability of the gadgets.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.

4:42PM J16.00010: The Perils of Embedding for Sampling Problems* JEFFREY MARSHALL (Presenter), NASA Ames Research Center, and USRA, ANDREA DI GIOACCHINO, Dipartimento di Fisica, University of Milan and INFN, ELEANOR RIEFFEL, NASA Ames Research Center — Current quantum annealers impose constraints on the structure of the cost Hamiltonian due to the connectivity of the qubits. This means that in order to solve many problems of interest, one is required to embed the native graph into the hardware graph. The effect of embedding for sampling is more pronounced than for optimization, since one needs to consider states at all energies, and not just the ground states. We argue that as the problem size grows, the chance of a sample being in the logical subspace is exponentially suppressed. It is therefore necessary to construct post-processing techniques to evade this exponential sampling overhead, to project from the embedded distribution one is physically sampling from, back to the logical space. We observe that the simplest projection technique, majority vote, can fail quite spectacularly at preserving distribution properties. Furthermore, we show that even with care, one cannot avoid biasing the statistics. On the positive side, we demonstrate a new projection technique which substantially out-performs majority vote.

*We appreciate support from the AFRL Information Directorate under grant F4HBKC4162G001 and the Office of the Director of National Intelligence and the Intelligence Advanced Research Projects Activity, via IAA 145483.
4:54PM J16.00011: Reproducing the Performance Enhancement of Adiabatic Reverse Annealing

MATTHEW KOWALSKY (Presenter), Physics, University of Southern California, TAMMEM ALBASH, University of New Mexico — We propose a conventional (forward) quantum annealing protocol with a diagonal catalyst of programmable strength \( \lambda \). By adjusting \( \lambda \) we demonstrate an exponential improvement in the efficiency of quantum annealing for solving the p-spin model, reproducing the performance improvements of adiabatic reverse annealing\(^1\). Our protocol allows us to identify the enhancement mechanism of such approaches: balancing Hamiltonian terms in a way that mitigates discontinuous shifts in the global minimum of the semiclassical potential. This observation allows us to identify and solve other problems amenable to such protocols.

*The research is based upon work (partially) supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office contract W911NF-17-C-0050.

5:06PM J16.00012: Reverse quantum annealing with dissipation

GIANLUCA PASSARELLI, Dipartimento di Fisica "E. Pancini", Università di Napoli "Federico II", KA WA YIP (Presenter), Univ of Southern California, PROCOLO LUCIGNANO, Dipartimento di Fisica "E. Pancini", Università di Napoli "Federico II", DANIEL A LIDAR, Univ of Southern California, HIDETOSHI NISHIMORI, Tokyo Institute of Technology — Reverse annealing is a variant of quantum annealing where one initializes the system in a random classical state. The transverse field is first increased and then decreased at an inversion point, to find a better output state than the initial state of a given optimization problem. The procedure may be iterated with the last output state as the new input state.

[1] studied the unitary dynamics of reverse annealing of the fully-connected ferromagnetic p-spin model. Here we investigate the performance of reverse annealing for the p-spin model in a low-temperature open system setting. We study a system of qubits with collective and individual system-bath interaction models. We simulate the Markovian dynamics over a range of initial states and inversion points, and show that the relaxation mechanism gives an overall enhancement of performance over the closed-system setting. We also analyze the case of pausing at the inversion point, and show that prolonged relaxation near the avoided crossing can allow us to find the correct ground state solution with near certainty.

*Work supported by CINECA award under the ISCRA initiative, and by IARPA and ARO under Contract No. W911NF-17-C-0050.
Quantum annealing in a degenerate two-level system — SHOHEI WATABE (Presenter), Tokyo University of Science, YUYA SEKI, SHIRO KAWABATA, National Institute of Advanced Industrial Science and Technology — Quantum annealing is a method for avoiding the increase of the calculation cost of the combinatorial optimization problem. Since the combinatorial optimization problems are ubiquitous, quantum annealing machine with high efficiency and scalability will give an immeasurable impact on many fields. An idea for finding high success probability is one of the most important issues for quantum annealing. In this presentation, we show that a degenerate two-level system that is called quantum Wajnflasz-Pick model may provide the higher success probability than the conventional spin-1/2 model in a weak longitudinal magnetic field region. The origin of the higher success probability can be understood from the fact that the Hamiltonian in this model can be reduced into that of the spin-1/2 model. In the reduced Hamiltonian, the effective longitudinal magnetic field may open the energy gap, which suppresses the Landau–Zener tunneling providing leakage of the ground state.

*This presentation is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO), Japan. This work is also supported by Nanotech Career-up Alliance (Nanotech CUPAL), Japan Science and Technology Agency (JST).

Tuesday, March 3, 2020 2:30 PM - 5:18 PM

Session J17 DQI: Focus Silicon Spin Qubits in Double Quantum Dots — Susan Clark, Sandia National Laboratories - Tag(s): Focus

Si based quantum computer architecture and associated engineering challenges — MAUD VINET (Presenter), PIERRE-ANDRE MORTEMOUSQUE, LOUIS HUTIN, BENOIT BERTRAND, XAVIER JEHL, YANN-MICHEL NIQUET, GAËL PILLONNET, GÉRARD BILLIOT, MARC SANQUER, CEA Grenoble, BAPTISTE JADOT, EMMANUEL CHARION CHANRION, MATIAS URDAMPILLETA, TRISTAN MEUNIER, Néel Institute, CNRS — Si-based QC appears as a promising approach to build a quantum processor; thanks to the size of the qubits, the quality of the quantum gates and the VLSI ability to fabricate billions of closely identical objects. The quality of Si spin qubits has improved very fast with the introduction of isotopically purified 28Si. In this presentation, we will share our quantum accelerator architecture and will present progress made towards the actual demonstration of this architecture. We will show data ranging from material development to packaging with insights in device design. We will review the technological challenges that are still to be tackled. We will highlight how we leverage tight-binding simulations to develop a QCAD activity (quantum bit computer aided design).

*This work is partially funded by ERC Synergy grant QuCube and by French Agence Nationale de la Recherche and EU H2020 projects.
3:06PM J17.00002: A Valley Hot-Spot Driven Singlet-Triplet Qubit in a Silicon MOS DQD*
RYAN JOCK (Presenter), Sandia National Laboratories, NOAH T JACOBSON, Center for Computing Research, Sandia National Laboratories, MARTIN RUDOLPH, DAN R. WARD, MALCOLM S. CARROLL, DWIGHT R LUHM AN, Sandia National Laboratories — Electron spins in silicon quantum dots (QDs) have gained traction as a promising qubit platform due to the controllability of qubit-qubit interactions and the availability of mature silicon microelectronics fabrication techniques. However, confining electrons to QDs at the Si/SiO\textsubscript{2} interface has recently been shown to produce stronger than expected spin-orbit (SO) physics. Here, we present a novel operating mode of a singlet-triplet qubit that exploits an inter-valley SO interaction to drive high-orthogonality, electrical-only qubit control. We employ this interaction to produce a high-performance qubit with operational S-T\textsubscript{0} rotation frequencies exceeding 200 MHz and a quality factor, Q = f x T\textsubscript{2}*, near 20. Utilizing SO effects to drive qubits offers the advantage of all-electrical control, avoiding the need for micromagnets or on-chip microwave strip-lines, and allows for a characterization of the MOS platform without the added fabrication complexity of additional nano-fabricated metal layers.

*Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the DOE’s National Nuclear Security Administration under contract DE-NA0003525.
Learning the states of double quantum dot systems: A ray-based approach

JUSTYNA ZWOLAK (Presenter), National Institute of Standards and Technology, Gaithersburg, MD 20899, USA, THOMAS MCJUNKIN, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706, USA, SANDESH KALANTRE, Joint Quantum Institute, University of Maryland, College Park, MD 20742, USA, SAMUEL NEYENS, EVAN R MACQUARRIE, Department of Physics, University of Wisconsin, Madison, WI 53706, USA, LISA F EDGE, HRL Laboratories LLC, 3011 Malibu Canyon Road, Malibu, California 90265, USA, MARK ALAN ERIKSSON, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706, USA, JACOB TAYLOR, National Institute of Standards and Technology, Gaithersburg, MD 20899, USA

— Given the progress in the construction of multi-quantum dot (QD) arrays in both 1D and 2D [1,2], it is imperative to replace the current practice of manual tuning to a desirable electronic configuration with a standardized and automated method. Recently, we have experimentally realized an auto-tuning paradigm proposed by Kalantre et al. [3] that combines machine learning (ML) and optimization routines, with ConvNets used to characterize the state and charge configuration of single and double QD states from measurements via the conductance of a nearby charge sensor [4]. Now we expand on this work and propose a novel approach where we use 1D traces (“rays”) measured in multiple directions in the gate voltage space to describe the position of the features characterizing each state (i.e., to “fingerprint” the state space). Using these “fingerprints” instead of full-sized 2D scans we train an ML algorithm to differentiate between various state configurations. Here, we report the performance of the ray-based learning on experimental data and compare it with our image-based approach.

Spin shuttling in a silicon double quantum dot*  

FLORIAN GINZEL  
(Presenter), Department of Physics, University of Konstanz, D-78457 Konstanz, Germany, ADAM MILLS, JASON PETTA, Department of Physics, Princeton University, Princeton, New Jersey 08544, USA, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — Motivated by the demand[1] for long and intermediate range interaction in quantum information devices and recent developments[2,3] we theoretically analyze the dynamics of an electron during a detuning sweep in a silicon double quantum dot (DQD) occupied by one electron, and investigate possibilities and limitations of spin transport. Spin-orbit interaction and an inhomogeneous magnetic field which can introduce errors are included in our model. Interactions that couple the position, spin and valley degrees of freedom open a number of avoided crossings in the spectrum allowing for diabatic transitions and interfering paths. The outcome of a spin shuttling protocol is explored by means of numerical simulations and an approximate analytical model based on the solution to the Landau-Zener problem. We find that constructive interference can ensure a high transport fidelity even for a fast protocol. Exploiting destructive interference between different paths the DQD can also act as a spin or valley filter.

*This work has been supported by the ARO grant W911NF-15-1-0149.

Towards an electrically controlled spin-valley quantum dot qubit in silicon*  
NICHOLAS PENTHORN (Presenter), JOHN ROONEY, JOSHUA S SCHOENFIELD, California State University, Los Angeles, LISA F EDGE, HRL Laboratories, HONGWEN JIANG, California State University, Los Angeles — Electrical control of electron spins in semiconductor quantum dot qubits requires some form of spin-electric field interaction, typically as a micromagnet-induced field gradient. However, electron spins are known to couple to valley states in silicon [1], which could afford a new method for spin control without the need of a micromagnet or native spin-orbit interaction. Building on our recent result of electrical control of a valley qubit in a Si/SiGe double quantum dot [2], we show that the valley splitting can be tuned by 32 μeV with modest voltages on local gates. Using real-time spin relaxation measurements on a single electron in this device with a variable external field, we see evidence of spin-valley mixing signified by a “hot spot” with high spin relaxation below 500 mT. Additionally, we show our progress on implementing valley-mediated spin qubit operations.

*This work was supported by U.S. ARO through Grant. No. W911NF1410346.
3:54PM J17.00006: Charge noise induced spin decoherence in a double quantum dot: Effects of a micromagnet*  XINYU ZHAO (Presenter), XUEDONG HU, State Univ of NY - Buffalo — Charge noise is one of the most important error sources for quantum gates in semiconductor systems. We study the decoherence of an electron spin in a double quantum dot in the presence of an inhomogeneous magnetic field. An exact dynamical equation is derived directly from the microscopic Hamiltonian, which allows us to investigate the impact of the non-Markovian properties of the quantized bosonic environment. We show that non-Markovian dynamics could cause a notable correction when measuring spin relaxation time. Our results reduce to the one predicted by the traditional Redfield master equation when Born-Markov approximation is applied. The spin relaxation and dephasing caused by the charge noise is suppressed by certain factors since the noise is indirectly (through the artificial spin-orbit interaction from the micromagnet) coupled to spin. We show these factors strongly depend on the system parameters such as detuning, tunneling strength, field gradients in vertical or horizontal directions. Our results present a systematic approach to study decoherence processes caused by charge noise, particularly for quantum dots in an inhomogeneous magnetic field.

*We acknowledge financial support by US ARO via grant W911NF1710257.

4:06PM J17.00007: Universal quantum logic in hot silicon qubits  HARMEN EENINK (Presenter), LUCA PETIT, MAXIMILIAN RUSS, WILLIAM I.L. LAWRIE, NICO HENDRICKX, Delft University of Technology, JIM CLARKE, Components Research, Intel Corporation, LIEVEN M VANDERSYPEN, MENNO VELDHORST, Delft University of Technology — Large scale quantum computation can leverage significantly from semiconductor fabrication technology, to allow for quantum integrated circuits, hosting quantum hardware and control circuitry all on the same chip. However, leading qubit approaches operate at very low temperatures below 100 mK, where cooling power is extremely limited, and this severely impacts the perspective for practical quantum computation. Demonstrating qubit operation at elevated temperatures would therefore be a major breakthrough in the effort towards scalable quantum systems. Here, we study quantum operations in a silicon two-qubit system, operated at a temperature of 1.1 K. We perform readout using Pauli spin blockade and obtain coherent single-qubit control via electron-spin-resonance, with fidelities exceeding 99 %. We show tunability of the exchange interaction between the two spins from 0.5 up to 18 MHz and use this mechanism to execute coherent two-qubit controlled rotations (CROT). We additionally investigate the temperature dependence of the coherence times, which we find surprisingly robust against thermal noise. Our results mark an important step for the realization of quantum integrated circuits, a scalable approach towards practical quantum computation.
4:18PM J17.00008: Intel Spin Qubits: Automated low-temperature measurement and statistical data analysis for improved fabrication and device design  ROMAN CAUDILLO (Presenter), FLORIAN LUTHI, LESTER LAMPERT, THOMAS WATSON, DAVID J MICHALAK, ERIC HENRY, PAYAM AMIN, HUBERT C GEORGE, STEPHANIE BOJARSKI, BRENNEN MUELLER, RAVI PILLARISSETTY, JEANETTE MARIE ROBERTS, JIM CLARKE, Intel Corporation — Spin qubits in silicon are in many ways similar to state-of-the-art transistor devices, and they can both be manufactured with today's 300mm equipment and processes. The 300mm fab infrastructure is a powerful tool because of its excellent process control that results in high-quality devices with high reliability; however, it requires feedback from device performance grounded in statistical analysis of large data sets. Similarly, for quantum dots, automation and statistical data analysis of low-T measurements can be used to address challenges such as minimizing charge noise and TLS's in dielectrics and other on-chip materials, as well as eliminating spurious dots. Here we present an automated approach to tuning up quantum dots and extracting gate crosstalk, charging energy (E_c), leverarm, charge noise, and other device performance metrics, which are then fed back to device design and the fabrication process for iterative improvements in performance. Automation, and the large data sets that result, not only enable high-throughput measurements for rapid fabrication improvements, but also allow characterization of device limitations in new ways, including identifying regions of badness and the location of TLS's, and ultimately will point the way toward high-performance qubits.

4:30PM J17.00009: Intel Quantum Dot Devices: temperature dependence of electrical characteristics and correlating noise measurements for improved measurement turnaround  FLORIAN LUTHI (Presenter), ROMAN CAUDILLO, THOMAS WATSON, LESTER LAMPERT, OTTO ZIETZ, HUBERT C GEORGE, STEPHANIE BOJARSKI, BRENNEN MUELLER, PAYAM AMIN, ERIC HENRY, DAVID J MICHALAK, RAVI PILLARISSETTY, JEANETTE MARIE ROBERTS, JIM CLARKE, Intel Corporation — Quantum computing promises to tackle exciting and computationally difficult problems. Intel is leveraging 50 years of experience in semiconductor manufacturing to develop silicon-based spin qubits. One of the key challenges is the measurement bottleneck: Data acquisition at low temperatures (10 mK) is slow, and only few samples can be characterized per cooldown. Nonetheless, these measurements provide the ultimate feedback to device fabrication and design. At Intel, this problem is highlighted to the extreme: every week, thousands of SiMOS quantum dot devices are fabricated on 300 mm wafers, yet only a small fraction of these can be measured at mK temperatures. The need for low-temperature electrical characterization can be reduced by understanding the temperature dependence of device data, enabling learning from measurements at elevated temperatures. Furthermore, correlations between directly relevant quantities (such as quantum dot charge noise) and device properties which are measured more quickly (such as pinch-off noise) are investigated. These quick-turn monitors enable faster feedback to improve fab and pave the way to automated wafer-scale characterization of quantum dot devices at intermediate temperatures (2-4 K); this will help alleviate the measurement bottleneck.
4:42PM J17.00010: Fabrication process and failure analysis for robust quantum dots in silicon  JOHN DODSON ( Presenter), NATHAN HOLMAN, BRANDUR THORGRIMSSON, SAMUEL NEYENS, EVAN R MACQUARRIE, RYAN H FOOTE, THOMAS MCJUNKIN, University of Wisconsin - Madison, LISA F EDGE, HRL Laboratories, SUSAN NAN COPPERSMITH, MARK ALAN ERIKSSON, University of Wisconsin - Madison — We investigate several yield limiting steps in the fabrication of overlapping aluminum gate quantum dot devices in Si/SiGe. The thin, ~2 nm oxide that grows natively on aluminum and low thermal budget of aluminum devices presents a challenge for fabrication of quantum dot arrays with high yield. Gate-to-gate leakage from pinholing of the aluminum oxide, damage from electrostatic discharge (ESD), low breakdown voltages and gate geometry/morphology all present a significant risk of device failure in the active region. Additionally, dewetting of aluminum and formation of alloys during fabrication of interconnects from the active region of the device to the bond pads can result in failure of electrical signal transmission. We present low-temperature oxidation techniques for a thicker aluminum oxide with breakdown voltages of over 4 volts, reducing the risk of damage due to ESD and gate-to-gate leakage. TEM images of overlapping gate structures identify failure modes stemming from gate geometry/morphology. Finally, we investigate the fabrication of interconnects between the active region and device bond pads to introduce thermal anneals into the fabrication process, prevent damage due to ESD, and to identify the maximum processing temperature at different stages of device fabrication.

4:54PM J17.00011: Simplified MOS Quantum Dots for Materials Characterization  JOSHUA POMEROY (Presenter), ARUNA N RAMANAYAKA, YANXUE HONG, KE TANG, RYAN STEIN, MICHAEL DAVID STEWART, National Institute of Standards and Technology — Using single-layer metal gate patterns, metal-oxide-semiconductor (MOS) quantum dot devices with charge sensors are fabricated and measured as a simplified approach to developing more rigorous qualifying metrics than transport for materials and interfaces. Materials and interfaces are often identified as sources of charge traps and time instabilities difficult to assess with transport techniques, and the ability to form quantum dots and charge sense in these systems enables charge offset drift and, potentially, spin relaxation measurements to critically assess the feasibility of the materials and methods for use in qubit applications. Various multiple-dot designs with charge sensors have been fabricated, and the tunability and charge offset stability of these devices will be discussed in the context of developing tools for qualifying materials for quantum.
Development of simulator for silicon quantum dot devices based on semiclassical device modeling

Hidehiro Asai (Presenter), Shota Iizuka, Junichi Hattori, Tsutomu Ikegami, Koichi Fukuda, Takahiro Mori, AIST

Recently, the novel design for qubit integration has been vigorously investigated for the realization of fault-tolerant quantum computers and the noisy intermediate-scale quantum (NISQ) technology. Silicon qubits have attracted much attention as a promising candidate for a building block of integrated quantum circuits because they can utilize cutting edge nanofabrication facilities for conventional logic devices. In order to develop the qubit suitable for large-integrated quantum circuits and design whole picture of quantum circuits and its peripheral control circuits, the simulation tool for supporting the qubit design is strongly required, like technology computer aided design (TCAD) for conventional transistor design. In this presentation, we report our recent development of a prototype simulator which can simulate the basic characteristics of silicon quantum dot devices as a basis of spin qubit. We utilize semi-classical device simulation as solvers of Poisson equation and classical current continuity equation combined with newly-developed tunneling and Coulomb-blockade models to calculate transport in quantum dot devices. As a demonstration of the simulation, we are going to show calculation examples of charge stability diagrams for some quantum dot devices.

Session J18 DAMOP: Exploring Ergodicity-Breaking Through Nonequilibrium Order, Quantum Chaos and Integrability

205 - Bryce Gadway, University of Illinois at Urbana-Champaign - Tag(s): Invited
2:30PM J18.00001: Entanglement entropy of highly excited eigenstates of many-body lattice Hamiltonians* [Invited]  MARCOS RIGOL (Presenter), Pennsylvania State University — The average entanglement entropy of subsystems of random pure states is (nearly) maximal [1]. In this talk, we discuss how the average entanglement entropy of subsystems of highly excited eigenstates of integrable and nonintegrable many-body lattice Hamiltonians (with a conservation law) differ from that of random pure states. For translationally invariant quadratic models (or spin models mappable to them) we prove that, when the subsystem size is not a vanishing fraction of the entire system, the average eigenstate entanglement exhibits a leading volume-law term that is different from that of random pure states [2]. We argue that such a leading term is universal for translationally invariant quadratic models [3] and, likely, also for interacting integrable models [4]. For highly excited eigenstates of a particle-number-conserving quantum chaotic model away from half filling, we find that the deviation from the maximal value grows with the square root of the system's volume, when 1/2 of the system is traced out. Such a deviation is proved to occur in random pure states with a fixed particle number and normally distributed real coefficients [5].

3:06PM J18.00002: Universal operator growth and emergent hydrodynamics in quantum systems* [Invited]  EHUD ALTMAN (Presenter), University of California, Berkeley — I will present a hypothesis on universal properties of operators evolving under many-body Hamiltonian dynamics. I will define a measure of operator complexity and argue that it generically grows exponentially in time, with an exponent α, measurable through the properties of a physical retarded correlation function. Furthermore, the complexity exponent places a sharp bound on Lyapunov exponents λ ≤ 2α characterizing chaos, generalizing the known universal low-temperature bound λ ≤ 2πT. In a sense the complexity growth exponent offers a measure of chaos that does not rely on having a nearby semiclassical limit. I will illustrate the results in paradigmatic examples such as non-integrable quantum spin chains, the Sachdev-Ye-Kitaev model, and classical models. Finally I will present applications of this approach to computation of Hydrodynamic transport coefficients and for characterizing the many-body localization transition in disordered systems.

4:18PM J18.00004: Matthias Weidemuller Invited Talk [Invited] —
4:54PM J18.00005: Kinetically constrained dynamics and electron-phonon interactions in Rydberg quantum simulators* [Invited] IGOR LESANOVSKY (Presenter), Institute for Theoretical Physics, University of Tuebingen — Rydberg quantum simulators, i.e. highly excited atoms held in optical tweezer arrays, are amongst the most advanced platforms for the implementation and study of strongly interacting spin systems. An interesting dynamical regime is reached when one atom that is brought to a Rydberg states facilitates the excitation of another nearby one. The resulting dynamics can be similar to that of epidemic spreading and also may form an ingredient for observing non-equilibrium phase transitions. In my talk I will discuss recent results concerning the analysis of constrained Rydberg spin dynamics in the presence of disorder which is caused by the coupling of electronic degrees of freedom and lattice vibrations. I will focus on incoherent and coherent regimes, discussing the breaking of ergodicity and the dressing of facilitated spins by phonons, respectively.

*The research leading to these results has received funding from the EPSRC Grants No. EP/M014266/1 and EP/R04340X/1 via the QuantERA project “ERyQSenS”. Support was also received from the Deutsche Forschungsgemeinschaft (DFG) within the SPP 1929 Giant interactions in Rydberg Systems (GiRyd) and The Leverhulme Trust [Grant number RPG-2018-181].

Session J19 DMP: DMP Prize Session 207 - Antoinette Taylor, Los Alamos Natl Lab - Tag(s): Invited

2:30PM J19.00001: David Adler Lectureship Award Talk: Epitaxial Oxides: From Basic Science to Application [Invited] CHANG-BEOM EOM (Presenter), University of Wisconsin - Madison — Oxide materials are the most abundant compound in the earth’s crust and possess a wide range of electrical, optical, and magnetic properties. For instance, insulators, high quality metals, dielectrics, ferroelectrics, piezoelectrics, semiconductors, ferromagnetics, transparent conductors, ionic conductors, multiferroics superconductors, and nonlinear optical materials have all been produced using oxide materials. Oxide materials have enormous potential as the fundamental building block of new generations of electronic, magnetic, optical and electromechanical devices. We create these materials by artificially layering various atoms including oxygen at the single atom level, as well as stacking of epitaxial membranes. Our goal is to create new materials and heterostructures with novel properties likely to advance basic science and future applications. I will present advances in epitaxial oxide systems in general, and highlight several examples of how our research has played a role in understanding fundamental solid state phenomena at the atomic scale and in the discovery of new materials. Atomic layer control of novel oxide heterointerfaces may provide some of the answers that we need to continue the electronics revolution, particularly for frontier nanoscale devices. I will discuss the challenges and opportunities in this exciting field.
We studied the state of matter under extreme conditions and found new phenomena and materials, including polymeric nitrogen, transparent sodium, electrically conducting hydrogen, and superconductivity in various substances. Room-temperature superconductivity is becoming realistic given dramatic progress in conventional superconductivity: the critical temperature is $T_c = 203$ K in H3S under high pressures of about 150 GPa. We found even higher, nearly room temperature superconductivity in superhydride LaH10 with $T_c \approx 250$ K, following the theoretical predictions. This and yttrium and calcium superhydrides can be considered as a close realization of metallic hydrogen.

We will discuss prospects for further increase of $T_c$ to room temperature, which naturally is expecting for hydrides at high pressures. We will present recent studies on YHx and other compounds that are considered as potential room-temperature superconductors. We will consider various directions to explore high-temperature conventional superconductivity at low and ambient pressures.

3:42PM J19.00003: Edward A. Bouchet Award Talk: Controlling Dissipation in Superconductors: the Oxymoron that Leads to New Superconducting Phases and Transitions* [Invited] NADYA MASON (Presenter), University of Illinois at Urbana-Champaign — In this Bouchet Award talk, I will first briefly discuss why I feel that it is important to balance research, service, and outreach. I will then discuss my research on “dissipative” superconducting systems. In particular, superconductors are exciting materials for basic physics and applications because they conventionally exhibit zero-resistance and zero-dissipation. In contrast, unconventional superconductors—including high-temperature superconductors and hybrid superconductor-normal (S-N) systems relevant to quantum computation—combine superconductivity with dissipative normal metal-like states. Yet dissipation has been difficult to control and parametrize. Here, I will discuss electrical transport experiments on hybrid superconductor-normal metal systems where the dissipation is controlled, leading to new understanding of superconducting states and transitions. In particular, I will show how superconductivity is established in granular S-N systems, how metallic states appear in arrays of S-N systems as the normal metal fraction is increased, and how magnetic fields can be used to control a variety of dissipative phase transitions. The results are relevant to understanding the role of dissipation in superconducting systems, and in correlated materials in general.

**4:18PM J19.00004: APS Medal for Exceptional Achievement in Research: The Metal-Insulator Transition in Strongly Interacting Electron Systems in Two Dimensions** [Invited]  MYRIAM SARACHIK (Presenter), Physics, City College of New York, CUNY — Over the course of my long career in physics my research has covered a variety of topics, including early measurements of the resistance minimum that provided the experimental key to the Kondo effect, metal-insulator transitions (MITs) and macroscopic quantum tunneling of the magnetization in molecular magnets. My work during the last few years has focused on the apparent metal-insulator transition that occurs in strongly interacting systems of electrons in two dimensions, where no metallic behavior and no metal-insulator transition were believed to be possible. In this talk I will give a thumbnail history of research on the 2D metal-insulator transition, the debate concerning whether a metallic phase exists in two dimensions, and whether this MIT is a quantum phase transition, as claimed by many (including me). I will report surprising results [1] that shed new light on the nature of the metal-insulator transition in 2D.

*My research has been supported over the years by City College (CCNY), the PSC (Professional Staff Conference) through CUNYFRAP (the CUNY Faculty Research Award Program) and grants from the Department of Energy, the National Science Foundation, the Air Force Office of Scientific Research, the Army Research Office and the US-Israel Binational Science Foundation.*

2:30PM J20.00001: A mechanistic view of collective filament motion in active nematic networks  MORITZ STRIEBEL, ISABELLA GRAF (Presenter), ERWIN A FREY, Ludwig Maximilian University of Munich — Protein filament networks are structures crucial for force generation and cell shape. A central open question is how collective filament dynamics emerges from interactions between individual network constituents. To address this question we study a minimal but generic model for a nematic network where filament sliding is driven by the action of motor proteins. Our theoretical analysis shows how the interplay between viscous drag on filaments and motor-induced forces governs force propagation through such interconnected filament networks. We find that the ratio between these antagonistic forces establishes the range of filament interaction, which determines how the local filament velocity depends on the polarity of the surrounding network. This force propagation mechanism implies that the polarity-independent sliding observed in Xenopus egg extracts, and in vitro experiments with purified components, is a consequence of a large force propagation length. We suggest how our predictions can be tested by tangible in vitro experiments whose feasibility is assessed with the help of simulations and an accompanying theoretical analysis.

2:42PM J20.00002: Time varying mechanical response of cytoskeletal networks [Invited] MOUMITA DAS (Presenter), Rochester Institute of Technology — Actin filaments and microtubules are critical components of the cytoskeleton, a composite network of filamentous polymers and regulatory proteins. The synergistic interplay of networks of actin filaments and microtubules and their continuous disassembly and reassembly via active de/re-polymerization play a crucial role in a wide range of mechanical properties and processes, including cell stiffness, shape change, and motility. While in-vitro actin networks have been intensely investigated over the past two decades due to their promise for understanding cell mechanics and designing smart materials, questions remain as to how the composite nature of the cytoskeleton and de/re-polymerization kinetics of individual filaments impact the collective, time-varying mechanics of cytoskeletal networks. This talk will discuss an integrated approach consisting of theory and experiments, that seeks to address these questions. In particular, we will describe the mechanical response of composites made of interconnected networks of semiflexible and stiff filaments, time-varying responses of these networks, and how they can be explained by mathematical models that couple the time-evolution of filament lengths with rigidity percolation theory. Our results provide insights into mechanisms that enable cells to exhibit a myriad of mechanical properties and can inform the general principles underlying the mechanics of a large class of dynamic systems and biomaterials of current interest.

*This research was funded in part by the Research Corporation and the Keck Foundation.
The cytoskeleton, composed of actin, microtubules, and associated motor and binding proteins, self-organizes into different structures and morphologies to drive diverse mechanical processes in eukaryotic cells. While in vitro actomyosin networks are well-characterized, few studies have examined how the structure and activity of these networks are altered by the presence of microtubules. We previously synthesized steady-state actin-microtubule networks, finding that mechanical properties, such as network elasticity, depend on molecular interactions between actin and microtubules, such as the degree of crosslinking and bundling. Here, we create active actin-microtubule networks by adding the motor protein myosin. Using confocal microscopy and microrheology, we characterize how the network structure evolves during motor activity, and connect how microscopic changes in network structure affect the mechanical properties of the network. Our results shed important new light on how actin-microtubule interactions influence the structure, mechanics and activity that motor-driven cytoskeleton networks exhibit.

3:30PM J20.00004: Probing length scale-dependent viscoelasticity from bending fluctuations of filaments  KENGO NISHI (Presenter), SUFI RAJA, Duke University, FRED C MACKINTOSH, Rice University, CHRISTOPH F. SCHMIDT, Duke University — Micron-sized beads are commonly used to perform microrheology in soft media. The size of the particles sets the length scale at which properties are probed. This can limit results when the properties of the medium vary with length scale. A typical example of such a system are living cells. Cells are constructed hierarchically, with structural elements ranging from nano- to mesoscopic scales. Here, we introduce the use of semi-flexible filaments/tubes to probe scale-dependent dynamics. We analyze shape fluctuations of semi-flexible filaments. We show that the bending dynamics of filaments can be used to probe the physical properties of such media at multiple scales, corresponding to the wavelengths of the modes analyzed.
3:42PM J20.00005: Triggering salt-induced contraction of cytoskeletal networks with microfluidics*  SHEA RICKETTS (Presenter), PAWAN KHANAL, CHRISTOPHER CURRIE, Univ of San Diego, MICHAEL RUST, Univ of Chicago, MOUMITA DAS, Rochester Institute of Technology, JENNIFER L ROSS, Syracuse, RAE M ROBERTSON-ANDERSON, Univ of San Diego — The mechanical tunability and morphology of the cytoskeleton is determined by interacting networks of semiflexible actin filaments and rigid microtubules. By altering the chemical environment of the cytoskeleton, actin and microtubule networks can dynamically change and rearrange to form entanglements, crosslinks and bundles. For example, increasing the concentration of divalent salt can induce crosslinking and bundling of actin filaments. Here, we use microfluidics and confocal fluorescence microscopy to show that increasing salt concentration triggers contraction of cytoskeleton networks in the absence of motor proteins. Specifically, we use microfluidics to cyclically vary the salt concentration over the course of minutes to hours while simultaneously visualizing the triggered structural changes to the networks and measuring the contraction velocity. Our measurements shed new light on how varying environmental conditions can dynamically tune the morphology of actin-microtubule networks and trigger active contraction without motor proteins.

*NIH Award #R15GM123420 and a W.M. Keck Foundation Research Grant.

3:54PM J20.00006: Slow stress relaxation of transient-crosslinked biopolymer networks  SIHAN CHEN (Presenter), TOMER MARKOVICH, FREDERICK COLIN MACKINTOSH, Rice Univ — It is well established that the unbinding of crosslinkers enables transient-crosslinked biopolymer networks to flow at long times. A recent experiment, however, shows that exerting prestress on such a network leads to near solid-like viscoelastic response. In this talk I will propose a microscopic theory for the rheology of transient networks under prestress. We show that the solid-like dynamics naturally appears as a result of the coupling between the strain-stiffening of semiflexible polymers and the transient nature of the crosslinkers. Our theory predicts the scaling behavior of shear modulus over the whole frequency regime and quantitatively fits the experimental data. This theory may also explain similar slow stress relaxation previously found in living cells.

4:06PM J20.00007: Electric Field Guidance of Actin Waves*  QIXIN YANG (Presenter), MATT HOURWITZ, LEONARD CAMPANELLO, University of Maryland, College Park, BEDRI SHARIF, PETER DEVREOTES, Department of cell biology, Johns Hopkins University, JOHN T FOURKAS, WOLFGANG LOSERT, University of Maryland, College Park — Directional cell migration induced by a DC electric field (DC EF) is an important physiological process involved in wound healing, development, and regeneration. This phenomenon is modulated by the self-generating waves of signaling molecules and actin traveling on cell membranes. It has been shown that chemical perturbations of wave components lead to changes in migratory behaviors. Here we first study how a DC EF provides a unidirectional perturbation of the actin wave patterns, then study the combined perturbation by a DC EF and nanotopography. By quantifying spatial-temporal actin wave patterns, we show that DC EFs can guide actin wave propagation, lead to inhomogeneous activities of actin waves, and alter cell migratory modes.

*This work is funded by the Air Force Office of Scientific Research grant FA9550-16-1-0052
**4:18PM J20.00008: Exploring the effects of actin-binding proteins on the percolation of actin networks using a mean field model**
CARLOS BUENO (Presenter), Systems, Synthetic and Physical Biology, Rice University, JAMES LIMAN, Department of Bioengineering, Rice University, NICHOLAS SCHAFER, Center for Theoretical Biological Physics, Rice University, MARGARET CHEUNG, Department of Physics, University of Houston, PETER G WOLYNES, Center for Theoretical Biological Physics, Rice University — The actin cytoskeleton is a dynamical system that can exert forces and transmit forces between the cell and its environment. The dynamical and rheological properties of the actin cytoskeleton are modulated by actin binding proteins (ABPs). Some ABPs, such as α-actinin or Arp2/3, connect different actin filaments thereby changing the topology of the network. Other ABPs, such as myosin, can also exert forces on the network thus altering its dynamic behavior. In this work we model an actin system and its interaction with α-actinin, myosin and Arp2/3 using ordinary differential equations and stochastic mechanochemical simulations. We then use a mean field approach to quantify how the concentrations of different ABPs affect the connectivity and rigidity of the network. We find that the presence of Arp2/3 increases the connectivity of the network. We also discuss the conditions needed for force exertion and transmission in this system. We expect that this result may provide a theoretical insight into how ABPs affect the ability of the actin cytoskeleton to exert and transmit forces.

**4:30PM J20.00009: Mechanical stability of microtubule lattices under high crowdedness**
LUKASZ SZATKOWSKI (Presenter), ROHITH ANAND VARIKOTI, RUXANDRA I DIMA, Department of Chemistry, University of Cincinnati — Microtubules (MTs) are hollow cylindrical biopolymers of tubulin subunits that play key roles in cells. Understanding their functions in cilia or neurons is difficult because MTs associate in highly crowded bundled arrays. For example, it is unclear how this crowdedness or confinement and the mutual interaction between MTs chains relate to the anisotropy of MT lattices. Because of the large degree of confinement in MT bundles, the use of experimental techniques to answer such questions is not easy. In contrast, computational modeling methods do not exhibit the experimental limitations when studying MTs bundles. Still, most of the existing models treat MTs as an elastic polymer network, in which the anisotropy of the lattice is built in and which excludes the possibility of formation of cracks in the lattice during force application. Our coarse-grained molecular simulations of the response of MT lattices to applied forces allow us to study formation and propagation of cracks. We present a modified indentation protocol to determine the mechanical response of MT lattices under conditions which mimic high confinement. Our model shows that the strength of interactions between MT in bundles has substantial influence on the magnitude of the forces that induce cracks in MT lattices.
4:42PM J20.00010: Understanding the Topology of Microtubules  VARSHA SUBRAMANYAN (Presenter), KESAV SARANYAN KRISHNAN, KAY L KIRKPATRICK, University of Illinois at Urbana-Champaign, SARASWATHI VISHVESHWARA, Molecular Biophysics Unit, Indian Institute of Science, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — The phenomenon of dynamical instability in microtubules is of immense importance in understanding transport within the cell. In recent times, these polymeric proteins have been studied as mechanical lattices possessing a topological edge mode (Phys. Rev. Lett. 103, 248101 (2009)). We extend this idea by modelling the microtubule as a cylindrical lattice of dimers, with interactions between dimers modelled by a hopping Hamiltonian. We show the emergence of topological edge modes, and propose the modelling of dynamic instability as a phase transition. We explicitly determine the conditions for the existence of these edge modes by setting up appropriate difference equations. We speculate on the biological implications of these results, by mapping the dynamic instability of microtubules to the propagation of lattice defects, and also discuss possible methods of computational/experimental verification via microscopic network models of microtubules.

4:54PM J20.00011: The role of multivalent actin-binding proteins in remodeling actomyosin networks*  YOSSI ELIAZ (Presenter), MARGARET CHEUNG, Physics, University of Houston; Center for Theoretical Biological Physics, Rice University — We explore the contribution of multivalent actin-binding proteins (ABPs) in remodeling actomyosin networks by using mesoscopic computer simulations. We model ABPs as junctions with varied multi-valencies that enable bundling or branching of actin filaments, which result in diverse morphologies of actomyosin networks. We developed network theory-based order parameters that quantify connectivity between graph nodes in order to analyze emergent morphologies in actomyosin networks. First, we show that ABPs, such as calmodulin-dependent kinase II (CaMKII), with multivalency greater than two not only increase the thickness of actin bundles, but also promote their arborization. Second, myosin motor proteins accelerate the arborization of actin filaments bundled by CaMKII. Because CaMKII is as abundant as actin filaments in neurons, it plays an important role in remodeling the morphology of actin filaments in actomyosin networks; CaMKII's chemical binding to actin filaments alters the mechanical properties of actomyosin networks that underpin the plasticity of dendritic spines.

*This work was supported by the National Science Foundation under Grants No. NSF CHE-1743392, No. NSF PHY-1427654, and No. NSF OAC-1531814.
Mechanical properties of branched actin networks

MEHDI BOUZID
(Presenter), LPTMS, CNRS, CESAR VALENCE-GALLARDO, PMMH, ESPCI, LARA KOEHLER, LPTMS, CNRS, GIUSEPPE FOFFI, LPS-Orsay, University of Paris Sud, JULIEN HEUVINGH, OLIVIA DU ROURE, PMMH, ESPCI, MARTIN Lenz, LPTMS, CNRS — Gels of fibrous bio-polymers are ubiquitous within cells and their rigidity is crucial for their function. Our current understanding of their elastic response is usually understood as an interplay between the bending and stretching of their filaments. This point of view however fails when applied to the weakly coordinated branched actin networks found throughout the cell. Through experiments, simulations and theory, we show that their elasticity crucially involves reversible entanglements between their filaments. Additional entanglements may get locked in during network growth, setting the final properties of the network. These properties could be key to understanding how moving cells dynamically adapt their cytoskeleton to their environment.

Hydrodynamic effects on the motility of crawling eukaryotic cells*

MELISSA H MAI (Presenter), BRIAN CAMLEY, Johns Hopkins University — Eukaryotic cell motility is crucial during development, wound healing, the immune response, and cancer metastasis. Some eukaryotic cells can swim, but cells more commonly adhere to and crawl along the extracellular matrix. We study the relationship between hydrodynamics and adhesion that describe whether a cell is swimming, crawling, or combining these motions. Our simple model of a cell, based on the three-sphere swimmer, is capable of both swimming and crawling. As cell-matrix adhesion strength increases, the influence of hydrodynamics on migration diminish. Cells with significant adhesion crawl with speeds much larger than their nonadherent, swimming counterparts. We predict that, while most eukaryotic cells are in the strong-adhesion limit, increasing environment viscosity or decreasing cell-matrix adhesion could lead to hydrodynamic effects even in crawling cells. Signatures of hydrodynamic effects include dependence of cell speed on medium viscosity or the presence of a nearby substrate as well as interactions between noncontacting cells. These signatures are suppressed at large adhesion strengths, but even strongly adherent cells will generate fluid flows advecting passive particles and swimmers.

Session J21 GERA: Photovoltaic Materials and Phenomena 302
2:30PM J21.00001: Role of defects in MAPbI₃ to modulate optical absorption, and solar efficiency

POOJA BASERA (Presenter), SASWATA BHATTACHARYA, Physics, Indian Institute of Technology, IIT Delhi — Methylammonium lead halide (MAPbI₃) perovskite has emerged as one of the frontier optoelectronic semiconductors. To avoid lead-toxicity, the role of Sn-substitution and Pb-vacancy (Pb-\(\bullet\)) is addressed in regulating the stability and solar cell efficiency of MAPb\(_{1-X-Y}\)Sn\(_X\)I\(_3\) perovskite using hybrid density functional theory (DFT). We find, to reduce the Pb-content from pristine MAPbI₃, Sn-substitution has favorable thermodynamic stability than Pb-\(\bullet\). High optical absorption coefficient (red shifted) and maximum solar cell efficiency are obtained in MAPb\(_{1-X-Y}\)Sn\(_X\)I\(_3\) for \(0 \leq X \leq 0.5\). The role of spin-orbit coupling (SOC) and electron self-interaction error are examined carefully. Despite SOC has a significant role in artificially shifting the electronic bands, it doesn't affect the relative hierarchy of formation energies of different defected configurations. However, electron self-interaction plays an important role in determining the same. We find a local/semi-local functional (e.g. PBE) gives a completely opposite trend to determine thermodynamic stability w.r.t HSE06+SOC.

YASHIKA GUPTA (Presenter), ANSHUMAN KUMAR, LOQM, Department of Physics, Indian Inst of Tech-Bombay — Organic-Inorganic Lead based perovskite solar cells offer a promising alternative to present day Si-solar cell, reaching an efficiency of almost 25% in a span of less than ten years. However, perovskite based cells still face stability and toxicity issues due to their constituents elements like organic molecules (Methylammonium, Butylammonium etc.) and heavy metal ions (Lead) thus limiting it's prospects towards commercialization. A lot of efforts have been made towards improving the stability of these lead base perovskites to improve their stability by introducing a heavy metal cation into conventional perovskite materials to generate a 2D structure, called Ruddlesden-Popper Perovskite with improved stability than the conventional 3D perovskites. But the issue of Lead toxicity remains. In this work, we propose use of plasmonics as an efficient method to improve the efficiency 2D Ruddlesden Popper perovskite solar cell. The use of plasmonic structures will result in improved light harvesting in the cell while keeping the perovskite layer thickness to minimum and hence reducing the toxic content of the cell giving it a fighting chance for practical applications.
2:54PM J21.00003: Scaling law for excitons in layered 2D perovskites systems: Dion-Jacobson (DJ) phases and Alternating Cation in the Interlayer space (ACI) phases  
Hao Zhang (Presenter), Siraj Sidhik, Wenbin Li, Rice Univ, Jacky Even, INSA Rennes, Jean-Christophe Blancon, Aditya Mohite, Rice Univ — Layered two-dimensional (2D) hybrid perovskites are emerging types of semiconductor quantum wells (QWs) with highly promising opto-electronic applications. These solution-processed materials offer tunability of opto-electronic properties, which can be achieved by varying quantum well thickness (n-value). For instance, our previous work has demonstrated the scaling behavior of excitons with different quantum well thickness in Ruddlesden-Popper (RP) Perovskites. Besides the well-studied RP perovskites, there’re other crystal structures such as Dion-Jacobson (DJ) and Alternating Cation in the Interlayer space (ACI) phases, whose intrinsic exciton and charge carrier properties still remain unrevealed. Here, using optical spectroscopy, we perform detailed studies of the optical and electronics properties on DJ and ACI systems, such as exciton fine structure, electron-phonon coupling and defect states, and demonstrate their scaling behavior with quantum well thickness. These results will bridge the gap between optical properties of 2D and 3D perovskite crystals, leading to better design of opto-electronics devices. The tendency of how different 2D perovskites phases merge into unique 3D perovskite will give us a deeper understanding of the fundamental physics of perovskite materials.

3:06PM J21.00004: Increasing open-circuit voltage in CdTe solar cells through passivation of the previously inaccessible front interface  
Deborah McGott (Presenter), Yegor Samoilenko, Colorado School of Mines, Brian Fluegel, National Renewable Energy Laboratory, Colin Wolden, Colorado School of Mines, Matthew Reese, National Renewable Energy Laboratory — Cadmium telluride (CdTe) is the leading commercialized thin-film photovoltaic (PV) technology with over 25-GW-scale annual production and record device efficiency of 22.1%. However, a major obstacle to achieving higher efficiencies in CdTe is a stubbornly low open-circuit voltage ($V_{OC}$) of ~800-900 mV despite having a near ideal bandgap of 1.45 eV. Surface passivation, particularly of the front interface, is thought to be critical to reduce electron-hole recombination and increase $V_{OC}$. The front interface, however, is buried under microns of material during standard growth of superstrate CdTe and made inaccessible. Here, we use a novel thermo-mechanical liftoff technique to expose the buried front interface, then passivate the surface to improve minority carrier lifetime measured using time-resolved photoluminescence (TRPL). We then complete the device by depositing a transparent front contact to correlate $V_{OC}$ changes in the front interface and minority carrier lifetime.
3:18PM J21.00005: Valley Photovoltaics: Experimental Evidence for a Practical Route towards the Realization of the Hot Carrier Solar Cell*  
KYLE R DORMAN (Presenter),  
HAMIDREZA ESMAIELPOUR, Homer L. Dodge Department of Physics & Astronomy, University of Oklahoma, DAVID K FERRY, School of Electrical, Computer, and Energy Engineering, Arizona State University, TETSUYA D MISHIMA, MICHAEL B SANTOS, VINCENT R. WHITESIDE, IAN R SELLERS, Homer L. Dodge Department of Physics & Astronomy, University of Oklahoma — Hot carrier solar cells offer the potential to increase the efficiency of single gap solar cells beyond 60%. Here a new and viable route is proposed where photoexcited electrons are scattered to and collected from the L and X valleys. We demonstrate proof-of-principle results for an InGaAs/AlInAs heterojunction solar cell that shows an operating voltage (~1.4 eV) in excess of the InGaAs absorber bandgap (0.75 eV) under 1-sun AM 1.5G. Hot carriers are confirmed in simultaneous monochromatic current–voltage and photoluminescence measurements. Hot carrier operation in this simple commercially mature system is driven by the transfer, storage, and extraction of hot carriers in the satellite valleys of InGaAs. Combining intervalley scattering and the Gunn Effect allows the majority of photoexcited electrons to be harnessed with voltages defined by the upper valley separation, and thus an optimized system would exceed the Shockley-Queisser limit for a single bandgap solar cell. A mismatch in the valley degeneracy across the n+-AlInAs/n-InGaAs interface currently limits the performance, but a clear route to the realization of such a device in traditional III-V technologies is presented.

3:30PM J21.00006: PMEG and PMPG (plasmonic multi-electron and multi-photon generation) for PV  
LINDEN HAYES (Presenter), Physics, Boston College, LINGPENG LUO, CONG CHEN, South China Normal University, KRZYSZTOF KEMPA, Physics, Boston College, JINWEI GAO, South China Normal University, FRANK SHIH-YU TSUNG, MICHAEL NAUGHTON, Physics, Boston College — We have recently shown that by embedding nanoparticles possessing properly-tuned plasmonic resonances in the small gap semiconductor absorber of a solar cell that it is possible to achieve significant plasmonic multi-electron generation (PMEG)[1]. Synthesis efforts are underway to construct a perovskite-nanoparticle system in order to experimentally verify the viability of PMEG to increase the efficiency of the solar cell.

An additional method of using nanoparticles to enhance the efficiency of solar cells by utilizing the downconverting properties of nanoparticles, plasmonic multi-photon generation (PMPG) is also being investigated. In downconversion, high energy incident photons are converted into multiple lower energy photons that more closely correspond to the bandgap of a solar cell. This should simultaneously increase the efficiency of the cell and, in the case of perovskites, increase the long term stability, as these absorbers are negatively impacted by incident UV light. Synthesis of this system is also underway.

3:42PM J21.00007: Suppressing deep-trap formation in Cu$_2$ZnSnS$_4$-based solar cells  ROBERT WEXLER (Presenter), SAI GAUTAM GOPALAKRISHNAN, Princeton University, EMILY CARTER, UCLA — Cu$_2$ZnSnS$_4$ (CZTS) is a cheap, nontoxic, easy-to-synthesize, and stable solar cell absorber material. Despite these advantages over Si, GaAs, CdTe, CuIn$_x$Ga$_{1-x}$Se$_2$, and hybrid perovskites, CZTS-based solar cells are plagued by low efficiencies (12.6%) compared to the Shockley-Queisser limit (33.7%). This 21.1% efficiency deficit was suggested recently to be due to the formation of defect clusters involving the Sn$_Zn$ antisite, which induces deep-trap states and therefore promotes carrier recombination. In this talk, we present density functional theory calculations of defect thermodynamics to show that these deep-trap defect clusters can be suppressed in CZTS via Ge- and Se-codoping. Additionally, we will describe an electrostatic mechanism for the suppression of deep defects by Ge that can be readily applied to other kesterite-type absorber materials and therefore used to design next-generation CZTS-inspired solar cells.

3:54PM J21.00008: A low-temperature-low-intensity study of flexible CIGS solar cells*  HADI AFSHARI (Presenter), BRANDON DURANT, COLLIN BROWN, Univ of Oklahoma, KHALID HOSSAIN, Amethyst Research Incorporated, DMITRY POPLAVSKYY, MiaSolé Hi-Tech Corp, IAN R SELLERS, Univ of Oklahoma — Commercially available lightweight and flexible CIGS solar cells are investigated for their performance under low intensity low temperature (LILT) conditions governing outer planets Mars, Jupiter, and Saturn. Current density-voltage under varying temperatures and illumination intensities, including concentrated solar, as well as electroluminescence measurements is performed to investigate the effects of conditions in deep space. A barrier to minority carrier extraction is observed and attributed to the acceptor rich defect layer near the CIGS absorber/CdS buffer interface. The effect of this barrier on power generation is presented and shown to decrease after light soaking, due to a transition between the so-called relaxed to metastable states. The power conversion efficiencies are shown to be higher for LILT conditions compared to terrestrial application.

4:06PM J21.00009: Interfacial Properties of Solar Energy Materials from DFT: P3HT/ZnO and CdS/Graphene  LEAH BENDAVID (Presenter), Vassar College, LIAT H. KUGELMASS, Cornell University, AUSTIN ATSANGO, Stanford University, REID W. SMITH, Vassar College — We present two projects that demonstrate how computational quantum chemistry is used to better understand materials for solar energy applications. In the first project, we use density functional theory (DFT) to examine the P3HT/ZnO solar cell and the mechanism by which interfacial modification with PCBA and doping with Sr enhances photovoltaic efficiency. We find that the enhancement in photovoltaic efficiency is not due to changes in equilibrium structures or adhesion strengths. Rather, the impacts of Sr-doping and PCBA are linked to changes to the energy level alignments. In the second project, we focus on CdS/graphene photocatalytic interfaces. Using DFT calculations, we study the interfacial properties of CdS(0001)/graphene and a CdS/graphene bilayer, and examine whether doping with B/N can strengthen interfacial adhesion. The CdS/graphene bilayer is found to exhibit high interplanar distances and low adhesion energies, characteristic of dispersion-dominated interfacial adhesion. Doping graphene does not significantly modify the strength of adhesion, but it does enable modulation of the band edge and Fermi level alignments. The CdS(0001)/graphene interface is found to be similarly adhered via dispersion interactions, but here, doping with B strengthens interfacial adhesion.

4:18PM J21.00010: Polymer solar cell incorporating PEDOT:PSS films and MEH-PPV nanopillars*  ARCHANA KUMARI (Presenter), Slippery Rock Univ — Poly[2-methoxy-5-(2-ethylhexyloxy)-1.4-phenylenevinylene] (MEH-PPV) is an attractive polymer for organic solar cells which were fabricated with spin coating technique using capillary force through the pores in to the channels of the alumina templates on the Glass/ITO substrates. The nanopillars were studied using UV-Vis absorption spectroscopy and found an enhanced absorption as compared to same thickness of MEH-PPV films. Organic solar cells will be fabricated with structures as Glass/ITO/TiO₂/PEDOT:PSS/ MEH-PPV nanopillars/Al, where MEH-PPV acts as an electron donor and TiO₂ semiconductor material is used as an acceptor in polymer solar cell. PEDOT:PSS can improve performance by enhancement of hole collection, exciton diffusion and photocarrier transport. Surface morphology of the nanopillars in solar cell will be studied using Scanning Electron Microscopy, and various other characterization techniques such as UV-Vis spectroscopy, PL spectroscopy, energy dispersive X-ray spectroscopy and atomic force microscopy will be used. The performance of the solar cells will be determined by I-V characterization. Optimization of the dimensions of the nanopillars and thickness of the film will be done to obtain maximum efficiency of the devices.

4:30PM J21.00011: Hot carrier dynamics in Quantum Well Solar Cells (Thermal Photon Gain)  BRANDON DURANT (Presenter), Univ of Oklahoma, KEITH BARNHAM, Physics, Imperial College, VINCENT R. WHITESIDE, IAN R SELLERS, Univ of Oklahoma — Quantum well solar cells (QWSCs) have been shown to inhibit hot carrier thermalization relative to bulk materials and have therefore stimulated significant interest as a potential absorber region in third generation hot carrier solar cells. Investigations of high quality InGaAs/GaAsP QWs in GaAs p-i-n solar cells have recently alluded to the possibility of hot carrier extraction in device structures through the measurement of a diode ideality factor of $n < 1$. In order to prove the carriers extracted in these systems are in fact “hot,” simultaneous current density-voltage (JV) and photoluminescence (PL) measurements are performed to directly compare the carrier dynamics and photovoltaic performance in such devices. Several transitions complicate the PL spectra of QWs making determination of the carrier temperature via fitting of the high energy tail using simple Planck's law methods insufficient. Therefore, full spectral fitting is performed in order to extract the carrier temperature while considering the occupation of higher energy states in the QWs, which is then related to ideality factor determined in electrical measurements.

4:42PM J21.00012: Giant Photovoltaic Effect in Magnetic Materials  OLES MATSYSHYN, INTI SODEMANN (Presenter), Max Planck Institute for the Physics of Complex Systems — We investigate a rectification process present in materials that break both inversion and time reversal symmetries. At second order in electric fields, this effect is inversely proportional to the relaxation rate, and, therefore, the rectified current would be infinity in a "naive" ideal clean and zero temperature limit. Employing Floquet theory, we show, however, that there is a non-perturbative correction in the electric field strength that regularises this divergence, but, which ultimately leads to a giant photo-current generation. Therefore, this effect offers a promising alternative paradigm for solar cell technologies.

4:54PM J21.00013: Thermodynamics of Photovoltaic Conversion with Nonreciprocal Processes  ANDREI SERGEEV (Presenter), US Army Rsch Lab - Adelphi, KIMBERLY SABLON, Office of the Deputy Assistant Secretary of the Army for Research and Technology — Nonreciprocal photon and electron processes can violate Kirchhoff's law, detailed balance, and chemical equilibrium in the system of electrons and phonons. As the fundamental Shockley – Queisser limit of photovoltaic conversion is directly based on detailed balance, nonreciprocal processes can improve the efficiency beyond the Shockley – Queisser limitation. We derived thermodynamic limits of efficiency of photovoltaic converters with nonreciprocal processes and consider various realization of nonreciprocal converters. We demonstrate that even dissipative nonreciprocal processes can increase the conversion efficiency beyond the Shockley – Queisser limit. The thermodynamic theory is applied to solar energy conversion, laser power beaming, and thermophotovoltaic conversion.

Direct Observation of shift and ballistic photovoltaic currents

AARON BURGER (Presenter), Electrical and Computer Engineering, Drexel University, RADHE AGARWAL, Materials Science and Engineering, Drexel University, ALEXEY APRELEV, Physics, Drexel University, EDWARD SCHRUBA, Electrical and Computer Engineering, Drexel University, ALEJANDRO GUTIERREZ-PEREZ, VLADIMIR M. FRIDKIN, JONATHAN E SPANIER, Materials Science and Engineering, Drexel University — The quantum phenomenon of shift photovoltaic current was predicted decades ago, but this effect was never observed directly because shift and ballistic currents coexist. The atomic-scale relaxation time of shift, along with the absence of a photo-Hall behavior, has made decisive measurement of shift elusive. Here, we report a facile, direct-current, steady-state method for unambiguous determination of shift by means of the simultaneous measurements of linear and circular bulk photovoltaic currents under magnetic field, in a sillenite piezoelectric crystal. Comparison with theoretical predictions permits estimation of the signature length scale for shift. Remarkably, shift and ballistic photovoltaic currents under monochromatic illumination simultaneously flow in opposite directions. Disentangling the shift and ballistic contributions opens the way for quantitative, fundamental insight into and practical understanding of these radically different photovoltaic current mechanisms and their relationship.

Bulk photovoltaic effect induced by elliptically-polarized light

LINGYUAN GAO (Presenter), ANDREW MARSHALL RAPPE, University of Pennsylvania — Shift current has been considered as one of the major origins for bulk photovoltaic effects. In this study, using time-dependent perturbation theory, we investigate the light polarization effect on shift current. We give a general formula for shift current induced by elliptically-polarized (EP) light, which represents the most general form of a polarized light. By using a two-band model widely applied in 2D materials, we calculate the EP shift current quantitatively, and compare it with the linearly-polarized shift current and circularly-polarized injection current.

2:30PM J22.00001: Building with melanin: Low complexity Glycera jaw protein is master of multitasking* [Invited] J HERBERT WAITE (Presenter), University of California, Santa Barbara — In protein structure-function relationships, there is a widely held view that complex functions require complex structures. Recent studies with a low complexity protein from the jaws of Glycera, a benthic marine polychaete, appear to challenge this. Used for grasping and injecting venom, the jaws are stiff, sharp, durable and wear resistant. Proteins (50 wt %) are one of three jaw components including melanin (40 wt %) and copper (10 wt %) present as a copper mineral (atacamite) and Cu$^{2+}$ ions. Although jaw stiffness is correlated with melanin not mineral, little was known about the protein contribution until its recent characterization and recombinant expression. The Glycera jaw protein has an extremely low complexity sequence in which GGH repeats represent 80% of the composition. Notwithstanding such monotony, GJP exhibits the following distinct properties: 1) it binds 26 equivalents of Cu per protein, 2) catalyzes oxidation of Dopa to Dopa-quinone en route to melanin, 3) templates a sheet-like assembly (32 nm thick) of melanin at the air-water interface, and 4) forms a structural network with melanin and Cu in the stacked sheets of higher order architecture.

*We thank NSF grant DMR 1720256 for partial support.

3:06PM J22.00002: Memory and learning in biomolecular soft materials CHARLES COLLIER (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Lab, JOSEPH NAJEM, Mechanical Engineering, Penn State, STAN WILLIAMS, Electrical and Computer Engineering, Texas A&M University, GRAHAM TAYLOR, T&T Scientific Corporation, CATHERINE SCHUMAN, Computer Science Division, Oak Ridge National Laboratory, ALEX BELIANINOV, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, BENJAMIN DOUGHTY, Chemical Sciences Division, Oak Ridge National Laboratory, RYAN WEISS, MD SAKIB HASAN, GARRETT ROSE, Electrical Engineering and Computer Sciences, University of Tennessee, STEPHEN SARLES, Mechanical Aerospace and Biomedical Engineering, University of Tennessee — Neuromorphic elements have been predominantly solid-state devices which simulate the resistive and capacitive behaviors needed for neural networks and brain-inspired computing, but in non-brain-like ways. We are integrating lipid and polymer bilayer membranes with micro- and nanofabrication to develop fundamentally new types of neuromorphic elements that have the composition (biomolecules), structure (biomembranes), and switching mechanism (voltage-sensitive ion channels) of real biological synapses, and operate at lower power than the current state-of-the-art. Our devices consist of insulating, nm-thick lipid or polymer-based bilayer membranes that assemble at the interfaces of two or more aqueous droplets in oil, and that have demonstrated both memristive and memcapacitive behaviors, including memory resistance and capacitance, synaptic functions such as paired-pulse facilitation and depression, spike rate dependent plasticity, voltage-dependent inactivation and recovery, and charging hysteresis. These behaviors are linked to electrostriction, an electromechanical phenomenon that encompasses both electrowetting and electrocompression in the membrane, which are changes in membrane area and thickness due to charging in the presence of electric fields.
3:18PM J22.00003: Formation temperature of biomaterials through geologic time* [Invited]
KRISTIN BERGMANN (Presenter), SAM GOLDBERG, NOAH ANDERSON, ADAM JOST, Massachusetts Institute of Technology MIT, PUPA GILBERT, Physics, University of Wisconsin, Madison, CORINNE MYERS, University of New Mexico — The well-known secular increase in δ^{18}O values of both calcitic and phosphatic marine fossils through early Phanerozoic time suggests three end-member hypotheses 1) early Paleozoic surface temperatures were high, in excess of 40°C (tropical MAT), 2) the δ^{18}O value of seawater has increased by up to 7–8‰ VSMOW over Paleozoic time, or 3) early Paleozoic samples are more significantly altered than younger materials, with the secular trend reflecting these differences in post-depositional processes. Carbonate clumped isotope analysis, in combination with petrographic and elemental analysis, has the capacity to deconvolve fluid composition from temperature effects and therefore to determine which of these hypotheses is best supported. A sample suite including calcitic, aragonitic and phosphatic marine fossils from the last 500 million years indicate surface temperatures in tropical seas were similar to slightly warmer than today (avg. 26-38°C) in the early Paleozoic, while the oxygen isotope budget of seawater appears to be similar to that of today.

3:54PM J22.00004: Nano-optical characterization of photosynthetic bacteria-2D material coupled system
SHARAD AMBARDAR (Presenter), ZACHARY FREY, DMITRI V VORONINE, Univ of South Florida — Atomically thin 2D materials especially TMDs grown laterally, on combining with other TMDs form heterostructures with atomically sharp interfaces. We use conventional far-field (FF) photoluminescence (PL) and near-field (NF) tip-enhanced photoluminescence (TEPL) to investigate the bio-sensing applications of TMD materials by depositing photosynthetic cyanobacteria on MoS_2-WS_2 heterostructure grown on SiO_2/Si substrate. The energy transfer between the 2D materials and the photosynthetic bacteria leads to formation of an energy funnel at the pole of the bacteria. Due to this, the photoluminescence at the pole is high and is enhanced due to the cyanobacteria. The coupling between the photosynthetic bacteria and 2D material can be used for production of sustainable energy resources.
4:06PM J22.00005: African Elephant Sensing Capabilities through Skin and Hair* ANDREW SCHULZ (Presenter), Mechanical Engineering, Georgia Institute of Technology, COLIN J BOYLE, Mechanical Engineering, Imperial College London, CLAIRE A HIGGINS, Bioengineering, Imperial College London, DAVID HU, Mechanical Engineering, Georgia Institute of Technology — The mouse and the elephant share a common sensing mechanism, vibrissae, or whiskers. In this study, we dissect an African elephant trunk and perform histology and measurement of the mechanical properties of the skin. We observe both long and short vibrissal hairs, ranging from 1 cm at the base of the trunk to 8 cm at the base. The length of hairs is likely associated with the different requirements at each position. Skin surrounding the vibrissae is stiffer, which may help the vibrissae better receive information. The dorsal part of the trunk is also stiffer than the ventral side, which may help the trunk grasp objects using the ventral portion. Through experiments conducted with histological and tensile test we report the different characteristics of the dermis. Heterogeneous properties of the skin in the elephant may give inspiration to designing of new flexible surfaces for biologically inspired soft robotic manipulators.

4:18PM J22.00006: The role of residual stresses in biomineral morphogenesis revealed by 3D dark-field x-ray microscopy* [Invited] VANESSA SCHÖPPLER (Presenter), IGOR ZLOTNIKOV, BCUBE, TU Dresden — Residual stresses occur in numerous synthetic, geological and biogenic crystals having desirable or undesirable effects on materials performance. Recent studies have shown the significance of residual stresses in the mechanical functionality of a number of biomineralized tissues. However, the role of these forces in biomineral morphogenesis was never previously examined, mainly due to the lack of an appropriate multiscale characterization approach. Most of the state-of-the-art methods are either surface techniques yielding 2D information or allow limited 3D analysis of very small sample volumes. In this work, we employed the recently developed technique—dark-field x-ray microscopy—to study the relationship between residual stresses and crystallographic properties of biogenic calcite in the prismatic ultrastructure in the bivalves Pinna nobilis and Pinctada nigra in 3D. This method, developed at the European Synchrotron Radiation Facility, utilizes magnifying refractive lenses to map lattice distortions with an angular resolution of 0.001° and allows to analyze millimeter sized samples with a spatial resolution of 50 nm. Whereas the prisms in P. nobilis have an almost perfect single crystalline character, the prisms in P. nigra gradually change their crystallographic orientation and split into sub-prismatic domains. Due to the high angular resolution of the method, we were able to obtain unprecedented detail on the mosaicity of prisms in the two organisms and to demonstrate a correlation between internal lattice strains and local crystallographic properties of biogenic calcite in 3D. By comparing the experimental data from the two species, we not only shed a new light on the relationship between structure and texture during biomineralized tissues formation, but also demonstrate the role of internal stresses in biomineral morphogenesis.

4:54PM J22.00007: Effect of Sea Water pH on the Maturation of Marine Mussel Plaques
JUSTIN BERNSTEIN (Presenter), University of California, Santa Barbara, EMMANOUELA FILIPPIDI, Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, J HERBERT WAITE, MEGAN VALENTINE, University of California, Santa Barbara — Marine mussel plaques are an exceptional model for wet adhesives. Despite understanding their protein composition, we do not know how soluble proteins are rapidly processed into load-bearing structures. Here, we examine the effects of seawater pH on the time evolution of the internal microstructures in Mytilus californianus plaques. Experimentally, plaques deposited by mussels on glass surfaces are immediately collected, placed into pH-controlled artificial seawater for varying times, and characterized using scanning electron microscopy and tensile testing. We found a pH dependent transition from a liquid-like state to a porous solid within 30 minutes for pH ≥ 6.7; these plaques are load-bearing. By contrast, samples maintained at pH 3.0 showed no porosity and no measurable strength. Interestingly, we found no differences in cuticle thickness, suggesting that cuticle mechanics may be compromised at low pH. Our results suggest that sea water infusion after deposition is critical to the rapid formation of internal structures, which in turn plays an important role in the plaques’ mechanical performance.

5:06PM J22.00008: Mechanics and Adhesive Performance of Mussels on Roughness- and Geometry-controlled 3D printed Substrates
YOUNGHOON KWON (Presenter), JUSTIN BERNSTEIN, MEGAN VALENTINE, University of California, Santa Barbara, NOY COHEN, Israel institute of technology — Marine mussels have the remarkable ability to adhere to a variety of natural and artificial surfaces under hostile environmental conditions. Although the molecular composition of mussel adhesives has been well studied, a mechanistic understanding the physical origins of mussels' impressive adhesive strength remains elusive. Here, we investigated the role of substrate roughness and geometry in the adhesive performance of mussels. Using 3D printing, sandblasting, and laser texturing we created substrates with differing surface treatments and introduced these to mussels, which in turn adhered to the engineered surfaces via plaque-thread byssal structures. Tensile testing with in situ imaging was used to determine the adhesion strength and mechanical properties of the mussel adhesive plaques under various conditions. Our results inform the relationships between adhesive performance and substrate properties, give insight into the physical governing factors of mussel adhesion, and provide design criteria for development of synthetic adhesives for use on complex, textured surfaces.

2:30PM J23.00001: Resource-rich environments can reduce stability and diversity in microbial communities by strengthening interspecies interactions  CHRISTOPH RATZKE, JULIENE BARRERE, JEFFREY GORE (Presenter), Massachusetts Institute of Technology MIT — Organisms – especially microbes – tend to live in complex communities. While some of these ecosystems are very bio-diverse, others aren’t, and while some are very stable over time others undergo strong temporal fluctuations. Despite a long history of research and a plethora of data it is not fully understood what sets biodiversity and stability of ecosystems. Theory as well as experiments suggest a connection between species interaction, biodiversity, and stability of ecosystems, where an increase of ecosystem stability with biodiversity is often observed. However, what causes these connections remains unclear. Here we show in microbial ecosystems in the lab that the concentrations of available nutrients can set the strength of interactions between bacteria. At high nutrient concentrations, extensive microbial growth leads to strong chemical modifications of the environment, causing more negative interactions between species. These stronger interactions exclude more species from the community – resulting in a loss of biodiversity. At the same time, these stronger interactions also decrease the stability of the microbial communities, providing a mechanistic link between species interaction, biodiversity and stability.

2:42PM J23.00002: Niche-Neutral Transition in a Lotka-Volterra Model of Diverse Ecosystems  JIM WU (Presenter), Princeton University, DAVID J. SCHWAB, City University of New York, PANKAJ MEHTA, Boston University — Niche and neutral theory are two prevailing, yet much debated, ideas in ecology proposed to explain the patterns of biodiversity. Whereas niche theory emphasizes selective differences between species and interspecific interactions in shaping the community, neutral theory supposes functional equivalence between species and points to stochasticity as the primary driver of ecological dynamics. In this work, we draw a bridge between these two opposing theories. Starting from a Lotka-Volterra (LV) model with demographic noise and random symmetric interactions, we analytically derive the stationary species abundance distribution and extract the population statistics. Using these results, we demonstrate the existence of a phase transition between niche and neutral regimes, thus reconciling how neutral-like statistics may arise from a diverse community of species with different traits.
2:54PM J23.00003: Competition-driven strategies for controlling multistable microbial communities  VERONIKA DUBINKINA (Presenter), University of Illinois at Urbana-Champaign, AKSHIT GOYAL, The Simons Centre for the Study of Living Machines, NCBS, YULIA FRIDMAN, National Research Center “Kurchatov Institute”, PARTH PRATIM PANDEY, SERGEI MASLOV, University of Illinois at Urbana-Champaign — Microbial communities often need particular species compositions, or community states, to perform a certain function. Because these communities play crucial roles in human health and industry, we need to maintain them in particular desirable states, and prevent them from reaching undesirable ones. What makes this task especially challenging is that microbial communities are often multistable; both desirable and undesirable states may be possible in the same environmental conditions. Due to these complications, we still lack pragmatic and reliable strategies to fulfill this task. Here, we propose two strategies to control multistable microbial communities: that of controlling the colonization order in which species are introduced into a community, and that of controlling the supply of nutrients to a community. Both strategies are driven by competition for nutrients between microbial species. As a proof of concept, we illustrate their implementation in a resource-explicit model. Our proposed strategies have the potential to greatly improve existing methods to engineer and manipulate real microbial communities, such as in industrial bioreactors and the human gut.

3:06PM J23.00004: Long-range patterns of activity shaped by signaling interactions within bacterial communities*  JAMES BOEDICKER (Presenter), KALINGA PAVAN T SILVA, Tahir YUSUFALY, Univ of Southern California — Bacteria communicate to coordinate macro-scale patterns of gene expression and associated group behaviors such as biofilm formation. Cells secrete, sense, and respond to small chemical signals in a process known as quorum sensing. Within diverse bacterial communities, signal exchange is modulated by signaling interactions between different cell types, including interference through signal crosstalk and signal destruction. Our work explored how signaling interactions between multiple cell types shape global patterns of gene expression. We examined how community composition modulated signal-dependent gene expression using both experiments and reaction-diffusion models. In some communities, the pattern of gene expression followed a 2D percolation transition, controlled by the ratio of signal producing and signal destroying strains in the community. At a critical amount of interference, signal exchange was disrupted and long-range communication was suppressed. We explored the limitations of diffusive communication and strategies cells could use to coordinate behavior at length scales exceeding distances over which diffusion is effective.

3:18PM J23.00005: Ecological interactions constrain the coexistence of generalists and specialists during coevolution in microbial communities  
AKSHIT GOYAL (Presenter), Massachusetts Institute of Technology MIT — Natural microbial communities are complex ecosystems in which species with different metabolic strategies—both generalists and specialists—stably coexist. We do not understand how coevolution within a community can both lead to, and stabilize, such coexistence, and how generic we expect it to be. Here, we propose and study a minimal model of a co-evolving microbial community shaped by ecological interactions. Our model combines competition and cooperation for nutrients with evolutionary game theory. In doing so, it makes three broad and surprising predictions about co-evolved microbial communities. First, we find that generalists and specialists coexist only in a narrow range of ecological interactions; in all other regimes, specialists dominate. Second, we find that co-evolving with others makes it strikingly difficult for generalists to evolve a correlation between their nutrient preferences and growth rates; such a correlation is often observed in experiments. Finally, we find that communities with a greater fraction of generalists are also likely to have more stable states, which can be tested. This model provides a simple framework through which to quantify and make testable predictions about coevolution in microbial communities.

3:30PM J23.00006: Criticality on topologically disordered systems and the Harris criterion*  
HATEM BARGHATHI (Presenter), THOMAS VOJTA, Missouri Univ of Sci & Tech — To test the stability of clean critical points against quenched spatial disorder, Harris introduced the criterion \( d\nu > 2 \). Its predictions are in agreement with the vast majority of analytical and numerical results on phase transition in disordered systems. However, in systems where disorder arises from random connectivity, a number of violations of the Harris criterion have been reported. We recently introduced \([1]\) a modified stability criterion, \( (d+1)\nu > 2 \), for systems in which the presence of topological constraints suppresses disorder fluctuations, resulting in a violation of the usual Harris criterion. However, some recent results on topologically disordered systems appear to violate even the modified criterion. To uncover the source of such apparent violations we perform a detailed statistical analysis of such systems together with large-scale Monte Carlo simulations.

**3:42PM J23.00007: The Emergence of Spatial Patterns in Tree Yield: A New Model for the Masting Phenomenon**  
SHADISADAT ESMAEILI (Presenter), University of California at Davis, ALAN HASTINGS, University of California at Davis, Santa Fe Institute, KAREN ABBOTT, Case Western Reserve University, JONATHAN MACHTA, University of Massachusetts Amherst, Santa Fe Institute, VAHINI REDDY NAREDDY, University of Massachusetts Amherst — The emergence of patterns of synchrony is ubiquitous across many fields, including ecological systems in which synchrony can be both favorable and detrimental. The prevalence of synchrony creates the expectation of the existence of detail-independent principles that can explain and predict this phenomenon and its emergence. A notable example of synchrony is the “masting” phenomenon observed in many plant species in which individual plants show variable annual production (bearing), which is spatially correlated. External forces and local dynamics can lead to the emergence of spatial patterns or full synchrony in such systems. Currently, existing models for masting phenomenon, while proposing a mechanism for alternate bearing, do not address the spatial patterns observed in real data. In this talk, we introduce a new model to emulate the observed spatial patterns and study the effects of local coupling and external forces on the dynamics of the system.

**3:54PM J23.00008: Binary Decisions of Large Cliques of Evidence Accumulators**  
BHARGAV KARAMCHED (Presenter), Univ of Houston, ZACHARY KILPATRICK, Applied Mathematics, University of Colorado - Boulder, KRESIMIR JOSIC, MEGAN STICKLER, WILL OTT, Univ of Houston, BENJAMIN LINDNER, Physics, Humboldt University — We consider cliques of N evidence accumulators making a binary decision based on noisy observations. Each agent's evidence is a drift-diffusion process on a symmetric, bounded domain with absorbing boundaries. An agent makes an immutable decision when their evidence reaches one of the boundaries (thresholds). Prior to a decision, each agent's evidence is an independent stochastic process. Following a decision, each agent's evidence receives a bump equal to the value of the threshold corresponding to the decision. In large cliques, such a decision can induce a large fraction of the agents to agree with the initial decider. If the first decider is correct, this bodes well for the overall performance of the clique. However, if the initial decider is incorrect, the overall performance of the clique can be disastrous. We derive asymptotic results conveying what fraction of agents agree with the initial decider upon observing their decision and how the remaining agents decide thereafter to agree with the initial decider or collectively disagree with them. We also show how the framework of the evidence accumulation in cliques can be modified so that it is self-correcting and, even if the first decision is wrong, have the majority of the clique choose the correct decision.
4:06PM J23.00009: Identifying Suspicious Users and Products to Predict New Opinions
SUKHWAN CHUNG (Presenter), Physics, University of Notre Dame — An opinion network describes how a person values an object, which can be another person or product. This type of network is ubiquitous because humans constantly evaluate their surroundings. Analyzing an opinion network can bring deeper understanding of what and how people are thinking, but at the same time, a malicious attempt to influence such network can be harmful to the public. One problem naturally arising while studying opinion networks is identifying users leaving intentionally fake opinions to influence the opinions of others. Another question that can be asked is how to predict a person's opinion towards another. In this work, a solution to those issues is suggested using the Rev2 algorithm (developed by S. Kumar, et al) and the principle of maximum entropy. The Rev2 algorithm is used to assign a suspiciousness score to users based on how much the user's action deviates from the rest. Also, a quality index will be assigned to products based on reliable opinions. Using this information, the principle of maximum entropy is invoked to produce the most unbiased prediction of new opinions. The proposed solution is tested against public network data including a user-to-user trust network of Bitcoin platform users and a user-to-product rating network of Netflix users.

4:18PM J23.00010: Optimal evidence accumulation on social networks* BHARGAV KARAMCHED, SIMON STOLARCZYK, KRESIMIR JOSIC, University of Houston, ZACHARY KILPATRICK (Presenter), University of Colorado, Boulder — To make decisions we are guided by the evidence we collect, as well as the opinions of friends and neighbors. How do we integrate our private beliefs with information we obtain from our social network? To understand the strategies humans use to do so, it is useful to compare them to observers that optimally integrate all evidence. Here we derive network models of rational agents who accumulate private measurements and observe decisions of their neighbors to choose between two options. The resulting information exchange dynamics has interesting properties: When one option is preferred, the absence of a decision can be increasingly informative over time. In recurrent networks an absence of a decision can lead to a sequence of belief updates akin to those in the literature on common knowledge. In large networks, a single decision can trigger a cascade of agreements and disagreements that depend on the private information agents have gathered. Our approach provides a bridge between social decision making models in the economics literature, which largely ignore the temporal dynamics of decisions, and the single-observer evidence accumulator models used widely in neuroscience and psychology.

4:30PM J23.00011: Sensitivity of collective outcomes identifies pivotal components*
EDWARD LEE (Presenter), Cornell University, DANIEL M KATZ, MICHAEL J BOMMARITO, Chicago-Kent School of Law, Illinois Institute of Technology, PAUL GINSPARG, Cornell University — The relation between collective outcomes and individual behavior is a central question in social science, biology, and statistical physics. Using the information geometry of minimal models from statistical physics, we develop a general approach for identifying key "pivotal" components on which aggregate statistics depend most sensitively. For political voting, pivotal blocs are like swing voters on whom the distribution of majority-minority divisions depends most sensitively. Analogously, collective market movement may be characterized by a few important stock indices, or the identity of a community on Twitter may hinge on a few individuals. In neural networks, pivotal components may be important for determining collective states. Our approach may help evaluate how political bodies change with membership or analyze the robustness of social institutions and biological networks to targeted perturbation.

4:42PM J23.00012: Community optimization and ruggedness of ecological landscapes*
ASHISH B. GEORGE (Presenter), KIRILL S KOROLEV, Boston University — Many applications require the assembly of an optimal microbial community that maximizes biofuel production, crop yield, or remediation potential. The number of combinations in which these communities can be assembled grows exponentially with the number of species. Therefore, optimization strategies have to rely on heuristic algorithms that iteratively select the best community from a small set of trial communities. The success of such strategies depends on the ruggedness of the landscape of community function. We show that consumer-resource models with and without cross-feeding have unique steady states that depend only on the presence or absence of species in the community. Thus, community selection is a search on an ecological landscape in close analogy with evolution on fitness landscapes in population genetics. We report typical ruggednesses of such landscapes, and discuss how they depend on inter-specific interactions and environmental conditions. We also determine the conditions under which landscape ruggedness can be estimated from incomplete data.

4:54PM J23.00013: History-dependent tradeoffs in changing environments* [Invited] MIKHAIL TIKHONOV (Presenter), Washington University, St. Louis — Performance tradeoffs, which simple models typically postulate, are known to themselves evolve. This leads to a curious feedback loop: evolutionary history shapes tradeoff strength, which, in turn, shapes evolutionary future. Using a simple model, I will show that this feedback can lead to counterintuitive consequences in the context of multiple or changing environments: specifically, a direct exposure to some environment of interest will, in general, no longer be the most effective way of achieving highest fitness in it. I will demonstrate three different mechanisms for how alternate exposure strategies can prove more effective: inducing a more evolvable architecture, counteracting a form of “use it or lose it”, or relying on horizontal gene transfer; and will discuss the prospects of linking these theoretical expectations to experiments.

Session J24 GSNP DFD: Crystallization, Jamming, and Glassy Behavior

2:30PM J24.00001: Nucleation in Granular Media Undergoing Cyclic Shear [Invited] WEIWEI JIN (Presenter), COREY SHANE O'HERN, Yale University, CHARLES RADIN, Department of Mathematics, University of Texas at Austin, MARK SHATTUCK, The City College of New York, HARRY L SWINNEY, University of Texas at Austin — Recent experiments have found that homogeneous nucleation occurs in dense granular materials undergoing cyclic shear from an initially disordered state. In the experiments, the mm-sized grains are under gravitational loading and interact via frictional contact forces. In this work, we carry out discrete element method simulations to determine the contributions of friction and gravity to crystallization of granular materials during cyclic shear. We show that cyclic shear of frictionless granular materials in the absence of gravity gives rise to a first-order-like phase transition from a disordered state to a polycrystalline state with domains of face-centered cubic and hexagonal close packed positional order. The polycrystalline ordering develops through homogeneous nucleation, i.e., spontaneous formation of crystalline clusters far from the boundaries of the system. The small crystalline clusters typically shrink before they reach a critical size, above which crystallites with no preferred orientation grow to reach the system size. Thus, gravitational loading and frictional forces are not necessary to induce crystallization in driven granular media.
3:06PM J24.00002: Structural and Mechanical Characteristics of the Disordered-Ordered Transition in Mechanically Stable Sphere Packings  HIDEYUKI MIZUNO, The University of Tokyo, KUNIYASU SAITO, Tohoku University, LEO SILBERT (Presenter), Central New Mexico Community College — Using the discrete element method, we generate mechanically stable sphere packings in three dimensions that span a wide range in structural order, ranging from fully amorphous through to (quasi) ordered structures, as characterized by the globally averaged bond orientational order parameter. While amorphous systems exhibit features consistent with hyperuniformity – suppressed density fluctuations in the long-wavelength limit – as the packing structure becomes more ordered, the low-wavenumber limit of the static structure factor grows with increasing order. As the packing pressure, $p$, is varied from the marginally rigidity ($p \sim 0$) to more robust systems ($p >> 0$), the packing coordination number, $z$, follows a familiar scaling relation with pressure, $\Delta z = z - z_0 \sim p^{1/2}$, where $z_0 = z(p=0)$. While it has previously been noted that $\Delta z$ is the control parameter that determines packing properties, here we show how packing structure plays an influential role on the mechanical properties of the packings. Specifically, we find that the elastic (bulk and shear) moduli, generically referred to as $M$, become functions of both $\Delta z$ and structure, to the extent that, $M - M_0 \sim \Delta z$. Here, $M_0$ are the values of the elastic moduli in the zero-pressure limit, whose values depend on the structure of the packing.

3:18PM J24.00003: Isostatic, ordered disk packings  PHILIP TUCKMAN (Presenter), KYLE VANDERWERF, Yale University, MARK SHATTUCK, The City College of New York, COREY SHANE O’HERN, Yale University — Numerous studies have shown that disordered, jammed disk packings are isostatic (with the same number of contacts as the number of degrees of freedom) and can occur over a wide range of packing fractions, $\varphi_{\text{min}} < \varphi_j < \varphi_{\text{max}}$. For systems composed of 2D bidisperse disks with half large and half small particles, and diameter ratio $r = 1.4$, $\varphi_{\text{min}} \approx 0.84$ and $\varphi_{\text{max}} \approx 0.855$. Further, these disordered, isostatic packings display similar structural and mechanical properties, such as the power-law scaling of the excess contact number $\Delta z$ and shear modulus $G$ with pressure $p$. In this work, we show that isostatic, ordered jammed packings of nearly monodisperse disks also occur over a range of packing fractions, $\varphi_{\text{O,min}} < \varphi_j < \varphi_{\text{xtal}}$, where $\varphi_{\text{xtal}} \approx 0.907$ is the packing fraction for a triangular lattice. These packings are achieved by first generating packings of monodisperse disks, then changing the sizes of a fraction of the disks by a small amount, then finding the nearest jammed packing. Here, we characterize the structural and mechanical properties of these isostatic, ordered jammed packings.
3:30PM J24.00004: Athermal fluctuations in disordered crystals  PAPPU ACHARYA (Presenter), SURAJIT SENGUPTA, TCIS, TIFR, BULBUL CHAKRABORTY, Brandeis University, KABIR RAMOLA, TCIS, TIFR — We analyze the fluctuations in particle positions and inter-particle forces in disordered jammed crystals in the limit of the weak disorder. We demonstrate that such athermal systems are fundamentally different from their thermal counterparts, characterized by constrained fluctuations of forces perpendicular to the lattice directions. We develop a disorder perturbation expansion in polydispersity about the crystalline state, which we use to derive exact results to linear order. We show that constrained fluctuations result as a consequence of local force balance conditions, and are characterized by non-Gaussian distributions which we derive exactly. We analytically predict several properties of such systems, including the scaling of the average coordination with polydispersity and packing fraction, which we verify with numerical simulations using soft disks with one-sided harmonic interactions.

3:42PM J24.00005: Mechanically stable sphere packings at arbitrarily low densities  ROBERT DENNIS (Presenter), ERIC CORWIN, Univ of Oregon — Lightweight materials can be formed by creating mechanically rigid structures with a combination of compressive and tensile forces. By considering purely compressive forces in sphere packings, we determine the limits on creating low density rigid systems. An Apollonian packing proves that a rigid packing can completely fill space, but proof for the existence of a lowest density rigid packing was unknown. The previously known lowest density packings are constructed by diluting simple crystals, but we present a new construction based on rigid bridges. This new construction not only demonstrates that lower density packings can be achieved, but it can be used to create rigid packings with densities arbitrarily close to zero. We demonstrate the rigidity of these low density packings using both established and novel procedures and we explore the properties of these configurations to gain a deeper understanding of the limits of rigidity in repulsive systems. Such constructions not only lay an old puzzle to rest, but enable the development of new lightweight materials.

3:54PM J24.00006: Real-space renormalization of randomly vacated lattices: a renormalization group for jamming?  ABE CLARK (Presenter), US Naval Postgraduate School — Jamming occurs in granular materials, as well as in emulsions, dense suspensions, and other amorphous, particulate systems. When the packing fraction $\varphi$, defined as the ratio of particle volume to system volume, is increased past a critical value $\varphi_c$, a liquid-solid phase transition occurs, and grains are no longer able to rearrange. Previous studies have shown evidence of spatial correlations that diverge near $\varphi = \varphi_c$, but there has been no explicit spatial renormalization group (RG) scheme that has captured this transition. Here, I present a candidate for such a scheme, using a block-spin-like transformation of a randomly vacated lattice of grains. I define a real-space RG transformation based on local mechanical stability. This model displays a critical packing fraction $\varphi_c$ and gives estimates of critical exponents in two and three dimensions.
Critical scaling for yield is independent of distance to isostaticity

Granular materials, suspensions, foams, and emulsions can form amorphous jammed states. These states can yield when subjected to a shear stress $\tau$. When $\mu = \tau/p$, where $p$ is the system pressure, exceeds a critical value $\mu_c$, jammed states become inaccessible and flow persists indefinitely. Near $\mu = \mu_c$, long-range cooperative effects become dominant, as shown by the success of recent nonlocal rheological models. Long-range cooperativity in these systems is often framed in terms of the isostatic jamming point, which occurs at $p = 0$. The relationship between isostatic jamming and yielding is not fully understood. Here, using simulations of quasi-statically sheared soft sphere packings, we observe critical behavior near $\mu = \mu_c$, with a diverging length scale $\xi \sim |\mu - \mu_c|^{-\nu}$, that is independent of distance to isostaticity over a wide range of $p$. The critical scaling functions and values of the scaling exponents are nearly independent of distance to isostaticity despite the large range of $p$. Our results demonstrate that yielding of jammed systems represents a critical transition that is distinct from the isostatic point. Our results may also be useful in deriving and improving nonlocal rheological models.

The Influence of the Wall on Confined Random Packing of Rods

We experimentally study the random packing of rods into small containers, and in particular, examine the influence of the container surface on the packing. Our experiments use cylindrical containers of different radii, and rods of aspect ratio 8. As previously seen, rods packed into smaller cylindrical containers yielded lower volume fractions than in larger containers. In this current work, we coat the inner vertical surface of the containers with sandpaper to change the enhancement of friction between the wall and the rods. We find a linear relationship between the volume fraction $f$ and $1/R$ (using the radius $R$ of the container). The intercept gives the infinite-radius container extrapolated volume fraction, and the slope quantifies how strongly the walls affect the packing. As might be expected, rougher sandpaper results in a stronger influence from the walls. Surprisingly, sandpaper also influences the infinite-radius extrapolation volume fraction.

Two-stage jamming in semiflexible polymers and fibers

We find that jamming in model freely rotating polymers with bond angle $\theta_0$ occurs in two stages. The first, precursor stage occurs when the average number of unique interchain contacts $Z_{\text{chain}}$ jumps discontinuously as chains “entangle” at a packing fraction $\varphi_e(\theta_0)$. Entanglement is a necessary but not a sufficient condition for mechanical rigidity; systems rigidify (i.e. jam) at $\varphi_j(\theta_0) > \varphi_e(\theta_0)$, and $Z_{\text{chain}}$ jumps discontinuously again at $\varphi_j(\theta_0)$. These discontinuities become sharper as polymers stiffen (as $\theta_0$ decreases). We find that $\varphi_e(\theta_0) \sim 0.8 \varphi_j(\theta_0)$ despite the fact that both decrease by a factor of nearly two as polymers stiffen. Our results for small $\theta_0$ may also describe jamming phenomena in fiber networks.

Support from NSF Grant No. DMR-1555242 is gratefully acknowledged.
4:42PM J24.00010: Low frequency vibrations of deformable particles  
DONG WANG  
(Presenter), ARMAN BOROMAND, MICHAEL MURRELL, Yale University, MARK SHATTUCK, The City College of the City University of New York, COREY SHANE O’HERN, Yale University — Disk packings at jamming onset exhibit an excess of low-frequency vibrational modes compared to the number predicted by Debye scaling. The excess number of modes, which controls the mechanical response of packings, decreases as the packings are compressed above jamming onset. In this work, we calculate the spectrum of vibrational modes from the eigenvalues of the dynamical matrix for truly deformable particles at jamming onset as a function of the shape parameter $A = p^2/(4\pi a)$, where $p$ is the perimeter and $a$ is the area of the particle. We show that there is an excess number of low frequency, collective modes in the density of vibrational modes for jammed packings of deformable particles over a wide range of particle shape both above and below the characteristic value $A \approx 1.15$ at which the system is confluent.

4:54PM J24.00011: Structure and dynamics during training of memory in jammed packings  
IAN GRAHAM  
(Presenter), ANDREA JO-WEI LIU, University of Pennsylvania — Jammed packings can be trained by intermediate-amplitude quasistatic oscillatory shear to fall into periodic trajectories in which the same multiple local minima are explored in each period. Here we ask how the rearrangement dynamics and stroboscopic snapshots of packing structure evolve during the training process. We use persistent homology to characterize the structure. We characterize rearrangements in terms of T1 events and classify them as reversible if they return to their initial configuration and irreversible if they do not. At the end of the training process, irreversible T1 events must vanish when the system falls into a periodic trajectory (develops a memory). We find that the structure varies continuously during the training, but that the nature and number of T1 events remains nearly constant until the last cycle or two before the system develops memory. Thus, observable changes in structure have relatively little effect on dynamics until near the end of the training process, in contrast with glassy dynamics, in which extremely subtle changes in structure lead to enormous changes in dynamics.

5:06PM J24.00012: Measuring the Granular Density of Modes in 3D via Impact  
ELI OWENS  
(Presenter), SYDNEY BLUE, SALEM C WRIGHT, Presbyterian College — The jamming transition is an important feature of granular materials, with prior work showing an excess of low frequency modes in the granular density of states (or modes). In this work, we present an experimental method for acoustically measuring the granular density of modes using a single impact event to excite vibrational modes in the granular material. We test three different granular materials, all of which are composed of spherical plastic beads. The first two systems are monodisperse collections of either 6 mm or 8 mm diameter beads. The third system is a bidisperse mixture of the previous two bead sizes. During data collection, the particles are confined to a 30x30x20 cm box; on top of this box, and resting on the granular material is a light, rigid sheet onto which weights can be placed. To excite the material, an impactor is dropped on top of the system. The response of the granular material to the impact pulse is recorded by piezoelectric sensors buried throughout the material, and the density of modes is computed from the spectrum of the velocity autocorrelation of these sensors. Our initial measurements of the density of modes differentiate between the three different systems and between different pressure states.
5:18PM J24.00013: Quenching to field-stabilized magnetization plateaus in the unfrustrated Ising antiferromagnet*  ADAM IAIZZI (Presenter), YING-JER KAO, Natl Taiwan Univ — We study the square-lattice Ising antiferromagnet in a uniform field using single spin flip Metropolis algorithm dynamics. Starting from an infinite temperature state, we perform an instantaneous quench to finite $T$. Under this protocol, the field stabilizes two magnetization plateaus in a regime where the equilibrium magnetization is zero. This occurs despite the absence of intrinsic disorder or frustration. These metastable plateau states are extremely stable, even for small sizes and moderate temperatures. Ergodicity is restored near the edges of the plateaus. The plateaus can be understood as ‘tilings’ of stable local configurations. Once the system reaches one of these tiled states, the probability of flipping even a single spin is exponentially suppressed. Although the details of the plateaus will depend on the update scheme, the underlying principle causing the breakdown of ergodicity is quite general. This simple case can thus provide a paradigm for understanding ergodicity breakdown in Monte Carlo dynamics more generally.

Session J25 GSNP DSOFT DCP: Physics of Liquids II 402 - Yang Zhang, University of Illinois at Urbana-Champaign - Tag(s): Focus

2:30PM J25.00001: Using Algebraic and Geometric Topology to Characterize Hierarchical Organization in Complex Solutions and Their Interfaces* [Invited]  AURORA CLARK (Presenter), Washington State Univ — Complex, multicomponent, solutions are often characterized by multiple length and timescale correlations that challenge chemical intuition. Recently developed tools are leveraging graph-theoretical interpretations of the intermolecular networks of interactions in such systems, supporting topological data analysis as a means to characterize organizational patterns, from the identification of molecular species and solvation environments, to new interpretations of fluid phase transformation. One may interpret these topological descriptors as high-dimensional order parameters that can also be used to enhance sampling of the energy landscape. Complementary geometric topological methods of liquid surfaces have also emerged as a powerful tool for the identification of interfacial structures responsible for transport. Ongoing work is combining both the algebraic and geometric topology formalism to create a holistic approach that relates hierarchical organizational patterns to structure and even function within complex solutions and their interfaces.

*This work was funded by the Department of Energy Basic Energy Sciences Separations program grant DE-SC0001815.
3:06PM J25.00002: Hanging droplets from liquid surfaces  GANHUA XIE (Presenter), JOE FORTH, Lawrence Berkeley National Laboratory, SHIPEI ZHU, Department of Mechanical Engineering, The University of Hong Kong, BRETT HELMS, PAUL ASHBY, Lawrence Berkeley National Laboratory, HO CHUENG SHUM, Department of Mechanical Engineering, The University of Hong Kong, THOMAS RUSSELL, Polymer Science and Engineering Department, UMass — Nature uses surface tension to support dense objects on liquid surfaces, from water striders to insect larvae for mating and survival, which has inspired fabrication of man-made robotic systems for transport across water. These systems present hydrophobic surface to prevent sinking. Here, we show that a droplet of a denser aqueous solution, containing a polyelectrolyte can hang on the surface of a less dense aqueous solution containing an oppositely charged polyelectrolyte. The magnitude of the interfacial forces acting on the droplet and the shapes of the hanging droplets can be controlled by releasing heights of the droplet and the polyelectrolyte concentrations. Coacervate sacs with homogeneous and heterogeneous surfaces can be produced that hang from the surface and, by capillary forces, form well-ordered arrays. Controlled locomotion and rotation can be achieved by functionalizing the hanging droplets with magnetic microparticles. The suspended droplets are in direct contact with air enabling in situ manipulation of the droplets and using the encapsulated aqueous phases for compartmentalized cascading chemical reactions with selective transport. These hanging droplets have potential applications in functional micro-reactors, micro-motors and biomimetic micro-robots.

3:18PM J25.00003: Dipolar dimer liquid  JUNYI ZHANG (Presenter), Princeton University — A lattice liquid model, dipolar dimer liquid (DDL), is proposed motivated by the water. The DDL on the bipartite lattice may be exactly mapped to the annealed Ising model on random graphs. We showed that there exists a phase transition of the DDL when the density is not too small. In the low temperature phase, which we called glacia phase, the polar charges are ordered while the dimers are still free to move and rotate. On two-dimensional square lattice and honeycomb lattice, we may bound the critical temperature $T_G$ by comparing the Ising model on random graphs to the exactly-solved Ising models.

3:30PM J25.00004: Extended equation of state for non-ideal mixtures near the consolute critical point.  YEYGENII RUDNIKOV (Presenter), MYKOLA POTOMKIN, Taras Shevchenko National University of Kyiv — The problem of constructing the equations of state and calculating the thermodynamic parameters of mixtures near the liquid-liquid critical point using the parameters of their components remains an urgent task of the condensed matter physics. To solve it, the new method of choosing the countdown start for calorific values is founded, in which the corresponding states law for liquids is satisfied. An analysis of thermodynamic consistency conditions in the dissolution of solution components allow concluding that a consistent calculations of the mixture parameters for variable values are approximate due to excessive non-additive contributions to them; similar calculations are exact for values which remain constant for components. Using the proposed approach for liquid components of obtained and literature data for mixtures C4H8O2 - H2O, CH4O – C6H14, C6H7N – D2O, the constant combinations of thermodynamic parameters have been found. It allowed using the consistent rules for calculating the calorific parameters of mixture and obtaining the parameters of the theory of critical mixtures.
3:42PM J25.00005: Numerical Modeling of Room Temperature Ionic Liquids*  
KATHERINE KLYMKO (Presenter), JOHN BELL, Lawrence Berkeley National Laboratory, ALEJANDRO GARCIA, Physics, San Jose State University, SEAN CARNEY, Math, UT Austin, ANDY NONAKA, Lawrence Berkeley National Laboratory — We present a mesoscale numerical model for room temperature ionic liquids. The model uses a fluctuating low Mach number formulation based on a thermodynamically consistent formulation. Repulsion effects between the different ions are represented by an excess free energy. We first investigate the structure of the fluid to quantify the interplay between electrostatic forces and repulsion of the different ions. We then investigate the structure of the electric double layer that forms at a solid surface at fixed potential as a function of the applied voltage. Finally, we investigate the effect of composition dependence of the electric permittivity in the presence of an external field.

3:54PM J25.00006: Evaporation of Lennard-Jones Monomer-Dimer Mixtures*  
BINGHAN LIU, SHENGFENG CHENG (Presenter), Virginia Tech — Evaporation and condensation are important physicochemical processes for the conversion between liquids and gases. We use Lennard-Jones (LJ) liquids as model systems to study the nonequilibrium physics of evaporation. The evaporation of pure LJ fluids has been studied extensively. However, the studies on evaporating liquid mixtures are limited and the relevant physics is poorly understood. Here we employ molecular dynamics simulations to study the evaporation behavior of LJ monomer-dimer mixtures. During fast evaporation, the concentration of LJ dimers, which are less volatile, increases significantly from the bulk of the mixture to the evaporating liquid-vapor interface. Correspondingly, the concentration of LJ monomers exhibits a negative gradient in the same region. In other words, the LJ monomers and dimers stratify in the region below the evaporating interface. Furthermore, the degree of stratification is stronger at higher evaporation rates. The effect of evaporative cooling on stratification is also clarified on the basis of thermophoresis. This stratification phenomena may be utilized to separate suspended particles interacting differently with the components of an evaporating liquid mixture.

Decomposing thermal fluctuations in fluids with hydrodynamic modes

XIAOHUI DENG (Presenter), China / Hong Kong University of Science and Technology — Presenter: Xiaohui Deng

Authors
Xiaohui Deng (Hong Kong University of Sci&Tech)
Xiaoyu Wei (Hong Kong University of Sci&Tech)
Xiaoping Wang (Hong Kong University of Sci&Tech)
Ping Sheng (Hong Kong University of Sci&Tech)

Abstract
Thermal fluctuations are usually manifest as tiny displacement velocity variations or as molecular self diffusion. We report the analytic solution of the complete set of 2D hydrodynamic modes in a channel geometry, under the Navier slip boundary condition. By using this complete set, thermal fluctuations and their consequences can be expressed in terms of the hydrodynamic modes. In particular, the fluctuation dissipation theorem can be written in terms of the eigenvalues of the hydrodynamic modes as an expression for the diffusion constant $D$. Our work offers a new perspective on fluid system’s inherent thermal fluctuations and its reliance on the boundary condition. In particular, it offers a way to spatially tune the thermal fluctuations by modulating the hydrodynamic boundary condition

Correlation between local viscosity and the atomic-level stresses in liquids

TAKUYA IWASHITA (Presenter), Oita University — Liquids are ubiquitous, but the atomic origin of the viscosity remains unknown because of structural disorder. To study the relationship between viscosity and local structures we performed molecular dynamics simulations on various metallic liquids. Here the local structures of the liquids are characterized by the atomic-level stresses which describe the local mechanical states. We showed strong correlation between local viscosity and atomic-level stress in the liquids; for example, the atomic sites under compression are more unstable against shear than those under tension. The results indicate a universal structure-dynamics relationship in liquids.

4:30PM J25.00009: Importance of nuclear quantum effects on the hydration of chloride ion*

JIANHANG XU (Presenter), ZHAORU SUN, FUJIE TANG, Department of Physics, Temple University, DEYU LU, Center for Functional Nanomaterials, Brookhaven National Laboratory, XIFAN WU, Department of Physics, Temple University — The solvation structure of Cl\(^{-}\) ion in aqueous solution is determined by the H-bonding between the solvated ion and surrounding water molecules, which is in competition with the water-water H-bonds in the solvent. We performed \textit{ab initio} path-integral molecular dynamics simulations based on the SCAN functional. We find that quantum nuclei tilt the above balance compared to conventional classical simulations. Nuclear quantum effects (NQE) weaken the ion-water H-bonding strengths as shown by the increased first-peak position in the ion-oxygen pair distribution function. In turn, the H-bond interactions among water molecules in the solvent become effectively strengthened. As a result, the population of interstitial water molecules increases in the first coordination shell, which are non-bonded to Cl- ion, however, are H-bonded to other water molecules in a tetrahedral network. By including NQEs, our local dielectric response function calculations suggest that the surrounding water molecules electronically screen the charge of Cl\(^{-}\) more effectively than the classical counterpart. Our resulting solvation structures are in excellent agreement with the recent neutron scattering experiments by Soper \textit{et al}.

4:42PM J25.00010: Connectedness of the configuration space of hard disk systems*

OZAN ERIK OK (Presenter), JEREMY KYLE MASON, Materials Science and Engineering, University of California, Davis — Hard disk systems are often regarded as prototypes for simple fluids, and can offer valuable insight into the origins of phase transitions and glass transitions in general. A phase transition is usually believed to occur when averages of thermodynamic quantities over the accessible part of the configuration space change discontinuously. A phase transition could then be driven by a discontinuous change in the accessible region, and this depends on the connectedness of the configuration space as a function of disk radius. A regularized potential energy function is defined on the configuration space, the critical points of which correspond to configurations where the topology of the configuration space changes, and are extensively sampled for small numbers of disks. Knowledge of the critical points allows the configuration space to be decomposed into regions that are homeomorphic to spheres of known dimensions, but does not indicate how these regions are attached to one other. Preliminary attaching maps are then found using the zero-temperature string method, resulting in a complete characterization of the topology of the configuration space of hard disk systems for small numbers of disks.

The stability-limit conjecture revisited

PHEERAWICH CHITNELAWONG (Presenter), Queen's University, FRANCESCO SCIORTINO, Sapienza University of Rome, PETER POOLE, St. Francis Xavier University — The stability-limit conjecture (SLC) proposes that the liquid spinodal of water returns to positive pressure in the supercooled region, and that the apparent divergence of water’s thermodynamic response functions as temperature decreases are explained by the approach to this reentrant spinodal. Subsequently, it has been argued that the predictions of the SLC are inconsistent with general thermodynamic principles. Here we reconsider the thermodynamic viability of the SLC by examining a model equation of state for water first studied to clarify the relationship of the SLC to the proposed liquid-liquid phase transition in supercooled water. By demonstrating that a binodal may terminate on a spinodal at a point that is not a critical point, we show that the SLC is thermodynamically permissible in a system that has both a liquid-gas and a liquid-liquid phase transition. We also describe and clarify other unusual thermodynamic behavior that may arise in such a system, particularly that associated with the so-called “critical-point-free” scenario for a liquid-liquid phase transition, which may apply to the case of liquid Si.

Session J26 DBIO DSOFT: Multimodal Optical Trapping/Microscopy/Spectroscopy of Living Matter 403 - Minjoung Kyoung, University of Maryland Baltimore County (UMBC) - Tag(s): Focus

Development and Application of Three-Dimensional Multi-Resolution Imaging* [Invited] HAW YANG (Presenter), Princeton University — A complex system contains dynamics that span several orders of time scales over several length scales that are spatially non-homogeneous. Examples include virus (or nanoscale drug delivery vehicle) uptake by a living cell and particle percolation through a dynamically reconfiguring medium. The spatial heterogeneity and the lack of separation of time scales are such that ensemble-averaged experimental approaches tend to miss the mechanism-defining steps in such processes. In this presentation, we explain how a multi-resolution approach helps to elucidate dynamics in complex systems. We then describe the basic ideas and implementations for these types of instrument. Applications to biological and materials systems will also be discussed.

The U.S. Department of Energy and the Princeton University Schmidt Transformative Technology Fund are grateful acknowledged for their financial support.
3:06PM J26.00002: Avalanching Upconverting Nanoparticles for Super Resolution Imaging*
EMMA XU (Presenter), CHANGHwan LEE, KAIYUAN YAO, Columbia University, BRUCE COHEN, EMORY CHAN, Lawrence Berkeley National Laboratory, YUNG DOUG SUH, Korea Research Institute of Chemical Technology, P. JAMES SCHUCK, Columbia University — Photon avalanche (PA) is a photon energy upconversion excitation mechanism. It enables nonlinear dependence on excitation power, which is a key factor for various applications in photon science. One exciting application is that it suggests a possible approach to super-resolution imaging with a simple confocal microscope system. Here, we introduce avalanching upconverting nanoparticles (AUCNPs), NaYF₄ nanocrystals doped with Thulium ions. The presence of PA was verified by time-resolved photoluminescence measurement. Upon the exitation of 1064nm laser, the resolution of 2-dimensional photoluminescence map was resolved to 90nm as a result of high nonlinearity, more than 4 times of diffraction-limited imaging resolution. AUCNPs are thus a promising new method for super resolution bioimaging.

3:18PM J26.00003: Mechanical unzipping of DNA molecules in parallel using nanophotonic tweezers
FAN YE (Presenter), JAMES T. INMAN, MICHELLE D. WANG, Physics, Cornell University / HHMI — Optical trapping is a valuable technique widely used in biological and materials sciences, covering size scales ranging from the single molecule to the cellular level, and force scales from sub piconewton (pN) to tens of pN. In the past decades, the rapid development of nano techniques has bolstered the emergence of nanophotonic tweezers. The ability of nanostructures to direct and confine light beyond the diffraction limit enables miniaturized, on-chip devices with abilities beyond microscope-based optical traps. Our lab has developed and implemented such an on-chip device - the nanophotonic standing-wave array trap (nSWAT) [1,2]. The nSWAT is based on Si or Si₃N₄ waveguides and allows for controlled and precise manipulation of trapped single biomolecule (such as DNA) arrays via microparticle handles. Here, we present an nSWAT that achieves manipulation forces large enough to mechanically unzip an array of DNA molecules at room temperature. This benchmark achievement is another step closer to the full realization of nanophotonic tweezers’ capabilities, promising increased accessibility and expansion of these platforms to a wide range of biological and biomedical research topics.

A Simple Approach to Optical Trapping Analysis*  
JAVIER E HASBUN, JAMES HOWARD, ZACHARY PATTERSON-GOSS, SUVRANTA KUMAR TRIPATHY (Presenter), Univ of West Georgia — Optical tweezers provide a noninvasive approach for detecting pico-newton forces with nanometer level spatial resolutions [1]. We have developed a simplified model of an optically trapped micron-sized particle using a modified version of a numerical approach [2]. The equations of motion associated with the model assume a low Reynolds number and the stochastically simulated bead behavior is carried out in two dimensions. The passive power spectrum analysis and equipartition theorem analysis confirm the agreement between simulated and experimental data. Based on the experimental and simulation analysis this simple approach can be used to gain information about bead's confining environment such as local temperature and viscosity.

Bacterial proteomes are predictable from cellular Raman spectra*  
KENICHIRO F KAMEI (Presenter), Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo, KOSEKI J KOBAYASHI-KIRSCHVINK, Klarman Cell Observatory, Broad Institute of MIT and Harvard, HIDENORI NAKAOKA, YUICHI WAKAMOTO, Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo — Whole-cell Raman spectra reflect its molecular composition and allow us to distinguish cellular states in a label-free and non-destructive manner. Previously, we showed that in S. pombe and E. coli, cellular Raman spectra and transcriptomes were linked quantitatively and that the transcriptomes could be inferred from Raman spectra (Kobayashi-Kirschvink et al., Cell Systems, 2018). We now ask whether Raman spectra could also be connected to other types of omics information. Using quantitative proteome data of E. coli cultured under various conditions (Schmidt et al., Nature Biotechnology, 2016), we show that proteomes can be linked to and reconstructed from cellular Raman spectra. These results suggest that cellular Raman spectra have the potential to unravel and integrate multi-omic states of cells non-destructively, and therefore show great promise in establishing live-cell omics.

3:54PM J26.00006: Live measurements of transcriptional bursting and dynamic gene regulation in early fly embryos*  
PO-TA CHEN (Presenter), BENJAMIN ZOLLER, MICHAL LEVO, THOMAS GREGOR, Princeton University — Gene regulation is intrinsically dynamic: from the microscopic molecular events underlying transcriptional bursting, to genes cross-regulating each other in the context of a genetic network during cellular fate specification. However, knowledge about the transcriptional dynamics of individual genes and the coordinated dynamics of multiple genes in their endogenous context is largely missing. We have developed an optimized 2-photon microscope to measure realtime gene activity in early fly embryos. Our data is highly quantitative making higher-order noise and cross-correlation analysis between multiple simultaneously measured genes possible. Focusing on the gap gene network, we measure endogenous transcriptional activity of individual and multiple genes simultaneously to test a novel time-dependent mathematical framework for transcriptional bursting dynamics and link these to transcriptional states at the network level. We are addressing two questions in particular: What are the dynamics of transcriptional bursting for individual genes, and how are they related to fluctuations of a key regulator? And how do the complex out-of-equilibrium dynamics of individual genes affect the dynamics of the gene regulatory network as a whole?

4:06PM J26.00007: The Origin of Enhanced Enzyme Motility Probed with Optical Tweezers  
TIAN HUANG (Presenter), JIN TAE PARK, HYUK KYU PAK, STEVE GRANICK, Institute of Basic Sciences — Ingenious prior observations show that enzymes in solution display enhanced diffusivity when they catalyze chemical reactions but too little is known about the mechanism. A serious impediment to understanding is that the forces generated during enzyme catalysis are not known. In this talk, we will discuss our effort to measure these forces by using optical tweezers. The displacement probability distribution is enhanced as if the temperature were increased, but the reasons are different.

4:18PM J26.00008: Multimodal microscopy through optimal integration of wide-field and focused-beam laser illumination*  
SANG-HYUK LEE (Presenter), Physics and Astronomy, Rutgers University — Microscopy can be largely classified into two groups according to how light illuminates specimen: 'wide-field' or 'focused-beam' illumination microscopy. The two microscopy modalities are often integrated into the same instrument, especially for the purpose of combining optical tweezers and fluorescence imaging, with typically employing separate lasers for the two illumination schemes. We have developed a new microscope platform that enables operation of the same laser for the both modalities interchangeably or simultaneously in a way scalable to multiple lasers. In this talk, I will describe the design of the instrument and its application to the multimodal imaging and spectroscopy of biological systems.

*This research is supported by grants from DOE (DE-SC0019313) and NSF (1825433).
4:54PM J26.00009: Near-field optical interferometer for refractive index sensing*  ABBAS GHAFFARI (Presenter), KEVIN GIA DO, ROBERT RIEHN, North Carolina State University — Single-molecule sensing for biological physics predominantly uses fluorescence sensing due to the high signal to volume ratio. However, it is far from an ideal detection mode since fluorescence sensing requires the chemical modification of biological molecules. A better alternative is the sensing of refractive index changes due the introduction of a biomacromolecule. Here we introduce a near-field optical interferometer that detects the presence of nanoparticles and proteins by measuring the deflection of a light, and not transmission as commonly performed.

*We acknowledge funding from the National Institutes of Health (GM126887).

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

Session J27 FIAP DMP GIMS: Experimental optical spectroscopic measurements of 2D materials 404 - Ying Wang, University of California, Berkeley

2:30PM J27.00001: Giant nonlinear optical modulation based on layered materials beyond EFISH  YING WANG (Presenter), JUN XIAO, SUI YANG, XIANG ZHANG, University of California, Berkeley — The efficient modulation of optical signals is central to communication and computing, the key in emerging data science revolution. Towards the realization of on-chip nonlinear optical applications such as on-demand nonlinear optical sources and neutral network, electrical-field-induced second harmonic generation (EFISH) dominates the development because of its ubiquitous presence in different material systems. However, its third order nature grinds itself to be a weak and inefficient process. A new mechanism that directly controlling second-order electric susceptibility to realize efficient nonlinear tunability is on demand. We report an electrically controlled new strategy to achieve giant and broadband modulation of second-order optical nonlinearities with an ultra-large modulation strength as well as efficiency. This demonstration will have a profound impact to optical communication and photonic computation.
2:42PM J27.00002: Probing the Influence of Dielectric Environment upon Volume-confined Hyperbolic phonon Polaritons  ALIREZA FALI (Presenter), University of Georgia, SAMUEL T WHITE, Department of Physics and Astronom, Vanderbilt University, THOMAS G FOLLAND, Department of Mechanical Engineering, Vanderbilt University,, NEDA AGHAMIRI, University of Georgia, JOSHUA D CALDWELL, Department of Mechanical Engineering, Vanderbilt University,, RICHARD F HAGLUND, Department of Physics and Astronom, Vanderbilt University, YOHANNES ABATE, University of Georgia — The unique ability of hyperbolic phonon polaritons (HPhPs) to confine long-wavelength light to nanoscale volumes in low-loss, naturally hyperbolic materials – such as hexagonal boron nitride (hBN) – has generated immense interest. We employ nano-scale imaging and spectroscopy techniques to elucidate the characteristics of HPhPs to elucidate polariton characteristics as a function of the complex refractive index of the substrate, including the impact of both the real and imaginary contributions. Although higher-order polariton modes exhibit wavelengths weakly sensitive to the environment, the principal mode strongly depends on the substrate dielectric constant. Furthermore, we demonstrate a reconfigurable hyperbolic metasurface comprised of a heterostructure of hBN in direct contact with the phase-change material (PCM) single-crystal vanadium dioxide (VO2). Metallic and dielectric domains in VO2 provide spatially localized changes in the local dielectric environment, enabling launching, reflection, and transmission of hyperbolic phonon polaritons (HPhPs) at the PCM domain boundaries, and tuning the wavelength of HPhPs propagating in hBN over these domains.

2:54PM J27.00003: Polarized Raman spectroscopy in monolayer ReSe2*  GEOVANI CARVALHO DE RESENDE (Presenter), Univ Fed de Minas Gerais, BRUNO CARVALHO, Física Teórica e Experimental, Universidade Federal do Rio Grande do Norte, MARCOS PIMENTA, Univ Fed de Minas Gerais — Raman spectroscopy is a powerful tool to study two-dimensional compounds and has been widely used to obtain important information of their electronic and vibrational structures. In the case of graphene and MoS2-type compounds, the Raman spectrum is isotropic when the light polarization lies in the layer plane. However, for low-symmetry materials such as black phosphorus and triclinic transition metal dichalcogenides, the spectra are polarized dependent and polarized Raman spectroscopy should be used. By changing the angle between the light polarization and the crystallographic axes, the elements of the Raman tensors for the different phonon modes can be determined. Previous studies in black phosphorus showed that Raman tensor elements are complex numbers, but the physical origin of the phase differences are not yet well understood. In this work, polarized Raman spectroscopy is used to investigate the anisotropic behavior in monolayer ReSe2. The angular dependence of the polarized Raman spectra using different polarization configurations is obtained for the 18 Raman active modes as well as the Raman tensor elements for each mode. It was also observed that the principal axes of those Raman tensors are not along the crystallographic axes.

*CNPq, CAPES, FAPEMIG and INCT-Nanocarbono.
JIAN MAO (Presenter), STEPHANE KENA-COHEN, Engineering Physics, Polytechnique Montreal — Black phosphorus (BP) emerges as a promising optoelectronic material because of its outstanding electrical and optical properties. [Proc. Natl. Acad. Sci. USA 2015, 112 (15), 4523-30.]. Like graphite, BP has a layered structure and can be exfoliated into nanosheets from its bulk form through mechanical and liquid exfoliation. Mechanical exfoliation (the scotch-tape method) has been predominantly used for proof-of-concept devices [Nat. Nanotechnol. 2014, 9 (5), 372-7], but it is inherently unscalable and typically produces BP sheets with lateral size below ten micrometers. For practical applications, scalable approaches for the fabrication of BP large-area films are essential. We will present our results on the development of a Langmuir-Blodgett (LB) protocol which is well suitable for assembling BP nanosheets into thin films. Through functionalization, we achieve large-area (centimeters), homogenous, and smooth BP thin films. With ZnO as an electron transport layer and 1,1-Bis[(di-4-tolylamino)phenyl]cyclohexane (TAPC) as a hole transport layer, the BP films are fabricated into photodiodes, which show responsivity from visible to infrared region. Our work highlights the great potential of BP for applications in near- and mid-infrared detection and imaging.

3:18PM J27.00005: Photocurrent Spectroscopy of Titanium Trisulfide Nanoflakes* ZHEN LIAN (Presenter), TIANMENG WANG, ZHIPENG LI, SUFEI SHI, Rensselaer Polytechnic Institute — Titanium trisulfide (TiS3) is an emerging 2D semiconductor which possesses a direct bandgap in the near-infrared regime, along with strong polarization-dependent electronic and optical properties, making it a promising material for various optoelectronic applications. However, constrained by the infrared response, it is challenging to characterize the bandstructure of TiS3 via optical spectroscopy, especially for devices based on thin layer TiS3, which often exist in the form of ribbon due to their quasi-1D atomic structure. In this work, we carry out low-temperature polarization-dependent photocurrent spectroscopy characterization of TiS3 ribbons. We clearly resolve the bandgap of TiS3 for both thick and thin flakes, and the results are consistent with the theoretical expectation. Our findings are crucial to the understanding of the electronic structure of TiS3 and lay the foundation for future device applications.

* This work is supported by the NY State Empire State Development's Division of Science, Technology and Innovation (NYSTAR) through Focus Center-NY–RPI Contract C150117.
3:30PM J27.00006: Substrate-Mediated Hyperbolic Phonon Polaritons in MoO$_3$  JEFFREY J. SCHWARTZ (Presenter), NIST & University of Maryland, SON LE, NIST & Theiss Research, SERGIY KRYLYUK, ALBERT DAVYDOV, ANDREA CENTRONE, NIST — Hyperbolic phonon polaritons (HPhPs) are hybrid excitations of light and coherent charge oscillations that exist in strongly optically anisotropic 2D materials (e.g., MoO$_3$). These polaritons propagate through the material's volume with long lifetimes, enabling novel mid-infrared nanophotonic applications by compressing light to sub-diffraction dimensions. Here, the dispersion relations and HPhP lifetimes (up to $\approx 2$ ps) in single-crystal $\alpha$-MoO$_3$ are determined by Fourier analysis of real-space, nanoscale-resolution polariton images obtained with the photothermal induced resonance (PTIR) technique. Measurements of MoO$_3$ crystals deposited on periodic gratings showed longer HPhP propagation lengths ($\approx 2 \times$) and lower optical compressions in suspended regions compared to regions in direct contact with the substrate. Additionally, PTIR data reveal polymeric contaminants, resulting from sample preparation, localized under parts of the MoO$_3$ crystals. This work enhances the ability to engineer nanophotonic devices by leveraging substrate morphology to control polariton propagation.

3:42PM J27.00007: Giant second harmonic generation from polar van der Waals Bismuth tellurohalide semiconductors  PRASHANT PADMANABHAN (Presenter), Center for Integrated Nanotechnologies, Los Alamos National Laboratory, SAMUEL GILINSKY, Department of Physics, Northern Arizona University, KEVIN KWOCK, Columbia Univ, NICHOLAS SIRICA, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, JAEGOOK KIM, SANG-WOOK CHEONG, Department of Physics, Rutgers University, ROHIT P PRASANKUMAR, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Rashba materials from the Bismuth tellurohalide family of polar layered van der Waals (vdW) semiconductors hold great promise for nonlinear optical (NLO) applications, since their broken spatial inversion symmetry leads to a large second-order nonlinear optical polarizability, $\chi^{(2)}$. Here, we report the first second harmonic generation (SHG) studies of the bulk polar semiconductors BiTeBr and BiTeI. Our results reveal that BiTeBr, in particular, hosts a large SHG response, comparable to that of archetypal semiconductors and larger than other vdW materials. In contrast to BiTeBr, the response of BiTeI is substantially smaller, suggesting that their relative halide polarity plays a key role in the dramatically different nonlinear optical response. Furthermore, we compared our results to the nonlinear optical response of the Weyl semimetal TaAs, which has previously been shown to produce extremely large SHG, under identical conditions and observe that BiTeBr has nearly half the nonlinear conversion efficiency of TaAs, despite the absence of any known topological properties. This suggests that the BiTeX family of compounds, particularly the BiTeBr compound, are ideal candidates for NLO applications.
3:54PM J27.00008: Nanoscale imaging and spectroscopy of charge carrier distribution with terahertz and mid infrared near-field nanoscopy  NEDA AGHAMIRI (Presenter), University of Georgia, FLORIAN HUTH, ANDREAS J HUBER, neaspec GmbH, ALIREZA FALI, University of Georgia, RAINER HILLENBRAND, CIC nanoGUNE, YOHANNES ABATE, University of Georgia — We perform terahertz (THz) and mid infrared nanoscopy to probe and quantify charge carriers in doped semiconductor surfaces and doped Si nanowires at the nanoscale. We introduce hyperspectral THz nano-imaging by combining scattering-type scanning near-field optical microscopy (s-SNOM) with THz time-domain spectroscopy (TDS). We describe the technical implementations that enabled this achievement and demonstrate its performance. Combination of nanoscale spectroscopy and Drude model allows for measuring—noninvasively and without the need for Ohmic contacts—the local mobile carrier concentration of the differently doped semiconductor areas.

4:06PM J27.00009: Raman Studies on Polytypism in Layered Gallium Selenide  SOO YEON LIM (Presenter), JAE-UNG LEE, Physics, Sogang University, JUNG HWA KIM, Materials Science and Engineering, UNIST, LIANGBO LIANG, Xiangru Kong, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, THANH-HUONG THI NGUYEN, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, ZONGBHOON LEE, Materials Science and Engineering, UNIST, SUNGLAE CHO, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, HYEONSIK M CHEONG, Physics, Sogang University — Gallium selenide (GaSe) is one of layered group-III metal monochalcogenides, which has an indirect bandgap of 3.0 eV in monolayer and a direct bandgap of 2.0 eV in bulk phase unlike other conventional transition metal dichalcogenides (TMDs) such as MoX$_2$ and WX$_2$ (X=S and Se). Since GaSe has high photo-responsivity and external quantum efficiency (EQE) in the UV-range, it can be used as a photodevice such as a photodetector [1]. In bulk phase, four polytypes designated as $\beta$-, $\epsilon$-, $\gamma$-, and $\delta$-GaSe have been reported. Since different polytypes result in different optical and electrical properties even for the same thickness, identifying the polytype is essential in utilizing this material for various optoelectronic applications. We found different ultra-low-frequency Raman spectra of inter-layer vibrational modes even for the same thickness due to GaSe polytypism. By comparing the ultra-low-frequency Raman spectra with theoretical calculations and high-resolution electron microscopy measurements, we established the correlation between the ultra-low-frequency Raman spectra and the polytypes for trilayer GaSe. We further found that the AB-type stacking is more stable than the AA'-type stacking in GaSe.

4:18PM J27.00010: Ultrafast Carrier Recombination from Quantum Pillars in Black Silicon*  
SEREF KALEM (Presenter), Department of Electronics, Bahcesehir University — We report on ultrafast photoluminescence (PL) phenomena from black silicon produced by ion etching using chlorine plasma. An ultrafast blue PL component competing with non-radiative recombination at surface defects was quantified as originating from the no-phonon transition. This component involves two decay processes with a peak energy at 480 nm: a fast component of 6 ps followed by a component of 48 ps decay time constant. It exhibits also a slow component in the red spectral region with a time constant of about 2.5 ns. When it is oxidized, slow band at around 600 nm is enhanced in intensity to the detriment of blue emission band. This process results in a much slower states assuming 3-components exponential decay. Ultrafast PL decay leads to transfer of carriers to long-lived defect states as evidenced from red emission at around 2 eV. Time-correlated single photon counting revealed a life-time of about 5 ns for these states. The results are discussed in terms of electronic band structure modification at reduced sizes and surface point defects.

*This work was funded by European Commission LASERLAB-EUROPE program (LLC001765).

4:30PM J27.00011: Anisotropic optical and structural properties of hexagonal boron nitride epilayers probed by optical ellipsometry*  
MICHAEL MCKAY (Presenter), JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ — Hexagonal boron nitride (h-BN) is a 2D layered material that has gained increasing attention in recent years due to its unique physical properties that make h-BN a promising material for DUV optoelectronics and solid-state neutron detectors. There are many material properties still uncertain, including h-BN's optical constants. The anisotropic index of refraction of h-BN free-standing epilayers grown by metal organic chemical vapor deposition were measured using spectroscopic ellipsometry in the UV spectral range. It was found that the index of refraction for $E_{\perp c}$-axis (ordinary) is much higher than $E_{\parallel c}$-axis (extraordinary). The scattered data for the index of refraction of h-BN reported earlier for various h-BN materials can be explained by including the inclination of turbostratic (t-) phase layers or the change of the c-plane orientation of individual layers. Our results show that ellipsometry can be used to characterize the crystalline quality of h-BN epilayers by determining the average inclined angle of t-phase layers within the sample while being non-invasive and highly sensitive.

*This research was supported by DOE ARPA-E (No. DEAR0000964). H. X. Jiang and J. Y. Lin are grateful to the AT&T Foundation for the support of Ed Whitacre and Linda Whitacre endowed chairs.
4:42PM J27.00012: Unraveling nonlinear formation and relaxation of excitons in atomically thin 2D semiconductors  MATTHEW STRASBOURG (Presenter), CORY JOHNS, Montana State University, Bozeman, THOMAS DARLINGTON, JIM SCHUCK, JAMES C HONE, Mechanical Engineering, Columbia University, NICHOLAS J BORYS, Montana State University, Bozeman — Transition metal dichalcogenide semiconductors are layered van der Walls materials that exhibit exceptional optoelectronic properties in monolayer form. Their atomically thin nature and reduced long-range dielectric screening make them ideal systems in which to study many-body electronic states. Here, the dynamics of several higher-order exciton states in monolayer-WSe$_2$ are probed using temperature-, energy-, and power-dependent time-resolved optical spectroscopy. These studies reveal a complex interplay between multiexciton states and single-exciton states in 2D materials that depends on both the density and excitation energy of the initial exciton population. In addition, the presence of defect-bound excitons is found to drastically alter the formation of multiexciton states. This competition between exciton trapping and multiexciton formation highlights the need for high-quality materials to enhance multiexciton physics. Understanding these formation and relaxation dynamics of the rich manifold of exciton states is critical for leveraging this new class of 2D semiconductors for advanced technologies.

4:54PM J27.00013: Dipole Orientation Shift of Ga$_2$Se$_2$ by Quantum Confinement* KE XIAO (Presenter), TENGFEI YAN, XIAODONG CUI, The University of Hong Kong — In the family of III-VI monochalcogenides M$_2$X$_2$ (M = Gallium, Indium; X = Sulfur, Selenide, etc), the interlayer interaction and the electronic band edges share the contribution of the same chalcogenide atomic orbits. This makes quantum confinement and interlayer interaction play a subtle role in 2 dimensional (2D) monochalcogenides crystals. In this report we study the direction-resolved photoluminescence of 2D Ga$_2$Se$_2$ at various thickness. We observe that the in-plane dipole radiation survives but out-of-plane dipole radiation fades at 2D limit.

*The work was supported by GRF17317316, CRF7036 of Hong Kong research council and Croucher Foundation.
**5:06PM J27.00014: Valley Phonons and Exciton Complexes in a Monolayer Semiconductor**
MINHAO HE (Presenter), PASQUAL RIVERA, University of Washington, DINH VAN TUAN, University of Rochester, NATHAN P WILSON, University of Washington, MIN YANG, University of Rochester, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, JIAQIANG YAN, DAVID MANDRUS, Oak Ridge National Laboratory, HONGYI YU, University of Hong Kong, HANAN DERY, University of Rochester, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington — The coupling between spin, charge, and lattice degrees of freedom plays an important role in a wide range of fundamental phenomena. Monolayer semiconducting transitional metal dichalcogenides have emerged as an outstanding platform for studying these coupling effects because they possess unique spin-valley locking physics for hosting rich excitonic species and the reduced screening for strong Coulomb interactions. Here, we report the observation of multiple valley phonons – phonons with momentum vectors pointing to the corners of the hexagonal Brillouin zone, in monolayer WSe$_2$. We find that these valley phonons lead to efficient intervalley scattering of quasi particles in both exciton formation and relaxation. This leads to a series of photoluminescence peaks as valley phonon replicas of dark trions, and the identification of intervalley exciton near charge neutrality.

**5:18PM J27.00015: Microcavity Organic Light Emitting Diodes with Higher Order Resonance Modes**
EKRAJ DAHAL (Presenter), BENJAMIN ISENHART, DAVID ALLEMEIER, Univ of Vermont, KAREN CIANCIULLI, Asheville School, MATTHEW WHITE, Univ of Vermont — Organic light emitting diodes (OLED) have a characteristic broad spectral width. The output emission characteristic of the light source can be controlled by the use of a microcavity. A microcavity OLED has metal electrodes encasing the organic layer which allow for the unique bandwidth narrowing and angle resolved spectral emission. We investigate the emission spectrum through the fundamental and higher order resonant modes using a single organic emitter molecule, just by designing the microcavity structure alone. We use Tris(8-hydroxyquinolinato)aluminium, Alq3, as the emissive layer (EML) with the electron transport layers (ETL) and hole transport layers (HTL) added in between the metal electrodes. The output characteristic (spectral bandwidth and viewing angle) of the microcavity is affected by its optical path length. The desired design is achieved by varying the thickness of the ETL, EML, and HTL layers which make up the microcavity. We generate the full visible spectrum at the forward emission and the angle resolved emission spectrum for various order resonance modes.

**Session J28 FIAP GDS: New Ways of Seeing with Data Science**

**2:30PM J28.00001: Data science and video games**
SPENCER STIRLING (Presenter), Activision — A video game is a microcosm combining tracking capabilities (movement, attack, defense, scoring), marketplace data (microtransactions), and social networking (chat, user-generated content, friend networks). We use machine learning to touch each of these facets, hoping to improve engagement, profitability, and fun! Projects include cheat detection, churn mitigation, marketing optimization, and toxicity detection.
3:06PM J28.00002: Modeling complex physical systems with big data and machine-learning
[Invited] HENDRIK HAMANN (Presenter), SIYUAN LU, IBM TJ Watson Research Center — Modeling complex physical systems continues to be a major challenge in many fields of science and technology. In this talk we present a general framework, which advances such endeavor. Specifically, we describe the development of a machine-learning based model blending architecture for statistically combining multiple models for improving the accuracy of an application-specific forecast or prediction. Most importantly, we demonstrate that in addition to parameters to be predicted or forecasted, including additional state parameters which collectively define a situation as machine learning input provides enhanced accuracy for the blended result. ANOVA (analysis of variance) shows that the error of individual models can have a substantial dependence on the situation. The machine-learning architecture effectively reduces such situation dependence error and thus produces more accurate results compared to conventional multi-model ensemble approaches based on simplistic equally or unequally weighted model averaging. The framework is first illustrated in the context of weather forecasting, which is arguably one of the hardest problems in physics, not only because of the complexity and scale of the problem but also given the additional complication that predictions/forecasts have to be made using limited observation at sparse locations. We will also demonstrate that the framework is applicable to other applications.

3:42PM J28.00003: Machine learning for seeing and hearing more [Invited] PATRICK F RILEY (Presenter), Google Accelerated Science, Google — Modern machine learning has had some of its greatest successes in perceptual problems like image and sound understanding. Extracting relevant information from such high dimensional input is frequently the challenge in scientific data understanding as well. I'll survey some exciting results from the Google Accelerated Science team in the areas of cellular imaging for biomedical research, extracting surprising results from human clinical imaging, and disease staging from auditory signals. Collectively these show the promise of further machine assistance in making sense of scientific data, with a great deal of exciting work still to come.
In this talk, I will discuss how SPM can be greatly enhanced via careful and tailored use of machine/statistical learning methodologies in every aspect, from data acquisition to real-time analytics to model comparison and selection. I will show that Gaussian process regression and active learning schemes can enable increases in sampling efficiency in large dimensional spaces, enabling new experiments that were previously unfeasible. Moreover, complete information acquisition in conjunction with statistical learning methodologies can enable new SPM techniques with enhanced spectral and spatial resolution that are orders of magnitude faster than existing state of the art techniques [2]. Finally, the use of Bayesian methodologies for model fitting and model selection can enable a rigorous uncertainty-quantified answer regarding the appropriate cantilever dynamics model to employ in analyzing dynamic atomic force microscopy data. These methods that are developed point towards an autonomous future of ‘self-exploring’ SPM systems for physics knowledge generation.

**Immunotherapy Modeling: Molecular Interaction and Recognition of MHC/peptide/TCR Complexes** [Invited] RUHONG ZHOU (Presenter), IBM Thomas J. Watson Research Center — Cancer immunotherapy has been among the most promising breakthroughs in oncology, particularly in the case of immune check point inhibitors, however, the effective response rate remains quite low, only about 20-30%. In this talk, I will talk about our recent collaborative work which solves one mystery behind this low response rate with molecular modeling and machine learning techniques. We found that patients with certain HLA genotype (HLA-B44) have consistently higher survival rate, while patients with some other type (HLA-B15) have much poorer survival rates. It's also shown that patients harboring tumors with very high mutation rates responded disproportionately well to these immune checkpoint inhibitor treatments. Large scale molecular dynamics simulations further reveal that HLA-B15 proteins with poorer therapeutic outcomes had structural appendages (HLA bridges with residues Arg62, Ile66, and Leu163) that closed over the cancer neoantigens with much less flexibility. The same techniques have also been applied to the design and development of vaccines for HIV and T1D, which has been of great interest as well in recent years. With a combined in silico and in vivo approach, we studied the TCR/peptide/HLA interactions from multiple clonotypes specific for a well-defined HIV-1 epitope, and found that effective and ineffective clonotypes bind to the terminal portions of the peptide-HLA through similar salt bridges, but their hydrophobic side-chain packings can be very different, which accounts for the major part of the differences among these clonotypes. Meanwhile, a novel super potent autoantigen has been identified for T1D, which opens new door for potential T1D vaccine. Together with state-of-the-art free energy perturbation calculations for point mutations on antigens, our results clearly indicate a direct structural basis for heterogeneous T cell function.

Session J29 DSOFT GSNP: Emergent Mechanics of Active, Robotic, and Living Materials II 501 - Corentin Coulais, Univ of Amsterdam - Tag(s): Focus

2:30PM J29.00001: Rectification of energy and motion in non-equilibrium parity violating metamaterials [Invited] ZHENGHAN LIAO, WILLIAM THOMAS MARK IRVINE, SURIYANARAYANAN VAIKUNTANATHAN (Presenter), University of Chicago — Uncovering new mechanisms for rectification of stochastic fluctuations has been a longstanding problem in non-equilibrium statistical mechanics. Here, using a model parity violating metamaterial that is allowed to interact with a bath of active energy consuming particles, we uncover new mechanisms for rectification of energy and motion. Our model active metamaterial can generate energy flows through an object in the absence of any temperature gradient. The nonreciprocal microscopic fluctuations responsible for generating the energy flows can further be used to power locomotion in, or exert forces on, a viscous fluid. Taken together, our analytical and numerical results elucidate how the geometry and inter-particle interactions of the parity violating material can couple with the non-equilibrium fluctuations of an active bath and enable rectification of energy and motion.
3:06PM J29.00002: Robotic swarms as adaptive active matter  WEERAPAT PITTAYAKANCHIT (Presenter), MARTIN FALK, JIAYI WU, ARVIND MURUGAN, HEINRICH M. JAEGER, University of Chicago — The field of active matter has been closely tied to swarming behaviors from its origins. However, a key feature of natural swarms, feedback regulation of activity in space and time, is usually absent in active matter models. Here, we study a model of active matter with adaptive activity inspired by recent experiments on mechanically coupled robotic swarms. We allow for self-propulsion to be modulated over space and time based on local stresses and strains and study how such self-regulated activity modifies transport and the jamming phase diagram.

3:18PM J29.00003: Rheology of Active Polymer-like T. Tubifex Worms  ANTOINE DEBLAIS (Presenter), SANDER WOUTERSEN, DANIEL BONN, Univ of Amsterdam — Of all complex fluids, it is probably the rheology of polymers we understand best. In-depth insight into the entanglement and reptation of individual polymers allows us to predict for instance the shear-thinning rheology and the behaviour in virtually any flow situation of practical importance. The situation is markedly different when we move from passive to active polymers where the coupling of filament activity, hydrodynamic interactions, and conformations open the way to a plethora of novel structural and dynamical features. Here we experimentally study the rheology of long, slender and entangled living worms (Tubifex tubifex) and propose this system as a new type of active polymer. Its level of activity can be controlled by changing the temperature or by adding small amounts of alcohol to make the worms temporarily inactive. This allow us to unlock existing experimental limitations and to unravel the recent fundamental questions on the mechanical and flow properties of such assembly.

3:30PM J29.00004: Collective Behavior of Worm Blobs  YASEMIN OZKAN-AYDIN (Presenter), DANIEL I GOLDMAN, SAAD BHAMLA, Georgia Inst of Tech — We study the aggregation of blackworms (Lumbriculus variegatus) into large ensembles of entangled, living “blobs” composed of thousands of slender bodies knotted together. To understand the mechanism and advantages of aggregation in these worm blobs, we systematically expose them to various environmental stresses including light and temperature. The diameter of the worm blob can be controlled by both light stimulus history and light intensity. At low light intensity, the blob dilates; conversely, increasing the light intensity contracts the blob and leads to a more entangled and tightly packed state. This behavior also affects the collective movement under thermal stress. Under high light intensity (>1500 Lux) we find that a 5 g (~600 hundred) worm blob placed under a linear temperature gradient between 15 to 50°C stays as a blob and moves collectively to the cold side with a speed of 0.35± 0.01 cm/min. In contrast, if the light intensity is reduced to 400 lux, the worm blob dissipates and individual worms crawl to the cold side with a speed of 0.21± 0.03 cm/min. We find that the number of surviving worms increases when they move as a blob.
3:42PM J29.00005: Predicting Crowd Dynamics Using Local Structure* JULIA GIANNINI (Presenter), ETHAN STANIFER, M. LISA MANNING, Syracuse University — Unstable and active disordered materials exhibit interesting collective properties and nontrivial dynamics. While the behavior of amorphous solids under shear is relatively well-understood, the instabilities in active systems remain difficult to characterize and predict. In the context of dense crowd dynamics, existing work has analyzed position fluctuations in a self-propelled particle (SPP) model to identify Goldstone modes and soft spots in models for human crowds. This analysis requires time-resolved trajectory information in order to form predictions for collective behavior, which can be cumbersome. To address this issue, we have developed a novel method to generate static packings in an artificial potential that reproduce the packing structures in a class of point-of-interest active SPP crowd simulations. These static packings then allow us to precisely identify local structural defects that govern dynamical group behavior, so that we can predict the locations of material-like failures in dense, active SPP models. Unlike previous methods, these predictions can be derived from a single snapshot and could be relevant to preventing dangerous emergent phenomena in real crowd systems.

3:54PM J29.00006: The dynamics of in-silico active filamentous elastic swimmers explored using Brownian dynamics simulations DENIZ AKPINAROGLU (Presenter), ARVIND GOPINATH, University of California, Merced — Slender elastic filaments when continuously deformed by active or actuating forces fields can move persistently. In filament-motor assays for instance, animating forces act directionally along the filament; forces thus follow the ensuing filament motion thereby driving and sustaining the deformation. Here, we study the spatiotemporal dynamics of a computationally minimal swimmer - an active elastic filament attached to a viscous cargo that can move in a plane. Locomotion is achieved via competition between activity, elasticity, dissipation and boundary constraints. Examination of the emergent phase space allows us to identify three distinct stable locomoting forms attained by the filament-cargo complex - straight, rotation, and oscillatory flutter. We show that transitions between these states may be triggered by ramping or dampening noise, by tuning global elasticity and by adjusting the type or softness of the connection between the cargo (head) and the filament (tail). Furthermore, these in-silico swimmers move as soft blobs with effective spatial extent primarily determined by a combination of activity and elasticity. Our results allow for a nuanced understanding of the patterns seen in assays and also offer rules that may guide the design of synthetic soft microswimmers.
**4:06PM J29.00007: Controlled reversal of vortex chirality in populations of colloidal rollers**

BO ZHANG (Presenter), ANDREY SOKOLOV, OLEKSIY SNEZHKO, Argonne Natl Lab — Chiral active liquids composed of spinning individual units represent a new class of active materials where both energy and angular momentum is injected at the microscopic level. Spontaneous emergence of particle flocks and global polar states are prime examples of remarkable collective dynamics and self-organization recently observed in active chiral liquids. Formation of the globally correlated polar states in such systems proceeds through an emergence of a macroscopic steadily rotating vortex that spontaneously selects a clockwise or counterclockwise global chiral state. We demonstrate in experiments and simulations that active chiral liquids in a collective vortex state exhibit memory and the subsequent formation of the polar states is not random. Our results provide new fundamental insights into mechanisms of formation of collective polar states in active systems.

**4:18PM J29.00008: Mechanics of ultrasonically levitated active granular membranes**

MELODY LIM (Presenter), University of Chicago, ANTON SOUSLOV, University of Bath, VINCENZO VITELLI, HEINRICH M. JAEGER, University of Chicago — We explore granular rafts in an acoustic trap consisting of hundreds of macroscopic particles. These close-packed rafts are self-assembled by a sonic depletion force mediated by scattering, which establishes short-range attractions between the constituent particles [1,2]. We show that droplets of this granular fluid display emergent surface tension and elasticity. These droplets interact with the acoustic field, inducing forces and torques that drive coalescence, deformations, and break-up. We use a persistent torque in the acoustic field to extract the droplet surface tension. At the same time, active fluctuations in the acoustic field act as an effective temperature, driving the droplet to explore its configurational space. Microstructural measurements, and the fluctuation spectra of the droplet perimeter, reveal the far-from-equilibrium dynamics of this granular active membrane.

4:30PM J29.00009: Impact of wall constraint on the dynamics of self-propelled particles*
RYOICHI YAMAMOTO (Presenter), FEDERICO FADDA, JOHN J. MOLINA, Kyoto Univ — The presence of wall constraint strongly affects the motions of dispersed particles in a fluid. A striking example can be seen in the dynamics of self-propelled particles near fluid/solid boundaries where the single (collective) motion of such particle(s) depend sensitively on the detailed flow profile around them. In the present study, we investigate the dynamics of two popular types of self-propelled particles, i.e., spherical micro-swimmers (squirmers) and rolling spheres (Quincke rollers) on a flat plate and by means of direct numerical simulation of fluid/particle composite systems with fully resolving the hydrodynamics.

4:42PM J29.00010: Construction of non-equilibrium structures by insect aggregations: the case of fire ants  
ROBERT WAGNER (Presenter), TONG SHEN, FRANCK J VERNEREY, KRISTEN SUCH, ETHAN HOBBBS, University of Colorado, Boulder — Active matter networks are ubiquitous in nature and synthetic materials, ranging from molecular-scale polymers to macroscale swarms of social insects. These materials are characterized by their transient, reversible crosslinks and non-equilibrium state. Due to these reversible bonds and non-equilibrium states, active matter networks can exhibit directed viscous flow and morphogenesis. One such set of active matter networks is the aggregations formed by the bodies of red imported fire ant (Solenopsis invicta). These ants aggregate into floating rafts when placed in water, and will form steady-state, convective towers if given vertical rods around which to nucleate. In this presentation, we explore the mechanical rules individual fire ants follow on the surfaces of these towers by measuring their statistical velocity distribution, parking rates, and unparking rates, through imaging analysis. We then present and numerically employ a theoretical framework, that bridges these physical rules to the emergent behavior, to replicate the global morphologies observed. Thus, verifying that the postulated physical rules explain the global morphological response of this active matter system and generally informing our understanding of what drives these collective mechanical phenomena.

Session J30 DSOFT GSNP DBIO: Composite Active Materials 502 - John Berezney, Brandeis Univ - Tag(s): Focus
2:30PM J30.00001: Comparison of different approaches to single particle tracking of enzymes displaying enhanced diffusion
MENGQI XU (Presenter), JENNIFER L ROSS, Physics, Syracuse University — Enzymes have been shown to perform faster diffusion with the presence of their substrate. Recently, we have revealed new insights of this emergent enzyme activity using single particle tracking (SPT). We found that while the overall mobility of enzyme is improved by 2-3 folds at saturated substrate concentration, the mode of diffusion remains Brownian. Meanwhile, in order to achieve long trajectories, a polymer brush coated surface and a large viscous polymer was utilized to slow down the diffusion, raising questions as to the effect of these additives. Here, we investigate the effect of the surface coating by replacing the polymer brush with a lipid bilayer; we also replace the crowding polymers with a smaller viscous molecule, glycerol. We make the same diffusion measurements and compare the results from both methods. We found a faster diffusion together with an artificial anomalous exponent for enzymes diffusing on lipid bilayer. Also, the presence of high percentage of glycerol, leads to the failure in reproducing enhanced diffusion due to the low enzymatic reaction rate in such a high viscous environment. Our results indicate the critical responsibility of the polymer brush in slowing the diffusion and enabling the direct reporting on single enzyme enhanced diffusion.

2:42PM J30.00002: Vortices, space-time braids and loops in the membrane of a living cell.
JINGHUI LIU (Presenter), PEARSON MILLER, Physics, Massachusetts Institute of Technology, JÖRN DUNKEL, Mathematics, Massachusetts Institute of Technology, NIKTA FAKHRI, Physics, Massachusetts Institute of Technology — Topological defects determine the structure and function of matter over a wide range of scales. Many advances have been made in understanding and controlling the defect dynamics in active and passive non-equilibrium fluids. Yet, it remains unknown whether the statistical laws which govern the dynamics of defects in classical or quantum fluids extend to active living matter. Here, we show a defect-mediated turbulence underlies the complex wave propagation patterns of Rho-GTP signaling proteins on the membrane of starfish oocytes. Our experiments reveal that the phase-velocity field extracted from Rho-GTP concentration patterns exhibits vortical defect motions and annihilation dynamics reminiscent of those seen in quantum systems. Space-time analyses of defect trajectories reveal the existence of two characteristic types of braids: loops braided by multiple pairwise creation and annihilation events, and long-lived defect pairs that wiggle and form braid groups. Several key statistics and scaling laws of the defect dynamics, braids and loops can be captured by a generic complex Landau-Ginzburg continuum theory, suggesting space-time braids and loops are useful topological measures for unraveling information scrambling and transmission in dissipative living systems.
2:54PM J30.00003: Creation and evolution of defects in composite biopolymer nematics
KIMBERLY WEIRICH (Presenter), RUI ZHANG, JUAN DE PABLO, University of Chicago — Structured soft materials have internal order that give rise to unusual mechanical properties and emergent organization of inclusions. Here we present a composite structured liquid formed from biopolymers of distinct rigidities, actin and DNA. Actin filaments, well below their persistence length, behave as rigid rods while long polymers of DNA, well above their persistence length, form globular molecules. Crowded into a thin layer, actin filaments form a nematic liquid crystal phase within the DNA domains. As these nematic phases grow and coalesce, defects in the actin nematic filled with DNA are created. We investigate the evolution of these soft, polymer filled defects and compare the dynamics to a continuum model of lyotropic liquid crystal. From the model, we use the defect shape to extract material properties of the liquid crystal. Our results suggest a novel structured soft composite, potentially informing physical mechanisms of controlling material properties and templating functional polymeric materials.

3:06PM J30.00004: Microtubule based composite active matter [Invited] ZVONIMIR DOGIC (Presenter), University of California, Santa Barbara — Active matter dynamics is determined by the balance between active stresses generated by the motile component, and the passive viscous or elastic stresses that arise due to deformation of the background material. In many current formulations of active matter Independent control of active and reactive stresses is not possible. For example, in microtubule-based 2D active nematics, decreasing ATP concentration simultaneously decreases the magnitude of the active stresses and increases the elasticity of the liquid crystalline materials. This limits the range of accessible dynamical states, while also impeding quantitative tests of theoretical models. Recent advances in formulation of microtubule based active matter has enabled dispersion of these motile elements in various passive soft materials including phase separated suspensions, viscoelastic networks and 3D colloidal liquid crystals. These new model systems of composite active matter exhibit diverse dynamical states that are not accessible in previous one components systems.
**3:42PM J30.00005: Information and motility exchange in collectives of active particles**

MATTEO PAOLUZZI (Presenter), CNR-ISC Inst for Complex Systems, MARCO LEONI, University Paris Sud, M CRISTINA MARCHETTI, University of California Santa Barbara — Active systems exploit the interplay of autonomous motility and mechanical interactions to spontaneously organize in complex patterns. In many situations, the collective behavior of active agents is driven by the exchange of information that can change the state of the agents. In a minimal model of information exchange, we have studied numerically run-and-tumble runners with an additional two-state internal variable that specifies their motile or nonmotile state. Motile particles change irreversibly into nonmotile ones upon collision with a nonmotile particle. Once turned non-motile, they can reacquire their motility or "reawaken" at a rate \( m \). When \( m=0 \), the system relaxes to an absorbing fractal aggregate of non-motile particles, with fractal dimension controlled by density and tumbling rate [1]. For finite reawakening, we find motile, non-motile and mixed states that can organize in complex spatial patterns. We characterize the kinetics of approach to the steady state and its structure in terms of tumbling and reawakening rates.

**3:54PM J30.00006: Corralling Active Brownian Particles With "Active Billiard" Particles**

ALEXANDRA NILLES (Presenter), Computer Science, University of Illinois at Urbana-Champaign, ANA PERVAN, THOMAS BERRUETA, TODD MURPHEY, Mechanical Engineering, Northwestern University — We examine the role of boundary conditions in a heterogenous active matter system in a bounded domain. The system consists of two types of particles: active Brownian particles, such as Janus particles, and "active billiard" particles, inspired by microorganisms that move in straight paths until they bounce off boundaries at a specific angle determined by their body morphology. This model has been of recent interest in robotics but also applies to microscale active matter systems. Here, we develop a parameterized model of particle type mixtures and characterize how "corralling" behavior emerges. We define corralling as system configurations where the billiard particles converge to a stable periodic orbit with a greater density of active Brownian particles within the convex hull of the orbit than its complement. We confirm that corralling behavior occurs in our model active matter system, in simulation. In previous work, we analytically determined the conditions guaranteeing such stable orbits, as a function of environment geometry and billiard departure angle. We will present extensions of this theoretical approach to statistical models of our example active matter system, with a focus on developing strategies for control.

4:06PM J30.00007: Spontaneous demixing of mixed active-passive suspensions.  MARCO POLIN (Presenter), STEVEN WILLIAMS, Univ of Warwick, RAPHAËL JEANNERET, Ecole Normale Superieure Paris — Understanding the properties of active matter is currently driving a rapid growth in soft- and bio-physics. Some of the most important examples of active matter are at the microscale, and include active colloids and suspensions of microorganisms, both as a simple active fluid and as mixed suspensions of active and passive elements. In these systems, recent work has started to provide a window into new phenomena including activity-induced depletion interactions, phase separation, and the possibility to extract net work from active suspensions. Building on current research in our group exploring the physics of colloid-microswimmer interactions we are interested in understanding how external control of the dynamics of the active component can be used to alter the transport of passive cargo. Here we report on new experiments studying the behaviour of active-passive systems under spatial confinement. We show that the spatial inhomogeneity in swimmers’ distribution and orientation resulting from confinement has a dramatic effect on the spatial distribution of passive particles, with the colloids accumulating either towards the boundaries or towards the bulk of the sample depending on the size of the container. We show that this can be used to induce the system to de-mix spontaneously.

4:18PM J30.00008: Unifying descriptions of phase separation in multi-component driven, steady-state systems.*  GARRETT WATSON (Presenter), ERIK LUIJTEN, Northwestern University — Combined experimental and computational work has shown that a nonequilibrium driven system of Janus particles exhibits phase behavior that is accurately described by the standard Ising model. This suggests that certain steady-state, yet nonequilibrium systems may be described by thermodynamic equilibrium universality classes. Such a description would allow precise control over the phase behavior of active particles, enabling us to design the next generation of active materials analogous to the widespread application of phase separation in creating conventional materials. We examine the generality of this proposition by considering multi-component systems of composite active particles that may belong to other universality classes.

*NSF GFRP
4:30PM J30.00009: Phase Diagram of a 2D system of Granular Self-propelled Particles*
ZHEJUN SHEN (Presenter), NARAYANAN MENON, Univ of Mass - Amherst — We report experiments on the phase behaviour of granular squares as a function of number density and activity. The granular particles are energized by vibrating them on a horizontal plane and are designed to have polar activity along a body diagonal. The activity of particles (quantified by the persistence length of motion along the mobility direction) can be controlled by varying the gap between top cover and bottom base. We find that adding activity to the particles qualitatively modifies their phase diagram. At large enough activity, particles always migrate to the boundary and form a high-density ordered state. At smaller values of activity, different phases are seen as a function of density. At low density, the particles form an isotropic liquid. As the density is increased, particles separate into a high-density ordered region while the remaining particles remain in the fluid state. Above a finite density, the phase coexistence curve terminates and all particles freeze into an ordered state. The start and end density of the coexistence region is found to be a function of density. We also discuss dynamics within the dense, ordered state.

*Acknowledge NSF DMR1905698

4:42PM J30.00010: Irreversibility in biological active matter [Invited]  NIKTA FAKHRI (Presenter), Massachusetts Institute of Technology MIT — Cellular structures constantly consume and dissipate energy on a variety of spatiotemporal scales in order to function. While progress has been made in elucidating their organizing principles, much of their thermodynamics remains unknown. In this talk, I will address the question: why measure dissipation in such nonequilibrium systems? I will show that by measuring a multi-scale irreversibility (time-reversal asymmetry) one can extract model-independent estimates of the time-scales of energy dissipation based on time series data collected in an experimental biological system. I further demonstrate that the irreversibility measure maintains a monotonic relationship with the underlying biological nonequilibrium activity. The basic idea of estimating irreversibility for various levels of coarse-graining is quite general; we expect it to lead to important inferences whenever there is a well-defined notion of dissipative scale.

Tuesday, March 3, 2020 2:30 PM - 5:42 PM

Session J31 DSOFT: Workshop: Grand Challenges in Soft Matter and Opportunities for Microgravity Research 503 - Paul Chaikin, New York University - Tag(s): Focus
2:30PM J31.00001: Hot topics and lukewarm opportunities for soft matter science up in the sky* [Invited] ROBERTO PIAZZA (Presenter), Politecnico di Milano Univ — I will first discuss some topics in soft matter that truly deserve to be investigated in microgravity conditions, focusing in particular on spontaneous restructuring processes in colloidal gels, referring to our recent experience with the NASA ACE T10 mission too, and on thermal forces in complex fluids. I shall then present the new opportunities given by the ESA COLIS facility for optical correlation spectroscopy to be installed on the ISS in a couple of years. Finally, however, I shall also point out some limiting factors that tend to cool my enthusiasm towards space experiments in our field.

*PRIN Project ID 2017Z55KCW, “Soft Adaptive Networks” by the Italian Ministry for Education, University and Research
ESA Topical Team "Colloids in microgravity"

3:06PM J31.00002: Non-equilibrium behaviour of colloidal systems.* [Invited] DAAN FRENKEL (Presenter), Univ of Cambridge — There is an explosion of interest in the collective properties of active matter. This interest is understandable because it is exciting to step outside the confines of the classical statistical mechanics that was developed to describe systems at or near equilibrium.

However, many puzzles remain about the way in which active matter is propelled. In my talk, I shall discuss some of these problems and indicate how the study of colloidal systems in the presence or absence of gravity might help us gain a better understanding of the physical processes that drive active matter.

*This work was partially funded by the Horizon 2020 program through 766972-FET-OPEN-NANOPHLOW.
3:42PM J31.00003: Squeezing order out of disorder* [Invited] STEFANO MARTINIANI (Presenter), Chemical Engineering & Materials Science, University of Minnesota, BUMING GUO, Physics, New York University, YUVAL LEMBERG, Physics, Technion - IIT, PAUL M CHAIKIN, Physics, New York University, DOV LEVINE, Physics, Technion - IIT — Computable Information Density (CID), the ratio of the length of a losslessly compressed data file to that of the uncompressed file, is a measure of order and correlation in both equilibrium and nonequilibrium systems. I will show that correlation lengths can be obtained by decimation, thinning a configuration by sampling data at increasing intervals and recalculating the CID. When the sampling interval increases above the system's correlation length, correlations vanish and the data becomes incompressible. The correlation length critical exponents are thus accessible with no a-priori knowledge of an order parameter or even the nature of the ordering. The critical scalings for the length scales obtained by CID agree well with those from the decay of two-point correlation functions \( g_2(r) \) when they exist. But CID also reveals a correlation length with the right scaling when \( g_2(r) = 0 \), as we demonstrate by “cloaking” the data with a Rudin-Shapiro sequence. Finally, I will show how CID revealed previously unknown ordering phenomena, such as a cascade of phase transitions in the BML traffic model, and a "checkerboard" dynamical instability in the parallel update Manna sandpile model.

*This work was primarily supported by the National Science Foundation Physics of Living Systems Grant No. 1504867.

4:18PM J31.00004: ESA microgravity program for Soft Matter research MARCO BRAIBANTI (Presenter), European Space Agency — The International Space Station offers a unique environment to study Soft Matter systems, which are susceptible to the effect of gravity. For instance, gravitational stresses are known to influence the structure of colloidal crystals and gels and even the glass transition. Moreover, in microgravity the absence of drainage affects the stability of foams and emulsion stability and offer the possibility to study "wet" foams and low viscosity emulsions which cannot be stabilized on ground. Finally, granular matter quickly sediment under gravity. Under microgravity conditions the process of cooling (the loss of energy due to collisions between particles) can be studied disentangled by sedimentation.

For this purpose, the European Space Agency is developing non-conventional scattering methods like Depolarized Dynamic Light Scattering (DDLS), Time Resolved Correlation (TRC), Diffusing Wave Spectroscopy (DWS) and Shadowgraph that will be implemented in different experiments using different instruments. This will enable the systematic study of Soft Matter systems which covers the entire range of particle sizes from colloids to granular materials.
4:30PM J31.00005: Electric field driven aggregation of negatively and positively polarized particles in dilute suspensions* BORIS KHUSID (Presenter), QIAN LEI, EZINWA ELELE, Chemical and Materials Engineering, New Jersey Institute of Technology — A variety of colloidal structures observed in terrestrial experiments could also have been influenced by gravity effects (particle sedimentation, convection, etc.) It is often assumed that weightlessness simulated in a time-averaged sense by slowly rotating a specimen in a clinostat about an axis perpendicular to the gravity direction that is widely used in biological tests would reduce the effect of gravity on suspensions. Experiments on a non-buoyancy-matched suspension in flights in NASA Zero-gravity aircraft revealed that particle patterns formed in a clinostat and under normal gravity are actually similar. A requirement for matching densities between particles and a solvent severely limits possibilities to study the field-induced structuring in colloids in terrestrial experiments. Long-term microgravity in ISS offers unique opportunity to employ not density matched suspensions to explore a wide range of the mismatch of electric characteristics between particles and a solvent. We will report experimental data on the field driven structure formation in suspensions and present our approach to the development of ISS experiments. The aim is to understand mechanisms of structure formation and suggest novel routes for creating functional materials.

4:42PM J31.00006: Structure and dynamics of a two-dimensional colloid of liquid droplets* CHRISTOPH KLOPP (Presenter), Department of Nonlinear Physics, Otto von Guericke University Germany — Free-standing liquid crystal bubbles were prepared in microgravity on the International Space Station (ISS) in order to study the hydrodynamics of inclusions in quasi 2D fluid systems [1]. The layered structure in in of smectic A and C phases allows the preparation of thin and homogeneous films. Arrays of droplets of molten film material can be formed near the clearing point when the inner layers of the film melt and the film undergoes thinning transitions. The droplets interact repulsively with each other, they spontaneously forming nearly approximately regular triangular lattices in smectic A films, with short range positional order. Local lattice cell parameters depend on droplet sizes. These structures can be considered as genuine, two-dimensional (2D) colloidal crystals. We investigate the internal dynamics in these lattices [2]. The mobility of each droplet in its six-neighbor cage is determined by the ratio of cage and droplet sizes, rather than by the droplet size as in isolated droplets.

Anisotropic 2D colloids can show a plethora of liquid crystalline phases including nematic, columnar and smectic. Due to the ability to control the shape and forms, zirconium phosphate nanoplates have been utilized as a model system. We will discuss the challenges for controlling the size, shape and forms of 2D materials in general. We also present results on control of their self-assembly using external fields including shear, electromagnetic, optical, temperature gradient and gravity.

We acknowledge financially supported by NASA (NASA-NNX13AQ60G).

Model hard ellipsoids: the practical matter of producing them

Model hard colloids have a great deal of relevance to physics and in particular the study of their phase behavior which can mimic that of simple atomic liquids and solids. "Nearly hard colloidal sphere" suspensions were formulated 35 years ago by the Ottewill group (Univ. of Bristol) and Imperial Chemical Industries Ltd., which were used by Pusey and van Megen in their seminal study of the phase behavior of hard-sphere colloids. We report on our efforts to reproduce and refine this benchmark polymer colloid, including the recent synthesis of hard ellipsoids for random and ordered packing studies in microgravity*. The custom-made samples are composed of linear polymer chains of poly(methyl methacrylate), functionalized with photo-crosslinkable moieties and fluorescent molecules. The resulting ellipsoidal shapes are about 1 micron in size and stabilized with surface-grafted poly(12-hydroxystearic acid) chains. The particles are dispersed in a refractive index matching fluid and particle aspect ratios vary from 1 to 4.

5:18PM J31.00009: Coarsening of two-dimensional island emulsions on smectic liquid crystal bubbles in microgravity*  CHEOL PARK (Presenter), ERIC MINOR, JOSEPH E MACLENNAN, MATTHEW GLASER, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado Boulder, CHRISTOPH KLOPP, TORSTEN TRITTEL, RALF STANNARIUS, Institute of Solid State Physics, Otto von Guericke University — Two-dimensional island emulsions in molecularly thin, tethered smectic liquid crystal bubbles in microgravity are observed to coarsen via coalescence and Ostwald ripening in both the smectic A and smectic C phases. We report here on the observed dynamics of island growth and disappearance in the absence of coalescence at locations in the island emulsion far from the meniscus around the bubble inflation needle. This Ostwald ripening occurs as a result of the system’s tendency to reduce its energy through a decrease in the total length of the island boundaries, a process that is generally dependent on the surface and line tensions and the disjoining pressure of the islands. Smaller islands generally have a higher disjoining pressure than their larger neighbors, which results in permeative flow from the smaller to the larger islands. We will also describe emulsion coarsening by island coalescence and compare the experimentally observed coarsening dynamics with simulations.

5:30PM J31.00010: Temperature-gradient-induced thermomigration in smectic liquid crystal bubbles and freely suspended films in microgravity*  NOEL ANTHONY CLARK (Presenter), CHEOL PARK, ERIC MINOR, JOSEPH E MACLENNAN, Physics and Soft Materials Research Center, University of Colorado Boulder, MATTHEW GLASER, TORSTEN TRITTEL, ALEXEY EREMIN, KIRSTEN HARTH, RALF STANNARIUS, Institute of Solid State Physics, Otto von Guericke University — In-plane temperature gradients were applied to tethered smectic bubbles on the ISS during the OASIS mission and to thin freely-suspended smectic films during suborbital rocket flights in order to study the Marangoni effect in a 2D fluid in microgravity. Tethered bubbles of smectic A liquid crystal were inflated in a temperature-controlled chamber. An emulsion of islands subsequently generated on the bubble with an air jet was initially homogeneously distributed over the entire bubble surface. When the inflation syringe was heated, however, the islands moved away from the point of heating, with the island velocity decreasing as they migrated away from the syringe. The islands appear to be moving with the background film, not as a direct consequence of the thermal gradient. In flat films, on the other hand, in-plane temperature gradients were observed to cause two specific Marangoni effects, directed flow and convection patterns.

3:06PM J32.00002: Mobility Gradient of Polymer Chains near a Solid Interface* [Invited] KEIJI TANAKA (Presenter), HUNG K. NGUYEN, DAISUKE KAWAGUCHI, Kyushu Univ — Polymer composites have been widely used in a variety of engineering fields. The performance and functionality of the composites are closely related to the quality of the interface between polymer and filler. Thus, it is important to study polymer behavior at the filler interface. The local conformation of rubbery chains in direct contact with a quartz substrate was here examined by interface-sensitive sum-frequency generation (SFG) spectroscopy. SFG signals, which could be obtained from functional groups only oriented at the interface, were clearly observed for the rubber polymer in a film at room temperature which was much higher than the bulk glass transition temperature ($T_g$). When the film was thermally annealed, rubbery chains at the quartz interface changed their conformation to one with a lower energy state, accompanied by the randomization of both the main and side chain parts. The characteristic temperature, at which interfacial chains started to lose their orientations, was much higher than the bulk $T_g$. Also, the extent found to be more remarkable for the spin-coated film than for the solvent-cast one. This implies that the stress accumulated at the interface, which resulted from the centrifugal force during the spin-coating process, accelerates the mobility of chains there. Then, the relaxation dynamics of rubbery chains at the quartz interface were directly probed as a function of distance from the quartz surface using time-resolved evanescent wave-induced fluorescence anisotropy (TRFA), dielectric relaxation spectroscopy (DRS) and SFG spectroscopy. We found the presence of the dynamics gradient of chains in the interfacial region with the quartz surface. The segmental relaxation of chains in the strongly adsorbed layer at the interface could be slower than that of bulk chains by more than 10 orders.

3:42PM J32.00003: Direct observation of mobility of thin polymer layers via asymmetric interdiffusion using neutron reflectivity measurements* KOJI FUKAO (Presenter), MEGUMI OOE, KAIRI MIYATA, JUN YOSHIOKA, Department of Physics, Ritsumeikan University, NORIFUMI L. YAMADA, KEK — In this study, we investigated the diffusion dynamics at the interface between deuterated poly(methyl methacrylate) (d-PMMA) and protonated PMMA (h-PMMA) in two-layered thin films of d- and h-PMMA layers via neutron reflectivity (NR) measurements during annealing above the glass transition temperature $T_g$. When $T_g$ of d-PMMA was higher than that of h-PMMA, the d-PMMA layer thickness increased with annealing time $t_a$, and simultaneously the h-PMMA layer thickness decreased. However, the opposite $t_a$ dependence of the layer thicknesses was observed, if the $T_g$ of d-PMMA was decreased. This change in the $t_a$ dependence of the layer thickness was related to the change in the mobility of the d-PMMA layer. With the decrease in the d-PMMA layer thickness when the h-PMMA layer thickness was maintained, the $t_a$ dependence of the layer thickness changed, and the mobility of the d-PMMA layer dramatically increased. Hence, the $T_g$ of the d-PMMA layer decreased with the decrease in the d-PMMA layer thickness. These results suggest that the mobility and $T_g$ of thin polymer films can be determined by interfacial dynamics via NR measurements.

3:54PM J32.00004: Reconciling Computational and Experimental Trends in the Temperature Dependence of Interfacial Mobility in Polymer Films* JACK DOUGLAS (Presenter), WENGANG ZHANG, National Institute of Standards and Technology, FRANCIS STARR, Department of Physics, Wesleyan University — Many measurements have indicated that thin supported polymer films in their glass state exhibit an interfacial layer of enhanced mobility whose thickness grows upon heating, as found also in crystalline materials approaching their melting temperature $T_m$, while simulations and limited measurements of such films above their glass transition temperature $T_g$ instead exhibit a region of enhanced mobility whose thickness $\xi$ grows upon cooling. To better understand these contradictory trends, we performed MD simulations over a $T$ range over which our simulated polymer films enters a glassy state, and found that the relaxation time $\tau_\alpha$ within the film interior, relative to the polymer-air interfacial region, exhibits a maximum near the observed computational glass transition temperature, $T_{g,c}$, reconciling previous measurements and simulations of supported polymer films in their glass and liquid states. Correspondingly, we also observe that the interfacial mobility scale exhibits a maximum near $T_{g,c}$ but the scale of collective polymer segment exchange motion increases monotonically upon cooling below $T_{g,c}$ so that the interfacial mobility scale is no longer linked to the scale of collective motion in the non-equilibrium glass state.

4:06PM J32.00005: Ellipsometry Modeling with Gradient in Refractive Index Resolves Unrealistic Density Increases in Thin Polymer Films and Demonstrates Inhomogeneous Film Structure Decoupled from Dynamics  YIXUAN HAN (Presenter), CONNIE ROTH, Emory University — We show polystyrene (PS), poly(methyl methacrylate) (PMMA), and poly(2-vinylpyridine) (P2VP) all exhibit similar large increases in refractive index with decreasing film thickness for ellipsometry data modeled by a homogeneous Cauchy layer. Such increases in refractive index have been interpreted by others recently as large increases in density (~25%) via the Lorentz-Lorenz relation, despite being physically unrealistic. We demonstrate that an ellipsometric layer model with a gradient in refractive index provides more physically realistic parameters for very thin films, retaining a bulk-like refractive index for much of the film’s interior, while exhibiting a sharp gradient in index near the free surface whose breadth grows from 4 to 9 nm with decreasing film thickness from 50 to 30 nm. Such an inhomogeneous film structure would invalidate the use of homogeneous Cauchy layers and the Lorentz-Lorenz relation whose derivation is based on assuming an isotropic distribution of dipoles. Surprisingly the refractive index gradient has an opposite trend to that based on a simple density correlation to dynamics. A higher refractive index near the free surface could reflect more optimized molecular packing from surface mobility, similar to vapor deposited stable molecular glasses.

4:18PM J32.00006: Density Measurements of Thin Polymeric Films using Magnetic Levitation*  SAMUEL ROOT (Presenter), RUI GAO, SHENCHENG GE, GEORGE M. WHITESIDES, Harvard University — When a polymeric film—supported by a sacrificial release layer—is placed in a paramagnetic solution between two magnets, it lifts off and levitates to a height that is linearly dependent upon the mass density. Using the principle of magnetic levitation, we construct a simple metrology for directly measuring the mass density of polymeric films down to 3 nm thick—an important quantity for understanding the glassy dynamics of such films. We validate the technique with several polymer films with a range of densities (1-1.4 g cm$^{-3}$) and by measuring density variations as a function of thickness in polystyrene and polymethylmethacrylate films. Our results are in agreement with existing data obtained by reflectometry experiments and confirm the trends previously observed in PS and PMMA, with important implications for understanding the dynamics of such glassy systems. Moreover, we demonstrate the potential utility of our technique for studying crystallization in ultrathin films of polymers using polyethylene as a model system. MagLev of thin polymeric films provides a simple, accessible metrology that will be useful for polymer scientists and engineers to study and optimize the properties of thin films for electronics, barriers, and separation membranes.

**4:30PM J32.00007: Polymeric Liquid Layer Densified by Surface Acoustic Wave**

TIANHAO HOU, JINGFA YANG, Institute of Chemistry, Chinese Academy of Sciences, WEN WANG, Institute of Acoustics, Chinese Academy of Sciences, JIANG ZHAO (Presenter), Institute of Chemistry, Chinese Academy of Sciences — With the application of surface acoustic wave (SAW) of 39.5 MHz to a model polymer liquid film, polyisobutylene, deposited on the solid substrates, the liquid film is densified, proved by the decrease of film thickness and the increase of refractive index, measured by ellipsometry. Rotational motion of fluorescent probes doped inside the liquid film, measured by polarization-resolved single molecule fluorescence microscopy, is retarded and the dynamical heterogeneity is reduced. It is demonstrated that the application of SAW of high frequency makes the thin polymeric liquid film densified and more dynamically homogeneous.

**4:42PM J32.00008: Investigating molecular origins of mechanical stress during deformation of polymer glasses: in-situ birefringence measurements**

DA HUANG (Presenter), MASOUD RAZAVI, SHIQING WANG, Univ of Akron — In absence of microscopic experimental tools to investigate molecular deformation due to macroscopic deformation of glassy polymers, we monitor in real time the emergence of birefringence at different temperatures during ongoing uniaxial tensile deformation, stress relaxation and creep. By comparing the stress-optical behavior among PS, PMMA and bisphenol A PC where the optical anisotropy arises from either side group (PS) or backbone (PMMA and PC), we can learn about the intermolecular and intramolecular contributions to mechanical stress and obtain more insights into the stress-optical relationship identified in the mechanical deformation of these glassy polymers.

**4:54PM J32.00009: Light-facilitated dewetting in amorphous selenium thin films**

AIXI ZHANG (Presenter), University of Pennsylvania, DANIXA RODRIGUEZ, Department of Chemistry, University Of Puerto Rico at Cayey, RICHARD B STEPHENS, ZAHRA FAKHRAAI, University of Pennsylvania

— Properties of glass thin films deviate from bulk for various materials, such as polymers, molecular glasses, and metallic glasses. When the film thickness is below a certain threshold, fast surface dynamics plays a strong role. Here, we study dewetting and glass transition temperature ($T_g$) of amorphous selenium (a-Se) thin films. A unique property of a-Se is that it forms random chain length and exhibits structural flexibility through bond breakage and formation of new bonds or over-coordinated sites upon above bandgap light irradiation. We investigate light-induced fluidity in a-Se and its effect on the length scale and the magnitude of enhancement in surface dynamics. Isothermal dewetting experiments are performed on a-Se films of different thicknesses below and above $T_g$. The hole-growth rate satisfies non-slip dewetting conditions. Thus, the growth velocity is directly related to the film's viscosity. Both the viscosity and activation energy in thin films are enhanced compared to the bulk. Films that start to deviate from bulk can be as thick as 100 nm, while this length scale turned out to be about 30 nm in most organic glasses. By applying various illumination condition, we study the relationship between the film structure and enhanced surface dynamics.

**5:06PM J32.00010: Geometry-Dictated Wrinkle Patterns in Vapor-Deposited Thin Films on Liquid Substrates**

ROBERT ENRIGHT (Presenter), LAURA BRADLEY, Polymer Science and Engineering, Univ of Mass - Amherst

— Surface patterns and wrinkles in thin films are of fundamental and technological interest for their use in tuning morphological, mechanical, optical, and surface properties. Here, we use initiated chemical vapor deposition (iCVD) to generate polymer films with controlled wrinkle patterns and geometries. The iCVD technique is a solvent-free method to produce functional polymer coatings by free-radical polymerization of surface adsorbed monomers. Previously, iCVD has been used to produce parallel and herringbone wrinkles by deposition onto pre-strained elastomers and random wrinkles by deposition onto compliant amorphous substrates. We examine wrinkle formation in thin films on liquid substrates. The resulting wrinkle patterns are dictated by the topography and boundaries of the liquid surface pinned in micropost arrays with various post sizes, spacings, and shapes. Properties of the wrinkled films also depend on the iCVD deposition conditions. This presentation will demonstrate control of the wrinkle patterns and elucidate the mechanism of wrinkle formation in thin films grown on liquid surfaces.

In situ Molecular Aggregation Structure Analyses on Glassy Polymers during Mechanical Deformation* KEN KOJIO (Presenter), AYA FUJIMOTO, TOMOKO KAJIWARA, CHAO-HUNG CHENG, SHIORI MASUDA, NATTANEE DECHNARONG, KENTO FUKADA, KAZUTAKA KAMITANI, ATSUSHI TAKAHA, Kyushu Univ — Poly (methyl methacrylate) (PMMA) and polycarbonate (PC) were chosen as a glassy polymer. Molecular aggregation structure and stretching properties of these glassy films were investigated by polarized high-speed camera observation and synchrotron X-ray wide-angle and small-angle scattering techniques during uniaxial and bulge deformation processes. 

$M_n$ of PC was 30k. $M_n$ of PMMAs were 70k and 1.2M. During both uniaxial and bulge deformation processes, PMMA-70k showed brittle nature, and PC and PMMA-1.2 M showed ductile property. In situ wide-angle X-ray scattering measurement revealed that increase in interchain distance during bulge deformation. Also, polarized high-speed camera observation revealed that PMMA-1.2M showed a wrinkle structure. This structure must be related to emergence of ductile property of PMMA-1.2M.

2:30PM J33.00001: BREAK —
3:06PM J33.00002: Packing Frustration in Block Copolymer Double Gyroids: Is it really all about the tubular domains?*  
ABHIRAM REDDY (Presenter), University of Massachusetts - Amherst, XUEYAN FENG, EDWIN THOMAS, Rice University, GREGORY GRASON, University of Massachusetts - Amherst — Understanding the molecular-scale mechanisms that lead to self-assembly of complex 3D morphologies remains an active area of research in soft matter systems. Block copolymers (BCPs) provide an exciting avenue to probe these mechanisms due to advancements in theory, synthesis and characterization tools. In this talk, we will revisit the thermodynamic connection between stability of triply-periodic network (TPN) phases, such as the Double Gyroid (DG), and packing frustration, or the variation in chain extension required by space filling constraint. We propose Medial Thickness (MT) analysis which provides a generic and practical measure of domain thickness of BCP morphologies of any arbitrary topology. Based on MT analysis of both theoretical models and experimental measurements of inter-block dividing surfaces of DG, we argue that previous measures of domain thickness severely overestimate both magnitude and dispersity of chain extension required to fill the tubular domains of TPN, belying the heuristic picture that their dominant thermodynamic costs arise from the stretching to reach the center of tubular interconnects. These insights also lead us to revisit longstanding question about absence of DG in the equilibrium phase diagram of strongly-segregated BCPs.

*DOE-BES(DE-SC0014599)

3:18PM J33.00003: Effects of Tacticity on the Formation of Bicontinuous Phases in Diblock Copolymers  
CHI TO LAI (Presenter), AN-CHANG SHI, McMaster Univ — The most prominent feature of block copolymers is their ability to self-assemble into ordered structures with periods typically on the scale of 10-100 nm. The symmetry of these ordered structures can depend on a number of factors, including block composition, strength of interactions, conformational asymmetry and tacticity. Tacticity is defined as the order of neighboring dangling groups along a polymer backbone, and influences many properties, ranging from thermal to rheological to conformational. In particular, block copolymers of the same composition with different tacticities could form different microphases. Recent experiments on stereoregular diblock copolymers have also observed the existence of the bicontinuous double-diamond phase, which is not found in neat atactic diblock copolymers. On the other hand, the effects of tacticity on self-assembly is yet to be completely understood. We develop a toy model to incorporate the effects of tacticity within the theoretical framework of self-consistent field theory. We then examine how the formation of bicontinuous phases in diblock copolymers is affected by the inclusion of tacticity effects.
3:30PM J33.00004: Cylindrical to Lamellar Microdomain Order to Order Transition upon Heating for Upper Critical Ordering Transition Block Copolymer* SEONGHYEON AHN (Presenter), YESEONG SEO, Department of Chemical Engineering, Pohang Univ of Sci & Tech, CHAO DUAN, LIXUN ZHANG, WEI-HUA LI, Department of Macromolecular Science, Fudan University, JINKON KIM, Department of Chemical Engineering, Pohang Univ of Sci & Tech — For block copolymers with upper critical ordering transition (UCOT) where $\chi$ decreases with increasing temperature, the sequence of order to order transition (OOT) upon heating of AB diblock and $A_1BA_2$ triblock copolymers with UCOT is as follows: lamellae to gyroids to cylinders to spheres before order to disorder transition. However, the opposite direction OOT is impossible in UCOT block copolymers.

Here, we investigated the OOT of polystyrene-block-polyisoprene-block-polystyrene-block-polyisoprene ($S_1I_1S_2I_2$) linear tetrablock copolymer. Very interestingly, this block copolymer showed cylindrical to lamellar microdomains transition upon heating. This behaviour is the exactly opposite to commonly observed OOT for linear AB diblock and $A_1BA_2$ triblock copolymers with upper critical ordering transition, where lamellar microdomains have been transformed to cylindrical microdomains upon heating. This interesting transition sequence is due to the chain architecture of linear tetrablock copolymer with two PS and two PI blocks.

3:42PM J33.00005: Unique self-assembly behaviors of ABCA tetrablock copolymer* QIONG XIE (Presenter), WEI-HUA LI, Department of Macromolecular Science, State Key Laboratory of Molecular Engineering of Polymers, Fudan University, Shanghai, China. — The self-assembly behavior of linear ABCA tetrablock copolymers is investigated using self-consistent field theory (SCFT). Although the general mechanism of block copolymer self-assembly has been well established, the self-assembly behaviors of some block copolymers are still hard to be understood and are even quite counterintuitive. Here we focus on the self-assembly of symmetric ABCA linear tetrablock copolymer. Our results indicate that the Janus-like superspherical phase can exist stably when the Flory-Huggins interaction between B and C blocks is much larger than the other two interactions. Moreover, a helical-Janus spherical phase is predicted to compete with the Janus phase. Meanwhile, the Janus-like supercylinder is predicted to be only metastable, and instead supercylinders composed of B/C-helices and B/C-stacked-disks are predicted to be stable. The stability of these novel structures is mainly dictated by the competition between the stretching energy and interfacial energy.

3:54PM J33.00006: Tuning Helical Structures via Designed Block Copolymer Systems*  
MEI-JIAO LIU (Presenter), Department of Chemistry, Zhejiang Sci-Tech University, Hangzhou, China, WEI-HUA LI, Department of Macromolecular Science, Fudan University, Shanghai, China — Block copolymers confined in nanopores provide unique achiral systems for the formation of helical structures. With AB diblock copolymers, stable single and double helical structures are observed. Aiming to obtain more different helical structures, we replace AB diblock copolymer with linear ABC triblock copolymers. We speculate that a core-shell superstructure is formed within the nanopore, which is composed of a C-core cylinder wrapped by B-helices within the A-shell. A number of helical structures with strands ranging from 1 to 5 are predicted by self-consistent field theory (SCFT), and in general, the number of strands decreases as the volume fraction of C-block increases in a given nanopore. More surprisingly, the variation of helical strand in the confined system is in an opposite trend to that in the bulk, which is mainly resulted by the constraint of the cylindrical confinement on the change of the curvature between the outer A-layer and the inner B/C-superdomain. Furthermore, adding C homopolymers to ABC triblock copolymers, the helical structures with more strands are predicted. Our work demonstrates a facile way to fabricate different helical superstructures.

4:06PM J33.00007: Miscibility Enhancement in Polyisoprene-Polyolefin Block Copolymers via Styrene Incorporation*  
SRAVYA JANGAREDDY (Presenter), RICHARD REGISTER, Princeton University — Polydienes like polyisoprene (PI) and polyolefins like hydrogenated mid-vinyl polybutadiene (hPB) generally show limited compatibility (high interaction energy density, X). Both the regular mixing model and the copolymer equation suggest that styrene units (S) should boost inter-block miscibility when incorporated in small amounts into hPB, up to 40 wt% S, via random copolymerization. Mixing thermodynamics in symmetric polydiene-polyolefin block-random copolymers composed of PI and a selectively saturated random copolymer of mid-vinyl polybutadiene and styrene (hSBR) were investigated via location of the order-disorder transition (ODT) temperatures. Block and “block-random” copolymers were prepared by anionic polymerization, followed by selective saturation of the butadiene units. ODT measurements show that X is 0.74 MPa at 0 wt% S, and exhibits the predicted parabolic variation with wt% S, with a minimum in X near 40 wt% S. Near the minimum, one-phase and two-phase blends of an hSBR with PIs of two different molecular weights, revealed that 0.10 < X < 0.16 MPa, indicating that the copolymer equation provides a better description of the mixing thermodynamics than the regular mixing model (for which X = 0 at the minimum).

4:18PM J33.00008: WITHDRAWN ABSTRACT
4:30PM J33.00009: Pattern Imprinted Polyacrylonitrile Thin Films Using an Ionic Liquid

CHUQING YUAN (Presenter), REBECCA BARRY, Department of Chemical and Biomolecular Engineering, Univ of Houston, KATHRYN BEERS, Materials Science & Engineering Division, National Institute of Standards & Technology, ALAMGIR KARIM, Department of Chemical and Biomolecular Engineering, Univ of Houston — Polyacrylonitrile (PAN)-based conductive graphitic microstructures have tremendous potential for a variety of applications such as patterned electrodes, and anisotropic conductive films in the electronics industry due to its high carbonization yield. However, because of the crystallinity and high melting point of pristine PAN, thin films are difficult to get patterned at routine temperatures and pressures via methods such as capillary force lithography (CFL), a straightforward lithographic technique. We demonstrate that adding ionic liquid (IL) can greatly improve the imprintability of PAN by decelerating the crystallization rate and providing the needed mobility at accessible temperatures for efficient mold filling. The effect of IL additives concentration, annealing temperature and hold time of patterned PDMS elastomer on the imprintability of PAN are well-correlated in a balancing act. The resulting patterned films demonstrate extraordinary IL removal ability at the end of the process, and thermal stability of final patterned structures, promising results on easy patterning route to create graphitic structures after carbonization for multitude of applications ranging from sensors to membranes.

4:42PM J33.00010: Glass Transitions in PS-TiO\textsubscript{2} Nanocomposites

MIRCEA CHIPARA (Presenter), ELVIA CURIEL IZAGUIRRE, DORINA CHIPARA, MATAZ ALCOUTLABI, University of Texas Rio Grande Valley — Atactic polystyrene is considered a fully amorphous polymer. Homogeneous solutions of atactic polystyrene in chloroform were obtained by adding the two components and stirring the mixture for 4 hours. After homogenization, the polystyrene-chloroform solutions were moved in a larger beaker and sonicated for about 1 hour. Then, deionized water was suddenly added to the polymer solution, without interrupting the sonication process. The added volume of water was typical twice the volume of the polymer solution. The sonication was stopped after 15 minutes and the polymer was collected and then dried in an oven at 90°C, for about 12 h. Full water evaporation was confirmed by TGA. Nanocomposites of PS-TiO\textsubscript{2}, containing various amounts of TiO\textsubscript{2}, have been obtained by using this procedure. It was expected that the rapid collapse of the polymeric chain (as the nonsolvent was added) would trap the nanofiller within the polymeric matrix.

The as-obtained nanocomposites were investigated by using a TA Instruments Q 50 DSC at various heating and cooling cycles ranging between 5 °C/min to 30 °C/min. The research is focused on the effect of heating/cooling rates (ranging between 5 °C/min to 30°C/min) and of the concentration of TiO\textsubscript{2} on the glass transition temperature of PS-TiO\textsubscript{2} nanocomposites.
The pliable morphology of block copolymer crystals [Invited] EDWIN THOMAS (Presenter), XUEYAN FENG, Materials Science, Rice Univ, CHRISTOPHER BURKE, Polymer Science, University of Massachusetts, MUJIN ZHUO, HUA GUO, KAIQI YANG, AMANDA SUAREZ, WENPENG SHAN, Materials Science, Rice Univ, ABHIRAM REDDY, ISHAN PRASAD, Polymer Science, University of Massachusetts, RONG-MING HO, National Tsing Hua University, APOSTOLOS AVGEROPOULOS, Ioannina University, GREGORY GRASON, Polymer Science, University of Massachusetts — Block copolymers form soft crystals of ‘mesoatomic’ building blocks comprised of many thousands of molecules, whose sub-unit-cell configurations couple strongly to sub- and super-strate boundary conditions and symmetries. High-fidelity 3D tomographic structural information from both the near-surface as well as interior regions is key to understanding the properties of a given polymer structure. BCPs having a tubular network morphology are particularly attractive for applications ranging from photonic crystals to 3D batteries. Additionally, such complex 3D structures are quite sensitive to confinement by interfaces. We study the 3D domain morphology of a solution-cast block copolymer double gyroid. Analysis reveals that the morphology reconstructs in the near surface regions as well as with non-affine deformation of the sub-unit-cell symmetry in the interior region. Such strongly pliable morphological behavior has strong implications for properties, raising the question as to whether highly perfect cubic self assembled BCP structures are possible.

Session J34 DPOLY: Dillon Medal Symposium 506 - Richard Register, Princeton University

Structured Polymer Colloids by Flash NanoPrecipitation [Invited] RODNEY PRIESTLEY (Presenter), Princeton University — Colloids with internal and external structure have shown great promise in applications ranging from biosensors to optics to drug delivery, where the overall particle structure is paramount to performance. The growing demand for such nanomaterials motivates the development of a scalable processing platform for their production. Here, we demonstrate that Flash NanoPrecipitation (FNP), a rapid and inherently scalable colloid precipitation technology, can be used to prepare structured colloids from homopolymers, polymer mixtures and block copolymers. As revealed by a combination of experiments and simulations, by varying key process parameters and functional groups within the polymers, a range of structured colloids can be produced without any modification to the FNP process. Finally, in one application, we demonstrate how ionomer-based Janus colloids can be used to stabilize Pickering emulsions.
3:06PM J34.00002: Exploiting supramolecular associations in interpenetrating networks and elastomers* LASHANDA KORLEY (Presenter), University of Delaware — Supramolecular interactions may hold the key to the development of network systems with tunable mechanics and modulated architecture, such as observed in the muscle protein titin. It is the dynamic nature of these physical associations that we have exploited in the design of tough supramolecular materials that super-impose covalent and non-covalent interactions to tailor tensile response. We have developed supramolecular elastomers and interpenetrating network (IPN) systems that probe the interplay of non-covalent and covalent interactions in structural organization and mechanical response. By tailoring physical associations via control of self-assembly and composition, we have demonstrated enhanced supramolecular dynamics driven by architecture and toughness enhancements due to phase behavior. Recently, non-covalent interaction strength, network regularity, and chemoresponsiveness have been utilized as handles to derive gradient materials and to induce actuation behavior.

3:18PM J34.00003: Droplet aggregates as model systems for connecting granular systems to continuum mechanics: how few is too few?* KARI DALNOKI-VERESS (Presenter), JEAN-CHRISTOPHE ONO-DIT-BIOT, JOHNATHAN HOGGARTH, McMaster Univ — In recent years we have developed a method to produce microscopic monodisperse oil droplets in an aqueous environment. With an attractive interaction between the droplets, monodisperse droplets form perfect crystalline aggregates, while a blend of small and large droplets allows us to prepare a disordered glass. By carefully tuning the adhesion forces between the droplets, the aggregates provide model systems for studying various physical phenomena that are not accessible by investigating molecular systems. Here I will provide a brief overview of experiments we have carried out to address two fundamental questions. How does a system transition from crystal to glass, when blending large and small droplets? And secondly, how does a system transition from a few particles, to many particles, where continuum models are valid. These experiments enable us to study the transition from few-to-many, and crystal-to-glass.

*Financial support was provided by the National Sciences and Engineering Research Council of Canada (NSERC).
3:30PM J34.00004: Evolution of polymer conformation during droplet-to-particle formation
JOAO CABRAL (Presenter), Imperial College London — Motivated by ubiquitous spray drying approaches in the manufacturing of polymer particles and composites, we experimentally investigate the mechanism and kinetics of particle formation by controlled solvent extraction and evaporation of polymer solution droplets. We employ microfluidics and acoustic levitation to precisely handle the polymer droplets in controlled environments. We then couple our experimental platforms with small angle neutron scattering (SANS) to elucidate chain conformation under equilibrium conditions and along the particle formation pathway, supplemented by optical and electron microscopies that characterise overall external and internal particle morphologies. We examine three model systems: two water-soluble polymers, poly(vinyl alcohol) and semi-flexible polyelectrolyte sodium carboxymethyl cellulose, and high-glass transition, semicrystalline poly(2, 6-diphenyl-p-phenylene oxide). We investigate the roles of composition (with respect to c* and c**), molecular mass, viscosity, and salt addition. Equipped with this knowledge, we then predictively design and fabricate polymer particles and capsules with prescribed dimensions, shape, porosity, microstructure and dissolution profile, and discuss complementarity with ‘flash nanoprecipitation’ methods.

3:42PM J34.00005: Gelation of Methylcellulose Chains Versus Methylcellulose Fibers
TIMOTHY LODGE (Presenter), SVETA MOROZOVA, S. PIRIL ERTEM, MCKENZIE COUGHLIN, FRANK S BATES, University of Minnesota — Upon heating in aqueous solutions, MC reversibly self-assembles into ~ 7-10 nm fibrils that percolate, resulting in physical gelation. We have chemically crosslinked both MC solutions at room temperature, and MC physical fibril gels at 80 °C, and compare the swelling and shear modulus properties. Hydroxyl moieties on MC were substituted with allyl groups, with a degree of substitution of about one pendant double bond per nine anhydroglucose repeat units. The allyl groups undergo crosslinking in the presence of a photo-initiator and UV light. Chemically crosslinking MC fibril gels at 80 °C results in opaque solid materials, and locks in the fibril structure, which persists even on cooling to room temperature. The shear modulus $G'$ increases modestly with temperature, and the volume fraction scaling is consistent with previous results for fibril gels. On the other hand, chemically crosslinking MC solutions at room temperature leads to clear, solid hydrogels which no longer form fibrils. Instead, swelling measurements show that the MC gels shrink by an order of magnitude when the temperature is increased from 25 °C to 80 °C. The equilibrium polymer volume fraction and $G_c$ are consistent with established theories for crosslinked polymer chains.

3:54PM J34.00006: Non-linear Deformation of Polymer Grafted Nanoparticles
RAMANAN KRISHNAMOORTI (Presenter), Chemical and Biomolecular Engineering, Univ of Houston — Linear viscoelastic properties of polymer grafted nanoparticles indicate that the systems behave like elastic solids with elastic moduli that scale with concentration of the nanoparticles and with the molecular weight of the polymer chains grafted to the particles. We studied the non-linear viscoelastic properties of such polymer grafted nanoparticle melts through a systematic examination of steady shear behavior and the recovery after cessation of flow. The local re-arrangement of particles and the formation of slip-planes and the regenearation of local order upon cessation of flow dominate the flow and recovery properties of these nanocomposites.
Harnessing nanoparticle vibrations to probe surface mobility and glass transition

EUNSOO KANG, BARTLOMIEJ GRACZYKOWSKI, GEORGE FYTAS (Presenter), Max Planck Institute for Polymer Research, KATELYN RANDAZZO, RODNEY PRIESTLEY, Princeton University — Advances in polymer nanoparticle synthesis and assembly techniques have enabled new applications, from drug delivery carriers to novel coatings. However, the polymer dynamics, especially at the particle surfaces of architected colloids, must be understood in order to realize their potential. Brillouin light spectroscopy as a direct probe of the particle surface mobility via nanoparticle vibrations, reveal the correlation between the glass transition behavior and surface dynamics and the presence of a low frequency mode extremely sensitive to particle-particle interactions. These are enabled by the surface mobility which can be engineered by different shell architecture layers. We demonstrate that a thin shell layer is able to eliminate the effect of enhanced particle surface mobility and drastically modify the structure of nanoparticle assembly. Surface mobility is strongly affected by the application of pressure modifies enabling a facile soldering of the colloidal film.

Non-Equilibrium Effects in Polymer Nanocomposites

SANAT KUMAR (Presenter), Columbia Univ — We have previously shown that the polymer nanocomposites, especially those that involve pure polymer-grafted nanoparticles, have a solid-like mechanical response with extraordinarily long relaxation times. In parallel with these efforts here we show that the structure and dynamics of these materials (and apparently for all nanocomposites) relax over similarly long times. The implications of these results for our understanding of this class of hybrid materials will be explored.

Programming surface energy driven Marangoni convection to pattern polymer films*

CHRISTOPHER ELLISON (Presenter), University of Minnesota — The Marangoni effect describes how fluid flows in response to gradients in surface energy. We recently developed a method for photochemically preprogramming surface energy patterns in glassy polystyrene (PS) thin films. Patterned UV irradiation through a mask selectively dehydrogenates PS, increasing surface energy in the UV exposed regions compared to the unexposed regions. After heating the film to the liquid state, transport of polymer occurs from regions of low surface energy to regions of high surface energy. This method can be harnessed to rapidly manufacture polymer films possessing prescribed three-dimensional topographies reflective of the original light exposure pattern without solvent washes or etching procedures. To better understand this phenomenon, a theoretical model will be presented that reveals the physics of this process, its limits and ways to apply it efficiently for various target metrics.

4:42PM J34.00010: Influence of Pore Morphology on the Diffusion of Water in Triblock Copolymer Membranes

DIPAK ARYAL, MICHAEL P HOWARD, RITUPARNA SAMANTA, University of Texas at Austin, SEGOLENE ANTOINE, RACHEL A SEGALMAN, University of California at Santa Barbara, THOMAS TRUSKETT, VENKATRAGHAVAN GANESAN (Presenter), University of Texas at Austin — Understanding the transport properties of water in self-assembled block copolymer morphologies is important for furthering the use of such materials as water-purifying membranes. In this study, we used coarse-grained dissipative-particle-dynamics (DPD) simulations to clarify the influence of pore morphology on the self-diffusion of water in linear-triblock-copolymer membranes. We considered representative lamellar, cylindrical, and gyroid morphologies and present results for both the global and local diffusivities, as well as the structural characteristics of water in the pores. Our results suggest that the diffusivity of water in the confined, polymer-coated pores differs from that in the unconfined bulk. Explicitly, in confinement, the mobility of water is reduced by the hydrodynamic friction arising from the hydrophilic blocks coating the pore walls. We demonstrate that in lamella and cylindrical morphologies, the latter effects can be rendered as a universal function of the pore size relative to the brush height of the hydrophilic blocks.

4:54PM J34.00011: Enhanced Conductivity via Homopolymer-Rich Pathways in Block Polymer Composite Electrolytes

THOMAS EPPS (Presenter), MELODY A MORRIS, Univ of Delaware — The BP electrolyte polystyrene-block-poly(oligo-oxyethylene methacrylate) [PS-b-POEM] was blended with POEM homopolymers of varying molecular weights to explore the impact of polymer additives on ion conductivity. The incorporation of a higher molecular weight homopolymer additive promoted a ‘dry brush-like’ homopolymer distribution within the BP self-assembly and led to higher lithium salt concentrations in the more mobile homopolymer-rich region, increasing overall ionic conductivity relative to the ‘wet brush-like’ and unblended composites. Furthermore, using $^7$Li solid-state nuclear magnetic resonance spectroscopy, we found a temperature corresponding to a transition in lithium mobility ($T_{Li\ mobility}$) that was a function of blend-type. $T_{Li\ mobility}$ was found to be 39 °C above $T_g$ in all cases. Interestingly, the ionic conductivity of the blended BPs was highest in the ‘dry brush-like’ composites even though these composites had higher $T_g$s than the ‘wet brush-like’ composites, suggesting that homopolymer-rich conducting pathways formed in the ‘dry brush-like’ assemblies had a larger influence on conductivity than the greater lithium ion mobility in the ‘wet brush-like’ blends.

5:06PM J34.00012: Comparison of macroscopic and microscopic measurements of segmental dynamics in aging polymer glasses

MARK EDIGER (Presenter), JOSH RICCI, TREVOR BENNIN, ENRAN XING, University of Wisconsin - Madison — Optical probe reorientation experiments and mechanical stress relaxation measurements in the linear response regime were performed during aging of glasses of poly(methyl methacrylate) (PMMA) and poly(D,L-lactide) (PLA). For each polymer, across all aging times and temperatures, an excellent correlation is observed between the relaxation times for mechanical and optical experiments with the two observables showing a power law relationship with an exponent near one. For PMMA, relaxation times for the two observables in crosslinked and uncrosslinked materials follow the same correlation. The probe reorientation method has previously been utilized to track changes in segmental dynamics during nonlinear deformations. Our new experiments validate the conclusion that probe reorientation is a good reporter of segmental dynamics in the glass, in the linear response regime. The strong agreement between macroscopic and microscopic measurements of mobility in the aging polymer glasses contrasts to recent work on colloidal and metallic glasses.

5:18PM J34.00013: Confinement Effects on Dye Diffusivity in Polymer Films Depend on Polymer Molecular Weight: Relation to Fragility-Confinement Effects

JOHN TORKELSON (Presenter), TONG WEI, TIAN LAN, Northwestern University — We studied the translational diffusivity of 9,10-bis(phenylethynyl)anthracene ($D_{dye}$) in supported, polystyrene (PS) films. Relative to bulk films and near $T_g$, $D_{dye}$ is reduced by 80 - 90% in 100-nm-thick, high molecular weight (MW) PS (400 kg/mol) films. These results are associated with fragility-confinement effects, with fragility decreasing in films with decreasing thickness below ~ 200 nm. Fragility reflects the breadth of the cooperative segmental relaxation distribution: that breadth narrows with confinement. The thickness dependence of $D_{dye}$ reflects the time scales associated with the fast relaxation tail of that distribution. At thickness below ~200 nm, the distribution narrows, with the shortest relaxation times shifting to longer times, leading to a reduction in $D_{dye}$. We also studied $D_{dye}$ in low MW PS (6 kg/mol). Because 6 kg/mol PS exhibits much lower bulk fragility than high MW PS, confinement has a much-reduced effect on low MW PS fragility: both fragility and $D_{dye}$ in 100-nm-thick low MW PS films are unchanged from bulk. Thus, for thicknesses where fragility-confinement effects are observed (high MW PS), $D_{dye}$ also exhibits confinement effects. By suppressing fragility-confinement effects by using very low MW PS, confinement effects on $D_{dye}$ are also suppressed.

Session J35 GMED: Physics of Medical Imaging, Measurement, and Tissue Characterization 110 - Wojciech Zbijewski, Johns Hopkins University
2:30PM J35.00001: Imaging the brain across scales using light, magnetic fields, and models*

MICHÈLE DESJARDINS (Presenter), Univ of Laval — Functional Magnetic Resonance Imaging (fMRI) is a powerful tool to map brain activity non-invasively and is the foundation of tens of thousands of published neuroscience studies. However, fMRI does not measure neurons directly. Instead, in the most common form of fMRI called Blood Oxygen Level Dependent (BOLD), changes in the concentration of paramagnetic deoxyhemoglobin in the blood are detected. Although BOLD is correlated with neural activity, its interpretation in healthy and diseased brain remains limited. Animal models provide invaluable insight for studying the cellular origin of fMRI. In mice, state-of-the-art optical technologies have been developed to probe neuronal activity, blood flow and oxygenation while manipulating cell-type-specific neuronal activity.

A framework for imaging the brain of awake behaving mice across scales, from two-photon microscopy at the micrometer scale to macroscopic fMRI, will be demonstrated. High-resolution 3D images of cerebral vasculature measured in mice can be graphed into a connected network to model blood circulation and oxygen diffusion. In this model, the physics of magnetic resonance are leveraged to predict human brain imaging signals. Applications in neuroscience and fundamental cancer research will be discussed.

*NSERC; FRQNT.

2:42PM J35.00002: Calculation of carbon-ion beam's range in different media used for radiation therapy

PANAGIOTA GALANAKOU (Presenter), THEODORA LEVENTOURI, WAZIR MUHAMMAD, Florida Atlantic University — Carbon-ion radiotherapy (CIRT) is a new radiation modality with significant physical and biological advantages over photon irradiation. Range assessment is a major challenge and it is considered the key for using the full potential of carbon ion therapies. The purpose of this research is to develop a novel and practical method for monitoring accurately the carbon ion range in different types of tissue during treatment. The proposed method is based on the Doppler Shift Effect of Prompt Gammas (PGs), which give real-time information due to the instantaneous nuclear de-excitation, and thus PG shifted energy can quantify the mean carbon energy with respect to PG spectrum, and then the predicted range can be calibrated. We develop a mathematical model with initial carbon ion energies within the range of 100MeV/u-450 MeV/u for different detection angles of 0°-90°, and different target materials including water, air, and soft tissue. The results of our calculations are verified by Monte Carlo simulations.
2:54PM J35.00003: MRI Mapping of Heat Dissipation from Polydopamine Particles under Infra-Red Irradiation  JANUSZ HANKIEWICZ, JOHN STROUD, ZBIGNIEW J CELINSKI, BioFrontiers, University of Colorado, Colorado Springs, YURIY GARBOVSKIY, Physics, Connecticut State Colleges & Universities, AIMING LU, KRZYSZTOF GORNY, DAVID WOODRUM, Radiology, Mayo Clinic College of Medicine, STEFAN JURGA, KOSMA SZUTKOWSKI, RADOSLAW MROWCZYNSKI (Presenter), NanoBioMedical Center, Adam Mickiewicz University — Polydopamine (PDA) is a new nanomaterial with promising properties for photothermal therapies. We investigated heating of phantoms made of agar gel with different concentrations (from 1 to 200 mg/ml) of PDA 100 nm particles. Spectrophotometry measurements show significant absorption in near-infrared range with increases below 300 nm. The laser beam (808 nm, 5W) was guided through a fiberglass guide and dispersed by a diffuser. A 25 ml phantom was placed in styrofoam thermal insulation. The temperature of the phantom after 5 minutes of continuous laser irradiation increased dramatically for concentrations above 100 mg/ml. For concentration of 200 mg/ml, an increase of 41 ºC was achieved, about 14 times higher than for the control pure agar gel. Larger phantoms were studied in MRI settings to obtain heat dissipation maps, i.e. relative change of temperature in the phantom volume for different laser irradiation time and power. Temperature maps were obtained by analyzing the phase change due to proton resonance frequency shift (PRF). PRF results were compared to measurements using four miniature MRI compatible temperature sensors. Results allowed us to determine thermal gradients produced by single point heating which may be useful in MRI guided laser ablations of cancers.

3:06PM J35.00004: Multi-Regularization Reconstruction of One-Dimensional $T_2$ Distributions in Magnetic Resonance Relaxometry*  CHUAN BI, National Institutes of Health - NIH, YVONNE M. OU, Mathematical Sciences, University of Delaware, WENSHU QIAN, YOU ZHUO, RICHARD SPENCER (Presenter), National Institutes of Health - NIH — Measurements of $T_2$ relaxation time distributions in magnetic resonance relaxometry are increasingly used to probe microstructural details of materials or tissues. However, extracting the model from the acquired data is a severely ill-conditioned problem. Tikhonov regularization and related methods are widely used to address this. Methods such as the L-curve and generalized cross-validation (GCV) select a single regularizer to obtain an optimal approximation to the underlying distribution. However, this procedure does not make use of the information content of the non-selected regularized results; given the lack of definitive criteria for regularization parameter selection, this represents a potential loss of substantial information. In contrast, we propose a new reconstruction method, Multi-Reg, incorporating a range of calculated regularized solutions. Multi-Reg is based on a dictionary of noise-corrupted regularized reconstructions of distribution basis functions. We demonstrate that Multi-Reg can out-perform the L-curve or GCV methods in simulation analyses of Gaussian distribution components, and present experimental results on mouse spinal cord and human muscle tissue.

*Supported by the Intramural Research Program, National Institute on Aging, National Institutes of Health.
3:18PM J35.00005: Hidden Dangers in MRI: Investigating Heating of Metallic Objects from Switching Gradient Fields*  JOHN STROUD (Presenter), University of Colorado, Colorado Springs, KARL STUPIC, NIST, TUCKER WALSH, TIM READ, ZBIGNIEW J CELINSKI, JANUSZ HANKIEWICZ, University of Colorado, Colorado Springs — With the number of medical implants increasing every year it is inevitable that some patients with implants will at some time undergo an MRI procedure. Investigating the safety of implants during an MRI scan is vital as with current medical record keeping it can be difficult to track implants, which may put patients in possible danger. It is known in MRI oscillating magnetic fields produced by an MRI scanner have the potential to induce eddy currents in metallic implants in turn these eddy currents can heat surrounding tissue and may potentially cause damage to healthy tissue. However, much of the research evaluating the safety risks that are associated with imaging around metallic implants has focused mainly on the magnetic component of RF radiation present in the MRI scanner, and not much attention has been paid to switching gradient fields in MRI which oscillate at much lower frequencies. We investigate local heating of conductive materials within an MRI scanner producing quantitative data on the position dependence of induced EMF and heating, as well as the interaction between different gradients within the scanner. This work will assist in evaluating any dangers that may be present to patients with a metallic implants.

*Funded by the Undergraduate Research Academy at UCCS

3:30PM J35.00006: Superparamagnetic particles as MRI temperature contrast agent JANUSZ HANKIEWICZ (Presenter), JOHN STROUD, BioFrontiers, University of Colorado, Colorado Springs, STEPHEN RUSSEK, National Institute of Standards and Technology Boulder, KAREN LIVESEY, CASEY CHALIFOUR, Physics, University Colorado Colorado Springs, GIACOMO PARIGI, Magnetic Resonance Center, University of Florence, Italy, ZBIGNIEW J CELINSKI, ROBERT CAMLEY, BioFrontiers, University of Colorado, Colorado Springs, DOROTA LACHOWICZ, ANGELIKA KMITA, MARTA GAJEWSKA, ELA TRYNKIEWICZ, ROMA WIRECKA, MAREK PRZYBYLSKI, Academic Centre for Materials and Nanotechnology, AGH University of Science and Technology, Krakow, Poland — A method of MRI temperature contrast developed by our group, which employs temperature dependent local field inhomogeneities due to a presence of micrometer sized magnetic particles and corresponding changes in image intensity (T2* contrast), faces limitations due to particle size. For human applications, large particles cannot be used as they face problems with delivery and secretion. Smaller particles are required. However, spin transverse relaxation process for such particles is no longer governed by a static dephasing regime and T2* temperature dependent inhomogeneity contributions vanish due to averaging by spin motion. We hypothesize that superparamagnetic particles may provide contrast mechanisms only if nuclear relaxation is temperature dependent. To test this hypothesis, we used Mn-Zn ferrite superparamagnetic particles with an average size of 7.8 ± 2.1 nm. Particles with a 2 mM concentration were embeded in agar gel for NMR and MRI measurements at temperature 5 - 50 °C. At 3.0 T, NMR results show that T1 is temperature independent, while observed NMR linewidth drops from 130 Hz to 70 Hz and T2 increases from 1.3 ms to 2.8 ms. Intensity of T2 weighted MR images depends linearly on temperature, providing the contrasting mechanism necessary for temperature determination.
3:42PM J35.00007: Modeling of human body tissue compositions for Monte Carlo algorithm of Proton therapy dose computation with the Single Energy Computed Tomography Calibration Curve  MARYAM GHASEMI GHONCHEHNAZI (Presenter), Florida Atlantic University, GRANT EVANS, CHARLES SHANG, South Florida Proton Therapy Institute — Proton dose computation with most planning systems rely on single energy computed tomography (CT) images in which the relative proton stopping-power ratio (SPR), mass density and the relative electron density are derived from CT Hounsfield units (HU). Using a proton Monte Carlo dose calculation algorithm in treatment planning system (TPS), a CT number of each pixel in patient CT image is converted to mass density; then the proton stopping power ratio is computed. The accuracy of proton dose computation in Monte Carlo algorithm relies on conversion from HU to mass density. We explore the potential improvement in determining mass density to reduce the uncertainty in predicting the proton range in patients. The Stoichiometric method is used to calculate the CT scanner specific parameters related to the photoelectric effect, coherent scattering, and Compton interactions, in order to model the CT number of human body tissue compositions. In the stoichiometric calibration curve, elemental compositions and densities of 34 “standard” human biological tissues have been taken from the ICRU report 44. Our results demonstrate that a more accurate prediction of HU to mass density can be achieved by the stoichiometric calibration curve for proton therapy dose computation (rms error 0.81%).

3:54PM J35.00008: Method, Mechanism, and Metrology for Measurement of Multi-Dimensional MTF in Medical Imaging  PENGWEI WU (Presenter), MAHADEVAPPA MAHESH, Johns Hopkins University, JOHN BOONE, University of California, Davis, JEFFREY H SIEWERDSEN, Johns Hopkins University — The spatial resolution characteristics of CT and cone-beam CT (CBCT) systems is well characterized by the spatial-frequency-dependent modulation transfer function (MTF). Emerging scanner technologies and reconstruction algorithms challenge conventional methods for MTF assessment, including the degree to which the system / image exhibits 3D resolution characteristics that are isotropic (vary in direction), stationary (vary with location), and linear (vary with contrast). We report an angled-edge test tool and oversampling method to measure the MTF in any direction in 3D image data, with extension to a spherical test tool for measurement in all directions. One particular direction (45° relative to the axial plane) is shown to avoid null space effects in cone-beam geometries and provide useful 1D quantitation of the fully 3D resolution characteristics. This method was tested using a mobile C-arm CBCT system and a high-resolution diagnostic CT scanner and shown to reveal underlying sources of non-isotropic resolution characteristics – for example, asymmetric apodization filters, detector binning modes, and focal spot size. The angled-edge or spherical test tools provide a practical means for quantitative characterization of 3D MTF characteristics for medical imaging systems.
4:06PM J35.00009: A novel approach to lead concentration measurements in bone using the L-shell x-ray fluorescence and strontium Kβ/Kα ratio.* MIHAI GHERASE (Presenter), JOSH JARDENIL, SARAH KROEKER, California State University, Fresno — Lead (Pb) is a well-known toxic element which accumulates in the bone after years or decades of exposure. Long-term Pb exposure is, therefore, assessed by in vivo bone Pb concentration measurements. In vivo bone Pb x-ray fluorescence (XRF) measurements are typically done in tibia bone to minimize the soft tissue (ST) x-ray attenuation. Bone Pb L-shell XRF (LXRF) can use compact XRF systems – a useful feature for potential bone Pb surveys. An optimal grazing-incidence position (OGIP) method was developed in our lab to enhance Pb detection by mitigating the x-ray scatter. The obstacle to in vivo applications is the unknown ST x-ray attenuation. The average ST x-ray linear attenuation coefficient and ultrasound-measured thickness past approach gave inaccurate results. In our method, the measured Kβ/Kα ratio of strontium (an essential trace element in the bone) was used to estimate the ST attenuation of the Pb x-rays. Plaster-of-Paris (poP) bone phantoms made with known Pb and Sr concentrations and polyoxymethylene (POM) ST phantoms of varying thickness were measured. The concordance correlation coefficients between the computed and the known Pb concentrations were in the -0.444 to 0.998 range.

*Research was supported by an NIH award #SC2GM121187.

4:18PM J35.00010: Quantifying Macroscopic and Microscopic Radiation Dose Enhancement with Gold Nanoparticles for a Range of Therapeutic Energies* TARA GRAY (Presenter), University of Texas at San Antonio, NEMA BASSIRI, Radiation Oncology, University of Texas Health Mays Cancer Center, SHAQUAN DAVID, DEVANSHI PATEL, University of Texas at San Antonio, NEIL KIRBY, Radiation Oncology, University of Texas Health Mays Cancer Center, KATHRYN MAYER, University of Texas at San Antonio — The purpose of this study is to computationally quantify the macroscopic and microscopic radiation dose enhancement effects of different sizes and shapes of gold nanoparticles. A MicroSelectron HDR Ir-192 brachytherapy seed and a Varian 600C gantry head with 6 MV and 18 MV photon energies were modeled using Monte Carlo N-Particle radiation transport software (MCNP 6.2, Los Alamos National Laboratory). The repeating structures capability of MCNP6.2 was utilized to simulate nanoparticles of varying sizes inside a tumor with a diameter of 1 x 1 x 1 cm³. Additionally, a phase space file was created to compute dose deposited from secondary electrons around single nanoparticles of varying shapes (nanocubes, nanoprisms and nanospheres). Macroscopic simulations show an increase in dose enhancement generally with increasing mass percentage of gold and compare well with experimental results. Microscopic simulations show an increased dose enhancement of 20% - 50% due to secondary electrons up to 1 µm from the nanoparticle and is highest for nanoprisms due to a larger surface area to volume ratio. This work indicates the potential for gold nanoparticles to provide significant dose enhancement and more effective tumor cell killing in radiation oncology practice.

*San Antonio Medical Foundation
4:30PM J35.00011: Dependence of deep learning-based whole organ segmentation on training dataset size in computed tomography (CT) images  DANIEL HUFF (Presenter), AMY J WEISMAN, ROBERT JERAJ, Medical Physics, University of Wisconsin - Madison — A significant drawback of deep learning-based medical image segmentation is its reliance on large amounts of labeled training data. However, little literature has characterized the dependence of model performance on the amount of training data provided. Here, we examine this dependence in the application of abdominal organ segmentation on patient CT images.

Two public datasets, BTCV (N=30) and VISCERAL.eu (N=20), were used for training. A third dataset, pancreasCT (N=43) was used as an independent test set. Segmentation was performed for five abdominal organs: liver, spleen, kidneys, stomach, and pancreas. Instances of the same CNN were trained on a varying number of randomly selected training scans (N=5-50). The architecture used was DeepMedic, a 3D patch-based CNN. Performance was measured with Dice coefficient, average surface distance, and 95% Hausdorff distance.

We observe that segmentation performance improves with increasing training dataset size, but in some cases plateaus before the whole training set is used. Absolute performance of our model is comparable to literature while minimizing the amount of labelled data required. This work has implications for optimizing deep learning-based image segmentation pipelines by minimizing time spent on unnecessary dataset labelling.

4:42PM J35.00012: Monte-Carlo simulation of X-ray energy spectrum for single and dual-energy radiography  NASTARAN KHAMOOSHI (Presenter), Physics and energy engineering, Amirkabir university of technology — Single-energy radiography is one of the most everyday nondestructive/noninvasive image methods that generate detailed images of tumors, nodules, cracks, defects, and discontinuities inside the human body or an object. Dual-energy X-ray is a novel technique which uses two X-ray spectrums for imaging. It can produce much higher contrast for radiographs for when two different subjects with different atomic numbers are close to each other. In this study, X-ray beam geometry has been precisely implemented in the code. Tungsten target anode material and the angle of 20 degrees is used as typical X-ray source’s anode. Electron-photon transformation cross-sections have been taken from ENDF data libraries. Photon energy distribution finally calculated exactly after inherent and/or additional filters. Effects of filtering materials with different thicknesses on HE and LE have been investigated. Excellent agreement results obtained in the spectrums generated by our Monte-Carlo simulation by IPEM software and experimental data. In this study filter quality effect has been conducted as well. The results of this investigation are very important in optimizing dose calculation, image quality consideration and a lot of other parameters in the area of the medical and industrial imaging field.
Complex impedance quantification of cell migration for the physics of cancer*   

MICHAEL J. MIMLITZ (Presenter), ANDREW J. WALThER, MICHAEL MERRICK, CATHERINE WEEDER, JOE BAMESBERGER, HARIs AKHTER, HONOUR DJAM, ANDREW EKPENYONG, Creighton University — Cell migration is a crucial step in cancer metastasis, the complex process which accounts for over 90% of cancer-related deaths. There is emerging evidence that radiotherapeutic doses meant to kill cancer cells can promote metastasis by enhancing cell migration. Here we quantify radiation-induced changes in cell migration as part of the physics of cancer: a novel research frontier unraveling the roles of physical properties of cells in cancer. We used a standard laboratory irradiator to irradiate both non-cancer (HCN2 neurons) and cancer cells (T98G glioblastoma) with 2 Gy, 10 Gy and 20 Gy of X-rays. To assess cell migration post-irradiation, we used a commercially available device, ECIS Z-Theta, which non-invasively measures and converts complex cell-substrate electric impedance into series resistance and capacitance in real time. We also used CdSe/ZnS core-shell quantum dots to quantify molecular changes in cells following radiotherapy. Both irradiated cell lines showed significantly (p <0.01) enhanced migration compared to non-irradiated cells, within the first 40 hours following irradiation with 20 Gy. Our results suggest cell migration as a new therapeutic target in antimetastasis strategies for improved radiotherapy outcomes.

*Creighton University Startup Grant (to AEE).

Test-retest Reproducibility for Resting State Networks in fMRI

MARGARITA LOPEZ (Presenter), Univ Veracruzana, BRENDA BEDolla-MoCTezuma, Psicología, Universidad del Valle de México — Resting state networks (rsN) are important to assess the neural connectivity in the brain in repose. The assessment of the rsN could help to the diagnosis and treatment of different psychological and psychiatric disorders, for example different studies have found that the DMN is affected in patients with major depression. The BOLD signal could be affected and change by technical and physiological factors as: movement, cardiac function, different potioning of the subject in the scan, the hour of the day, etc. for that reason is important to evaluate the rsN reproducibility between subjects and sessions. In the present study we obtain the rsN for 36 volunteer healthy subjects (18-60 years old) in three different sessions separated by 15 days each one, we acquired two different BOLD rsfMRI sequences (eyes open) with different spatial resolution in a 3T scanner with a 32 head sense channel coil, the FE-EPI sequences have the following parameters TE/TR = 30/ 2000 ms, FA = 75, FOV= 240 mm x 240 mm x 123 mm, matrix 80x 78 x 35, with isometric spatial resolution of 3 mm and other with anisotropic resolution. The Intraclass Correlation Coefficient (ICC) was calculated and we found the ICC between first and second sessions less than the ICC between second and third sessions.

Session J36 DQI: DQI Invited Session: Quantum Memories for Superconducting Qubits 601/603 - Anja Metelmann, Princeton University - Tag(s): Invited
ALEXANDER GRIMM (Presenter), Yale University — Superpositions of two opposite-phase coherent states in an oscillator, so-called Schrödinger-cat states, can be used to encode a qubit protected against phase-flip errors. Such a protected “cat qubit” has the potential to significantly reduce the overhead associated with quantum error correction. However, the practical operation of a cat qubit faces several challenges: Its basis states are highly excited states of the oscillator and need to be stabilized in order to maintain the protection. At the same time, the system has to be compatible with fast gates on the encoded qubit and a quantum non-demolition (QND) readout of the encoded information.

In this talk, we will present our recent experimental results on the stabilization of an error-protected cat qubit through the interplay between Kerr nonlinearity and single-mode squeezing in a superconducting microwave resonator. Our experiment demonstrates a full set of single-qubit gates and QND-readout on timescales significantly shorter than the relevant decoherence times.

*Work supported by: ARO, ONR, NSF, AFOSR, YQI, and YINQE

JEREMIE GUILLAUD (Presenter), MAZYAR MIRRAHIMI, Quantic, Inria Paris — Quantum error correcting codes provide, when operated below the threshold, an arbitrary good protection against noise, thus solving the decoherence problem for quantum information processing. However, the actual implementation of the most promising ones, such as the surface code, comes at the price of tremendous physical resources to reach a sufficient level of protection. We present a 1D repetition code based on the so-called cat-qubits as a viable candidate for a massive reduction in the hardware requirements for universal and fault-tolerant quantum computation. The cat-qubits that are stabilized by a two-photon driven dissipative process, exhibit a tunable noise bias where the effective bit-flips are exponentially suppressed with the average number of photons. Exploiting this noise bias, we build, at the level of the repetition cat-qubit, a universal set of fully protected logical gates. Remarkably, this construction avoids the costly magic states preparation, distillation and injection, even for non-Clifford gates.

3:42PM J36.00003: Detection of optical photons from a superconducting qubit* [Invited] ALP SIPAHIGIL (Presenter), Caltech — The ability to convert a superconducting qubit excitation to an optical photon would enable the incorporation of superconducting quantum processors in optical quantum networks. In this talk, we present an integrated device platform for converting a qubit excitation to an optical photon via piezo-optomechanical transduction. We first describe the design and fabrication of a nanomechanical resonator with strong piezoelectric coupling to a transmon qubit and a large optomechanical coupling rate. We then discuss experiments using this mechanical mode as an intermediary to convert a qubit excitation to an optical photon in two steps. First, we dynamically tune the qubit frequency to perform a swap operation between the qubit and the mechanical mode. This is followed by an optical pulse that upconverts the phonon to an optical photon via the optomechanical interaction. We detect the resulting photons and demonstrate optical photon generation from a transmon qubit. We measure qubit Rabi oscillations using single optical photon detection to characterize the transducer’s noise and efficiency. Finally, we discuss prospects for optically mediated entanglement generation between remote superconducting circuits using this platform.

4:18PM J36.00004: Quantum information processing using multimode cavities* [Invited] SRIVATSAN CHAKRAM (Presenter), University of Chicago — Multimode superconducting microwave cavities provide a hardware efficient means of engineering a large Hilbert space with high coherence, suitable for quantum simulations and information processing. Coupling to a superconducting transmon circuit results in random access control [1], with logic gates possible between arbitrary pairs of cavity modes. I will present our progress towards realizing such a processor using the quantum flute - a seamless rectangular 3D multimode cavity, with a tailored mode dispersion and lifetimes approaching a millisecond for ~10 modes. We present various schemes for controlling the cavity states using interactions mediated by the dispersively coupled transmon. 4-wave mixing processes induced by the non-linearity of the transmon can be used to exchange quantum states between the transmon and the cavity modes in a few hundred nanoseconds. When driven off-resonantly, these sideband drives can be used to controllably dress the cavity states, and engineer novel multimode interactions that are useful for quantum simulations. These interactions can also be used to compensate multimode-state-dependent Stark shifts, and perform generalized parity measurements, crucial for high fidelity gate operations and quantum error correction.

*This research was supported by Samsung Advanced Institute of Technology Global Research Partnership.
Encoding a qubit in logical quantum states with wavefunctions characterized by disjoint support and robust energies can offer simultaneous protection against relaxation and pure dephasing. Using a two-dimensional circuit-quantum-electrodynamics architecture, we experimentally realize a superconducting 0-π qubit, which hosts protected states suitable for quantum-information processing. Our multi-tone spectroscopy measurements reveal the energy level structure of the system, which can be precisely described by a simple two-mode Hamiltonian. We find that the circuit realizes an effective one-dimensional crystal with two sub-lattices, where the geometrical phase difference between Wannier states localized at adjacent phase unit cells leads to interference effects associated with tunneling of pairs of Cooper pairs. The parity symmetry of the qubit results in charge-insensitive levels connecting the protected states, allowing for logical operations. The measured relaxation (1.6 ms) and dephasing times (25 μs) demonstrate that our implementation of the 0-π circuit not only broadens the family of superconducting qubits but also represents a promising candidate for the building block of a fault-tolerant quantum computer.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

2:30PM J37.00001: Circuit QED theory and experiment: Encoding quantum information in harmonic oscillators* [Invited] STEVEN GIRVIN (Presenter), Yale Quantum Institute, Yale University — ‘Circuit quantum electrodynamics’ is the theory of non-linear quantum optics extended to the study of microwave photons strongly interacting with ‘artificial atoms’ (Josephson junction qubits) embedded in superconducting electrical circuits. Recent remarkable theoretical and experimental progress in our ability to measure and manipulate the quantum states of individual microwave photons is leading to novel applications ranging from accelerating dark matter searches to quantum error correction using bosonic codes that have successfully extended the lifetime of quantum information. This talk will present an elementary introduction to the basic concepts underlying circuit QED and describe several recent novel experiments demonstrating these new found capabilities.

*This work was supported by the Army Research Office under Grant Number W911NF-18-1-0212, by the National Science Foundation under Grant Number DMR-1609326 and by the Yale Quantum Institute.

3:06PM J37.00002: Phase-Controlled Topological Superconductivity* [Invited] CHARLES MARCUS (Presenter), Microsoft Corp — This talk will explore alternative routes to generating Majorana zero modes, finding similarities between Majorana modes in vortex cores of 2D and 3D topological superconductors and schemes based on one-dimensional semiconductor-superconductor hybrids in a strong Zeeman field. Phase winding in vortices and full-shell nanowires has a 2D analog as well, which is phase control across an SNS junction, which in the presence of spin-orbit coupling and Zeeman field, also generates leads to topological superconductivity. Results from recent experiments will be discussed in the context of this unified picture.

*We thank Microsoft and the Danish National Research Foundation for support. Materials provided by Microsoft Quantum Materials Labs in Copenhagen and Purdue.

3:42PM J37.00003: Mechanics and applications of bio-conformable electronics* [Invited] NANSHU LU (Presenter), University of Texas at Austin — Seamlessly merging human body with electronics can not only digitize our body for internet of health and human-computer interaction, but also deliver therapeutics or even augment our capabilities. As human organs are soft and curvilinear, it is important to understand and rationally design the conformability of soft electronics to human tissue. This talk will present 2D and 3D analytical and numerical models along with experimental validations for the conformability of flexible and stretchable electronics on rigid and soft curvilinear surfaces. It will also introduce reversible physical adhesives based on cratered surfaces that can attach securely on bio-tissue but easy to remove and reuse. Noninvasive and invasive bio-conformable electronics will be demonstrated in this talk.

*National Science Foundation Grants CMMI-1301335, CMMI-1663551, ECCS-1509767, and CNS-1738293.
4:18PM J37.00004: Supersolidity in the ultracold: when atoms behave as solid and superfluid at the same time [invited] FRANCESCA FERALINO (Presenter), Univ of Innsbruck —

Ultracold quantum gases are both an ideal test-bed platform to address key questions in quantum physics and a powerful resource to realize novel paradigms and novel phases of quantum matter. Moreover, the potential of such systems is becoming ever more enabling as scientists acquire an increasingly fine control over optical manipulation and inter-particle interactions.

Recently, a novel class of atomic species, possessing an exceptionally strong magnetic character is entering the stage, offering a new conceptual twist for the field. In our laboratories in Innsbruck, we have realized the first dipolar Bose-Einstein condensate and Fermi gas of the highly magnetic Erbium species and the first dipolar quantum mixture of Erbium and Dysprosium.

I will report on our recent observations of the elusive and paradoxical supersolid state of quantum matter, using both Erbium and Dysprosium ultracold gases. Such paradoxical phase, in which crystal rigidity and superfluid flow coexist, has intrigued scientists across different disciplines for decades. It now became possible to create supersolidity in the ultracold thanks to the unique interplay between long-range dipolar interactions, contact interactions, and a powerful stabilization mechanism based on quantum fluctuations.

4:54PM J37.00005: Strange Metals and Black Holes* [Invited] SUBIR SACHDEV (Presenter), Harvard University — The ‘strange metal’, a state of matter formed by electrons in many modern materials, including the compounds which exhibit high temperature superconductivity. In this state, electrons quantum entangle with each other and conduct electric current collectively (rather than one-by-one, as in an ordinary metal like copper). Quantum entanglement also has remarkable effects near the horizon of a black hole, leading to the Bekenstein-Hawking black hole entropy, and the Hawking temperature. Surprisingly, there is a deep connection between the nature of quantum entanglement in strange metals and black holes, and this has led to mutually beneficial insights. This connection is simply described by the Sachdev-Ye-Kitaev model, which leads to a common set of equations describing the quantum dynamics of certain strange metals and black holes. I will describe recent progress in developing a theory of strange metals building on the solvable SYK model.

Session J38 FOEP FPS: Outreach and Public Science Communication 607 -
James Kakalios, University of Minnesota - Tag(s): Invited, Outreach, Undergrad Friendly
MATTHEW J O’DOWD (Presenter), Lehman College — Traditional efforts to engage the public with science have led to a growing science fandom, and yet these broad positive feelings don’t seem to correlate with improving scientific literacy. It seems our approach to science communication need an overhaul, however methods employed by traditional media are heavily constrained by institutional wisdom and the profit motive. But new forms of media such as YouTube are allowing the next generation of science communicators to test old wisdom and experiment with new methods.

PBS Space Time has been at the forefront of this experiment, having spent the last five years communicating unusually complex topics in physics and astronomy to a lay audience. In this talk we share some of the unintuitive insights that we and other YouTubers have gained, and discuss how these can be implemented by anyone to help close the science communication gap.

JEANNA BRYNER (Presenter), Live Science — Science communication — Why is it so important? Science plays a vital role in the world, from the discovery of new drugs to futuristic technologies that promise to help support human life on Mars. But if that science is not communicated clearly, the people who rely on scientific knowledge are left confused and perhaps less likely to trust scientists and science in general. In addition to bolstering trust in science, your words could inspire a person to enter a scientific field or give them a deeper understanding of the world and their place in it. Explaining the beauty of quantum physics, the wonders being created inside a particle accelerator or the mind-boggling energy of a supernova can open another’s eyes to the boundless nature of science.

In this talk, I will describe what good science communication looks like and the many avenues it can take, from social media posts to full features in digital and print news publications. Whether you’re interested in dipping your toe into the waters of communicating science to the public or hope to dive right in, this talk will give you tips and resources to get you started.

FRANCIS SLAKEY (Presenter), American Physical Society — How many constituent requests does a typical congressional office get every day? How much time do staff have to process a request, before they have to move on to the next one? What approach makes it easiest for staff to respond? We’ll explore the answers to each of those question and consider the resulting boundary conditions for effective communication with policymakers: keep it tight, make it compelling, have a crystal clear ask. We’ll see what we can learn from a related format – the evening local 1/2 hour news broadcast -- where time is precious, and information is conveyed quickly and efficiently. We'll then have audience volunteers tackle some real-world cases to see how effective communication with policymakers works in practice.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM
Ground and excited states of open-shell systems from a spin-flip Bethe-Salpeter approach* [Invited] DAVID STRUBBE (Presenter), Physics, University of California, Merced — Open-shell systems, including molecules and defects, are interesting platforms for spin physics and quantum information. Their multi-determinantal states are difficult to handle with conventional first-principles calculations. A solution from quantum chemistry is the spin-flip (SF) approach: the ground and excited states are considered as spin-flipping excitations of a single-determinant high-spin reference state. The SF approach was originally used with wavefunction-based approaches such as configuration interaction, then later extended to time-dependent density-functional theory (TDDFT), showing some successes. Standard TDDFT approximations, however, have well-known deficiencies including treatment of charge-transfer excitations and condensed phases. Therefore, we introduce a spin-flip approach to the GW/Bethe-Salpeter approach (GW/BSE), taking advantage of a similar structure of the equations to TDDFT, but with an \textit{ab initio} long-ranged and non-local interaction kernel, which enables more accurate calculations of excited states. I will discuss the theory of the spin-flip BSE method and our implementation with the Octopus and BerkeleyGW codes, and show our investigation of the critical issues of spin contamination and convergence with number of states in BSE. We have demonstrated success of SF-BSE on some simple problems. In the torsion of the ethylene molecule (C_2H_4), which transitions between singlet and triplet ground states, we found excellent agreement with higher-level and more expensive calculation methods, and a consistency at the equilibrium geometry with standard BSE calculations. We find good results also for the Si atom’s singlet-triplet splitting, which has been problematic for TDDFT. Given these successes on small systems, I will discuss prospects for application of our approach to problems in condensed phases.

*U.S. Department of Energy, Office of Science, Basic Energy Sciences, CTC and CPIMS Programs, Award DE-SC0019053.
All-electron Implementation of Bethe-Salpeter Equation Method: Development and Application

YI YAO (Presenter), Department of Chemistry, University of North Carolina at Chapel Hill, DOROTHEA GOLZE, Department of Applied Physics, Aalto University, CHI LIU, Department of Mechanical Engineering and Materials Science, Duke University, PATRICK RINKE, Department of Applied Physics, Aalto University, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University, YOSUKE KANAI, Department of Chemistry, University of North Carolina at Chapel Hill — A new all-electron implementation of the Bethe-Salpeter Equation (BSE) method for optical excitations is presented. We benchmarked the accuracy of our implementation on low lying optical excitations of organic molecules in the Thiel benchmark set for validation, and the basis-set dependence is carefully analyzed. We then integrated the core-GW approach by Golze et al. into our BSE implementation for X-ray absorption spectroscopy (XAS). We compare our results for K-edge XAS spectra of small organic molecules to earlier EOM-CCSD work by Peng et al. We found the accuracy of our BSE approach is comparable to or better than EOM-CCSD, which gives the errors within 0.5 eV of experimental value for the test set. The implementation for extended periodic systems is discussed lastly with examples of liquid water and crystalline silicon.

Efficient Construction of 4-point Green’s Function in Real-Space Representation using Permutation Sampling Monte Carlo method

NICOLE SPANEDDA (Presenter), PETER MCLAUGHLIN, ARINDAM CHAKRABORTY, Syracuse University — A principle challenge in constructing the 1-particle Green's function is the steep scaling of computational cost with increasing system size. We address this problem by transforming the Green's function into real-space representation and calculating all required integrals using the Permutation Sampling Monte Carlo method (PSMC). We started with the frequency-domain representation of the self-energy and performed Laplace transformation to obtain a 4-point representation of the self-energy in position basis. The main benefit of PSMC is that it avoids the steep scaling associated with the traditional methods of constructing the self-energy. Specifically, we avoided AO-to-MO integral transformation and explicit representation of the self-energy in particle-hole basis. In this work we demonstrated the linear scaling of computational cost with the number of molecular-orbital basis functions that was achieved by the PSMC method. Consequently, PSMC can be applied to systems that are computationally impractical using conventional methods. We used PSMC to calculate the ionization potentials of PbS quantum dots (Pb4S4-P140S140).
**3:30PM J39.00004: Equation of motion coupled-cluster approach for multi-electron excitations in x-ray spectra**

JOHN REHR (Presenter), FERNANDO VILA, JOSHUA KAS, University of Washington, KAROL KOWALSKI, BO PENG, Pacific Northwest National Laboratory — We present a real-time equation of motion coupled cluster approach [1] for calculations of multi-electron excitations in core-level x-ray absorption and emission spectra. Integration of the equations to leading order in particle-hole excitations yields a cumulant representation of the core-hole spectral function. Absorption and emission spectra are then calculated in terms of a convolution of an effective one-body x-ray spectrum and the core-hole spectral function. Comparisons with determinantal approaches and with the Delta-SCF approximation are also discussed. Illustrative calculations are discussed separately [2].

*Supported by the Center for Scalable, Predictive methods for Excitation and Correlated phenomena (SPEC) which is funded by the U.S. DOE, Office of Science, Basic Energy Sciences, Division of Chemical Sciences, Geosciences, and Biosciences.

**3:42PM J39.00005: Real-time EOM-CCS Green's function method for the core spectral functions**

FERNANDO VILA (Presenter), JOHN REHR, University of Washington, BO PENG, KAROL KOWALSKI, PNNL — X-ray photoemission spectra (XPS) typically exhibit satellite peaks associated with many-body excitations that have proved difficult to simulate from first principles. We address this problem using a real-time equation-of-motion coupled-cluster-singles (RT-EOM-CCS) approach for the core spectral function. RT methods provide a versatile approach to electronic response, but have not been widely applied using CC theory. In RT-EOM-CCS, the Green's function (GF) for an \( N \)-electron system is computed from the overlap between the initial core-excited \(|N-1>\) wavefunction and its time-propagated form \(|N-1,t>\). The latter is approximated using a CC ansatz with time-dependent amplitudes. The EOM of the overlap is solved using a centered predictor-corrector approach. We show that the form of the overlap is analogous to that in the static CC equations, and that the form of the GF is related to that in the cumulant approach. Finally, we present results for low \( N \) systems.

*Supported by the Center for Scalable, Predictive methods for Excitation and Correlated phenomena (SPEC), funded by the U.S. DOE, Office of Science, BES, Division of Chemical Sciences, Geosciences, and Biosciences, with computer support from DOE-NERSC.
3:54PM J39.00006: Neutral Excitation Energies of Crystalline Solids from Periodic Equation-of-Motion Coupled-Cluster Theory  

XIAO WANG (Presenter), Center for Computational Quantum Physics, Flatiron Institute, TIMOTHY BERKELBACH, Department of Chemistry, Columbia University — There have been increasing interests in the development of high-accuracy, wavefunction-based quantum chemistry methods, such as coupled-cluster theory, with periodic boundary conditions for electronic structure problems of crystalline solids. We present an ab initio study on electronically excited states of solids using Gaussian-based periodic equation-of-motion coupled-cluster theory with single and double excitations (EE-EOM-CCSD). EE-EOM-CCSD provides a quantitative treatment of singly excited states, such as excitons and plasmons, and a qualitative treatment of doubly excited states, such as biexcitons. Results of optical band gaps, exciton binding energies, and exciton dispersions will be presented for a variety of inorganic insulators and semiconductors.

4:06PM J39.00007: Fingerprints of dynamical correlation in electron spectroscopies [Invited]  

MATTEO GATTI (Presenter), LSI, CNRS, Ecole Polytechnique — One of the great challenges of condensed-matter physics is the description, understanding, and prediction of the effects of the Coulomb interaction on materials properties. In electronic spectra, the Coulomb interaction causes a renormalization of excitation energies and a transfer of spectral weight. Most importantly, it can lead to qualitatively new structures, such as satellites in photoemission or double-plasmon resonances in energy-loss spectra. Being a genuine signature of dynamical correlation, they are absent in a non-interacting picture but can be understood in terms of the coupling between different elementary excitations.

In this framework, a key physical ingredient is the dynamical screening of the Coulomb interaction, containing charge excitations such as plasmons and excitons. It can be accurately calculated within time-dependent density-functional theory (including double plasmons [1]) or by solving the Bethe-Salpeter equation. Its microscopic picture can be obtained from the mixed dynamic structure factor that is measured by coherent inelastic X-ray scattering spectroscopy [2]. Building upon a detailed knowledge of dynamical screening, the cumulant expansion of the Green's function can efficiently explain plasmon and exciton satellites in the photoemission spectra of several materials, ranging from simple metals to correlated transition-metal oxides [3]. Finally, the combined effect of many-body interactions and experimental conditions can lead to novel signatures in the measured spectra [4], underlining the need to bridge the gap between theory and experiments.

4:42PM J39.00008: Biexcitons and exciton dynamics in low-dimensional systems from an *ab initio* interacting Green's function formalism*  

FELIPE DA JORNADA (Presenter), Materials Science and Engineering, Stanford University, ANDREA CEPELLOTTI, Materials Science & Mechanical Engineering, Harvard University, STEVEN LOUIE, Department of Physics, UC Berkeley — The synthesis of quasi low-dimensional materials, such as the monolayer transition metal dichalcogenides (TMDs), opened the door to studying new classes of systems with nanoscale dimensionality confinement and weak electronic screening, leading to strongly enhanced electron interactions. Many of these systems host a variety of charged and neutral multiparticle excitations – such as excitons, trions, and biexcitons. We present here a first-principles formalism based on the interacting Green’s function to compute and understand these excitations and their dynamics. We apply our formalism and its associated code on high performing computers to the monolayer TMDs, predicting a diversity of multiparticle excitations with large binding energies (~20 meV) and complex valley and spin textures. We also show how this formalism can be employed to investigate other exciton-exciton interactions to understand challenging phenomena involving dynamics from first principles.

*This work was supported by the Center for Computational Study of Excited-State Phenomena in Energy Materials (C2SEPEM) at LBNL, funded by the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources provided by NERSC and XSEDE.

4:54PM J39.00009: Electron-hole attraction effect under time-dependent electric field within a generalized Landau-Zener model  

YASUSHI SHINOHARA (Presenter), School of Engineering, The Univ of Tokyo — The exchange term is a crucial term for first-principles electronic structure theories, leading to accurate prediction within hybrid-functional for density-functional theory and the most simple many-body effect as a term in the Hartree-Fock (HF) equation. This term is also crucial for the description of the electronically excited state, namely excitonic influence on dielectric function either due to bound- or unbound-excitons. In spite of its importance in photoabsorption spectra, the effect of the (screened) exchange term for nonlinear phenomena has not been investigated well because of severe calculation cost. Higher energetic electron-hole pairs in high-order harmonic generation spectra are reported by using one-dimensional HF simulation, compared with an independent particle system[1]. The effect is totally from modulation of the mean-field via a density-matrix change to a self-consistent solution of the HF equation. We develop a much simpler model that has an electron-hole attraction term imitating the exchange term on the top of the Landau-Zener model to investigate the dynamical effect of electron-hole attraction. We have observed a pronounced gap renormalization by increasing the field strength.

5:06PM J39.00010: First principle excited state calculations using a frequency–dependent geminal–screened electron–hole interaction kernel  
PETER MCLAUGHLIN (Presenter), ARINDAM CHAKRABORTY, Syracuse University — A primary computational limitation for excited state methods is the inclusion of virtual or unoccupied states in the calculations. The inclusion of these states increases the calculation cost for excited state calculations. We present the frequency–dependent geminal–screened electron–hole interaction kernel (FD–GSIK) method for describing electron–hole correlation in electronically excited many–electron systems. FD–GSIK avoids using unoccupied orbitals for kernel construction by performing infinite–order summation of particle–hole excitation and representing it as a compact real–space operator. The central idea of our approach is to use Löwdin partitioning technique to construct a frequency–dependent and r12–explicitly correlated operator for treating electron–hole correlation for the excited state wave function that is derived from first principles and is parameter–free. Evaluation of all integrals were performed in real space using stratified Monte Carlo, which avoided the steep computational cost of evaluation, storage and transformation of the atomic orbitals to molecular orbitals. The FD–GSIK was applied to large nanoparticles including Pb$_{140}$S$_{140}$, Pb$_{140}$Se$_{140}$, and Cd$_{144}$Se$_{144}$, to obtain excitation and electron–hole binding energies.

5:18PM J39.00011: Atomic relativistic approximation for $ab$ initio prediction of excited-state potential energy surfaces and X-ray spectra*  
TIANYUAN ZHANG (Presenter), JOSEPH M KASPER, XIAOSONG LI, University of Washington — The atomic relativistic approach is a formally simple and linear scaling ansatz that exploits the locality of the relativistic effect. Studies have shown that this approximation introduces moderate error on ground state absolute energy in the presence of short bonds between heavy nuclei. However, scientists have not investigated its accuracy on computing excited states for absorption spectra and excited-state potential energy surfaces. In this work, we demonstrate atomic exact two-component (X2C) predictions of the L$_{2,3}$-edge X-ray absorption spectra of five representative heavy-atom-centered molecules and the excited-state potential energy curves of the platinum dimer (Pt$_2$). Surprisingly, not only the errors to full X2C results in core excitation energies are negligible on the order of 0.01 eV, but the oscillator strengths also agree well with those from full X2C computations. Meanwhile, the atomic X2C potential energy curves and crossings of Pt$_2$ are almost indistinguishable from the full X2C ones.

*The development of the two-component electronic structure method is funded by the US Department of Energy (DE-SC0006863). The development of non-perturbative spectroscopic methods is supported by the National Science Foundation (CHE-1856210).

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

Session J40 DCOMP DMP: Matter in Extreme Environments II: Liquids, Geological, and Complex Materials 705 - Tiange Bi - Tag(s): Focus
2:30PM J40.00001: Using liquid informed searches to predict high pressure and finite temperature phase transitions* [Invited] STANIMIR BONEV (Presenter), Lawrence Livermore Natl Lab — Recent developments in computational algorithms have enabled crystal structure prediction at high pressure conditions, leading the way to the discovery of materials with unexpected and fascinating properties. However, structure prediction at finite temperature remains a challenge, while advances in experimental platforms and measurement techniques have opened up access to the properties of matter via a wide range of pressure-temperature pathways. In this talk, I will discuss the use of structural information and/or sampling from liquid simulations to predict high pressure phase transitions and crystal structures at finite temperature conditions. The techniques will be illustrated with examples of successful applications on several systems, including magnesium, nitrous oxide, and nitrogen.

*This work was performed at LLNL under the auspices of the U.S. DOE under Contract DE-AC52-07NA27344.

3:06PM J40.00002: Ab initio investigation of post-PPV transitions in $\text{MgGeO}_3$ and $\text{NaMgF}_3$* KOICHIRO UMEMOTO (Presenter), ELSI, Tokyo Institute of Technology, RENATA WENTZCOVITCH, Columbia University — We present an ab initio investigation of the pressure induced behavior of $\text{MgGeO}_3$ and $\text{NaMgF}_3$, traditional low-pressure analogs (LPAs) of $\text{MgSiO}_3$. The latter undergoes post-post-perovskite (post-PPV) transitions which are exceedingly important in planetary sciences, but at very high pressures of $>\sim500$ GPa [1-3]. Although neither $\text{MgGeO}_3$ nor $\text{NaMgF}_3$ are perfect LPAs of $\text{MgSiO}_3$, in overall both display similar dissociation and recombination transitions and the novel types of phases displayed by $\text{MgSiO}_3$ but at much lower pressures easily achievable in diamond anvil cells. Both systems also confirm the ultimate tendency of $\text{MgSiO}_3$ toward the dissociation into its elementary binaries, i.e., $\text{AX}$ and $\text{BX}_2$. We also predict potential metastable phase transitions that may occur more easily than dissociation/recombination reactions under insufficiently heated compression.

*This research was supported by JSPS-Kakenhi and MEXT as “Exploratory Challenge on Post-K computer”.
Ronald Cohen (Presenter), Carnegie Inst of Washington — Using density functional theory and the QUANTUM ESPRESSO code, first-principles molecular dynamics simulations have been performed over a wide range of pressures and temperatures, for pure Fe, pure H, and Fe-H solutions. Pressures range from 0 to 100 MB (10 TPa) and temperatures from 2000-40000 K. From these results the equations of state are fit for extreme conditions in planetary core from Earth to Jupiter and beyond. Transport properties are also being computed from snapshots of the MD runs. Good agreement is found with new experiments and results are consistent with a thermally driven dynamo over Earth history.

This work is supported by NSF CSEDl grant EAR-1901813 and the Carnegie Institution for Science. It was funded previously by the ERC Advanced Grant ToMCaT. The author gratefully acknowledges the Gauss Centre for Supercomputing e.V. (www.gauss-centre.eu) for funding this project by providing computing time on the GCS Supercomputer SuperMUC-NG at the Leibniz Supercomputing Centre (www.lrz.de).

Renata Wentzcovitch (Presenter), Department of Applied Physics and Applied Mathematics, Columbia University, Juan J Valencia-Cardona, Chemical Engineering and Materials Science, University of Minnesota, Gaurav Shukla, Department of Earth Sciences, Indian Institute of Science Education and Research Kolkata, Kanchan Sarkar, Department of Applied Physics and Applied Mathematics, Columbia University — The major mineral phase of the Earth’s lower mantle, (Al,Fe)-bearing bridgmanite, transitions to a seemingly layered structure known as post-perovskite at Earth’s deep lower mantle conditions. Despite extensive investigations, there are still important aspects of this transformation that need clarification. Here, we address this transition in (Al$^{3+}$, Fe$^{3+}$), (Al$^{3+}$), (Fe$^{2+}$) and (Fe$^{3+}$)-bearing bridgmanite using ab initio calculations, particularly the phase boundary dependence on the chemistry and acoustic velocity changes across this transformation. These results help us to constrain possible seismic signatures of this phase transition, which is necessary for a better understanding of the nature of the D” region. While our results are consistent with previous mineral physics studies, we find that the seismic features produced by the post-perovskite transition depend on the chemical composition of bridgmanite. Therefore, the absence of a D” seismic discontinuity or signature of a double-crossing of the post-perovskite phase boundary has clear implications for the local aggregate chemistry and/or temperature.

Life in Extreme Environments: Material Properties of the Enzymes

TOSHIKO ICHIYE (Presenter), Georgetown University — Life on Earth has been found in many extremes of pressure $P$ and temperature $T$. Understanding how life works at high $P$ and high $T$ has implications for the origin of life on Earth and for the search for extraterrestrial life. In addition, extremes of $P$ and $T$ are used in sterilization and food preservation. To understand how the proteins necessary for life can function at extremes, we use a combination of molecular dynamics simulations of enzymes in aqueous solution, combined with experimental data, to understand how their material properties affect their biochemical activity. We will discuss the effects of $P$ and $T$ on enzymes, evolutionary timescale adaptations in the material properties of enzymes for extremes, and rapid response changes in the intracellular environment to protect enzymes against extremes.

Express: nonstop calculations with the Quantum ESPRESSO

QI ZHANG (Presenter), Department of Applied Physics and Mathematics, Columbia University, MICHEL MARCONDES, Department of Earth and Environmental Sciences, Columbia University, HONGJIN WANG, Department of Computer Science, Columbia University, JINGYI ZHUANG, Department of Earth and Environmental Sciences, Columbia University, PEDRO DA SILVEIRA, RENATA WENTZCOVITCH, Department of Applied Physics and Mathematics, Columbia University — The intrinsic complexity of ab initio mineral physics studies inspired the development of workflows to automate long and extensive sequences of ab initio calculations [1]. This complexity emerges from the need to sample thermodynamic and chemical phase space for useful geophysical applications. Here we introduce Express, a new generation of Python and Julia workflows designed to facilitate calculations of thermoelastic and thermochemical properties of materials.

Various materials properties can be computed, e.g., static equation of state, phonon density of states, static elasticity, thermal equation of state, and thermodynamic properties. They work either separately or jointly. Each workflow consists of three steps: 1) pre-processing: dynamic generation and validation of input files for the target software; 2) processing: submission, supervision of jobs, and retrieval of results; 3) post-processing: analyses of outputs and error handling.

Express codes are concise and come with user-friendly APIs to be integrated into other codes. It currently supports Quantum ESPRESSO, but other ab initio software is expected to be supported in the future.

Ab initio simulation of heat and charge transport in water at planetary pT conditions

FEDERICO GRASSELLI (Presenter), SISSA - Scuola Internazionale Superiore di Studi Avanzati, Trieste, LARS PETER STIXRUDE, Earth, Planetary, and Space Sciences, University of California at Los Angeles, STEFANO BARONI, SISSA - Scuola Internazionale Superiore di Studi Avanzati, Trieste — The transport properties of water at extreme pT conditions govern the evolution of icy planets, such as Uranus and Neptune, and moons, such as Europa or Encelado. New theoretical and data-analysis methods have been recently developed to estimate accurate transport coefficients of electronically gapped materials from ab initio equilibrium molecular dynamics and the Green-Kubo theory of linear response [1-3]. In this talk we report on recent results of the application of these methods to heat and charge transport in water at the extreme pT conditions occurring in the interior of icy giants, in all the different relevant phases (partially dissociated liquid, solid, and super-ionic) [4]. These results are finally employed to build a model of the thermal evolution of Uranus, which accounts for its hitherto poorly understood very low luminosity.

First-principles predictions of electrical and thermal conductivity of liquid and solid iron at Earth core conditions

KAI LUO (Presenter), RONALD COHEN, Geophysical Laboratory, Carnegie Institution of Science — Transport properties such as thermal and electrical conductivities of the liquid iron alloy are critical in understanding the dynamic history of Earth's outer core and the evolution of the geomagnetic field. These conditions (beyond ~200 GPa) pose great challenges to experimental measurement. In contrast, first-principles simulation is not subject to this limitation and allows explorations of a wider range of conditions.

We use Kubo theory to compute transport properties from first-principles molecular dynamics (FPMD) simulations, incorporating scattering of electrons by disorder and thermal vibrations using density functional theory, and by other electrons using dynamical mean field theory. Studying pure liquid and solid iron at such conditions, we address the saturation effects and calibrate the violation of the Wiedemann-Franz law.

4:30PM J40.00009: Anomalous structural behaviour near a Mott transition in compressed Ca$_2$RuO$_4$  
HARRY KEEN (Presenter), Univ of Edinburgh, STEPHEN R JULIAN, University of Toronto, ANDREAS HERMANN, Univ of Edinburgh — Ca$_2$RuO$_4$ has a rich phase diagram, featuring a metal-insulator transition with a structural distortion upon cooling, antiferromagnetic ordering upon further cooling, and metallisation and ferromagnetic order, followed by a further structural transition, under pressure. It is one end member of the Ca$(2-x)$Sr$(x)$RuO$_4$ series that includes the proposed triplet superconductor Sr$_2$RuO$_4$ at the other end. Ca$_2$RuO$_4$ shows intriguing collective phenomena in its own right, several of which are intricately linked to structural distortions of the RuO$_6$ octahedra, which in turn are susceptible to pressure-induced changes. In fact, Ca$_2$RuO$_4$ shows an unusual c-lattice expansion under hydrostatic compression. However, the structural and electronic properties of Ca$_2$RuO$_4$ under pressure have not been investigated in detail before. Here, we study the high-pressure phase evolution of Ca$_2$RuO$_4$ using density functional theory (DFT) and DFT+U calculations. We show that the c-lattice expansion in the metallic high-pressure phase as well as details of the octahedral arrangements can be described if the on-site repulsion U is fine-tuned appropriately. The sensitivity to the size of U highlights how close the metallic phase remains to the Mott insulating phase.

4:42PM J40.00010: Theoretical Prediction of Novel Materials with the XtalOpt Evolutionary Algorithm  
XIAOYU WANG (Presenter), PATRICK AVERY, State University of New York at Buffalo, DAVIDE M. PROSERPIO, Università degli Studi di Milano, CORMAC TOHER, STEFANO CURTAROLO, Duke University, EVA ZUREK, State University of New York at Buffalo — The XtalOpt evolutionary algorithm for crystal structure prediction has been extended to enable the prediction of materials with specific properties. A fitness function has been implemented wherein the user can denote the percent contribution that enthalpy and the property (e.g. Vickers hardness obtained via a macroscopic hardness model and the shear modulus as determined via machine learning, percentage of hydrogen atoms that do not form H-H bonds, or density of states at the Fermi level) have on the fitness function. We have used XtalOpt to search for hard and stable carbon allotropes. Several novel carbon allotropes that are superconducting or possess super-long sp$^3$-sp$^3$ bonds were found. We also discovered novel hydrides that could potentially be conventional superconductors.
4:54PM J40.00011: Ab initio investigation of hydrogen-bond disorder in δ-AlOOH*

CHENXING LUO (Presenter), TIANQI WAN, ZIYU CAI, Department of Applied Physics and Applied Mathematics, Columbia University, KOICHIRO UMEMOTO, Earth-Life Science Institute, Tokyo Institute of Technology, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University — δ-AlOOH (δ) is an important carrier of water in the lower mantle. Attempts to resolve the structure of δ revealed that hydrogen bonds (H-bond) “symmetrize” under compression in a process similar to the high-pressure ice VII- or ice VIII-X transition. Like H₂O-ice, δ has its own “ice-disorder rules” and disorder is also observed experimentally prior to H-bond symmetrization [1]. H-bond disorder in δ had been suggested by an ab initio study as a possibility based on its broad band of Raman active OH-stretching modes [2].

In this ab initio study, we address the H-bond disordering process that precedes its symmetrization from several perspectives, including a) the accuracy of standard DFT functionals to address the structural properties of δ, b) vibrational stability and the pressure-range of validity of the quasiharmonic approximation (QHA), and c) order-disorder transition using a multi-configuration QHA calculation at 300 K. With these results, we reproduce the structural behavior and the neutron diffraction peculiarities under pressure.

5:06PM J40.00012: Thermal Conductivity of CaSiO₃ Perovskite at Lower Mantle Conditions*

ZHENG ZHANG (Presenter), Columbia Univ, KOTARO ONGA, Tokyo Institute of Technology, DONG-BO ZHANG, Beijing Normal University, KENJI OHTA, Tokyo Institute of Technology, TAO SUN, University of the Chinese Academy of Sciences, KEI HIROSE, The University of Tokyo, RENATA WENTZCOVITCH, Columbia Univ — Thermal conductivity (κ) of mantle minerals modulates strongly both the style of mantle convection and the time scale of the mantle and core cooling. It is therefore a fundamental parameter for geodynamic modeling. Cubic CaSiO₃ perovskite (CaPv) is believed to be the third most abundant mineral in the lower mantle (LM) (6 – 10 wt%). However, despite its importance, investigations of its properties are challenging because of its strong anharmonicity, particularly κ since prevailing theoretical approaches encounter difficulties in dealing with its strong anharmonicity. Experimental measurements at relevant high pressures and temperatures are equally challenging. Therefore, no previous estimate of CaPv’s κ exists at mantle conditions, experimental or theoretical. Here we present ab initio quantum mechanical results of this property obtained using an established phonon quasiparticle approach that can address the strongly anharmonic situation in CaPv. These results are substantiated by direct experimental measurements of this property at LM conditions. These results and data agree very well and reveal a surprisingly large κ of cubic CaPv compared to MgSiO₃-perovskite, which is only weakly anharmonic.

5:18PM J40.00013: Determination of Diffusion Constants and Partial Pressures in the Adsorption of Methane-Propane and Methane-Ethane Mixtures  VALLE ROY ZACHARY (Presenter), Univ of Missouri - Columbia, GONZALO DOS SANTOS, Universidad de Mendoza, TODD LOMBARDI, CARLOS WEXLER, Univ of Missouri - Columbia — Natural gas (NG) has advantages vs. gasoline/diesel: lower CO$_2$ emissions per unit energy, less emission of NOx's, particulate matter and unburned hydrocarbons. However, storing NG is problematic due to its low density, requiring very high pressures, costly compression and storage systems. A solution is storage by adsorption in porous media such as activated carbon (AC). NG is comprised mainly of methane, thus most studies have focused on adsorption of pure methane. Here we investigate the influence of heavier alkanes commonly found in NG (propane, ethane) on the adsorption process.

We performed extensive molecular dynamics simulations of mixtures of methane-propane and methane-ethane at $T=300$-$400$K and $P=0$-$600$atm. The system considered were AC's comprised of slit-shaped pores with interlayer spacings $H=8$-$20$Å. We observed that heavier hydrocarbons adsorb preferentially, but remain mobile, promising for the intended application. We also solved a common problem with simulations of molecules with high adsorption affinity: the difficulty to determine their partial pressure. We developed an Arrhenius-type relationship allowing the calculation of these partial pressures from relationships between energy distributions of the different molecules in the simulations.

Session J41 GMAG: Spin, Charge, Thermal Interactions, and Conversion 707 - Jiahao Han, Massachusetts Institute of Technology MIT
2:30PM J41.00001: Spin pumping under magnetic field gradient  HIROKI ARISAWA (Presenter), Institute for Materials Research, Tohoku University, SHUNSUKE DAIMON, Department of Applied Physics, The University of Tokyo, YASUYUKI OIKAWA, Advanced Institute for Materials Research, Tohoku University, TAKASHI KIKKAWA, Institute for Materials Research, Tohoku University, EIJI SAITO, Department of Applied Physics, The University of Tokyo — The spin pumping effect is the generation of a spin current by spin waves in a ferromagnet. Its properties have enthusiastically been investigated mainly in uniform magnetic fields, but they are yet to be explored well in nonuniform magnetic fields. Meanwhile, a recent study reported an interesting behavior of spin waves that the wave number of spin waves is converted to another value during its propagation under inhomogeneous magnetic fields. This fact indicates that spin current emission via the spin pumping effect can be spatially tuned taking advantage of the spin-wave wave number conversion in nonuniform magnetic fields. In this talk, we report spatially nonuniform spin current generation by the spin pumping effect under a magnetic field gradient in a Pt/Y₃Fe₅O₁₂ bilayer system. We found that a spin current generated by spin waves is nonlocally enhanced depending on the magnetic field gradient. We explain the result on the basis of the wave number conversion of spin waves, considering its dispersion relation spatially varying with the magnetic field gradient. Our results offer a new insight of spin current generation utilizing nonuniform magnetic fields.

2:42PM J41.00002: Drag induced giant anomalous Nernst effect in Ferromagnetic MnBi  BIN HE (Presenter), Solid State Chemistry, Max Planck Institute for Chemical Physics of Solids, CUNEYT SAHIN, Department of Physics and Astronomy, The University of Iowa, STEPHEN R BOONA, The Ohio State University, BRIAN SALES, Oak Ridge National Lab, JOSEPH P C HEREMANS, The Ohio State University, MICHAEL FLATTÉ, Department of Physics and Astronomy, The University of Iowa, CLAUDIA FELSER, Max Planck Inst — Anomalous Nernst effect (ANE) is the thermal equivalent to the Anomalous Hall effect (AHE). It has been observed in various materials and attributed to the Berry curvature of topological materials. In this talk, we present the observation of giant anomalous Nernst effect in MnBi single crystals. In addition to intrinsic contribution from the band structure, magnon drag also contributes to the anomalous Nernst signal in MnBi crystals, resulting in a giant anomalous Nernst thermopower of 18 μV/K at 0.6 T. At the same time, we also observe a magnon drag thermopower and positive magnetothermal conductivity. This magnon drag induce anomalous Nernst effect can be viewed as a self-spin Seebeck effect, which provides alternative path of understanding the electron magnon interaction.
Electrically-induced ferromagnetism in diamagnetic FeS$_2$*  

JEFF WALTER (Presenter), Department of Physics, Augsburg University, BRYAN VOIGT, Department of Chemical Engineering and Materials Science, University of Minnesota, EZRA DAY-ROBERTS, School of Physics and Astronomy, University of Minnesota, KEI HELTEMES, Department of Physics, Augsburg University, TURAN BIROL, Department of Chemical Engineering and Materials Science, University of Minnesota, RAFAEL FERNANDES, School of Physics and Astronomy, University of Minnesota, CHRIS LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota — Recent years have seen increasingly impressive demonstrations of all-electrical control of magnetism, including electrolyte-gating-induced ferromagnetism in non-ferromagnetic materials. These demonstrations, however, involve induction of ferromagnetism from some other finite-spin magnetic state, e.g., antiferromagnetic, paramagnetic, etc. In this work we use ionic liquid gating, which can induce electron densities >10$^{14}$ cm$^{-2}$, to achieve voltage-induced ferromagnetism in diamagnetic (i.e., zero-spin) FeS$_2$ single crystals. Temperature-dependent transport measurements establish a remarkably reversible positive-bias-induced insulator-metal transition, accompanied by inversion of the FeS$_2$ surface conduction channel to $n$-type. Anomalous Hall effect measurements then reveal an accompanying onset of voltage-induced soft 2D ferromagnetism, with Curie temperature up to ~20 K. These results are supported by DFT-based tight-binding modelling that indicates induction of Stoner FM by gate-controlled band filling.

Spin to charge and charge to spin conversion in a Dirac semimetal*  

WILSON YANEZ (Presenter), RUN XIAO, Physics, Pennsylvania State University, JACOB T HELD, Chemical Engineering and Materials Science, University of Minnesota, DI XIAO, JEFFREY G RABLE, Physics, Pennsylvania State University, ENRIQUE GONZÁLEZ, Physics and Electronics, University of Puerto Rico at Humacao, YONGXI OU, ANTHONY R. RICHARDELLA, Physics, Pennsylvania State University, K. ANDRE MKHOYAN, Chemical Engineering and Materials Science, University of Minnesota, NITIN SAMARTH, Physics, Pennsylvania State University — We report evidence of spin to charge and charge to spin conversion at room temperature in thin films of the archetypal three-dimensional Dirac semimetal Cd$_3$As$_2$ grown by molecular beam epitaxy. This has been detected by means of ferromagnetic driven spin pumping (SP) and spin torque ferromagnetic resonance (ST-FMR) in NiFe/Cd$_3$As$_2$ heterostructures. Analysis of the frequency and power dependence of the SP signal and of the symmetric and antisymmetric contributions to the mixing voltage in ST-FMR show that the behavior of these processes is consistent with previously reported spin to charge conversion mechanisms in heavy metals and topological insulators. Finally, we compare the efficiency of these phenomena with the one due to the inverse spin Hall effect in NiFe/Platinum bilayers.

*This work is supported by SMART/nCORE/SRC/NIST, the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331, 2DCC-MIP/NSF DMR-1539916 and the Office of Graduate Educational Equity Programs and Eberly College of Science at The Pennsylvania State University.
3:18PM J41.00005: Spin Seebeck effect in Pt/SrMnO$_3$ heterostructures  ESWARA PHANINDRA VALLABHANENI (Presenter), ARJIT DAS, TAMALIKA BANERJEE, physics, univ of Groningen — Spin Seebeck effect (SSE) is one of the effective ways of generating pure spin currents driven by thermal gradients and has been extensively explored in spin caloritronics, an active branch in spintronics. In recent years, the focus has shifted to antiferromagnetic insulators (AFM-I), where spin currents created by a thermal gradient has been studied. Thermal gradients across the AFM-I film produce pure spin currents in an adjacent heavy metal layer such as platinum (Pt) due to non-equilibrium distribution of thermal magnons. These spin currents can be detected as a transverse charge current across the Pt layer via inverse spin Hall effect. Here, we have performed systematic investigations of SSE employing two measurement geometries, local and non-local configurations, on oxygen (non-)stoichiometric-SrMnO$_3$ thin films, which exhibit weak-ferromagnetic, insulating behavior down to low temperatures. Controlled experiments as a function of the applied dc bias, magnitude and orientation of applied magnetic field were used to disentangle the role of possible magnetic proximity effects. We observe a quadratic dependence of the SSE signal in Pt/SrMnO$_3$ with the applied current density. SSE is an important tool to detect and study magnon transport in hitherto unexplored complex oxides.

3:30PM J41.00006: Longitudinal Spin Seebeck effect in Pyrochlore Iridates with Bulk and Interfacial Dzyaloshinskii-Moriya interaction*  BOWEN MA (Presenter), University of Texas at Austin, BENEDETTA FLEBUS, University of California, Los Angeles, GREGORY A FIETE, Northeastern University — The longitudinal spin-Seebeck effect (SSE) in magnetic insulator|non-magnetic metal heterostructures has been theoretically studied primarily with the assumption of an isotropic interfacial exchange coupling. Here, we present a general theory of the SSE in the case of an antisymmetric Dzyaloshinskii-Moriya interaction (DMI) at the interface, in addition to the usual Heisenberg form. We numerically evaluate the dependence of the spin current on the temperature and bulk DMI using a pyrochlore iridate as a model insulator with all-in all-out (AIAO) ground state configuration. We also compare the results of different crystalline surfaces arising from different crystalline orientations and conclude that the relative angles between the interfacial moments and DM vectors play a significant role in the spin transfer. Our work extends the theory of the SSE by including the anisotropic nature of the interfacial DMI in magnetic insulator|non-magnetic metal heterostructures and can suggest possible materials to optimize the interfacial spin transfer in spintronic devices.

*NSF Grant No. DMR-1729588, NSF Materials Research Science and Engineering Center Grant No. DMR-1720595, the Simons Foundation, and a QuantEmX grant GBMF5305 from ICAM and the Gordon and Betty Moore Foundation.
3:42PM J41.00007: Spin Seebeck effect in Vanadium Tetracyanoethylene  
YUANHUA ZHENG (Presenter), SETH KURFMAN, ANDREW FRANSON, EZEKIEL JOHNSTON-HALPERIN, JOSEPH P C HEREMANS, Ohio State Univ - Columbus — Vanadium tetracyanoethylene (V(TCNE)$_x$, $x \sim 2$) is an organic based ferrimagnetic coordination compound, with extremely low Gilbert damping which is comparable to yttrium iron garnet. Due to its non-crystalline nature, it is interesting to investigate how spin waves propagate in the material. One possible way is through thermally driven spin pumping, namely spin Seebeck effect (SSE). Here, we present a systematic study on the temperature and thickness dependence of SSE in V(TCNE)$_x$. The thin films (thickness on the order of 100 nm) are grown via chemical vapor deposition on a platinum layer on sapphire substrate. By applying a temperature gradient perpendicular to the V(TCNE)$_x$/Pt, a large SSE signal is collected. Further analysis on the temperature and thickness dependence helps us understand the length scales of the propagation of spin waves.

*YZ and JPH acknowledge CEM, an NSF-MRSEC under grant number DMR-1420451. SK, AF and EJH acknowledge NSF Award under award number 1808704.

3:54PM J41.00008: Temperature Dependence of the Anomalous Nernst Coefficient for Ni$_{80}$Fe$_{20}$ Determined with Metallic Nonlocal Spin Valves  
RACHEL BENNET ( Presenter), Univ of Denver, ALEX HOJEM, Physics, University of California San Diego, BARRY L ZINK, Univ of Denver — The anomalous Nernst effect, which generates an out-of-plane charge voltage in response to a thermal gradient perpendicular to the magnetization of a ferromagnet, can play a significant role in any spintronic device where large thermal gradients exist.[1] Since they typically include features deep within the submicron regime, nonlocal spin valves can be made very sensitive to this effect by lowering the substrate thermal conductance.[2] Thus, material parameters are extremely important to the performance of these devices. Although studies have been conducted into the thickness dependence of the anomalous Hall coefficient for permalloy, little is known about the temperature dependence of the anomalous Nernst coefficient.[3,4]

Here, we use nonlocal spin valves suspended on thin silicon nitride membranes to determine the temperature dependence of the anomalous Nernst coefficient of 35 nm thick permalloy (the NiFe alloy with 80% Ni) from 78 K to 300 K.

*NSF grant ECCS-1610904
4:06PM J41.00009: Magneto-thermoelectric effect in lanthanum orthoferrite with Pt overlayer*  WEIWEI LIN (Presenter), Department of Physics and Astronomy, Johns Hopkins University, JIAMING HE, JIANSHI ZHOU, Department of Mechanical Engineering, University of Texas at Austin, BOWEN MA, Department of Physics, University of Texas at Austin, GREGORY A FIETE, Department of Physics, Northeastern University, CHIA-LING CHIEN, Department of Physics and Astronomy, Johns Hopkins University — Spin caloritronic phenomena, utilizing heat flow to transport spin signals with minimal or no charge current, are of fundamental interest with important applications. We have observed nontrivial magneto-thermoelectric effects in lanthanum orthoferrite (LaFeO$_3$) perovskite single crystals with Pt overlayer at room temperature. The LaFeO$_3$ is a canted antiferromagnetic insulator with weak magnetization of about 0.04 $\mu_B$ per Fe atom along the c-axis, which is only 1% of that of the common ferromagnet iron. The amplitude of magneto-thermovoltage in the Pt/LaFeO$_3$ with an in-plane temperature gradient is comparable to those of the longitudinal spin Seebeck effect and inverse spin Hall effect in Pt/yttrium iron garnet. It provides a sensitive probe of very weak magnetization in the insulator, which can be manipulated by a magnetic field of the order of 10 mT. However, from the thermoelectric measurement configurations and the angular dependence on the applied magnetic field, our results are distinctly different from those of the anomalous Nernst effect and longitudinal spin Seebeck effect. We attribute our results to a thermal magnon transport at the Pt/LaFeO$_3$ interface.

4:18PM J41.00010: Effects of CoFeAl Alloy Composition on Magnetization Dynamics and Magnetic Thermal Transport*  RAMYA MOHAN (Presenter), YIWEI SUN, SUVEEN MATHAUDHU, SINISA COH, RICHARD WILSON, University of California, Riverside — The lifetime of magnetic excitations in metals is governed by scattering rates between magnons and electrons. Recent investigations [1, 2] document how electronic band structure engineering in magnetic alloys allows for suppression of magnon scattering rates; e.g. Co$_{0.25}$Fe$_{0.75}$ thin-films display low magnetic damping ($\alpha \sim 10^{-4}$). My talk will focus on experimental measurements that demonstrate how ultrafast magnetization dynamics and transport properties of CoFeAl magnetic alloys depend on alloy composition. To explore the magnetization dynamics, I use a time-resolved MOKE set-up to observe ultrafast demagnetization in a few hundred femtoseconds followed by precessional dynamics. Through TDTR measurements, I check if lower electron-magnon scattering rates lead to improved thermal transport. My investigation sheds light on how magnon-electron scattering rates govern dynamics on femtosecond (ultrafast demagnetization), nanosecond (magnetic precession and damping), and microsecond time-scales (thermal transport of energy).

*This work was supported by the U.S. Army Research Laboratory and the U.S. Army Research Office under grant # W911NF-18-1-0364.
Investigation of thermal Hall conductivity in hexagonal LuFeO$_3$ type multiferroics

HENA DAS (Presenter), SERGEY NIKOLAEV, Laboratory for Materials and Structures, Tokyo Tech World Research Hub Initiative (WRHI), Institute of Innovative Research, Tokyo Institute of Technology — Materials those exhibit electric and magnetic ordering simultaneously in their ground states and show electric field control of magnetism, may also exhibit novel/enhanced thermal Hall transport phenomena [Nat. Mater. 16, 797 (2017)] that have immense utilitarian worth in various device applications. In this study, we have investigated topology of the magnonic bands and the magnon-mediated thermal transport of the LuFeO$_3$ type novel multiferroics, in which the geometric origin of the ferroelectricity induced not only a net magnetization but also non-trivial magnetoelectric couplings [Nature Communications 5, 2998 (2014), Nature Materials 13, 163-167 (2014)]. We have employed the framework of linearized spin wave and linear response theories to study thermal conductivity as a function of the ferroelectric trimer lattice distortion. The calculated thermal Hall conductivity shows a non-trivial dependence on the ferroelectric distortion. We have also discussed the thermal transport in multiferroic LuFeO$_3$ and LuMnO$_3$ as case studies involving real materials.

Phase transitions and magnetocaloric effects in the Heusler compounds Ni$_2$Mn$_{0.70}$Cu$_{0.30}$Ga and Ni$_2$Mn$_{0.70}$Cu$_{0.25}$Cr$_{0.05}$Ga

SUNDAY AGBO (Presenter), MAHMUD KHAN, Miami University — The structural, magnetic and magnetocaloric properties of Ni$_2$Mn$_{0.70}$Cu$_{0.25}$Cr$_{0.05}$Ga and Ni$_2$Mn$_{0.70}$Cu$_{0.30}$Ga Heusler alloys have been investigated by x-ray diffraction, magnetization, transport, and DSC measurements. For the Ni$_2$Mn$_{0.70}$Cu$_{0.25}$Cr$_{0.05}$Ga alloy, a first order coupled magnetostructural phase transformation near room temperature with a thermal hysteresis of ~1 K was observed. In the vicinity of the transition, large magnetic entropy changes of ~39 J/kg K (while warming) and ~17 J/kg K (while cooling) was observed for a field change of 50 kOe. For the Ni$_2$Mn$_{0.70}$Cu$_{0.30}$Ga material, the first order phase transition with a thermal hysteresis of ~7 K was observed near 345 K. For a field change of 50 kOe, peak magnetic entropy changes of -17 J/kg K and -33 J/kg K were observed for warming and cooling, respectively. The electrical resistivity data showed interesting behavior near the phase transitions. The experimental results will be presented and discussed considering the coupling and de-coupling of the first order structural and second order magnetic phase transitions in the materials.
4:54PM J41.00013: Theory of spin magnetic quadrupole moment and temperature-gradient-induced magnetization*  ATSUO SHITADE (Presenter), AKITO DAIDO, YOUICHI YANASE, Kyoto Univ. — We formulate what we call gravitomagnetoelectric (gravito-ME) effect, in which the magnetization is induced by a temperature gradient. Although the Kubo formula for the gravito-ME effect provides an unphysical divergence at zero temperature, we prove that the correct susceptibility is obtained by subtracting the spin magnetic quadrupole moment from the Kubo formula. It vanishes at zero temperature and is related to the ME susceptibility by the Mott relation. We explicitly calculate the gravito-ME susceptibility in a Rashba ferromagnet and show its experimental feasibility.

J41.00014: Oscillatory spin pumping in Nb/NiFe/Nb junctions*  YUNYAN YAO (Presenter), RANRAN CAI, ICQM, Peking Univ. Beijing 100871, P. R. China., YASUMASA TSUTSUMI, RIKEN Center for Emergent Matter Science (CEMS), Wako 351-0198, Japan., YANG MA, WENYU XING, YUAN JI, CHEN XIE, ICQM, Peking Univ. Beijing 100871, P. R. China., SEE-HUN YANG, IBM Research - Almaden, San Jose, California 95120, USA., SADAMICHI MAEKAWA, RIKEN Center for Emergent Matter Science (CEMS), Wako 351-0198, Japan., WEI HAN, ICQM, Peking Univ. Beijing 100871, P. R. China. — The quantum size-induced oscillating physical phenomena has attracted a lot of interest in condensed matter physics and materials science. In this talk, I will discuss the oscillatory spin pumping in the Nb(100nm)/NiFe/Nb(100nm) trilayer structure. In the normal state of Nb, via systematical varying the thickness of NiFe from 5nm to 20nm, an oscillating Gilbert damping is observed. This oscillating behavior can be attributed to the quantum-interference effect of angular momentum transfer between the local precessing magnetic moment and conduction electrons in thin NiFe that was theoretically predicted by Mills [1]. As the NiFe layer is thin and coupled to nonmagnetic Nb layers, quantum-interference effect of the spin-polarized electrons shows up, which gives rise to the oscillating spin-transfer torque to the NiFe. This oscillating feature is observed to be largely enhanced below the superconducting critical temperatures in the Nb/NiFe/Nb Junctions.

2:30PM J42.00001: Ultra-low-power switching of IrMn/CoFeB/MgO structure with voltage-controlled spin-orbit torque  SHOUZHONG PENG (Presenter), JIAQI LU, WEIXIANG LI, LEZHI WANG, HE ZHANG, WANG KANG, ZHAOHAO WANG, Fert Beijing Institute, BDBC, School of Microelectronics, Hefei Innovation Research Institute, Beihang University, XIANG LI, KANG-LUNG WANG, Department of Electrical Engineering, University of California, Los Angeles — How to efficiently manipulate magnetization remains one of the key challenges for spintronic devices and magnetic random-access memories[1-3]. Here we experimentally demonstrate the ultra-low-power and field-free switching of perpendicular magnetization by a combination of spin-orbit torque (SOT) and voltage-controlled magnetic anisotropy effect. Firstly, field-free SOT switching is achieved with the aid of an in-plane exchange bias (EB) generated in the perpendicularly magnetized IrMn/CoFeB/MgO structure. Then we explore the VCMA effect and observed a clear reduction of perpendicular magnetic anisotropy (PMA) when a gate voltage is applied. A VCMA coefficient of 35 fJ/Vm is obtained in this structure, comparable to that of the Ta/CoFeB/MgO structure. By applying a gate voltage of 0.6 V on this film, the SOT switching current can be significantly reduced, resulting in a critical switching current of 6.2 MA/cm². Finally, an ultra-low-power and high-density spintronic memory array based on voltage-controlled SOT is proposed and demonstrated by both experiments and hybrid CMOS/MTJ simulations.

2:42PM J42.00002: Electrical noise in magnetic tunnel junctions due to magneto-structural transitions of CoFeB/MgO interfaces*  AREZOO ETESAMIRAD (Presenter), DAVID NELSON, KEANUHEA DAILEY, Physics and Astronomy, University of California, Riverside, JORDAN A KATINE, Western Digital, San Jose, ILYA KRIVOROTOV, Physics and Astronomy, University of California, Irvine, IGOR BARSUKOV, Physics and Astronomy, University of California, Riverside — Magnetic tunnel junctions (MTJs) play a central role in spintronics research as memory elements, nanoscale microwave oscillators, local magnetic sensors, and neuromorphic network components. Understanding and controlling electric noise in MTJs is a prerequisite for employing them in next-generation applications. Here, we study MTJ nanopillars of 50 nm diameter consisting of CoFeB free layer, MgO tunnel barrier, and CoFe based synthetic antiferromagnet. We observe random telegraph noise which is frequently found in MTJs and yet not fully understood. Varying the temperature in the range of 80-300 K for an MTJ in the parallel state, we encounter anomalous device resistance (steps) attributed [1,2] to magneto-structural phase transitions of iron oxide clusters at the CoFeB/MgO interface. At temperatures of these anomalies, telegraph noise shows a significant increase. This correlation suggests that the oxide clusters have a significant impact on MTJ noise characteristics.

2:54PM J42.00003: Finite-size Kosterlitz-Thouless transition in Fe/W(001) ultrathin films*

DAVID VENUS (Presenter), JORDAN ATCHISON, AMANJOT BHULLAR, BRYCE NORMAN, McMaster Univ — The Kosterlitz-Thouless (KT) transition involves the unbinding of topological excitations (vortex-antivortex pairs) in an infinite, isotropic, 2DXY system. In real 2D ferromagnetic films, it is not clear that such a transition occurs in the presence of crystalline anisotropy and finite size effects. We report MOKE magnetic susceptibility measurements $\chi(T)$ of 4-fold in-plane ultrathin Fe/W(001) films, where a prominent peak is observed. Above the peak temperature, the paramagnetic susceptibility is in excellent agreement with the form expected for a vortex-antivortex gas: $\chi(T) = \chi_0 \exp[B/(T/T_{KT} - 1)]^a$, with $a = 0.50\pm0.03$ and $B = 3.48\pm0.16$. In accord with finite size KT theory, the KT transition temperature, $T_{KT}$, is tens of K below the susceptibility peak, giving a “finite size” consistent with $\mu$m magnetic domains. Fitting instead to a power law, as would be consistent with a 2nd order transition, gives unphysical parameters $\gamma_{eff} = 3.7\pm0.7$ and a Curie temperature $T_{\gamma}$ far below the peak temperature. Below the peak, the measured susceptibility has a complicated behaviour qualitatively consistent with the re-emergence of 4-fold anisotropy and magnetic domains.

3:06PM J42.00004: Spin-Orbit-Torque Field-Effect Transistor (SOTFET): A New Magnetolectric Memory*

XIANG LI (Presenter), PHILLIP DANG, JOSEPH CASAMENTO, ZEXUAN ZHANG, OLALEKAN AFUYE, ALYSSA B. APSEL, DARRELL SCHLOM, DEBDEEP JENA, DANIEL C. RALPH, HUILI XING, Cornell University — Spin-based memories are attractive for their non-volatility and high durability but provide modest resistance changes, whereas semiconductor logic transistors are capable of large resistance changes but lack memory function with high durability. The recent availability of multiferroic materials provides an opportunity to directly couple the change in spin states of a magnetic memory to a charge change in a semiconductor transistor. In this work, we propose and analyze the spin-orbit-torque field-effect transistor (SOTFET), a device with the potential to significantly boost the energy efficiency of spin-based memories, and to simultaneously offer a palette of new functionalities. Analysis of the memory aspect indicates that the SOTFET can offer orders of magnitude increase in the on-off resistance ratio compared to existing magnetic memories, which can potentially lower the operation energy significantly. We establish a quantitative model of the operations of the SOTFET. From the model, the materials needs for the successful operation are identified and the feasibility of the SOTFET is proved in a properly designed CoFe/BiFeO$_3$ gate stack.

3:18PM J42.00005: Pulsed or Microwave Currents Induced Random Telegraph Signal in a Magnetic Tunnel Junction*  RAJAPKASYALAGE RAJAPAKSE (Presenter), NICHOLAS PENTHORN, Physics and Astronomy, University of California, XIAOJIE HAO, ZIHUI WANG, YIMING HUAI, Avalanche Technology, HONGWEN JIANG, Physics and Astronomy, University of California — Recent work has shown creation and dynamics of magnetic skyrmions, without the Dzyaloshinskii-Moriya interaction, in the free layer of a magnetic tunnel junction (MTJ) at a temperature of 4K [1]. In order to study how skyrmions, the topological excitations, can be protected against disorders and temperature fluctuations, we have extended our experimental investigation to higher temperatures, up to 200K, for various device sizes. For the intermediate resistance state, initiated by pulse or microwave currents, we have observed stochastic switching between two resistance states, commonly referred as the random telegraph signal (RTS). Statistics of the observed RTS depends on device temperature and microwave stimulation while the corresponding relations have been studied. In conjunction with micro-magnetic simulations, we discuss the interplay of the topological skyrmion and disorder-induced domains in MTJs.

*The work was supported by National Science Foundation (NSF under Grant No. DMR-1809155).

3:30PM J42.00006: Controlling long-range skyrmion lattices using field and temperature in Fe/Gd multilayers*  LISA DEBEER-SCHMITT (Presenter), Oak Ridge National Lab, RYAN DESAUTELS, Seagate Technology, NAN TANG, Material Science Department, University of Tennessee, SERGIO MONTOYA, CMRR, University of California San Diego, W L. N. C. LIYANAGE, Material Science Department, University of Tennessee, SHEENA PATEL, Physics, University of California San Diego, MICHAEL FITZSIMMONS, Oak Ridge National Lab, ERIC FULLERTON, CMRR, University of California San Diego, JULIE ANN BORCHERS, NIST Center for Neutron Research, National Institute of Standards and Technology, DUSTIN GILBERT, Material Science Department, University of Tennessee — Ordered magnetic skyrmion lattices presents a playground of new and interesting physics to explore. This opportunity is provided by the topological nature of the skyrmion. We have recently fabricated thin-films of amorphous Fe and Gd multilayers that support skyrmions and skyrmion lattices at room temperature and zero applied magnetic field. These skyrmions are stabilized by dipolar interactions, rather than the Dzyaloshinskii–Moriya interaction (DMI). By varying the film thickness and alloy composition we can alter the dipole interactions relative to the exchange and anisotropy and thus control the skyrmion size, pitch, and stability. Using small angle neutron scattering (SANS), we demonstrated that once formed these dipole skyrmions are stable over a large field and temperature range including zero field and room temperature. We observe temperature and field dependent changes in the scattering vector (Q) for peak scattering related to the skyrmion lattice spacing. The origin of this change has led us to identify a key requirement necessary for the range of stability that we have observed in these amorphous thin films.

Multi-probe, laser-scanning optical microscopy for investigation of novel magnetic domain structures and boundaries  
AUSTIN KACZMAREK (Presenter), LIUYAN ZHAO, Univ of Michigan - Ann Arbor — Spin ordering in a magnetic material leads to the breaking of time-reversal symmetry along with some crystallographic symmetries, defining the magnetic symmetry group of the magnetic phase. Multiple degenerate ground states always exist, related through these broken symmetries, leading to interesting magnetic domain structures in macroscopic samples, which potentially host novel low-dimensional phases at the domain boundaries. In this talk, I will present our development of a spatially resolved, diffraction limited, ultrafast laser-based optical scanning microscope, which includes measurement capabilities of the magneto-optic Kerr effect (MOKE), a direct measure of broken time-reversal symmetry, and the optical second harmonic generation rotational anisotropy (SHG RA), a sensitive probe to broken spatial symmetries. I will present a comparison between this scanning-based microscope and a more traditional wide-field microscope. I will then discuss our experimental results on resolving magnetic domain structures in two types of antiferromagnetism, Ising and Heisenberg, on a honeycomb and a triangle lattice respectively. Finally, I will discuss the possibility of incorporating time-resolution into the aforementioned static probes.

Chirality-driven growth of stripe domains in Co/Ni/Pt-based multilayers*  
JEFFREY BROCK (Presenter), RAJASEKHAR MEDAPALLI, ERIC FULLERTON, Center for Memory and Recording Research, University of California, San Diego — The interfacial Dzyaloshinskii-Moriya interaction (iDMI) arising from inversion asymmetry at interfaces between magnetic materials and heavy metals with large spin-orbit coupling can transform DWs from Bloch to chiral Néel, leading to asymmetric DW propagation in the presence of a symmetry-breaking in-plane magnetic field. However, stripe domain growth in systems with iDMI is not yet well understood. Here we present an experimental study of [Co(0.7 nm)/Ni(0.5 nm)/Pt(0.7 nm)]N (1 ≤ N ≤ 5) multilayers designed to have asymmetric Pt/Co and Ni/Pt interfaces and perpendicular anisotropy. Kerr microscopy reveals that for N ≥ 3, reversal occurs via stripe domains and that when a static in-plane magnetic field is applied, the growth directionality is strongly linked to the field strength. For low fields, the domains grow roughly perpendicular to the field – a directionality not predicted by current understanding of the iDMI. The propagation direction becomes strongly collinear to the field at higher field magnitudes, as expected from the iDMI. Possible explanations in terms of a mixed domain wall with a mixed chiral Neel and chiral Bloch character will be discussed.

4:06PM J42.00009: High tunability of synthetic antiferromagnets applied in magnetic field sensing and memory devices*  
KANG WANG (Presenter), YIOU ZHANG, GANG XIAO, Department of Physics, Brown University — We investigated magnetic configurations in synthetic antiferromagnets (SAFs) of CoFeB/Ta/CoFeB by tuning interlayer exchange coupling (IEC, the energy density is denoted by $J_{ex}$) and perpendicular magnetic anisotropy (PMA, $K_u$). Two magnetic layers are either ferromagnetic or antiferromagnetic coupling, depending on both the non-magnetic layer thickness ($d_{NM}$) and the ferromagnetic layer thickness. Besides spin-flip transitions in SAFs with large PMA, we observed the canted magnetic configurations and spin-flop transitions when $K_u < J_{ex}/d_{NM}$. Most interestingly, the transfer curve of anomalous Hall resistance (magnetizations) becomes linear when tuning IEC and PMA to moderate values. This allows for applications in anomalous Hall effect (AHE) sensors with ultrahigh magnetic field detectability. Noise spectra reveal the magnetic field detectability reaches 100 nT/√Hz (at 1 Hz) at room temperature and decreases to sub-µT/√Hz (at 1 Hz) at 150 K. The studies indicate that the synthetic antiferromagnets are good candidates for both the magnetic memory devices and ultra-detectable magnetic field sensors with high thermal stability.

4:18PM J42.00010: Dynamic Skyrmion-Mediated Switching of Perpendicular MTJs: Scaling to 20 nm with Thermal Noise*  
MD MAHADI RAJIB (Presenter), WALID AL MISBA, DHRITIMAN BHATTACHARYA, JAYASIMHA ATULASIMHA, Virginia Commonwealth Univ — One method of creating and annihilating skyrmions in confined geometries is to use Voltage-Controlled Magnetic Anisotropy (VCMA) [1, 2, 3]. Previous study shows that robust voltage controlled ferromagnetic reversal from “up” to “down” state in the soft layer of a p-MTJ can be achieved by creating and subsequently annihilating an intermediate skyrmion state [4] in the presence of room temperature thermal noise and anisotropy variation across grains [4]. However, when scaling to 20 nm, thermal noise can annihilate the skyrmions, for example, by randomly moving the core towards the boundary of the nanostructure. Thus, a region of different anisotropy in the skyrmion core may be needed to stabilize the skyrmion state allowing competitive scaling. Here, we will investigate the extent to which the skyrmion mediated switching scheme can scale to lateral dimensions ~ 20 nm in ferromagnets.

4:30PM J42.00011: Skyrmion Breathing Modes in Synthetic Ferri- and Antiferromagnets*

MARTIN LONSKY (Presenter), AXEL HOFFMANN, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Magnetic multilayers that combine strong spin-orbit interaction with lacking inversion symmetry can give rise to the presence of topologically nontrivial spin textures, so-called magnetic skyrmions. Recent studies have indicated strongly enhanced propagation velocities of skyrmions in antiferromagnets and compensated ferrimagnets [1]. At the same time, it is unclear how magnetic compensation may affect dynamic excitations of magnetic skyrmions, such as breathing modes which entail an oscillation of the skyrmion size at GHz frequencies [2]. Here, we present micromagnetic simulations of these excitations in synthetic ferri- and antiferromagnets. The observed features in the calculated power spectra show a systematic dependence on the coupling strength between the individual layers and are related to pure breathing modes as well as to hybridizations of breathing and spin wave modes that are characteristic for the considered geometry. Based on these simulations, we then discuss the impact of these results for potential skyrmion sensing.

4:42PM J42.00012: Voltage Control of magnetic Skyrmions in patterned nanodots*

DHRITIMAN BHATTACHARYA (Presenter), Virginia Commonwealth Univ, SEYED ARMIN RAZAVI, HAO WU, BINGQIAN DAI, KANG-LUNG WANG, University of California, Los angeles, JAYASIMHA ATULASIMHA, Virginia Commonwealth Univ — Manipulation of magnetic skyrmions that are fixed in space can lead to the implementation of computing devices with smaller footprint. Moreover, if the control is achieved solely via applying an electric field, additional advantage of energy efficiency can be obtained. We have previously shown the feasibility of such a scheme by annihilating and creating skyrmions in a thin film of IrMn/CoFeB/MgO using Voltage Control of Magnetic Anisotropy (VCMA) [1]. However, in patterned structures, due to the confinement effect, complete reversal of skyrmion polarity as well as skyrmion mediated ferromagnetic reversal can be achieved using only voltage pulses [2, 3]. Here we propose to show this behavior in patterned nanodots of CoFeB sandwiched between an oxide and a heavy metal layer. We will also study the intermediate magnetic states during the reversal by performing magnetic force microscopy (MFM) imaging under in situ voltage. Finally, micromagnetic simulations will be presented that corroborate our experimental observations.

*NSF SHF Small Grant #1909030
The Dzyaloshinskii-Moriya Interaction (DMI) gives rise to chiral magnetic structures, which include chiral spin-chains and skyrmions. DMI requires broken inversion symmetry and can exist in the bulk as well as at interfaces. We use Brillouin Light Scattering spectroscopy (BLS) to determine the DMI from the non-reciprocal frequency-shift of Damon-Eshbach spin-waves [1]. In order to gain deeper insight into the underlying physics of DMI and explore ways, on how to tune the DMI through interface modifications, we prepared multiple sample series to study different aspects of the DMI, examples are: 1.) A Cu/Co\textsubscript{90}Fe\textsubscript{10} and a Pt/Co\textsubscript{90}Fe\textsubscript{10} sample series were in-situ oxidized for different times and subsequently capped to prevent any further oxidation. Density functional theory (DFT) calculations have demonstrated that the hybridization and the associated charge transfer is important for DMI at oxide interfaces. We determined that the spectroscopic splitting factor $g$ is correlated to the DMI. This is an indirect confirmation of the theory predictions. [2] 2.) We introduced a Cu dusting layer at the interface between CoFeB and Pt to disrupt the Heisenberg exchange directly at the interface. SQUID magnetometry shows that the Cu dusting layer reduces the proximity magnetization in the Pt as well. The proximity magnetization is a direct result of the exchange coupling and can be seen as a measure for its strength. 3.) So far, most work on DMI has been carried out for highly symmetric interfaces. Low symmetry systems can have anisotropic DMI. We prepared a Pt/Fe(110) sample and found that the DMI is anisotropic with the strongest DMI along the [001] direction, which coincides with the magnetic easy axis. We compared the results for the DMI with DFT calculations.

Session J43 DCOMP DAMOP DCMP: Precision Many-Body Physics V: Dynamics and Finite Temperature Properties 702 - Thomas Schaefer, Ecole Polytechnique - Tag(s): Focus
2:30PM J43.00001: T-linear resistivity and spectroscopy of hot metals and cold atoms: DMFT, SYK and beyond [Invited] ANTOINE GEORGES (Presenter), Collège de France, Paris and Flatiron Institute, New York — Many materials with strong electronic correlations display metallic-like resistivity up to very high temperature, with values exceeding the Mott-Ioffe-Regel (MIR) criterion (‘bad metals’). Understanding transport in this regime, in relation to spectroscopic probes such as optical conductivity and ARPES, raises the fundamental question of transport in regimes where long-lived quasiparticles may not exist. Recently, cold atomic gases in optical lattices have offered a beautiful experimental platform to investigate this question without the intervening effect of phonons. Even more challenging is the crossover into a ‘strange metal’ regime at lower temperatures, in which resistivity becomes smaller than the MIR value while still departing from Fermi liquid behaviour.

I will review recent work on these questions in the context of Dynamical Mean Field Theory and the Sachdev-Ye-Kitaev models, as well as high-temperature series expansions and several computational approaches. I will emphasize some commonalities between these approaches, and assess what is established at this point and which questions are still open.

3:06PM J43.00002: SYK non-Fermi-liquid solution of the Hubbard model* AARAM J. KIM (Presenter), Department of Physics, King’s College London, PHILIPP WERNER, Department of Physics, University of Fribourg, EVGENY KOZIK, Department of Physics, King’s College London — The bold-line diagrammatic technique solution of the Hubbard model in the strong coupling regime is of an SYK non-Fermi-liquid (nFL) type, obtained in a controlled way by the numerically exact diagrammatic Monte Carlo method. In the atomic (zero-hopping) limit, the solution corresponds to the unphysical branch of the Luttinger-Ward functional, for which the SYK model is the exact solution at the second order. Interestingly, the Green’s function retains its scaling form at higher orders. The solution for the doped 2d Hubbard model features an SYK-type nFL regime in a wide intermediate temperature range enclosed by the low-temperature Fermi-liquid and the high-temperature atomic limit. The possibility of SYK physics taking place in the Hubbard model is discussed.

3:18PM J43.00003: Variational Schrieffer-Wolff Transformations for Quantum Many-body Dynamics* JONATHAN WURTZ (Presenter), PIETER W CLAEYS, ANATOLI S POLKOVNIKOV, Boston Univ — Building on recent results for adiabatic gauge potentials, we propose a variational approach for computing the generator of Schrieffer-Wolff transformations, and demonstrate its accuracy in spin chains and fermionic systems. Because of their variational nature, the generator goes beyond standard perturbative regimes and has accuracy controlled by the locality of the ansatz. This allows for precision non-equilibrium many-body dynamics far from integrable regimes, and can be considered as improvements to the Truncated Spectrum Approach.

*NSF DMR-1813499 and AFOSR FA9550-16-1-0334
3:30PM J43.00004: Investigating non-integrable quantum many-body systems with sub-exponential computational effort  PAVAN HOSUR (Presenter), Univ of Houston — Non-integrable quantum systems - systems with no or few conserved quantities - are generically exponentially hard to solve. Recent developments have proven, at least for small system sizes, that these systems satisfy the eigenstate thermalization hypothesis (ETH). Specifically, their physical properties such as expectation values of simple observables and few-point correlation functions, depend smoothly on macroscopic variables such as the energy density, particle density etc. This behavior explains, qualitatively, how statistical mechanics and ergodicity emerges from quantum mechanical laws for such systems. In this talk, an algorithm will be presented that enables quantitative predictions based on the ETH. In particular, it can simulate finite temperature properties of non-integrable systems with sub-exponential effort by exploiting the ETH. By expressing an eigenstate density matrix as truncatable series of orthogonal polynomials of the Hamiltonian, it will require only sparse matrix multiplication instead of matrix diagonalization. Moreover, it will store sparse matrices as vectors in the Fock space of operators, which reduces storage requirements from exponential to polynomial. Benchmarks between the algorithm and exact diagonalization on prototypical models will be shown.

3:42PM J43.00005: Space- and time-crystallization effects in multicomponent superfluids  BORIS SVISTUNOV (Presenter), NIKOLAI PROKOF'EV, Univ of Mass - Amherst — We observe that space- and time-crystallization effects in multicomponent superfluids—while having the same physical origin and mathematical description as in the single-component case—are conceptually much more straightforward. Specifically, the values of the temporal and spatial periods are absolute rather than relative, and the broken translation symmetry in space and/or time can be revealed with experiments involving only one equilibrium sample. We discuss two realistic setups—one with cold atoms and another one with bilayer superconductors—or observation of space and time crystallization in two-component counterflow
3:54PM J43.00006: A generic quantum Monte Carlo approach for electronic correlations in out-of-equilibrium systems.  CORENTIN BERTRAND (Presenter), Simons Foundation, SERGE FLORENS, Univ. Grenoble Alpes, CNRS, Institut Néel, F-38000 Grenoble, France, OLIVIER PARCOLLET, Simons Foundation, XAVIER WAINITAL, Univ. Grenoble Alpes, CEA, IRIG-PHELIQS, GT F-38000 Grenoble, France — We propose a systematic approach to the non-equilibrium dynamics of strongly interacting many-body quantum systems, building upon the standard perturbative expansion in the Coulomb interaction. High order series are derived from a determinantal diagrammatic Quantum Monte Carlo in the real time Keldysh formalism.

Such an algorithm was already designed by Profumo at al. (PRB, 91 245154 (2015)) and can compute perturbation series for single quantities after an arbitrary long (real) time evolution. We improved it to compute an entire time-dependent function in a single run. With a similar sampling method and computation time, the new algorithm gather much more information and give access to dynamical quantities directly in real frequencies.

The algorithm has been tested on the Anderson impurity model at equilibrium, and applied to the same system driven out of equilibrium by a bias voltage. In these systems, we obtained 10 orders of the Green's function perturbation series. To reach the non-perturbative regime, we developed a robust resummation scheme based on conformal transforms of the complex plane in the perturbation parameter.

4:06PM J43.00007: Dynamic Behavior of Strongly Coupled Quantum Dots  PHILIPP DUMITRESCU (Presenter), Simons Foundation, MARJAN MAČEK, Univ. Grenoble Alpes, CORENTIN BERTRAND, Simons Foundation, XAVIER WAINITAL, Univ. Grenoble Alpes, OLIVIER PARCOLLET, Simons Foundation — We study a system of strongly correlated quantum dots, using a recently developed diagrammatic quantum Monte Carlo approach. Here, one calculates high orders of Schwinger-Keldysh perturbation theory and uses numerical resummation to obtain spectral functions directly in real time. We show that even non-Fermi liquid behavior of strongly coupled quantum dots can be revealed. We study this behavior in both equilibrium and in situations where the dots are driven by an external current.
4:18PM J43.00008: Dynamical properties of the spin-boson model using real-time quantum Monte Carlo*  OLGA GOULKO (Presenter), Boise State University, GUY COHEN, MOSHE GOLDSTEIN, Tel Aviv University, HSING-TA CHEN, University of Pennsylvania — We present results for the real-time dynamics of the spin-boson model (a two-state system coupled to a bath of non-interacting harmonic modes) using the inchworm Monte Carlo algorithm. In particular, we study the population difference between the two states at strong system-bath coupling. We focus on sub-Ohmic spectral densities of the bosonic bath, where the system exhibits a second order quantum phase transition between localized and delocalized regimes. The inchworm algorithm is efficient over a wide range of temperatures (including low, intermediate, and high temperatures) and thus allows us to examine the changes in dynamics as the temperature is increased above zero and the emergence of a quantum critical fan.

4:30PM J43.00009: Reconstructing Nonequilibrium Regimes of Quantum Many-Body Systems from the Analytical Structure of Perturbative Expansions  CORENTIN BERTRAND, Simons Foundation, SERGE FLORENS, CNRS, OLIVIER PARCOLLET (Presenter), Simons Foundation, XAVIER WAINTAL, CEA-Grenoble — We present a systematic approach to the nonequilibrium dynamics of strongly interacting many-body quantum systems, building upon the standard perturbative expansion in the Coulomb interaction. High-order series are derived from the Keldysh version of the determinantal diagrammatic quantum Monte Carlo algorithm. The reconstruction of physical quantities beyond the weak-coupling regime is obtained using a conformal change of variable, based on the approximate location of the singularities of these functions in the complex U plane, and a Bayesian inference technique, that takes into account additional non-perturbative relations, in order to control the amplification of noise occurring at large interaction. The approach is then applied to the Anderson quantum impurity model in the quantum dot geometry in and out of equilibrium.

4:42PM J43.00010: Time-symmetric stochastic action in curved phase-space  

PETER DRUMMOND (Presenter), MARGARET REID, RIA RUSHIN JOSEPH, Swinburne Univ of Tech — Quantum field dynamics is equivalent to a forward-backward stochastic process in both time directions, and can be calculated from an equilibration in a fifth space-time dimension [1]. Stochastic time-symmetric action principles in a curved phase-space are central to these results. They can be used to compute a stochastic bridge, the probability for random paths between two states, with any positive or negative diffusion. Such bridges have other precision applications, in fields ranging from many-body quantum dynamics to cell biology, control theory and finance.

Numerical methods and examples of solutions to the resulting stochastic partial differential equations in a higher time-dimension are obtained. These give agreement with exact solutions for bosonic quantum field dynamics, including entangled systems. This novel approach may lead to useful computational techniques, as the action principle is real. Of more fundamental significance is that it provides an ontological model of reality [2] in cosmological models, and allows an interpretation of objective measurement without wave-function collapse.

4:54PM J43.00011: Bounding the finite-size error for simulations of quantum many-body systems  

ZHIYUAN WANG (Presenter), KADEN HAZZARD, Rice Univ, MICHAEL FEIG, Honeywell Intl — Finite size errors are ubiquitous in numerical simulations of quantum many body systems, and an estimation of these errors is crucial to the assessment of the reliability of their results. In this talk I present rigorous upper bounds on finite size error of local observables measured in gapped ground states of locally-interacting systems, as well as in real time quench dynamics simulations initiated from a product state. The key step of our method relies on the well-known Lieb-Robinson (LR) bound, which is a direct consequence of locality. We show that the error bounds are practically useful, enabled by the recent tightening of the LR bounds [1]. For example, in a ground state simulation of the transverse field Ising model with J=1, h=2 and L=25 sites, the relative error for a center site observable is less than 2% and decays exponentially with system size. In a quench dynamics simulation of the same model, the relative error bound remains to be within 1% up to the time at which the system equilibrates, and decays superexponentially with system size at fixed time.

5:06PM J43.00012: Thermofield theory for finite-temperature many-body physics*  
Gaurav Harsha (Presenter), Thomas M Henderson, Gustavo E Scuseria, Rice Univ — Wave function methods are widely used to study ground-state properties of many-electron systems in condensed matter physics and chemistry, and have therefore seen tremendous development over the last fifty years or so. But standard wave function techniques cannot easily be used to compute thermal properties, because doing so requires the entire spectrum and the problem becomes computationally intractable. Thermofield dynamics, which has seen widespread application as a field-theoretical tool to study non-equilibrium properties, provides a wave function representation for the thermal density matrix. In this talk, I will present our recently developed framework (arXiv:1901.06753 and 1907.11286) which shows how the thermofield theory can be utilized to construct finite-temperature generalizations of ground-state wave function methods. I will provide an example of thermal coupled cluster theory and present results for its performance on standard electronic and spin systems.

5:18PM J43.00013: Analytical continuation of transport functions with deep neural networks*  
Simon Verret (Presenter), Mila, Université de Montreal & IQ, Université de Sherbrooke, Reza Nourafkan, Samuel Desrosiers, André-Marie Tremblay, Université de Sherbrooke — In the last few years, deep neural networks have proved to be highly efficient tools to address the problem of analytical continuation of the Matsubara Green’s function [1,2,3,4]. Extending these tools to reconstruct spectral representation of correlation function for transport quantities would be very beneficial because for several of transport quantities, such as Hall conductivity and Seebeck effect [5,6], the spectral weight is not strictly positive, restricting the use of the maximum entropy method. In this work, we extend the use of deep neural networks to the case of the longitudinal conductivity, in particular the DC-conductivity. We explore various modern architectures of neural network and various tailored-made loss functions for this problem.

2:30PM J44.00001: Quantifying Uncertainty in First-Principles Predictions of Phonon Properties and Thermal Conductivity [Invited]

ALAN MCGAUGHEY (Presenter), HOLDEN LOW PARKS, VENKAT VISWANATHAN, Carnegie Mellon Univ — We present a robust method for quantifying the uncertainty in phonon properties and thermal conductivity predicted from density functional theory calculations using the BEEF-vdW exchange-correlation (XC) functional. The procedure starts by displacing atoms in an equilibrium structure and using the energies of the perturbed structures to determine harmonic and anharmonic force constants. BEEF-vdW generates an ensemble of energies for each perturbed structure as a computationally efficient post-processing step by perturbing the XC functional and solving for the energy non-self consistently. Thus, each perturbed structure yields an ensemble of energies. This energy ensemble is then used to determine an ensemble of force constants, which is then used as input to lattice dynamics calculations and a solution of the Boltzmann transport equation. This procedure results in ensembles for the phonon frequencies, group velocities, and lifetimes, and overall heat capacity and thermal conductivity, whose spreads can be used to quantify uncertainty. Results for silicon, graphene, and graphite are presented and compared to predictions from the PBE, RPBE, and PBEsol XC functionals.

3:06PM J44.00002: From Coherent State Statistics to the Frozen Phonon Model*

CHRISTOPHER FECHISIN (Presenter), ERIC JOHNSON HELLER, Harvard University — We present a formalism for employing the basis of coherent states for analytical and numerical computations involving systems at thermal equilibrium. We identify an integration measure on the complex plane which may be understood as the weight function for a thermal distribution of coherent states. When applied to phonons in a thermally occupied harmonic crystal, this method yields an intuitive and rigorously quantum mechanical justification of the frozen phonon model of thermal diffuse scattering. In this and many other applications, the semiclassical dynamics of coherent states can mediate the application of classical reasoning to otherwise intractable quantum problems, including those involving anharmonic potentials. We also discuss and refine the concept of “quasi-elastic” scattering.

*This project was funded in part by the Harvard College Herchel Smith Undergraduate Research Fellowship.
**3:18PM J44.00003: Anomalous elasticity of 2D materials beyond self-consistent approximation**

DAVID SAYKIN (Presenter), Department of Physics, Stanford University, IGOR BURMISTROV, Landau Institute for Theoretical Physics, VALENTIN KACHOROVSKIĬ, Ioffe Physico-Technical Institute, IGOR GORNYI, Karlsruhe Institute of Technology — We study elastic properties of two-dimensional crystalline materials, such as graphene. It is known that in 2D membranes strong thermal fluctuations of flexural phonons lead to dramatic change of phonon spectrum and, as a result, in anomalous material-independent elastic properties, such as non-linear Hooke’s law under the low stress and auxetic behavior.

We compute elastic moduli \( \eta \) and Poisson ratio \( \nu \) of 2D membrane in the approximation of high embedded dimensionality \( d_c = 2 + d \). We go beyond one-loop approximation and find that famous self-consistent screening approximation is only as good as first-order approximation. Most remarkably, we analyze a case of disordered membrane and find new disorder-dominant phase, where all the critical exponents are different from the clean case. We find that phase transition happens at finite temperature in contrast to the prediction given by self-consistent screening approximation, that transition is only possible at absolute zero.

Presented work is a continuation of the results reported in papers PhysRevB.97.125402, PhysRevB.92.155428.

**3:30PM J44.00004: Continuity of phonon dispersion curves in layered ionic crystals**

NATALIE A HOLZWARTH (Presenter), YAN LI, WILLIAM KERR, Wake Forest Univ — We investigate in detail the origin of apparent discontinuities and mode disappearances in phonon band diagrams of ionic materials having hexagonal and other anisotropic structures. The phenomenon is due to the coupling of some of the vibrational modes to long wavelength electromagnetic waves within the material as described in 1951 by Huang. Modern analyses by Giannozzi, Gonze, Baroni, and others, based on density functional theory and density functional perturbation theory, have been implemented in several first principles code packages such as ABINIT and QUANTUM ESPRESSO. These use the so-called non-analytic correction to the dynamical matrix to correctly represent the modified longitudinal optical vibrational modes. In this work, we extend the analysis to include the transverse phonon-photon modes as well. The combination of the longitudinal and transverse phonon-photon mode dispersions are continuous functions of the wavevector \( \mathbf{q} \). These effects are demonstrated for cubic and hexagonal BN.

3:42PM J44.00005: Theoretical Analysis of Vibrational Lineshapes from Molecular Dynamics

ANDREW CUPO (Presenter), DAMIEN TRISTANT, KYLE REGO, VINCENT MEUNIER, Rensselaer Polytechnic Institute — The conventional spectral method for extracting anharmonic phonon properties from molecular dynamics (MD) requires prohibitively long simulations as the fitting function relies on the infinite time approximation. To that end, we derived the spectral lineshapes for arbitrary simulation lengths, while retaining the frequency shift and lifetime as fitting parameters. The theory was illustrated for graphene, hexagonal boron nitride, and silicon at the density functional theory (DFT) level, with up to nearly a factor of nine reduction in the required simulation time to reach convergence in the vibrational properties as compared to the standard approach. Such improvement in the convergence is expected in general provided the phonon anharmonicity is sufficiently weak, resulting in well-defined renormalized phonon quasiparticles. Application of the proposed approach has the potential to be far reaching as the theory applies equally well to ab initio MD based on DFT, time-dependent DFT dynamics, and parameterized force-fields and is thus expected to have important impact on topics ranging from strongly-correlated materials with sophisticated treatment of electron-electron interactions to biological systems.

3:54PM J44.00006: Influence of spin-orbit coupling and Rashba interaction on the electron-phonon renormalized electronic energy levels

VÉRONIQUE BROUSSEAU-COUTURE (Presenter), Département de physique, Université de Montréal and RQMP, Montréal, Québec, Canada, XAVIER GONZE, Institute of Condensed Matter and Nanosciences, UCLouvain, Louvain-la-Neuve, Belgium and Skolkovo Institute of Science and Technology, Moscow, Russia, MICHEL COTE, Département de physique, Université de Montréal and RQMP, Montréal, Québec, Canada — Electron-phonon (e-p) interaction calculations from first-principles are well documented in the literature. The predominance of non-adiabatic effects in the zero-point renormalization (ZPR) of the band gap for polar materials has been recently assessed in the light of the Fröhlich interaction. Yet, even for benchmark materials, spin-orbit coupling (SOC) is frequently neglected to reduce the numerical cost of calculations. SOC manifests itself in the electronic structure through the split-off energy and by lifting band degeneracies away from time-reversal invariant momenta (TRIM). This modification of the energy levels will affect both e-p coupling energies and ZPR. Materials lacking inversion symmetry also exhibit an in-plane shift of the band extrema away from the TRIM, known as Rashba splitting. This could lead to resonant couplings at finite phonon wavevectors, which will strengthen the EP coupling energies.

We explicitly compute e-p coupling energies and ZPR for binary semiconductors, using density-functional perturbation theory (DFPT), with and without SOC. We also investigate Rashba semiconductor BiTeI. We finally analyze our results in the light of a three-dimensional Fröhlich Hamiltonian, including both SOC and Rashba interaction.

4:06PM J44.00007: Anharmonicity in Zirconium Hydrides: a first-principles study combined with inelastic neutron scattering  
JIAYONG ZHANG (Presenter), North Carolina State University, YONGQIANG CHENG, ALEXANDER KOLESNIKOV, Oak Ridge National Laboratory, JERRY BERNHOLC, WENCHANG LU, North Carolina State University, ANIBAL J. RAMIREZ-CUESTA, Oak Ridge National Laboratory — Zirconium Hydrides and Deuterides are candidates for neutron moderators and fuel-rod cladding materials. We investigate anharmonic phenomena in these materials using inelastic neutron scattering (INS) and lattice dynamics calculations within the framework of density functional theory (DFT). We observe multiple sharp peaks below harmonic (free) multi-phonon bands in the experimental spectra, which do not show up in the simulated INS spectra based on the harmonic approximation. We have thus carried out a detailed study of the anharmonicity by exploring the 2D potential energy surface with DFT calculations and solving the corresponding 2D single-particle Schrödinger equation of the H/D atom in zirconium hydrides/deuterides to get the eigenfrequencies. The results describe well the experimental INS spectra, showing harmonic behavior of the fundamental modes and strong anharmonicity at higher energies. The DFT calculations were carried out with the real-space multigrid (RMG) and VASP codes, and the experimental INS spectra were measured with the VISION spectrometer at the Spallation Neutron Source, Oak Ridge National Laboratory.

4:18PM J44.00008: Phonon-induced topological phase transition in SnTe*  
JOSE D. QUERALES-FLORES (Presenter), Tyndall National Institute, Cork, Ireland, PABLO AGUADO-PUENTE, Queen's University Belfast, Belfast, UK, DORDE DANGIC, Tyndall National Institute, Cork, Ireland, JIANG CAO, Nanjing University of Science and Technology, Nanjing, China, TCHAVDAR TODOROV, MYRTA GRÜNING, Queen's University Belfast, Belfast, UK, STEPHEN B FAHY, IVANA SAVIC, Tyndall National Institute, Cork, Ireland — Unlike the topologically trivial semiconductor PbTe, SnTe has an inverted band gap at the L point that gives rise to a topological crystalline insulating phase protected by mirror symmetry [1]. In this work, we calculate the temperature renormalization of the electronic band structure of SnTe. We account for the energy shift of the electronic states due to thermal expansion, and electron-phonon interaction using the nonadiabatic Allen-Heine-Cardona formalism within density functional perturbation theory [2,3]. Corrections to the electronic band structure due to electron-electron interaction are obtained using many-body perturbation theory (GW). We capture the decrease of the direct gap with temperature yielding a temperature-induced phase transition to a topologically trivial phase at ~800 K. We find that both thermal expansion and electron-phonon interaction have a considerable effect on these temperature variations. We also analyze the temperature dependence of the electron-phonon self-energy.

Phonon renormalization and four-phonon scattering in semiconductors and insulators

NAVANEETHA KRISHNAN RAVICHANDRAN (Presenter), DAVID BROIDO, Boston College —

In semiconductors and insulators, heat is carried by phonons. Conventional ab initio methods for thermal conductivity ($k$) of materials assume that the lowest order theory of 3-phonon scattering sufficiently describes thermal transport. Here we show that this is not the case for several materials where higher-order 4-phonon scattering can significantly affect $k$. Furthermore, we show that for many naturally occurring materials, phonon scattering is so strong that not only is 4-phonon scattering important, but the underlying phonon quasiparticle picture itself can break down. To address this issue, we present a novel ab initio method that features an anharmonic many-body renormalization scheme to create well-defined phonon quasiparticles with weakened interactions, and includes both 3-phonon and 4-phonon scattering to obtain $k$ [1]. We demonstrate the method's success by comparing with experimental data of $k$ for many common semiconductors and insulators. Our work presents a unified ab initio framework to accurately predict the thermal properties of solids with varying bond strengths.

Ab-initio calculation of Seebeck coefficient of transition-metal elements

HISAZUMI AKAI (Presenter), Univ of Tokyo, SONJU KO, Tokyo Institute of Technology — Ab-initio calculation of the Seebeck coefficient $S$ of transition metal elements are performed within the framework of Kubo–Greenwood formula. The difficult points of calculating $S$ are that, firstly, at $T = 0K$, the conductivity of pure metal diverges. Second, the Fermi surfaces of transition metals composed of many different states where the constant relaxation time approximation breaks down. To overcome the difficulties, we included the effects of electron-phonon scattering in the calculation of $S$. We exploited the Korringa–Kohn–Rostoker (KKR) Green's function method combined with the Kubo–Greenwood formula. The electron-phonon scattering was taken into account through ab-initio phonon calculations and an alloy analogy applied to the local static phonons. The KKR coherent potential approximation (KKR–CPA) was used for the latter. The calculated Cu resistivity and the Seebeck coefficients for various transition-metal elements at finite temperature show reasonable overall agreements with experiments. The present approach provides us with a framework applicable to a wide range of materials, including pure metals, compounds, ordered and disordered alloys.

4:54PM J44.00011: Understanding the Restoring Force From a Local Bonding Perspective: A First-Principles Picture of Phonons and Elasticity* ETHAN RITZ (Presenter), GURU BAHADUR KHALSA, HSIN-YU KO, ROBERT DISTASIO, NICOLE A BENEDek, Cornell University — Though the calculation of bulk elastic quantities and phonon frequencies using modern ab-initio techniques is now routine, understanding the crystal chemical origins of these properties is still an open question. How do we relate the value of a specific bulk elastic constant or vibrational mode to chemically intuitive ideas about local structure and bonding, especially when our calculations are often done in a spatially delocalized Bloch basis? Using a basis of maximally localized Wannier functions, we partition the total electronic energy onto real space representations of occupied states, as well of the curvature of that energy with respect to mechanical deformations and phonon distortions. By understanding how the energy of each individual bond changes with these distortions, we can obtain orbitally decomposed, chemically specific understanding of bulk properties. We use this approach to explore various perovskite oxides, exploring the chemical origins of elasticity, structural phase transitions, Grüneisen parameters, and thermal expansion properties, and discuss the possibility of enhancing or controlling these properties.

5:06PM J44.00012: Finite temperature electronic properties of diamond and diamondoids* ARPAN KUNDU (Presenter), Pritzker School of Molecular Engineering, University of Chicago, MARCO GOVONI, Argonne National Laboratory, MICHELE CERIOTTI, Ecole polytechnique federale de Lausanne, FRANCOIS GYGI, University of California, Davis, GIULIA GALLI, Pritzker School of Molecular Engineering, University of Chicago — Accurate calculations of electron-phonon coupling are essential to predict the finite temperature (T) properties of materials and molecules, especially those containing light-atoms. We present an approach to compute electron-phonon coupling which treats the motion of ions quantum mechanically, through the use of path-integral calculations, and the electronic states at the DFT or many-body-perturbation theory (MBPT) level. In particular, we carried out simulations for diamond and diamondoids by coupling the first-principle molecular dynamics code Qbox (http://qboxcode.org) with i-PI (http://ipi-code.org), a path integral simulation package, and we obtained single-particle energy levels within MBPT using the WEST code (http://west-code.org). We present results for different cluster sizes and surface terminations and we compare the zero-temperature limit of our simulations with results recently reported for electron-phonon coupling at T=0 [1].

*Supported by the Midwest Integrated Center for Computational Materials (MICCoM) as part of the Computational Materials Sciences Program funded by DOE/BES.
The FeTi system is amenable to computational investigations due to its simple crystal structure and minimalist Fermi surface. A thermally-driven electronic topological transition that results in anomalous phonon softening was recently reported to occur in FeTi at elevated temperatures as new features appear in the Fermi surface and new spanning vectors increase electronic screening of particular phonon modes. We investigated the pressure dependence of the electronic structure and the phonon dispersions using density functional theory and uncovered an octahedral splitting with an energy difference that increases with pressure and a Kohn anomaly with a wavevector that decreases with pressure. The calculated Fe partial phonon density of states are in agreement with nuclear-resonant inelastic x-ray scattering measurements and show that the phonons stiffen at different rates.

Session J45 DCOMP GDS DSOFT DPOLY: Emerging Trends in Molecular Dynamics Simulations and Machine Learning I

Pankaj Rajak (Presenter), LCF, Argonne National Laboratory — In recent years, machine learning models based on supervised learning has shown tremendous success in materials property prediction such as band gap, elastic modules, thermo-electric properties that has accelerated the discovery of new materials. However, applicability of these supervised learning-based ML models is limited, and they cannot be used for complex tasks such as inverse design of materials structure, where the input to the ML model is desired property and the output is structure of the material. Deep leaning models based on reinforcement learning and deep generative model can be used for inverse design of materials. In particular, in this talk we will discuss about (1) designing MoS$_2$ kirigami structure with desired stretchability, (2) computational synthesis of layered materials using reinforcement learning and (3) a generative model based on graph convolution to design polymer structure with desired dielectric properties.

This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-SC0014607. An award of computer time was provided by the Innovative and Novel Computational Impact on Theory and Experiment (INCITE) program. This research used resources of the Argonne Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC02-06CH11357.
3:06PM J45.00002: Unbiasing machine learning for molecular dynamics: emphasising out-of-equilibrium geometries using clustering

GRÉGORY CORDEIRO FONSECA (Presenter), IGOR POLTAVSKYI, ALEXANDRE TKATCHENKO, University of Luxembourg — Machine learning (ML) force-fields (FF) became an increasingly popular tool in computational physics due to their speed and accuracy. By construction, ML models are often biased towards more abundant "close-to-equilibrium" states. A small mean error does not guarantee accurate prediction for rare "out-of-equilibrium" configurations, which are typically underrepresented in reference datasets.

We propose a method to train unbiased ML FF, which leads to equally accurate predictions independently of the density of training data. To achieve this, we divide datasets into smaller subsets (clusters) based on data similarities. Then, the quality of a ML model is evaluated for each individual cluster, thereby revealing problematic cases. Representative data for each problematic cluster is added to the training set, and the ML model is retrained. The improved learning process results in a flattening of the prediction errors throughout the reference data. The method is applied to molecular trajectory datasets, decreasing the largest errors of the obtained ML FF up to an order of magnitude.

3:18PM J45.00003: Challenges in developing an extremely accurate many-body force field

ELIZABETH DECOLVENAERE (Presenter), RIAN CORT KORMOS, ALEXANDER DONCHEV, JOHN L KLEPEIS, DAVID E. SHAW, D. E. Shaw Research — Our group has been working to develop a physics-motivated, generalizable model fit only to quantum chemical data that reproduces experimental values of condensed phase properties across a wide range of conditions. Developing such a model is challenging and requires better physical models and higher accuracy quantum chemical reference data than are typically used when developing force fields for molecular dynamics simulations. I will describe some of our recent work that leverages machine learning ideas to generate high-accuracy quantum chemical reference data for the fitting of two-body and many-body models. I will also outline some theoretical and practical challenges in modeling many-body interactions and show a few preliminary results on small molecules of biochemical interest.

3:30PM J45.00004: Uncertainty quantification in molecular simulations with dropout neural network potentials

MINGJIAN WEN (Presenter), University of California, Berkeley, ELLAD B. TADMOR, University of Minnesota, Twin Cities — Machine learning interatomic potentials (IPs) can provide accuracy close to that of first-principles methods, such as density functional theory (DFT), at a fraction of the computational cost. This greatly extends the scope of accurate molecular simulations, providing opportunities for quantitative design of materials and devices on scales hitherto unreachable by DFT methods. However, machine learning IPs have a basic limitation in that they lack a physical model for the phenomena being predicted and therefore have unknown accuracy when extrapolating outside of their training set. In this paper, we propose a new class of Dropout Uncertainty Neural Network (DUNN) potentials, which provide rigorous uncertainty estimates that can be understood from both Bayesian and frequentist statistics perspectives. As an example, we develop a DUNN potential for carbon and show how it can be used to predict uncertainty for static and dynamical properties including stress and phonon dispersion in graphene. In addition, we show that DUNN uncertainty estimates can be used to detect configurations outside the training set, and in some cases, can serve as a predictor for the accuracy of a calculation.
3:42PM J45.00005: Improving Fidelity and Transferability of Machine-Learned Reactive Interatomic Models Through Active Learning  REBECCA LINDSEY (Presenter), LAURENCE FRIED, NIR GOLDMAN, SORIN BASTEA, Lawrence Livermore Natl Lab — Force fields of machine-learned (ML) topography are ideal for describing complex phenomena including condensed phase chemistry, but parameterization is often challenging due to the proclivity for overfitting exhibited by high-flexibility models. Active learning provides an alternative route to robust ML model development, however there is no “one-size-fits” all solution. In this work, we present the Chebyshev Interaction Model for Efficient Simulation (ChIMES), a ML force field targeting chemistry in condensed phase systems. ChIMES models are comprised of linear combinations of Chebyshev polynomials explicitly describing many-body interactions and thus can also exhibit overfitting. We discuss development of a ChIMES active learning scheme leveraging physical intuition and Shannon information theory for systematic improvements in fidelity and transferability of resulting models.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

3:54PM J45.00006: Uncertainty quantification of classical interatomic potentials in OpenKIM database*  YONATAN KURNIAWAN (Presenter), CODY PETRIE, KINAMO JAHALI WILLIAMS, MARK TRANSTRUM, Brigham Young Univ - Provo — Interatomic models (IMs) are used in molecular modeling to predict material properties of interest. The development of a single IM can take anywhere from several months to years and relies on expert intuition, and yet these potentials are usually only valid for a particular application of interest. Extending existing IMs to new applications is an active area of research. Quantifying the uncertainty of an IM can tell us how much we can trust the predictions it makes. I compare Bayesian (Markov Chain Monte Carlo) and Frequentist (profile likelihood) methods to quantify uncertainty of IM parameters. I demonstrate these methods on Lennard-Jones and Morse potentials fit to triclinic crystal configurations from the OpenKIM database. Results indicate that these models are "sloppy" in some of their parameters, i.e., likelihood surfaces have long, narrow canyons and broad, flat plateaus. I discuss the relative strenghts and weaknesses of each approach.

*This work is supported by the NSF under award CMMT-1834332.

4:06PM J45.00007: Molecular dynamics density and viscosity simulations of alkanes  PAVAO SANTAK (Presenter), GARETH CONDUIT, Univ of Cambridge — We use molecular dynamics to study liquid density of small branched alkanes and kinematic viscosity of linear alkanes. The density models compare well to experimental values, with an average absolute deviation of 3.38 g/l. We run non-equilibrium molecular dynamics simulations for viscosity to explore its shear rate profile, which is used to extrapolate Newtonian viscosity. We develop a new method to systematically identify the range of shear rates at which the simulations are performed. We compare our models of linear alkanes as a function of temperature and pressure with experimental values, obtaining an average percent error of -1.1%.
Study of the microstructure of amorphous silicon and its effect on Li transportation with neural network potential*  

WENWEN LI (Presenter), YASUNOBU ANDO, AIST — The machine learning-based simulation methods have attracted much attention recently. In this talk, neural network (NN) potential is used to study Li diffusion mechanism in amorphous silicon (α-Si).

The structure and property of the experimental α-Si sample are significantly affected by the experimental fabrication method. In this work, the NN potential was used to generate a series of atomic structures of α-Si with different degrees of disorder. By systematically comparing various structural and vibrational properties with experiments, we can determine the corresponding theoretical model for experimental samples prepared with a certain method.[1]

The kinetics of Li diffusion in α-Si is one of the most important issues for its performance as the anode of lithium-ion battery. The effect of structural order on Li diffusion behavior is investigated with NN potential. We found that Li transportation needs higher activation energy in the highly disordered α-Si matrix. The result can be explained with the “trap” mechanism.

*Our works presented in this talk were supported by a project (No. P16010) commissioned by the New Energy and Industrial Technology Development Organization (NEDO).

Relative entropy indicates an ideal concentration for structure-based coarse graining of binary mixtures*  

DAVID ROSENBERGER (Presenter), Los Alamos National Laboratory, NICO F. A. VAN DER VEGT, Chemistry, TU Darmstadt — Many methodological approaches have been proposed to improve systematic or bottom-up coarse-graining techniques to enhance the representability and transferability of the derived interaction potentials. Here, we shift the focus away from methodological aspects and rather raise the question whether we can overcome the disadvantages of a given method in terms of representability and transferability by systematically selecting the state point at which the CG model gets parametrized. We answer this question by applying the inverse Monte Carlo (IMC) approach—a structure-based coarse-graining method—to derive effective interactions for binary mixtures of simple Lennard-Jones (LJ) particles, which are different in size. For such simple systems we indeed can identify a concentration where the derived potentials show the best performance in terms of structural representability and transferability. This specific concentration is identified by computing the relative entropy which quantifies the information loss between different IMC models and the reference LJ model at varying mixture compositions.

*Financial support is granted by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) through Project No.233630050-TRR 146.
4:42PM J45.00010: Exploring, fitting, and characterizing the configuration space of materials with multiscale universal descriptors  NOAM BERNSTEIN (Presenter), United States Naval Research Laboratory, VOLKER L DERINGER, Department of Chemistry, University of Oxford, GÁBOR CSÁNYI, Department of Engineering, University of Cambridge — Descriptors of the environment of an atom in a material give a similarity metric between different structures. We present a universal set of multiscale Smooth Overlaps of Atomic Position (SOAP) parameters that can be used for a wide range of purposes. For each atom type these consist of two or more SOAP expansions of the smoothed atomic neighbour density with cutoffs (and proportionately scaled smoothness parameters) related by a constant factor, covering bond lengths from the shortest to the longest expected for that species in the system. These descriptors can be used as part of an automatic interatomic potential generation process by combining iterated random structure search (RSS) with Gaussian Approximation Potential (GAP) fitting. We show results from the GAP-RSS process for elemental and multicomponent systems, as the procedure simultaneously explores and fits a wide range of structures. The descriptors can also be used in the context of characterization of large sets of configurations. As an example, we show the results of large scale and long time simulations such as quenching of a liquid into an amorphous structure, and the relation between the fitting data set of a potential and the configurations that occur in tests of physically meaningful material properties.

4:54PM J45.00011: Predictive Atomistic Simulations of Materials using SNAP Data-Driven Potentials  AIDAN THOMPSON (Presenter), MITCHELL WOOD, MARY ALICE CUSENTINO, JULIEN TRANCHIDA, Computational Multiscale, Sandia National Laboratories, NICHOLAS LUBBERS, Computer Computational Statistical Sciences, Los Alamos National Laboratory, STAN MOORE, Computational Multiscale, Sandia National Laboratories, RAHUL GAYATRI, Application Performance, NERSC, Lawrence Berkeley National Laboratory — Molecular dynamics (MD) is a powerful materials simulation method whose accuracy is limited by the interatomic potential (IAP). SNAP is an automated methodology for generating accurate and robust application-specific IAPs. SNAP is formulated in terms of a set of general four-body geometric invariants that characterize the local neighborhood of each atom. This approach has been used to develop potentials for diverse materials, including metals (Ta, W), metal alloys (AlNbTi), III-V semiconductors (InP), and plasma-facing materials (W/Be/He/H/N). Each SNAP IAP is trained on DFT calculations of energy, force, and stress for many small configurations of atoms. Cross-validation analysis and evaluation on test problems are used to further improve IAP fidelity and robustness. Varying the number of geometric descriptors allows a continuous tradeoff between computational cost and accuracy. The resultant potentials enable high-fidelity MD simulations of these materials, yielding insight into their behavior on lengthscales and timescales unreachable by other methods. The relatively large computational cost of SNAP is offset by combining LAMMPS' spatial parallel algorithms with Kokkos-based hierarchical multithreading, enabling the efficient use of Peta- to Exa-scale CPU and GPU platforms.
5:06PM J45.00012: Accurate and Data-Efficient Machine Learning Force Fields for Periodic Systems  
LUIS GÁLVEZ-GONZÁLEZ (Presenter), Programa de Doctorado en Ciencias (Física), Universidad de Sonora, HUZIEL SAUCEDA, STEFAN CHMIELA, Machine Learning Group, Technische Universität Berlin, ALVARO POSADA-AMARILLAS, Departamento de Investigación en Física, Universidad de Sonora, LAURO OLIVER PAZ-BORBÓN, Instituto de Física, Universidad Nacional Autónoma de México, KLAUS-ROBERT MÜLLER, Machine Learning Group, Technische Universität Berlin, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg — It remains a substantial challenge to develop machine learning force fields that combine accuracy, efficiency, and physical interpretability, especially for complex periodic systems. In this work, we present an extension of the symmetrized gradient-domain machine learning (sGDML) framework [1][2] for periodic systems, which allows the construction of accurate molecular force fields with high data efficiency. We test this implementation in a variety of systems, including 2D materials, bulk materials and surfaces, for which we achieved errors of less than 1 kcal/mol/Å for atomic forces using less than 100 training points. Furthermore, in the particular case of graphene this error was achieved training on 20 samples. The low errors from sGDML calculations on phonon dispersion relations and thermodynamic properties compared to those obtained directly from DFT further confirm the predictive power of the model. These results extend the applicability of machine learning to increasingly complex periodic materials.

5:18PM J45.00013: Phase diagrams of nuclear pasta phases in neutron star matter  
JORGE MUNOZ (Presenter), JORGE ALBERTO LOPEZ, University of Texas, El Paso — Neutron stars are the remnants of the supernova explosion of a massive stars and gravitational collapse and have densities that approach that of atomic nuclei. Nuclear pasta is a theoretical type of nuclear matter that is hypothesized to exist within their core. We performed classical molecular dynamics simulations with modified Pandharipande potentials at temperatures from 0.2 to 4 MeV, densities from 0.04 to 0.08 nucleons/fm3, and proton fraction from 0.1 to 0.5. We built a dataset of configurations by selecting 9,600 uncorrelated instants from the simulations and calculated the Minkowski functionals (volume, surface, integral mean curvature, and Euler characteristic) from which the phase of the nuclear pasta at each instant can be determined. We then used the dataset to train a neural network that allowed us to build phase diagrams for nuclear pasta phase similar to those that are used in traditional materials research.

Session J46 GMAG: Single Molecule Magnets  
708 - Selvan Demir, Michigan State Univ -  
Tag(s): Focus
2:30PM J46.00001: The power of typicality applied to magnetic molecules and low-dimensional quantum spin systems* [Invited] JUERGEN SCHNACK (Presenter), Univ Bielefeld — Molecular or low-dimensional quantum spin systems often prevent an exact calculation of their magnetic properties due to a prohibitively large size of the related Hilbert spaces. Typicality-based approaches such as the finite-temperature Lanczos method allow to investigate rather large systems with unprecedented accuracy. This way quantum critical as well as magnetocaloric properties of large cyclic clusters could be elucidated. For the kagome lattice antiferromagnet it became possible to model a lattice of size N=42 (!) quasi exactly. This enabled us to study in particular that the low-lying density of singlet states moves up in energy contrary to common believe. In addition, we could demonstrate for lattices up to 72 sites that magnon crystallization occurs slightly below the saturation field, an effect driven by the existence of flat energy bands.

*Computing time at the Leibniz Center in Garching (Germany) is gratefully acknowledged.

3:06PM J46.00002: Effect of substrate on characteristics of the Mn₃ dimer* ZAHRA HOOSHMAND (Presenter), RAINIER BERKLEY, TALAT S. RAHMAN, Department of Physics, University of Central Florida — Single-molecule magnets (SMMs) are considered candidates for next generation information technology. These molecules possess high spin and their ground states can be tuned. The Mn₃ dimer is such an example in which the Mn₃ triangles are connected via linkers to form either the ferromagnetic (FM) or the antiferromagnetic (AFM) ground state. One challenge for SMMs is finding a suitable substrate that keeps their magnetic properties intact. We present results of our spin-polarized density functional theory calculations of the adsorption and interactions of Mn₃ dimers on graphene and monolayer hexagonal boron nitride (h-BN). We show that while graphene is benign, h-BN has interesting interaction with the SMMs. We compare the effect of these two substrate on the magnetic properties and electronic structure of the Mn₃ dimers. We also show that charge corrections need to be accounted for in the calculations for reliable description of the isolated as well as supported Mn₃ dimers. Results will be compared with available and ongoing experimental results.

*This work is supported by DOE-DE-SC0019330.
A DFT Study of Single-Molecule Magnets (Mn$_3$ Dimers)*

RAINIER BERKLEY
(Presenter), ZAHRA HOOSHMAND, Physics, Univ of Central Florida, JIE-XIANG YU, HAI-PING CHENG, Physics, University of FL, TALAT RAHMAN, Physics, Univ of Central Florida — Single-molecule magnets (SMMs) have become of increasing interest for magnetic technology. This is due to their many quantum phenomena and the ability to modify their structure and magnetic properties. It is thus important that SMM properties be characterized; thus, two configurations of the Mn$_3$ dimer ferromagnetic (FM) and antiferromagnetic (AFM) have been studied via Density Functional Theory (DFT). Our calculations for the total spin of the FM (S = 12) and AFM (S = 0) configurations of the isolated dimers, agrees with the experimental spin results per monomer (S = 6)\(^1\) only when the dimers are charged (+2) (similar to molecules in solvent). This charge issue brings about long range jellium effects which have to be corrected in DFT. Our results shed insight into the differences between the magnetic anisotropy, magnetic coupling constants and the spin for both the neutral and the charged (+2) versions of the FM and AFM dimer as a comparison. The application of the Makov-Payne method, for charge corrections, results in very small changes to the magnetic anisotropy and the magnetic coupling constants for both charged version of the Mn$_3$ dimers.

Atomic-clock transition behavior in a Cr$_7$Mn molecular nanomagnet*

GAJADHAR JOSHI, ILIJA NIKOLOV, GUANCHU CHEN, Amherst College, DANIEL SAVA, GRIGORE TIMCO, RICHARD WINPENNY, Department of Chemistry, University of Manchester, JONATHAN FRIEDMAN (Presenter), Amherst College — A clock transition (CT) occurs at an avoided level crossing where the transition frequency is independent on the magnetic field. Enhancement of $T_2$ has been observed at clock transitions in some molecular nanomagnets, suggesting these systems as viable spin qubits [1,2]. The study of such systems can elucidate the mechanisms of decoherence since spin-spin interactions are suppressed at CT. A CT is observed in the $S = 1$ molecular magnet Cr$_7$Mn with pulsed electron-spin resonance. The Carr-Purcell Meiboom-Gill (CPMG) pulse sequence in dilute samples of Cr$_7$Mn increases $T_2$ more than an order of magnitude over that obtained with a Hahn echo sequence, indicating that a significant decoherence mechanism arises from fluctuations that are slower than the delay between the CPMG pulses (~1 us). We also observe electron spin echo envelope modulation (ESEEM) at fields slightly away from the zero-field avoided crossing. Remarkably, CPMG provides a significant enhancement to $T_2$ when the pulse period matches the ESEEM period, suggesting that CPMG dynamically decouples the molecular and the nuclear spins.

Chemical Approaches to Quantum Information Science

Stephen Von Kugelgen, Daniel Laorenza, Northwestern University, Joseph Zadrozny, Chemistry, Colorado State University, Chung-Jui Yu, Danna Freedman (Presenter), Northwestern University — Synthetic chemistry enables us to build up systems from the bottom up with angstrom scale precision. We harness this precise synthetic control towards the emerging challenge of quantum information science (QIS), in which we are creating and understanding qubits, the smallest unit of a QIS system. Our approach enables fundamental insight into the factors that contribute to electronic spin decoherence, the creation of qubits with millisecond coherence times, and the creation of arrays of qubits. These results and others will be described.

The muon-fluorine interaction: a model quantum system for exploring decoherence

Stephen Blundell (Presenter), John Wilkinson, Physics, University of Oxford, Franz Lang, ISIS, STFC, Tom Lancaster, Physics, University of Durham — In non-magnetic fluorides, an implanted muon will stop very close to the highly electronegative fluoride ion, or very often stop between two of them. The dipolar interaction between the fluorine nuclei spins and the muon spin gives rise to a characteristic signature which characterises the state. The remaining fluorine nuclei are more distant and usually ignored, since their coupling to the muon is weaker. We show that taking them properly into account allows one to model the data in greater quantitative detail, understand the stopping site more accurately, and explore how the quantum information held by the state decoheres into its environment.

We thank EPSRC (UK) for funding.

Decoherence of Molecular Qubits: Insights From Quantum Many-Body Simulations

Jia Chen, University of Florida, Cong Hu, University of Connecticut, John Stanton, Hai-Ping Cheng, Xiaoguang Zhang (Presenter), University of Florida — Quantum properties of magnetic molecules will drive their applications in quantum information science. Electron spin decoherence time in such molecules depends strongly on molecular structure. A synthetic study of a series of vanadyl molecular qubits by Danna Freedman’s group found that the decoherence time decreases as size of molecule increases. To explain this counterintuitive experimental result and provide insights for decoherence in molecular qubits in general, we combine ab-initio electronic structure calculations and quantum many-body simulation to study hyperfine interactions between electron and hydrogen nuclear spins and their effects on electron spin decoherence. We show that, for an isolated molecule, decoherence is always incomplete, but the residual coherence decreases as the size of the molecule increases. This result explains the experimentally observed diffusion barrier for decoherence, also suggests a quantitative approach to connect molecular structure and diffusion barrier.

This work was supported as part of the Center for Molecular Magnetic Quantum Materials (M2QM), an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0019330.
Counterintuitive Control of Molecular Magnetic Relaxation via Chemically Tunable Electron-Spin Baths  
IAN MOSELEY, JOSEPH ZADROZNY (Presenter), Colorado State Univ — Magnetic molecules are critical components in current and next generation applications in molecular imaging and information processing. Toward functionality in these applications, long spin-lattice and spin-spin relaxation times are desired. However, most magnetic molecules display fast relaxation times when in the presence of a magnetic environment. Bioimaging and information storage environments are nuclear and electron spin-rich. Hence, we need to understand how to design long relaxation times in highly magnetic environments. This presentation will detail our efforts toward that knowledge by studying the spin-bath-to-molecule interaction via molecular chemistry and magnetic analysis. Specifically, we will discuss the response of the relaxation times in a set of cobalt-containing molecules to a chemically tunable magnetic environment as determined by electron spin resonance and alternating current magnetic susceptibility. In the long term, these fundamental studies will deliver design principles for molecules with long relaxation times in magnetically chaotic environments.

Investigating the Magnetic Properties of the Giant Mn$_{84}$ Torus*  
DIAN-TENG CHEN (Presenter), Department of Physics and Quantum Theory Project, University of Florida, ASHLYN HALE, GEORGE CHRISTOU, Department of Chemistry, University of Florida, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — The giant single-molecule magnet Mn$_{84}$ has a shape of torus of eighty-four Mn$^{3+}$ ions ($S=2$). As the manganese atoms in Mn$_{84}$ are all bridged by O$_2^-$ or MeO$^-$ groups, strong pairwise exchange interactions between these manganese atoms are expected. Even though the magnetic susceptibility of this system has been measured experimentally, its electronic-magnetic structure and spin-spin couplings remain unknown. In this work, we investigate these interactions using first-principles calculations, from which a Heisenberg model is developed. The exchange coupling constants are extracted by fitting to the total energies of different spin configurations of Mn$_{84}$. In addition, we compute the magnetic anisotropy energy by including spin-orbital couplings.

*This work was supported by the US Department of Energy's EFRC program under Grant No. DE-SC0019330.
5:06PM J46.00010: Adjustable coupling and in-situ variable frequency probe with loop-gap resonators for cw and pulse electron paramagnetic resonance spectroscopy up to X-band*

GAJADHAR JOSHI (Presenter), JAMES KUBASEK, ILIJA NIKOLOV, BRENDAN SHEEHAN, Amherst College, THOMAZ DE ANDRADE COSTA, R. A. ALLÃO CASSARO, Instituto de Quimica, Universidade Federal do Rio de Janeiro, JONATHAN FRIEDMAN, Amherst College — In standard electron paramagnetic resonance (EPR) spectroscopy, the frequency of an experiment is set and the spectrum is acquired using magnetic field as the independent variable. There are cases in which it is desirable instead to fix the field and tune the frequency such as when studying atomic-clock transitions at avoided level crossings in molecular nanomagnets and other spin qubits [1,2,3]. We have designed and tested an adjustable frequency and variable coupling EPR probe with loop-gap resonators (LGRs) that works at a temperature down to 1.8 K [4]. The frequency is tuned by adjusting the height of a dielectric piece of sapphire inserted into the gap of an LGR; coupling of the microwave antenna is varied with the height of the antenna above the LGR. We demonstrate the operation of our probe with continuous wave EPR by mapping out avoided crossings for the Ni₄ single-molecule magnet to determine the tunnel splittings with high precision.

*Supported by NSF under Grant No. DMR-1708692, and by the Amherst College Dean of Faculty. R. A. Allão Cassaro thanks FAPERJ and CNPq for support.

5:18PM J46.00011: A Very-Low-Cost Flexible Electron Spin Resonance Spectrometer for Molecular Nanomagnet Experiments*

CHARLES COLLETT (Presenter), Department of Physics, Muhlenberg College, Allentown, PA 18104, USA, JONATHAN FRIEDMAN, Department of Physics & Astronomy, Amherst College, Amherst, MA 01002, USA — Electron spin resonance (ESR) spectroscopy is a useful tool for exploring and manipulating a wide variety of systems, including molecular nanomagnets. Commercial spectrometers offer high sensitivity in specific frequency bands, but are both expensive and limited in their experimental flexibility. We have developed an ESR spectrometer based on a cheap and readily-available field-programmable gate array (FPGA), which, when combined with loop-gap resonators (LGRs), enables spectroscopy on a budget at a wide range of frequencies. I will present the spectrometer design along with benchmark results demonstrating its sensitivity and flexibility with two different combinations of cryostat and magnet, and discuss future experiments on molecular nanomagnets.

*Work supported by U. S. National Science Foundation under Grant Nos. DMR-1310135 and DMR-1708692, and the Muhlenberg College and Amherst College Deans of Faculty.
2:30PM J47.00001: Understanding the Magnetic-Field Anisotropy of Kitaev Materials
AHMED RAYYAN (Presenter), JACOB GORDON, HAE-YOUNG KEE, Univ of Toronto — The Kitaev spin liquid remains the most theoretically well-understood quantum spin liquid due to the exact solvability of the Kitaev model. However, other interactions such as the off-diagonal spin interactions render the model non-integrable, but give rise to the magnetic order seen at low temperatures in candidate materials. Recently it was shown that when a magnetic field is applied along a certain direction, the magnetic order melts into an intermediate-field phase before the spins are fully polarized. A thorough understanding of the interplay between field and spin exchange anisotropy is required to understand field-induced phases. To this end, we present the classical and quantum phase diagrams of the extended anisotropic Kitaev model under different magnetic field directions.

2:42PM J47.00002: Majorana-magnon crossover by a magnetic field in the Kitaev model*
YUKITOSHI MOTOME (Presenter), JUNKI YOSHITAKE, Department of Applied Physics, The University of Tokyo, JOJI NASU, Department of Physics, Yokohama National University, YASUYUKI KATO, Department of Applied Physics, The University of Tokyo — Kitaev quantum spin liquids host Majorana fermions via the fractionalization of spins. In a magnetic field, the Majorana fermions were predicted to comprise a topological state with anionic excitations, which has attracted great attention by the recent discovery of the half-quantized thermal Hall conductivity. Nevertheless, a reliable theory remains elusive for the field effect, especially at finite temperature. Here we present unbiased large-scale numerical results for the Kitaev model in a wide range of magnetic field and temperature, obtained by continuous-time quantum Monte Carlo simulations. We find that the unconventional paramagnetic region showing fractional spin dynamics extends at finite temperature, far beyond the field range where the topological state is expected at zero temperature. Our results show the confinement-deconfinement behavior between the fractional Majorana excitations and the conventional magnons.

*This work is supported by Grant-in-Aid for Scientific Research under Grant No. JP16H02206, JP18H04223, JP18K03447, and JP19K03742, and by JST CREST (JP-MJCR18T2).

2:54PM J47.00003: Spin-one Kitaev model, same but different?
ILIA KHAIT (Presenter), HAE-YOUNG KEE, YONG-BAEK KIM, Univ of Toronto — We study various properties of the spin-one Kitaev model on honeycomb lattices consisting of two and three-leg ladder geometries using density matrix renormalization group. We discuss similarities to the spin-half model, and outline differences. Our results suggest that the spin-one model is a bona fide spin liquid candidate.
3:06PM J47.00004: Vacancy-induced Low-energy States in the Kitaev Model* WEN-HAN KAO (Presenter), School of Physics and Astronomy, University of Minnesota, JOHANNES KNOLLE, Department of Physics, Technical University of Munich, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, NATALIA PERKINS, School of Physics and Astronomy, University of Minnesota — Since 2006, the Kitaev honeycomb model has attracted significant attention due to the exactly solvable spin-liquid ground state with fractionalized Majorana excitations [1] and the possible materialization in magnetic Mott insulators with strong spin-orbit couplings [2]. Recently, the 5d-electron compound H$_3$LiIr$_2$O$_6$ has shown to be a strong candidate of Kitaev physics considering the absence of long-range ordered magnetic state [3]. In this work, we demonstrate that a finite density of random vacancies gives rise to a remarkable pile up of low-energy states and possibly explains the experimental findings in H$_3$LiIr$_2$O$_6$. We study both the free-flux and the vacancy-induced bound-flux background and their responses to additional time-reversal symmetry-breaking term, which imitates the magnetic field in real experiments.

*We acknowledge the US Department of Energy, Office of Science, Basic Energy Sciences under Award No. DE-SC0018056.

3:18PM J47.00005: Field induced phases of the Kitaev-Γ ladder* ERIK SORENSEN (Presenter), Physics, McMaster University, ANDREI CATUNEANU, JACOB GORDON, HAE-YOUNG KEE, Physics, University of Toronto — The Kitaev spin model on honeycomb lattice has attracted significant attention since the emergence of α-RuCl$_3$ as a promising Kitaev spin liquid candidate in the presence of a magnetic field. While the mechanism of such a field-induced Kitaev spin liquid is not yet fully understood, theoretical studies have shown that the bond-dependent Γ and Kitaev interactions are equally significant in α-RuCl$_3$ leading to a minimal spin-$\frac{1}{2}$ Kitaev-Γ (KG) model. In the pure antiferromagnetic Kitaev limit, previous numerical studies have shown gapless states for a range of intermediate field strengths, leading to the suggestion of a U(1) spin liquid phase. However, a possibility of incommensurate magnetic orderings cannot be excluded. Employing large-scale numerical techniques, we study the KG model in a two-leg ladder system in the presence of a magnetic field for the entire phase space of the KG model, finding both disordered and incommensurate ordered phases near the antiferromagnetic Kitaev region. We discuss the models limitations and relation to the two-dimensional honeycomb lattice.

*Supported by NSERC of Canada, SHARCNET (www.sharcnet.ca) and Compute Canada (www.computecanada.ca)
3:30PM J47.00006: Field-Driven Phenomena in 2-d and 3-d Kitaev Magnets*  CIARAN HICKEY (Presenter), SIMON TREBST, University of Cologne, MATTHIAS GOHLKE, Okinawa Institute of Science and Technology, CHRISTOPH BERKE, University of Cologne — Kitaev's honeycomb model is an exactly solvable spin model that realises a quantum spin liquid ground state, with fractionalised excitations in the form of Majorana fermions and plaquette flux excitations. Recent studies have shown that applying an external magnetic field can give rise to a rich set of field-driven phenomena, including the appearance of a gapless U(1) spin liquid. However, the Kitaev model is not unique to the honeycomb lattice, the model can in fact be defined, and exactly solved, on a range of tri-coordinated lattices in two and three dimensions. This naturally provides an enormous playground within which to study field-driven phenomena in quantum spin liquids. We will discuss a number of examples and construct a generic phase diagram for the Kitaev model in the presence of a magnetic field.

*We acknowledge support from the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation), Projektnummer 277101999 – TRR 183 (project B01).

3:42PM J47.00007: Magnetic Field Induced Competing Phases in Spin-Orbital Entangled Kitaev Magnets*  LI ERN CHERN (Presenter), Univ of Toronto, RYUI KANEKO, HYUN-YONG LEE, Institute for Solid State Physics, University of Tokyo, YONG-BAEK KIM, Univ of Toronto — There has been a great interest in magnetic field induced quantum spin liquids in Kitaev magnets after the discovery of neutron scattering continuum and half quantized thermal Hall conductivity in the material $\alpha$-RuCl$_3$. In this work, we provide a semiclassical analysis of the relevant theoretical models, which enable us to treat large system sizes approximating the thermodynamic limit. We find a series of competing magnetic orders with fairly large unit cells at intermediate magnetic fields, which are mostly missed by previous studies. We show that quantum fluctuations are typically strong in these large unit cell orders, while the spin wave dispersion resembles a scattering continuum. The huge quantity of magnon bands with finite Chern numbers also gives rise to an unusually large thermal Hall conductivity. Given the highly frustrated nature of the spin model, the large unit cell orders are likely to melt into the putative spin liquid in the quantum limit. Our work provides an important basis for a thorough investigation of emergent spin liquids and competing phases in Kitaev magnets. [arXiv:1905.11408]

Numerical Studies of the Kitaev-Gamma Model Under a Magnetic Field

Recently, there has been excitement generated around α-RuCl$_3$ as a candidate for the material realization of the Kitaev spin liquid (KSL). Beyond the dominant ferromagnetic (FM) Kitaev interaction, subleading spin interactions are required to explain the zig-zag (ZZ) magnetic ordering and behaviour of α-RuCl$_3$ under a magnetic field. On the basis of exact diagonalization (ED) and DMRG, an antiferromagnetic (AFM) Gamma interaction was found to be essential for stabilizing the KSL under tilted magnetic fields. A subsequent classical study of the Kitaev-Gamma model found a multitude of large unit cell magnetic orders due to the competition between Gamma and the applied field. Furthermore, an infinite tensor product state (iTPS) study found that these classical orders are melted by quantum fluctuations, giving way to two nematic paramagnetic states. The topological nature of these nematic phases and their relation to the KSL remain unknown. Here we present results obtained with ED to address these open questions.

This work was supported by the Natural Sciences and Engineering Research Council of Canada, and the Center for Quantum Materials at the University of Toronto.

Vison crystals in an extended Kitaev model on the Honeycomb lattice

I will introduce an extension of the Kitaev honeycomb model by including four-spin interactions that preserve the local gauge structure and hence the integrability of the original model. This extended model emerges naturally from generic time reversal invariant perturbations to the Kitaev honeycomb model. The model has a rich phase diagram containing five distinct vison crystals, as well as a symmetric -flux spin liquid with a Fermi surface of Majorana fermions and a sequence of Lifshitz transitions. We will discuss possible experimental signatures of the different phases, including finite-temperature Monte Carlo calculations of the specific heat and the static vison structure factor. Finally, we will see how different topologically ordered Z$_2$ quantum spin liquids with abelian and non-abelian anyons emerge naturally from this model, complementing the liquids with Chern numbers equal to 0, 1 and -1 that appear in the Kitaev honeycomb model.

Partitioning the phase diagram of pyrochlore and Kitaev magnets using graph theory

Highly frustrated magnets host rich exotic states of matter such as spin liquids and hidden orders. Those phases can occur in various forms and are notoriously difficult to identify. In this talk, I will show that the combination of a kernel method and graph partitioning theory provides an efficient framework to unravel the complex phase diagram of frustrated magnets. It delimits regimes of both classical spin liquids and broken symmetry phases, including hidden orders, and provides the analytical order parameters and/or characteristic local constraints. The method is demonstrated by examples of pyrochlore and Kitaev magnets but applies to general (semi-)classical spin systems.
4:54PM J47.00011: Quantum Spin Liquid and Proximate Magnetic Orders in Magnets with Spin-Orbit Coupling*  ANIMESH NANDA (Presenter), International Centre for Theoretical Sciences, Tata Institute of Fundamental Research, Bangalore, India, KUSUM DHUCHAR, Department of Physics, Indian Institute of Technology Palakkad, India, SUBHRO BHATTACHARJEE, International Centre for Theoretical Sciences, Tata Institute of Fundamental Research, Bangalore, India — Quantum phase transitions out of magnetic orders in quantum spin liquid (QSL) phases have gained much recent attention in the context of several spin-orbit coupled magnets such as α-RuCl$_3$, Yb$_2$Ti$_2$O$_7$ etc. In this talk, I shall report our theoretical calculations about the nature of such unconventional phase transition in a class of experimentally relevant Hamiltonians in the honeycomb magnets. In particular, we shall show how such deconfined quantum phase transitions are naturally captured in terms of the condensation of the fractionalised excitations of the QSL. In addition, we shall show how to think about such transitions in terms of the domain walls of the magnetically ordered phases.

Session J48 DCMP: Superconductivity: Nickelates  Mile High Ballroom 1A - Bing Lv, University of Texas at Dallas

2:30PM J48.00001: The Superconducting Phase Diagram of the Infinite-Layer Nickelates*  DANFENG LI (Presenter), BAI YANG WANG, KYUHO LEE, MOTOKI OSADA, Stanford University, BERIT GOODGE, LENA FITTING KOURKOUTIS, Cornell University, HAROLD HWANG, Stanford University — The recently discovered superconducting infinite-layer nickelate, Nd$_{0.8}$Sr$_{0.2}$NiO$_2$ [1], provides an additional platform of studying the physics of the high-$T_c$ superconductors in a cuprate-like system. The possible similarities and differences in the electronic structure to cuprates have been debated and attracted a lot of interest. One particular question among them is whether there is a “dome-shape” in the superconducting phase diagram of this new superconductor upon varying the Sr doping, analogous to that of cuprates. Here, we present a first study of such doping dependence of transition temperatures, lattice spacings as well as transport properties, to which controlling the crystallinity and nickel oxidation state across different dopings by our approaches to materials synthesis appears to be essential.

2:42PM J48.00002: Efforts to Synthesize Bulk Superconducting Infinite-Layer Nickelates: R$_3$Ni$_3$O$_7$ and Other Phases Prepared by Hydrogen Reduction of RNiO$_3$**

GREGORIO PONTI (Presenter), QUINN D. B. TIMMERS, ZACHARY P. KUKLINSKI, JOHN MARKERT, Department of Physics, University of Texas at Austin — Recently, superconductivity in a nickelate was reported$^1$ in an apparently hole-doped RNiO$_2$ (“infinite-layer”) film (with $R \approx$ Nd$_{0.8}$Sr$_{0.2}$), after CaH$_2$ reduction. We have prepared both parent and electron- and hole-doped specimens of the bulk, nearly simple-perovskite RNiO$_3$ structures: $R_{1-x}A_x$NiO$_3$ [$R = \text{Nd, Pr, (La,Y)}; A = \text{Sr, Ce, Th}$] using high oxygen pressure (200 bar) at high temperatures ($T \approx$1000°C). We reduced these phases in several ways in an effort to produce bulk infinite-layer materials. For reduction in 5% H$_2$ in Ar, and for $T >$ 400°C, we find excess reduction to pure metal(s) or elemental oxides. But for temperatures in the range 300–375°C (reduction times of hours), we have synthesized a number of nickelate structures in bulk, dense form, suitable for transport and other measurements. One product is the “337” structure: R$_3$Ni$_3$O$_7$. X-ray diffraction, electrical resistivity, magnetic, and other data indicate that $n$-doping (Ce$^{4+}$) induces structural and electronic changes in the 337 material, and thus may provide an alternative path to “Ni$^{2+}$/Ni$^{1+}$” superconductivity. We also report other product phases and, thus, a rich reduced-nickelate phase diagram.

$^1$D. Li et al., Nature 572, 624 (2019).

**Support: University of Texas, College of Natural Sciences Freshman Research Initiative
Superconductivity was recently discovered in the infinite-layer nickelate Nd$_{0.8}$Sr$_{0.2}$NiO$_2$.\textsuperscript{1} To proceed with further systematic studies in the superconducting properties of this material, it is important to establish a reproducible method to synthesize single-phase, single-crystalline Nd$_{0.8}$Sr$_{0.2}$NiO$_2$. The synthetic route to this infinite-layer nickelate structure poses two major challenges. First, the precursor perovskite phase is difficult to stabilize due to the unusually high formal nickel valence of Ni$^{+3.2}$ and the structural instability induced by chemical doping. Second, topochemical reduction on perovskite nickelates have shown limitations in coherent transition to the infinite-layer phase.\textsuperscript{2}

After careful optimization, we have successfully established a reproducible method to stabilize Nd$_{0.8}$Sr$_{0.2}$NiO$_2$ (001) epitaxial thin films on SrTiO$_3$ (001) substrate by pulsed-laser deposition and CaH$_2$-assisted topochemical reduction. The details of the optimization process and the dependence of structural and superconducting properties on growth conditions will be discussed.

3:06PM J48.00004: A superconducting praseodymium nickel oxide with infinite-layer structure*  
MOTOKI OSADA (Presenter), BAI YANG WANG, DANFENG LI, KYUHO LEE, Stanford University, BERIT GOODGE, LENA FITTING KOURKOUTIS, Cornell University, HAROLD HWANG, Stanford University — Nickel oxide compounds, which are analogous to copper oxides, have been intensively investigated in the past decades since the discovery of high-$T_c$ superconductivity in copper oxides. The recent discovery of superconductivity in a neodymium nickel oxide of infinite-layer structure suggests the possible existence of a family of superconducting nickel oxide. Here, we present the synthesis of an infinite-layer praseodymium nickel oxide by topochemical reduction of the precursor perovskite thin films using calcium hydride as reagent. We report the observation of superconductivity with $T_c$ of 9-12 K in such compound upon doping with strontium, Pr$_{0.8}$Sr$_{0.2}$NiO$_2$. Details of the materials synthesis of the infinite-layer structure, measurements on temperature-dependence of resistivity and Hall coefficient will be discussed in this presentation.

3:18PM J48.00005: Atomic Lattice and Electronic Structure of Superconducting Nickelate Thin Films*  
BERIT GOODGE (Presenter), Cornell University, DANFENG LI, KYUHO LEE, MOTOKI OSADA, BAI YANG WANG, HAROLD HWANG, Stanford University, LENA FITTING KOURKOUTIS, Cornell University — The recent discovery of superconductivity in Sr-doped NdNiO$_2$ is an important development for condensed matter physics [1]. Nominally similar in structure to the infinite-layer cuprate superconductors, the nickelates present a complementary platform for investigating the underlying physical mechanisms driving superconductivity in these systems. The stabilization of superconducting samples is, however, as yet limited to thin film geometries, raising the importance of spatially localized characterization techniques capable of probing only the regions of interest without contributions from the substrate. Here, we harness the high spatial and energy resolution achieved with scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS) to explore both the lattice and electronic structure of these superconducting thin films. Structurally, the effects of different growth parameters are explored across several films within the nickelate series. Electronically, we investigate possible similarities to the cuprate superconductors.

*This work is supported by DOD AFOSR (FA 9550-16-1-0305), DOE BES MSD (DE-AC02-76SF00515), and the Moore Foundation (GBMF4415).
3:30PM J48.00006: In Situ Synchrotron X-ray Studies of Nickelate Growth and Reduction*

YAN LI (Presenter), XI YAN, Materials Science Division, Argonne National Laboratory, ZHAN ZHANG, Advanced Photon Source, Argonne National Laboratory, HUA HUAN WANG, Institute of High Energy Physics, Chinese Academy of Sciences, HUA ZHOU, Advanced Photon Source, Argonne National Laboratory, DILLON FONG, Materials Science Division, Argonne National Laboratory —

Long-sought non-cuprate superconductivity has recently been discovered in epitaxial thin films of alloyed neodymium nickelate (Nd$_{0.8}$Sr$_{0.2}$NiO$_2$) [1]. Interestingly, the superconducting phase is only observed in the infinite layer A$_1$B$_1$O$_2$ or ‘112’ phase, and not the more typical A$_1$B$_1$O$_3$ (‘113’) perovskite phase. Reduction of the 113 to the 112 phase generally requires use of a strong reducing agent like hydrides. However, the topotactic transition process involving significant oxygen loss is intrinsically non-trivial and remains elusive for precise synthesis control. Here we present the results of in situ synchrotron X-ray studies on the growth of nickelate heterostructures by pulsed laser deposition (PLD). We employ a Nd$_{0.8}$Sr$_{0.2}$NiO$_3$ target for the growth of Nd$_{0.8}$Sr$_{0.2}$NiO$_3$/SrTiO$_3$ (001) heterostructures and NdNiO$_3$ and SrNiO$_x$ targets for the growth of nickelate superlattices. We will discuss the relationships between phase stability and the oxygen concentration for different deposition parameters prior to CaH$_2$ reduction. The results of in situ studies of the reduction process to realize square-planar nickelates will also be described.

3:42PM J48.00007: Transport Characterization of Infinite Layer Nickelate Superconductor*

BAI YANG WANG (Presenter), DANFENG LI, KYUHO LEE, Physics, Stanford University, BERIT GOODGE, Applied and Engineering Physics, Cornell University, MOTOKI OSADA, Physics, Stanford University, LENA FITTING KOURKOUTIS, Applied and Engineering Physics, Cornell University, HAROLD HWANG, Physics, Stanford University —

The recently discovered infinite layer nickelate superconductor presents a potential new family of unconventional superconductors [1]. While sharing similar crystal structure with infinite layer cuprates, the electronic properties can be non-trivially distinct due to the relatively extreme valence state of Ni$^{1+}$. DFT calculations have also pointed out potential involvement of multiple bands [2]. In this sense, a careful comparison against the cuprate system is imperative in obtaining a proper and unbiased view of the nickelate superconductivity. Furthermore, detailed characterization of the difference between the two systems may provide new insights into the ingredients of superconductivity in layered oxide systems. As a step in this direction, we investigate and report the magnetotransport properties of nickelates in both the normal and superconducting state.

Electronic structure of the parent compound of superconducting infinite-layer nickelates

MATTHIAS HEPTING, DANFENG LI, CHUNJING JIA, SLAC National Accelerator Lab., HAIYU LU, Stanford University, E. PAIRS, YI TSENG, Paul Scherrer Institute, X. FENG, SLAC National Accelerator Lab., MOTOKI OSADA, EMILY BEEN, Stanford University, YASUYUKI HIKITA, SLAC National Accelerator Lab., Y. CHUANG, ZAHID HUSSAIN, Lawrence Berkeley Lab., KEJIN ZHOU, A. NAG, MIRIAN GARCIA-FERNANDEZ, Diamond Light Source, MATTEO ROSSI, SLAC National Accelerator Lab., HSIAO-YU HUANG, DI-JING HUANG, Taiwan Photon Source, ZHIXUN SHEN, Stanford University, THORSTEN SCHMITT, Paul Scherrer Institute, HAROLD HWANG, B. MORITZ, SLAC National Accelerator Lab., JAN ZAANEN, Leiden University, THOMAS DEVEREAUX, WEI-SHENG LEE (Presenter), SLAC National Accelerator Lab. — Very recently, the first superconducting nickelate has been discovered, opening a new field of research. The novel superconductor is a Sr-doped infinite layer nickelate NdNiO$_2$, which is isostructural to the infinite-layer cuprates and possesses the same nominal 3d electron count. Yet, it is important to experimentally characterize the electronic state of the parent compound from which the superconductivity emerges. In this presentation, we will present data of soft x-ray spectroscopy (XAS and RIXS) near the Ni L-edge and O K-edge on parent compound RNiO$_2$ (R = La, Nd). Together with LDA + U calculations, the gross feature of the electronic structure and a low energy effective model for the infinite layer nickelate will be discussed.

Doping evolution of the electronic structure of Sr-doped NdNiO$_2$

MATTEO ROSSI (Presenter), HAIYU LU, DANFENG LI, CHUNJING JIA, EMILY BEEN, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA, Y. CHUANG, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, KEJIN ZHOU, Diamond Light Source, Harwell Science and Innovation Campus, Didcot, Oxfordshire OX11 0DE, United Kingdom, ZHIXUN SHEN, BRIAN MORITZ, THOMAS DEVEREAUX, HAROLD HWANG, WEI-SHENG LEE, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA — Since the discovery of high-temperature superconductivity in cuprates, many efforts have been devoted to reproduce their electronic structure by proper material engineering. Nickel oxides occupy a prominent place since they are theoretically proposed to host superconductivity. After intense research, superconductivity has been recently discovered in Sr-doped NdNiO$_2$. Theory and experiments have been conducted to understand the electronic structure of the parent compound NdNiO$_2$. Yet, spectroscopic information about how Sr-doping affects the electronic states is still lacking. In this presentation, I will discuss the doping evolution of the electronic structure, as revealed by our recent experimental results from x-ray absorption spectroscopy (XAS) and resonant inelastic x-ray scattering (RIXS).
**4:18PM J48.00010: Exotic electronic structure in cuprate-like trilayer nickelate Pr$_4$Ni$_3$O$_8$**

HAOXIANG LI, PEIPEI HAO (Presenter), KYLE GORDON, Physics, University of Colorado-Boulder, HONG ZHENG, JUNJIE ZHANG, Material Science Division, Argonne National Lab, XIAOQING ZHOU, Physics, University of Colorado-Boulder, JOHN MITCHELL, Material Science Division, Argonne National Lab, DANIEL DESSAU, Physics, University of Colorado-Boulder — As sharing similar layered structure and close electron configuration with the high-Tc cuprate superconductors, various series of nickel oxides have naturally become potential candidates for cuprate analogues. A previous study found a rare metallic state lying in the trilayer nickelate Pr$_4$Ni$_3$O$_8$ (Pr438) with a quasi-2D lattice structure, which together with similar d-electron counting to the overly hole-doped cuprates and strong orbital polarization near the Fermi energy has drawn more attention to this compound[1]. Here we present a more direct and detailed study of the electronic structure of Pr438, with a combination of the Angle-resolved photoemission spectroscopy and Density-functional-theory calculations. Our spectroscopy data shows a non-gapped Fermi surface resembling the heavily hole-doped cuprates residing in the Fermi-liquid regime, bearing both electron- and hole-pockets, as has been corroborated by DFT calculations. These combine the predominant d$_{x^2-y^2}$ feature and strong hybridization between the Ni-3d and O-2p states, rendering Pr438 an extraordinary analogue to cuprates, making it a promising host for superconductivity.

**4:30PM J48.00011: Electronic Correlations in Nickelate Analogues of Cuprate Superconductors**

JONATHAN KARP (Presenter), Department of Applied Physics and Applied Math, Columbia University, MANUEL ZINGL, Center For Computational Quantum Physics, Flatiron Institute, ANTIA S. BOTANA, Department of Physics, Arizona State University, MICHAEL NORMAN, Materials Science Division, Argonne National Laboratory, ANDREW MILLIS, Department of Physics, Columbia University — Motivated by recent experiments on tri-layer (Pr4Ni3O8) and infinite layer (NdNiO2) analogues of cuprate superconductors, we use a combination of density functional and dynamical mean field (DFT+DMFT) methods to perform a comparative study of the metal-insulator and magnetic phase diagrams, many body electronic structure, and conduction band many-body mass enhancements of cuprate and nickelate materials. In the Ni materials the transition metal d-bands are more widely separated in energy from the O-p bands than in the cuprates, suggesting that the nickelates are more accurately modelled by a Hubbard model than are the cuprates. The role of Nd-derived d-bands in the physics of the nickelates is discussed and the possibility that in the nickelate case other Ni-d orbitals may be relevant is analyzed. Preliminary results on superconductivity within the DMFT approximation will be presented.

Electronic Structure across the Rare-Earth Series in Superconducting Infinite Layer Nickelates

EMILY BEEN (Presenter), Physics, Stanford, WEI-SHENG LEE, HAROLD HWANG, SIMES, SLAC, JAN ZAANEN, Leiden Institute of Physics, Leiden University, THOMAS DEVEREAUX, BRIAN MORITZ, CHUNJING JIA, SIMES, SLAC — The exciting discovery of superconductivity in oxygen-reduced monovalent nickelates has raised a new platform for the study of unconventional superconductivity, with similarities and differences to the cuprate high temperature superconductors. General trends appear in the infinite nickelates RNiO2 with rare-earths R spanning across the Lanthanides. The role of oxygen charge transfer diminishes in comparison to the cuprates, with an increased and prominent role played by rare-earth 5d electrons near the Fermi level when traversing from La to Lu. A decrease in lattice volume indicates that the magnetic exchange additionally grows, which may be favorable for superconductivity. However, compensation effects from the itinerant 5d electrons presents a close analogy to Kondo or Anderson lattices, indicating a more complex interplay between charge transfer, bandwidth renormalization, compensation, and magnetic exchange.

This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under contract DE-AC02-76SF00515.

Hybridization and correlation effects in the electronic structure of infinite-layer nickelates

YUHAO GU, Institute of Physics, Chinese Academy of Science, SICHEN ZHU, XIAOXUAN WANG, Department of Physics, New York University Shanghai, JIANGPING HU, Institute of Physics, Chinese Academy of Science, HANGHUI CHEN (Presenter), Department of Physics, New York University Shanghai — We combine density functional theory and dynamical mean field theory to study the electronic structure of infinite-layer nickelate NdNiO2. Without considering correlation effects on Ni, we find adjacent NiO2 planes are coupled by a metallic Nd spacer layer. However, the largest hybridization between Ni-\(d_{x^2-y^2}\) state and itinerant electrons origins from an interstitial-s orbital instead of Nd-\(d\) orbitals. Correlation effects on Ni reduces the hybridization between Ni-\(d_{x^2-y^2}\) state and itinerant electrons and when sufficiently strong, they can open a Mott gap, which is separated by the lower Hubbard band of Ni-\(d_{x^2-y^2}\) state and hybridization states (interstitial-s and Nd-\(d\) orbitals). With correlation strength increasing, antiferromagnetic ordering occurs before the metal-insulator transition. Experimentally long-range magnetic order has not been observed in NdNiO2. This places NdNiO2 in a paramagnetic metallic phase in which the hybridization between Ni-\(d_{x^2-y^2}\) and itinerant electrons is non-negligible and Ni correlation strength is moderate.

H.C. acknowledges the funding of National Natural Science Foundation of China (Grant No. 11774236) and NYU University Research Challenge Fund.
KWAN-WOO LEE (Presenter), Division of Display and Semiconductor Physics, Korea University, Sejong, MI-YOUNG CHOI, Department of Applied Physics, Korea University, Sejong, WARREN PICKETT, Department of Physics, University of California, Davis — For a long time, condensed matter physicists have a question whether there may be nickelates that can host a cuprate-type superconductor. Very recently, NdNiO$_2$ by 20%-Sr doping leads to superconducting up to $T_c=15$ K, while another most promising candidate LaNiO$_2$ has never been superconducting. These discovery has been rejuvenated the long standing issue. In this presentation, we will focus on a primary distinction between NdNiO$_2$ and LaNiO$_2$. An obvious difference is that La$^{3+}$ is closed shell and nonmagnetic, while Nd$^{3+}$ with Hund’ rule ground state $S=3/2$, $L=6$, $J=9/2$ has a Curie-Weiss moment of about $3\mu_B$. Our results indicate that this magnetic interaction in Nd$_{0.8}$Sr$_{0.2}$NiO$_2$ causes spin-disorder broadening of the $\Gamma$-centered Nd-driven electron Fermi surfaces and should be included in models of normal and superconducting states of Nd$_{0.8}$Sr$_{0.2}$NiO$_2$.

* NRF of Korea Grants No.NRF-2019R1A2C1009588 (K.W.L and M.Y.C) and NSF Grant DMR 1607139 (W.E.P).

SIHEON RYEE, HONGKEE YOON, TAEKJUNG KIM, MIN YONG JEONG, MYUNG JOON HAN (Presenter), KAIST — To understand the superconductivity recently discovered in Nd$_{1-x}$Sr$_x$NiO$_2$, we carried out LDA+DMFT (local density approximation plus dynamical mean-field theory) and magnetic force response calculations. The on-site correlation in Ni-3$d$ orbitals causes notable changes in the electronic structure. The calculated temperature-dependent susceptibility indicates the localized character of its spin moment. We also analyzed the low-frequency behavior of self-energy and resulting correlation strength. Remarkable new finding is that magnetic interactions in this material become two-dimensional by hole doping. While the undoped NdNiO$_2$ has the sizable out-of-plane interaction, hole dopings strongly suppress it. This two-dimensionality is maximized at the hole concentration of $\delta \approx 0.25$. Further analysis as well as the implications of our new findings are presented.
2:30 PM J49.00001: Coulomb correlation in noncollinear antiferromagnetic α-Mn

AKI PULKKINEN (Presenter), LUT University, BERNARDO BARBIELLINI, LUT University and Northeastern University, JOHANNES SAMULI NOKELAINEN, LUT University, VLADIMIR SOKOLOVSKIY, DANIL BAIGUTLIN, OLGA MIROSHKINA, MIKHAIL ZAGREBIN, VASILIY BUCHELNIKOV, Chelyabinsk State University, CHRISTOPHER LANE, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University, JIANWEI SUN, Tulane University, KATARIINA PUSSI, ERKKI LAHDERANTA, LUT University — We discuss the interplay between magnetic and structural degrees of freedom in elemental Mn. The equilibrium volume is shown to depend critically on the magnetic interactions between the Mn atoms. While the standard generalized-gradient-approximation underestimates the equilibrium volume, a more accurate treatment of the effects of electronic localization and magnetism is found to solve this longstanding problem. Our calculations reveal the presence of a magnetic phase in strained α-Mn that has been reported previously in experiments. This new phase of strained α-Mn is found to exhibit a noncollinear spin structure with large magnetic moments.

2:42 PM J49.00002: Magnetic and electronic properties of tetragonal GeNFe3

MARI TSUMURAYA (Presenter), DAVID SINGH, Physics, The University of Missouri — GeNFe3 has a tetragonal symmetry at room temperature with a space group I4/mcm. Previous studies unveiled its physical properties, such as a spin-glass behavior and anomalous Hall effect. Through first-principles calculations, we report magnetic and electronic properties of GeNFe3 with tetragonal structure.

*Work at the University of Missouri was supported by the Department of Energy, Award number DE-SC0019114

2:54 PM J49.00003: The effect of Si substitution on the magnetocaloric properties of Al1.2-xSi_xFe_2B_2 intermetallic system

MD SAKHAWAT HOSSAIN HIMEL (Presenter), MAHMUD KHAN, Department of Physics, Miami University — The AlFe2B2 material has drawn considerable attention recently due to its magnetocaloric properties near room temperature. Here, we have investigated the magnetic and magnetocaloric properties of a series of Si-doped Al1.2-xSi_xFe_2B_2 (0 ≤ x ≤ 0.25) compounds by x-ray diffraction, scanning electron microscopy (SEM), and dc magnetization measurements. The samples were prepared by arc-melting followed by drop-casting and annealing. The x-ray diffraction patterns confirmed that all samples exhibited the single-phase Cmmm-type orthorhombic crystal structure. SEM micrographs confirmed the homogeneity of the samples. A second-order ferromagnetic phase transition was observed near room temperature for all samples. While the Curie temperature (Tc) was minutely effected due to Si doping, the magnetocaloric properties were significantly enhanced. A peak magnetic entropy change of 7.39 Jkg⁻¹K⁻¹ was observed in the doped samples for a field change of 50 kOe. The experimental results and related discussion will be presented in detail.
**3:06PM J49.00004: A first-principles study of the impact of paramagnetism on grain boundary segregation in FeMn alloys**

OMKAR GOPALKRISHNA HEGDE (Presenter), TILMANN HICKEL, CHRISTOPH FREYSOLDT, JOERG NEUGEBAUER, Max Planck Inst fuer Eisenforschung GmbH — To understand the impact of paramagnetism on defect energetics and kinetics is, though conceptually and computationally challenging, important for designing Fe-based alloys. Since magnetic degrees of freedom change faster than atomic degrees of freedom in the high-temperature paramagnetic state, the atoms move according to an averaged force instead of instantaneous forces attained from each spin configuration.

Therefore, a new computationally efficient method based on spin-space averaging [1] has been developed to handle magnetic disorder next to defects, which uses the spin constraint tool developed in the DFT code S/PHI/nX. First, we focus on vacancies in the FeMn system, for which we demonstrate that paramagnetism significantly affects atomic relaxations as well as vacancy diffusion barriers and thereby explain why Mn diffusion shows a different temperature dependence than Fe-self diffusion in α-Fe. Next, we expand our method to extended defects and show that paramagnetism has a significant effect on the grain boundary segregation of Mn. Finally, we combine our results to reveal the chemo-magneto-structural coupling underlying Mn segregation to grain boundaries in Fe alloys.

*Funding from IMPRS-SurMat is acknowledged.

**3:18PM J49.00005: Tuning of the collapsed tetragonal phase transition in the SrTM$_2$P$_2$ (TM = transition metal) system**

GUILHERME GORGON LESSEUX (Presenter), RAQUEL RIBEIRO, SERGEY L. BUD'KO, PAUL C CANFIELD, Iowa State University and Ames Laboratory — The tetragonal to collapsed tetragonal phase transition$^1$ combines dramatic changes in structural, electronic, and (sometimes) magnetic states. This phase transformation can be controlled by application of hydrostatic pressure or uniaxial stress and offers the possibility of achieving shape memory behavior combined with remarkable super-elastic properties in intermetallic compounds.$^2$ For the SrTM$_2$P$_2$ system, given that the collapse occurs when P-P bonding takes place across Sr plane, TM substitution is the least perturbative substitution that can be made. As part of our effort to broaden our understanding and control of this transition, we have studied the effects of transition metal substitution on SrNi$_2$P$_2$. Here we report on solution growth and transport measurements on single crystals of SrTM$_2$P$_2$ (TM = Ni, Rh, Pd, Cu) which are potential hosts for the tetragonal collapse transition. Particularly, the effects of Rh-doping on SrNi$_2$P$_2$ will be discussed.

3:30PM J49.00006: First Principles study of enhanced stability of Au@Pt nanoparticles on MoS₂ support through alloying kinetics

TIMOTHY T YANG, Department of Materials Science and Engineering, University of Pittsburgh, BOAO SONG (Presenter), Department of Mechanical and industrial Engineering, University of Illinois at Chicago, WISSAM A SAIDI, Department of Materials Science and Engineering, University of Pittsburgh, REZA SHAHBAZIAN-YASSAR, Department of Mechanical and industrial Engineering, University of Illinois at Chicago — Two-dimensional MoS₂ supported Pt and Au@Pt nanoparticles (NPs) have received great attention for various catalysis applications. Deep understanding on the NPs migration and coalescence under different service conditions is crucial to enhance their stability. Herein, we employ first-principles density functional theory calculations to study the stabilities and diffusion kinetics of supported Au@Pt NPs at room temperature up to 400 °C in atmospheric hydrogen and vacuum environments. We show that Pt at the bottom layer of the NP interacts strongly with the MoS₂ substrate resulting in a strong adhesion energy. However, the adhesion energy is reduced in hydrogen environment due to strong Pt-H interactions. Further, we show that smaller NPs are more favored in alloy form rather than core/shell due to the facile diffusion kinetics at the edges. Our results are validated using transmission electron microscopy, showing that small size Au@Pt alloy NPs are more stable than the larger ones with the Au core in contact with MoS₂ substrate and Pt shell in contact with hydrogen. The present work gives insights to the degradation mechanisms of the NPs supported on substrates and offers strategies to enhance their stability.

3:42PM J49.00007: Quantum Quench and f-Sum Rules on Linear and Non-linear Conductivities*

HARUKI WATANABE (Presenter), MASAKI OSHIKAWA, Univ of Tokyo — Electric conductivity is one of the most important response properties of materials. The "frequency sum rule" is a non-perturbative constraint on the conductivity integrated over all frequency. In this talk, we give a new derivation to the f-sum rule for general quantum many-particle systems by considering a quench process. We then extend the discussion to higher order responses and derive various types of new sum rules on nonlinear conductivities.

3:54PM J49.00008: Binary and ternary metallic compounds with soft magnetic properties: predictions from density functional theory calculations  
AKANSHA SINGH (Presenter), AARON P. STEBNER, CRISTIAN CIOBANU, Colorado School of Mines — Nanocrystalline magnetic materials have fundamental and technological importance, due to their soft magnetic properties. These materials have a two-phase microstructure, a nanocrystalline ferromagnetic phase with $D0_3$ structure and a residual amorphous alloy phase. FINEMET (Fe$_{73.5}$Si$_{13.5}$Nb$_3$B$_9$Cu$_1$, with the nanocrystalline phase Fe$_3$Si) is one such material, having large saturation magnetization, low magnetocrystalline anisotropy, and coercivity. Still, it has some disadvantages related to its brittleness and power dissipation. With the aim of finding better soft magnetic alloys, we performed a systematic computational search across binary ($D0_3$, formula $X_3Z$) and ternary ($L_{21}$, $XY_2Z$) compounds, using generalized gradient approximation calculations. We choose the 3d-transition metals (Sc, Ti, V, Cr, Mn, Fe, Co and Ni) as $X$ or $Y$ element, and Al, Si, P, Ga, Ge, As, In, Sn and Sb as $Z$, for a total of 576 alloy combinations. We have filtered the best candidates based on their magnetization, crystalline anisotropy, heat of formation, and ductility. We have thus found 12 compounds (including, e.g., Fe$_3$Sn, Fe$_3$Ga, Fe$_3$Sb, MnCo$_2$As) that can have properties superior to Fe$_3$Si. Our results may offer guidance for future synthesis efforts aimed at discovering new and superior soft magnetic materials.

4:06PM J49.00009: Ab initio thermodynamics of carbides in high Mn steels  
LEKSHMI SREEKALA (Presenter), Computational Materials Design, Max Planck Inst fuer Eisenforschung GmbH, POULUMI DEY, Materials Science and Engineering, Technische Universiteit Delft, TILMANN HICKEL, JOERG NEUGEBAUER, Computational Materials Design, Max Planck Inst fuer Eisenforschung GmbH — The addition of Cr to high-Mn steels improves their corrosion resistance. At the same time, it has been experimentally reported that the alloying with Cr yields a substantial increase in the number of carbides, like cementite and Fe$_{23}$C$_6$. They can contribute to a precipitation hardening of the material, but also provide interfaces that might be critical for hydrogen embrittlement. In the present work, we therefore use density functional theory to determine the thermodynamic driving force for the formation of carbides as a function of the chemical composition of the alloy. These investigations are performed at finite temperatures considering the vibrational, electronic and magnetic contributions to the free energy of formation. We analyze the critical role of Cr by determining the partitioning of Cr and Mn into the carbides. At the same time, the role of these alloying elements for the solution enthalpy of H in the carbides is determined. We report that the chemical trends for the carbides show surprising differences from the behavior in the Fe-Mn matrix.
4:18PM J49.00010: Atomic-level defect formation mechanism in high-entropy alloys  CHI-HUAN TUNG (Presenter), Natl Tsing Hua Univ, GUAN-RONG HUANG, WEI-REN CHEN, Oak Ridge National Lab, SHOU-YI CHANG, Natl Tsing Hua Univ —
With the aid of atomistic simulations, we found that in solid solution alloys the soft spots detected by the the spatial distributions of low frequency vibration modes served as precursors of atomic level rearrangement. In high-entropy alloys, the successive defect growth has a chain-like manner which relied on the coupling of local shear transformations and vortex like atomic motion. This mechanism resembles the reported nucleation mechanism of shear transformation zone in metallic glasses, which is different from the dislocation slip induced planer fault growth in dilute solution alloy. In addition to the distinct defect formation mechanism, the extremely short correlation length of mechanical heterogeneity in high-entropy alloys also suppressed the synchronized motions of the dislocation line. This effect impeded the long-ranged dislocation slip and contributed to strong strain hardening ability. Our study reveals the critical defect formation mechanism at the atomic level and provides the theoretical description of various signature mechanical properties of high-entropy alloys.

4:30PM J49.00011: Drag viscosity of metals and its connection to Coulomb drag  YUNXIANG LIAO (Presenter), VICTOR GALITSKI, University of Maryland, College Park — Shear viscosity is a key parameter in the hydrodynamic description of fluids, including electronic matter - an interdisciplinary subject that has attracted an increasing amount of interest recently. Related to the rate of momentum transport, viscosity is given by the retarded correlation function of the momentum current, i.e., the stress tensor, in the linear response theory. In this work, we find that there exists a previously overlooked contribution to viscosity, which originate from the interacting part of the stress tensor. This new contribution, which we name drag viscosity, is connected to the frictional drag forces induced by the long-range interactions. A related phenomenon is the Coulomb drag of a double-layers electronic system, which measures the rate of charge transport originating from scattering between quasiparticles in different layers in the presence of Coulomb interactions. Using the diagrammatic approach in the Keldysh formalism, we derive the drag viscosity of the 2D and 3D electronic systems as well as the drag resistivity of the 2D double-layers systems. At low enough temperatures, both the drag viscosity and resistivity exhibit quadratic temperature dependence which becomes linear as temperature increases.
4:42PM J49.00012: Local structure analysis of carbon in ferritic steel by C K-edge X-ray absorption fine structure and multiple scattering calculations  
KAKERU NINOMIYA  
(Presenter), Kyushu University, YUSUKE TAMENORI, KAZUKI TSURUTA, Japan Synchrotron Radiation Research Institute, MAIKO NISHIBORI, Kyushu University — The ferritic steel with supersaturated solid solution carbon remarkable increase in hardness by heat treatment (so-called aging) at low temperature. This has been considered to cause by the formation of the carbon cluster in ferritic steel. In this study, we aimed to understand the local structure changes of solid solution carbon in ferritic steel with aging by soft X-ray absorption spectroscopy. In the C K-edge X-ray absorption near edge structure (XANES) spectrum, extended X-ray absorption fine structure (EXAFS) analysis by peak fitting is difficult due to parameter restrictions based on the sampling theorem. Therefore, we proposed the analysis method of C-Fe bond length ratio based on Natoli’s law. Because solid solution carbon in bcc-Fe is a $D_{4h}$ point group symmetry, it is expected that the peak position of C-Fe $\sigma^*$ state splits in the xy and z directions. We found that the C-Fe bond length ratio, $l_{xy}/l_z$, began to decrease with the formation of carbon clusters. Therefore, it suggests that the C-Fe$z$ bond was expanded by the increase of local carbon concentration due to the formation of carbon clusters, and structure transition of bcc to bct occurred.

4:54PM J49.00013: Accelerating Materials Discovery through Bezier Interpolation of Electronic Band Structure*  
NATHAN FOULK  
(Presenter), JEREMY JORGENSEN, GUS HART, Department of Physics and Astronomy, Brigham Young University — One important part of DFT calculations is the numerical integral of the electronic band structure. Unfortunately, this critical step of DFT simulation is the most computationally expensive, because each k-point requires solving the Kohn-Sham equations, an eigenproblem, in a large basis set. Almost all of the error in the band energy integral comes from misrepresenting the Fermi surface, so the most important part of any integration technique is approximating the Fermi surface correctly. Current DFT codes approximate the bands using three-dimensional Riemann sums, which represent the Fermi surface very poorly. We present an integration technique of interpolating the bands using Bezier surfaces in order to more accurately represent the Fermi surface, and thereby achieve the same accuracy with fewer k-points. We also explore further improvement by using an adaptive mesh refinement technique in those integration regions which contain the Fermi surface. Preliminary results suggest that 1 meV accuracy can be achieved using ~10× fewer k-points.

*We thank the Office of Naval Research for generously funding a major portion of this project through grant MURI N00014-13-1-0635.
5:06PM J49.00014: Exploring band topology of engineered materials using deep neural networks  VITTORIO PEANO (Presenter), FLORIAN SAPPER, FLORIAN MARQUARDT, Max Planck Inst for Sci Light — This talk focuses on the first applications of our deep Neural Network (NN) based approach to band structure calculations. A distinctive feature of our approach is that our NN does not predict the band structure directly but rather learns to predict the parameters of an auxiliary Tight-Binding (TB) model. This TB model gives then access not only to the band structure but also to the topological properties of the Bloch waves.

The applications we consider are geared towards engineered materials such as photonic and phononic crystals in that we use as an input of our neural network the unit cell geometry. We demonstrate the use of our NN to perform efficiently the statistical analysis of the topological properties of selected distributions of potentials. Our analysis is based on recent break-throughs in the understanding of band structure topology and ties to the the systematic classification of all natural materials based on their electronic topological properties (sometimes known as Topological Quantum Chemistry). Moreover, we demonstrate the use of our NN for optimization (random or gradient based) of band structures in the design of (i) band inversions, (ii) physical implementations of fragile topology, (iii) physical implementations of selected topological TB models.

5:18PM J49.00015: Micro-Structure and Transport Mechanism in Graphene Copper Composites  RAJU GHIMIRE (Presenter), Nanoscience and Microsystems Engineering, University of New Mexico — The addition of nanocarbons to copper (Cu), specifically in the form of graphene (GN), has shown to enhance copper's physical properties. GN-Cu nanocomposites can potentially achieve a higher current carrying capacity and a lower temperature-sensitivity of electrical resistivity compared with copper. These characteristics make GN-Cu materials interesting for several applications including but not limited to interconnects, high current power lines, and elevated-temperature rotating machines. Charge conduction in these materials is controlled by microstructural features as well as nanoscale interfacial phenomena between the GN and Cu. In this work, we analytically investigated the possibilities for an improved electrical conductivity in GN-Cu composites. Subsequently, GN-Cu samples were prepared by the consolidation of CVD Cu-graphene films under high pressures and temperatures. The effects of processing time, temperature, and pressure on both the structure and physical properties of the GN-Cu composite films were investigated. Finally, in-situ conductivity measurements of the Cu-GN interfaces were carried out. These measurements provide insights into transport mechanisms in nanocarbon-metal composites.

Session J50 DCMP: Quantum Criticality and Phase Transitions  Mile High
Ballroom 1C - Emilian Nica, Arizona State Univ
2:30PM J50.00001: Superconductivity from quantum fluctuations of itinerant quantum critical points  YUNCHAO HAO (Presenter), YANG QI, Fudan Univ, KAI SUN, University of Michigan — In the vicinity of a quantum critical point, critical fluctuations can often act as glue for the formation of BCS pairs, which is one important path way towards unconventional superconductivity. Recently, thanks to the development in quantum numerical techniques, such as sign-problem-free quantum Monte Carlo simulations, new insights and unbiased numerical understanding about this phenomenon become accessible. In particular, the numerical results suggest superconductivity emerged from these quantum critical points are highly diversified and are highly sensitive microscopic details. In this study, we investigate these systems utilizing analytic approach. By exploring different model systems and compare with numerical results, we aim at understanding universal properties behind these diversified behaviors.

2:42PM J50.00002: Critical properties of antiferromagnetic and valence-bond-solid transitions in lattice quantum electrodynamics  NIKOLAI ZERF, Humboldt-Universität zu Berlin, RUFUS BOYACK, University of Alberta, PETER MARQUARD, DESY, Zeuthen, JOHN A GRACEY, University of Liverpool, JOSEPH MACIEJKO (Presenter), University of Alberta — Lattice gauge theories underlie the effective low-energy description of many strongly correlated electron systems, such as frustrated magnets and high-temperature superconductors, but can now also be simulated directly in cold atom experiments. Elucidating the phase diagram of lattice gauge theories is thus an important problem with a wide range of applications to condensed matter physics. Recent sign-problem-free quantum Monte Carlo simulations of lattice quantum electrodynamics (QED) with $N$ flavors of fermions on the square lattice have found evidence of continuous quantum phase transitions between a critical deconfined phase at small gauge coupling and confined antiferromagnetic (for $N=2$) or valence-bond-solid (for $N=4,6,8$) phases at large gauge coupling. We derive Landau-Ginzburg-Wilson theories of the QED-Gross-Neveu(-Yukawa) type for these transitions, find stable renormalization-group fixed points corresponding to the observed quantum critical points, and compute their critical exponents using epsilon and large-$N$ expansions.

2:54PM J50.00003: Structure of Quantum Entanglement at a Finite Temperature Critical Point*  TARUN GROVER (Presenter), TSUNG-CHENG LU, University of California, San Diego — We propose a scheme to characterize long-range quantum entanglement close to a finite temperature critical point using tripartite entanglement negativity. Across a conventional order-disorder transition, tripartite negativity does not exhibit any singularity in the thermodynamic limit, in contrast to the short-range component of negativity, which is singular. This indicates that the long-distance critical fluctuations are completely classical, allowing one to define a ‘quantum correlation length' that remains finite at the transition despite a divergent physical correlation length.

Universal Prethermal Dynamics in Gross-Neveu-Yukawa Criticality

SHAOKAI JIAN (Presenter), University of Maryland, College Park, SHUAI YIN, Sun Yat-Sen University, BRIAN SWINGLE, University of Maryland, College Park — We study the prethermal dynamics of the Gross-Neveu-Yukawa quantum field theory, suddenly quenched in the vicinity of a critical point. We find that the universal prethermal dynamics is controlled by two fixed points depending on the size of the quench. Besides the usual equilibrium chiral Ising fixed point for a shallow quench, a dynamical chiral Ising fixed point is identified for a deep quench. Intriguingly, the latter is a nonthermal fixed point without any equilibrium counterpart due to the participation of gapless fermionic fields. We also find that in the scaling regime controlled by the equilibrium fixed point, the initial slip exponent is rendered negative if there are enough flavors of fermions, thus providing a unique signature of fermionic prethermal dynamics. We then explore the temporal crossover between the universal scaling regimes governed by the two universality classes. Possible experimental realizations are also discussed.

Critical behavior near the many-body localization transition in driven open systems

ZALA LENARCIC (Presenter), University of California, Berkeley, ORI ALBERTON, ACHIM ROSCH, University of Cologne, EHUD ALTMAN, University of California, Berkeley — In a many-body localized (MBL) system, the coupling to an external bath typically breaks local integrals of motion. Thus the system relaxes to a unique thermal steady state. When the bath is non-thermal or when the system is weakly driven out of equilibrium, local conservation laws can be excited far from any thermal equilibrium value. I will show how this property can be used to study the MBL phase transition in weakly open systems. Here, the strength of the coupling to the non-thermal bath plays a similar role as a finite temperature in a T=0 quantum phase transition. By tuning this parameter, we can detect key features of the MBL transition: the divergence of dynamical exponent due to Griffiths effects and the critical disorder strength.

We propose a new order parameter, based on the fluctuations in local temperatures. For vanishing strength of coupling to the bath, fluctuations vanish on the ergodic side, while they are large on the MBL side. By increasing the coupling strength, fluctuations grow with a fractional exponent related to the inverse dynamical exponent on the ergodic side, while they decrease monotonically on the MBL side. This paves the way for studies of the MBL transition with new numerical approaches and, importantly, also with solid-state experiments.
3:30PM J50.00006: B$_{1g}$ Raman response near an Ising-nematic quantum critical point: properties of a quasielastic peak*  
XIAOYU WANG (Presenter), Natl High Magnetic Field Lab, EREZ BERG, Weizmann Institute of Science — Raman scattering has long been used to probe dynamical electronic correlations in various condensed matter systems. Here we present a theoretical study of the B$_{1g}$ channel Raman response in the vicinity of an Ising-nematic quantum critical point (QCP) in two space dimensions. We show the appearance of a “quasi-elastic peak” as the QCP is approached. The peak frequency is related to the relaxation rate of the deformation of the Fermi surface in the angular momentum l=2 channel, while the peak intensity is directly proportional to the Ising-nematic thermodynamic susceptibility. We discuss our results in the context of iron selenide materials which host such a quantum critical point.

*XW acknowledge support from National MagLab, which is funded by the National Science Foundation (DMR-1644779) and the state of Florida making all taxpayers stakeholders in our science.

3:42PM J50.00007: Nematic fluctuations in the Hubbard models*  
TIANYI LIU (Presenter), Stanford University, EDWIN HUANG, University of Illinois at Urbana-Champaign, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University — An electron nematic is an electronic phase with translation symmetry, but broken rotational symmetry. Signatures of nematic fluctuations have been observed in strongly correlated materials such as cuprates, iron pnictide, and iron chalcogenide superconductors, and may be related with other sorts of broken symmetries such as charge or spin density waves. Here we report calculations of the nematic susceptibilities from determinant quantum Monte Carlo (DQMC) simulations of the Hubbard models, for various model parameters, doping levels, and temperatures. We draw possible connections between these susceptibilities to other phenomena observed in the Hubbard model.

*Supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under contract DE-AC02-76SF00515. Computational work is performed on the Sherlock cluster at Stanford University.
3:54PM J50.00008: Direct Measurement of the Soft Mode Driving a Quantum Phase Transition*

MATTHEW LIBERSKY (Presenter), Caltech, RYAN D MCKENZIE, University of British Columbia, DANIEL SILEVITCH, Caltech, PHILIP STAMP, University of British Columbia, THOMAS F ROSENBAUM, Caltech — Understanding the excitations, fluctuations, and dynamics at a quantum phase transition is an important research thrust in pure condensed matter and atomic physics. An important question remains of whether critical excitations remain in the presence of an external spin bath, as is the case for many real-world implementations of quantum systems. Addressing this issue is necessary for connecting theory and modeling to observations and device design. Here, we directly measure the low energy excitation modes of a well-known realization of the quantum Ising model in transverse field, LiHoF$_4$, using microwave spectroscopy techniques to probe energies below what is accessible via neutron scattering experiments. Instead of the single excitation expected for a simple quantum Ising system, we find and characterize a remarkable array of modes arising from coupling of the spin-$1/2$ Ising electronic spins to a bath of spin-$7/2$ Ho nuclear spins, the lowest of which indeed softens at the quantum critical point. These results suggest that quantum criticality persists in the presence of a spin bath and that similar modes may exist in other quantum Ising systems, including adiabatic quantum computers.

*The work at Caltech was supported by DOE Basic Energy Sciences.

4:06PM J50.00009: Duality Web on a 3D Euclidean Lattice and Manifestation of Hidden Symmetries

JUN HO SON (Presenter), JING-YUAN CHEN, SRINIVAS RAGHU, Stanford Univ — We generalize our previous lattice construction of the abelian bosonization duality in 2+1 dimensions to the entire web of dualities as well as the $N_f=2$ self-duality, via the lattice implementation of a set of modular transformations in the theory space. The microscopic construction provides explicit operator mappings, and allows the manifestation of some hidden symmetries. It also exposes certain caveats and implicit assumptions beneath the usual application of the modular transformations to generate the web of dualities. Finally, we make brief comments on the non-relativistic limit of the dualities.

4:18PM J50.00010: London penetration depth in disordered unconventional superconductors with competing interactions*

MAXIM KHODAS (Presenter), Hebrew University - Jerusalem, MAXIM DZERO, Kent State Univ - Kent, ALEX LEVCHENKO, University of Wisconsin-Madison — A topic of an interplay between disorder and competing electronic phases in multiband superconductors have recently got renewed interest in the context of iron-based superconductors. In my talk I will present a theory of disordered unconventional superconductor with competing magnetic order. Our discussion will be based on the results obtained for on a two-band model with quasi-two-dimensional Fermi surfaces, which allows for the coexistence region in the phase diagram between magnetic and superconducting states in the presence of intraband and interband scattering induced by doping. We will demonstrate that disorder has a crucial effect on the magnetic field penetration depth as a function of disorder scattering rates.

*The work of M.D. was financially supported by NSF-DMR Grant No. 1506547. The work of A.L. was financially supported by DOE-BES Grant No. DESC0017888
4:30PM J50.00011: Magnetic phase transitions in quantum spin-orbital liquids*  SHI FENG (Presenter), NIRA KirkumAR PATEL, Department of Physics, The Ohio State University, PANJIN KIM, National Security Research Institute, Korea, JUNG HOON HAN, Department of Physics, Sungkyunkwan University, NANDINI TRIVEDI, Department of Physics, The Ohio State University — We investigate the spin and orbital correlations of a superexchange model with spin S=1 and orbital L=1 relevant for 5d^4 transition metal Mott insulators, using exact diagonalization and density matrix renormalization group (DMRG). For spin-orbit coupling λ=0, the orbitals are in an entangled state that is decoupled from the spins, leading to emergent spin-orbital separation within spin-orbital interacting system. We find two phases with increasing λ: (I) the S2 phase with two peaks in the structure factor for λ < λ_{c1} ≈ 0.34 J, where J is the ferromagnetic exchange, and (II) the S1 phase λ_{c1} < λ < λ_{c2} ≈ 1.2 J with antiferromagnetic correlations. The λ = 0, S2 and S1 phases are shown to exhibit power law correlations, indicative of a gapless phase. Increasing λ > λ_{c2} leads to a product state of local spin-orbital singlets that exhibits exponential decay of correlations, indicative of a gapped phase. Using mean-field like approximation, we demonstrate that our model can be approximated with the well-known Uimin-Lai-Sutherland (ULS) model with an external field.

4:42PM J50.00012: Universal quantum glass transition on the Bethe lattice  IZABELLA LOVAS (Presenter), TU Munich, CATALIN PASCU MOCA, GERGELY ZARAND, Budapest University of Technology and Economics — We study the Coulomb glass behavior emerging from the interplay of interactions and disorder, by examining a model of spinless fermions at half filling on the Bethe lattice [1,2]. We consider the limit of infinite coordination number, where we combine dynamical mean field theory with a Hartree-Fock approximation to investigate the glass transition and the properties of the glassy phase in the presence of full replica symmetry breaking. This approach allows us to study the opening of the Efros-Shklovskii pseudogap in the glassy phase, and grants us access to the spectral function. In particular, we demonstrate the universal scaling collapse of the pseudogap and the spectral function at close to zero temperatures, where the melting of the glass is governed by the quantum fluctuations induced by the hopping of fermions. We show that this quantum scaling function differs from the classical scaling function of the thermal transition of the spin glass limit. Our results should be relevant for the glassy dynamics observed in Si inversion layers, persisting in the metallic phase [3].

4:54PM J50.00013: Atomic-scale fragmentation and collapse of antiferromagnetic order in a
doped Mott insulator*  HE ZHAO (Presenter), Boston College, SUJIT MANNA, Indian Institute of
Technology Delhi, ZACH PORTER, XIANG CHEN, University of California, Santa Barbara, ANDREW
UZDEJCZYK, Boston College, JAGADEESH MOODERA, Massachusetts Institute of Technology, ZIQIANG
WANG, Boston College, STEPHEN WILSON, University of California, Santa Barbara, ILIJA ZELJKOVIC,
Boston College — Measuring magnetic and electronic properties at atomic length scales would
provide crucial insight into the physics of doped antiferromagnetic Mott insulators, but this has
been difficult to achieve. We use spin-polarized scanning tunneling microscopy (SP-STM) to
visualize the periodic spin-resolved modulations originating from the antiferromagnetic order in
a \( J_{\text{eff}} = \frac{1}{2} \) strongly spin-orbit coupled Mott insulator \( \text{Sr}_2\text{IrO}_4 \). We discover that near insulator-to-
metal transition (IMT), the long-range antiferromagnetic order melts into a spatially fragmented
state with short-range correlations. Importantly, we find that the short-range antiferromagnetic
order is locally uncorrelated with the observed spectral gap magnitude. This suggests that static
short-range antiferromagnetic correlations are unlikely to be the cause of the inhomogeneous
closing of the spectral gap and the emergence of pseudogap regions near the IMT in doped
\( \text{Sr}_2\text{IrO}_4 \). Our work establishes SP-STM as a powerful tool for revealing atomic-scale magnetic
information in complex oxides.

*We gratefully acknowledge the support from the US Department of Energy Early Career Award
DE-SC0020130.

5:06PM J50.00014: Phase Structure of Isotropic and Anisotropic Ising Models at Complex
Couplings*  SANKHYA BASU (Presenter), VADIM OGANESYAN, Department of Physics, GC and CSI,
CUNY, CHRIS A HOOLEY, SUPA, School of Physics and Astronomy, University of St Andrews — In this
work, we study the phase structures and phase transitions that arise in both the Isotropic and the
Anisotropic Ising Models by analytically continuing away from real coupling – both temperature
and field. In particular, we observe that away from real temperatures, Yang-Lee circle theorem
indeed breaks down, even for the Isotropic Ising Model. We also observe symmetry breaking of
the global minima of the free energy away from real temperatures in the high temperature
phase. We use both analytical as well as numerical techniques based on Tensor Network
formulations (Tensor Renormalization Group(TrG), Higher Order Tensor Renormalization
Group(HOTRG)) to access these novel regimes in the phase space that is out of reach of standard
Monte Carlo techniques.

Tuesday, March 3, 2020 2:30 PM - 5:18 PM

Session J51 DCMP: Optoelectronic Properties of 2D Materials Mile High
Ballroom 1D - Shaowei Li, University of California, Berkeley
2:30PM J51.00001: van der Waals photothermoelectric effect in atomic layer heterojunctions*  
YUNQIU (KELLY) LUO (Presenter), Cornell University, TONG ZHOU, Physics, University at Buffalo, State University of New York, MAHESH R NEUPANE, Sensors and Electron Devices Directorate, U.S. Army Research Laboratory, ALEX MATOS ABIAGUE, Physics and Astronomy, Wayne State University, RYAN BAILEY-CRANDELL, MICHAEL J NEWBURGER, IGOR LYALIN, Physics, Ohio State University, IGOR ZUTIC, Physics, University at Buffalo, State University of New York, ROLAND KAWAKAMI, Physics, Ohio State University — Two-dimensional (2D) van der Waals (vdW) heterostructures provide exceptional opportunities for new physics and devices due to their unprecedented ability to tune the electronic, optical, magnetic and spintronic properties by atomic layer stacking and electrostatic gating. Harnessing this versatility requires a fundamental understanding of light-matter interactions and establishing new functionalities for photon-charge and photon-spin conversions. Here, we report the first observation of a highly-tunable vdW photothermoelectric effect in dual-gated MoS$_2$/graphene junctions with a striking multiple-polarity switching of photocurrent as a function of junction bias and carrier density. In stark contrast to photovoltaic effects arising from excitonic absorption in MoS$_2$, the vdW photothermoelectric effect originates from photoexcitation of hot electrons in graphene and thermoelectric transport across the vdW junction. Systematic studies of photoconductance as a function of photon energy and intensity reveal vdW photothermoelectric effect as the dominant mechanism for photocurrent generation at room temperature, as opposed to excitonic absorption. These findings provide an important step for understanding and control of vdW-interface devices.

*NSF MRSEC DMR-1420451

2:42PM J51.00002: Realizing precise charge neutrality in van der Waals heterostructure p-n junctions through data intensive photoresponse imaging  
TREVOR ARP (Presenter), Physics and Astronomy, University of California, Riverside, FATEMEH BARATI, Physics, New York University, SHANSHAN SU, ROGER LAKE, University of California, Riverside, NATHANIEL GABOR, Physics and Astronomy, University of California, Riverside — In atomically thin materials, the narrow phase space for exciton–phonon interactions could be used to engineer unusual devices that mimic molecular optical transitions. A van der Waals heterostructure tuned to a charge neutral state allows for the formation of excitons where the electron and hole are localized in different materials. Such interlayer excitons have a well-defined dipole moment making them sensitive to the interlayer electric field and out-of-plane vibrations. To isolate the behavior of interlayer excitons and explore their dynamics, we employ Multi-Parameter Dynamic Photoresponse Microscopy on encapsulated heterostructures composed of monolayer MoSe$_2$ and bilayer WSe$_2$. Gathering a large set of spatial photocurrent images as a function of source-drain and gate voltages, we unambiguously identify the charge neutrality condition. We observe that the system can be tuned to exhibit clear rectification with highly uniform spatial dependence in the heterojunction consistent with the formation of a two-dimensional distributed p-n junction at charge neutrality. Under these precise charge neutrality conditions, we observe striking spectroscopic features that reveal highly unusual exciton-phonon interactions.
Enhanced intrinsic photovoltaic effect in tungsten disulphide nanotubes

YIJIN ZHANG (Presenter), Max Planck Institute for Solid State Research, TOSHIYA IDEUE, MASARU ONGA, FENG QIN, RYUJI SUZUKI, Univ of Tokyo, ALLA ZAK, HIT-Holon Institute of Technology, RESHEF TENNE, Weizmann Institute of Science, JURGEN HUBERT SMET, Max Planck Institute for Solid State Research, YOSHIHIRO IWASA, Univ of Tokyo — Transition metal dichalcogenides (TMDs) are representative 2D materials. Group VI-B TMDs in 2H-type crystal structure have a semiconducting band structure. One of their unique features is the controllability of the crystal symmetry. The inversion symmetry inherent in bulk TMDs can be broken by isolating a monolayer. Various optoelectronic functionalities have been demonstrated by breaking this inversion symmetry. A further reduction of crystal symmetry can be achieved by rolling up 2D sheets to form a tubular structure. In such TMD nanotubes, not only the inversion symmetry but also mirror and rotation symmetries can be broken simultaneously, leading to a polar structure. We have investigated the photovoltaic effect in intrinsic WS\textsubscript{2} with different crystal symmetries and observed a sizable photovoltaic effect from TMD nanotubes without \textit{p-n} junction. Such a phenomenon is called bulk photovoltaic effect (BPVE). In our study BPVE was observed in WS\textsubscript{2} nanotubes only, indicating a importance of the polar structure to enhance BPVE.

Carrier transport dynamics in 2D semiconductors optoelectronic devices

PAN P ADHIKARI, PHYSICS, Clemson University, PEIJIAN WANG, Physics, University at Buffalo, KANISHKA KOBBEKADUWA, EXIAN LIU, PHYSICS, Clemson University, HAO ZENG, Physics, University at Buffalo, JIANBO GAO (Presenter), PHYSICS, Clemson University — Despite that 2D semiconductors have promising optoelectronic and electronic applications, our fundamental understanding of its carrier transport dynamics is still in its infancy. In general, it remains challenging to unravel the carrier transport properties in devices since they are altered in the presence of defects/impurities or trap states. An ultrafast probe or high quantum efficiency device (the ratio between electrons collected to photon number), or both, are required to elicit carrier transport properties before significant carrier trapping into trap states and recombination occur.

In this work, we integrate black phosphorus and WS\textsubscript{2} in an ultra-high-speed photodetector structure with sub-25 ps response time to study the carrier transport dynamics. We elucidate the nature of transport mechanisms in different temporal regimes: pre-trapping and band-like transport in early time up to nanoseconds, followed by multiple trapping and release (MTR) hopping transport. In addition to demonstrating visible and infrared high-speed photodetectors, our study reveals the fundamental device physics, leading to device performance manipulation.
3:18PM J51.00005: Nanoscale Mapping of Photoconductivity Enhanced by Localized Charge Traps in the Grain Structures of MoS$_2$ Monolayer  HYESONG JEON (Presenter), Department of Materials Science and Engineering, Seoul National University, Seoul, 08826, Korea, MYUNGJAE YANG, TAEYOUNG KIM, TAKHEE LEE, Department of Physics and Astronomy, Seoul National University, Seoul, 08826, Korea, SEUNGHUN HONG, Department of Physics and Astronomy, and Institute of Applied Physics, Seoul National University, Seoul, 08826, Korea — We present a method for the nanoscale mapping of photoconductivity and charge trap density in the grain structures of a monolayer molybdenum disulfide (MoS$_2$). In this method, the lateral current and noise maps were measured by scanning the MoS$_2$ surface with a nanoscale conducting contact probe. The measured data were analyzed to obtain the sheet resistance and charge trap density maps in the MoS$_2$ grain structures. Interestingly, the sheet resistance was found inversely proportional to the charge trap density in the grains. It was explained by the sulfur vacancies working as both charge hopping sites and traps in the MoS$_2$ monolayer. When illuminated with a light, the regions with a relatively high trap density showed a high photoconductivity. These results indicate that high photoconductivity was enhanced by charge traps. This method can be a powerful tool for the basic research about noises and the device applications based on two-dimensional materials.

3:30PM J51.00006: Effect of light-matter interaction on the ballistic conductance of an irradiated dice material  DIPENDRA DAHAL (Presenter), The Graduate Center, City University of New York, GODFREY GUMBS, Physics and Astronomy, Hunter college, City University of New York — We derived closed-form analytic expressions for the transmission coefficient of quasiparticles impinging on a square electrostatic potential barrier and step formed by split gates on a dice material which is irradiated by circularly polarized light. A consequence of modifying the states by the dressing field is to suppress Klein tunneling for head-on collision. Our results for transmission are employed in the Landauer-Buttiker formalism to examine the ballistic transport properties for varying barrier widths, incident quasiparticle energy, and light intensity. A comparison is made between our results for dressed and undressed states.
3:42PM J51.00007: Spatially resolved photoconductivity mapping of MoS$_2$ / WS$_2$ lateral heterostructures  
SAMUEL BERWEGER (Presenter), National Institute of Standards and Technology, Boulder, CO, HANYU ZHANG, National Renewable Energy Laboratory, Golden, CO, PRASANA K SAHOO, Indian Institute of Technology, Kharagpur, BENJAMIN M KUPP, Pennsylvania State University, State College, PA, JEFFREY L BLACKBURN, ELISA M MILLER, National Renewable Energy Laboratory, Golden, CO, DIMITRI VORONINE, University of South Florida, Tampa, FL, THOMAS M WALLIS, PAVEL KABOS, National Institute of Standards and Technology Boulder, CO, SANJINI U NANAYAKKARA, National Renewable Energy Laboratory, Golden, CO — The presence of free carriers directly affects the optical properties of transition metal dichalcogenides. For instance, free carriers directly underpin the competition between neutral excitons and carrier-bound trions and they strongly affect radiative and nonradiative decay pathways. However, despite their fundamental importance for TMDs, spatially resolved studies of the carrier distribution and the associated photoresponse remain challenging. Here we use scanning microwave microscopy (SMM, also called microwave impedance microscopy, MIM) to study the spatial carrier distribution in MoS$_2$/WS$_2$ lateral heterostructures under dark conditions as well as under illumination with photon energy-resolved narrowband illumination. We find strong spatial variations in the photoconductive response throughout the flakes studied. We further find significant long-term dynamics in the optically generated free carriers that manifest themselves in persistent charging and discharging and are strongly correlated with observed spatial variations in the steady-state photoconductive response. A comparison with spatially resolved photoluminescence mapping reveals excellent agreement between the local conductivity determined by SMM and the interplay between trion and exciton emission characteristics.

3:54PM J51.00008: Controllable beam slicing through fractional phase shifts accumulated at an atomically-thin interface*  
MYUNGJAE LEE (Presenter), James Frank Institute, University of Chicago, FAUZIA MUJID, Department of Chemistry, University of Chicago, ANDREW YE, Pritzker School of Molecular Engineering, University of Chicago, JIWOONG PARK, Department of Chemistry, University of Chicago — The interface between different media has been one of the crucial sources of light-matter interactions where properties of light, such as intensity, phase, or polarization, may change. One previously unexplored regime is when light propagates parallel to and bisected by the interface. Here, we realized an optically suspended and atomically-thin interface based on wafer-scale monolayer MoS$_2$ on fused silica that is immersed inside index-matching liquid. With this system we observed that a beam propagating along the interface is sliced into two sub-beams leaving a node at the interface. We quantified the upper and lower bounds of absorption and concluded that the atomically-thin interface behaves like a partial mirror that reflects light with an additional phase shift, which results in self-interference with the incident beam. In addition, we found that the degree of interference can be tuned by using interfaces with different number of MoS$_2$ layers. Our results indicate that the value of phase shift by a monolayer is a fraction of $\pi$, not an integer of $\pi$, which is unexpected from classical interfaces.

*This work was primarily supported by the Air Force Office of Scientific Research (FA9550-16-1-0347).
4:06PM J51.00009: Engineering the exciton spontaneous emission time in MoSe$_2$ monolayer

BO HAN (Presenter), CÉDRIC ROBERT, HONGHUA FANG, Institut National des Sciences Appliquées de Toulouse, MARINA SEMINA, Ioffe institute, DELPHINE LAGARDE, EMMANUEL COURTADE, Institut National des Sciences Appliquées de Toulouse, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, Ibaraki 305-0044, Japan, THIERRY AMAND, BERNHARD URBASZEK, Institut National des Sciences Appliquées de Toulouse, MIKHAIL GLAZOV, Ioffe institute, XAVIER MARIE, Institut National des Sciences Appliquées de Toulouse — Encapsulation of monolayers such as MoSe$_2$ in hexagonal boron nitride (hBN) yields narrow optical transitions approaching the homogenous exciton linewidth. In time-resolved photoluminescence measurements we demonstrate that the exciton radiative lifetime in the MoSe$_2$ monolayer can be tuned by a factor 10 (typically from 1 to 10 ps) as a function of the hBN thickness. This variation is a consequence of the Purcell effect and it is in very good agreement with the calculated dependence using transfer matrix techniques [1]. We show that the exciton linewidth measured in cw photoluminescence can be controlled as well. The variation of the charged exciton lifetime due to cavity-like effects will also be discussed.

4:18PM J51.00010: Optical Switching Based on a Single Layer of WSe$_2$* ZHENG SUN

(Presenter), Astronomy and Physics, University of Pittsburgh, KE XU, Chemical and Petroleum Engineering, University of Pittsburgh, JONATHAN BEAUMARIAGE, Astronomy and Physics, University of Pittsburgh, JIERUI LIANG, SUSAN FULLERTON-SHIREY, Chemical and Petroleum Engineering, University of Pittsburgh, DAVID WAYNE SNOKE, Astronomy and Physics, University of Pittsburgh — Two-dimensional materials are an emerging class of new materials with a wide range of electrical and optical properties and potential practical applications. Single layers materials such as semiconducting transition metal dichalcogenides with MX$_2$ stoichiometry, where M is a transition metal element from group VI (M=Mo, W) and X is a chalcogen (X=S, Se, Te) are gaining increasing attention as promising gate insulators and channel materials for field-effect transistors. Here, we report a type of optical switching based on a single-layer WSe$_2$ transistor. A side gate controls the polarization of the ions in PEO:CsClO$_4$, after which we can turn on and off the photoluminescence using a back gate. An on-off ratio of 90 is observed under constant pump light intensity. We believe the “off” and “on” states originate from the net electric field produced by the polarized ions and the back-gate, which aligns the dipole within the WSe$_2$ either in the same way or in the opposite way.

*We acknowledge the U.S. Army Research Office under MURI Award No. W911NF-17-1-0312. K.X., J.L., and S.K.F.-S. acknowledge funding from the National Science Foundation, Grant No. 1607935.
Excitonic Complexes in a Charge Tunable WSe2 Monolayer Device
CEDRIC ROBERT, EMMANUEL COURTADE, DELPHINE LAGARDE, LPCNO, University of Toulouse, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS Tsukuba, BERNHARD URBASZEK, THIERRY AMAND, XAVIER MARIE (Presenter), LPCNO, University of Toulouse — Transition Metal Dichalcogenides (TMD) monolayers have emerged as exciting 2D materials for optoelectronics and spintronics. Due to the large exciton binding energies and strong spin-orbit coupling, these materials can host various and robust excitonic complexes. The encapsulation of TMD monolayers into hBN combined with the constant improvement of the material quality now enable to reproducibly observe and control these excitonic complexes in the optical spectra.
In this work, we study a WSe2 monolayer embedded into a charge tunable device made of graphite electrodes and hBN. This allows us to study excitonic complexes in different doping regimes (neutral, n or p). We systematically performed magneto-photoluminescence/reflectivity and time resolved photoluminescence as a function of doping to identify the nature of the excitonic transitions based on their characteristic Landé g-factor and their temporal dynamics. The fine structure of the trion (intervalley, intravalley, dark trion) will first be discussed. Phonon assisted transitions (momentum mismatch dark exciton and spin forbidden dark exciton) are also identified. Finally the origin of more complex transitions observed under high n type doping will be discussed.

Widely Tunable Mid-Infrared Light Emission in Thin-Film Black Phosphorus
*CHEN CHEN (Presenter), Yale University, XIAOBO LU, Washington University in St. Louis, BINGCHEN DENG, XIAOLONG CHEN, QIUSHI GUO, CHENG LI, CHAO MA, SHAOFAN YUAN, ERIC SUNG, Yale University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, LI YANG, Washington University in St. Louis, FENGNIAN XIA, Yale University — In this work, we report the widely tunable mid-infrared light emission from dual-gate hexagonal boron nitride (hBN)/Black Phosphorus (BP)/hBN heterostructure devices. The photoluminescence (PL) from a ~20-layer BP flake can be continuously tuned from 3.7 to 7.7 μm with a moderate displacement field of 0.48 V/nm, spanning 4 μm in mid-infrared. The PL emission remains perfectly linear-polarized regardless of the bias field due to the preservation of the optical transition rule. We further performed first-principles calculation to investigate the gate dependence of the band structure and optical conductivity in BP. Moreover, together with theoretical analysis we show that the radiative decay probably dominates over other nonradiative decay channels in the PL experiments. Our results reveal the great potential of thin-film BP in widely tunable, mid-infrared light emitting and lasing applications.

WOOJOO LEE (Presenter), Physics, University of Texas at Austin, LI-SYUAN LU, WEN-HAO CHANG, Department of Electrophysics, National Chiao Tung University, CHIH-KANG SHIH, Physics, University of Texas at Austin — The emergence of van der Waals (vdW) 2D electronic materials and their heterostructures, especially the semiconducting family of transition metal dichalcogenides (TMD), has opened a new frontier of science and technology. Although interesting novel devices have been created using these 2D electronic materials and heterostructure, they are created only as discrete single devices. Namely, they are not scalable. A scalable material platform must satisfy the following conditions: (a) the ability to create single continuous layer of a continuous area of the same orientation, (b) the ability to stack dissimilar semiconducting layers to form wafer size heterostructures that are laterally homogeneous. Here we report successful development of a wafer size monolayer, quasi continuous and single orientation (but containing twins) platform of TMD that can be exfoliated and transferred to create wafer size TMD semiconducting heterostructures (in this case, monolayer MoS$_2$ on multilayer MoSe$_2$) with atomically clean interface. We use angle resolved photoemission to probe the electronic structure of such heterostructure and their respective constituents, revealing evidence of strong hybridization near the zone center.

5:06PM J51.00014: Emergent optical properties in crystalline, semiconducting 2D covalent organic framework / TMD heterostructures  

HALLEH BALCH (Presenter), Physics, University of California, Berkeley, AUSTIN EVANS, Chemistry, Northwestern University, RAGHUNATH DASARI, Chemistry, Georgia Tech, RUOFAN LI, Physics, Cornell, SIMIL THOMAS, HONG LI, Chemistry, Georgia Tech, DANQING WANG, Physics, University of California, Berkeley, JEAN-LUC E BREDAS, SETH R. MARDER, Chemistry, Georgia Tech, DANIEL C. RALPH, Physics, Cornell, WILLIAM DICHTEL, Chemistry, Northwestern University, FENG WANG, Physics, University of California, Berkeley — Two dimensional covalent organic frameworks are a new class of Van der Waals materials formed of periodic, covalently-bound lattices of planar organic molecules. The symmetry, lattice constant, optical, and electronic properties of 2D COFs can be controlled via choice of molecular constituents, which give rise to lattice properties not present in the component parts. To date, 2D COFs have been limited by large bandgaps, low coupling, and poor control of material morphology. Here, we present results on a new semiconducting 2D covalent organic framework and the unusual optical properties that emerge in COF / TMD heterostructures and when exfoliated to few-layer sheets. We characterize the structure by X-ray scattering, TEM, AFM, transport, and optical spectroscopy, and demonstrate facile manipulation onto arbitrary experimental platforms. Our data demonstrates that the formation of a highly crystalline and semiconducting 2D COF permits thickness-dependent optical properties not previously observed in 2D covalent organic frameworks. We further demonstrate thickness-dependent energy transfer dynamics in semiconducting COF / TMD heterostructures and outline directions of future research.
J51.00015: Sub-picosecond hot electron transfer in WS\textsubscript{2}/hBN/p-Si hybrid structure revealed by energy- and time-resolved photoemission electron microscopy*  
YAOLONG LI (Presenter), YUNAN GAO, XIAOYONG HU, QIHUANG GONG, Peking Univ — Carrier transfer plays a central role in all optoelectronic applications. It can occur much faster in low dimensional materials than in conventional bulk materials, which can be exploited in developing ultrafast and high-efficient optoelectronic devices. Here, we report an ultrafast hot electron transfer study in a hybrid structure of monolayer WS\textsubscript{2} on p-type silicon substrate separated by thin layer of hexagonal boron nitride (hBN). We studied the ultrafast electron transfer dynamics by an energy- and time-resolved photoemission electron microscopy, and determined that photoexcited electrons transfer to p-type silicon via two paths of a direct hot-electron transfer on a sub-picosecond timescale and another one of intra-band carrier cooling and subsequent electron transfer on a timescale of a few picoseconds. The transfer rate and the relative weight of the two paths can be quantitatively determined, which depends on excitation wavelength and the thickness of the hBN layer.

2:30PM J52.00001: Microstructure structure of air-grown UN\textsubscript{x}O\textsubscript{y} on nitrogen-rich uranium nitride*  
XIAOFANG WANG (Presenter), ZHONG LONG, RONGGUANG ZENG, YIN HU, KEZHAO LIU, Institute of Materials, China Academy of Engineering Physics — Uranium nitrides have aroused great attention for their important application in the corrosion protection of metallic uranium, due to formation of a nanoscale surface oxide layer when exposed to air or an oxygen-including atmosphere that slows or protects against further oxidation, but direct observations on the microstructure of oxide layer and the relationship of the crystal structure between the oxide layer and the underlying uranium nitride remain unresolved. In this work, oxide formation on surface of nitrogen-rich uranium nitride was investigated using X-ray photoelectron spectroscopy (XPS), auger electron spectroscopy (AES), aberration-corrected transmission electron microscopy (TEM), and high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM) coupled with electron energy-loss spectroscopy (EELS). XPS and AES studies indicated that the oxidized layer on UN\textsubscript{2-x} film is ternary compound uranium oxynitride (UN\textsubscript{x}O\textsubscript{y}) in about 10 nm thickness. TEM/HAADF-STEM and EELS studies revealed the UN\textsubscript{x}O\textsubscript{y} crystallizes in the FCC CaF\textsubscript{2}-type structure with the lattice parameter close to the CaF\textsubscript{2}-type UN\textsubscript{2-x} matrix. The work can provide further information to the oxidation mechanism of uranium nitride.

Segregation Effects and Charge Transport in Yttria-Stabilized Zirconia Thin Films on Langasite Substrates

FIRAS MAHYOB (Presenter), GEORGE BERNHARDT, ROBERT LAD, Univ of Maine — Yttria-stabilized zirconia (YSZ) is widely used as a bulk ceramic in solid-state oxygen sensors due to its high ionic conductivity, chemical inertness, and stability up to 1500°C. In thin film form, YSZ is an attractive component for use in wireless microwave acoustic sensors to monitor conditions within harsh industrial environments. In this work, RF-magnetron sputter deposition was used to synthesize YSZ (8%Y2O3-92%ZrO2) films with thicknesses from 15nm to 200nm on piezoelectric langasite (La3Ga5SiO14) substrates at growth temperatures from 25-600°C. X-ray diffraction indicated that the cubic YSZ films grow with preferred (111) out-of-plane texture on the langasite substrate with random in-plane orientation. Scanning electron microscopy revealed the presence of stress hillocks at the YSZ/langasite interface, and this was minimized at a 400°C deposition temperature where extremely smooth films were obtained as determined by x-ray reflectivity. Post-deposition air annealing caused yttria segregation to the film surface region as evidenced by increases in the Y3d/Zr3d photoelectron peak area ratio upon annealing up to 1000°C. This segregation is accompanied by an increase in film ionic conductivity and larger YSZ grain size as measured by high temperature impedance spectroscopy.

Surface reconstruction of TiO2 nanocrystals

ARAM YOON, XIAO ZHANG, ANDRE SCHLEIFE, JIAN-MIN ZUO (Presenter), University of Illinois at Urbana-Champaign — One of the best studied photocatalysts is TiO2. As chemical reactions occur on surfaces, the surface of TiO2 has been extensively investigated [1]. However, focus has largely been on 2D surfaces of bulk crystals, while real catalysts are nanocrystals or nanoparticles. Surface reconstruction on a nanocrystal is expected to be different with multiple facets. Here, we report on reconstructed surfaces on rutile nanocrystals studied by environmental transmission electron microscopy [2]. The reconstruction is imaged using an electron direct detection detector (DDD). The DDD provides significantly improved signal/noise ratio and high spatial resolution. Using these new approaches [3], we observed the surfaces of {110}, {210}, and {100} on TiO2 nanocrystals at atomic resolution and compared with previous models and with DFT calculations of atomic positions and total energies. Most importantly, the results allow an examination of surface reconstruction dependence on nanocrystal sizes.

3:06PM J52.00004: Epitaxial Growth of Sr$_3$Al$_2$O$_6$ by Pulsed Laser Deposition as a Water-Soluble Sacrificial Layer for GaAs Deposition  IMRAN KHAN (Presenter), BILL MCMAHON, ANDREW NORMAN, ANDRIY ZAKUTAYEV, National Renewable Energy Laboratory — Despite the record high efficiency for GaAs solar cells, its terrestrial application is limited due to both the particularly high costs related to the required single crystal substrates and the epitaxial growth. A water-soluble lift off layer could reduce costs by avoiding the need for toxic etchants, substrate re-polishing and expensive process steps.

Sr$_3$Al$_2$O$_6$ (SAO) is a water soluble, cubic oxide with lattice constant 15.84Å. This is close to $(2\sqrt{2})a_{GaAs}$, giving a close lattice match after 45° lattice rotation. We investigated the epitaxial growth of high structural quality SAO on single crystal SrTiO$_3$ (STO) substrates by pulsed laser deposition, and the feasibility of subsequently growing GaAs epitaxially on top of it. We identified that the SAO film quality is strongly dependent on the growth temperature and O$_2$ partial pressure. An STO capping layer was grown on the SAO to protect from moisture induced degradation. XRD spectra for the films with optimized deposition parameters showed epitaxial SAO aligned to the STO (100) substrate. TEM analysis revealed that the grown SAO films are epitaxially crystalline throughout the thickness. The epitaxial growth of the STO capping layer is a qualitative indication for the high quality of the SAO surface.
3:18PM J52.00005: Surface and Interface Energetics of Pyrite-type Materials* JOSEPH
MINNICH (Presenter), Department of Physics, American University, ANDREW O’HARA, SOKRATES T
PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — Materials with the pyrite
crystal structure, such as iron and cobalt sulfide, are composed of earth-abundant
elements with potential applications in photovoltaics, catalysis, and spintronics. While the surface
properties of FeS$_2$ have received significant attention in the literature, less is known about the
surface
properties of other pyrite-type materials like CoS$_2$ as well as the interfaces between these
materials. In this
work, we perform calculations using density functional theory (DFT) to gain insight into the
surface and
interface energetics of these pyrite materials. Specifically, we compute the energies for several
low-index
surface orientations with different surface terminations (i.e., sulfur-rich to sulfur-poor). We
compare the
minimal surface energy and interface energy between the two materials along these directions.
Extending
the basic surface characterization, we also include the effects of ligands bound to these surfaces.
The
results provide insights concerning the observed epitaxy of these materials in hybrid
nanoparticle
experiments and provide guidance for additional experiments regarding the growth of structures
utilizing
these materials.

3:30PM J52.00006: Atomic scale dynamic process of oxide growth during copper oxidation* MENG LI, MATTHEW T CURNAN, WISSAM A SAIDI, JUDITH YANG (Presenter), Univ of Pittsburgh —
Understanding oxide growth mechanism during metal oxidation is essential for rational design
and control of oxides for applications in catalysts, sensors, as well as corrosion protection.
Despite ample research on bulk oxidation, little is known on the initial oxide growth process. In
this work, we use correlated in situ Environmental Transmission Electron Microscope, DFT
simulation, quantitative data extraction and statistical analysis to investigate the dynamic atomic
process of initial oxide growth. An unusual layer-by-layer growth of Cu$_2$O island along Cu$_2$O(110)
plane is observed, instead of along the previously assumed Cu$_2$O(100) plane that is parallel to the
Cu surface. Statistical analysis of growth dynamics indicates a diffusion limited monolayer growth
process. DFT results showed Cu$_2$O(110) has lower surface energy, favorable Cu and O diffusion
barriers and adsorption energies during oxidation, leading to easier Cu$_2$O monolayer formation
along Cu$_2$O(110). These results shed new light on surface oxidation process.

3:42PM J52.00007: Structure and electro-optical properties of Sr$_x$Ba$_{1-x}$Nb$_2$O$_6$ films grown by molecular beam epitaxy.* ILYA BESKIN (Presenter), JACQUELINE GELER KREMER, AGHAM POSADAS, ALEXANDER DEMKOV, University of Texas at Austin — With the rise of processor speed, optical fibers are replacing copper wires in carrying data between computer boards. Silicon photonics has applications in not only chip interconnects, but also neuromorphic and quantum computing. The Pockels effect offers a way to build fast, low power modulators of optical signals. The Pockels effect uses an electric field to change the index of refraction in a material. One can make devices that encode or alter information using the phase of light. Sr$_x$Ba$_{1-x}$Nb$_2$O$_6$ (SBN) has been shown to have one of the highest available Pockels coefficients (~850pm/V). SBN was grown by molecular beam epitaxy on SrTiO$_3$ (STO) substrates and STO can be used to integrate materials on Si. The growth was monitored with Reflective High Energy Electron Diffraction. Composition and oxidation states were measured in-situ by X-Ray Photoemission Spectroscopy. X-Ray Diffraction was used to verify the crystal phase and orientation of the SBN crystal.

*The work is supported by the Air Force Office of Scientific Research under grant FA9550-18-1-0053

3:54PM J52.00008: Probing TiO$_2$ as a potential filter material for adsorption and destruction of chemical warfare agents* ROMAN TSYSHEVSKIY (Presenter), University of Maryland, College Park, MONICA MCENTEE, ERIN DURKE, CCDC Chemical Biological Center, TIANYU LI, MATTHEW LEONARD, EFRAIN RODRIGUEZ, University of Maryland, College Park, CHRISTOPHER KARWACKI, CCDC Chemical Biological Center, MAIJA M KUKLA, University of Maryland, College Park — An atomistic level understanding of mechanisms of adsorption and decomposition of chemical agents on components of filtration materials is required for improvements of existing and design of new materials for chemical protection. Here, we present a comprehensive study of sarin interactions with TiO$_2$ performed by means of quantum chemical calculations and a combination of IR and XPS measurements. Computational modeling was used to reveal mechanisms of sarin adsorption and decomposition on an ideal (defect free) and hydroxylated TiO$_2$ rutile (110) and anatase (101) surfaces, whereas experimental measurements were performed for TiO$_2$ nanoparticles and synthesized mesoporous materials. Calculations revealed strong adsorption of sarin on both the ideal rutile and anatase surfaces, although high activation barriers preclude a decomposition of sarin. The presence of water, on the other hand, reduces binding strength of sarin to rutile and anatase, but promotes the decomposition of sarin. Results of computational modeling were found in good agreement with experimental measurements.

*This work was supported by US DOD through DTRA (HDTRA11910001). R.T. and M.M.K acknowledge support from XSEDE (DMR-130077), NERSC (Contract DE-AC02-05CH11231), MARCC and UMD supercomputing resources.
Thin films of Hf-based oxides gained importance after the discovery of the ferroelectricity in these materials\textsuperscript{1}. One of the ways to achieve ferroelectricity in HfO\textsubscript{2} is doping with metals such as Zr and Al to modify the crystal structure towards orthorhombic symmetry. In Hf based oxide thin films prepared by doping, multiple crystal phases could emerge. In this work, we theoretically investigated the stability of the possible structures that could be present in Al doped HfO\textsubscript{2} using quantum mechanical methods. Specifically, using plane wave density functional theory, the monoclinic, tetragonal, orthorhombic, and rhombohedral phases of aluminum doped hafnia were geometrically optimized. The resulting equilibrium structures for 3\%, 6\%, and 7\% Al doped hafnia structures will be used as theoretical reference structures for EXAFS spectra obtained Al doped HfO\textsubscript{2} thin films.

Keywords: Density functional theory, ferroelectricity, doped hafnia

Investigation of the thickness-dependent optical properties of ZnO films on Si and SiO$_2$ substrates from the Mid-infrared to the Vacuum-ultraviolet using UV and FTIR spectroscopic ellipsometry

NUWANJULA SAMARASINGHA ARACHCHIGE (Presenter), STEFAN ZOLLNER, New Mexico State University, Las Cruces, NM, United States., DIPAYAN PAL, AAKASH MATHUR, AJAIB SINGH, RINKI SINGH, SUDESHNA CHATTOPADHYAY, IIT Indore, Indore, India. — The conventional approach to describe the dielectric function $\varepsilon$ as a sum of oscillators sometimes fails because each term only has a single broadening parameter. Instead, we find it more convenient to describe $\varepsilon$ as a product of Drude, TO/LO phonon, and electronic interband transition factors. Specifically, we explore the behavior of phonon and excitonic absorption in bulk zinc oxide (ZnO) and ZnO thin films grown on Si and SiO$_2$ using UV/VIS and FTIR spectroscopic ellipsometry. We characterized the structural properties of our ZnO films with x-ray diffraction, x-ray reflectivity, and atomic force microscopy.

We find that the real and imaginary parts of $\varepsilon$ in ZnO films on Si and SiO$_2$ are much smaller than in bulk. Excitonic enhancement, absorption coefficient, and refractive index decrease monotonically with decreasing film thickness. The impact of the excitonic contribution to $\varepsilon$ was described by Tanguy [1]. We also fit our ellipsometric spectra by describing the dielectric function of ZnO using the Tanguy model. Also, we investigate the thickness dependence of the Born effective charge, high-frequency and static dielectric constant, and exciton parameters.

Surface structure and electronic properties of $a$, $b$, and $e$ polymorphs of Ga$_2$O$_3$

TENGFEI CAO (Presenter), ROHAN MISHRA, Mechanical Engineering & Materials Science, Washington University in St. Louis — Ga$_2$O$_3$ is an emerging wide-band-gap semiconductor that exhibits diverse phases with varying electronic properties. $\varepsilon$-Ga$_2$O$_3$, a metastable polymorph, has recently been reported to be a ferroelectric semiconductor with potential application in power and high-frequency electronics [1]. Although there have been numerous attempts to grow $\varepsilon$-Ga$_2$O$_3$ on various substrates, single-phase $\varepsilon$-Ga$_2$O$_3$ thin films have not been reported. An investigation of the stability of the surface of $a$, $b$, and $e$ polymorphs of Ga$_2$O$_3$ can facilitate the synthesis of phase-pure thin films. Results of first-principles calculations of the surface stability of the three Ga$_2$O$_3$ polymorphs as a function of the chemical potential along with their electronic properties will be presented. The stability of its (001) polar surface of Ga$_2$O$_3$ as a function of polarization and thickness will be presented. Moreover, electronic structure calculations indicate a lack of quantum confinement in $\alpha$-Ga$_2$O$_3$ thin-films. Finally, different substrate effects on the stability of the three Ga$_2$O$_3$ polymorphs will be talked.

This work was supported by NSF DMR-1931610.
Atomistic determination of the surface structure of Cu$_2$O (111) and Cu$_2$O (110): experiment and theory*  

JEFFREY GUEST (Presenter), Center for Nanoscale Materials, Argonne National Laboratory, RUI ZHANG, Department of Physical and Material Sciences, Anhui University, LIANG LI, Center for Nanoscale Materials, Argonne National Laboratory, LASZLO FRAZER, Centre of Excellence in Exciton Science, University of New South Wales, KELVIN B. CHANG, KENNETH R POEPPELMEIER, Department of Chemistry, Northwestern University, MARIA CHAN, Center for Nanoscale Materials, Argonne National Laboratory — Photocatalytic reactions on the surface of cuprous oxide (Cu$_2$O) hinge on atomic scale structure of the defected Cu$_2$O surfaces; however, to date, the atomic morphologies of these surfaces have not been unambiguously characterized. In this work, high-resolution ultrahigh vacuum (UHV) scanning tunneling microscopy (STM) and density functional theory (DFT) calculations combined with STM simulations have been used to determine the structure of the defected (111) and (110) surfaces of a Cu$_2$O bulk crystal. Under STM, the imaged Cu$_2$O (111) surface is dominated by coordinatively unsaturated copper atoms, and atomic-scale defects including the Cu vacancy and the O-vacancy-induced local surface restructuring [1,2] are identified. The Cu$_2$O(110) surface reveals aggregation of defects and periodic distortions of the atomic rows.

4:54PM J52.00013: Structural and Electrical Properties of Pulsed Laser Deposited Yttrium Doped Zirconium Oxide Thin Film Stabilization* MATTHEW MELFI (Presenter), SARAH TUTTLE, SAMANTHA DALLI, KELLEN MURPHY, MEHMET ALPER SAHINER, Seton Hall Univ — Solid Oxide Fuel Cells (SOFC) are devices that use electrochemical reactions to convert chemical energy from fuel to electricity. In comparison with coal power plants, a SOFC produces a higher electrical conversion efficiency. SOFC is a possible candidate for energy production. However, at higher temperatures (800-1000°C) it creates a lower ionic conductivity, which limits the SOFC. When lowering the temperature, the ohmic resistance increases, as a thin film. In our research a YSZ, layer will be produced from a fine dimple grain structure allowing high flow of O\textsubscript{2} mobility. This mobility increases ionic conductivity and decreases ohmic loss. The goal of our research is to determine if the YSZ thin film synthesis lead to minimum ohmic resistance of the films at optimum film thickness. The method that is used is to test different molecular ratios of the YSZ and deposit the ratios with different energy levels onto different substrates, including conductors, semi-conductors, and insulators, and compare the properties of the YSZ layer. The thin films will be characterized through electrical measurements such as 4-Point Probe Resistivity measurements as well as AFM, SEM, and EDX Spectroscopy for the structural and compositional characterization.

5:06PM J52.00014: Time-resolved Nanosecond-Laser Recrystallization of Amorphous FeDy-O Thin Films in the (S)TEM* KRISHNA KOIRALA (Presenter), CHENZE LIU, University of Tennessee, Knoxville, TATIANA ALLEN, University of Tennessee-Chattanooga, RAMKI KALYANARAMAN, GERD DUSCHER, University of Tennessee, Knoxville — Iron-Dysprosium oxide thin film can be an amorphous semiconductor with unusual magneto-optic properties. The properties of amorphous materials are often governed by local structure and recrystallization mechanism is important for the stability of the materials system as well as engineering of properties. To investigate the structure and chemical composition of this material, we employed laser processing inside the (S)TEM with simultaneous High-Resolution Transmission Electron Microscopy (HRTEM) imaging, Electron Diffraction, and Electron Energy Loss Spectroscopy (EELS) measurements. It shows that the structural change in amorphous FeDy-O can be seen as early as with 100 ns single laser pulse at the laser fluency of 1.49E6 J/cm\textsuperscript{2} as indicated by the emergence of sharp diffraction rings from initial broad and diffuse diffraction ring. The pulsed laser-induced changes were studied up to 10,000 pulses where intense Brag's spots were visible. Our results provide insight on unique way of understanding the local structure evolution and time resolution of the recrystallization process with laser pulses and allow us to conclude back onto the amorphous atomic arrangement of this material system.

J52.00015: Ionic liquid gate induced modifications of oxides surface

YUECHEN ZHUANG

(Presenter), BIN CUI, HAO YANG, FANG GAO, STUART PARKIN, Max Planck Institute of Microstructure Physics — Intense electric fields developed during gating at the interface between an ionic liquid (IL) and an oxide layer have been shown to lead to significant structural and electronic phase transitions in the entire oxide layer. An archetypical example is the reversible transformation between the brownmillerite SrCoO$_{2.5}$ and the perovskite SrCoO$_3$ engendered by ionic liquid gating. In this presentation, we show using in-situ atomic force microscopy studies, with photothermal excitation that allows for high quality measurements in the viscous environment of the ionic liquid, that the edges of atomically smooth terraces at the surface of SrCoO$_{2.5}$ films are significantly modified by IL gating but that the terraces themselves remain smooth. The edges develop ridges that we show, using complementary X-ray photo emission spectroscopy studies, result from the adsorption of hydroxyl groups. Our findings open up opportunities for electrically controlled surface modifications in emergent ionitronic applications.

2:30PM J53.00001: Atomic-scale spectroscopy of 2D Transition metal dichalcogenide heterostructures

SARA SHABANI (Presenter), ABHAY PASUPATHY, Columbia Univ — Bilayers of 2H-WSe2 and 2H-MoSe2 form a type-II semiconductor heterostructure. A number of interesting optoelectronic phenomena have been observed in such heterostructures including charge transfer excitons, photovoltaic and photothermal effects, and Mott transitions at high exciton density. In this talk, we will describe complementary single-particle measurements of the electronic structure of these heterostructures using scanning tunneling microscopy (STM) and spectroscopy. Using a large-area exfoliation technique, coupled with pre-patterned electrodes to make ohmic contact to these bilayers, we have succeeded in fabricating devices that are compatible with surface-sensitive probes such as STM and angle resolved photoemission. We will describe the spatial structure of the bilayers including the effect of lattice mismatch on the electronic properties, as well as spectroscopic measurements performed under optical illumination both below and above the Mott threshold.
2:42PM J53.00002: Unraveling the Tunneling Spectrum of Bernal Stacked Bilayer Graphene*  
JOHN DAVENPORT (Presenter), ZHEHAO GE, FREDERIC JOUCKEN, EBERTH A QUEZADA, Physics Dept., University of California: Santa Cruz, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS Japan, JAIRO VELASCO JR., Physics Dept., University of California: Santa Cruz — Scanning tunneling spectroscopy (STS) has recently provided important insight on the symmetry breaking effects and correlated states in magic angle twisted bilayer graphene (MATBLG). Conventional STS, however, can unintentionally change the dynamic band structure of MATBLG sheets due to the unavoidable and prominent electric field from the STS probe tip. Such an effect can obscure the intrinsic nature of correlated electron states present in MATBLG. We will discuss our latest experimental progress towards using a simpler tunneling system—planar tunneling spectroscopy nanodevices—to controllably probe the dynamic band structure of Bernal-stacked bilayer graphene. Our methods can be applied to MATBLG as well as other two-dimensional material systems that have a dynamical band structure.

2:54PM J53.00003: Proximity-induced superconducting gap in the quantum spin Hall edge state of monolayer WTe$_2$*  
FELIX LUEPKÉ (Presenter), DACEN WATERS, Carnegie Mellon University, SERGIO DE LA BARRERA, Massachusetts Institute of Technology, MICHAEL WIDOM, Carnegie Mellon University, DAVID MANDRUS, University of Tennessee, Knoxville, JIAQIANG YAN, Oak Ridge National Lab, RANDALL M FEENSTRA, BENJAMIN HUNT, Carnegie Mellon University — Van der Waals heterostructures allow the combination of different material properties, e.g. non-trivial topology and superconductivity in order to create a topological superconducting state. In my talk, I demonstrate a novel dry-transfer flip technique which allows to place atomically-thin layers of WTe$_2$, a quantum spin hall system, on NbSe$_2$, a van der Waals superconductor. Using scanning tunneling microscopy and spectroscopy (STM/STS), we demonstrate atomically clean surfaces and interfaces and the presence of a proximity-induced superconducting gap in the WTe$_2$ for thicknesses from a monolayer up to 7 crystalline layers. At the edge of the WTe$_2$ monolayer, we show that the superconducting gap coexists with the characteristic spectroscopic signature of the QSH edge state [1]. Taken together, these observations provide conclusive evidence for proximity-induced superconductivity in the QSH edge state in WTe$_2$, a crucial step towards realizing 1D topological superconductivity and Majorana states in this van der Waals material platform.

3:06PM J53.00004: Observation of Deep In-gap States of Line and Point defects in Monolayer WS₂ via Scanning Tunneling Microscopy and Spectroscopy*  MADISEN HOLBROOK (Presenter), WEI-TING HSU, CHIH-KANG SHIH, University of Texas at Austin — Atomic defects in crystalline semiconductors strongly affect their electronic properties, such as electron transport and optical response. Defects in two dimensional (2D) semiconductors, such as transition metal dichalcogenides (TMD’s), have a more dramatic impact than bulk counterparts due to less screening and increased substrate interactions. In particular, different atomic vacancies have been reported, but their role in the electronic structure must be established. Deep in-gap states were predicted for different defect structures in 2D TMD’s, but direct experimental observation of defect structure and electronic properties is necessary to tailor TMD’s for device design. Here we report the creation of point and line defects in WS₂ monolayers by vacuum annealing. The electronic properties and structure of these defects was probed using scanning tunneling microscopy and spectroscopy. We find these defects have a rich variety of deep in-gap states, shedding light on the role of defects in TMD electronic properties.

3:18PM J53.00005: Determination of the trigonal warping orientation in Bernal-stacked bilayer graphene via quasiparticle interference imaging*  FREDERIC JOUCKEN (Presenter), ZHEHAO GE, EBERTH A QUEZADA, Physics, University of California, Santa Cruz, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba, Japan, JAIRO VELASCO JR., Physics, University of California, Santa Cruz — The existence of strong trigonal warping around the K point for the low energy electronic states in multilayer graphene films and graphite is well established. It is responsible for phenomena such as Lifshitz transitions and anisotropic ballistic transport. The absolute orientation of the trigonal warping with respect to the center of the Brillouin zone is however not agreed upon. Here, we use quasiparticle scattering experiments on a gated bilayer graphene/hexagonal boron nitride heterostructure to resolve this disagreement. We compare Fourier transforms of scattering interference maps acquired at various energies away from the charge neutrality point with joint density of states simulations. This comparison permits unambiguous determination of the trigonal warping orientation for bilayer graphene at low energy. Our experimental technique is promising for studying quasi-directly fine features of the band structure of two-dimensional materials such as band topologies and Lifshitz transitions.

3:30PM J53.00006: Charge/spin density waves at the edges and mirror twin boundaries of Transition Metal Di-Chalcogenides*  
SRIDEVI KRISHNAMURTHI (Presenter), Univ of Twente —  
Grain boundaries and edges of two-dimensional semiconducting TMDCs MX₂ (M=Mo,W; X=S,Se,Te) exhibit metallicity, which is remarkably robust against variations in structure or stoichiometry. The origin of these metallic boundary states lies in the lattice polarization and the states are topologically protected by the D₃h symmetry of the TMDC lattice. From first-principles (DFT+U) calculations we show, however, that symmetry breaking at edges or boundaries leads to one-dimensional charge and spin density wave (C/SDW) instabilities. Such C/SDWs are commensurable with a period of three lattice sites, dictated by the lattice symmetry, and open up a band gap. The resulting electronic structure agrees well with experimental measurements on, for instance, the mirror twin boundary.

3:42PM J53.00007: Quantum spin Hall effect in twisted bilayer WTe₂ measured with STM*  
DACEN WATERS (Presenter), FELIX LUKAS LÜPKE, BENJAMIN HUNT, RANDALL M FEENSTRA, Physics Department, Carnegie Mellon University —  
Tungsten telluride is a two-dimensional (2D) material that exhibits a range of properties, depending on the number of layers. Bilayers are reported to be a topologically trivial semimetal that exhibit a ferroelectric effect¹. In the monolayer (ML) limit, WTe₂ has been shown to be a quantum spin Hall (QSH) insulator², resulting in topologically protected edge modes. In this work, we report scanning tunneling microscopy and spectroscopy (STM/STS) studies of twisted bilayers of WTe₂ for a variety of configurations. We find that tunneling spectra of the twisted bilayers resemble that of decoupled monolayers for twist angles ≥5°, and observe edge states to exist at the boundaries of the twisted bilayer regions, in contrast to the case of the trivial bilayer. To study exfoliated WTe₂ in STM, which is air sensitive, we utilize a novel transfer technique³ that enables stacking in an inert gas environment but maintains an atomically pristine surface available for surface probe measurements.

*The authors would like to thank the US Department of Energy (DE-SC0018115, SC0014506) and the National Science Foundation (DMR-1539916, 1626099, 1809145) for their support.
Disorder-induced nonlinear Hall effect with time-reversal symmetry

ZONGZHENG DU, Southern University of Science and Technology, CHUNMING WANG, Shanghai Normal University, SHUAI LI, HAIZHOU LU (Presenter), Southern University of Science and Technology, XINCHENG XIE, Peking University — The nonlinear Hall effect has opened the door towards deeper understanding of topological states of matter. It can be observed as the double-frequency Hall voltage response to an ac longitudinal current in the presence of time-reversal symmetry. Disorder plays indispensable roles in various linear Hall effects, such as the localization in the quantized Hall effects and the extrinsic mechanisms of the anomalous, spin, and valley Hall effects. Unlike in the linear Hall effects, disorder enters the nonlinear Hall effect even in the leading order. Here, we derive the formulas of the nonlinear Hall conductivity in the presence of disorder scattering. We apply the formulas to calculate the nonlinear Hall response of the tilted 2D Dirac model, which is the symmetry-allowed minimal model for the nonlinear Hall effect and can serve as a building block in realistic band structures. More importantly, we construct the general scaling law of the nonlinear Hall effect, which may help in experiments to distinguish disorder-induced contributions to the nonlinear Hall effect in the future. This work will be insightful for studying the disorder effects in the nonlinear Hall effect.

Intrinsic orbital moment and prediction of a large orbital Hall effect in the 2D transition metal dichalcogenides

SAYANTIKA BHOWAL (Presenter), SASHI SEKHAR SATPATHY, Univ of Missouri - Columbia — Orbital Hall effect (OHE) is the phenomenon of transverse flow of orbital angular momentum caused by an applied longitudinal electric field. From density-functional and tight-binding model studies, we predict the existence of a large OHE in the 2D transition metal dichalcogenides (TMDC) due to the intrinsic orbital moment induced by the broken inversion symmetry of the system. We show that monolayer TMDC, the prototypical example of broken inversion symmetric 2D material, have a hitherto-unknown intrinsic orbital moment in the momentum space, which in turn leads to a large OHE with possible applications in the newly emerging field of orbitronics. The orbital moment and the OHE appear even in absence of the spin-orbit coupling (SOC) and give rise to “valley dependent spin splitting” and spin Hall effect in presence of SOC. We show that the OHE can also be tuned by a transverse electric field due to the orbital Rashba coupling, that produces an additional orbital texture which in turn modifies the OHE.

4:18PM J53.00010: Magnus Hall effect*  MICHAL PAPAJ (Presenter), LIANG FU, Massachusetts Institute of Technology MIT — A new type of a linear response Hall effect is predicted in time-reversal-invariant systems with built-in electric field at zero magnetic field. The Hall response results from a quantum Magnus effect where a self-rotating Bloch electron wavepacket moving under electric field develops an anomalous velocity in the transverse direction. We show that in the ballistic limit the Magnus Hall conductance measures the distribution of the Berry curvature on the Fermi surface.

*This work was supported by DOE Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-SC0018945.

4:30PM J53.00011: The Curious Magnetic Properties of Orbital Chern Insulators  JIHANG ZHU (Presenter), ALLAN MACDONALD, University of Texas at Austin — Chern insulator ferromagnets are characterized by a quantized anomalous Hall effect, and have so far been identified experimentally in magnetically-doped topological insulator (MTI) thin films and in bilayer graphene moiré superlattices. We classify Chern insulator ferromagnets as either spin or orbital, depending on whether the orbital magnetization results from spontaneous spin-polarization combined with spin-orbit interactions, as in the MTI case, or directly from spontaneous orbital currents, as in the moiré superlattice case. We argue that in a given magnetic state, characterized for example by the sign of the anomalous Hall effect, the magnetization of an orbital Chern insulator will often have opposite signs for weak n and weak p electrostatic or chemical doping. This property enables pure electrical switching of a magnetic state in the presence of a fixed magnetic field.

4:42PM J53.00012: Hall Conductivity of Two-Dimensional Electrons in an Abrikosov Magnetic Flux Lattice*  JONATHAN SCHIRMER (Presenter), Pennsylvania State University, RAVI KHANDELWAL, Physics, Indian Institute of Science, Bangalore, KENJI WATANABE, NIRM, TAKASHI TANIGUCHI, Kyoto Univ, PRATAP RAYCHAUDHURI, Tata Institute of Fundamental Research, JAINENDRA JAIN, CHAOXING LIU, Pennsylvania State University, ANINDYA DAS, Physics, Indian Institute of Science, Bangalore — We study, both theoretically and experimentally, the Hall transport of two-dimensional electrons exposed to a magnetic field produced by an Abrikosov flux lattice. Our experiments on monolayer graphene-hBN-NbSe2 heterostructure demonstrate a substantial reduction in the Hall conductivity as the temperature is reduced from above the superconducting critical temperature of NbSe2, when the magnetic field is uniform, to below, where the magnetic field bunches into an Abrikosov flux lattice. We provide a quantitative explanation of this phenomenon by evaluating the cumulative Berry curvature of occupied states using a lattice model, while also taking account of disorder, and extrapolating to the continuum limit. A fundamental role is played by a correlation between the Berry curvature and the energy within Landau levels broadened by the non-uniform magnetic field.

*U.S. Department of Energy, Office of Basic Energy Sciences, Grant No. desc0005042
4:54PM J53.00013: Energy gaps of low filling factor quantum Hall states in two-dimensional Indium Selenide. DMITRY SHCHERBAKOV (Presenter), PETR STEPANOV, JIAWEI YANG, Ohio State Univ - Columbus, SHAHRIAR MEMARAN, WENKAI ZHENG, National High Magnetic Field Lab, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Namiki Tsukuba Ibaraki, Japan, LUIS BALICAS, National High Magnetic Field Lab, CHUN NING LAU, Ohio State Univ - Columbus — Indium selenide is a promising two-dimensional semiconductor with thickness-dependent bandgap and high electron mobility. We have fabricated high mobility few-layer InSe devices and studied them in quantum Hall regime. Landau levels at filling factors between 1 and 10 are resolved. Energy gaps at different magnetic fields, gate voltage and temperatures will be discussed.

5:06PM J53.00014: Non-perturbative valley Hall effect in graphenes* WEI-YUAN TU (Presenter), CI LI, HONGYI YU, WANG YAO, The University of Hong Kong — Valley Hall currents can be induced in graphene by breaking its version symmetry that opens a gap which is usually very small. A finite electric field can easily exceed the adiabatic limit on which the standard semiclassical theory for the valley Hall effect is based. Here we provide a non-perturbative formulation for valley Hall effect. We show that the non-perturbation effects of the electric field directly lead to an oscillating anomalous velocity in the coherent evolution of an electron, in contrast to the stationary one inherited to the adiabatic limit. By properly taking into account the decoherence effect, we obtain a steady-state valley Hall current that is in all orders of the electric field. It clearly shows nonlinearity in the Hall conductivity to high electric-field values and still retains the intrinsic role of the Berry curvature. Through the inspection of the non-perturbative effect of the electric field, it becomes obvious that the valley Hall conduction in gapped graphene is mediated by the interference between the electric field induced electron-hole excitations and the fermi sea.

5:18PM J53.00015: Edge channels in graphene with proximity-induced Spin-Orbit Interaction
TARO WAKAMURA, SOPHIE GUERON (Presenter), NIANTHENG WU, MEYDI FERRIER, HÉLÈNE BOUCHIAT, Laboratoire de Physique des Solides Orsay, U. Paris Sud, U. Paris Saclay, CNRS, France, CECILIA MATTEVI, PAWEL PALCZYNSKI, MAURO OCH, Imperial College London, UK, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, Japan — Enhancing spin-orbit interaction (SOI) in graphene may lead to new properties, including a possible Quantum Spin Hall state, characterized by counterpropagating, spin-polarized channels at the edges of graphene. We previously demonstrated how graphene coupled to Transition Metal Dichalcogenides (TMDs) acquires a strong and mirror-symmetric spin-orbit interaction, especially with monolayers of WSe2 and WS2. The signature of induced spin-orbit was weak antilocalization (positive magnetoresistance) in mesoscopic samples with normal contacts at low temperature [1, 2]. In this talk I will present our recent measurements of supercurrents induced through graphene/WS2 heterostructures connected to high-critical-field superconductors. I will discuss how signatures of edge conduction are detected for both graphene coupled to hBN and graphene coupled to WS2 in short Josephson junctions, but how the edge channels are far more dominant in long junctions of graphene coupled to WS2, and visible also at high magnetic fields applied perpendicularly to the graphene plane.

Session J54 DCMP: Bulk-Boundary Correspondence and Classification of Topological Phases Mile High Ballroom 2A

2:30PM J54.00001: Realizing the bulk-boundary correspondence for anomalous symmetry-enriched topological phases DANIEL BULMASH (Presenter), MAISSAM BARKESHLI, University of Maryland, College Park — We construct models of anomalous 2+1D symmetry-enriched topological phases (SETs) on the surfaces of 3+1D symmetry-protected topological phases, providing an explicit realization of the bulk-boundary correspondence for SETs. Our construction takes as input the symmetry fractionalization data and does not require a priori knowledge of the SET’s anomaly. Our method works for both non-permuting and anyon-permuting symmetry actions on both Abelian and non-Abelian topological orders. We discuss the extraction of the absolute anomaly using our construction.
2:42PM J54.00002: Bulk-boundary correspondence for (2+1)D symmetry protected topological phases*  KYLE KAWAGOE (Presenter), MICHAEL LEVIN, University of Chicago — A universal property of symmetry protected topological (SPT) phases is that they have low energy boundary modes that are protected under the symmetry. This fact inspires an important problem in the theory of SPT phases: How does one identify a bulk SPT phase given a low energy theory of its boundary? This question is particularly challenging in the case of interacting SPT phases where band theory approaches are inapplicable. In this talk, we present a general method for solving this problem in the case of (2+1)D interacting bosonic systems with internal (non-spatial) symmetries.

*This work was supported by the Simons Foundation through the "Ultra-Quantum Matter" Simons Collaboration.

2:54PM J54.00003: Correlated bulk-boundary correspondence of the higher-order topological insulator*  KOJI KUDO (Presenter), TSUNEYA YOSHIDA, YASUHIRO HATSUGAI, Univ of Tsukuba — In this talk, we propose a novel topological state which we call “higher-order topological Mott insulator” (HOTMI) [1]. It gives a distinct bulk-boundary correspondence from a conventional higher-order topological insulator; $d$-dimensional bulk topology of the HOTMI predicts the emergence of gapless states not in charge excitations but in spin excitations around $(d-n)$-dimensional boundaries with $n = 2, \ldots, d$. We numerically demonstrate that the Hubbard model on the kagome lattice gives the 2nd-order HOTMI states for $d = 2$. Specifically, the corner-Mott states appearing in the system under the open boundary condition, which is gapless only in the spin excitations, are predicted by the $Z_3$ spin Berry phase calculated in the bulk system.

*The work is supported by JSPS KAKENHI Grant Numbers JP16K13845 (Y.H.), JP17H06138, JP18H05842 (T.Y.), and JP19J12317 (K.K.).

3:06PM J54.00004: Anomaly and symmetry fractionalization of mirror-symmetric fermionic topological orders  BINBIN MAO (Presenter), CHENJIE WANG, The University of Hong Kong — We study symmetry fractionalization and quantum anomaly in general 2D fermionic topological orders with the mirror reflection symmetry. A set of constraints on mirror fractionalization and an explicit anomaly indicator formula are derived. Our derivation is based on the recently developed folding approach, which was originally proposed in bosonic topological orders. The anomalous mirror-symmetric topological orders can only live on the surface of 3D topological crystalline superconductors, and we establish a direct bulk-boundary correspondence.
3:18PM J54.00005: Computing the Classification of Fermionic Symmetry-Protected Topological States  
YUNQING OUYANG (Presenter), Department of Physics, Fudan University, QING-RUI WANG, ZHENGCHENG GU, Department of Physics, The Chinese University of Hong Kong, YANG QI, Department of Physics, Fudan University — The bosonic symmetry protected topological (SPT) states are classified by the cohomology groups of the symmetry group. However, for interacting fermionic systems, the classification is much more complicated. It was until very recent that a breakthrough was made on the classification and construction of fermionic SPT states based on the concept of equivalence class under finite-depth symmetric fermionic local transformations. However, though layers of data for classification and construction can be obtained theoretically, the formalism based on the bar resolution of symmetry groups (also known as the inhomogeneous cochains) makes it impossible for realistic computation due to high computational costs. To solve these problems, we first design reduced resolutions for general groups by group extension, then we apply the chain maps between the bar resolution and reduced resolution to solve the obstruction function to get the unobstructed layers of data. Meanwhile, to simplify the computation, we apply the technique of spectral sequence. Finally, we give a classification of fermionic SPTs protected by 2D wallpaper-group symmetries.

3:30PM J54.00006: Non-Abelian reciprocal braiding of Weyl nodes and fragile topology  
ADRIEN BOUHON (Presenter), NORDITA, QUANSHENG WU, Physics, EPF Lausanne, ROBERT-JAN SLAGER, Physics, Harvard University, TOMAS BZDUSEK, LSM, Paul Scherrer Institut — Weyl nodes trapped within $C_2T$ symmetric planes (i.e. -crystalline rotation combined with time reversal) acquire a non-Abelian topological charge on top of their chirality. E.g. three-level systems realize the quaternion group [1]. The non-Abelian nature of Weyl nodes can alternatively be captured by the Euler class [2,3], which itself can be efficiently computed through the Wilson loop as the winding number of a Pfaffian [3]. These tools allow us (i) to design minimal experimental setups, and (ii) to search for material candidates. Furthermore, we show that additional crystalline symmetries can lead to the obstruction of the Euler class which naturally gives rise to nontrivial fragile topology.

3:42PM J54.00007: Topology of SO(5) monopoles and three dimensional Dirac semimetals
PALLAB GOSWAMI (Presenter), ALEXANDER TYNER, SHOUVIK SUR, Northwestern University — The topological properties of Kramers degenerate band structures generally emerge from non-trivial textures of underlying SO(5) Berry's vector potential. The linear touching between a pair of Kramers degenerate energy bands at isolated points of momentum space along an n-fold axis of rotation gives rise to three dimensional Dirac semimetals, where the Dirac points act as singularities of SO(5) gauge fields. Even though considerable progress has been made in recent years toward understanding the stability of Dirac points in the presence of parity, time reversal and discrete rotational symmetries, as of now there is no clear definition of topological invariants for Dirac points and any arbitrary momentum plane that is perpendicular to the direction of nodal separation. We will show how the implementation of global rotational symmetry causes an U(1) x U(1) abelian gauge fixing of SO(5) vector potential, allowing us to define monopole invariants and quantized "spin Chern" numbers respectively for the Dirac points and the two dimensional planes perpendicular to the direction of nodal separation. We also demonstrate that generic form of Kramers degenerate Dirac semimetals do not support protected helical Fermi arcs.

*NSF DMR-1720139

3:54PM J54.00008: Duality between supercohomology fermionic SPT (symmetry-protected-topological) phases and higher-group bosonic SPT phases
YU-AN CHEN (Presenter), Physics, Caltech, TYLER ELLISON, Physics, University of Washington, NATHANAN TANTIVASADAKARN, Physics, Harvard — The first part of this talk will introduce generalized Jordan–Wigner transformation on arbitrary triangulation of any simply connected manifold in arbitrary dimensions. This gives a duality between any fermionic systems and a new class of $\mathbb{Z}_2$ lattice gauge theories. This map preserves the locality and has an explicit dependence on the second Stiefel–Whitney class and a choice of spin structure on the manifold. In the Euclidean picture, this mapping is exactly equivalent to adding topological terms, Steenrod square, to the spacetime action. The second part of the talk is the application of this boson-fermion duality on SPT phases. By the boson-fermion duality, we are able to show the equivalent between any supercohomology fermionic SPT and some higher-group bosonic SPT phase in arbitrary dimensions. Particularly in (3+1)D, we will show a unitary quantum circuit for any supercohomology fermionic SPT state with gapped boundary construction.
Non-Abelian anomalies in multi-Weyl semimetals

RENATO M. A. DANTAS (Presenter), FRANCISCO PENÁ-BENÍTEZ, Max Planck Inst, BITAN ROY, Lehigh University, PIOTR SUROWKA, Max Planck Inst — We construct the effective field theory for time-reversal symmetry breaking multi-Weyl semimetals (mWSMs), composed of a single pair of Weyl nodes of (anti-)monopole charge $n$, with $n = 1, 2, 3$ in crystalline environment. From both the continuum and lattice models, we show that a mWSM with $n > 1$ can be constructed by placing $n$ flavors of linearly dispersing simple Weyl fermions in a bath of an $SU(2)$ non-Abelian static background gauge field. Such an $SU(2)$ field preserves certain crystalline symmetry (four-fold rotational or $C_4$ in our construction), but breaks the Lorentz symmetry, resulting in nonlinear band spectra. Consequently, the effective field theory displays $U(1) \times SU(2)$ non-Abelian anomaly, yielding anomalous Hall effect, its non-Abelian generalization, which we further substantiate by numerically computing the regular and "isospin" densities from the lattice models of mWSMs. Altogether our findings unify the field theoretic descriptions of mWSMs of arbitrary monopole charge $n$ (featuring $n$ copies of the Fermi arc surface states), predict signatures of non-Abelian anomaly in table-top experiments, and pave the route to explore anomaly structures for multi-fold fermions, transforming under arbitrary half-integer or integer spin representations.

Entanglement Entropy of Generalized Moore-Read Fractional Quantum Hall State Interfaces

RAMANJIT SOHAL (Presenter), Physics, University of Illinois at Urbana-Champaign, BO HAN, Physics, University of Cambridge, LUIZ SANTOS, Physics, Emory University, CHI YAN JEFFREY TEO, Physics, University of Virginia — Topologically ordered phases of matter can be characterized by the presence of a universal, constant contribution to the entanglement entropy known as the topological entanglement entropy (TEE). The TEE can been calculated for Abelian phases via a "cut-and-glue" approach by treating the entanglement cut as a physical cut, coupling the resulting gapless edges with explicit tunneling terms, and computing the entanglement between the two edges. We provide a first step towards extending this methodology to non-Abelian topological phases, focusing on the generalized Moore-Read (MR) fractional quantum Hall states at filling fractions $\nu=1/q$. We consider interfaces between different MR states and write down explicit tunneling terms, which we motivate using an anyon condensation picture. We compute the entanglement entropy for an entanglement cut lying along the interface. Our work provides new insight towards understanding the connections between anyon condensation, gapped interfaces of non-Abelian phases, and TEE.

*We acknowledge support from NSERC of Canada, NSF, and ERC.
4:30PM J54.00011: Majorana zero modes in the presence of many-body interactions

MACIEJ MASKA (Presenter), ANDRZEJ WIECKOWSKI, MARCIN MIERZEJEWSKI, Department of Theoretical Physics, Wroclaw University of Science and Technology — Recently, there has been substantial progress in methods of identifying local integrals of motion in interacting integrable models or in systems with many-body localization [1]. We show that one of these approaches can be utilized for constructing local, conserved, Majorana fermions in systems with an arbitrary many-body interaction [2]. Then, we discuss how the many-body interactions influence the spatial structure and the lifetime of the Majorana modes. Finally, we determine the regime for which the information stored in the Majorana correlators is also retained for arbitrarily long times at high temperatures. We show that it is included in the regime with topologically protected soft Majorana modes, but in some cases is significantly smaller.

4:42PM J54.00012: The Nieh-Yan Anomaly: Torsional Landau Levels, Central Charge and Anomalous Thermal Hall Effect

ZE-MIN HUANG (Presenter), University of Illinois at Urbana-Champaign, BO HAN, University of Cambridge, MICHAEL STONE, University of Illinois at Urbana-Champaign — The Nieh-Yan anomaly is the anomalous breakdown of the chiral U(1) symmetry caused by the interaction between torsion and fermions. We study this anomaly from the point of view of torsional Landau levels. It was found that the torsional Landau levels are gapless, while their contributions to the chiral anomaly are canceled, except those from the lowest torsional Landau levels. Hence, the dimension is effectively reduced from (3+1)d to (1+1)d. We further show that the coefficient of the Nieh-Yan anomaly is the free energy density in (1+1)d. Especially, at finite temperature, the thermal Nieh-Yan anomaly is proportional to the central charge. The anomalous thermal Hall conductance in Weyl semimetals is then shown to be proportional to the central charge, which is the experimental fingerprint of the thermal Nieh-Yan anomaly.
4:54PM J54.00013: Bulk-edge and bulk-hinge correspondence in inversion-symmetric insulators*  
RYO TAKAHASHI (Presenter), YUTARO TANAKA, SHUICHI MURAKAMI, Tokyo Inst of Tech - Tokyo — We show that a slab of a three-dimensional inversion-symmetric higher-order topological insulator (HOTI) in class A is a 2D Chern insulator, and that in class AII is a 2D $Z_2$ topological insulator. We prove it by considering a process of cutting the three-dimensional inversion-symmetric HOTI along a plane, and study the spectral flow in the cutting process [1]. We show that the $Z_4$ indicators, which characterize three-dimensional inversion-symmetric HOTIs in classes A and AII, are directly related to the $Z_2$ indicators for the corresponding two-dimensional slabs with inversion symmetry, i.e. the Chern number parity and the $Z_2$ topological invariant, for classes A and AII respectively [2]. The existence of the gapless hinge states is understood from the conventional bulk-edge correspondence between the slab system and its edge states. Moreover, we also show that the spectral-flow analysis leads to another proof of the bulk-edge correspondence in one-dimensional inversion-symmetric insulators.

5:06PM J54.00014: Surface Topological Order for Higher-Order Topological Phases of Matter*  
APOORV TIWARI (Presenter), Paul Scherrer Institute, MINGHAO LI, Physics, ETH Zurich, ANDREI BERNEVIG, Princeton University, TITUS NEUPERT, Physics, University of Zurich, SIDDHARTH PARAMESWARAN, Physics, University of Oxford — We show that the chiral Dirac and Majorana hinge modes in three-dimensional higher-order topological insulators (HOTIs) and superconductors (HOTSCs) can be gapped while preserving the protecting $C_{2n}T$ symmetry upon the introduction of non-Abelian surface topological order. In both cases, the topological order on a single side surface breaks time reversal symmetry, but appears with its time-reversal conjugate on alternating sides in a $C_{2n}T$ preserving pattern. In the absence of the HOTI/HOTSC bulk, such a pattern necessarily involves gapless chiral modes on hinges between $C_{2n}T$-conjugate domains. However, using a combination of K-matrix and anyon condensation arguments, we show that on the boundary of a 3D HOTI/HOTSC these topological orders are fully gapped and hence `anomalous'. Our results suggest that new patterns of surface and hinge states can be engineered by selectively introducing topological order only on specific surfaces.

*This project has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation program (Marie SklodowskaCurie grant agreement No 701647).

Tuesday, March 3, 2020 2:30 PM - 5:06 PM

Session J55 DCMP: Photoemission Studies of Topological Materials Mile
High Ballroom 2B - Michael Osofsky, United States Naval Research Laboratory
2:30PM J55.00001: Evolution of the band structure of α-Sn(001) thin film on InSb(001)  KO-HSUAN CHEN (Presenter), Department of Physics, National Tsing Hua University, KENG-YUNG LIN, Department of Physics, National Taiwan University, SHENG-WEN HUANG, Department of Physics, National Tsing Hua University, CHAO-KAI CHENG, Department of Physics, National Taiwan University, HSIAO-YU LIN, Department of Physics, National Tsing Hua University, SHANG-WEI LIEN, TAY-RONG CHANG, Department of Physics, National Cheng Kung University, CHENG-MAW CHENG, National Synchrotron Radiation Research Center, MINGHWEI HONG, Department of Physics, National Taiwan University, JUEINAI KWO, Department of Physics, National Tsing Hua University — Determining the topological phase of a material is a popular research route in condensed matter physics. For elemental material of α-Sn, its topological phase has been under debate. α-Sn(001) with in-plane compressive strain is expect to be a topological Dirac semimetal in theory, but experimental evidence of 3D Dirac state is still lacking. In contrast, a spin-momentum locked topological surface state (TSS) was found for α-Sn(001) on InSb(001), suggesting a topological insulator (TI). In this work, molecular beam epitaxy grown α-Sn(001) on InSb(001) and the thickness dependent angle-resolved photoemission spectroscopy (ARPES) study from 3 bilayers (BLs) to 370 BLs are reported. Streaky (2×1) reflection high energy electron diffraction patterns and narrow θ-rocking curve (FWHM of 0.0163°) in x-ray diffraction indicated an excellent crystallinity. Sharp TSSs were attained by ARPES in films thicker than 6 BLs without resorting to extra doping or surface treatments. No TSSs were observed for film thinner than 5 BLs, indicating a crossover from 3D TI to trivial insulator. In an extremely thick α-Sn film of 370 BLs, no evident k_z dependence on the Dirac state was found in photon energy range of 10-40 eV, suggesting α-Sn(001) on InSb(001) more likely to be in TI phase.

2:42PM J55.00002: Band structure study of elemental topological material α-Sn on InSb(111)B  KENG-YUNG LIN (Presenter), Natl Taiwan Univ, KO-HSUAN CHEN, SHENG-WEN HUANG, Natl Tsing Hua Univ, CHAO-KAI CHENG, Natl Taiwan Univ, CHENG-MAW CHENG, Natl Synchrotron Rad Res Ctr, MINGHWEI HONG, Natl Taiwan Univ, JUEINAI KWO, Natl Tsing Hua Univ — Research efforts on studying the band structure of elemental topological α-Sn have increased substantially in recent years. Bulk α-Sn is a zero-gap material with an inherent band inversion due to spin-orbit coupling. Interestingly, theoretical calculation proposed strained-induced topological phase transitions from topological Dirac semimetal (TDS) to topological insulator (TI) in α-Sn thin films. Among them, compressively strained α-Sn thin films on InSb(111)B were experimentally claimed to be a 3D TDS for 30-bilayer (BL) film by angle-resolved photoemission spectroscopy (ARPES). In this work, α-Sn thin films were grown on InSb(111)B by molecular beam epitaxy (MBE) with epi-InSb as the starting surfaces prepared in the same MBE chamber. Single-crystal α-Sn thin films with excellent crystallinity and smooth surface morphology were characterized by X-ray diffraction and atomic force microscopy; their band structures were studied by ARPES. Much clearer band dispersions were observed for our 30-BL film compared to those in the literature, with virtually no k_z dependence over a wide photon energy range from 18 eV to 52 eV for the claimed 3D Dirac state. Our results, therefore, do not support the 3D TDS phase observed in the previous work.

Clarifying superconducting proximity effects in topological insulating \((\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3\) films on niobium

JOSEPH HLEVYACK (Presenter), University of Illinois at Urbana-Champaign, SAHAND NAJAFZADEH, Institute for Solid State Physics, University of Tokyo, MENG-KAI LIN, University of Illinois at Urbana-Champaign, TAKAHIRO HASHIMOTO, AKIHIRO TSUZUKI, TSUBAKI NAGASHIMA, Institute for Solid State Physics, University of Tokyo, WEILU ZHANG, Shangzhi University, AKIKO FUKUSHIMA, Institute for Solid State Physics, University of Tokyo, YOJI NAKAZAKI, SHUK SHIN, Institute for Solid State Physics, University of Tokyo, DAVID FLOETOTTO, Center for Soft Nanoscience, University of Muenster, JOSE AVILA, Synchrotron SOLEIL, JAMES N ECKSTEIN, University of Illinois at Urbana-Champaign, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign — Coupling a topological insulator (TI) with an s-wave superconductor (SC) can initiate p-wave-like pairing in the nontrivial surface states. However, this proximity-induced pairing is still not well understood and challenging to realize, possibly due to a short superconducting coherence length and/or Fermi surface/lattice mismatch at the TI/SC interface. Using a novel cleavage-based “flip-chip” method, we have successfully prepared single-crystalline \((\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3\) thin films with a predetermined thickness (2-5 quintuple layers) on bulk Nb substrate. By carefully tuning the composition \(x\), we confirm using angle-resolved photoemission spectroscopy (ARPES) that the Fermi level lies in the band gap for all \((\text{Bi}_{1-x}\text{Sb}_x)_2\text{Te}_3\) films, thus yielding a lightly n-doped TI on a SC even in the thin-film limit. Proximity-induced superconducting gaps in these samples are measured by ultrahigh-resolution laser ARPES. The results will be compared with those from prior studies of heavily n-doped TI films on Nb. Our study helps to reveal the mechanisms of proximity-induced pairing in TIs and also underscores the limitations of using the proximity effect to realize topological superconductivity.

Topological chiral crystals

TYLER COCHRAN (Presenter), GUOQING CHANG, ILYA BELOPOLSKI, Princeton University, KAUSTUV MANNA, Max-Planck-Institute for Chemical Physics of Solids, DANIEL S SANCHEZ, ZIJIA CHENG, XIAN YANG, DANIEL MULTER, SONGTIAN ZHANG, NANA SHUMIYA, MAKSYM LITSKEVICH, JIAJIN YIN, Princeton University, SUYANG XU, Havard University, CLAUDIA FELSER, Max-Planck-Institute for Chemical Physics of Solids, HSIN LIN, Academia Sinica, ZAHID HASAN, Princeton University — Topological chiral crystals host guaranteed topological crossings in the bulk band structure and can possess Fermi arc surface states that span the entire surface Brillouin zone [1]. These materials can give rise to novel optical and magneto-transport response. In this presentation, we discuss recent photoemission experiments exploring the topology of chiral fermions [2]. By combining measurements with ultraviolet and soft x-ray incident photons, we determine the topological invariant directly. Our results shed new light on the relationship between structural chirality and topology.

3:18PM J55.00005: Observation of topological surface state in a superconducting material*  
GYANENDRA DHAKAL (Presenter), MD MOFAZZEL HOSEN, Univ of Central Florida, AYANA GHOSH, University of Connecticut, CHRISTOPHER LANE, Los Alamos National Laboratory, KAROLINA GÓRNICKA, MICHAL J. WINIARSKI, Gdansk University of Technology, KLAUSS DIMITRI, FIROZA KABIR, CHRISTOPHER SIMS, SABIN REGMI, WILLIAM NEFF, Univ of Central Florida, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, JIAN-XIN ZHU, Los Alamos National Laboratory, TOMASZ KLIMCZUK, Gdansk University of Technology, MADHAB NEUPANE, Univ of Central Florida — The discovery of the topological insulator phase has ignited massive research interests in novel quantum materials. Topological materials with superconductivity further invigorate the importance of materials providing the platform to study the interplay between these two unique states. However, the candidates of such materials are rare. Here, we report a systematic angle-resolved photoemission spectroscopy (ARPES) study of superconducting material CaBi$_2$ [ $T_c$ = 2 K], corroborated by the first-principles calculations. Our study reveals the presence of topological Dirac state at the corner-point of the Brillouin zone with topological protection. Furthermore, our transport measurements show the presence of large magnetoresistance in this compound. Our results provide a platform to study the superconductivity and topology in CaBi$_2$.

3:30PM J55.00006: Electronic structure of PtPb$_4$ studied by Angle-Resolved Photoemission Spectroscopy*  
KYUNGCHAN LEE (Presenter), DAIXIANG MOU, LIN-LIN WANG, NA HYUN JO, YUN WU, BENJAMIN SCHRUNK, JOHN WILDE, MANH CUONG NGUYEN, AMELIA ESTRY, CAI-ZHUANG WANG, ANDREAS KREYSSIG, SERGEY L. BUD’KO, KAI-MING HO, PAUL C CANFIELD, ADAM KAMINSKI, Department of Physics and Astronomy, Iowa State University/Ames Laboratory — We investigate the electronic structure of PtPb$_4$ by using ultrahigh resolution, laser based Angle Resolved Photoemission Spectroscopy(ARPES) and Density functional theory(DFT) calculations. This material is a compound related to PtSn$_4$, which exhibits exotic topological properties such as Dirac node arcs. The Fermi surface(FS) of PtPb$_4$ has at least two electron pockets at the center of the Brillouin zone(BZ) and several hole pockets around the zone boundaries. Although the crystal structure has 4-fold symmetry, the ARPES data reveals a FS with only 2-fold symmetry, showing a rectangular FS sheet around X points and two intersected circular FS sheet around Y points. X-ray scattering data points to the stacking order as a key factor for the breaking of the 4-fold symmetry observed in ARPES data. The experimental results are in a reasonable agreement with the DFT calculations.

* Research at Ames Laboratory was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering. Ames Laboratory is operated for the U.S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358.
3:42PM J55.00007: Gating monolayer WTe$_2$ devices in nano-ARPES  PAUL NGUYEN (Presenter), Physics, University of Washington, CHENG CHEN, ROLAND KOCH, AARON BOSTWICK, Advanced Light Source, Lawrence Berkeley National Laboratory, NATAILIE TEUTSCH, Physics, University of Warwick, VIKTOR KANDYBA, ALEX VICTOROVICH BARINOV, Elettra - Sincrotrone Trieste S.C.p.A, NEIL R WILSON, Physics, University of Warwick, YULIN CHEN, Physics, University of Oxford, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Laboratory, XIAODONG XU, DAVID COBDEN, Physics, University of Washington — We investigate the effects of electrostatic doping on a 2D topological semimetal, monolayer WTe$_2$, employing nanometer-resolution angle-resolved photoemission spectroscopy (nano-ARPES). The exfoliated WTe$_2$ monolayer flake rests on an hBN flake and is capped by a monolayer of hBN to prevent oxidation and allow cleaning. During the photoemission measurements a gate voltage can be applied between a thin graphite electrode beneath the hBN and a graphene contact that overlaps the WTe$_2$ on top. The gate is observed to shift the Fermi energy by more than 100 meV, from valence to conduction band of monolayer WTe$_2$. The temperature and doping dependence of the spectrum yield insights into the nature of the bulk conductivity.

3:54PM J55.00008: Electronic Structure of Topological Material CaMnSb$_2$  HONGTAO RONG (Presenter), JUNBAO HE, YONGQING CAI, GUODONG LIU, LIN ZHAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, XINGJIANG ZHOU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences — AMnPn$_2$ (A = Ca, Sr, Ba, Eu, Yb; Pn = Sb, Bi) compounds are new kind of topological materials. Theoretical studies indicate that AMnPn$_2$ host an anisotropic Dirac cone near the Fermi surface. Here we report our high-resolution laser-based angle-resolved photoemission measurements on the electronic structure of CaMnSb$_2$. The Fermi surface of CaMnSb$_2$ mainly consists of one hole pocket around the Brillouin zone center and two tiny hole pockets at the Brillouin zone boundary which are consistent with the first principle calculations. In addition, we observe four additional points located at the hole pocket around the Brillouin zone center along the high symmetry directions which is hard to be accounted for by band structure calculations.
4:06PM J55.00009: Coexistence of topological nontrivial phase and Rashba-type surface state in HoSb*  

MD MOFAZZEL HOSEN (Presenter), GYANENDRA DHAKAL, Univ of Central Florida, BAOKAI WANG, Northeastern University, NARAYAN POUDEL, Idaho National Laboratory, BAHADUR SINGH, Northeastern University, KLAUSS DIMITRI, FIROZA KABIR, CHRISTOPHER SIMS, SABIN REGMI, WILLIAM NEFF, Univ of Central Florida, DANIEL MURRAY, Idaho National Laboratory, FRANZISKA WEICKERT, National High Magnetic Field Laboratory, KRZYSZTOF GOFRYK, Idaho National Laboratory, OREST PAVLOSIUK, PIOTR WISNIEWSKI, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, ARUN BANSIL, Northeastern University, MADHAB NEUPANE, Univ of Central Florida — Using the high resolution angle-resolved photoemission spectroscopy (ARPES), magnetotransport, and parallel first-principles modeling, we report the discovery of a topologically nontrivial state coexisting with a Rashba-type surface state in a rare earth monopnictide semimetal. Our theoretical analysis reveals the presence of bulk band inversions at the Γ and X points of the Brillouin zone (BZ). Interestingly, the upper part of the observed Rashba-type surface state coincides with the nontrivial surface state at the X point. Magnetotransport study indicates that HoSb can be characterized as a correlated nearly-complete electron-hole-compensated semimetal. Therefore, our findings provide HoSb as a new materials platform for exploring the interplay between coexisting topological and Rashba-type surface state and the non-saturating XMR effect in the rare earth monopnictide family.

4:18PM J55.00010: Observation of spin polarized surface states in polar Weyl semimetal MoTe2  

YUMA TANAKA (Presenter), MOHAMMAD SAEED BAHRAMY, Department of Applied Physics, University of Tokyo, HIDEFUMI TAKAHASHI, Graduate School of Engineering Science, Osaka University, KENTA KURODA, KOICHIRO YAJI, AYUMI HARASAWA, TAKESHI KONDO, SHIK SHIN, Institute for Solid State Physics, University of Tokyo, SHINTARO ISHIWATA, Graduate School of Engineering Science, Osaka University, KYOKO ISHIZAKA, Department of Applied Physics, University of Tokyo — Since the theoretical prediction of the low temperature phase as a type-II Weyl semimetal, the electronic structure of β-MoTe2 has been actively studied by angle-resolved photoelectron spectroscopy. Until now, some segment-like band features resembling Fermi arcs are experimentally observed, which are indicative of the topological surface states connecting the bulk Weyl nodes. However, the band dispersions near the Fermi level is complicated, and clear interpretation is not easy. Here we investigate the spin polarizations of the Fermi arc features for both polar terminations by utilizing the high-resolution spin and angle-resolved photoelectron spectroscopy (SARPES). For respective surface terminations, the different patterns and spin polarizations of Fermi arcs are clearly observed. In the presentation, we will compare the result with the first-principles calculation and discuss the details of the spin polarized surface states.
Symmetry plays a major role in all disciplines of physics. Within the field of topological materials, there is a great interest in understanding how the mechanics of crystalline and internal symmetries protect nodal line type features in respect to spin orbit coupling. Additionally, the surface environment of a material can severely impact the surface states that are probed by angle resolved photoemission spectroscopy (ARPES). For the first time, we report the experimental observation of topological surface states in the nodal loop semimetal HfP2 using ARPES which is supported by our first principles calculations. Our study shows termination dependent surface states in this compound which are linked to three unique nodal loops that are confirmed to be topologically non-trivial. This work demonstrates that transition metal dipnictides provide a good platform to study non-trivial topological states protected by nonsymmorphic symmetry.

*This project is supported by the Air Force Office of Scientific Research under award number FA9550-17-1-0415 and the National Science Foundation (NSF) CAREER award DMR-1847962.
Due to a higher order bulk boundary correspondence, a higher-order topological insulator hosts one-dimensional helical edge states around the hinges of the crystal. However, spectroscopic evidence for topological hinge states has been so far limited to semimetallic materials [1], where the measured edge conductivity is blurred by bulk carries. In this contribution, we show evidence for topological hinge states in a semiconducting quasi-one-dimensional material. Importantly, the crystal has naturally cleavable top and side surfaces which are stacked via van-der-Waals forces, and therefore the electronic structure around the hinge can be investigated in a cleaved surface or in an exfoliated thin flake. Our experiments by high-resolution angle-resolved photoemission spectroscopy reveal quasi-1D states inside the bulk band gap. Moreover, the corresponding signals with high conductivity are detected at the edges of the crystal by microwave impedance microscopy. These observations, therefore, indicate the existence of topological hinge states in a 1D stacking material.

Topological insulators are bulk semiconductors that manifest in-gap surface states with massless Dirac-like dispersion due to the topological bulk-boundary correspondence principle. These surface states can be manipulated by the interface environment to display various emergent phenomena. Here, we use angle-resolved photoemission spectroscopy (ARPES) and scanning tunnelling microscopy (STM) to investigate the interplay of crystallographic inhomogeneity with the topologically ordered band structure in a model topological insulator. We develop quantitative analysis methods to obtain spectroscopic information in spite of a limited dwell time on each measured point. We find that the band energies vary on the scale of 50 meV across the sample surface, and this enables single-sample measurements that are analogous to a multi-sample doping series. By focusing separately on the bulk and surface electrons we reveal a hybridisation-like interplay between fluctuations in the surface and bulk state energetics.
Topological Lifshitz transitions and Fermi arc manipulation in Weyl semimetal NbAs  
HAIFENG YANG (Presenter), ShanghaiTech University, LEXIAN YANG, Tsinghua University, ZHONGKAI LIU, ShanghaiTech University, YAN SUN, Max Planck Institute for Chemical Physics of Solids, ANDREI BERNEVIG, Princeton University, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, BINGHAI YAN, Weizmann Institute of Science, YULIN CHEN, University of Oxford — Surface Fermi arcs (SFAs), the unique open Fermi-surfaces (FSs) discovered recently in topological Weyl semimetals (TWSs), are unlike closed FSs in conventional materials and can give rise to many exotic phenomena, such as anomalous SFA-mediated quantum oscillations, chiral magnetic effects, three-dimensional quantum Hall effect, non-local voltage generation and anomalous electromagnetic wave transmission. Here, by using in-situ surface decoration, we demonstrate successful manipulation of the shape, size and even the connections of SFAs in a model TWS, NbAs, and observe their evolution that leads to an unusual topological Lifshitz transition not caused by the change of the carrier concentration. The phase transition teleports the SFAs between different parts of the surface Brillouin zone. Despite the dramatic surface evolution, the existence of SFAs is robust and each SFA remains tied to a pair of Weyl points of opposite chirality, as dictated by the bulk topology.

Observation of unconventional chiral fermions with long Fermi arcs in CoSi  
ZHICHENG RAO (Presenter), Institute of Physics — In condensed system, Chiral fermions exist at nodes (that is, robust band-crossing points protected from being gapped by nontrivial band topology) that carry a nonzero Chern number. Recently, we reported two types of unconventional chiral fermions in CoSi, which are threefold-degenerate node at point and fourfold-degenerate node at R point. These nodes at point and R point carry nonzero Chern number and we observed two surface Fermi arcs on surface to connect their projection on (001) surface, which are related by a π rotation about Γ. Further, we show the two helical surface states encircle the projection of Γ point and R point, which can reveal the topological nature of bulk nodes in CoSi.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM  
Session J56 DCMP: Mott Physics Theory and Calculations  
Mile High Ballroom 2C - Congjun Wu, University of California, San Diego
Resistive switching, a phenomenon in which the resistance of a device can be modified by applying an electric field, is the basis for emerging technologies such as neuromorphic computing. Volatile switching is specially promising, as it may allow for the implementation of artificial spiking neurons. This type of switching is observed in Mott insulators featuring an insulator-to-metal transition which can be triggered by applying an external voltage: the material becomes conducting if a threshold is exceeded. Such switching takes place in a filamentary fashion. Despite intense research, it is not yet known how these filaments nucleate, grow and relax. We combine reflectivity and transport measurements to image the switching process with spatial and temporal resolution. Three Mott insulators are analyzed: VO$_2$, V$_2$O$_3$ and V$_3$O$_5$, finding remarkable differences in the filament expansion process. We will show how these differences provide a unique insight to identify which mechanism drives the Mott transition: Joule heating or electric field.

The Mott transition as a topological phase transition

We show that the Mott metal-insulator transition in the standard one-band Hubbard model can be understood as a topological phase transition. The approach is inspired by the observation that the Mott pole in the self-energy is pinned throughout the insulating phase, similar to the zero-energy spectral pole corresponding to a localized surface state in topological systems. We use NRG-DMFT to solve the infinite-dimensional Hubbard model, and represent the resulting local self-energy in terms of the boundary Green's function of an auxiliary tight-binding chain without interactions. We find a rich structure in the parameters of the auxiliary chain, which we show are of generalized SSH model type. The Mott transition corresponds to a topological phase transition in this auxiliary system, characterized by its analytic properties. We devise simple toy models for the auxiliary chains that capture the basic physics of the metallic and insulating Hubbard model phases, as well as in the scaling limit near the transition.
Parting the Fermi Sea at the Mott Point: Dynamics of Correlated Electrons Reveals the Mechanism Underpinning Mottness

YUTING TAN (Presenter), NHMFL, Florida State University, ANDREJ PUSTOGOW, University of California, Los Angeles, ROLAND RÖSSLHUBER, ECE UYKUR, ANNETTE BÖHME, ANJA LÖHLE, RALPH HÜBNER, Physikalisches Institut, Universität Stuttgart, JOHN A SCHLUETER, Division of Materials Research, National Science Foundation, VLADIMIR DOBROSavljevic, NHMFL, Florida State University, MARTIN DRESSEL, Physikalisches Institut, Universität Stuttgart — By increasing the interaction among conduction electrons, a Fermi-liquid-type metal turns into a Mott insulator. This first-order phase transition should exhibit a regime where the adjacent ground states coexist, leading to electronic phase separation, but the range near T=0 remained unexplored because it is commonly concealed by antiferromagnetism. Here we map the genuine low-temperature Mott transition by applying dielectric spectroscopy under pressure to quantum-spin-liquid compounds. The dielectric permittivity uniquely distinguishes all conduction regimes around the Mott point, allowing us to reliably detect insulator-metal phase coexistence below the critical endpoint. Via state-of-the-art theoretical modeling we establish the coupling between segregated metallic puddles as the driving source of a colossal peak in the permittivity reaching $\varepsilon_1 \approx 10^5$ within the coexistence region. Our results indicate that the observed inhomogeneities are the consequence of phase separation emerging from strong correlation effects inherent to Mottness, suggesting a similar 'dielectric catastrophe' in other correlated materials.

Kinetics of thermal Mott metal-insulator transition in the Hubbard model

GIA-WEI CHERN (Presenter), Physics, University of Virginia — We present the first-ever microscopic dynamical simulation of the temperature-controlled Mott metal-insulator transition in the Hubbard model. By combining the efficient Gutzwiller method with molecular dynamics simulations, we demonstrate that the transformation from the correlated metal to the Mott insulator proceeds via the nucleation and growth of the Mott droplets. We show that after an initial incubation period, the early stage of the phase transformation is characterized by a constant nucleation rate and an interface-controlled cluster growth mechanism, consistent with the classical theory developed by Kolmogorov, Johnson, Mehl, and Avrami. This is followed by a novel intermediate stage of accelerated phase transformation that is characterized by avalanche behavior similar to the Barkhausen noise in magnetization dynamics. The implications of our findings for the recent nano-imaging experiments on metal-insulator transition of correlated materials are also discussed.

This work is partially supported by the Center for Materials Theory as a part of the Computational Materials Science (CMS) program, funded by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
3:18PM J56.00005: Nature of Mott transition in a hydrogen lattice  ZIJIAN LANG, Tsung-Dao Lee Institute & Shanghai JiaoTong University, SUDESHNA SEN, University College Dublin, VLADIMIR DOBROSAVLJEVIC (Presenter), Florida state University, WEI KU, Tsung-Dao Lee Institute & Shanghai JiaoTong University — Mott transition, an electron correlation induced metal-insulator transition, has long been realized in many materials. Yet, the microscopic nature of the transition proposed by Mott has not been carefully examined in these materials, even by modern theories. This is because Mott's original proposal makes use of non-linear change of screening of long-range Coulomb interaction that are almost always ignored in simple models used in previous study of Mott transition. Here we study the Mott transition of an artificial hydrogen lattice including both the long-range Coulomb interaction and the strong on-site correlation, via a dynamical mean-field extension of density functional calculation. We found that in the relevant range of lattice spacing, the system is in the charge-transfer regime, namely the charge fluctuation involves mostly higher energy orbitals beyond 1s one, rendering a single-band Hubbard model inadequate. Our study challenges Mott's original microscopic picture and reveal some key physics of metal-insulator transition in realistic materials.

3:30PM J56.00006: Mott Insulating States of Anisotropic SU(4) Dirac Fermions*  YU WANG (Presenter), HAN XU, School of Physics and Technology, Wuhan University, CONGJUN WU, Department of Physics, University of California, San Diego — We employ large-scale projector quantum Monte Carlo simulations to study the ground-state properties of the SU(4) Hubbard model on a square lattice with a staggered flux configuration. By varying the on-site repulsion and the flux, our simulations demonstrate phase transitions between the Dirac semimetal, antiferromagnetic (AFM) and valence-bond-solid (VBS) phases. We find a continuous AFM-VBS phase transition. The direct second-order transition between different symmetry-breaking phases suggests deconfined critical points which form the boundary between the AFM and VBS phases. Near the deconfined critical points, we show that the AFM and VBS Binder ratios have the same critical exponents. As Hubbard U increases, the VBS order drops to zero, while the AFM moment has a finite value in the Heisenberg limit. It infers that the system with any flux eventually enters the AFM phases with increasing Hubbard U. By analysis of the gap opening mechanism, it is shown that both the columnar VBS ordering and the plaquette VBS ordering emerge in the VBS phase, and thus the phase diagram features two tricritical points where the semimetal, AFM and VBS phases meet.

**3:42PM J56.00007: Pseudogap, van Hove Singularity, Maximum in Entropy and Specific Heat for Hole-Doped Mott Insulators**

ALEXIS REYMBAUT, SIMON BERGERON, R. GARIOUD, M. THÉNAULT, MAXIME CHARLEBOIS, Institut quantique, Université de Sherbrooke, P. SÉMON, Brookhaven National Laboratory, ANDRE-MARIE TREMBLAY (Presenter), Institut quantique, Université de Sherbrooke — The first indication of a pseudogap in cuprates came from a sudden decrease of NMR Knight shift at a doping-dependent temperature $T^*$. Since then, experiments have found phase transitions at a lower $T^*_{\text{phase}}(\delta)$. Using plaquette cellular dynamical mean-field for the square-lattice Hubbard model at high temperature, where the results are reliable, we show that $T^*(\delta)$ shares many features of $T^*_{\text{phase}}(\delta)$. The remarkable agreement with several experiments, including quantum critical behavior of the electronic specific heat, supports the view that the pseudogap is controlled by a finite-doping extension of the Mott transition. We propose further experimental tests.

**3:54PM J56.00008: Superconducting instability in an exactly solvable model of a doped Mott insulator**

PHILIP PHILLIPS, LUKE YEO (Presenter), EDWIN HUANG, University of Illinois at Urbana-Champaign — Regarding the cuprate superconductors as doped Mott insulators, we solve a toy model that exhibits both Mottness and superconductivity. We show that the Hatsugai-Kohmoto model, an exactly solvable model exhibiting a non-trivial Mott insulator-to-non-Fermi liquid metal transition, exhibits a superconducting instability. The instability is present in the non-Fermi liquid metal phase at half-filling, persists for a wide range of dopings away from half-filling, and terminates once the Mott parameter exceeds a critical strength.

*NSF DMR-1919143
4:06PM J56.00009: Intertwined Mott insulating behavior, magnetic quantum criticality, and superconductivity in a two-band Hubbard-like model: A Quantum Monte Carlo study
MORTEN HOLM CHRISTENSEN (Presenter), University of Minnesota, XIAOYU WANG, National High Magnetic Field Laboratory, Florida State University, YONI SCHATTNER, Department of Physics, Stanford University, EREZ BERG, Department of Physics, Weizmann Institute of Science, RAFAEL FERNANDES, University of Minnesota — The interplay between superconductivity and magnetism in correlated systems is an outstanding question in condensed matter physics. It has been recently shown that the two-band spin-fermion model, in which electrons interact with pre-existing magnetic fluctuations, can be simulated by Quantum Monte Carlo (QMC) without the fermionic sign-problem. Here we go beyond this approach and present sign-problem-free QMC results of a two-band microscopic model in which both superconductivity and magnetism arise from the very same inter-band repulsion, without pre-existing bosons mediating the electronic interactions. Our simulations reveal the interplay between a host of different phenomena as the interaction strength is increased. A wide magnetic dome appears at moderate values of the interaction, whereas a narrow superconducting dome emerges around the magnetic quantum critical point located on the less strongly correlated side of the phase diagram. Interestingly, a Mott transition is nearly coincident with this magnetic phase boundary, and is manifested by a change in the magnetic dynamics from overdamped to propagating. The emergence of superconductivity only in the former region provides important clues about the nature of the pairing glue in unconventional superconductors.

4:18PM J56.00010: Excitons in Mott insulator* TSUNG-SHENG HUANG (Presenter), CHRISTOPHER BALDWIN, MOHAMMAD HAFEZI, VICTOR GALITSKI, University of Maryland, College Park — We study the behaviors of excitons formed by spinless charges in the antiferromagnetically ordered phase of Mott insulators. We start from the slave fermion Hubbard model with linear spin wave approximation on the bosonic spinons and obtain the dispersion of dressed doublons and holons using self-consistent Born approximation. We derive the Bethe-Salpeter equation for the two particle Green's function of dressed doublon and holon to find the bound states between a doublon and a holon and identify them as excitons. We investigate several properties of Mott excitons.

*T-S. H. would like to thank Physics Frontier Center at the Joint Quantum Institute for supporting this project.
4:30PM J56.00011: Block-spiral magnetism of the low-dimensional orbital-selective Mott phase

JACEK HERBRYCH (Presenter), Wroclaw University of Science and Technology, JONAS HEVERHAGEN, University of Stuttgart, GONZALO ALVAREZ, Oak Ridge National Laboratory, MARIA DAGHOFER, University of Stuttgart, ADRIANA MOREO, ELBIO DAGOTTO, University of Tennessee — Competing interactions can lead to novel states of matter including frustrated magnetism, an extensive field of research both from the theoretical and experimental perspectives. Here, we show that competing energy scales present in the low-dimensional orbital-selective Mott phase (OSMP) induce an exotic magnetic order, never reported before. Neutron scattering experiments on iron-based 123 ladder materials (where OSMP is relevant) already confirmed theoretical prediction of block-magnetism (magnetic order of the form $\uparrow\uparrow\downarrow\downarrow$). Now we argue that another novel phase can be stabilized in multiorbital Hubbard models, i.e., `block-spiral state'. In the latter, the magnetic islands form a spiral propagating through the chain but with the blocks maintaining their identity, namely rigidly rotating. This complex spiral state is stabilized without any apparent frustration. Phenomenological simpler models that accurately capture both electronic and spin degrees of freedom are also discussed.

4:42PM J56.00012: Local structural study of novel mott-insulating cousins of the iron pnictides

BHUPENDRA KARKI (Presenter), ALAA ALFAILAKAWI, Department of Physics and Astronomy, University of Louisville, BENJAMIN FRANDSEN, Department of Physics and Astronomy, Brigham Young University, MINGHU FANG, Department of Physics, Zhejiang University, M. S. EVERETT, JOERG C. NEUEFEIND, Neutron Scattering Division, Oak Ridge National Laboratory, BYRON FREEOLON, Department of Physics and Astronomy, University of Louisville — Iron oxy-chalcogenides, La$_2$O$_2$Fe$_2$OM$_2$ ($M = S, Se$), is the layered materials formed from stacking layered units of La$_2$O$_2$ and Fe$_2$OM$_2$ ($M = S, Se$). We describe the structural properties of the La$_2$O$_2$Fe$_2$OM$_2$ ($M = S, Se$), by using pair distribution function (PDF) analysis and Rietveld refinement methods applied to neutron diffraction data. Our results show that $M = S$ and Se possess similar nuclear structure at low and room temperatures. Local crystal structure was studied by investigating deviations in atomic positions and orthorhombicity. By tracking the orthorhombicity parameter, we observe the local scale distortions between the tetragonal and orthorhombic structure in a typical range of 1-2 nm. These spatially limited distortions represent fluctuating nematic order which suggests the ubiquity of nematic fluctuations in iron-based superconductors and related materials. In addition, we found the discontinuity in c-lattice which may arise due to the buckling of Fe$_2$O plane. We anticipate that this buckling might be due to the change in octahedral height or tilting of the octahedral structure. Overall, these results suggest that the structural distortion may play a role in absence of superconductivity in these materials.

4:54PM J56.00013: Pseudogap transition within the superconducting phase in the three-band Hubbard model*  
SIDHARTHA SHANKAR DASH (Presenter), DAVID SENECHAL, Université de Sherbrooke — We use cluster dynamical mean field theory on a three-band Hubbard model for high-$T_c$ superconductors to study the superconducting phase at zero temperature, obtained when doping the charge transfer insulator, for several values of $U$. We observe a first-order transition within the superconducting phase, which separates the so-called underdoped and overdoped solutions. The transition to the underdoped solution is marked by a jump in the spectral gap, and on further underdoping the spectral gap increases while the superconducting order parameter decreases. This, we conclude, is caused by the onset of the pseudogap in the underdoped region, which contributes to the increasing spectral gap; this is consistent with the change in the source of condensation energy from potential energy, in the overdoped region, to kinetic energy in the underdoped region. We also observe that the $d$-wave node disappears within the superconducting phase at low values of hole doping, within the underdoped region. We see this as a manifestation of Mott physics operating at very low doping.

5:06PM J56.00014: Extending the Gutzwiller approximation to intersite interactions*  
GARRY GOLDSTEIN (Presenter), GABRIEL KOTLIAR, Rutgers University, New Brunswick, NICOLA LANATA, Physics, Aarhus University — We develop an extension of the Gutzwiller Approximation (GA) formalism which includes the effects of Coulomb interactions of arbitrary range (including density density, exchange, pair hopping and Coulomb assisted hopping terms). This formalism reduces to the ordinary GA formalism for the multi-band Hubbard models in the presence of only local interactions. This is accomplished by combining the $1/z$ expansion - where $z$ is the coordination number and only the leading order terms contribute in the limit of infinite dimensions- with a $P^2-I$ expansion, where $P$ is the Gutzwiller projector on a site $R$. The method is conveniently formulated in terms of a Gutzwiller Lagrange function. We apply our theory to the single band $t$-$J$ model and the extended single band Hubbard model. We find a Mott transition but for the extended Hubbard model. An enhanced valence fluctuations transition is also discovered.

5:18PM J56.00015: Dynamical t/U Expansion of the Doped Hubbard Model  WENXIN DING (Presenter), Anhui Univeristy, RONG YU, Renmin University — We construct a new U(1) slave spin representation for the single-band Hubbard model in the large-U limit. The mean-field theory in this representation is more amenable to describe both the spin-charge-separation physics of the Mott insulator at half-filling and the strange metal behavior at finite doping. By employing a dynamical Green's function theory for slave spins, we calculate the single-particle spectral function of electrons, and the result is comparable to that in dynamical mean-field theories. We then formulate a dynamical t/U expansion for the doped Hubbard model that reproduces the mean-field results at the lowest order of expansion. To the next order of expansion, it naturally yields an effective low-energy theory of a t – J model for spinons self-consistently coupled to an XXZ model for the slave spins. We show that the superexchange J is renormalized by doping, in agreement with the Gutzwiller approximation. Surprisingly, we find a new ferromagnetic channel of exchange interactions which survives in the infinite U limit, as a manifestation of the Nagaoka ferromagnetism.

Session J57 DMP DCOMP: 2D Semiconductors: opto-magnetic properties  Mile High Ballroom 3A - Jing Li, Los Alamos National Laboratory - Tag(s): Focus

2:30PM J57.00001: Landau quantized excitonic absorption and photoluminescence in a monolayer valley semiconductor  JEREMIAH VAN BAREN (Presenter), ERFU LIU, University of California, Riverside, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, YIA-CHUNG CHANG, Research Center for Applied Sciences, Academia Sinica, CHUN HUNG LUI, University of California, Riverside — We observe charge-density-dependent quantum oscillations in the excitonic absorption and luminescence of monolayer WSe$_2$ under magnetic fields up to B = 17.5 T. Valley-selective quantum oscillations occur for both the exciton and trions (or exciton-polarons) and reveal distinct intravalley and intervalley coupling between excitons and Landau levels (LLs). We observe spin- and valley-polarized LLs with filling factors $n = +0, +1$ in the lower conduction band and $n = -0$ to $-6$ in the valence band, including the Berry-curvature-induced $n = \pm 0$ LLs of massive Dirac fermions. The LL filling produces periodic plateaus in the exciton energy shift accompanied with sharp oscillations in the exciton absorption width and magnitude. This peculiar exciton behavior can be simulated by semi-empirical calculations. In addition, the experimentally deduced g-factors of the conduction band (g ~ 2.5) and valence band (g ~ 15) are much larger than the g-factors predicted in a single-particle model. Such g-factor enhancement implies strong many-body interactions at high charge density in monolayer WSe$_2$. The complex interplay between Landau quantization, excitonic effects, and many-body interactions, as demonstrated in our research, provides a new platform to explore novel correlated quantum phenomena.
Spin relaxation in InSe probed by time-resolved Kerr rotation

JOVAN NELSON (Presenter), Applied Physics Program, Northwestern University, TEODOR STANEV, Department of Physics and Astronomy, Northwestern University, TREVOR LAMOUNTAIN, Applied Physics Program, Northwestern University, HAOLIN CHEN, Department of Physics, Carnegie and Mellon, NATHANIEL PATRICK STERN, Department of Physics and Astronomy, Northwestern University — Two dimensional materials have shown much promise as a platform for novel optical and spin based devices. Recently, van der Waals layers of group-III monochalcogenide Indium Selenide (InSe) have attracted much attention because of their high electron mobility, strong second harmonic generation, and layered-dependent direct band gap. While these optical and electrical properties have been experimentally demonstrated, spin properties of InSe are still poorly understood despite intriguing predictions of layer-dependent optical spin selection rules. Here, we present measurements of spin relaxation in InSe using time-resolved Kerr rotation in the near infrared spectrum. These results will contribute to evaluating spin properties of the high-mobility carriers in InSe.

*This material is based upon work supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. 1324585, the National Science Foundation by award DMR-1905986 and the MRSEC program (DMR-1720319) at the Materials Research Center of Northwestern University.

Observation of strong valley magnetic response in monolayer transition metal dichalcogenide alloys of Mo$_{0.5}$W$_{0.5}$Se$_2$ and Mo$_{0.5}$W$_{0.5}$Se$_2$/WS$_2$ heterostructure

TING YU (Presenter), Nanyang Tech Univ — Monolayer (1L) transition metal dichalcogenide (TMD) alloys have emerged as a new material system towards future applications for electronic, optoelectronic and spintronic devices. Particularly, the unique valley physics associated with valley polarization and Zeeman effect opens new opportunities for valleytronic applications. However, valley magnetic response in 1L TMD alloys largely remains unexplored. Here, we report strong valley magnetic response of trions in Mo$_{0.5}$W$_{0.5}$Se$_2$ and Mo$_{0.5}$W$_{0.5}$Se$_2$/WS$_2$ heterostructures investigated by cryogenic magneto-photoluminescence microspectroscopy. The large $g$-factors have been extracted for Mo$_{0.5}$W$_{0.5}$Se$_2$ and Mo$_{0.5}$W$_{0.5}$Se$_2$/WS$_2$, respectively, which are attributed to the significant impact of strong Coulomb interactions on the trion emission under a perpendicular magnetic field. The reduction of the valley Zeeman splitting in the heterostructure of Mo$_{0.5}$W$_{0.5}$Se$_2$/WS$_2$ is explained in terms of the doping variation caused by the interlayer charge transfer between Mo$_{0.5}$W$_{0.5}$Se$_2$ and WS$_2$, which agrees well with our density functional theory calculations of the band alignment in the Mo$_{0.5}$W$_{0.5}$Se$_2$/WS$_2$ heterostructure. Our findings give new insights into the optical properties of 1L TMD alloys and the interlayer coupling and shed light on the valleytronics.
Revealing the exciton masses and dielectric properties of monolayer semiconductors with high magnetic fields

SCOTT CROOKER (Presenter), MATEUSZ GORYCA, JING LI, ANDREAS V. STIER, NHMFL - Los Alamos, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS-Tsukuba, EMMANUEL COURTADE, SHIVANGI SHREE, CEDRIC ROBERT, BERNHARD URBASZEK, XAVIER MARIE, INSA-Toulouse — In semiconductor physics, many essential optoelectronic material parameters can be experimentally revealed via optical spectroscopy in sufficiently large magnetic fields. For monolayer transition-metal dichalcogenide semiconductors, this field scale is substantial -- of order 100 tesla! -- due to heavy carrier masses and huge exciton binding energies. Here we report absorption spectroscopy of monolayer MoS$_2$, MoSe$_2$, MoTe$_2$, and WS$_2$ in very high magnetic fields to 91 T. We follow the diamagnetic shifts and valley Zeeman splittings of not only the exciton's 1s ground state but also its excited 2s, 3s, ... ns Rydberg states. This provides a direct experimental measure of the effective (reduced) exciton masses and dielectric properties. Exciton binding energies, exciton radii, and free-particle bandgaps are also determined. Unexpectedly, the measured exciton masses are significantly heavier than theoretically predicted, especially for the Mo-based monolayers. These results provide essential and quantitative parameters for the rational design of optoelectronic van der Waals heterostructures incorporating 2D semiconductors. [1] Goryca et al., Nature Comm. 10, 4172 (2019).

Spectroscopic signatures of few- and single layer MPS$_3$ ($M$= Mn, Ni, Fe) complexes

SABINE NEAL (Presenter), Department of Chemistry, University of Tennessee, Knoxville, HEUNG SIK KIM, Department of Physics, Kangwon University, KENNETH R O'NEAL, Department of Chemistry, University of Tennessee, Knoxville, AMANDA HAGLUND, Department of Materials Science and Engineering, University of Tennessee, KEVIN ARTHUR SMITH, Department of Chemistry, University of Tennessee, Knoxville, DAVID MANDRUS, Department of Materials Science and Engineering, University of Tennessee, HANS BECHTEL, Lawrence Berkeley National Lab, G CARR, Brookhaven National Lab, KRISTJAN HAULE, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, JANICE LYNN MUSFELDT, Department of Chemistry, University of Tennessee, Knoxville — Layered magnetic chalcogenides have become increasingly important over the last decade because they offer a unique platform for combining the complexity of bulk materials with the tunability of few- and single layer systems. These van der Waals complexes have been well studied by Raman spectroscopy, however, infrared spectroscopy is vastly underexplored due to the inability to overcome the diffraction limit. It is these ungerade infrared active modes that are vital in understanding material functionality. Synchrotron infrared nanospectroscopy, a fusion of near-field optical microscopy with high brightness infrared synchrotron radiation, has overcome this fight for photons and enabled a better understanding of size-induced effects, including symmetry breaking, that are quite different from the single crystal. This approach will be illustrated with members of the MPS$_3$ ($M$= Mn, Ni, Fe) family of complex chalcogenides.
3:30PM J57.00006: Imaging Spin-Split Impurity States in Monolayer Semiconductors

CALEB ZERGER (Presenter), ALEXANDER CONTRYMAN, HONG LI, TYLER LAYDEN, XIAOLIN ZHENG, HARI C. MANOHARAN, Stanford Univ — A two dimensional dilute magnetic semiconductor (2D-DMS) is a state sought after for its important implications for spintronics. It is predicted that this state could be achieved by doping monolayer transition metal dichalcogenides with magnetic dopants. Using scanning tunneling microscopy, we investigate the origins of a 2D-DMS state by probing the local density of states in magnetically doped monolayer dichalcogenide semiconductors. We find sharp features in the spectral maps due to an alignment of impurity states with the Fermi level due to tip-induced band bending (TIBB). By modeling the TIBB and comparing to density functional theory, we find evidence for strongly spin-split states in individual dopants, a necessary precursor to the 2D-DMS state. We also use these signatures to characterize impurity types in these samples, finding evidence for both transition metal substitutional dopants and dichalcogenide substitutions, which collectively alter the magnetic landscape.

3:42PM J57.00007: Spin-orbit coupling, exchange, and magnetism in exciton physics of 2D semiconductors

MENG WU (Presenter), ZHENGLU LI, TING CAO, STEVEN LOUIE, Department of Physics, University of California at Berkeley and Lawrence Berkeley National Laboratory — Interactions (e.g., spin-orbit coupling (SOC), electron-hole (e-h), magnetic ordering, etc.) often give rise to dramatic new features in the photophysics of 2D materials. With newly developed full-spinor \textit{ab initio} GW & Bethe-Salpeter equation (GW-BSE) methods, we investigate the interplay among these interactions in 2D semiconductors. We discover that e-h exchange interaction in monolayer transition metal dichalcogenides mixes the well-known A and B excitons that heretofore were believed to be completely independent of each other, since A and B excitons had been viewed as derived from inter-band transitions between different pairs of spin-polarized bands [1]. In another study, we elucidate the physical origin of giant excitonic and magneto-optical responses in monolayer CrI$_3$, a prototypical 2D ferromagnetic semiconductor [2]. Our calculations demonstrate that the optical properties of ferromagnetic monolayer CrI$_3$ are dominated by exciton states that extend over several unit cells. By simulating a realistic experimental setup, we further predict a strong dependence of magneto-optical Kerr effect signals on excitation frequency and substrate configuration.

Discovery of tunable excitons, giant valley orbital magnetic moment, and unconventional optical selection rules in bilayer graphene* [Invited]  LONG JU (Presenter), Massachusetts Institute of Technology MIT — Multilayer graphene in the rhombohedral stacking order is a unique semiconductor where the bandgap can be continuously controlled by an external electric field. It provides an exciting platform to study conventional exciton physics in the context of valley pseudospin and quantum geometry in an in situ tunable semiconductor bandgap. We employed the photocurrent spectroscopy technique to study AB-stacked bilayer graphene, and observed tunable exciton states with unusual optical selection rules, strong optical resonances and extremely narrow line width. Upon the application of a perpendicular magnetic field, a large valley-dependent magnetic moment was observed which can be traced back to the fundamental Berry curvature effect. We also observed inter Landau level transitions with unconventional optical selection rules, and established the continuous evolution from Coulomb-interaction-dominated to Landau-quantization-dominated optical response. We further used photoluminescence and Raman spectroscopy to study the exciton evolution with tunable carrier density. I will also discuss exciton physics in rhombohedral stacked graphene with more than 3 layers and the effect of Moire superlattice from hBN substrate.

Investigation of the magnetic interactions in WSe$_2$/WS$_2$ moiré superlattice  YANHAO TANG (Presenter), LIZHONG LI, TINGXIN LI, YANG XU, Cornell University, SONG LIU, KATAYUN BARMAK, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National institute for materials science, ALLAN MACDONALD, University of Texas at Austin, JIE SHAN, KIN FAI MAK, Cornell University — Moiré superlattices formed in two-dimensional (2D) atomic crystals present a powerful platform to study interacting quantum particles in a lattice. Here, we present optical reflection spectroscopy studies on angle-aligned WSe$_2$/WS$_2$ bilayers, which form moiré superlattices because of the difference in lattice constant between the two materials. We measure the dependence of the lowest-energy moiré exciton on magnetic field and doping density. At half filling of the first hole moiré band, we observe a Mott insulating state with antiferromagnetic Curie-Weiss behavior. Past half filling, our experiment suggests an antiferromagnetic to weak ferromagnetic quantum phase transition near 0.6 filling. These results can be understood based on a triangular lattice Hubbard model in the strong interaction regime.
5:06PM J57.00010: Probing Electronic Structure and Carrier Dynamics in the Ferromagnetic Semiconductor CrSiTe3

GIRIRAJ JNAWALI (Presenter), HOWARD E JACKSON, LEIGH M SMITH, Department of Physics, University of Cincinnati, STEPHEN WILSON, Materials Engineering, University of California, Santa Barbara — The layered ferromagnetic semiconductor CrSiTe3 (CST) has attracted great scientific attention due to its potential as a 2-dimensional ferromagnet with higher $T_c$ than in its bulk form. In order to understand the nature of magnetic correlations and possible magneto-optoelectronic applications, it is crucial to understand the electronic structure and photoinduced response near the band-edge in nanoscale samples. Here we present transient optical spectroscopy on exfoliated CST nanosheet samples at 300 K as well as at 10 K over an extended photon energy: 0.3 – 1.2 eV. We find clear signatures of optical transitions around 0.5 and 1.15 eV, which agree well with theoretical calculations of the indirect and direct conduction band edges. Photoexcited carriers are thermalized within a ps to the lattice through strong coupling to optical phonons and the subsequent decay persists over a nanosecond before undergoing recombination. Our work not only demonstrates direct measurements of the band structure but also sheds light on scattering behavior of photoexcited carriers in CST, which are critical for its future applications.

*We acknowledge the financial support of the NSF through grants DMR 1507844, DMR 1531373, and ECCS 1509706. S.D.W. acknowledges the support of NSF DMR 1505549.

5:18PM J57.00011: First principles studies of valley splitting in monolayer transition metal dichalcogenides on BiFeO3

ELIZABETH A PETERSON (Presenter), JEFFREY B NEATON, Lawrence Berkeley National Laboratory — Control of the spin and valley degrees of freedom of monolayer transition metal dichalcogenides (TMDs) via time reversal symmetry breaking at K and K' has been successfully demonstrated via magnetic substrates [1], which can generate significantly larger valley splitting than applied magnetic fields. Multiferroic substrates offer an avenue to develop valleytronics devices with switchable in-situ polarization. Using first principles density functional theory calculations, we predict that the ferromagnetically-ordered surface of Fe-terminated (111)-BiFeO3 substrates can produce valley splittings in WSe2 an order of magnitude larger than previously proposed magnetic substrates. We discuss the details of the orbital exchange interactions driving the splitting; and we also develop design principles for tuning the valley splitting through lattice alignment of the TMD monolayer with the substrate, as well as the identity and spin state of the magnetic substrate ions.

*This work is supported by supported by the Air Force Office of Scientific Research Hybrid Materials MURI under award number FA9550-18-1-0480. Computational resources provided by the Department of Energy via NERSC.

Steady-State Density Functional Theory for quantum transport and spectral functions

GIANLUCA STEFANUCCI (Presenter), Physics, University of Rome Tor Vergata, STEFAN KURTH, DAVID JACOB, NAHUAL SOBRINO, Departamento de Fisica de Materiales, Universidad del Pais Vasco UPV/EHU — Steady-State Density Functional Theory (i-DFT) is a formalism to describe open quantum systems in nonequilibrium steady states. i-DFT is based on the one-to-one correspondence between the pair density and steady current and the pair local potential and applied voltage. The resulting Kohn-Sham system features two exchange-correlation (xc) potentials, a local xc potential and an xc contribution to the voltage. After revisiting the fundamentals of i-DFT we apply the formalism to strongly correlated quantum dots at finite current and temperature. We show that the well-known discontinuity of the DFT xc potential at integer particle number bifurcates as the current starts flowing. We also show that the i-DFT formalism can be used to calculate the quantum system spectral function, a relevant quantity in photoemission spectroscopy.

3:06PM J58.00002: Linearized GW density matrix for molecules*  
FABIEN BRUNEVAL  
(Presenter), Service de Recherches de Métallurgie Physique, CEA-Saclay — The GW approximation is well known for the calculation of high-quality ionization potentials and electron affinities in solids and molecules. However, the Green's function contains much more information than the mere quasiparticle energies.

Most interestingly, an approximate density matrix can be obtained from the contraction of the GW Green's function. Here we test and assess the quality of this so-called linearized GW density matrix for several molecular properties. We show it is reliable to evaluate the total energy out of a non-self-consistent GW calculation, being an alternative to the famous RPA total energy expression.

Based on a comprehensive benchmark of 34 molecules, we compare the quality of the ionization potential [1] electronic density, Hartree energy, exchange energy, and the Fock operator expectation values [2] against other well-established quantum chemistry techniques. In particular, we show that the obtained linearized GW densities markedly differ from those calculated within the wide-spread quasiparticle self-consistent GW approximation.

3:18PM J58.00003: Dynamical excitations of charge states in diamond color centers*  
TATIANE PEREIRA DOS SANTOS (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — We perform a time-dependent computational study of nitrogen-vacancy centers in diamond under ion irradiation. The negatively charged nitrogen-vacancy (NV−) centers in diamond are potential candidates for solid-state qubits due to the possibility to manipulate single center's electronic spin states. However, the dynamics of charge transitions between NV centers of different charges, such as the neutral (NV0) and the positively charged (NV+) centers, are not fully understood. Using time-dependent ab initio calculations, we perform accurate dynamical simulations of ion projectiles propagating near NV centers in diamond and calculate the properties of the defect-related excited states under the projectile impact. We compare our results with a pristine diamond and calculate the dynamical properties of projectile-vacancy coupling for a set of ion projectiles at different velocities. We discuss the quantitative properties of the charge states of nitrogen-vacancy centers at a sufficiently short time-scale that are challenging to approach experimentally.

**3:30PM J58.00004: Recent progress in the first-principles quantum Monte Carlo: New algorithms in the all-electron calculations**  
KOSUKE NAKANO (Presenter), SISSA (International School for Advanced Studies), RYO MAEZONO, JAIST (Japan Advanced Institute of Science and Technology), SANDRO SORELLA, SISSA (International School for Advanced Studies) — First-principles quantum Monte Carlo (QMC) techniques, such as variational quantum Monte Carlo (VMC) and diffusion quantum Monte Carlo (DMC), are among the state-of-the-art numerical methods used to obtain highly accurate many-body wave functions. I will present recent improvements in a QMC code, TurboRVB: All-electron calculations in QMC are not as widely used as in DFT because the computational cost scales with $Z^{5.5-6.5}$, where $Z$ is the atomic number. We have recently developed new algorithms to drastically decrease computational costs of all-electron DFT (suitable for QMC)[1], and all-electron lattice regularized diffusion monte Carlo (LRDMC)[2,3]. I will present basic ideas of the new algorithms and show several applications such as a binding energy calculation of the sodium dimer[1].

*K. Nakano is grateful for a financial support from Simons Foundation. R. Maezono is grateful for financial supports from MEXT-KAKENHI (19H04692 and 16KK0097), from FLAGSHIP2020 (project nos. hp190169 and hp190167 at K-computer), and from the Air Force Office of Scientific Research(AFOSR-AOARD/FA2386-17-1-4049;FA2386-19-1-4015).

**3:42PM J58.00005: Thermo-Optical Properties of Organic Verdazyl Biradicals via UV-VIS Spectroscopy**  
OZGE GUNAYDIN-SEN (Presenter), CAITLYN CLARK, EMILY INGRAM, Lamar University, DAVID BROOK, San Jose State University — Recently, biradicals have attracted attention due to their magnetic properties which could be used in different fields such as electronics, computer technologies, and renewable energy. Unlike most of the other radicals, organic verdazyl biradicals are stable at room temperature which makes them easy to work with. We investigated the photo-physical properties (i.e. singlet-triplet spin gap) of verdazyl biradicals utilizing thermo-optical spectroscopy (UV-VIS) between room temperature and 400 K. The spectra were then analyzed using Beer's law and Curie population analysis to extract the singlet-triplet spin gap at several wavelengths by evaluating the excitations. The analysis suggests, stronger excitations are representative of $\pi \rightarrow \pi^*$ transitions while the weaker excitations are representative of forbidden $\pi \rightarrow \pi^*$ transitions. Switching between singlet ground and triplete excited states can lead to an improved understanding of the manipulation via change in temperature and possibly with the magnetic field.

*Welch foundation (V-0004) and SURF grant - Lamar University*
Semilocal exchange-correlation (xc) energy of a many-electron system is not exact for all one-electron densities. In 1981, Perdew and Zunger (PZ) subtracted the fully nonlocal self-interaction error orbital-by-orbital, making the corrected functional exact for all one-electron densities. Although the PZ self-interaction correction (SIC) eliminates many errors of semilocal functionals, it is often worse for equilibrium properties of molecules and solids. Nonempirical semilocal functionals are usually designed to be exact for uniform electron gases, but PZ SIC is not so designed. We have extrapolated from the Ne, Ar, Kr, and Xe atoms to estimate the relative errors of the PZ SIC xc energies (with localized SIC orbitals) in the limit of large atomic number: about +5.5% for the LSDA-SIC and about -3.5% for nonempirical generalized gradient (PBE)-SIC and meta-generalized gradient strongly constrained and appropriately normed (SCAN)-SIC approximations [1]. The SIC errors found here are considerably larger than the error previously estimated on the uniform gas using LSDA-SIC localized orbitals. These errors may explain the shortcomings of PZ SIC for equilibrium properties, opening the path to a generalized SIC.

*DE-SC0018331

The Fermi-Löwdin orbital self-interaction correction (FLO-SIC) method removes the spurious self-interaction from common density functional theory (DFT) approximations. Within FLO-SIC, Fermi orbitals are used as localized orbitals. Each of these orbitals is constructed using a point in real space, called Fermi-orbital descriptor (FOD). To obtain the minimum total energy, the set of FODs needs to be optimized. This optimization is challenging and time-consuming. Accordingly, ways to reduce the computational burden are desired. In this work, we present a way to constrain the FODs. We exploit the tendency of the FODs to arrange in symmetrical patterns considering different atomic shells and bonding situations [1]. We will show how such a constrained approach improves the efficiency of the FOD optimization by comparing to an unconstrained approach. Finally, we will discuss applications and future directions.

*This work is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, as part of the Computational Chemical Sciences Program under Award Number #DE-SC0018331.
4:18PM J58.00008: New Algorithms for the Fermi-Löwdin Orbital Self-Interaction Correction Calculations.* KAMAL SHARKAS (Presenter), JUAN E PERALTA, KOBLAR JACKSON, Central Michigan Univ — Self-interaction error (SIE) is in most approximate exchange-correlation functionals, and removing SIE is important for improving the performance of the Kohn-Sham density-functional theory (KS-DFT) when applied to systems of chemical and physical interest. The Fermi-Löwdin Orbital Self-Interaction Correction (FLO-SIC) methodology was recently introduced as a unitarily invariant reformulation of the Perdew-Zunger SIC scheme to remove unphysical SIE from DFT. We propose new algorithms that aim to speed up and extend the applicability of this methodology. The "two-step" algorithm was designed to reduce the number of times that orbital-dependent potentials need to be calculated in the self-consistency cycle, addressing one computational bottleneck of SIC calculations. We also introduced unified Hamiltonian formalism in FLOSIC as a way to solve the system of Schrödinger-like equations. An advantage of the unified Hamiltonian approach is that it can replace a cumbersome "Jacobi sweep" method with a well-optimized diagonalization routine. It also is a convenient formalism for allowing unoccupied states to "see" an SIC potential. We present atomic and molecular applications that show the performance of FLOSIC with these new algorithms.

*DE-SC0018331

4:30PM J58.00009: Perdew-Zunger Self-Interaction Correction in Neutral, Protonated, and Deprotonated Water Clusters* KAMAL WAGLE (Presenter), BISWAJIT SANTRA, Temple Univ, KAMAL SHARKAS, Central Michigan University, SHARMIN AKTER, RAJENDRA R ZOPE, TUNNA BARUAH, University of Texas, El Paso, KOBLAR JACKSON, JUAN E PERALTA, Central Michigan University, JOHN P. PERDEW, Temple Univ — We have assessed the importance of self-interaction correction (SIC) to density functional approximations (DFA) for the description of water-ion interactions. We have used LSDA, PBE, SCAN, and the Fermi-Löwdin orbital self-interaction correction (FLOSIC) in conjunction with these DFAs to calculate the binding energies of neutral, protonated [H$_3$O$^+$ (H$_2$O)$_n$], and deprotonated [OH$^-$(H$_2$O)$_n$] water clusters, where $n$ denotes the number of water molecules. Including SIC is important to obtain accurate binding energies for these clusters. We find that FLOSIC-SCAN not only improves the mean absolute error in the binding energy of all clusters but also preserves the energetic ordering of the low-lying water hexamers (prism, cage, book, and cyclic) that was difficult to achieve with many non-empirical DFAs. Moreover, many-body decomposition of the total binding energy reveals that FLOSIC-SCAN significantly reduces the two-body errors in SCAN calculations. The three-body and higher-order many-body errors are also small with FLOSIC-SCAN. This shows that FLOSIC-SCAN has the potential to overcome the limitations of SCAN in describing water and aqueous ions in condensed phases.

4:42PM J58.00010: Study of water cluster anions using the self-interaction corrected density functional approximations*  JORGE VARGAS (Presenter), PETER UFONDU, TUNNA BARUAH, University of Texas at El Paso, KOBLAR ALAN JACKSON, Central Michigan University, RAJENDRA ZOPE, University of Texas at El Paso — Accurate description of the excess charge in water cluster anions is challenging for standard semi-local and (global) hybrid density functional approximations (DFAs). Using the recent unitary invariant implementation of the Perdew-Zunger self-interaction correction (SIC) method by means of Fermi-Lowdin orbitals, we assess the effect of self-interaction error on the vertical detachment energies (vDEs) of water cluster anions with the local spin density approximation (LSDA), PBE-GGA, and the SCAN meta-GGA functionals. Removal of self interaction error corrects the electron overbinding tendency of the LSDA, PBE, and SCAN. The vDEs of water cluster anions, obtained from the total energy difference of anion and neutral, are significantly improved upon removal of self-interaction errors and are better than the hybrid B3LYP functional but fall short of MP2 accuracy. Removal of SIE results in substantial improvement to the eigenvalue of the extra electron. The negative of the highest occupied eigenvalue after SIC provides an excellent approximation to the vertical detachment energy especially for the SIC-PBE wherein the MAE of vDEs with respect to CCSD(T) is only 17 meV, the best amongst all approximations compared in this work.

4:54PM J58.00011: Fermi-Lowdin orbital self-interaction corrections applied to water clusters: Polarizabilities, dipole moments, and ionization energies*  SHARMIN AKTER (Presenter), Computational Science Program, University of Texas at El Paso, YOH YAMAMOTO, RAJENDRA ZOPE, TUNNA BARUAH, Physics, University of Texas, El Paso — The self-interaction (SI) error in density functional approximations (DFA) often leads to excessive delocalization of electron density. We examine the effect of self-interaction correction on the static dipole polarizabilities of small water clusters (H2O)n for n=1-6 using the Fermi-Lowdin self-interaction correction (FLOSIC) method. The static polarizability of a molecule determines its response to an applied static electric field. Density functional approximations generally overestimate the polarizabilities of molecules and atoms which is found to be improved by incorporation of SI correction. The polarizabilities of the water clusters are calculated with DFAs at the local, generalized gradient and meta-GGA levels. Previously optimized geometries at the CCSD(T) level are used for this calculation. Results show that the lower level approximations, LDA and GGA, overestimate the polarizability values whereas FLOSIC corrects the polarizabilities leading to better agreement with reference CCSD(T) values. We also investigate the effect of removing the self-interaction error on the dipole moments and ionization potentials of these clusters with different functionals. The results will be presented and discussed.

Session J59 DMP: Magnetic Weyl semimetals  Mile High Ballroom 3C
2:30PM J59.00001: Single-crystal neutron diffraction study of Dirac material EuMnSb₂

JOHN WILDE (Presenter), Physics and Astronomy, Iowa State University/Ames Laboratory, BENJAMIN UELAND, SIMON XAVIER RIBEROLLES, Ames Laboratory, DOMINIC H RYAN, McGill University, ANDREAS KREYSSIG, Physics and Astronomy, Iowa State University/Ames Laboratory, DAVID VAKNIN, Ames Laboratory, THOMAS HEITMANN, University of Missouri, YONG LIU, SERGEY L. BUD'KO, Ames Laboratory, ROBERT MCQUEENEY, Physics and Astronomy, Iowa State University/Ames Laboratory — EuMnSb₂ is a potential Dirac semimetal with Dirac fermions located in the Sb layers. These Dirac fermions have the potential to be controlled by a magnetic field if the magnetic order of the Eu or Mn sublattices couples to them. A large anisotropic magnetoresistance suggests that this coupling is strong in EuMnSb₂. Here we present results from single-crystal neutron diffraction experiments on EuMnSb₂. We find that the Eu and Mn magnetic sublattices order antiferromagnetically (AF) at 24(1) K and 324(1) K, respectively, with an additional magnetic phase transition at 9(1) K related to the coupling between both magnetic sublattices. Neutron diffraction shows that each AF phase is characterized by a magnetic unit cell equal to the chemical unit cell in contrast to Mossbauer measurements which suggest incommensurability. Our analysis indicates that the ordered Eu moments chiefly point perpendicular to the Sb planes and that the Mn moments align within the planes.

2:42PM J59.00002: Visualization of Antiferromagnetic Domain Walls in the Topological Semimetal EuMnBi₂

WENBO GE (Presenter), PAUL SASS, WEIDA WU, Rutgers University, New Brunswick, DIMUTHU OBEYSEKERA, JUNJIE YANG, Central Michigan University — The layered compound EuMnBi₂ is one such system where magnetic order coexists with Dirac fermions. The interplay between the uniaxial A-type antiferromagnetic (AFM) Eu magnetic order and quasi-2D Dirac fermions was recently observed to give rise to a multilayer quantum Hall state at high magnetic field above the spin-flop transition (> 5 T)¹. In this talk we will present magnetic imaging of AFM domain walls (DW) and their evolution across the spin-flop transition in the topological semimetal EuMnBi₂ using our cryogenic magnetic force microscope². Our results reveal that curvilinear AFM DWs naturally form when the sample is cooled below Tₐ (~ 22 K). Magnetic field dependence of the DW signal suggests enhanced susceptibility inside the DWs in the A-type AFM state. The DWs disappear above the spin-flop transition, and re-nucleate at different locations after reentry into the A-type AFM state. The direct visualization of AFM DWs in topological semimetals will help in the understanding of topological phenomena in correlated magnetic systems.

2:54PM J59.00003: Signature of spin-fermion coupling in the magnetic excitations of Dirac semimetal YbMnBi₂.* AASHISH SAPKOTA (Presenter), IGOR ZALIZNYAK, JOHN TRANQUADA, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, LAURA CLASSEN, Brookhaven National Laboratory; University of Minnesota, CEDOMIR PETROVIC, AIFENG WANG, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, MATTHW STONE, ANDREI T SAVICI, VASILE O GARLEA, Oak Ridge National Laboratory — In Dirac semimetals, coupling of Dirac charge carriers with magnetism can lead to novel phenomena with potential for technological applications [1, 2]. From this perspective, 112 ternary pnictogens (A,R)MnX₂ (A=Ca,Sr; R=Yb,Eu; X=Bi,Sb) represent an interesting family of Dirac materials where both the magnetism and Dirac electrons coexist, thereby providing an opportunity to study the spin-fermion coupling between Mn spins and Dirac electrons in Bi layer [2]. Previous studies of spin excitations in (Sr,Ca)MnBi₂ using inelastic neutron scattering (INS) have found no indication of such coupling because anomalous broadening found in itinerant magnets was absent [2]. However, our recent INS measurements of spin waves on YbMnBi₂ found a small and q-independent broadening in the spin waves, which is consistent with a significant spin-Dirac fermion coupling. Theoretical calculations show that the effect of coupling on the spin excitations is suppressed by a vanishing carrier density of states at the Dirac point. [1] A. Sapkota et al, arxiv 1908.08114 (2019), [2] M. C. Rahn et al, Phys. Rev. B 95, 134405 (2017).

3:06PM J59.00004: A Charge Density Wave Transition in NaₓMnBiᵧ magnetic semimetal

DESPINA LOUCA (Presenter), AARON WEGNER, Univ of Virginia — The I-Mn-V antiferromagnet, NaMnBi, was recently reported to develop a very large magneto-resistance (MR) up to 10,000 % at 2 K under a magnetic field of 9 T. A strong positive MR is present in crystals showing a semiconductor-to-metal transition (SMT) while, in the absence of an SMT, a modest (20 %) MR is achieved. Here, we show that upon cooling below the magnetic transition, a spatial modulation appears due to charge and defect ordering in a checkerboard pattern, with two kinds of displacement vectors q₁=(2/3, 0, 1) and q₂=(2/3, 1/3, 1/2). This couples to a superlattice transition (Tₛ) that lowers the symmetry from centrosymmetric P4/nmm to non-centrosymmetric P-4m2. In crystals with a large MR a close to room temperature Tₛ is observed with both q₁ and q₂ present. In crystals with low MR however, Tₛ is lower and only q₁ is observed. Tₛ breaks spatial inversion symmetry and marks the onset of a charge density wave instability.
ILYA BELOPOLSKI (Presenter), GUOQING CHANG, TYLER COCHRAN, JIAXIN YIN, SONGTIAN SONIA ZHANG, ZIJIA CHENG, XIAN YANG, NANA SHUMIYA, DANIEL MULTER, MAKSIM LITSKEVICH, ZAHID HASAN, Princeton University — Topological electronic phases in intrinsic magnets are of current interest. One common magnetic topological object is the Weyl line, a two-fold band degeneracy along a closed curve in bulk momentum space. Weyl lines arise naturally in the absence of time-reversal symmetry (absent in magnets) and in the presence of mirror symmetry (common in many space groups). I will present the observation of Weyl lines by ARPES in the room temperature magnet Co$_2$MnGa [1]. On the surface of the magnet, I observe drumhead surface states, pinpointing the bulk-boundary correspondence and suggesting a Berry phase topological invariant associated with the Weyl line. Next, the intrinsic Berry curvature contribution to the anomalous Hall response, determined from quantum transport, agrees with a prediction of the Weyl line Berry curvature based on ARPES and first-principles calculations [1]. I will comment on composite topological structures arising from pinning and linking of different Weyl lines. Lastly, I will discuss future directions in Co$_2$MnGa and other topological Weyl line magnets.

YU LIU (Presenter), CHRISTIAN MATT, HARRIS PIRIE, Department of Physics, Harvard University, NATHAN DRUCKER, Department of Applied Physics, Harvard University, ROBERT-JAN SLAGER, Department of Physics, Harvard University, NA HYUN JO, BRINDA KUTHANAZHI, SERGEY L. BUD'KO, PAUL C CANFIELD, Department of Physics & Astronomy, Iowa State University/Ames Laboratory, JENNIFER E. HOFFMAN, Department of Physics, Harvard University — Weyl semimetals are characterized by topologically protected Weyl nodes in the bulk and Fermi-arcs states with momentum-locked spin or chirality on the surface. Among various Weyl semimetals, magnetic Weyl semimetals are particularly attractive because they have fewer, more widely separated Weyl nodes. Additionally, their Weyl nodes can potentially be manipulated by external magnetic field or changes in the local moment ordering. Here we present a scanning tunneling microscopy and quasiparticle interference (QPI) study of the magnetic Weyl semimetal candidate CeBi. In particular, we resolve splitting of the Bi $p$ and Ce $d$ bands of CeBi with 9T external magnetic field, which is the necessary precondition for Weyl nodes. We also observe signatures of Fermi-arcs in the QPI pattern. The QPI-derived band structure of CeBi in different magnetic phases is also studied.

3:42PM J59.00007: Magnetic semimetals and quantized anomalous Hall effect in EuB$_6$*  
MIN NIE (Presenter), Stanford Univ — Exploration of the novel relationship between magnetic order and topological semimetals has received enormous interest in a wide range of both fundamental and applied research. Here we predict that "soft" ferromagnetic (FM) material EuB$_6$ can achieve multiple topological semimetal phases by simply tuning the direction of the magnetic moment. Explicitly, EuB$_6$ is a topological nodal-line semimetal when the moment is aligned along the [001] direction, and it evolves into a Weyl semimetal with three pairs of Weyl nodes by rotating the moment to the [111] direction. Interestingly, we identify a novel semimetal phase featuring the coexistence of a nodal line and Weyl nodes with the moment in the [110] direction. Topological surface states and anomalous Hall conductivity, which is sensitive to the magnetic order, have been computed and are expected to be experimentally observable. Large-Chern-number quantum anomalous Hall effect can be realized in its [111]-oriented quantum-well structure.

3:54PM J59.00008: Real-space imaging of surface-magnetism in magnetic Weyl semimetal candidate CeBi*  
CHRISTIAN MATT (Presenter), YU LIU, NATHAN C DRUCKER, HARRIS PIRIE, ROBERT-JAN SLAGER, Harvard University, NA HYUN JO, Ames Laboratory, BRINDA KUTHANAZHI, SERGEY L. BUD’KO, PAUL C CANFIELD, Iowa State University, JENNIFER E. HOFFMAN, Harvard University — Magnetic Weyl semimetals host chiral Weyl nodes in their bulk which are formed by broken time-reversal symmetry, caused, for example, by intrinsic ferromagnetic order. While the bulk-surface correspondence dictates the formation of Fermi arcs connecting Weyl nodes with opposite chirality, their momentum-space contour and their connectivity (i.e. which Weyl points they are connecting to), depends on surface properties. Here we use spin-polarized scanning tunneling microscopy to map the magnetic structure on the surface of CeBi at various bulk-magnetic phases. We find unexpected surface-magnetic order with strongly bias-dependent magnetic contrast and phase. We discuss our observation in terms of Fermi arc connectivity and magnetic interactions in CeBi.

4:06PM J59.00009: Effect of chemical substitution on the anomalous Hall effect of chiral-lattice antiferromagnet CoNb$_3$S$_6$

DINA MICHEL (Presenter), NISHCHAL THAPA MAGAR, NICHOLAS BISHOP, Department of Physics and Astronomy, George Mason University, LEKHNATH POUDEL, Department of Materials Science and Engineering, University of Maryland, College Park, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, JOHN MITCHELL, Materials Science Division, Argonne National Lab, NIRMAL GHIMIRE, Department of Physics and Astronomy, George Mason University — An ordinary Hall effect in a conductor arises due to the Lorentz force acting on the charge carriers. In ferromagnets, an additional contribution to the Hall effect, the anomalous Hall effect (AHE), appears proportional to the magnetization. It is also known that the AHE can arise in non-collinear and non-coplanar antiferromagnets due to scalar spin chirality. However, recently a large AHE was observed in a collinear antiferromagnet CoNb$_3$S$_6$ [1]. More recent theories have indicated that the AHE in CoNb$_3$S$_6$ may be inherently related to the chirality associated with the crystal structure [2,3]. The presence of a small ferromagnetic component plays an important role in revealing the AHE in CoNb$_3$S$_6$ which was limited to a narrow temperature range just below the Néel temperature. Here we will show that partial substitution of Co by Fe widens the temperature range and that the AHE in Co$_{1-x}$Fe$_x$Nb$_3$S$_6$ saturates at lower temperatures. We will discuss the importance of this observation in the context of recent theories of the AHE in collinear antiferromagnets.

4:18PM J59.00010: In-plane antiferromagnetic moments in axion topological insulator candidate EuIn$_2$As$_2$

YANG ZHANG, the school of Physics, Sun Yat-Sen University, KE DENG, the school of Physics, Southern University of Science and Technology, XIAO ZHANG, MENG WANG, the school of Physics, Sun Yat-Sen University, CAI LIU, the school of Physics, Southern University of Science and Technology, EIKE F. SCHWIER, SHIV KUMAR, Hiroshima Synchrotron Radiation Center, Hiroshima University, CHAOYU CHEN, the school of Physics, Southern University of Science and Technology, BING SHEN (Presenter), the school of Physics, Sun Yat-Sen University — Topological insulator with antiferromagnetic order can serve as an ideal platform for the realization of axion electrodynamics. In this paper, we report a systematic study of the axion topological insulator candidate EuIn$_2$As$_2$. A linear energy dispersion across the Fermi level confirms the existence of the proposed hole-type Fermi pocket. Spin-flop transitions occur with magnetic fields applied within the $ab$-plane while are absent for fields parallel to the $c$-axis. Anisotropic magnetic phase diagrams are observed and the orientation of the ground magnetic moment is found to be within the $ab$-plane. The magneto-resistivity for EuIn$_2$As$_2$ behaves non-monotonic as a function of field strength. It exhibits angular dependent evolving due to field-driven and temperature-driven magnetic states. These results indicate that the magnetic states of EuIn$_2$As$_2$ strongly affect the transport properties as well as the topological nature.
Determination of the magnetic order in the EuIn$_2$As$_2$, an axion insulator candidate

SIMON RIBEROLLES (Presenter), Division of Materials Science & Engineering, Ames Laboratory, BRINDA KUTHANAZHI, NA HYUN JO, ADAM KAMINSKI, PAUL C CANFIELD, Ames Laboratory, Iowa State University, THOMAS HEITMANN, Missouri Research Reactor, University of Missouri, DOMINIC H RYAN, Physics, McGill University, BENJAMIN UELAND, Division of Materials Science & Engineering, Ames Laboratory, ROBERT MCQUEENEY, Ames Laboratory, Iowa State University — EuIn$_2$As$_2$ is a Zintl compound recently reported as a possible first example of axion insulator with antiferromagnetic (AF) long-range order and characteristic colossal negative magnetoresistance. It thus represents a unique platform to investigate the physics of axion insulators and, in particular, to focus on the interplay between the AF order and the topologically protected features of the electronic band structure. Here, we present results from single-crystal magnetic diffraction experiments. Surprisingly, our results reveal the successive stabilization of two different sets of magnetic Bragg reflections indexed with the propagation vectors $k_1=(0,0,0.31)$ and $k_2=(0,0,0)$ below $T_{N1}=17$ and $T_{N2}=15$ K, respectively, despite the chemical unit cell containing only a single Eu site. The two magnetic structures are believed to coexist at $T\leq T_{N2}$, and were individually determined from refinement analyses. We will describe both magnetic structures and discuss the influence of our results upon the current understanding of the material's topological features.

*Work supported by the Center for the Advancement of Topological Semimetals, an Energy Frontier Research Center funded by the U.S. DOE Office of Science, Office of BES, through Ames Laboratory under its Contract No. DE-AC02-07CH11358.

Anomalous Hall effect with colossal magnetic saturation and coercivity in (111)-oriented pyrochlore Eu$_2$Ir$_2$O$_7$ thin films

XIAORAN LIU (Presenter), WENBO GE, MIKHAIL KAREEV, FANGDI WEN, Rutgers University, New Brunswick, EUN SANG CHOI, National High Magnetic Field Laboratory, WEIDA WU, JAK CHAKHALIAN, Rutgers University, New Brunswick — The pyrochlore iridates are a class of candidate materials for the topological Weyl semimetal, which can host hidden topological and magnetic phases in the thin film form. To investigate the intrinsic properties relevant to the Ir sublattices, we fabricated high-quality epitaxial (111)-oriented pyrochlore Eu$_2$Ir$_2$O$_7$ thin films on YSZ substrates, in which the Eu$^{3+}$ ions are magnetically silent. Temperature-dependent transport reveals an onset of the metal-insulator transition at $T_C$ around 110 K, similar to the bulk value. However, magneto-transport measurements reveal that below $T_C$ in the insulating phase with the non-colicinear all-in-all-out antiferromagnetic order, a distinct anomalous Hall effect (AHE) emerges combined with a butterfly-shape hysteretic magnetoresistance. The AHE gets strongly pronounced at lower temperatures, with colossal enhancement of both the saturation field $H_S$ and the coercivity $H_C$. These findings are signatures of the emergent interacting topological phases in thin films of [111]-oriented pyrochlore iridates.
4:54PM J59.00013: Domain Wall-Dependent Electrical Transport in a Magnetic Weyl Semimetal*  NICHOLAS QUIRK (Presenter), GUANGMING CHEN, NAN YAO, N. PHUAN ONG, Princeton University — Magnetic force microscopy reveals that microscale lamellae fabricated by focused ion beam microscopy of Co$_2$MnGa—a ferromagnetic Weyl semimetal—contain just a few magnetic domains which form a pattern that is different on the top surface than on the bottom. Transport measurements of electrical devices made from these lamellae with contacts on both faces show large resistance anisotropies that depend on in-plane and out-of-plane magnetic fields in different ways. These data taken together describe a very non-homogeneous current distribution which may result from the interaction of the Weyl fermions in this material with the magnetic domain walls.

*Gordon and Betty Moore Foundation

5:06PM J59.00014: Imaging the Electronic Structures in Antiferromagnetic Dirac Semimetal GdSbTe*  BALAJI VENKATESAN, CHIH-CHUAN SU, Institute of Physics, Academia Sinica, RAMESH BABU, Department of Physics, National Taiwan University, RAMAN SANKAR, Institute of Physics, Academia Sinica, FANGCHANG CHOU, Center for Condensed Matter Sciences, National Taiwan University, GUANG-YU GUO, Department of Physics, National Taiwan University, TIEN-MING CHUANG (Presenter), Institute of Physics, Academia Sinica — Dirac semimetals (DSMs) are characterized by topology- or symmetry-protected band crossings near the Fermi level that can form Dirac points, nodal lines, nodal surface or nodal chains in the electronic band structures. These unique band crossings can give rise to interesting properties such as large anisotropic magnetoresistance, chiral anomaly and flat optical conductivity. Moreover, magnetic DSMs can break the time reversal symmetry, where the interplay of symmetry, relativistic effects and the magnetic order can lead to novel quantum phases and offer the tunability of these quantum states with magnetic field. GdSbTe is a non-symmorphic semimetal with an antiferromagnetic phase below T=13K. By using spectroscopic imaging - scanning tunneling microscopy and first principle calculation, we investigated the surface and bulk electronic structures in GdSbTe across the magnetic transition and under magnetic field. Our quasiparticle scattering interference imaging and calculation showed the linear dispersion from Dirac bands over a wide energy range and are robust against different magnetic orders, suggesting the rigidity of the non-symmorphic crystalline symmetry protection in GdSbTe.

*This work is supported by Academia Sinica and Ministry of Science and Technology in Taiwan.
5:18PM J59.00015: Interplay between topology and magnetic excitations in topological nodal semimetal CeAlGe* THANH NGUYEN (Presenter), MINGDA LI, FEI HAN, NINA ANDREJEVIC, RICARDO PABLO PEDRO, Massachusetts Institute of Technology MIT, MATTHEW STONE, SONGXUE CHI, JAIME FERNANDEZ-BACA, MASAAKI MATSUDA, DAVID TENNANT, Oak Ridge National Laboratory — Weyl semimetals (WSMs) comprise of a novel condensed matter phase that carries emergent quasiparticles of topologically nontrivial chiral Weyl fermions and represent a key recent advance in the realm of strongly spin-orbit-coupled materials. Magnetic WSMs, in which the nontrivial Weyl fermions break time-reversal symmetry, enable the possibility of further discovering unexplored spin-electronic phenomena enabling feasible spintronic applications. In this talk, I will present results obtained from neutron scattering experiments performed on predicted type-II WSM, CeAlGe. Our measurements of low-energy spin waves as well as crystal-field excitations using time-of-flight and triple-axis inelastic neutron scattering highlight phenomena intertwining its nontrivial topology with its unusually intricate magnetic structure. Through the investigation of these excitations, this study elucidates the substantial coupling between the exotic magnetic configuration and the topological semimetallic electronic structure within this material, which may see a valuable role in future practical applications.

*We acknowledge funding from U.S. Department of Energy (DOE), Office of Science (SC), Basic Energy Sciences (BES), award No. DE-SC0020148.

Tuesday, March 3, 2020 2:30 PM - 4:42 PM

Session J60 DMP: Josephson Junctions with Topological Insulator Weak Links Mile High Ballroom 4A - David Cobden, University of Washington - Tag(s): Focus

2:30PM J60.00001: Josephson Junctions Using Weak-Links of Topological Crystalline Insulators* [Invited] JAMES WILLIAMS (Presenter), University of Maryland, College Park — Topological Crystalline Insulators (TCI) produce topological states of matter that rely on crystalline symmetry, opening new avenues to create and control the novel properties of the surface state. In this talk I will elucidate the properties of Josephson junctions that use SnTe -- a candidate TCI material -- as the weak link. Deviations from conventional junction properties are observed, including signatures of broken time reversal symmetry. The genesis of these effects, which arise from a confluence of multiple electronic bands, ferroelectric distortions and topology, will be detailed.

*Synthesis of narrow SnTe nanowires was supported by NSF 1743896. Doping of indium and transport characterizations of SnTe nanowires were supported by DOE DE-SC0014476. Measurements in this work was sponsored by the grants National Science Foundation A “Quantum Leap” Demonstration of Topological Quantum Computing (DMR-1743913) and Physics Frontier Center at the Joint Quantum Institute (PHY-1430094).
3:06PM J60.00002: Fusion and parity readout of Majorana bound states in lateral S-TI-S Josephson junctions*  JESSICA MONTONE (Presenter), GUANG YUE, GILBERT ARIAS, University of Illinois at Urbana-Champaign, XIONG YAO, DEEPTI JAIN, JISOO MOON, SEONGSHIK OH, Rutgers University, New Brunswick, DALE J VAN HARLINGEN, University of Illinois at Urbana-Champaign — We propose experiments designed to demonstrate the fusion of Majorana bound states (MBS) and to measure their parity in S-TI-S (Superconductor-Topological Insulator-Superconductor) lateral Josephson junctions. These junctions are expected to host MBS at Josephson vortex cores where the phase difference across the junction is an odd multiple of $\pi$. Our approach is to integrate Al-AlO$_x$-Al single-electron transistors, which are sensitive to the parity of the MBS pairs, with Nb-Bi$_2$Se$_3$-Nb Josephson junctions, in which the MBS can be created and manipulated to carry out fusion and braiding operations. We report progress toward implementing these schemes and incorporating them into circuits for quantum information processing.

*This work is supported by the National Science Foundation grants DMR-1610114 and DMR-1745304.

3:18PM J60.00003: Interfacial effects of proximitizing superconductivity in topological insulators*  ILAN ROSEN (Presenter), MOLLY P ANDERSEN, LINSEY RODENBACH, Stanford Univ, PENG ZHANG, LIXUAN TAI, GEN YIN, UCLA, MARC A. KASTNER, Stanford Univ, KANG L. WANG, UCLA, DAVID GOLDHABER-GORDON, Stanford Univ — The proximitization of superconductivity into time-reversal invariant topological insulators, as well as their magnetic counterparts, has produced exciting observations including anomalous Fraunhofer patterns[1, 2], finite momentum pairing[3], and fractional quantized conductances[4]. Yet even as the quality of topological materials rapidly improves, variations in behavior across different experiments and groups are not well understood. We postulate that the properties of the interface between superconducting metals and topological insulators play a key role, and we discuss our attempts to characterize and manipulate such interfaces, focusing on the (BiSb)$_2$Te$_3$ family of topological insulators.

*Research supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515.
3:30PM J60.00004: Interface and scattering potentials in topological insulator-superconductor heterostructures*  

EKLAVYA THAREJA (Presenter), ILYA VEKHTER, Louisiana State University, Baton Rouge — Many proposed applications of topological insulators rely on coupling them to superconductors in Josephson-type geometry. However, interface potentials at the boundary between a superconductor and a topological insulator can alter the dispersion and the spin texture of the topological states, thereby changing the nature of the proximity-induced superconducting order. Using effective low-energy models we study how these potentials, combined with the scattering at lateral junctions between superconducting and non-superconducting regions, change the spectra of the Andreev bound states and the Josephson current-phase relationship. We discuss the relevance of our findings to proposals for functional heterostructures.

*NSF via Grant No. DMR-1410741

3:42PM J60.00005: Superconductivity in \( \text{Sn}_{1-x}\text{In}_x\text{Te} \) thin films grown by molecular beam epitaxy*  

ANDREA BLIESENER (Presenter), JUNYA FENG, ALEXEY A TASKIN, YOICHI ANDO, Institute of Physics II, University of Cologne — \( \text{Sn}_{1-x}\text{In}_x\text{Te} \) is derived from the topological crystalline insulator \( \text{SnTe} \) which becomes superconducting when doped with Indium and it is one of the top candidates for topological superconductivity [1].

\( \text{Sn}_{1-x}\text{In}_x\text{Te} \) films have been grown by molecular beam epitaxy on a \( \text{Bi}_2\text{Te}_3 \) buffer layer, which has a good lattice matching for the growth in the (111) direction [2]. Using \textit{in situ} post-annealing procedures, we achieve robust superconductivity. To look for possible signatures of topological superconductivity, we fabricated tunnel junctions on the surface of the \( \text{Sn}_{1-x}\text{In}_x\text{Te} \) films. The tunnelling spectroscopy data shows a two-gap structure in the conductance spectra which points to the coexistence of bulk and surface superconductivity in the studied films.

*This project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation program (Grant Agreement No. 741121), the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under CRC 1238-277146847 (Subprojects A04, B01) as well as Germany’s Excellence Strategy—Cluster of Excellence Matter and Light for Quantum Computing (ML4Q) EXC 2004/1-390534769.
3:54PM J60.00006: Superconductivity of Topological Surface States and Strong Proximity Effect in Sn$_{1-x}$Pb$_x$Te-Pb Heterostructures  JINFENG JIA (Presenter), HAO YANG, YAO-YI LI, TENG-TENG LIU, DANDAN GUAN, SHI-YONG WANG, HAO ZHENG, CANHUA LIU, Shanghai Jiao Tong Univ, LIANG FU, Physics, MIT — Superconducting topological crystalline insulators are expected to form a new type of topological superconductors to host Majorana zero modes under the protection of lattice symmetries. The bulk superconductivity of topological crystalline insulators has been induced through chemical doping and proximity effect. However, only conventional full gaps are observed, so the existence of topological superconductivity in topological crystalline insulators is still controversial. Here, we report the successful fabrication of atomically flat lateral and vertical Sn$_{1-x}$Pb$_x$Te-Pb heterostructures by molecular beam epitaxy. The superconductivity of the Sn$_{1-x}$Pb$_x$Te-Pb heterostructures can be directly investigated by scanning tunneling spectroscopy. Unconventional peak-dip-hump gap features and fourfold symmetric quasiparticle interference patterns taken at the zero energy support the presence of the topological superconductivity in superconducting Sn$_{1-x}$Pb$_x$Te. Strong superconducting proximity effect and easy preparation of various constructions between Sn$_{1-x}$Pb$_x$Te and Pb make the heterostructures to be a promising candidate for topological superconducting devices to detect and manipulate Majorana zero modes in the future.

4:06PM J60.00007: Probing the location of Josephson vortices and the Majorana states bound to them in S-TI-S lateral Josephson junctions via Scanning SQUID Microscopy*  GILBERT ARIAS (Presenter), JESSICA MONTONE, ERIK D HUEMILLER, GUANG YUE, DALE J VAN HARLINGEN, Physics, University of Illinois Urbana-Champaign — Superconducting-Topological Insulator-Superconducting (S-TI-S) Josephson junctions are a promising platform for creating and manipulating Majorana bound states (MBS). The MBS are localized at the cores of Josephson vortices where the phase difference across the junction is an odd-multiple of π. They can be manipulated by applying fields and currents to carry out braiding operations for quantum information processing. To optimize braiding protocols, it is useful to track the motion of the vortices via local magnetic imaging. We are developing a Scanning SQUID Microscope in which the probe is a superconducting pickup loop with submicron dimensions. It is inductively-coupled to a commercial dc SQUID, providing the required field sensitivity and spatial resolution. In this talk, we report our progress towards imaging the Josephson vortices and the currents carried by the Majorana states.

4:18PM J60.00008: Excess Vortex-Vortex Supercurrent as Method for Readout of Majorana Parity in Fe(Se,Te)*  
BENJAMIN NOVEMBER (Presenter), Physics, Harvard University, JAY SAU, Physics, University of Maryland, College Park, JAMES WILLIAMS, Joint Quantum Institue, JENNIFER E. HOFFMAN, Physics, Harvard University — Topological superconductors are one of the most exciting new platforms for the development of topological quantum computing. Specifically, the Fe(Se,Te) family has been shown to host Majorana zero-energy modes (MZMs) in vortex cores [1], pairs of which can potentially be used as topologically protected qubits. However, there has been no previous calculations to suggest that the two distinct parity states can be distinguished experimentally. Through the use of an effective two-dimensional Fu-Kane model on the surface of $\text{FeTe}_x\text{Se}_{1-x}$, we approximate the $(p_x + ip_y)$ superconductor as an internal s-wave proximity effect on the topological surface states. We then numerically calculate the wavefunction solution to the resulting Bogoliubov-de Gennes equation for both spatially separated single vortices and the double vortex limit of complete overlap of the single vortex pair. Using these wavefunction solutions, we compute supercurrent generated by zero-energy mode splitting and the resulting magnetic field gradient above the surface. We conclude it is possible to measure the presence of this excess supercurrent, and thus the quantum state of the MZM pair, using magnetic force microscopy.

4:30PM J60.00009: Proximity effect at the superconducting-topological insulator interface from first principles*  
KYUNGWHA PARK (Presenter), Physics, Virginia Tech, BALAZS UJFALUSSY, Wigner Research Centre for Physics, Hungary — A topological insulator (TI) film in contact with an s-wave superconducting (SC) substrate has been extensively studied due to the possibility of hosting zero-energy Majorana states using the proximity effect. So far, theoretical studies have been carried out based on effective models. Experimental studies of TI-SC heterostructures showed inconsistent results on a dependence of the induced SC gap size on TI film thickness as well as on the proximity effect for the TI bulk states. The Fermi level is likely to cross both TI bulk and Dirac surface states. Here we investigate the proximity-induced SC gap at the interface TI and top TI surface states and bulk TI states, considering a Bi2Se3 film on a PdTe SC substrate within first-principles calculations. In this study, we solve the fully relativistic Kohn-Sham-Dirac-Bogoliubov-de Gennes equations for the heterostructure by introducing Cooper pairs within the screened Korringa-Kohn-Rostoker (SKKR) method. We present our results on the induced SC gap arising from TI bulk and surface states and its dependence on TI film thickness at several chemical potential values.

*The computational support was provided by SDSC under DMR060009N and VT ARC.
J60.00010: Multiple Pairs of Propagating Majorana Modes in the Vortex Line of Superconducting Quadratic Dirac Semimetals  
LUN HU, department of physics, University of California, San Diego, SHENSHAN QIN (Presenter), Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, CHEN FANG, JIANGPING HU, Beijing National Research Center for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, FU-CHUN ZHANG, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences — We study the vortex bound states in a class of three dimensional (3D) time reversal invariant quadratic Dirac semimetals. Assuming intrinsic s-wave superconductivity, we find that multiple Majorana modes can be bound to the vortex line for certain range of doping level. Specifically, due to the quadratic Dirac points in the band structures, quasi-1D Majorana modes carrying angular momentum ±1 and ±2 can propagate along the vortex line; for quadratic Dirac semimetals with nontrival Z2 topological character, additional 0D Majorana zero modes carrying angular momentum 0 can be bound at the end of the vortex line. Together with our work in linear Dirac semimetals (Phys. Rev. Lett. 123, 027003), we establish a complete correspondence between the topological properties of the normal state band structures and the vortex bound states in the s-wave superconducting state.

Session J61 DMP DCMP DCOMP: Fe-Based Superconductors - Nematicity III / ARPES  Mile High Ballroom 4B - Vitalii Vlasko-Vlasov, Argonne Natl Lab - Tag(s): Focus
2:30PM J61.00001: A local structure perspective on iron pnictides and chalcogenides: Insights gained from pair distribution function analysis* [Invited] BENJAMIN FRANDSEN (Presenter), Physics and Astronomy, Brigham Young University — The field of iron-based superconductivity, now well into its second decade of existence, continues to challenge and stimulate condensed matter physicists. One perennial issue of debate is the origin and implications of the electronic nematic phase. This state is characterized by a spontaneous breaking of four-fold rotational symmetry, which manifests as unequal occupations of the $d_{xz}$ and $d_{yz}$ orbitals, a tetragonal-to-orthorhombic structural phase transition, and (in many cases) stripe-type magnetic order. In addition to the statically ordered nematic phase observed widely in various families of iron-based superconductors, strong nematic fluctuations have also been found in broad regions of parameter space outside the ordered nematic state. Pair distribution function (PDF) analysis of x-ray and neutron total scattering data is a proven method of studying local, short-range structural correlations that deviate from the average structure, such as the orthorhombic distortions associated with nematic fluctuations in iron-based superconductors. Here, I will present recent PDF investigations of several representative families of iron-based superconductors. The results reveal the presence of local orthorhombic distortions across large regions of temperature-composition space and provide a detailed look at the temperature dependence and characteristic length scale of these distortions. The deeper understanding of the local structure of iron-based superconductors enabled by these PDF experiments will help clarify some of the outstanding questions relating to these fascinating materials.

3:06PM J61.00002: Time Reversal Symmetry Breaking in the FeTe$_{1-x}$Se$_x$ family of high Tc superconductors.* [Invited] PETER JOHNSON (Presenter), Brookhaven National Laboratory — Laser-based ARPES with variable light polarization offers a powerful probe of the electronic structure near the center of the Brillouin zone. Here the technique is used to examine the Fe-based superconductor family, FeTe$_{1-x}$Se$_x$. At the zone center we observe the presence of Dirac cones with helical spin structure as expected for topological surface states and as previously reported in the related FeTe$_{0.55}$Se$_{0.45}$.[1] These studies are compared with theoretical studies that take account of the disordered local magnetic moments related to the paramagnetism observed in this system. Indeed including the magnetic contributions in the theoretical description is necessary to bring the chemical potential of the calculated electronic band structure into alignment with experimental observation. In the bulk superconducting state for FeTe$_{0.7}$Se$_{0.3}$ the topological state appears to acquire mass below T$_c$. With a single state at the center of the zone, mass acquisition is indicative of time reversal symmetry breaking which in turn suggests the potential formation of ferromagnetism in the surface layer.

3:42PM J61.00003: Orbital transmutation in the nematic state of FeSe: the consequences for Raman and ARPES experiments* ANDREY CHUBUKOV (Presenter), University of Minnesota, MATTIA UDINA, MARCO GRILLI, LARA BENFATTO, Physics, "Sapienza" University of Rome, MORTEN HOLM CHRISTENSEN, RAFAEL FERNANDES, University of Minnesota — In this talk I will discuss nematicity induced change of the orbital composition of low-energy excitations in FeSe, and how it affects Raman and ARPES probes. I will argue that deep in the nematic state, hole and electron pockets become nearly mono-orbital, consistent with polarized ARPES measurements. I show that this leads to strong reduction of Raman intensity in B$_{1g}$ channel (in 1Fe zone), as observed in the measurements. The reduction comes about because for nearly mono-orbital pockets, B$_{1g}$ Raman response gets reduced by vertex corrections, which enforce charge conservation. I further discuss ARPES experiments at the M point ($\pi,\pi$). Deep in the nematic state, the two excitations, best visible in ARPES, have been identified as having xz and yz orbital character. However, they remain split above the nematic transition, in apparent contradiction to the fact that in the tetragonal phase the xz and yz orbitals are degenerate. We show that these experimental data are naturally explained by orbital transmutation of the excitations at M between tetragonal and nematic phases.

3:54PM J61.00004: Time-reversal symmetry-breaking superconductivity in FeSe$_{1-x}$S$_x$*

MINGWEI QIU (Presenter), KOHEI MATSUURA, TAKAAKI TAKENAKA, YUICHI SUGIMURA, TAKASADA SHIBAUCHI, Univ of Tokyo, QI SHENG, KOHTARO YAMAKAWA, YASUTOMO J UEMURA, Department of Physics, Columbia University, YIPENG CAI, ANDREA DAMASCELLI, RYAN P DAY, KENJI KOJIMA, Stewart Blusson Quantum Matter Institute, University of British Columbia, JAMES W BEARE, GREGORIE LUKE, Department of Physics & Astronomy, McMaster University, ZHAO GUO QIANG, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, YILUN GU, LICHENG FU, FANLONG NING, Department of Physics, Zhejiang University, MIKIHIKO SAITO, Univ of Tokyo — The FeSe$_{1-x}$S$_x$ superconductors involving non-magnetic nematic phase and its quantum criticality provide a unique platform to investigate the relationship between nematicity and superconductivity. The lifting of superconducting gap nodes due to twin boundaries has been observed experimentally, which suggests indirect evidence for time-reversal symmetry breaking (TRSB). It is consistent with the theoretical prediction that the superconducting order parameter breaks the time-reversal symmetry near the nematic twin boundaries. We have performed the muon spin rotation (μSR) measurements on FeSe and observed the spontaneous internal field below the superconducting transition temperature $T_c$, providing evidence for TRSB state in FeSe. Here we extend zero-field μSR studies to tetragonal FeSe$_{1-x}$S$_x$ (x=0.18, 0.2) without nematicity. We find that the μSR relaxation rate starts to grow below $T_c$ in these crystals. This indicates that weak but finite internal magnetic field is induced in the superconducting state, providing strong evidence for TRSB state not only near twin boundaries but also inside the bulk of FeSe$_{1-x}$S$_x$.

4:06PM J61.00005: An ARPES and STM/S investigation of the interplay between nematicity, orbital order, and superconductivity in FeSe*

MORGAN WALKER (Presenter), TIMOTHY BOYLE, ZITONG ZHAO, EDUARDO H DA SILVA NETO, JOURNEY BYLAND, JACKSON R BADGER, VALENTIN TAUFOUR, University of California, Davis, RYAN P DAY, SERGEY ZHDANOVICh, ANDREA DAMASCELLI, University of British Columbia, TOR PEDERSEN, SERGEY GOROVIKOV, Canadian Light Source — Nematic order coexists with a myriad of iron-based superconductors, suggesting it is an important actor in the mechanism behind the superconductivity in these compounds. Many of these materials also exhibit magnetism near the nematic and superconducting phases, complicating the quest to understand their relationship. Fortunately, FeSe has no magnetic ground state and is therefore a great candidate for disentangling the interplay between nematicity and superconductivity. We performed detailed scanning tunneling microscopy and spectroscopy (STM/S) and angle-resolved photoemission spectroscopy (ARPES) studies on single crystals of FeSe to investigate the interplay between nematicity, orbital order and superconductivity.

Nematicity is a phenomenon found in an increasing number of strongly correlated materials in close proximity to other quantum phases such as unconventional superconductivity. It is therefore important to understand its microscopic origin. The phase diagram of most iron-based superconductors contains a nematic phase. It breaks rotational symmetry and involves an in-plane anisotropy of lattice, spin and charge degrees of freedom. It is currently debated whether spin or orbital degrees of freedom are the driving force and whether there is a common microscopic mechanism in iron-based superconductors with and without magnetic order. We were able to combine angel-resolved photoemission spectroscopy (ARPES) with in-situ tuneable uniaxial strain and determine the momentum dependence of the nematic order parameter in FeSe and BaFe$_2$As$_2$. The order parameter has the same non-trivial symmetry in both compounds suggesting a universal behavior and a common microscopic mechanism.

**4:30PM J61.00007: Unprecedented Optical Anisotropy in Optimally Doped Iron-Based Superconductor**

LEONARDO DEGIORGI, ANIRBAN PAL (Presenter), MANUEL CHINOTTI, ETH Zurich —

The divergent nematic susceptibility, obeying a simple Curie-Weiss power law over a large temperature interval, is empirically found to be a ubiquitous signature in several iron-based materials across their doping-temperature phase diagram. The composition at which the associated Weiss temperature extrapolates to zero is found to be close to optimal doping, boosting the debate to what extent nematic fluctuations contribute to the pairing-mechanism and generally affect the electronic structure of iron-based superconductors. Here, we offer a comprehensive optical investigation [1] of the optimally hole-doped Ba$_{0.6}$K$_{0.4}$Fe$_2$As$_2$ over a broad spectral range, as a function of temperature and of tunable applied stress, which acts as an external symmetry breaking field. We show that the stress-induced optical anisotropy in the infrared spectral range is reversible upon sweeping the applied stress and occurs only below the superconducting transition temperature. These findings demonstrate that there is a large electronic nematicity at optimal doping which extends right under the superconducting dome.

4:42PM J61.00008: Strain effects in Fe-based superconductors: Nematicity, exotic magnetism and superelasticity*  
ROSER VALENTI (Presenter), VLADISLAV BORISOV, KARIM ZANTOUT, SANANDA BISWAS, STEPHEN WINTER, Goethe University Frankfurt — In this talk we will analyze the role of strain in some families of Fe-based superconductors. 
Via a combination of first principles-based calculations and many-body approaches we investigate nematicity, possible exotic magnetism and superelasticity in 122 and 1144 systems [1,2] and discuss possible origins of the discrepancy between ARPES measurements and electronic structure calculations in the nematic phase of FeSe [3] with the help of strain. This work is a collaboration with Paul Canfield, Seok-Woo Lee, Rafael Fernandes, Peter Hirschfeld and Brian Andersen.

4:54PM J61.00009: Bilayer Spliting and Unusual Superconducting Gap in KCa$_2$Fe$_4$As$_4$F$_2$ Superconductor with Double Fe$_2$As$_2$ Layers  
DINGSONG WU (Presenter), WENSHAN HONG, CHENGXIAO DONG, JIANGPING HU, SHILIANG LI, HUIQIAN LUO, LIN ZHAO, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Science, Beijing 100190, China — We report the first high resolution laser Angle-Resolved Photoemission Spectroscopy (ARPES) measurements on a newly discovered iron based superconductor, KCa$_2$Fe$_4$As$_4$F$_2$ (K12442) which has the K+-cations connecting double Fe$_2$As$_2$ layers separated by the insulating Ca$_2$F$_2$ block with a high TC of 34 K at stoichiometric composition. Total five hole like Fermi surfaces are clearly identified around Brillouin zone center Γ(0,0) point and four of them are possible from the bilayer splitting of two Fermi surfaces. A tiny electron like pocket is shown around M(±π,±π) points surrounded by four strong spots with their top just below Fermi level. All the hole like pockets around Γ(0,0) point exhibit nearly isotropic nodeless superconducting gap symmetry but with different gap sizes. Their gap sizes can neither be understood in the simple $|\cos(k_x)+\cos(k_y)|$ functional form due to the biggest gap size from one middle Fermi surface, nor be consistent with the so-called quasi-nesting between the Fermi pockets around Γ and M points because of mismatch of Fermi pocket size. Our observations provide new information and require new insight to understand the superconductivity mechanism in iron based superconductor.
5:06PM J61.00010: Pairing symmetry and capping layer influence of the superconductivity at FeSe/SrTiO$_3$ interface  YANAN LI (Presenter), TIMOTHY PILLSBURY, Pennsylvania State University, GRANT SMITH, ERZSEBET VINCENT, University of Chicago, ANTHONY R. RICHARDELLA, Pennsylvania State University, DAVID AWSCHALOM, University of Chicago, NITIN SAMARTH, Pennsylvania State University — Single unit cell FeSe films on SrTiO$_3$ have attracted growing attention due to the enhancement of the superconducting critical temperature ($T_c$) over its bulk value and the possibility of topological superconductivity. The pairing symmetry and mechanisms underlying the superconducting gap have been studied via angle-resolved photoemission spectroscopy (ARPES) and scanning tunneling spectroscopy (STS). Here, we report the synthesis and characterization of ultrathin FeSe films grown on SrTiO$_3$ by molecular beam epitaxy. We gain insight into the symmetry of the gap by measuring the angular dependence of the in-plane critical magnetic field. Additionally, to understand the discrepancy between $T_c$ measured by in-situ techniques (such as STS and ARPES) and ex-situ transport, we investigate how $T_c$ is influenced by varying the capping layer and Fermi energy. Supported by the University of Chicago, the Vannevar Bush Fellowship, and 2DCC-MIP/NSF DMR-1539916.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

Session J62 DMP: Excitons and Exciton Transport in Nanostructures

2:30PM J62.0001: Novel exciton transport in double-layer graphene structures*  JIA LI (Presenter), Brown University, YIHANG ZENG, Columbia University, XIAOXUE LIU, Brown University, QIANHUI SHI, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JAMES C HONE, CORY DEAN, Columbia University — A spatially indirect exciton is created when an electron and a hole, confined to separate layers of a double quantum well system, bind to form a composite boson. A system of such excitons is demonstrated to host a Bose–Einstein condensate phase at low temperature, featuring dissipationless exciton flow and perfect Coulomb drag. In this talk, I will discuss novel exciton phases in various double-layer structures characterized by exotic transport properties. In double monolayer graphene, an insulating exciton phase is stabilized in the presence of large density imbalance. With increasing temperature, the insulating phase “melts” into an exciton superfluid exhibiting perfect Coulomb drag. In double bilayer graphene, Coulomb drag measurement reveals strong anisotropy in exciton flow when $n = 0$ and $n = 1$ orbitals states are degenerate in one of the layers. Along the easy direction, drag measurement is consistent with an exciton condensate, whereas an anomalous drag response is observed in the orthogonal direction. These exotic exciton phases are studied in a multidimensional phase space defined by a variety of experimental parameters available to double-layer structures, which provides insight into the nature of electron correlation and the resulting physical structures.

Tunable polarons in a carbon nanotube electromechanical resonator

SERGIO DE BONIS (Presenter), CHANDAN SAMANTA, WEI YANG, CARLES URGELL, ICFO-The Institute of Photonic Sciences, BILJANA STAMENIC, BRIAN THIBEAULT, ECE Department, UCSB, FABIO PISTOLESI, CNRS, LOMA, Universite Bordeaux, ADRIAN BACHTOLD, ICFO-The Institute of Photonic Sciences — We demonstrate the formation of polarons in a nanotube electromechanical resonator by increasing the effect of the electron-phonon interaction to an unprecedented level. The polaronic nature of charge carriers results in the reduction of the electrical conductance by up to about half its value. The electron-phonon interaction suppresses the resonance frequency of the fundamental phonon mode by up to 25%. Our device is in the so-called ultra-strong coupling regime, where the electromechanical coupling per phonon is one order of magnitude larger than the resonance frequency. Our work establishes nanotube resonator as a possible platform for the demonstration of mechanical quantum bits and the study of quantum interference effects in the movement of an object consisting of 10^5–10^6 atoms.

Optical transition dipoles in quasi-two dimensional semiconductor nanomaterials

XUEDAN MA (Presenter), Argonne Natl Lab — Optical transition dipole moment is the key parameter in determining the interactions between an optical emitter and external electromagnetic fields. Understanding and having control over the transition dipole moments could lead to optoelectronic and photonic devices with unprecedented performance.[1,2] Transition dipole moments of materials can vary significantly depending on the materials’ band structures and compositions. In this work, we investigate the intrinsic optical transition dipole moments in quasi-two dimensional semiconductor nanomaterials, namely semiconductor nanoplatelets and quantum rings, to understand the influence of geometry and electronic structures on the transition dipole moments. Combining advanced quantum optical microscopy techniques with empirical tight-binding theory, we reveal strikingly different optical transition dipole properties in the two types of structures,[3,4] indicating the importance of material geometry and electronic structures in determining the transition dipole moments.

**3:30PM J62.00004: True Bilayer Exciton Condensate of One-Dimensional Electrons**

ADRIAN KANTIAN (Presenter), Uppsala Univ — We theoretically predict that a true bilayer exciton condensate, characterized by off-diagonal long-range order and global phase coherence, can be created in one-dimensional solid state electron systems. The mechanism by which this happens is to introduce a single particle hybridization of electron and hole populations, which locks the phase of the relevant mode and hence invalidates the Mermin-Wagner theorem. Electron-hole interactions then amplify this tendency towards off-diagonal long-range order, enhancing the condensate properties by more than an order of magnitude over the noninteracting limit. We show that the temperatures below which a substantial condensate fraction would form could reach hundreds of Kelvin, a benefit of the weak screening in one-dimensional systems.

*We thank Nordita for support. D. S. L. A. thanks ERC Project No. DM-321031 for financial support.*

**3:42PM J62.00005: Can trions crystallize in TMDC monolayers?**

ROMAN KEZERASHVILI (Presenter), Physics Department, New York City College of Technology, CUNY — Positively and negatively charged trions in monolayers of transition metal dichalcogenides (TMD) are bound with binding energies of 20-30 meV [1]. Based on the existence of the trions in TMD monolayers, one can propose that a dilute gas of trions, as composite fermions, forms a 2D Wigner crystal. This is similar to the 2D Wigner crystal formed by a dilute system of electrons. The formation of 2D Wigner crystal of the dilute system of trions in TMD monolayers is studied. We show how the reduction of dimensionality affects the binding energy of trions and their crystallization in TMD monolayers. The 2D trion gas in TMD is described using a Charge-Charge, Charge-Exciton, Exciton-Exciton interactions based on the screened Coulomb interaction - Keldysh potential [2]. The formation of the 2D Wigner crystal in the dilute system of trions in TMD monolayers, when the average distance between the trions is much larger than the radius of each trion is predicted. It is shown that the critical density of the formation of the trion Wigner crystal is greater than the critical density of the electron Wigner crystal in the same material.

Direct Visualization of Exciton Transport in Semiconductor Quantum Dot Nanostructures Using Time-Resolved Superresolution Microscopy*  

ALAN VAN ORDEN  
(Presenter), MEGAN DUNLAP, Department of Chemistry, Colorado State University, DUNCAN P. RYAN, PETER GOODWIN, JAMES WERNER, JENNIFER A HOLLINGSWORTH, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, MARTIN PAUL GELFAND, Department of Physics, Colorado State University — A time-resolved superresolution microscope to localize single emitters with nanometer precision and image their lifetimes with sub-nanosecond time resolution is described. This technique has been used to image semiconductor quantum dot (QD) nanostructures composed of single QD emitters that interact via resonance energy transfer. Photoemission from the nanostructures is imaged onto a 2x2 optical fiber array, and the fiber outputs are monitored using time-correlated single photon counting. The relative intensities reveal changes in the emission center as the QDs blink on and off. Emission centers separated by 10-nm or less can be distinguished based on changes in intensity and lifetime that occur when energy is transferred from donor to acceptor QDs. The distribution of centroid positions provide a direct visualization of the energy transport pathway through the nanostructure.

Electron-hole superfluidity controlled by a periodic potential in double layers of two-dimensional material*  

OLEG BERMAN  
(Presenter), ROMAN KEZERASHVILI, New York City College of Technology, YURI LOZOVIK, Institute of Spectroscopy, KLAUS ZIEGLER, University of Augsburg — We propose to control of electron-hole superfluidity in semiconductor coupled quantum wells and double layers of 2D material by an external periodic potential [1]. The latter can either be created by periodic gates attached to quantum wells or the double layers of 2D material or by the Moiré pattern of two twisted layers. Treating the electron-hole pairing within the mean-field approach, we apply the tight-binding approximation of the single electron spectrum and study the effect of the additional periodic potential on the electron-hole plasma-superfluid transition. The electron-hole pairing order parameter as a function of the temperature, the charge carrier density, and the gate parameters are obtained by minimization of the mean-field free energy. The second order phase transition between superfluid and electron-hole plasma, controlled by the external periodic potential, is studied for various parameters.

Exciton- and phonon-mediated electron ultrafast dynamics in semiconducting carbon nanotubes

STEFANO DAL FORNO (Presenter), MARCO BATTIATO, School of Physical and Mathematical Sciences, Nanyang Technological University — Semiconducting single-wall carbon nanotubes (SWCNTs) are ideal one-dimensional materials that have attracted much attention in the construction of novel optoelectronic devices. Their exceptional properties arise from the tunability of quantities such as chirality, twist angle and diameter. The understanding of scattering processes in CNTs is complex due to the non trivial interplay of different quasiparticles such as electrons, holes, phonons and excitons. In particular, due to the low dimensionality and the relatively high dielectric constant, excitons in SWCNTs possess very high binding energy and large spatial extent. It is therefore critical to model this theoretically hard problem to allow for the exploitation of CNTs properties in applications like low dimensional electronics or THz emission.

In this work we study the role of electron, hole, phonon and exciton coupling in (6,5) SWCNTs by theoretically modelling the experimental time-resolved absorption spectrum. We solve the full Boltzmann transport equation explicitly for high order scatterings and strongly out of equilibrium regimes. Our results show excellent agreement with experiments and show the capabilities of our newly developed numerical approach.

Electroluminescence from multi-particle exciton complexes in transition metal dichalcogenide semiconductors

MATTHIAS PAUR (Presenter), ADAY J. MOLINA-MENDOZA, Photonics Institute, TU Wien, RUDOLF BRATSCHITSCH, Institute of Physics and Center for Nanotechnology, University of Münster, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, THOMAS MUELLER, Photonics Institute, TU Wien — Light emission from higher-order correlated excitonic states has been recently reported in hBN-encapsulated monolayer WSe2 and WS2 upon optical excitation. These exciton complexes are found to be bound states of excitons residing in opposite valleys in momentum space, a promising feature that could be employed in valleytronics or other novel optoelectronic devices. However, electrically-driven light emission from such exciton species is still lacking. Here we report electroluminescence from bright and dark excitons, negatively charged trions and neutral and negatively charged biexcitons, generated by a pulsed gate voltage, in hexagonal boron nitride encapsulated monolayer WSe2 and WS2 with graphene as electrode. By tailoring the pulse parameters we are able to tune the emission intensity of the different exciton species in both materials. We find the electroluminescence from charged biexcitons and dark excitons to be as narrow as 2.8 meV.

*Nanyang Technological University, NAP-SUG grant.
4:42PM J62.00010: Strong plasmon coupling to high-energy band-nested excitons in 2D TMDCs

AARON ROSE (Presenter), JEREMY R. DUNKLIN, HANYU ZHANG, SANJINI U NANAYAKKARA, ELISA M MILLER, JAO VAN DE LAGEMAAT, National Renewable Energy Laboratory —

We show Rabi splitting of 244 meV at the C-exciton in the two-dimensional (2D) transition metal dichalcogenide (TMDC) MoS$_2$. The splitting is 9.5% of the transition energy (2.57 eV) in $k$-space (607 meV or 23.6% in $\theta$-space), which is ~2.5× the ratio observed in similar experiments at the A- and B-excitons and approaches the ultrastrong coupling limit. The large enhancement in the coupling strength is likely due to the nested conduction and valence bands found in the 2D TMDCs which leads to strong absorption. We measured the $k$-space dispersion of few-layer MoS$_2$ in a tunable plasmonic cavity at room temperature to observe the Rabi splitting. The band-nesting region of 2D TMDCs is under study for spontaneous charge-separation and slowed hot carrier cooling. Our observation suggests that strong coupling of the C-exciton in the 2D TMDCs may improve carrier lifetimes as well as enhance other quantum coherent phenomena such as polariton condensation or molecular hybridization for chemical reactions.

4:54PM J62.00011: Study of exciton diffusion in carbon-nanotube thin-films

YICHEN LI (Presenter), SAMUEL W BELLING, AMIRHOSSEIN DAVOODY, IRENA KNEZEVIC, Electrical and Computer Engineering, University of Wisconsin-Madison —

Carbon nanotubes have attracted considerable attention for their potential use in organic thin-film photovoltaic devices. Given the fact that the exciton-transfer properties are directly related to improving the efficiency of these devices, it is crucial to develop a model of exciton diffusion in various carbon nanotube composites and study the diffusion mechanism. Here, we focus on the role of different properties of carbon nanotubes, including chirality and spacing, on exciton diffusion. We generate realistic nanotube meshes with different properties through which the motion of excitons is tracked using a Monte Carlo simulation. Finally, we compare the calculated exciton diffusion rate and diffusion length to experiment and develop an understanding of how different conditions of carbon nanotube aggregation affect diffusion properties.

5:06PM J62.00012: Electric Field Effect of $T_C$ in Thin Flakes of the Excitonic Insulator Ta$_2$NiSe$_5$$^*$

MICHAEL MASTALISH (Presenter), ARASH FEREIDOUNI, KRISHNA PANDEY, RABINDRA BASNET, JIN HU, HUGH CHURCHILL, Physics, Univ of Arkansas-Fayetteville — The layered, small-gap semiconductor Ta$_2$NiSe$_5$ is a prominent excitonic insulator candidate with a $T_C$ of 326 K. We investigated the electric field effect of the excitonic insulator transition temperature in a device fabricated with thin (15 nm) Ta$_2$NiSe$_5$. Flakes of Ta$_2$NiSe$_5$ were obtained by mechanical exfoliation and transferred onto narrow bottom gates insulated with Al$_2$O$_3$, and the Ta$_2$NiSe$_5$ was then contacted with Cr/Au. Measurements of source-drain current as a function of temperature revealed a small yet sharp drop in current near $T_C$. A modest, reproducible shift of $T_C$ by approximately 1 K was observed under a transverse electric field of +/- 0.5 V/nm. Future experiments with this and similar devices will probe the origin of this field effect on $T_C$, as well as the unexpected sign of the change in current at $T_C$.

5:18PM J62.00013: Potential gradient control of room-temperature triangular-whispering gallery polariton condensate$$^*$

HYUN GYU SONG (Presenter), SUNGHAN CHOI, CHUNG HYUN PARK, SU-HYUN GONG, CHULWON LEE, MIN SIK KWON, DAE GWANG CHOI, KIE YOUNG WOO, YONG-HOON CHO, KAIST — Exciton polaritons offer hybrid nature of excitons and photons, which are interactive quasi-particles providing the potential energy manipulation. Although wide bandgap semiconductors form room-temperature polaritons, the fabrication of homogeneous planar microcavities is challenging due to low refractive index contrast and large lattice misfit in III-nitride systems. Consequently, lateral localization of planar cavities by disorder (potential fluctuation and dephasing) hinder the establishment of ballistic extensions of polariton condensates, an essential factor for any quantum controls. We introduce a room-temperature polariton system with low disorder capable of one-dimensional (1D) ballistic extension. Selectively grown GaN wires reduce disorder in both excitons by dislocation bending and photons by crystallographically defined hexagonal facet. This high-quality wire allows us to form room-temperature triangular-whispering gallery polariton condensates with ballistic extension controlled by the optical potential gradient. The correlation between transport characteristics from momentum and real space offers a strong indication of ballistic transport in this 1D system.

Session J63 DMP DCMP FIAP: Optical Probes and Imaging of Defects

High Ballroom 4D - Leora Dresselhaus-Cooper, Lawrence Livermore Natl Lab - Tag(s): Focus
Multi-modal microscopy and spectroscopy of wide band gap semiconductors

RACHEL OLIVER (Presenter), Materials Science and Metallurgy, University of Cambridge — The heart of materials science is the link between materials structure and properties. Traditionally, the small-scale structure of materials is often assessed using microscopy techniques, which may provide access to topography, crystallography, composition etc. The physical properties of material are more commonly assessed at a macroscopic level, often using spectroscopy techniques. Increasingly, however, advanced microscopes allow spectroscopy or other physical property measurements with nanoscale resolution.

One established technique that allows direct correlation of microscopy and spectroscopy is cathodoluminescence (CL) in the scanning electron microscope (SEM), in which the recombination of electron-hole pairs excited by the electron beam leads to emission of light that is collected and analysed spectroscopically. CL can be collected alongside structural/compositional data recorded in the SEM. This approach is often simply used for the collection of panchromatic CL images, mapping the total intensity of light emitted at each pixel. However, sophisticated CL systems allow not only the collection of time-integrated spectra, but also time-resolved measurements on the tens of picosecond timescale and data collection across a range of temperatures.

I will discuss the application of temperature- and time-dependent CL to a range of problems in wide-bandgap semiconductors, particularly defects and quantum wells in gallium nitride, addressing both the standard hexagonal form of this material and metastable cubic GaN. However, SEM only provides a limited subset of the structural information a materials scientist desires. Thus, I will introduce methods that allow different microscopy techniques to be brought to bear on exactly the same nanoscale structure, revealing more about its characteristics than any individual technique could achieve alone. In particular, I will discuss methods for combining SEM-CL with transmission electron microscopy, and scanning probe microscopy.

Far-infrared spectroscopy of shallow thermal donors and dilute impurities in high-purity silicon

VLADIMIR MARTINEZ (Presenter), DAVID BURNHAM TANNER, Department of Physics, University of Florida, Gainesville, FL, 32611, USA, RANA ADHIKARI, KOJI ARAI, AIDAN F BROOKS, CHRISTOPHER WIPF, LIGO, California Institute of Technology, Pasadena, CA 91125, USA — Silicon has uses as test-mass material for future gravitational-wave detectors and in high-resolution infrared spectroscopy in astronomy. The transparency of Si in the infrared region is critical to the effectiveness of these new devices. The temperature-dependent infrared transmission has been measured for high-purity silicon samples with impurity concentrations of \(\sim 10^{15}\) per cc. Measurements were made in a frequency range from 10–2000 cm\(^{-1}\) and temperatures from 10–300K. At 10 K, silicon is transparent in the far infrared (10–600 cm\(^{-1}\)) apart from narrow absorption lines caused by residual impurities. These absorption lines are mostly due to hydrogen-like transitions in donor and acceptor atoms as well as interstitial oxygen and will have a significant effect on the optimal operation of the Si device. At higher temperatures the electrons are ionized by the thermal energy in the crystal and become free elections, causing a Drude-like response in the far-infrared. Using the results of our transmission spectra, we can determine the type of impurities in the sample and their concentration.

**3:18PM J63.00003: Multidimensional Coherent Spectroscopy of Erbium Doped GaAs Quantum Wells**  
ROBERT BOUTELLE (Presenter), TRAVIS AUTRY, RICHARD MIRIN, KEVIN SILVERMAN, National Institute of Standards and Technology Boulder — Rare-earth ions are appealing for a broad array of applications. When embedded in crystalline matrices, they combine well protected spin and optically active transitions which are useful to store and process quantum information. When doped in semiconductors, they have been intensely investigated as a new class of electrically active infrared-emitting materials. To better understand the interaction of rare-earth doping, we investigate the effect of dilute erbium doping in GaAs quantum wells. When doped into GaAs, the Er$^{3+}$ ion substitutes Ga$^{3+}$ forming ErAs, which is known to have “coupled” magnetic and electronic properties. As a magnetic material, there is a strong exchange coupling between the relatively large local moments of the 4f and valence and conduction electrons near the Fermi level. Using multidimensional coherent spectroscopy, we attempt to elucidate excited-state structure and interactions of the Er$^{3+}$ doping in GaAs at different doping concentrations. This spectroscopy can characterize excited state dynamics and interactions.

---

**3:30PM J63.00004: Deep UV Photoluminescence and Chemical composition Analysis of Residual Impurities in Hexagonal boron nitride**  
NIKESH MAHARJAN (Presenter), Physics, Brooklyn College and the Graduate Center of CUNY, NEELAM KHAN, School of Science and Technology, George Gwinnett College, JAMES H. EDGAR, ELI JANZEN, Tim Taylor Department of Chemical Engineering, Kansas State University, MIM L NAKARMI, Physics, Brooklyn College and the Graduate Center of CUNY — Single crystal hexagonal boron nitride (h-BN) is an ultrawide (~6.0 eV) semiconductor under development for electronic, optoelectronic and nanophotonic devices. A key issue in these applications is the effect of impurities, especially oxygen, on its properties. Here the properties and compositions of h-BN and oxidized h-BN were compared. The deep UV photoluminescence spectra from h-BN samples were oxidized at 900 °C in dry and ambient air, had strong phonon-assisted band edge emissions along with a sharp atomic-like emission line at 4.09 eV, and its phonon replicas at 3.89 and 3.69 eV. The sharp emission line and phonon replicas were not observed in unoxidized sample. Comparative chemical composition analysis of the residual impurities was carried out using X-ray photoelectron spectroscopy (XPS) and time-of-flight secondary ion mass spectroscopy (TOF-SIMS) in order to identify the impurities related to the sharp transition. Our results of atomic like features could have potential applications in the solid-state single photon source for quantum information technologies.
3:42PM J63.00005: Independent determination of carrier densities and analysis of different recombination channels in GaAs PL and EL through Raman scattering of LO phonon – plasmon coupled mode*  
FAN ZHANG (Presenter), YONG ZHANG, Univ of North Carolina - Charlotte  
— Determining the carrier (electron) density $n$ is critical in many material and device characterization. An ABC model is widely used to describe the carrier recombination, where the contributions of non-radiative, radiative, and Auger recombination are partitioned, respectively, into the three terms in $R = A_n + B_n^2 + C_n^3$. In general, not only the partition is questionable, e.g., nonradiative contribution could be non-linear in $n$, but also a number of approximations are needed in order to determine $n$. It has been demonstrated recently that by combining photoluminescence (PL) and Raman imaging one can simultaneously obtain the spatial distribution of electron and hole density in a semiconductor material or device by first determining the electron density through Raman scattering of LO phonon – plasmon coupled (LOPP) mode [1]. This approach is extended to analyze carrier recombination processes in both PL and electro-luminescence (EL) with varying laser excitation and current injection level. The results indicate that nonradiative recombination typically exhibits non-linear dependence on $n$, as suggested by a recent analysis of EL in an InGaN LED [2].

3:54PM J63.00006: Understanding the Fluorescence Mechanism of Carbon Dots through Single-Molecule Excited-State Imaging*  
HUY NGUYEN (Presenter), University of Illinois at Urbana-Champaign, INDRAJIT SRIVASTAVA, Carle Illinois College of Medicine, JOSEPH W LYDING, University of Illinois at Urbana-Champaign, DIPANJAN PAN, Carle Illinois College of Medicine, MARTIN GRUEBELE, University of Illinois at Urbana-Champaign — We employed scanning tunneling microscopy (STM) and single molecule absorption STM (SMA-STM) to study the fluorescence mechanism in carbon dots (Cdots). The red- and blue-fluorescing Cdot samples were previously purified and characterized in bulk with standard spectroscopic techniques. Carbon dots were deposited on a thin hybrid PtAu film over a sapphire substrate via solvent-based aerosol deposition. We first performed current imaging tunneling spectroscopy (CITS) to resolve the spatial electronic structure of the adsorbed Cdots, estimating the quantity of defects, whether they were active or inactive as optical absorbers, and measuring energy levels of dopants. Then we applied SMA-STM to spatially resolve electronically excited defects, and used scanning tunneling spectroscopy (STS) in situ to look at the density of states at these locations during laser excitation and otherwise. We observed significant spatial variations in the band structure and detected increased defect quantity as fluorescence red-shifts. We further identified the energy levels involved in fluorescence and ultimately discuss the most plausible fluorescence mechanism, which does not depend on the size of the Cdot.

Charge sensing in CMOS devices using reflectometry

JOFFREY RIVARD (Presenter), CLÉMENT GODFRIN, Institut quantique, Universite de Sherbrooke, Canada, ALEXEI ORLOV, Departement of Electrical Engineering, University of Notre-Dame, USA, EVA DUPONT-FERRIER, Institut quantique, Universite de Sherbrooke, Canada —

Spin qubits in silicon are great candidates for scalable quantum information processors due to their long coherence time and compatibility with industrial CMOS fabrication lines.[1] Usual spin-readout techniques imply spin-to-charge conversion and charge readout by transport measurement. This requires multiple leads and limits the scalability of the system. A solution is to do charge sensing using RF-reflectometry measurement[2] for which only one lead is necessary to control and read the qubit.[3] The critical part is to obtain an impedance matching, at low temperature, between the resonant circuit and the RF-line. Finding this matching condition can be challenging considering the temperature dependence of each of the tank circuit component and the sample-to-sample capacitance variability. A solution is to use a varactor[4] to adjust in situ the circuit impedance. In this talk, we report on optimization of reflectometry setups at low temperature and discuss the use of tunable capacitors for in situ tuning targeting high sensitivity RF-measurement for spin qubit readout.

Infrared Transmission of Ge:Mn Thick Films Prepared by Ion Implantation and Post-Annealing*

LAILA HASSAN OBIED, Brock University, SJOERD ROORDA, Physics, University of Montreal, SHENQIANG ZHOU, SLAWOMIR PRUCNAL, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum, Dresden-Rossendorf, DAVID CRANDLES (Presenter), Brock University —

Approximately 3 micrometer thick Ge:Mn films were prepared by low temperature ion-implantation followed by post-annealing. XRD, SIMS, magnetometry and infrared transmission (100-6500 cm\(^{-1}\)) were used to characterize the films. The average Mn concentration in the amorphous implanted films is less than 0.3%. Annealing causes approximately 40-70% of Mn atoms to migrate to Mn-rich clusters or form Mn\(_5\)Ge\(_3\) while the remainder enters the Ge lattice and creates free holes. If annealed at high enough temperature the amorphous films become polycrystalline. Solid phase epitaxy does not occur. A Drude peak and structure in the mid-infrared absorption observed by infrared transmission provide evidence for free holes. The data suggest that the maximum solubility of Mn in Ge is less than 0.08 %.

**4:30PM J63.00009: Photon Statistics as an Analytical Tool in Solid-State Defect Systems**

REBECCA FISHMAN (Presenter), RAJ PATEL, DAVID HOPPER, TZU-YUNG HUANG, LEE BASSETT, University of Pennsylvania — Photon correlation spectroscopy is a versatile and widely used analysis technique with a broad history of applications ranging from molecular spectroscopy to exploration of fundamental quantum mechanical concepts. More recently, this method has been used to study quantum emission from defect complexes in solid-state systems for a variety of quantum technological applications. The predominant use of photon statistics in solid-state systems is as an indicator of single-photon emission, a desirable property for applications such as quantum key distribution and quantum repeaters. However, a more thorough analysis of photon statistics offers the potential to reveal characteristics of the system such as electronic structure, multi-level optical dynamics, and responses to external fields. We briefly discuss the history and development of photon correlation spectroscopy as a measurement tool and outline methods for proper acquisition and analysis of photon statistics. In addition, we use this analysis framework to study quantum emitters in hexagonal boron nitride and discuss how these methods can allow the determination of their electronic structure and optical dynamics.

**4:42PM J63.00010: Spatiotemporal Microwave Imaging of Photo-carrier Dynamics in Monolayer Semiconductors**

ZHAODONG CHU (Presenter), CHUN YUAN WANG, JIAMIN QUAN, University of Texas at Austin, CHENHUI ZHANG, King Abdullah University of Science and Technology, CHAO LEI, University of Texas at Austin, ALI HAN, King Abdullah University of Science and Technology, XUEJIAN MA, University of Texas at Austin, HAO-LING TANG, King Abdullah University of Science and Technology, DISHAN ABEYSINGHE, MATTHEW STAAB, University of Texas at Austin, XIXIANG ZHANG, King Abdullah University of Science and Technology, ALLAN MACDONALD, University of Texas at Austin, VINCENT TUNG, King Abdullah University of Science and Technology, CHIH-KANG SHIH, XIAOQIN (ELAINE) LI, KEJI LAI, University of Texas at Austin — The spatiotemporal evolution of photo-generated charge carriers in two-dimensional transition-metal dichalcogenides (TMDs) plays a crucial role for their optoelectronic applications. A comprehensive understanding of such dynamics, however, remains a challenging task. Here, we report the simultaneous spatial and temporal photoconductivity imaging in WS$_2$ monolayers by laser-illuminated microwave impedance microscopy. The diffusion length and carrier lifetime were directly measured. Time-resolved experiments indicate that the critical process for photo-carriers is the escape of holes from defect-induced trap states, which prolong the apparent lifetime of mobile electrons in the conduction band. This work provides fundamental knowledge on the defect-mediated spatiotemporal dynamics of charge carriers in 2D TMDs, paving the way for their applications in novel optoelectronic devices.
4:54PM J63.00011: Photodegradation of Si-doped GaAs Nanowire*  ANA CLARA SAMPAIO PIMENTA (Presenter), Univ Fed de Minas Gerais, HENRIQUE LIMBORÇO, Microscopy Centre of UFMG, JUAN CARLOS GONZÁLEZ PÉREZ, NESTOR CIFUENTES TABORDA, Univ Fed de Minas Gerais, SÉRGIO LUÍS LIMA DE MORAES RAMOS, Centre for Nanomaterial technology and Graphene, FRANKLIN MASSAMI MATINAGA, Univ Fed de Minas Gerais — Researching optical effects in nanowires (NWs) may requires high pump intensity that under ambient conditions can degrade NWs due to thermal oxidation. In this work we investigated the photodegradation of a single Si-doped GaAs NW by laser heating in air. To understand the changes occurred on the NW we carried out scanning electron microscopy (SEM), and energy dispersive X-ray (EDS), micro-Raman (μ-RS), micro-photoluminescence (μ-PL) spectroscopies in laser damaged regions as well as in non-affected ones. From Stokes and anti-Stokes peaks we estimated that the oxidation process starts at 661 K, resulting in two new modes at 200 and 259 cm\(^{-1}\). SEM and EDS showed a significant loss of As in the oxidized regions, but no erosion of the NW. μ-PL showed the near-band-edge emission of GaAs along the NW, as well as a new emission band at 755 nm corresponding to polycrystalline β-Ga\(_2\)O\(_3\) formation. Our results also indicate that neither amorphous As, nor crystalline As, were deposited at the surface of the NW. Combining different experimental techniques, this study showed the formation of polycrystalline β-Ga\(_2\)O\(_3\) by oxidation of the NW surface and the limits to perform spectroscopic investigations on individual GaAs NWs under ambient conditions.

*This work was funded by CNPq, FAPEMIG and CAPES.

5:06PM J63.00012: Defect induced photoluminescence in SnO\(_2\) nanostructures: Evaluation and Utilization for optical sensing and waveguide application  BINAYA SAHU (Presenter), RABINDRANATH JUINE, ARINDAM DAS, Indira Gandhi Centre for Atomic Research — Despite having an excellent reputation in resistive sensing and profound optical properties, SnO\(_2\) is less explored for optical sensing and waveguide application. In the current project SnO\(_2\) quantum dots [QDs~2.4 nm] and 1D NSs [d~500nm], are utilized for photoluminescence (PL) based NH\(_3\) sensing and waveguide application respectively. PL spectra collected from SnO\(_2\) QDs using 325 nm excitation show the rise of peaks at 2.77 and 2.96 eV in the presence of NH\(_3\). Sensor response (R) is calculated in different concentrations of NH\(_3\), (10-500 ppm) using the formula \(R = (I_{\text{gas}}-I_0)/I_0\) [I\(_{\text{gas}}\) and I\(_0\), PL intensity in the presence and absence of NH\(_3\)]. Defects on the surface of QDs, supported by pre-edge SnM\(_5\) resonance peak in XAS spectrum collected from QDs, form energy band just above the valance band and causes diminished PL peak at 2.77 and 2.96 eV. During the interaction, NH\(_3\) provides electron to SnO\(_2\) and enhance 2.77 and 2.96 eV related transition. Room temperature NH\(_3\) detection with excellent selectivity and high recovery rate ensures the technical importance of this work. Further waveguide application using SnO\(_2\) 1D NSs is realized by exciting single 1-D NSs with 325 nm LASER. Optical images and PL spectra were captured to confirm the defect induced PL is guided through 1D NSs.

Tuesday, March 3, 2020 2:30 PM - 5:30 PM
2:30PM J64.00001: Tuning the electronic and thermoelectric response of oxide superlattices by confinement, strain and interface polarity* [Invited] ROSSITZA PENTCHEVA (Presenter), Department of Physics, University of Duisburg-Essen — Transition metal oxides are prospective candidates for energy conversion applications e.g. as thermoelectrics owing to their chemical and thermal stability and in particular to their complex correlated nature. Nanostructuring and reduced dimensionality can lead to further performance enhancement. By combining DFT+U calculations and Boltzmann transport theory we explore the implications of interface polarity, confinement and strain on the thermoelectric properties of perovskite superlattices. Taking as an example LaNiO$_3$/SrTiO$_3$(001), we demonstrate that compatible n- and p-type materials can be realized by selective choice of the layer stacking at polar interfaces [1]. On the other hand, a strongly enhanced thermoelectric response is obtained in nonpolar LaNiO$_3$/LaAlO$_3$(001) superlattices due to the confinement-driven metal-to-insulator transition [2]. This concept is further extended to (SrXO$_3$)$_1$/(SrTiO$_3$)$_n$(001) SL with $X = V$, Cr, and Mn [3]. Last but not least, the thermoelectric response of topologically nontrivial phases is discussed.

*German Science Foundation CRC/TRR80, projects G3,G8.
A new method for heat to electricity conversion which takes advantage of the first order phase transformation of ferroelectric materials will be presented. Low temperature waste heat can be utilized with the proposed device in which a transfer of energy was successfully shown using a BaTiO$_3$ single crystal heated and cooled repeatedly through its phase transformation. [1] We use these results as a motivation for our discussion on the growth of ferroelectric thin films using the hybrid molecular beam epitaxy approach. High quality, epitaxial single crystal BaTiO$_3$ thin films were grown using this technique and showed a bulk-like phase transformation with thickness of 350 nm, an encouraging behavior for our device. By alloying with BaSnO$_3$, we also explore the BaTiO$_3$-BaSnO$_3$ system for its potential advantages for energy conversion including control over dielectric constant and Curie temperature. We will analyze structure and composition through high resolution x-ray diffraction and x-ray photoelectron spectroscopy as well discuss their effect on dielectric and ferroelectric properties.

3:18PM J64.00003: Artificial two-dimensional ferroelectric metal at room temperature*

MIKHAIL KAREEV (Presenter), Rutgers University, New Brunswick, YANWEI CAO, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, ZHEN WANG, Louisiana State University, SE YOUNG PARK, University of California Berkeley, Berkeley, YAKUN YUAN, Pennsylvania State University, XIAORAN LIU, Rutgers University, New Brunswick, SERGEY M NIKITIN, HIROFUMI AKAMATSU, Pennsylvania State University, DEREK MEYERS, Brookhaven National Laboratory, SRIMANTA MIDDEY, Indian Institute of Science, PAUL THOMPSON, European Synchrotron Radiation Facility, PHILIP RYAN, Argonne National Laboratory, PADRIAC SHAFER, ALPHA T. N’DIAYE, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, VENKATRAMAN GOPALAN, Pennsylvania State University, YIMEI ZHU, Brookhaven National Laboratory, KARIN M RABE, JAK CHAKHALIAN, Rutgers University, New Brunswick — Polar metals, commonly defined by the coexistence of polar crystal structure and metallicity, are thought to be scarce because the long-range electrostatic fields are expected to be fully screened by the conduction electrons of a metal. Moreover, reducing from three to two dimensions, it remains an open question whether a polar metal can exist. Here we report on the realization of a room temperature two-dimensional ferroelectric metal in a tri-color superlattice BaTiO3/SrTiO3/LaTiO3. A combination of advanced probes and DFT calculations have revealed the microscopic mechanisms of unusual periodic electric polarization, charge distribution, and orbital symmetry. Our results provide a route to create all-oxide artificial non-centrosymmetric quasi-two-dimensional metals with exotic quantum and topological states including potentially coexisting ferroelectric, ferromagnetic, and superconducting phases.

*This work was supported by the Gordon and Betty Moore Foundation EPiQS Initiative (GBMF4534).

3:30PM J64.00004: Tuning the correlation strength via cation order in double perovskites*

TURAN BIROL (Presenter), ARPITA PAUL, University of Minnesota — \( \text{A}_2\text{BB'O}_6 \) double perovskites often behave very differently than their parent compounds. This can lead to phenomena such as frustrated magnetism or half metallicity, which are often driven by inter-cationic charge transfer. In this talk, we study the V-Nb double perovskites, where V and Nb ions attain different valences despite coming from the same column in the periodic table. By performing first principles Density Functional Theory + Dynamical Mean Field Theory (DFT+DMFT) calculations, we show that the interplay of cation order and this charge transfer affect the electronic structure of \( \text{Sr}_2\text{VNB'O}_6 \) in a very interesting way, and gives rise to a phase diagram that includes correlated Hund's metallic, as well as Mott insulating phases.

Ferroelectric Polarization Induced Magnetic Order and Topological Hall Effect at the PbZr$_{0.2}$Ti$_{0.8}$O$_3$/SrIrO$_3$ Heterointerface* LE ZHANG (Presenter), Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln, MYUNG-GEUN HAN, YIMEI ZHU, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — The 5$d$ Iridate SrIrO$_3$ (SIO) is a paramagnetic semimetal with strong spin-orbit coupling (SOC) when prepared in the orthorhombic phase. In this study, we explore the possibility of inducing magnetic order and nontrivial chiral spin structures in ultrathin SIO films using the polarization field of a neighboring ferroelectric layer. We have fabricated high quality epitaxial PbZr$_{0.2}$Ti$_{0.8}$O$_3$ (PZT)/SIO (1.6-2 nm) heterostructures and demonstrated nonvolatile ferroelectric field-effect modulation of channel resistance. For the 1.6 nm SIO channel, we can reversibly control SIO between the metallic and insulating phases by switching the polarization field of PZT. More interestingly, in the insulating phase, the Hall effect measurements reveal features of hysteresis and topological Hall effect, suggesting a polarization-induced antiferromagnetic order. We ascribe it to the emerging interfacial Dzyaloshinskii–Moriya interaction due to strong SOC and polarization-enhanced inversion symmetry breaking. Our results demonstrate a feasible way to achieve electrically controlled magnetic order and design topological electronics at the heterointerface of complex oxides.

*This work was primarily supported by NSF under Award No. DMR-1710461.

Charge Engineering in Nickelate-based Mott Transistors Gated by Ferroelectrics* YIFEI HAO (Presenter), XUEGANG CHEN, LE ZHANG, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — We present a comprehensive study of ferroelectric-gated Mott transistors based on high quality epitaxial heterostructures composed of a ferroelectric Pb(Zr,Ti)O$_3$ (PZT) gate and a correlated oxide RNiO$_3$ ($R = \text{La, Nd, Sm}$) channel. For single layer nickelate channels, including Sm$_{0.5}$Nd$_{0.5}$NiO$_3$, NdNiO$_3$ (NNO), and LaNiO$_3$ (LNO), the resistance switching ratio $\Delta R/R_{\text{on}}$ increases exponentially with decreasing channel thickness until it approaches the electrical dead layer thickness, with the maximum $\Delta R/R_{\text{on}}$~194% observed in 1 nm LNO channel. Inserting a La$_{1-x}$Sr$_x$MnO$_3$ (LSMO) buffer layer results in up to two orders of magnitude increase in $\Delta R/R_{\text{on}}$ for devices with the same total channel thickness, with the maximum $\Delta R/R_{\text{on}}$ reaching 1,225% in the NNO/LSMO channel. The giant enhancement is attributed to the interfacial charge transfer effect between RNiO$_3$ and LSMO, which effectively reduces the carrier density in the active channel. Our studies address the key materials challenges that limit the application potential of epitaxial complex oxide-based field effect transistors.

*This work was supported by NSF Grant No. DMR-1710461 and SRC under GRC Task Number 2831.001.
Spin-dependent charge transport in crystalline BaTiO$_3$-germanium tunnel junctions* YICHEN JIA (Presenter), CHARLES H AHN, FREDERICK J WALKER, Yale University — The epitaxial integration of functional oxides on conventional semiconductors using advanced molecular beam epitaxy opens new opportunities for coupling their unique properties with semiconductors for post-CMOS computing paradigms. Here we measure spin-dependent transport in Permalloy-BaTiO$_3$-Ge tunnel junctions using the three-terminal Hanle technique. We show that the aligned conduction bands at the epitaxial BaTiO$_3$-Ge interface allow controllable charge transport between quantum tunneling and trap-assisted conduction through an external bias. In the quantum tunneling region, we observe a negative magnetoresistance with a full width at half maximum of ~100 mT when an external magnetic field is applied perpendicular to the BaTiO$_3$-Ge interface. The negative magnetoresistance evolves into a superposition of two peaks with opposite polarity and distinct linewidth when the trap-assisted conduction becomes dominant. Possible mechanisms include a spin-dependent transport model involving defect states in the heterostructure. The correlation between charge transport and magneto-resistive response is the basis of a sensitive technique to measure defects in oxide semiconductor heterostructures.

In plane strained Barium Titanate thin films directly integrable on Silicon* MARC REYNAUD (Presenter), Department of Physics, University of Texas at Austin, PEI-YU CHEN, Department of Chemical Engineering, University of Texas at Austin, SUNAH KWON, Department of Materials Science and Engineering, University of Texas at Dallas, BRYCE EDMONSON, Department of Chemical Engineering, University of Texas at Austin, MOON KIM, Department of Materials Science and Engineering, University of Texas at Dallas, JOHN G. EKERDT, Department of Chemical Engineering, University of Texas at Austin, AGHAM POSADAS, ALEXANDER DEMKOV, Department of Physics, University of Texas at Austin — Integrating ferroelectric materials onto Si is a critical part of the design new photonic devices such as optical modulators and switches. However, a difficult question to answer thus far has been how to optimize the crystalline orientation in these materials. One interesting material is Barium Titanate (BTO), because it exhibits the largest known Pockels effect which is the modulation of the refractive index by an electric field. However, many applications and device geometries require BTO with the polarization pointing in plane with the substrate, but so far it has proven difficult to optimize BTO to maximize in plane domains. Here, we present a method for the growth of single crystal BTO films that are entirely in plane and strain tunable. In this study, we use extensive X-ray characterization, TEM imaging and direct measurement of the Pockels coefficient in these films to show that the films are entirely in plane oriented BTO. This provides a method for high quality in plane oriented BTO to be directly integrated on Silicon.

Switching Rashba spin texture via interface with a ferroelectric compound*  XIAOLI ZHANG (Presenter), CARLOS MERA, ALEX ZUNGER, University of Colorado, Boulder — We study the microscopic factors controlling the switching of a Rashba(R) spin texture by switching the ferroelectric (FE) polarization of an underlying FE substrate. The spin polarization (SP) in R band depends on the direction of the intrinsic R electric dipole. Thus, an electric field changing the ferroelectric polarization should be able to reverse the Rashba SP. We study a heterojunction between FE PbTiO$_3$ (with TiO2 layers termination), and a R film of Pt, Pb, Rh, Ir, Au and Ag. We determine the role of FE slab thickness, passivation and atom relaxation on both the creation of R bands and SP switching. The FE polarization up (down) corresponds to the structural configuration with Ti above (below) O. Therefore, the R material, mainly interacts with Ti (O) for polarization up (Down). The R material then receives (donate) electrons for polarization up (down). Since Ti and O atoms mainly form the conduction and valence bands, respectively, we find that for up (down) polarization, R bands appear at the conduction (valence) bands. We find these R bands exhibit opposite helical spin texture for opposite ferroelectric polarization directions, allowing the possibility of control the SP direction with electric fields with an external electric field.

Reversal of Tunneling Electroresistance in Ferroelectric Tunnel Junctions by Interface Engineering  MING LI (Presenter), LINGLING TAO, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — A ferroelectric tunnel junction (FTJ) consists of two metal electrodes separated by a nm-thick ferroelectric barrier which allows quantum-mechanical tunneling through it. A tunneling electroresistance (TER) effect is a sizable change in resistance of a FTJ with reversal of ferroelectric polarization. Depending on the energy alignment between electrodes and barrier, the tunneling conductance can be dominated by either electrons or holes. For electron (hole) tunneling, the Fermi energy lies closer to the conduction band minimum (valence band maximum) of the barrier. Low (high) resistance is achieved when polarization is pointing to the electrode with longer screening length for electron (hole) tunneling, referred to as positive (negative) TER. In this work, using density functional theory calculations, we demonstrate the crossover between the electron-like and hole-like tunneling in a practical FTJ La$_{1-x}$Sr$_x$MnO$_3$/BaTiO$_3$/Pt with positive (La$_{1-x}$Sr$_x$O)$_{1-x}$/TiO$_2$ and negative (MnO$_2$)$_{x-1}$/BaO interface terminations. The positively (negatively) charged interface pulls down (up) the electrostatic potential energy at the interface and thus shifts Fermi energy of La$_{1-x}$Sr$_x$MnO$_3$ closer to the conduction band minimum (valence band maximum) of BaTiO$_3$, leading to positive (negative) TER.
**4:54PM J64.00011: Effect of Strain and Doping on the Magnetoelectric Coupling at LSMO/PZT Multiferroic Interfaces: An Ab Initio Study**  
KRISHNA ACHARYA (Presenter), IGOR VASILIEV, New Mexico State Univ — The magnetic properties of multiferroic materials can be controlled by the applied electric field. We apply *ab initio* methods based on density functional theory (DFT) to study the influence of strain on the magnetoelectric coupling at the (0,0,1) interface between PZT (PbZr$_{0.2}$Ti$_{0.8}$O$_3$) and LSMO at two different doping levels (La$_{0.5}$Sr$_{0.5}$MnO$_3$ and La$_{0.8}$Sr$_{0.2}$MnO$_3$). The effects of strain are modeled by applying a ±1%, uniaxial strain in the direction orthogonal to the LSMO/PZT interface. Our calculations show that the magnetic properties of the LSMO layer are strongly influenced by both the doping concentration and the applied uniaxial strain. The results of our study are consistent with the available experimental data.

**5:06PM J64.00012: Effect of confinement and octahedral rotations on the electronic, magnetic, and thermoelectric properties of Sr$X$O$_3$/SrTiO$_3$(001) superlattices, ($X$ = V, Cr, and Mn)*  
MANISH VERMA (Presenter), BENJAMIN GEISLER, ROSSITZA PENTCHEVA, Department of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — Transition metal oxides are an attractive class of materials for thermoelectric applications due to their chemical and thermal stability and environmental friendliness. Here we explore the effect of confinement and octahedral rotations on the electronic and thermoelectric properties of (Sr$X$O$_3$)$_1$/SrTiO$_3$$_n$(001) ($X$ = V, Cr, and Mn; n = 1, 3) superlattices by combining *ab-initio* simulations including an on-site Coulomb repulsion term and Boltzmann theory. We find that in the ground state, the superlattices always display finite octahedral rotations, which drive an orbital reconstruction and metal-to-insulator transition in SrVO$_3$ and SrCrO$_3$ single layers with ferro- and antiferromagnetic spin order, respectively. On the other hand, SrMnO$_3$ based superlattices exhibit antiferromagnetic spin order along with bulk-like properties. We show that tuning the quantum confinement plays an important role in improving the thermoelectric performance in these superlattices and the estimated electronic power factors compare favorably with some of the best performing transition metal oxide thermoelectrics.

*Funding by the DFG within CRC/TRR80 (G3 and G8) and computational time on LRZ supercomputer (pr87ro) are acknowledged.*
5:18PM J64.00013: Depth-resolved electronic structure of a BiFeO$_3$/La$_{0.7}$Sr$_{0.3}$MnO$_3$ superlattice investigated by standing-wave hard X-ray photoemission spectroscopy (SW-HXPS)  
HENRIQUE MARTINS (Presenter), University of California, Davis, ALEXANDER GRAY, Temple University, GIUSEPPINA CONTI, Materials Sciences Division, LBNL, INNA VISHIK, University of California, Davis, SLAVOMIR NEMSAK, Advanced Light Source, LBNL — Studies of artificially designed interfaces of transition metal oxide heterostructures enable opportunities to engineer new stable phases of matter, leading to novel complex devices. However, it is a challenge to identify the features in the electronic structure that induce these emergent interfacial phenomena. Here we have studied a prototypical ferroelectric/ferromagnetic interface between two perovskite oxides, BiFeO$_3$ and La$_{0.7}$Sr$_{0.3}$MnO$_3$, by Bragg-reflection standing-wave hard X-ray photoemission spectroscopy (SW-HXPS). The superior depth precision of the SW-HXPS provides information on interfacial and “bulk” signals, and it allows us to identify the character of the interfacial features in the electronic structure in correlation with the detailed depth information on chemical states.

Session J65 DMP: Semiconductors, Superconductors, and Molecular Qubits Mile High Ballroom 4F - Han Htoon, Los Alamos Natl Lab - Tag(s): Focus

2:30PM J65.00001: Magnetoelectric behavior in metal-organic complexes including spin crossovers compounds [Invited] VIVIEN ZAPF (Presenter), National High Magnetic Field Lab, Los Alamos National Lab — We explore metal-organic complexes that show unconventional routes to magnetoelectric behavior. Traditionally, magnetoelectric behavior has been most commonly studied in inorganic oxides, where ferro or antiferromagnetism couples to dielectric or ferroelectric properties. Such coupling allows an electric field to control and switch e.g. a quantum magnetic state or vice versa. This field contains a wealth of intriguing fundamental science, as well as applications being targeted in ultra-low power sensing, qubits, memories, tunable antennas, and other devices. In this talk I will review several of our recent efforts to extend this field of magnetoelectrics to metal-organic complexes, which contain transition metal ions and organic ligands. These compounds tend to have soft lattices that mediate magnetoelastic coupling, and a broad array of intriguing forms of magnetism going beyond (anti) ferromagnetism. I will begin with spin crossovers where the spin state of a transition metal ion changes with applied magnetic fields, thereby modifying the electric polarization. I will show results on Mn-based spin crossovers where magnetic fields toggle the spin state and thereby induce structural phase transitions or Jahn Teller effects. These structural changes result in very strong magnetoelastic coupling as well as complex phase diagrams. I will also discuss metal-organic frameworks that are effectively intrinsic heterostructures where magnetic and electric properties can be combined with flexible architectures. I will review the state of this nascent field and potential new directions.
On-chip Integrable Highly Spectrally Uniform Ordered Semiconductor Quantum Dot Single Photon Source Arrays for Scalable Quantum Optical Networks

JIEFEI ZHANG (Presenter), SWARNABHA CHATTARAJ, Univ of Southern California, SIYUAN LU, IBM Thomas J. Watson Research Center, ANUPAM MADHUKAR, Univ of Southern California — Scalable optical networks demand ordered and spectrally uniform single photon source (SPS) array integrable on-chip with photon manipulating units. Recently we demonstrated such SPSs based on a new class of spatially ordered and spectrally uniform InGaAs/GaAs mesa top single quantum dots (MTSQDs) [1,2] that are readily integrable, on-chip, with dielectric light manipulating units (LMUs) [1,3] based on 2D photonic crystal platform or collective Mie-like resonance of dielectric building block based metastructures. These MTSQDs have single photon emission purity > 99% ($g^{(2)}(0)<0.02$) at 9.4K [2]. The spectral uniformity of the nominally In$_{0.5}$Ga$_{0.5}$As MTSQD array is ~8nm limited by alloy fluctuation, but importantly reveal pairs of MTSQDs emitting within 300μeV [1,3]. In this talk we report studies on binary InAs/GaAs MTSQD in 5X8 arrays demonstrating striking spectral uniformity of 1.8nm (<2meV) over 1000um$^2$ area. The results highlight the potential of the spatially-ordered MTSQDs-LMU integrated system for realizing quantum optical circuits [3].

Fused LiNbO$_3$-(Al)GaAs hybrids for quantum dots optomechanics

EMELINE NYSTEN (Presenter), Lehrstuhl für Experimentalphysik I, Augsburg University, YONG-HENG HUO, Division of Quantum Physics and Quantum Information, University of Science and Technology of China, HAILONG YU, GUO-FENG SONG, Nano-Optoelectronics Laboratory, Chinese Academy of Sciences, ARMANDO RASTELLI, Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, HUBERT KRENNER, Lehrstuhl für Experimentalphysik I, Augsburg University — Surface acoustic waves (SAW) are a useful tool to control the emission of quantum dots (QDs). In particular, SAWs enable the injection of charge carriers into the dot or the modulation of their energy levels [1,2,3]. Here, we explore the possibility to enhance the interaction between the SAW and the QDs by transferring them on a strong piezoelectric LiNbO$_3$ substrate by epitaxial lift-off [4]. By employing multiharmonic transducers, we generate SAWs on LiNbO$_3$ over a wide range of radiofrequencies. We monitor their coupling to and propagation across the semiconductor membrane, both in the electrical and optical domain. We demonstrate the enhanced optomechanical tuning of the embedded QDs with increasing frequencies. This effect is verified by finite element modelling of our device geometry and attributed to an increased localization of the acoustic field within the semiconductor membrane [5]. The results of our study clearly show the large potential of our hybrid platform to integrate complex phononic and optomechanical circuitry with integrated QDs to study sound-matter coupling.

**3:30PM J65.00004: Optomechanical single photon frequency division multiplexing**

MATTHIAS WEISS (Presenter), Augsburg University, DANIEL WIGGER, Münster University, MAXIMILIAN NÄGELE, Augsburg University, KAI MÜLLER, JONATHAN J. FINLEY, Walter Schottky Institute, TU Munich, T. KUHN, Münster University, PAWEL MACHNIKOWSKI, Wroclaw University of Science and Technology, HUBERT KRENNER, Augsburg University — Here we report on the implementation of a hybrid nonlinear optomechanical scheme to generate frequency multiplexed of single photons from a single quantum dot. To this end, the excitonic optical transition of a single semiconductor quantum dot (QD) is coherently driven by a laser with a frequency of approximately 330THz and simultaneously dynamically strained by a surface acoustic wave (SAW) in the low GHz regime. The coherent optomechanical interaction caused by the QD mixes optical and acoustic frequencies, resulting in the generation of a frequency comb. Thus the collected resonance fluorescence signal, consisting of single photons, is emitted into these frequency bins, precisely split by the frequency $\omega_{\text{SAW}}$ of the SAW.

Furthermore the nonlinear interaction between two mutually coherent SAWs with frequencies $\omega_{\text{SAW}}$ and $2\omega_{\text{SAW}}$ allow for the intensity modulation of certain teeth of the comb. The probability of a single photon being emitted in a given frequency bin can be programmed, by the relative phase between the two SAWs. Introducing a frequency detuning of 50μHz between the two SAWs an intensity modulation of the teeth of the frequency comb with a period of approximately 5½ hours can directly be observed, verifying the extraordinary stability of our scheme.

**3:42PM J65.00005: Tailoring Nanoscale Crystal Polytype Selection for Quantum Confinement Engineering**

HONGLING LU (Presenter), SAMAN MONIRI, CALEB REESE, SUNYEOL JEON, ADAM KATCHER, TYLER HILL, HUI DENG, RACHEL GOLDMAN, Univ of Michigan - Ann Arbor — Electrically-controlled and integrable single photon sources are essential components of quantum information systems. Although semiconductor quantum dots (QDs), including InGaN/GaN QDs-in-nanowires, are promising for room temperature applications, their scalability is limited by alloy composition fluctuations. Here, we aim to create alloy-fluctuation-free QD arrays, namely poly-type QDs-in-NWs, using self-catalyzed NW growth at vapor-liquid-solid (VLS) triple-junctions. We demonstrate, for the first time, epitaxy of GaN NW ensembles and films with a significant ZB content on Si(001). In addition to presenting our novel two-step molecular-beam epitaxy (TS-MBE) approach to control Si$_x$N$_y$ layer formation and subsequent GaN phase selection, we reveal new insight into the relative roles of surface and step-edge diffusion on film to nanowire transitions. The NWs exhibit remarkable photoluminescence (PL) characteristics consisting of distinct emission from donor-acceptor pairs (DAP) and excitonic transitions related to both ZB and WZ GaN. This first demonstration of epitaxial growth and PL emission from ZB GaN NWs on Si(001) provides a crucial step toward the realization of GaN QDs-in-NWs for single photon emitters.

3:54PM J65.00006: Multiferroic triangular molecular qubits*  MARK PEDERSON (Presenter), Physics, University of Texas, El Paso, CARLO M CANALI, FHOKRUL ISLAM, Department of Physics and Electrical Engineering, Linneaus University, ALEXANDER I JOHNSON, Physics, Central Michigan University — The frustrated triangular single molecule magnets with half integer spins from an important class of molecular magnets that have potential application as qubits in quantum computing. The lack of inversion symmetry allows these molecular qubits to be manipulated by an external electric field. Among several candidate triangular molecules, Fe$_3$O(NC$_5$H$_5$)$_3$(O$_2$CC$_6$H$_5$)$_6$ molecular cation is particularly exciting since to date this is the only molecule in which the spin-electric coupling effect is observed experimentally. In this work, using standard density-functional methods, we demonstrate that the spin-electric behavior of this molecule could be even more interesting as there are energetically competitive reference states associated with both high and low local spins (S=5/2 vs. S=1/2) on the Fe$^{3+}$ ions. Each of these spin structures allow spin-electric coupling in their respective chiral ground states. The presence of nearly degenerate reference states, composed of high-spin and low-spin centers, is of potential interest for quantum sensing applications. In this talk we will also discuss the possibility of inducing spin-crossover between the low and high spin configurations by an external electric field.

4:06PM J65.00007: Supercurrent in All-Van-der-Waals Josephson Tunnel Junction*  QING LI (Presenter), Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, JOEL WANG, Research Laboratory of Electronics, Massachusetts Institute of Technology, MEGAN YAMOAH, DENIS BANDURIN, Department of Physics, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, JONILYN YODER, Massachusetts Institute of Technology (MIT) Lincoln Laboratory, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology — Superconducting quantum circuits have demonstrated tremendous progress over the past decade. However, current state-of-art of superconducting qubits still suffer strongly from dielectric two-level-systems (TLS), a major cause of qubit decoherence. Further advancement of qubit lifetime ultimately requires material and fabrication improvements that reduce TLS loss. In this work, we construct superconducting quantum devices with van der Waals (vdW) materials and their heterostructures, which feature crystalline layers with atomically precise interface. We fabricate high-quality, all-vdW parallel-plate capacitors and Josephson junctions – two key components in superconducting qubits. We then characterize the dielectric loss of the vdW capacitors and measure the Josephson response of the vdW tunnel junctions. We expect the advent of vdW qubits will enable both high coherence and small form factors.

Shadow lithography for in-situ growth of generic semiconductor/superconductor devices  DAMON CARRAD (Presenter), MARTIN BJERGFELT, THOMAS KANNE NORDQVIST, Center for Quantum Devices, University of Copenhagen, MARTIN AAGESEN, Danish Defense Research Center, FILIP KRIZEK, Center for Quantum Devices, University of Copenhagen, ELISABETTA FIORDALISO, DTU Nanolab, Technical University of Denmark, ERIK JOHNSON, Department of Mechanical Engineering, Technical University of Denmark, JESPER NYGÅRD, THOMAS SAND JESPERSEN, Center for Quantum Devices, University of Copenhagen — Current progress in Majorana and Andreev qubits and devices using semiconductor/superconductor nanowires is built on the hard proximity-induced superconducting gap obtained from epitaxial indium arsenide/aluminium interfaces. Devices are conventionally obtained by selectively etching superconductor segments from the semiconductor. However, this is currently only possible for InAs/Al hybrids, excluding the use of potentially more desirable materials (e.g. Nb, InSb) in functional devices. Here, we present a crystal growth platform based on three-dimensional structuring of growth substrates for synthesising semiconductor nanowires with in-situ patterned superconductor shells. The shadow lithography platform enables independent choice of material since etching is no longer required, and is highly flexible with regard to device geometry. We grow and characterise tunnel probe devices, Josephson junctions and Majorana islands using aluminium, niobium, tantalum and vanadium. The devices exhibit increased yield and electrostatic stability compared to etched devices, which we attribute to the obviation of damaging etch processes. The shadow lithography platform promises high yield, stable, reproducible Majorana devices using the best possible materials.

Engineered Chirality of One-Dimensional Nanowires* MEGAN BRIGGEMAN (Presenter), JIANAN LI, Physics and Astronomy, University of Pittsburgh, MENGCHEN HUANG, Physics, University of California-Santa Barbara, HYUNGWOO LEE, JUNG-WOO LEE, CHANG-BEOM EOM, Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Physics and Astronomy, University of Pittsburgh — Quantum transport in 1D geometries is fascinating in its own right, but it can also be regarded as a building-block for creating and exploring a variety of quantum systems. We have developed a flexible platform for creating 1D nanostructures at the LaAlO$_3$/SrTiO$_3$ interface using a conductive atomic force microscope lithography technique. Straight nanowire segments behave as electron waveguides with subband occupation that can be tuned with a gate and an external magnetic field. We can periodically perturb this waveguide, with 10 nm periodicity, to yield a chiral nanowire which exhibits striking oscillatory transmission as a function of both magnetic field and chemical potential. We discuss these results in terms of an engineered axial in-plane spin-orbit interaction within the spiral electron waveguide. These findings represent an important advance in the ability to design new families of quantum materials with emergent properties, and mark a milestone in the development of a solid-state 1D quantum simulation platform.

**4:42PM J65.00010: InSb Nanostructures for Advanced Quantum Devices**  GHADA BADAWY (Presenter), SASA GAZIBEGOVIC, PHILIPP LEUBNER, Eindhoven University of Technology, FRANCESCO BORSOI, TU Delft, SEBASTIAN HEEDT, Microsoft Corp Delft, JIE SHEN, TU Delft, FOLKERT DE VRIES, ETH Zurich, SEBASTIAN KOELLING, Eindhoven University of Technology, MARCEL VERHEIJEN, Eurofins, LEO P KOUWENHOVEN, Microsoft Corp Delft, ERIK BAKKERS, Eindhoven University of Technology — Indium-antimonide (InSb) nanowires (NWs) constitute a suitable platform for hosting Majorana zero modes, a key requirement for fault-tolerant topological quantum computing, due to their high electron mobility and strong spin-orbit coupling. Building devices based on InSb nanostructures, while maintaining their pristine quality has proven to be rather challenging. Firstly, brought forth by the difficulties to obtain high quality nanostructures and secondly due to the fabrication steps required to transform a single nanostructure into a working device.

Here, we show the growth of pure zinc blende InSb NWs and nanosheets. The high chemical purity of these nanostructures is reflected in the higher electron mobility values as compared to so far reported values for InSb nanostructures. Further, we use the high degree of control over growing both 1-dimensional (1D) and 2-dimensional (2D) nanostructures on the same substrate, to design *in-situ* quantum device structures. In particular, by relying on both InSb NWs and nanosheets to shadow deposit superconductors and normal metals we design a variety of devices ranging from Josephson Junctions to hybrid superconductor/semiconductor devices, while circumventing the harsh processing steps which degrade the device quality.

**4:54PM J65.00011: InSbAs two-dimensional electron gases as a platform for topological superconductivity**  CHRISTIAN MOEHLE (Presenter), CHUNG-TING KE, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, CANDICE THOMAS, Department of Physics and Astronomy and Station Q Purdue, Purdue University, MARIO LODARI, GIORDANO SCAPPUCCI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, SAURABH KARWAL, QuTech and Netherlands Organization for Applied Scientific Research (TNO), SARA METTI, CHARLES R. GUINN, Department of Physics and Astronomy and Station Q Purdue, Purdue University, RAY KALLAHER, GEOFFREY C. GARDNER, Microsoft Quantum at Station Q Purdue, Purdue University, MICHAEL MANFRA, Department of Physics and Astronomy and Station Q Purdue, Purdue University, SRIJIT GOSWAMI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Majorana zero modes, the fundamental building blocks of topologically protected qubits, can be realized in semiconductor-superconductor hybrid systems. Two-dimensional electron gases (2DEGs) with strong spin-orbit coupling offer a scalable platform for Majorana devices. Here, we investigate a new 2D hybrid system consisting of ternary InSbAs 2DEGs with epitaxially grown aluminum. Studying Josephson junctions in these systems allows us to estimate a large induced gap (200 μeV) and high interface transparencies (≈0.9). Furthermore, through weak anti-localization and quantum Hall measurements, we show that InSbAs has exceptionally strong spin-orbit interaction and a g-factor comparable to pure InSb. This unique combination of properties make InSbAs/Al 2DEGs a promising platform to study topological superconductivity.
5:06PM J65.00012: Stable quantum dots in an InSb two-dimensional electron gas  IVAN KULESH (Presenter), CHUNG-TING KE, Delft University of Technology, CANDICE THOMAS, Purdue University, SAURABH KARWAL, Netherlands Organization for Applied Scientific Research (TNO), CHRISTIAN MOEHLE, Delft University of Technology, SARA METTI, RAY KALLAHER, GEOFFREY C. GARDNER, MICHAEL MANFRA, Purdue University, SRIJIT GOSWAMI, Delft University of Technology — Indium antimonide (InSb) two-dimensional electron gases (2DEGs) have a unique combination of material properties: high electron mobility, strong spin-orbit interaction, large Landé g-factor, and small effective mass. This makes them an attractive platform to explore a variety of mesoscopic phenomena ranging from spintronics to topological superconductivity. However, there exist limited studies of quantum confined systems in these 2DEGs, often attributed to charge instabilities and gate drifts. We overcome this by removing the δ-doping layer from the heterostructure, and induce carriers electrostatically. This allows us to perform the first detailed study of stable gate-defined quantum dots in InSb 2DEGs. We demonstrate two distinct strategies for carrier confinement and study the charge stability of the dots. The small effective mass results in a relatively large single particle spacing, allowing for the observation of an even-odd variation in the addition energy. By tracking the Coulomb oscillations in a parallel magnetic field we determine the ground state spin configuration and show that the large g-factor (∼30) results in a singlet-triplet transition at magnetic fields as low as 0.3 T.

5:18PM J65.00013: Electron-phonon coupling in nitride superconductors from first principles: The effect of epitaxial strain and nitrogen concentration on superconducting properties*  BETUL PAMUK (Presenter), GURU KHALSA, Cornell University — The recent all-epitaxial integration of NbN superconductors with the III-Nitride family of semiconductors by molecular beam epitaxy has created an opportunity for scalable, integrated semiconductor/superconductor devices with access to industrial fabrication processes [Nature 555, 183–189 (2018)]. NbN has a large superconducting critical temperature ($T_c$) that makes it a useful superconducting component at liquid helium temperature, but its structural, metallic, and superconducting properties are extremely sensitive to growth conditions and nitrogen concentration. Group IV-B Nitrides (Ti, Zr, Hf) are chemically more stable than NbN, but their $T_c$’s are markedly smaller. Can the recent demonstration of epitaxial integration of transition metal nitrides with III-Nitrides be used as a strategy for tailoring their superconducting properties?

Using first-principles approaches we explore the effect of epitaxial strain and nitrogen concentration on Group IV-B Nitride superconducting properties. We find that both epitaxial strain and nitrogen concentration can drastically alter the electron-phonon coupling and potentially increase $T_c$ to temperature ranges sensible for superconducting devices.

Session J66 DCMP: The Superconductor-Insulator Transition: Beyond Universal Scaling

2:30PM J66.00001: Collapse of the Cooper pair phase coherence length at a superconductor-to-insulator transition* [Invited] SHAWNA HOLLEN (Presenter), Univ of New Hampshire — The superconductor-to-insulator transition (SIT) in quasi-2D thin films now serves as a canonical quantum phase transition (QPT). However, variation in its features between different material systems continues to raise perplexing questions about universality and universality classes in QPTs. A key to understanding the different manifestations of SITs has been through experimental probes of microscopic transport mechanisms. In this talk, I will present transport experiments on two morphologies of amorphous Bi quench-condensed films patterned with a nanohoneycomb array of holes, where the holes provide an embedded probe of local phase coherence. Films with smooth, nano-scale undulations in thickness exhibit a bosonic insulating phase that includes a giant magnetoresistance peak. In contrast, films of uniform thickness exhibit a fermionic insulating phase. The distinct phases are supported by the presence or absence of magneto-resistance oscillations that occur when Cooper pairs are phase coherent over a scale similar to the spacing of the nanohoneycomb array. These data provide a microscopic view of locally phase coherent Cooper pairs, confirm the existence of the bose insulator, and distinguish two classes of disorder-tuned SITs.

3:06PM J66.00002: Experimentally observed magnetic-field driven quantum phase transition in superconducting nanowires and its striking agreement with critical theory.* [Invited] ANDREY ROGACHEV (Presenter), University of Utah — We have discovered that a magnetic-field driven quantum phase transition (QPT) in MoGe superconducting nanowires can be fully explained by the pair-breaking critical theory with exponents $\nu=1$ and $z\approx 2$. We find that in the quantum critical regime, the electrical conductivity is in agreement with a theoretically predicted scaling function and, moreover, that the theory quantitatively describes the nonuniversal dependence of conductivity on the critical temperature, field magnitude and orientation, nanowire cross-sectional area, and microscopic parameters of the nanowire material. Our data analysis is very different from what was used in the past for QPT in superconducting films: (i) we have subtracted contribution of normal electrons, both Drude and quantum corrections, and found that QPT occurs only in the superconducting part of the system, (ii) we also have kept the critical exponents fixed to their theoretical values and not varied them in the scaling procedure. In the second part of the talk, we will briefly comment on reliability of the finite-size scaling analysis and present our work-in-progress on QPT in MoGe films. In these films we have not observed the bosonic “strange metal” phase. However, we have found some evidences of a pair-breaking QPT that occurs at about 0.1 of quantum conductance of Cooper pairs.

*This research was supported in part by the National Science Foundation under award numbers DMR-1611421 and DMR-1553991 and by the ERC Grant QUEST number 637815.
Theory of the pair-breaking quantum phase transition in superconducting nanowires* [Invited]  ADRIAN DEL MAESTRO (Presenter), Physics, University of Vermont, FRÉDÉRIC GAY, BENJAMIN SACÉPÉ, Univ. Grenoble Alpes, Institut Néel, ANDREY ROGACHEV, Physics, University of Utah — We present a theoretical description of a zero temperature phase transition between superconducting and diffusive metallic states in ultra thin wires induced by Cooper pair-breaking perturbations. Fluctuation corrections to BCS theory motivate a dissipative field theory that can be used to compute the universal scaling of the electrical and thermal conductivity in the quantum critical regime. In the large-N limit, we obtain predictions for transport in striking agreement with recent experimental measurements of the fluctuation conductivity of metallic nanowires in parallel and transverse magnetic fields. The ability to quantitatively describe the experiment goes beyond the usual scaling approach and validates the underlying pair-breaking mechanisms near the quantum phase transition. Extensions of the theory including the effects of disorder and higher dimensions are considered, with implications for the interpretation of transport measurements in superconducting films.

*This research was supported in part by the National Science Foundation under award numbers DMR-1611421 (A.R.) and DMR-1553991 (A.D.) and by the ERC Grant QUEST number 637815 (B.S.).

Low-temperature anomaly in disordered superconductors near $B_{c2}$ [Invited]  BENJAMIN SACEPE (Presenter), Institut Neel, CNRS Grenoble — Strongly disordered superconductors in a magnetic field display many characteristic properties of type-II superconductivity --except at low temperatures where an anomalous linear T-dependence of the resistive critical field $B_{c2}$ is routinely observed. This behavior violates the conventional theory of superconductivity, and its origin remains a long-standing puzzle. In this talk I will present systematic measurements of the critical magnetic field and current on disordered superconducting films of various levels of disorder. Surprisingly, our measurements show that the $B_{c2}$ anomaly near zero-temperature is accompanied by a clear mean-field like scaling behavior of the critical current. Our experimental findings together with theoretical considerations on the inherent vortex-glass state and its thermal fluctuations enable to explain the linear-T anomaly to occur in films as well as bulk superconductors with a slope that depends on the normal-state sheet resistance, in full agreement with the data.
4:54PM J66.00005: Quasiparticle screening near a bosonic superconductor-insulator transition revealed by magnetic impurity doping* [Invited] JAMES VALLES (Presenter), Brown University — While bosonic superconductor-insulator transitions (SIT) have been clearly observed in a number of thin film systems, the mechanisms driving the Cooper pair localization remain to be established. These SITs feature thermally activated Cooper pair transport in the insulating phase with an activation energy $T_0$ that grows continuously from zero at the critical point. Some models attribute this behavior to disorder effects that give rise to Anderson localization of Cooper pairs while others invoke Coulomb interaction effects that drive a Mott transition. I will describe experiments on ultrathin, nanoporous $\alpha$-Bi films that focus on how $T_0$ depends on the pairbreaking effects induced by magnetic impurity doping. I will discuss how the data provide strong evidence that the bosonic SIT in thin films is a Mott transition driven by Coulomb interactions that are screened by virtual quasi-particle excitations[1]. The dependence of these SITs on on underlying fermionic degrees of freedom distinguishes them from those occuring in micro-fabricated Josephson Junction Arrays, cold atom systems, and likely in high temperature superconductors with nodes in their quasiparticle density of states.

Session J67 DCMP: Correlations and Topology in Moiré Superlattices
Four Seasons 2-3 - Pablo Jarillo-Herrero, Massachusetts Institute of Technology MIT - Tag(s): Invited

2:30PM J67.00001: Correlated electronic states and Fermi surface topology in flat-band graphene layers* [Invited] EVA ANDREI (Presenter), Rutgers University, New Brunswick — Stacking two-dimensional atomic crystals, or applying a spatially periodic potential can radically change their electronic properties. In particular, it is possible to engineer conditions leading to the creation of extremely narrow energy, flat bands, where the quenched kinetic energy facilitates the emergence of correlated electronic states. This talk will highlight two examples where the electronic ground state and Fermi surface topology depend sensitively on the filling of the flat bands: stacked graphene layers$^{1,2}$ with a relative twist angle close to a magic value of $\sim 1^\circ$, and buckled graphene layers in which a periodically modulated pseudo-magnetic field creates flat electronic bands.

*Support through NSF-DMR 1708158 and DOE-FG02-99ER45742 is gratefully acknowledged.
Until recently, flat bands were achieved as Landau levels at high magnetic field. Recently, Pablo Jarillo-Herrero of MIT and coworkers demonstrated flat minibands in graphene-based superlattices, discovering correlated insulators and superconductors at different fillings. We have now discovered dramatic magnetic states in such systems. Specifically, in magic-angle twisted bilayer graphene also aligned with a hexagonal boron nitride (hBN) cladding layer, we observe a giant anomalous Hall effect and signs of chiral edge states. This all occurs at zero magnetic field, near 3 electrons per moire cell in the conduction miniband [1]. Remarkably, the magnetization of the sample can be reversed by applying a small DC current. Although the anomalous Hall resistance is not quantized, and dissipation is significant, we suggest that the system is an incipient Chern insulator, similar to an integer quantum Hall state. In a different superlattice system, ABC-trilayer graphene aligned with hBN, again near 3 electrons per moire cell a Chern insulator emerges [2]. A magnetic field of order 100 mT is needed to quantize the anomalous hall signal. This trilayer system can be tuned in-situ to display superconductivity instead of magnetism [3]. We will discuss possible magnetic states, and complementary probes to examine which state actually emerges as the ground state in each system.

*This research was primarily supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under contract DE-AC02-76SF00515.
In moire narrow band systems, periodic interlayer interactions can be used to engineer isolated superlattice bands in which the Coulomb interaction is comparable to the bandwidth. As in a Landau level, this leads to electron interaction dominated physics despite the low density of electrons, enabling full density control using electrostatic gates. Unlike Landau levels, however, moire flat bands occur under time reversal symmetric conditions. I will discuss experiments that observe the spontaneous breaking of time reversal symmetry in twisted bilayer graphene, observed as magnetic hysteresis. Remarkably, hysteresis is accompanied by a quantized anomalous Hall effect, persisting to zero magnetic field and elevated temperatures. I will discuss the origins of this effect in the spontaneous orbital polarization of the electron system into a single, topological nontrivial superlattice band, and show magnetic imaging data acquired using nanoSQUID on tip microscopy that confirms the orbital character of the magnetism and reveals mesoscopic domain dynamics.
Mapping the twist-angle disorder and unconventional Landau levels in magic angle graphene

The emergence of flat electronic bands and of the strongly correlated and superconducting phases in twisted bilayer graphene crucially depends on the interlayer twist angle upon approaching the magic angle $1.1^\circ$. Although advanced fabrication methods allow alignment of graphene layers with global twist angle control of about $0.1^\circ$, little information is currently available on the distribution of the local twist angles in actual magic angle graphene (MAG) transport devices. Here we map the local variations in hBN encapsulated devices with relative precision better than $0.002^\circ$ and spatial resolution of a few moiré periods. Utilizing a scanning nanoSQUID-on-tip, we attain tomographic imaging of the Landau levels in the quantum Hall state in MAG, which provides a highly sensitive probe of the charge disorder and of the local band structure determined by the local twist angle [1]. We find a correlation between the degree of twist angle disorder and the quality of the MAG transport characteristics. However, even state-of-the-art transport devices, exhibiting pronounced global MAG features, such as multiple correlated insulator states, high-quality Landau fan diagrams, and superconductivity, display significant variations in the local with a span that can be close to $0.1^\circ$. Devices may even have substantial areas where no local MAG behavior is detected, yet still display global MAG characteristics in transport. The derived maps reveal substantial gradients and a network of jumps. We show that the twist angle gradients generate large unscreened electric fields that drastically change the quantum Hall state by forming edge states in the bulk of the sample, and may also significantly affect the phase diagram of correlated and superconducting states. The findings call for exploration of band structure engineering utilizing twist-angle gradients and gate-tunable built-in planar electric fields for novel correlated phenomena and applications.

4:54PM J67.00005: Theory of flat bands, correlated insulators and superconductivity in graphene Moire heterostructures [Invited]  ESLAM KHALAF (Presenter), Harvard University — The remarkable discovery of correlated insulating behavior and superconductivity in twisted bilayer graphene (TBG) inspired a vast theoretical and experiment effort to (i) understand the origin of this behavior including the nature of symmetry breaking and the mechanism of the superconductivity and (ii) find similar systems which share some of its interesting properties while differing in some details leading to a wider range of possible phases. The purpose of this talk is to present some recent works contributing to the progress on these two fronts. In regards to (i), we will present an exhaustive discussion of possible mean field symmetry broken states in TBG [1]. By highlighting the existence of a hidden approximate symmetry in the model, we will identify a manifold of low-energy states whose competition is settled by small symmetry breaking terms and present numerical results supporting this argument. Furthermore, we will discuss their possible experimental signatures and comment on their compatibility with different experiments. Regarding (ii), we will discuss a related Moire system, twisted double bilayer graphene (TDB), which was recently synthesized experimentally [2] and shown to exhibit correlated insulating behavior and spin-triplet superconductivity. We will show the results of a thorough analysis of its band structure, correlated insulating state and superconducting phase which compare favorably with experimental findings [3].

Tuesday, March 3, 2020 2:30 PM - 5:30 PM

Session J68 DBIO: Theory Meets High-Precision Biology: Emergent Simplicity in Stochastic Organismal Dynamics  Four Seasons 4 - Srividya Iyer-Biswas, Purdue Univ - Tag(s): Invited

2:30PM J68.00001: Johan Paulsson Invited Talk [Invited] —
3:06PM J68.00002: Self-driven phase transitions in living matter [Invited]  JOSHUA SHAEVITZ  
(Presenter), Princeton University — The soil dwelling bacterium *Myxococcus xanthus* is an amazing organism that uses collective motility to hunt in giant packs when near prey and to form beautiful and protective macroscopic structures comprising millions of cells when food is scarce. I will present an overview of how these cells move and how they regulate that motion to produce different phases of collective behavior. Inspired by recent work on active matter and the physics of liquid crystals, I will discuss experiments that reveal how these cells generate nematic order, how defect structure can dictate global behavior, and how Myxo actively tune the Péclet number of the population to drive a phase transition from a gas-like flocking state to an aggregated liquid-droplet state during starvation.

3:42PM J68.00003: Stochastic intergenerational cell size homeostasis: Precision measurements, exact kinematics and emergent simplicities [Invited]  SRVIDYA IYER-BISWAS  
(Presenter), Purdue Univ — In this talk I will first establish that intergenerational bacterial cell size homeostasis is maintained under appropriate growth conditions, using our high-precision data on growth and division of individual *C. Crescentus* cells. Next, the emergent simplicities revealed by these data. To conclude, a theoretical framework consistent with observed scaling laws, sans fitting parameters, which captures the exact kinematics of stochastic intergenerational cell size homeostasis.

4:18PM J68.00004: Jamming and dynamic arrest in sheltered microbial communities* [Invited]  
OSKAR HALLATSCHEK (Presenter), University of California, Berkeley — Microbes often colonize spatially-constrained habitats, such as pores in the skin or crypts in the colon. The resulting micro-communities are often stable and contribute to the genetic diversity and function of our microbiomes. It is, however, unclear how spatial constraints influence microbial community assembly. By monitoring and modeling microbial populations under controlled microfluidic confinement, we find a rich spectrum of dynamical patterns that are controlled by the competition between density-dependent outflow and population growth. Our results show that density-dependent passive diffusion can drive a reproducing population to a jamming threshold. The resulting loss of mixing and intra-species competition controls the resilience and evolution of these sheltered communities.

How cell growth triggers cell division

JAN SKOTHEIM (Presenter), EVGENY ZATULOVSKIY, SHICONG XIE, SHUYUAN ZHANG, MARDO KOIVOMAGI, BENJAMIN REYES TOPACIO, DANIEL BERENSON, Stanford University — Cell size is fundamental to function in different cell types across the human body because it sets the scale of organelle structures, biosynthesis, and surface transport. Tiny lymphocytes squeeze through tight spaces to reach sites of infection, while the four orders of magnitude larger oocyte divides without growth to form the ~100 cell pre-implantation embryo. Despite the vast size range across cell types, cells of a given type are typically uniform in size because cells accurately couple cell growth to division. While some genes affecting cell size have been identified, the molecular mechanisms through which cell growth drives cell division had remained elusive. While it was expected that growth would act to increase the activities of the cyclin-dependent kinases (Cdk) known to promote cell division, this is not the case. Rather, we found that cell growth acts in the opposite manner. Cell growth triggers division by diluting proteins that inhibit cell division, Whi5 in yeast, and the retinoblastoma tumor suppressor Rb in human cells. Thus, inhibitor dilution provides one long sought mechanism coupling cell growth to cell division.

3:06PM J70.00002: Printing direction dependent microstructures in direct ink writing
LEANNE FRIEDRICH (Presenter), MATTHEW BEGLEY, University of California, Santa Barbara — Direct ink writing (DIW) can be combined with external fields to enable deposition of composite filaments with designed microstructures. Using acoustophoresis, we establish a narrow distribution of microparticles at the center of a direct write nozzle. In low-viscosity shear thinning inks, the particle distribution shifts and widens after deposition depending on the printing direction. We use particle image velocimetry and digital image analysis to characterize the flow field and particle distributions in the printed filament as a function of printing direction. We propose an analytical model for diagnosing sources of printing direction-dependent flows and particle distributions. Sources include anisotropy of the particle distribution in the nozzle, an asymmetric inertial disturbed zone near the nozzle, reshaping of a fluid-like square filament, rotation of a solid-like square filament, and printer calibration. Using the model, we propose strategies for mitigating or amplifying direction-dependent microstructures obtained via direct ink writing. The analytical model can also be adapted to similar direct-write applications to diagnose sources of direction dependence of printed microstructures.
3:18PM J70.00003: Polymer Network Formation in Epoxy-Acrylate Dual-Cure Thermoset Resins for Direct Ink Write Additive Manufacturing* LEAH APPELHANS (Presenter), JESSICA KOPATZ, JACLYNN UNANGST, Organic Materials, Sandia National Laboratory, ADAM COOK, DEREK REINHOLTZ, Advanced Materials Laboratory, Sandia National Laboratory — Dual-cure thermoset resins have been studied for many years for applications in adhesives and coatings. More recently dual-cure approaches have elicited interest for application to additive manufacturing methods such as stereolithography (SLA) and direct-ink-write (DIW). Development of methods to additively manufacture thermoset resins will enable additive approaches for a broad scope of materials including structural materials and advanced composites. The development of a dual-cure epoxy-acrylate thermoset resin for direct-ink-write AM will be described and the effect of resin composition and cure profiles on polymer network formation and final mechanical properties explored. Initial studies on the use of functionalized fillers as network crosslinkers will also be described.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

3:30PM J70.00004: Understanding the structure-property relationships of nanostructured epoxy inks for direct ink writing DEBORAH LIU, GAVIN DONELY, SIMON A ROGERS, DANIEL KROGSTAD (Presenter), University of Illinois at Urbana-Champaign — Direct ink writing (DIW) figures to be an important additive manufacturing technique in the future due to the wide variety of the materials that can be printed including polymers, hydrogels, nanocomposites and ceramic/metal slurries. Rather than material limitations, the main limitations are imposed by the rheological requirements of the inks – they need to behave as solids with no shear applied, yet readily flow when pressure is applied during the printing process. Over the last few years, we have been studying the structure-property relationships of nanostructured, 3D printable epoxy inks. Nanostructure has been imparted to the inks through the use of block copolymer micelles and/or inorganic nanoparticles. In this presentation, we will discuss how these nanostructures affects the rheology and the printability of the inks as well as the epoxy crosslinking kinetics.

3:42PM J70.00005: Chemical Approaches to Diversifying the 3D Printing Ecosystem [Invited] ANDREW BOYDSTON (Presenter), University of Wisconsin - Madison — Our research team focuses on discovering and developing new chemistry for additive manufacturing that can be integrated with cutting-edge engineering technologies. We place emphasis on: 1) incorporation of functional materials, particularly those that respond via conversion of mechanical force into chemical reactivity; 2) expansion of the materials space available for AM; and 3) selective multi-material printing from “all-in-one” mixed-resin vats. As a representative example, we will discuss progress toward simultaneous photo-radical/photo-cationic printing mechanisms for production of multimaterial parts.
**4:18PM J70.00006: 3D Control of Properties in Single-Material Digital Stereolithography for the Treatment of Growth Plate Injury**  
ASAIS CAMILA UZCATEGUI (Presenter), Materials Science and Engineering, University of Colorado, Boulder, CALLIE I. HIGGINS, National Institute of Standards and Technology, JOHN HERGERT, ARCHISH MURALIDHARAN, Materials Science and Engineering, University of Colorado, Boulder, JASON KILGORE, National Institute of Standards and Technology, STEPHANIE J. BRYANT, ROBERT R. MCLEOD, Materials Science and Engineering, University of Colorado, Boulder — A predominant challenge in tissue engineering is the need of a technique for producing structures with precise three-dimensional control of mechanical properties. We use pediatric physeal tissue engineering as a model application because damaged cartilage within the physis (growth plate) can lead to bone formation and asymmetric growth arrest. The growth plate has three distinct zones where cells evolve differently depending on the chemical and mechanical environment. Here, we present the first demonstration of micron scale 3D control of mechanical properties using a single cytocompatible material. Our findings indicate that the mechanical and chemical properties of materials patterned using stereolithography can be programmed by a model that accounts for the non-reciprocal relationship between intensity, time and conversion. In this work we use a poly(ethylene glycol) diacrylate based hydrogel to implement a step function and a gradual change in mechanical properties in 3D scaffolds. The model is validated by a novel application of atomic force microscopy. As a proof of concept, pillar structures were implanted into a rabbit model of physeal injury and there was an apparent reduction in bony bar reformation after 8 weeks of implantation.

**4:30PM J70.00007: Cure Depth Effects on Photopolymer Reactivity in Stereolithography 3D Printing**  
ANNA SMALLWOOD (Presenter), RYKELLE B. ADLEY, CAIUS J. JACOTT, CHANG RYU, Chemistry and Chemical Biology, Rensselaer Polytechnic Institute — The quality of 3D printed polymers produced by stereolithography (SLA) 3D printing depends heavily on the characteristics of the liquid photopolymer resin. Layer delamination may occur if a resin reacts too quickly upon UV irradiation, resulting in a failed print. Monomer conversion upon UV irradiation will be minimal if a resin reacts too slowly, which leads to the same result. Several characteristics of SLA resins show an ideal range within which print conditions are optimal. Resin characteristics may be tuned within this zone to achieve consistent 3D printing and desirable mechanical properties. These characteristics include monomer conversion, rate of polymerization, and photopolymerization onset time as a function of curing depth. This study seeks to investigate the effect of photoinitiator concentration on these characteristics. Resin reactivity will be monitored via real-time Fourier infrared spectroscopy by attenuated total reflectance (RT-FTIR ATR). Two photoinitiators will be employed as an additive to a commercial SLA resin and the reactive species in an original resin. A monochromatic UV LED will be employed at varying intensity as the UV source. Prints will be attempted with varying photoinitiator content and mechanical properties will be studied by tensile testing.
4:42PM J70.00008: Design and Fabrication of 3D Printed Polymer Composites using Grayscale Stereolithography  JOHN HERGERT (Presenter), ASAIS CAMILA UZCATEGUI, ARCHISH MURALIDHARAN, ROBERT R. MCLEOD, University of Colorado, Boulder — Polymer composites are fabricated using stereolithography by spatially modulating the intensity of light used to fabricate a part with regions of varying crosslinking density. A second polymer is preferentially in-swollen into the printed part where crosslinking density is low, thus forming a 3D printed composite with regions of varying stiffness. The initial part is printed using rubbery poly(ethylene glycol) diacrylate which is later swollen with acrylamide. The acrylamide monomer is polymerized to form an interpenetrating network that is glassy in regions where the acrylamide volume fraction is sufficiently high. A deterministic model for polymer conversion in the printing process is utilized to inform printing conditions such that final composite properties can be predicted. This model is validated using confocal Raman microscopy to independently resolve the local concentration of the two polymers throughout the composite.

4:54PM J70.00009: WITHDRAWN ABSTRACT —

5:06PM J70.00010: Theory and Implementation of Volumetric 3D Printing*  CHARLES RACKSON (Presenter), University of Colorado, Boulder, MAXIM SHUSTEFF, Center for Engineered Materials and Manufacturing, Lawrence Livermore, ROBERT R. MCLEOD, University of Colorado, Boulder — We discuss Volumetric 3D Printing, a type of additive manufacturing in which 2D patterns of light are projected into a rotating volume of photosensitive polymer material. The temporally-separated, spatially-overlapping patterns crosslink the material, resulting in an arbitrary (to within voxel resolution) 3D distribution of conversion within the material. We describe theoretical limitations to the method, experimental implementation, and how the coupling of optics and materials informs system design. Polymer design requirements such as viscosity and absorptivity are reviewed, as well as optical requirements including wavelength choice, brightness, and speckle mitigation.

*Funding provided by Lawrence Livermore National Laboratory
Stiffness can mediate the balance between hydrodynamic forces and avidity to impact the targeting of flexible polymeric nanoparticles in flow*  

SAMANEH FAROKHIRAD (Presenter), Department of Mechanical and Industrial Engineering, New Jersey Institute of Technology, ABHAY RANGANATHAN, Department of Anesthesiology and Critical Care, University of Pennsylvania, JACOB MYERSON, Department of Pharmacology, University of Pennsylvania, VLADIMIR R. MUZYKANTOV, Department of Pharmacology, University of Pennsylvania, PORTONOVO AYYASWAMY, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, DAVID M. ECKMANN, Department of Anesthesiology, Ohio State University, RAVI RADHAKRISHNAN, Department of Chemical and Biomolecular Engineering, University of Pennsylvania — We report computational investigations of deformable polymeric nanoparticles (NPs) under colloidal suspension flow and adhesive environment. We employ a coarse-grained model for the polymeric NP and perform Brownian dynamics simulations with hydrodynamic interactions and in presence of wall-confinement, particulate margination, and wall-adhesion for obtaining NP microstructure, shape, and anisotropic and inhomogeneous transport properties for different NP stiffness. Comparing our computational results for the amount of NP margination to the near-wall adhesion regime with those of our binding experiments in cell culture under shear, as well as those of tissue targeting measurements in vivo in mice, we found quantitative agreement on shear-enhanced binding, effects of particulate volume fraction, and effects of NP stiffness. The reported combined computational approach and results are expected to enable fine-tuning of design and optimization of flexible NP in targeted drug delivery applications.

Session K08 APS: Town Hall: Guide to Effective Practices for Physics Departments: Implications for Program Review and Accreditation
Program review is a reality for all colleges and universities. Whether this is regional accreditation, periodic external program review, or the department seeking certification or accreditation, there is a substantial amount of work required. The joint APS / AAPT guide: Effective Practices for Physics Programs (EP3), is a community-based effort to help physics programs conduct meaningful self-assessments, and respond to regional accreditation in ways that will maximize the value from the time spent by the department in developing and conducting these assessments. The guide will provide an opportunity for the department to transform the chore of self-assessment into a culture of continuous improvement, informed by evidence-based practices. It will include strategies for chairs to implement reforms, information on assessment practices, and a set of resources informing all aspects of a physics program. EP3 will train departmental reviewers to use these strategies and design principles in external program reviews.

**Session L01 DAMOP: Long-Ranged Interactions and Nonequilibrium Systems** 103 - Mikael Rechtsman, Pennsylvania State University

**8:00AM L01.00001: George E. Valley Jr. Prize Talk: Prethermal phases of matter in long-range interacting and classical many-body systems** [Invited] NORMAN YAO (Presenter), University of California, Berkeley — Recent advances suggest that physical systems, which are taken out of equilibrium, can exhibit phenomena fundamentally richer than their static counterparts. For example, certain phases of matter that are provably forbidden in equilibrium, such as discrete time crystals, have found new life in periodically driven, non-equilibrium systems. In this talk, I will define the essential features of time crystalline order and describe two new venues where such order can be observed: 1) in a 1D disorder-free, long-range interacting system and 2) in a classical spin system. In both cases, the underlying workhorse is Floquet prethermalization - a phenomena which occurs in the high frequency limit of periodically driven many-body systems; in particular, when the drive frequency is large compared with the local energy scales of the system, there can exist a long-lived quasi-steady state - a so-called "prethermal" state - in which ordered phases of matter can remain stable for exponentially long time scales.

**8:36AM L01.00002: Spin squeezing in the XXZ model with power-law interactions** CHUNLEI QU (Presenter), ANA M. REY, JILA, University of Colorado, Boulder — Spin squeezed states are known to be a useful resource for quantum metrology. Although there have been many proposals on how to generate spin squeezing, most of the dynamical generations involve collective Ising interactions via the so-called one axis twisting (OAT) model. In this talk, we will present our recent results on spin squeezing generation in the XXZ model with power-law interactions. Despite the inhomogeneous character of the spin couplings, we find this system can exhibit a level of spin-squeezing similar to that generated by the OAT model. We will report on our systematic investigation of this model and explain the mechanism responsible for the large spin squeezing generation. Our results are useful for state-of-the-art ultracold polar molecular experiments where pinned molecules in an optical lattice can interact with each other by long-range dipolar interactions and for trapped ion crystals featuring long-range interactions mediated by the phonon modes of the crystal.
8:48AM L01.00003: Persistence of power-law correlations in nonequilibrium steady states of gapped quantum spin chains  
JARRETT LANCASTER (Presenter), Physics, High Point University,  
JOSEPH P GODOY, Physics, Appalachian State University — The existence of quasi-long range order is demonstrated in nonequilibrium steady states in isotropic XY spin chains including of two types of additional terms that generate a gap in the energy spectrum. The system is driven out of equilibrium by initializing a domain-wall magnetization profile through application of external magnetic field and switching off the magnetic field at the same time the energy gap is activated. An energy gap is produced by either applying a staggered magnetic field in the transverse direction or introducing a modulation to the XY coupling. The magnetization, spin current and spin-spin correlation functions are computed in the thermodynamic limit at long times after the quench. For both types of systems, we find the persistence of power-law correlations despite the ground state correlation functions exhibiting exponential decay. It is discussed how these power-law correlations appear related to the periodic nature of the perturbation which generates the energy gap.

9:00AM L01.00004: Locality and Heating in Periodically Driven, Power-law Interacting Systems  
MINH CONG TRAN, JQI/QuICS, NIST/University of Maryland, College Park and KITP, UCSB,  
ADAM EHRENBERG, ANDREW GUO (Presenter), JQI/QuICS, NIST/University of Maryland, College Park,  
PARAJ TITUM, JQI/QuICS, NIST/University of Maryland, College Park and Applied Physics Laboratory, JHU,  
Dmitry Abanin, University of Geneva, ALEXEY V GORSHKOV, JQI/QuICS, NIST/University of Maryland, College Park and KITP, UCSB — Periodically driven quantum systems with local interactions take exponentially long to heat up. We study the heating time in periodically driven $D$-dimensional systems with interaction strengths that decay with the distance $r$ as a power-law $1/r^\alpha$. Using a theory based on linear response, we show that the heating time is exponentially long as a function of the drive frequency for $\alpha > D$. For systems that may not obey linear response theory, we use a more general Magnus-like expansion to show the existence of quasi-conserved observables, which implies exponentially long heating time for $\alpha > 2D$. We also generalize recent state-of-the-art Lieb-Robinson bounds for power-law systems from two-body to $k$-body interactions and thereby obtain a longer heating time than previously established in the literature. Additionally, we conjecture that the gap between the bounds from the linear response theory and the Magnus-like expansion does not stem from physical differences in the theories, but rather from the lack of tight Lieb-Robinson bounds for power-law interactions. We show that the gap vanishes in the presence of a hypothetical, tight bound, and report on recent steps toward achieving this ideal bound for one-dimensional systems.
9:12AM L01.00005: Origin of the slow growth of entanglement entropy in long-range interacting spin systems  SILVIA PAPPALARDI (Presenter), ALESSIO LEROSE, Interational School of Advanced Studies, SISSA — Long-range interactions allow far-distance quantum correlations to build up very fast. Nevertheless, numerical simulations demonstrated a dramatic slowdown of entanglement entropy growth after a sudden quench. In this work, we unveil the general mechanism underlying this counterintuitive phenomenon for generic d-dimensional quantum spin systems with slowly-decaying interactions. We demonstrate that the semiclassical rate of collective spin squeezing governs the dynamics of entanglement, leading to a universal logarithmic growth in the absence of semiclassical chaos. In fact, the standard quasiparticle contribution is shown to get suppressed as the interaction range is sufficiently increased. All our analytical results agree with numerical computations for quantum Ising chains with long-range couplings. Our findings thus identify a qualitative change in the entanglement production induced by long-range interactions and are experimentally relevant for accessing entanglement in highly-controllable platforms, including trapped ions, atomic condensates, and cavity-QED systems.

9:24AM L01.00006: Orthogonality catastrophe with long-range interactions  WEI XIA (Presenter), XIAOPENG LI, Department of Physics, Fudan University — Anderson orthogonality catastrophe is a fundamental property of fermions with a fermi surface subjected to a scattering potential. The case of finite-range potential has been well-understood. Recently, long-range interaction has been achieved in numerous quantum systems such as trapped ions, Rydberg atoms, and polar atoms/molecules. In this talk, I will present our recent study on Anderson orthogonality catastrophe with long-range interaction in one, two, and three dimensions. With a power-law type long-range interaction 1/r^α, we find in one dimension that there is critical α below which the conventional AOC scenario does not hold. In both two and three dimensions, we establish that the AOC holds generically for any value of α. This can be attributed to the energy barrier produced by angular motion in two and three dimensions, which is absent in one dimension. We show our theoretical results can be readily tested in trapped ions and tweezer-array confined Rydberg atoms.
Measurement-Induced Phase Transitions in Long-range Quantum Circuits

MAXWELL BLOCK (Presenter), YIMU BAO, SOONWON CHOI, EHUD ALTMAN, NORMAN YAO, Physics, University of California, Berkeley — Hybrid quantum circuits, in which random unitary gates are interspersed with projective measurements, can exhibit a phase transition between volume- and area-law scaling of steady-state entanglement entropy, owing to the competition between information scrambling and measurements. Long-range interactions can scramble information parametrically faster than short-range interactions, suggesting they may qualitatively modify the transition. In this talk, we study 1D long-range hybrid quantum circuits where each unitary is a random two-qubit Clifford gate with range sampled from a $1/r^\alpha$ power law distribution. We find that the presence of long-range interactions changes the universality of the transition: for $\alpha>3$, the critical exponents agree with studies of nearest-neighbor hybrid circuits, while for $\alpha<3$ the critical exponents change continuously with $\alpha$. In particular, we find the dynamical exponent $z<1$ for $\alpha<3$, indicating the transition cannot be described by conformal field theory. Moreover, for $\alpha<2$ the area-law scaling crosses over to a sub-volume law scaling in which entanglement entropy grows with system size, even under high measurement rates. Our work is especially relevant for hybrid quantum circuits realized in experimental systems with inherently long-range interactions.

Quantum Simulation and Computation with Programmable Rydberg Atom Arrays

ALEXANDER KEESLING (Presenter), HARRY LEVINE, AHMED OMRAN, GIULIA SEMEGHINI, SEPEHR EBADI, DOLEV BLUVSTEIN, HANNES PICHLER, MARKUS GREINER, Harvard University, VLADAN VULETIC, MIT, MIKHAIL LUKIN, Harvard University — Arrays of neutral atoms in reconfigurable geometries has arisen as a powerful platform for quantum science in the past few years. Strong and controllable interactions introduced through the Rydberg blockade mechanism lead to a rich set of both equilibrium and non-equilibrium many-body phenomena. Recently we have used a one-dimensional version of this platform to study the critical properties of various quantum phase transitions, generate large N-partite entangled states, and develop new techniques to implement two- and three-qubit quantum logic gates with high fidelity.

I will present recent progress towards extending our experimental platform to control hundreds of atoms in arbitrary two-dimensional geometries, and the new prospects for quantum simulation and computation in these large-scale atom arrays.

10:00AM L01.00009: Observation of nanoscale hydrodynamics in a strongly interacting dipolar spin ensemble in diamond --- Theory  FRANCISCO MACHADO (Presenter), CHONG ZU, BINGTIAN YE, BRYCE H KOBRIN, THOMAS MITTIGA, SATCHER HSIEH, PRABUDHYA BHATTACHARYYA, TIM O HOEHN, SOONWON CHOI, University of California, Berkeley, CHRISTOPHER LAUMANN, Boston University, DMITRY BUDKER, NORMAN YAO, University of California, Berkeley — Establishing a quantitative connection between the microscopic description of a quantum many-body system and its emergent macroscopic phenomena remains an important open problem. In this talk, we introduce a novel method that combines analytical, numerical, and experimental approaches to address this challenge. Strongly motivated by recent experiments that utilize strongly interacting dipolar spin ensembles in diamond, we present a framework to efficiently describe the spin dynamics. More specifically, starting from a microscopic Hamiltonian description of the spin ensemble, we construct an effective classical description of the spin polarization dynamics that accurately captures the experimental observations. Our method highlights a hybrid approach to study emergent hydrodynamics in strongly interacting quantum systems.

10:12AM L01.00010: Observation of nanoscale hydrodynamics in a strongly interacting dipolar spin ensemble in diamond --- Experiment*  CHONG ZU (Presenter), FRANCISCO MACHADO, BINGTIAN YE, BRYCE H KOBRIN, THOMAS MITTIGA, SATCHER HSIEH, PRABUDHYA BHATTACHARYYA, TIM O HOEHN, SOONWON CHOI, University of California, Berkeley, CHRISTOPHER LAUMANN, Boston University, DMITRY BUDKER, NORMAN YAO, University of California, Berkeley — Bridging the gap between microscopic quantum dynamics and macroscopic emergent phenomena is an important open problem in quantum many-body physics. In this talk, we introduce a novel platform, based upon nitrogen-vacancy (NV) color centers surrounded by a dense ensemble of substitutional nitrogen (P1) centers in diamond, to experimentally probe nanoscale spin diffusion. In this platform, the NV centers serve as both entropy sinks for initializing the P1 ensemble and time-resolved probes of local spin dynamics. Using a combination of static and driven fields, we are able to independently control different parameters such as the strength of interaction and disorder, allowing us to probe the quench dynamics of the strongly interacting spin ensemble under various conditions. We find that the late time dynamics of the P1 ensemble agrees with an effective description based on emergent hydrodynamics, from which we estimate diffusion coefficients.

A reconfigurable blue-detuned lattice for neutral atom quantum computing*  BRANDON GRINKEMEYER (Presenter), Harvard University, TRENT GRAHAM, MINHO KWON, ZACHARY A MARRA, XIAOYU JIANG, University of Wisconsin - Madison, MARTIN LICHTMAN, University of Maryland, College Park, MATTHEW F EBERT, MARK SAFFMAN, University of Wisconsin - Madison — We present a novel approach to forming a blue-detuned optical lattice for single Cesium atoms. This approach makes use of Acousto-Optic Deflectors (AOD) in conjunction with diffractive elements to form a lattice of crossed lines. Due to the frequency shifts introduced by the AOD we eliminate Talbot planes that have posed problems for previous blue-detuned trapping schemes. By using AODs we also gain control over the size and spacing of the traps. The tunability of the size of the trap offers a parameter that can be used to find a magic trapping condition for the ground and Rydberg states of the atom. Additionally, the ability to reconfigure spacing allows us to tune Rydberg interaction strengths. The combination of these degrees of freedom makes this trap ideal for studying quantum computation and simulation with neutral Rydberg atoms.

The Measurement-Driven Entanglement Phase Transition: Relation to Cluster Fragmentation*  SAGAR VIJAY (Presenter), Harvard University — We study the dynamics of a collection of spins evolving under unitary gates and random projective measurements, and in the absence of spatial locality. For a certain choice of Clifford unitary gates, we map the wavefunction of the spins to the state of an evolving cluster, which undergoes a dynamical "fragmentation" transition as a function of the measurement rate. This classical dynamical transition corresponds to a phase transition in the asymptotic state of the spins; above a critical rate of applied measurements, the system exists in a product state over extensively many subsystems, while below this threshold, the wavefunction is no longer separable, and all subsystems develop volume-law entanglement. We show that the scaling of the entanglement entropy, which is related to the connectivity of the evolving cluster, distinguishes between the two phases, and identify a protocol to measure a local order parameter for this transition. The dynamics of the cluster may be studied analytically to determine other properties of the state of the spins, such as the distribution of stabilizer lengths. We discuss the relevance of our results to the measurement-driven entanglement transition that has been observed in higher dimensions.

10:48AM L01.00013: Measurement-Induced Phase Transitions in Many-Body Localized and Integrable Systems  
YIMU BAO (Presenter), SOONWON CHOI, EHUD ALTMAN, University of California, Berkeley — Recent works have shown the competition between scrambling unitary dynamics and local projective measurements can lead to a phase transition in the dynamics of entanglement entropy. In integrable systems, the extensive number of conserved quantities strongly constrains the information scrambling. Here, we show that such systems can still exhibit an entanglement phase transition given an appropriate choice of measurement basis. We analyze a toy model of many-body localized systems as a paradigmatic example. If the observables being measured are not scrambled in unitary evolution, the growth of entanglement is prohibited by any finite rate of measurements. In contrast, if measured observables are scrambled, the unitary evolution can hide and protect quantum correlations from measurements, leading to a phase transition at a nonvanishing measurement rate. The phase transition in other integrable systems, such as free fermionic and Bethe-ansatz solvable systems are also explored. Our results further corroborate the understanding of the phase transition in terms of quantum error correcting properties of the scrambling dynamics.

Session L02 DAMOP: Interacting Ultracold Gases, Light-Matter Coupling, and Cavities

8:00AM L02.00001: Three-color fermions under local and next-neighbor interactions*  
ARTURO PÉREZ, ROBERTO FRANCO PEÑAVALOZA, JERESON SILVA VALENCIA (Presenter), Universidad Nacional de Colombia, Bogota — Graphene, Bechgaard salts, polymers and systems of adatoms on semiconductor surfaces can be described by an extended SU(2) Fermi-Hubbard model, which has a rich phase diagram that has been studied for decades. Ultracold atom setups have allowed testing and extending many ideas and concepts of condensed matter. Confining alkaline-earth-metal atoms, which have several hyperfine states allow to obtain SU(N>2) Fermi-Hubbard systems experimentally.

We study three-color (N=3) fermions confined in a one-dimensional optical lattice and consider local and next-neighbor interactions, obtaining an extended SU(3) Fermi-Hubbard model. Using DMRG, we build a phase diagram that contains two different charge density wave phases, a phase separation and spin-density wave phases for a global density of one-third.

*J.S.-V. is thankful for the support of DIEB-Universidad Nacional de Colombia (Grant No. 41402)
In conventional solid-state electron systems with localized states the ac absorption is linear since the inelastic widths of the energy levels exceeds the drive amplitude. The situation is different in the systems of cold atoms in which phonons are absent. Then even a weak drive leads to saturation of the ac absorption within resonant pairs, so that the population of levels oscillates with the Rabi frequency. We demonstrate that, in the presence of weak dipole-dipole interactions, the response of the system acquires a long-time component which oscillates with frequency much smaller than the Rabi frequency. The underlying mechanism of this long-time behavior is that the fields created in the course of the Rabi oscillations serve as resonant drive for the second-generation Rabi oscillations in pairs with level spacings close to the Rabi frequency. The frequency of the second-generation oscillations is of the order of interaction strength. As these oscillations develop, they can initiate the next-generation Rabi oscillations, and so on. Formation of the second-generation oscillations is facilitated by the non-diagonal component of the dipole-dipole interaction tensor.

Unidirectional flow of solitons with nonlinearity management MAJED ALOTAIBI (Presenter), Kuwait Univ, S. M. AL-MARZOUQ, H. BAHLOULI, Physics, King Fahd University of Petroleum and Minerals, U. AL KHAWAJA, United Arab Emirates University — Unidirectional flow of solitons is obtained with a localized modulation of the nonlinearity strength. The modulation takes the shape of an asymmetric double well with a slight difference between the potential depths. The results were established using numerical computations and then verified qualitatively using a variational approach. Our results suggest that the most important physics at the origin of the unidirectional flow is the excitation of the breathing modes in the scattering region. Simplified variational equations of motion suggested that the phenomenon can be observed if the soliton is scattered by a generic asymmetric effective double potential well.
**8:36AM L02.00004: Cooperative Light Emission in the Presence of Strong Inhomogeneous Broadening**

CHEN SUN (Presenter), Brown University, VLADIMIR Y CHERNYAK, Wayne State University, ANDREI PIRYATINSKI, NIKOLAI SINITSYN, Los Alamos National Laboratory — We study photon emission by an ensemble of two-level systems, with strong inhomogeneous broadening and coupled to a cavity mode whose frequency has linear time-dependence. The analysis shows that, regardless the distribution of energy level splittings, a sharp phase transition occurs between the weak and strong cooperative emission phases near a critical photonic frequency sweeping rate. The associated scaling exponent is determined. We suggest that this phase transition can be observed in an ensemble of negatively charged NV centers in diamond interacting with a microwave half-wavelength cavity mode even in the regime of weak coupling and at strong disorder of two-level splittings.

C. and N.A.S.), and by the J. Michael Kosterlitz Postdoctoral Fellowship at Brown University (C.S.). N.A.S. and A.P. also thank the support from the LDRD program at LANL.

**8:48AM L02.00005: "Signal Energy" of an Excited Dipolar Bose Gas driven by an Oscillating Dimple**

ASAAD R SAKHEL (Presenter), Physics, Al-Balqa Applied University, Salt 19117, Jordan, ROGER RAJI SAKHEL, Physics, Isra University, Amman 11622, Jordan — It is known that dipolar Bose-Einstein condensates (DBECs) display rich and fascinating features that are not observable in nonpolar BECs (Lahaye et al., Rep. Prog. Phys. 72, 126401 (2009)). As such, the present examination studies the dynamics of a DBEC, being motivated by the work of Sabari and Kumar (Eur. Phys. J. D 72, 48 (2018)) who examined the effect of an oscillating obstacle in a DBEC. We thus examine the "signal energy" of a trapped DBEC that is driven by an oscillating dimple potential. For this purpose we numerically solve the time-dependent Gross-Pitaevskii equation. The signal energy is related to the energy spectral density. It is demonstrated that the signal energy displays parametric resonances (PRs) at specific values of the dipole-dipole interaction parameter that can be controlled via the trapping geometry. The spacings between these values have been found to reveal information about the energy level structure of the external trap. The dynamics of the harmonic-oscillator (HO)-states occupancy obtainable from the modal coefficients $C_n(t)$ arising in the decomposition of the wave function $\Psi(x;t) = \sum_{n=0} C_n(t) \varphi_n(x)$, where $\varphi_n(x)$ is the usual HO function, as well as the phase-mismatch between $C_0(t)$ and $C_1(t)$ have been found to display challenging features at PR.
9:00AM L02.00006: Contour-time approach to the 2D disordered Bose-Hubbard model in the strong coupling regime.* MATTHEW FITZPATRICK (Presenter), ALI MOKHTARI-JAZI, MALCOLM P KENNEDY, Simon Fraser Univ — We develop a strong-coupling approach for calculating spatio-temporal correlations in the disordered Bose-Hubbard model. We consider systems that are prepared in highly-excited out-of-equilibrium density patterns and derive equations of motion for the disorder-averaged single-particle Green's function, allowing us to study the relaxation dynamics. We discuss how our formalism can be applied to the study of Bose glass and possibly many-body localized states in the context of recent cold experiments.

9:12AM L02.00007: Study of Low Energy Excitations of Cold Atomic Fermi Systems using Quantum Monte Carlo Methods KAELEYN DAUER (Presenter), ETTORE VITALI, ANNETTE LOPEZ, PATRICK KELLY, California State University, Fresno — The calculation of dynamical properties of quantum many-body theories is a big challenge from both the theoretical and computational point of view. Quantum Monte Carlo methods are considered to be some of the most accurate approaches for unravelling physical mechanisms in systems where correlations are so strong that simple approaches are doomed to fail. Most of the success of Quantum Monte Carlo techniques involve static properties of physical systems, like phase diagrams and density correlations. The extension to dynamical quantities, like the spectrum of density fluctuations or the spectral function is still a major challenge, despite some important recent successes. Cold atomic Fermi systems are unique due to the unprecedented experimental control that can be achieved and due to the flexibility of hamiltonians that can be engineered. This makes them a unique test ground for correlated methodologies like Quantum Monte Carlo. In this presentation we will review important recent advances in the calculations, and we will present new results about the spectrum of density fluctuations and spectral functions of Fermi gases.
**9:24AM L02.00008: Broadband sensitivity improvement via coherent quantum feedback with PT symmetry***

Xiang Li (Presenter), Rana Adhikari, California Institute of Technology, Vaishali Adya, Australian National University, Yanbei Chen, California Institute of Technology, Yifan Chen, Chinese Academy of Sciences, Maxim Goryachev, University of Western Australia, Yiqiu Ma, Huazhong University of Science and Technology, Jing Shu, Chinese Academy of Sciences, Michael Tobar, University of Western Australia, Robert L Ward, Australian National University, Chunnong Zhao, University of Western Australia — A conventional resonant detector is subject to a trade-off between bandwidth and peak sensitivity. This limitation can be traced back to the Quantum Cramer Rao Bound and the coherent state of the conventional resonator. The trade-off can be broken by injecting non-classical states (e.g., squeezed vacuum), but it often has stringent requirements on optical losses. Anomalous dispersion due to an unstable quantum system has been shown to be able to improve the bandwidth-sensitivity product by signal amplification and thus suffer less from losses. But stabilizing the system may cause technical complications and conceptual issues. Here we propose a simple stable quantum amplifier enabled by two-mode non-degenerate parametric amplification. We demonstrate that coherent broadband signal amplification can be achieved without incurring instability. As the amplifier operates at the threshold, one mode of the amplifier forms a PT-symmetric system of the original detector mode, while the other mode collects the signal and transfer it to the readout. We will discuss how to apply this strategy to gravitational-wave detectors.

**9:36AM L02.00009: Interacting Bose-Bose mixtures at finite temperature***

Arko Roy (Presenter), Miki Ota, Alessio Recati, Franco Dalfovo, University of Trento, INO-BEC Center and Dept. of Physics — We examine the role of thermal fluctuations in 2D uniform binary condensate mixtures of dilute atomic gases. In particular, we use the Stochastic Projected Gross-Pitaevskii formalism to probe the impact of non-condensate atoms to the phenomenon of phase-separation in two-component Bose-Einstein condensates. We demonstrate that, in comparison to zero temperature, there is a suppression in the phase-separation of the binary condensates at non-zero temperature. We also show that a mixed phase gives rise to a fully separated one at finite temperature. Finally, these phases are characterized by measuring the speed of sound at finite temperature.

*Provincia Autonoma di Trento*
9:48AM L02.00010: Superradiant Peierls transition in a multi-mode optical cavity  COLIN RYLANDS (Presenter), University of Maryland, College Park, BENJAMIN L LEV, Stanford University, JONATHAN KEELING, University of St. Andrews, VICTOR GALITSKI, University of Maryland, College Park — The strong matter-light coupling attainable in optical cavities has been employed with remarkable success to study quantum systems. It has facilitated the realization of many exciting phenomena from superradiance and self organization of matter to exciton-polaritons condensates. We consider such a system in which a one dimensional interacting Bose gas is loaded into a multi-mode optical cavity and subject to a pump field. Focusing on the steady state properties of the system we find that for sufficiently strong repulsive interactions a superradiant transition takes place which is accompanied by a metal insulator transition in the atomic system. In the limit of infinite repulsion this is attributable to the Peierls instability. Away from this special point we show that this still occurs however the nature of the transition changes and upon further reducing the interaction strength the system undergoes a transition to a gapless normal state.

10:00AM L02.00011: Microscopic Origins of the Hess-Fairbank Effect and its Consistency with the Second Law of Thermodynamics  ANTHONY J LEGGETT, DOUGLAS PACKARD (Presenter), University of Illinois at Urbana-Champaign — The history of applying kinetic theory to help us understand superfluid and BEC phenomena is a long and storied one, going back to the work of Landau and Khalatnikov [1]. Further developments were made using quantum field theoretic [2] and quantum optical methods [3]. We use these methods to study the nonequilibrium physics of Bose condensation and superfluid formation in a rotating quantum fluid. In particular, we examine the quantization of angular velocity observed at low rotational speeds, i.e. the Hess-Fairbank effect. We present results relating the transfer of atoms into a condensate or superfluid mode (at rest in the lab frame) to the overall generation of entropy, taking the rotating container of the fluid itself into account. Finally, we attempt to relate these results to the phenomenon of flux expulsion from a bulk superconductor, in light of recent critical papers on this topic [4].

Structure of chaotic eigenstates and their entanglement entropy

CHAITANYA MURTHY (Presenter), MARK SREDNICKI, University of California, Santa Barbara — We consider a chaotic many-body system (i.e., one that satisfies the eigenstate thermalization hypothesis) that is split into two subsystems, with an interaction along their mutual boundary, and study the entanglement properties of an energy eigenstate with nonzero energy density. When the two subsystems have nearly equal volumes, we find a universal correction to the entanglement entropy that is proportional to the square root of the system's heat capacity (or a sum of capacities, if there are conserved quantities in addition to energy). This phenomenon was first noted by Vidmar and Rigol in a specific system; our analysis shows that it is generic, and expresses it in terms of thermodynamic properties of the system. Our conclusions are based on a refined version of a model of a chaotic eigenstate originally due to Deutsch, and analyzed more recently by Lu and Grover.

This work was supported in part by the Microsoft Corporation.

Mixed spectra and partially extended states in a two-dimensional quasiperiodic model

ATTILA SZABO (Presenter), ULRICH SCHNEIDER, Univ of Cambridge — We introduce a two-dimensional generalisation of the quasiperiodic Aubry-André model. Even though this model exhibits the same duality relation as the one-dimensional version, its localisation properties are found to be substantially more complex. In particular, partially extended single-particle states appear for arbitrarily strong quasiperiodic modulation. They are concentrated on a network of low-disorder lattice lines, while the rest of the lattice hosts localised states. This spatial separation protects the localised states from delocalisation, so no mobility edge emerges in the spectrum; instead, localised and partially extended states are interspersed, giving rise to an unusual type of mixed spectrum. In the absence of interactions, this mixed spectrum also gives rise to complex dynamics, such as ballistic transport across the low-disorder lines, while the rest of the system remains localised. This behaviour is robust against disorder and other weak perturbations. Our model is thus directly amenable to experimental studies and promises fascinating many-body localisation properties.

This work was partly funded by the European Commision ERC Starting Grant QUASICRYSTAL and the EPSRC Grant (EP/R044627/1) and Programme Grant DesOEQ (EP/P009565/1).
Efimov physics in the presence of a Fermi sea  

MINGYUAN SUN  
(Presenter), Beijing University of Posts and Telecommunications — I will introduce the Efimov correlation in atomic system of two heavy bosons ($^{133}$Cs) immersed in a bath of light fermions ($^6$Li). Using the Born-Oppenheimer approximation, we identify two different regimes, depending on the Fermi momentum of light fermions ($k_F$) and the boson-fermion scattering length $a_s(< 0)$, where the presence of underlying Fermi sea plays distinct roles in the Efimov-type binding of bosons. Namely, in the regime $k_F |a_s| < 1$ ($k_F |a_s| > 1$), the Fermi sea induces an attractive (repulsive) effective interaction between bosons and thus favors (disfavors) the formation of bound state, which can be seen as the Efimov trimer dressed by the fermion cloud. Interestingly, this implies a non-monotonic behavior of these bound states as increasing the fermion density (or $k_F$). Moreover, we establish a generalized universal scaling law for the emergence/variation of such dressed Efimov bound states when incorporating a new scale ($k_F$) brought by the Fermi sea.

Session L03 GSCCM: Materials in Extremes: Phase Transitions  
Heather Whitley, Lawrence Livermore Natl Lab - Tag(s): Focus
8:00AM L03.00001: Probing liquid-liquid phase transitions under dynamic compression: an X-ray diffraction and ab initio MD study of selenium* [Invited] RICHARD BRIGGS (Presenter), AMY L COLEMAN, SHUAI ZHANG, Lawrence Livermore Natl Lab, DAVID R MCGONEGLE, Oxford University, FEDERICA COPPARI, AMALIA FERNANDEZ, MARTIN G GORMAN, MICHELLE C MARSHALL, RAYMOND SMITH, Lawrence Livermore Natl Lab, ORIANNA BALL, RYAN S MCWILLIAMS, University of Edinburgh, VITALI PRANKAPENKA, GSECARS, University of Chicago, CONOR KRILL, VINAY RASTOGI, JUNE WICKS, John Hopkins University, CYNTHIA BOLME, Los Alamos National Laboratory, PHILIP HEIMANN, ERIC CUNNINGHAM, HAEJA LEE, SLAC national accelerator laboratory, MALCOLM I MCMANON, University of Edinburgh, JON HENRY EGGERT, DAYNE FRATANDUONO, Lawrence Livermore Natl Lab — One of the most interesting phenomena of non-crystalline materials is polyamorphism, or the ability of an amorphous material, with medium range order, to exist in several distinct modifications. In liquids, the transition between these states has been termed the liquid-liquid phase transition (LLPT) and has been observed experimentally under static compression experiments in several materials. In selenium, ab initio calculations have shown significant changes in the liquid structure with increasing pressure, yet experimental data at high-pressure is limited. Even less is known regarding the evolution of the liquid structure under rapid shock compression and whether a LLPT between complex liquid structures can occur on nanosecond timescales. Here we report on femtosecond X-ray diffraction measurements of the LLPT in selenium following shock compression and release and find that the liquid structure transformations are dramatic and we show that they can occur on nanosecond timescales. The results are supported by molecular dynamic simulations of the liquid state at a range of pressure, temperature, density states covering the LLPT. Experiments were performed at the Matter at Extreme Conditions end-station of the Linac Coherent Light Source (LCLS). This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344.

*This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. DE-AC52-07NA27344. 8:36AM L03.00002: Ab-initio calculations of the phase diagram of Gold JOHANN BOUCHET (Presenter), FRANCOIS BOTTIN, VANINA RECOULES, GUNNAR WECK, CEA de Bruyeres-le-Chatel — We will present first principles calculations on the phase diagram of Gold up to 1TPa. To calculate the Gibbs free energies of the different structures (fcc, hcp, bcc...) we have performed calculations on the unit cells to obtain the cold curves and ab-initio molecular dynamics coupled with the temperature dependent energy potential (TDEP) method to calculate the vibational contribution to the free energy and capture the anharmonicity at high temperature. We compare our results to previous calculations and experimental data. We will also show results on thermodynamic data: thermal dilatation, Gruneisen parameter... and our calculations of the melting curve.
8:48AM L03.00003: A new metastable phase for shock compressed Copper  NILANJAN MITRA (Presenter), Indian Institute of Technology Kharagpur — Copper is utilized in many different applications within the shock compression community (such as pistons in NIF) primarily because it is believed that it does not undergo any solid-solid phase transition prior to melting. However, studies have demonstrated coordination number loss behind shock front. A recent MD study by the authors group demonstrated that solid-solid phase transition occurs in Cu under shock compression to that of the BCT phase [1]. However, any MD calculations are dependent on the interatomic force potentials used, which for the previous study was taken as EAM-Mishin potential for Cu having valence shell containing “s” orbitals. To rule out any forcefield issues, DFT studies were carried out. DFT studies are for 0K temperature, whereas under shock compression there is a significant rise in temperature for Cu samples. Thereby, Gibbs free energy calculation within the quasiharmonic approximation is carried out to demonstrate the feasibility of existence of BCT phase for Cu shock compressed along 001 direction [2], supporting previous postulation by Friedel.

Ref.

9:00AM L03.00004: Measurement of high pressure crystal structure and the pressure-temperature melt conditions in shock-compressed silicon carbide  RAYMOND SMITH (Presenter), Lawrence Livermore Natl Lab, ZIXUAN YE, JUNE WICKS, Johns Hopkins University, MARIUS MILLOT, DAYNE FRATANDUONO, DAVID J ERSKINE, JON HENRY EGGERT, Lawrence Livermore Natl Lab — Silicon Carbide (SiC) has many attractive properties including low density, high strength, high melting point, low wear coefficient and high chemical stability that lead to its extensive use in a wide range of industrial applications including as abrasives, shielding material on space craft; personal armor and as a potential ablator material for fusion capsules. Silicon carbide is also important in geology and planetary science. SiC grains - found in meteorites and impact sites – have an unusual isotopic signature which indicate that they are pre-solar in origin and provide constraints on stellar nucleosynthesis and on the stellar sources for the origin of the solar system. Several studies have also explored possible interior structure of carbon-rich planets in which SiC is a likely main constituent, but experimental data for the high-pressure properties of SiC is currently unavailable to test these models. Here we report on laser-driven nanosecond x-ray diffraction and shock-decay experiments on the Omega-EP laser facility located at the Laboratory for Laser Energetics (NY, USA). We present new data on the high pressure crystal structure, and pressure-temperature conditions for melt in single-crystal SiC samples.
Hurry up or take your time: kinetics of shock-driven phase transitions and dynamic x-ray diffraction.* [Invited] PATRICIA KALITA (Presenter), Sandia National Laboratories

— One of the unanswered questions in physics is how much time does a shock-driven phase transition need - i.e. its kinetics? And how does this time influence the end-result of the shock process?

Traditionally, phase transitions in dynamic compression are inferred from continuum data and compared to results from static compression experiments, shock-recovery, or calculations. With the development of time-resolved synchrotron dynamic x-ray diffraction (DXRD) combined with shock compression a new dawn is rising for the field of shock physics, as one can now probe atomic-scale changes in situ, with nanosecond resolution.

We will illustrate the atomic- and nanosecond-scale quantification of kinetics of shock-driven phase transitions in example materials. We will also show how we leverage two user facilities of the Advanced Photon Source: DCS and HPCAT, in synergistic dynamic/static compression experiments.

Experimental data analysis methods for the physics-based description of phase transition kinetics

JONATHAN BELOF (Presenter), PHILIP C MYINT, Lawrence Livermore Natl Lab, DANE M STERBENTZ, University of California, Davis — Experimental data analysis techniques for the determination of phase transformation kinetics under ramp compression are presented. The new techniques, which do not require any simulations, are described in three parts: (I) estimation of nucleation and growth rates via analysis of the velocimetry wave profile “loop”, (II) bounding of the metastability limit or “maximum over-pressurization” and (III) application of a universal scaling relation that sheds light on the time-dependence of the phase transition. The relatively simple analysis techniques presented are made available in an open source code for the community.

Funding support of this work was partially provided from the LLNL LDRD program under 16-ERD-037. This work is performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Experiments and Simulations of Shocked and Ramp-Compressed Metals to 5 Mbars

JEFFREY NGUYEN (Presenter), MINTA C AKIN, Lawrence Livermore Natl Lab, PAUL D ASIMOW, California Institute of Technology — In this report, we present a series of shocked and ramp compressed data on various metals including tantalum, iron and tin. These samples were shocked and ramp-compressed to pressures as high as 5 Mbars with graded density impactors (GDI). To analyze these data, we utilize both backward (characteristics) and forward analyses. The former method does not require a priori knowledge of a pressure drive, and often fails in the presence of strength or phase transition. By employing simulations in analysis of these experiments, we can improve experimental uncertainty as well as gain better understanding of phase transition and strength during ramp compression. In particular, we will examine the alpha-epsilon and solid-liquid transitions in iron. We will also report on recent efforts to characterize GDI in situ impedance profile.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
Experimental measures of the orientation dependence of the B1-B2 transformation in shock-compressed MgO

June Wicks (Presenter), Johns Hopkins University, Raymond Smith, Lawrence Livermore, Zixuan Ye, Johns Hopkins University, Marius Millot, Lawrence Livermore

Of the over 6,000 confirmed and candidate extrasolar planets discovered to date, those 1-4 times the radius of the Earth are found to be most abundant. MgO is expected to be a major component of the deep mantles of terrestrial planets and exoplanets. Its high-pressure transformation from a rocksalt (B1) structure to the B2 (CsCl) structure is expected to occur in rocky exoplanets greater than about 5 Earth masses in size. In this work, the structure and temperature of MgO upon shock compression over the 200-700 GPa pressure range was examined at the Omega-EP Laser facility. Laser drives of up to 2 kJ over 10 ns were used to shock compress single-crystal MgO. At peak compression, the sample was probed with He-α X-rays from a laser-plasma source. Diffracted X-rays were recorded on image plates lining the inner walls of a box attached to the target package. For each shot we measure pressure (velocity interferometry), density (x-ray diffraction) and shock temperature (pyrometry). We also probe orientation-dependence of the shock Hugoniot by conducting laser-driven decaying shock measurements of single crystal MgO [100], [111] and [110], and will discuss the importance of single crystal experiments to better improve phase diagram models of materials at extreme conditions.

Metastable conducting solid hydrogen at high pressures.

Ilnur Saitov (Presenter), Genry Norman, National Research University Higher School of Economics

The possibility of formation of metastable metallic hydrogen at normal pressure was predicted in [1]. In the present work, the density functional theory is applied for the calculation of the equation of state, the pair correlation function and density of states of solid hydrogen in the region of the possible formation of the conducting phase. A hysteresis of the dependence of pressure on density is observed in the pressure range from 350 GPa to 625 GPa. During compression, the transition of molecular hydrogen with the C2/c symmetry to a conducting atomic state with the C222_1 symmetry through an intermediate conducting molecular phase with Cmca-4 symmetry is observed. The results of calculation of the band structure of the molecular state Cmca-4 point to the semimetallic mechanism of conductivity. The possibility of the existence of conductive atomic solid hydrogen with P2_1/c symmetry under expansion up to a pressure of 350 GPa is shown.

10:36AM L03.00010: Ionization of H in iron oxy-hydroxide QINGYANG HU (Presenter), HPSTAR (Beijing) — The symmetrization of O-H bonds in hydroxide often induces a slightly first order phase transition. However, the phase transition causes dramatic reconfiguring of electronic properties. In this work, we pressurized a piece of iron oxy-hydroxide (FeO\textsubscript{2}H) up to 60 GPa. Upon the asymmetric O-H bonds symmetrize to O-H-O, the measured electric conductivity surged a few orders of magnitude higher. Combining with first-principle simulation, the symmetrization separates H\textsuperscript{+} ion from the hydroxyl OH\textsuperscript{-1} group by forming ionic-type double O-H bonds. Although the pressure range of symmetrization coincides with the high-low spin transition of Fe, the sudden boost of electric conductivity is against conventional spin-transition effect, which reduces conductivity. Therefore, the ionic phase transition of H is likely to be responsible for the change of conductivity. The ionization of H is among the many intriguing behaviors of H under extreme pressure conditions and may have profound influences for the fundamental processes in Earth’s deep interiors.

10:48AM L03.00011: High-Pressure-Induced Phase Transition in 1,3-Diphenylurea: the Approaching of N−H⋯O Hydrogen-Bonded Chains YUXIANG DAI (Presenter), YANG QI, Northeastern University — Under extreme pressure conditions, supramolecular materials can undergo many novel phenomena such as phase transition, polymerization, piezochromism, and negative compression. In our research plan, we selected a series of low-dimensional supramolecular materials to study the evolution of crystal structure and intermolecular interactions under high pressure. In this study, the crystal structure and hydrogen-bonded chains of 1,3-diphenylurea were found to appear abrupt changes when the pressure increased to 1.8 GPa. The intermolecular interactions, the vibrations of chemical groups and the molecular conformation were clearly distinguished from the initial state. The anisotropic compression of the original crystal structure and the occurrence of structural phase transition were derived from the remarkable shrink of distance between hydrogen-bonded chains. This study demonstrates that excessively reducing the space between of hydrogen-bonded chains will rearrange the self-assembly of supramolecular materials.

8:00AM L04.00001: Semiconductor Junctions for Photon Up and Downconversion: From Nanocrystals to Bulk Solids* [Invited] EMILY K RAULERSON, INKI LEE, BRITTANY R POLLOK, JON A BENDER, DANIEL E COTTON, SEAN ROBERTS (Presenter), University of Texas at Austin — Materials that repackage the energy of incoherent light, by either summing its photons together or dividing them into lower energy pairs, offer potential for new technologies for solar energy conversion, photon detection, catalysis, and quantum information science. Organic dimers, polymers, and extended solids that undergo singlet fission offer a potential means for achieving this goal as this process converts high-energy single spin-triplet excitons into pairs of low-energy spin-triplet exciton pairs. Likewise, singlet fission’s inverse, triplet fusion, can be used to combine low-energy exciton pairs into high-energy states. However, designing applications based on these materials necessitates design of both highly stable singlet fission/triplet fusion materials as well as hybrid organic:inorganic junctions that allow triplet excitons to interface with commercial semiconductor technologies. In this presentation, I will review our group’s efforts to produce covalently tethered structures for this purpose. The presentation’s first half will focus on the design of photostable single fission-capable solids based on perylenediimide dyes while its second half will focus on model semiconductor junctions that interface these and related materials with semiconductor quantum dots. Lessons learned from these studies will be used as a basis for designing silicon:organic structures that allow for spin-triplet exciton transfer across their junction.

8:36AM L04.00002: Efficient Triplet Harvesting in an Air-stable Diketopyrrolopyrrole Singlet Fission Solar Cell ANDREW LEVINE, JOSEPH HAMMER, SAUL BLAIN, MAJHARUL HOQUE, VISHAL NARANG, ADAM BRAUNSCHWEIG, MILAN BEGLIARBEKOV (Presenter), NanoScience, CUNY Advanced Science Research Center — Diketopyrrolopyrrole (DPP) is an air-stable molecule which has recently been shown through spectroscopic investigation to host excitonic singlet fission (SF). Here we synthesize DPP-based solar cells using dicyano naphthalene diimide (dCN NDI) acceptor molecules and quantify SF generated carrier extraction efficiency. The characteristic dependence of the photocurrent as a function of magnetic field, which is the unambiguous signature of SF, is observed. Furthermore, we show that DPP-based photovoltaic devices are remarkably air-stable, unencapsulated devices do not exhibit a degradation of electrical or photovoltaic properties as a result of aging. Therefore, DPP is promising material for organic SF photovoltaic devices.
A Kinetic Description of Ultrafast Excitation, Relaxation, and Charge Transfer in Ru Dye-Semiconductor Systems

THOMAS CHESHIRE (Presenter), Chemical Science Division, Lawrence Berkeley National Laboratory, JEB BOODRY, Department of Chemical and Biochemical Engineering, University of California, Berkeley, M KYLE BRENNAMAN, Department of Chemistry, University Of North Carolina Chapel Hill, PAUL G. GIOKAS, Coherent Inc., DAVID F. ZIGLER, Chemistry & Biochemistry Department, California Polytechnic State University, ANDREW MORAN, JOHN MICHAEL PAPANIKOLAS, GERALD J. MEYER, THOMAS MEYER, Department of Chemistry, University Of North Carolina Chapel Hill, FRANCES HOULE, Chemical Science Division, Lawrence Berkeley National Laboratory — We describe a predictive kinetic framework for ultrafast photophysics of ruthenium polypyridyl dyes in solution and on solid surfaces to probe how kinetic processes such as absorption, relaxation, and intersystem crossing affect excited state lifetimes. Employing a form of kinetic Monte Carlo that produces an absolute time base, we compute transient absorption (TA) signals and find excellent agreement with experimental spectroscopic data. We compare dye photophysics in solution to that of sensitized metal oxide films, where charge injection from the excited states may occur. Dye molecules have similar excitation and decay kinetics in solution and on ZrO$_2$ films where there is no charge transfer. In contrast, charge transfer to the semiconductor competes with intramolecular transitions for dyes bound to TiO$_2$. Comparison of simulated TA spectra to experiment allow rate coefficients for charge injection to be estimated. The kinetic framework is readily integrated into multiscale models for dye-sensitized light harvesting systems.

Fast algorithm for simulating nonlinear ultrafast spectroscopies

PETER ROSE (Presenter), JACOB KRICH, Univ of Ottawa — We present Ultrafast Ultrafast (UF$^2$) spectroscopy, a fast algorithm for calculating perturbative n-wave mixing signals in nonlinear optical spectroscopies including arbitrary optical pulse shapes and overlaps. It was demonstrated for closed systems, and we present here the extension to open systems, including vibronic systems with Lindblad or Redfield evolution. UF$^2$ is more computationally efficient than any method of which we are aware when the dimension of the relevant system Hilbert space is sufficiently small, as in energy-transfer systems. The speed of UF$^2$ comes from working in the eigenbasis of the time evolution operator, which enables costless time evolution between pulses, and performing the time evolution due to the pulses using the FFT and convolution theorem. We characterize the computational cost for a range of system sizes, showing when UF$^2$ gives significant speed improvements over other methods.

UF$^2$ automatically generates all Feynman diagrams for a specified phase-matching condition. It is well-suited to calculating higher-order signals (6-wave mixing and above). UF$^2$ allows easy and quick prediction of nonlinear optical spectra for a wide range of system parameters and optical pulse shapes.
9:12AM L04.00005: Enhancing vibrationally assisted energy transfer via vibrational cooperation and interference*  
ZENGZHAO LI (Presenter), LIWEN KO, ZHIBO YANG, Department of Chemistry, University of California, Berkeley, MOHAN SAROVAR, Sandia National Laboratories, BIRGITTA K WHALEY, Department of Chemistry, University of California, Berkeley — Vibrationally assisted energy transfer has recently been engineered in a trapped-ion quantum simulator [Gorman et al., Phys. Rev. X 8, 011038 (2018)]. Motivated by this demonstration, we investigate how cooperativity and interference of multiple vibrations enhance energy transfer. This is a step in the quest to reveal the extent of vibrational or vibronic mechanisms behind the phenomenon of long-time coherences in photosynthetic light harvesting systems. By analyzing a donor-bridge-acceptor trimeric chromophore system coupled to two vibrations, we identify features of one-, two-, and even four-phonon transfer processes and signatures of cooperativity and interference that provide maximum enhancement of energy transfer. Our findings of vibrational cooperativity and interference in excited state energy transfer are verifiable in trapped-ion quantum simulators.

9:24AM L04.00006: Electrochemical tuning Localized Surface Plasmon Resonance of Au-Ag core-shell nanoparticle for Surface-Enhanced Raman Scattering*  
JING GUO (Presenter), Physics, Florida International University, EUGENE LI, Herbert A. Ammons Middle, JIN HE, Physics, Florida International University — Active control of the localized surface plasmon in metallic nanoparticles is of fundamental importance for surface-enhanced Raman spectroscopy (SERS) application. By oxidation-reduction chemistry of Ag-AgCl shells or clusters on the surfaces of AuNP, we induced dielectric-conductive shell or clusters between AuNP and GME. Self-assembled monolayer modified on GME experienced different electromagnetic field produced by surface plasmon of Ag/AuNP or AgCl/AuNP, thus, induced extreme but reversible changes in SERS intensity. Meanwhile, the redox process of Ag-AgCl is confirmed by time-resolved electrochemical current (i-t). Simultaneously SERS and i-t measurement on Ag/AuNP-on-GME show our ability to manipulate the morphology of narrow inter AuNP-GME gaps. With the assistant of Ag shell or cluster on AuNP-on-GME, Raman enhancements can be tuned much more dramatically by electrochemical bias.

9:36AM L04.00007: Phonon-induced Spin State Relaxation in spin crossover molecule*
HAECHAN PARK (Presenter), HAI-PING CHENG, JIA CHEN, University of Florida — Spin crossover (SCO) materials have drawn intense attention lately due to its unique property to switch from low-spin to high-spin state by external stimuli. The relaxation time of the spin state is a critical quantity in all application areas. Whether SCO molecules are in solution or in crystal form, it is crucial to understand the spin dynamics of a single molecule. This study describes a method development that goes beyond our previous work on phonon-assisted electron relaxation processes where the total spin of the system remains unchanged. We discuss using spin-orbit coupling instead of kinetic energy of nuclei as a perturbation between states of different total spins. This method considers different nuclear positions in the configuration space generated by ab-initio molecular dynamics, which provides a suitable description for coupling between the vibrational modes of nuclei and the electron spins. We will demonstrate the dynamics of spin-dependent relaxation using our simulations

*This work is supported as part of M²QM, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #DE-SC0019330.

9:48AM L04.00008: Reveal the interplay between high frequency and low frequency intramolecular vibrational mode in ultrafast electron transfer reaction*
SHAHNAWAZ RATHER, BO FU (Presenter), GREG SCHOLES, Princeton University — We are presenting a theoretical study of an ultrafast electron transfer reaction by employing the Redfield theory of quantum dissipation dynamics and a model Hamiltonian involving three electronic states and two vibrational modes. Accompanying a pump-probe spectroscopy experiment of N, N'-Bis(2,6-methylphenyl)-3,4,9,10-pyrenetetracarboxylic Diimide (PDI) emerging in an electron-donating solvent, we are able to identify the role of vibronic coherence and the timescale separation due to the interplay between the high-frequency mode and the low-frequency mode. We found that vibronic coherences provide a complete blueprint of a three-stage process: an ultrafast ET event, an impulsive response of nuclear coherences (truest manifestation of Born-Oppenheimer approximation), and the relaxation of coherently prepared hot vibrational states. The outcome of this work also provides a potential design principle for preventing detrimental charge recombination in organic photovoltaics.

*S.R., B.F. and G.D.S. acknowledge support from the Division of Chemical Sciences, Geosciences, and Biosciences, Office of Basic Energy Sciences, of the U.S. Department of Energy through Grant No. DE-SC0015429.
The complex dynamics of ultrafast photoinduced reactions such as singlet fission are governed by their evolution along vibronically coupled potential energy surfaces. Here, I will describe our recent work on both understanding this coupling and manipulating it using ultrafast optical spectroscopy. Combining excited-state time-domain Raman spectroscopy and tree-tensor network state simulations, we construct the full 108-atom molecular movie of ultrafast singlet fission in a pentacene dimer, explicitly treating 252 vibrational modes on 5 electronic states. Our combined experimental and theoretical approach reveals the atomic-scale singlet fission mechanism and can be generalized to other ultrafast photoinduced reactions in complex systems. In other singlet fission systems, polydiacetylene and carotenoids, we experimentally demonstrate that S1 state (21Ag-) is a superposition state with strong contributions from spin-entangled pairs of triplet excitons (1(TT)). We further show that optical manipulation of the S1 (21Ag-) wavefunction using triplet absorption transitions allows selective projection of the 1(TT) component into a manifold of spatially separated triplet-pairs with lifetimes enhanced by up to one order of magnitude and whose yield is strongly dependent on the level of inter-chromophore coupling.

Wednesday, March 4, 2020 8:00 AM - 10:48 AM
8:00AM L05.00001: Manipulating nonadiabatic conical intersection dynamics by optical cavities [invited]  SHAUL MUKAMEL (Presenter), BING GU, Chemistry, University of California Irvine — Optical cavities hold great promise to manipulate and control the photochemistry of molecules. We demonstrate how molecular photochemical processes can be manipulated by strong light-matter coupling. For a molecule with an inherent conical intersection, optical cavities can induce significant changes in the nonadiabatic dynamics by either splitting the pristine conical intersections into two novel polaritonic conical intersections or by creating light-induced avoided crossings in the polaritonic surfaces. This is demonstrated by exact real-time quantum dynamics simulations of a three-state two-mode model of pyrazine strongly coupled to a single cavity photon mode. We further explore the effects of external environments through dissipative polaritonic dynamics computed using the hierarchical equation of motion method. We find that cavity-controlled photochemistry can be immune to external environments. We demonstrate that the polariton-induced changes in the dynamics can be monitored by transient absorption spectroscopy.

8:36AM L05.00002: Effect of Stokes shift on molecular polariton dynamics*  JUSSI TOPPARI (Presenter), Department of Physics and Nanoscience Center, University of Jyväskylä, GERRIT GROENHOF, Department of Chemistry and Nanoscience Center, University of Jyväskylä, TERO T HEIKKILÄ, Department of Physics and Nanoscience Center, University of Jyväskylä — Strong coupling between molecules and confined light, like surface plasmon polaritons (SPP) or cavity photons (CP), leads to a formation of polariton states manifested by a Rabi split in the absorption spectrum. This changes the energy landscape of the molecules and can alter their chemical behavior. However, the Stokes shift of the molecule can play an essential role here.

We have studied molecular polaritons involving SPPs or optical cavities and different molecules. While the emission of SPP is purely transverse magnetic (TM), that of a SPP-molecule polariton has also a transverse electric (TE) component with the TE/TM ratio following the molecular contribution. Interestingly, we observe that the larger the Stokes shift of the molecule is, the lower is the TE emission. For cavities, the angle dependent emission of the lower CP-molecule polariton while exciting the upper polariton, reveals different pathways depending again on the Stokes shift. While molecules with high Stokes shift seem to induce regular molecule relaxation and excitation of the lower polariton via the fluorescing state, the molecules with no Stokes shift relax to the lower polariton via coupling to vibrational states. In both cases the effect of the molecular relaxation is eminent.

*Funding by Academy of Finland
OLEKSIY ROSLYAK (Presenter), Department of Physics and Engineering Physics, Fordham University, ERIC BITTNER, Department of Chemistry, University of Houston, ANDREI PIRYATINSKI, Theoretical Division, Los Alamos National Laboratory — Using our generalization of the Dicke model for quantum emitters coupled to surface plasmon modes, we have predicted a reach phase diagram of plasmon-exciton-polaritons states depending on the interaction strengths between the surface plasmon modes and quantum emitters.¹ For the purpose of practical implications, we study R6G rhodamine dye quantum emitters placed in a plasmonic cavity. The cavity is constituted from metal nanoparticles forming a rectangular 2D lattice. CDA analysis reveals intricate combinations of a bright local surface plasmon resonance (LSPR) on each nanoparticle and dark diffractive orders present in periodic structures resulting in a sharp Fano shaped surface lattice resonance (SLR). Concentration dependent coupling to R6G simulated via effective dielectric medium approach at CDA and RCWA levels. Extracted coupling rates between the SLR and the rhodamine dyes allow us to map the problem on the Dicke Hamiltonian. The polariton branches of the Hamiltonian are evaluated and subsequent analysis of the associated state photon emission properties is performed.

Bose-Einstein condensation has been realized for various particles or quasi-particles, such as atoms, molecules, photons, magnons and semiconductor exciton polaritons. We have experimentally realized a new type of condensate: a BEC of hybrids of surface plasmons and light in a nanoparticle array [1]. The condensate forms at room temperature and shows ultrafast dynamics. We utilized a special measurement technique, based on formation of the condensate under propagation of the plasmonic excitations, to monitor the sub-picosecond thermalization dynamics of the system. Recently, we have achieved such Bose-Einstein condensation also at the strong coupling regime, and shown by varying the lattice size that the thermalization in these systems is a simulated process that occurs in 100 femtosecond scale [2]. This new platform is ideal for studies of differences and connections between BEC and lasing [3,4,5]. While usually lasing in nanoparticle arrays occurs at the centre of the Brillouin zone, we have now demonstrated lasing also at the K-point [6]. The lasing mode can be identified with the help of group theory. Clear lasing is observed despite a narrow band gap at the K-point, which is promising considering future studies of topological photonics.

Tailoring weak-to-strong coupling of a plasmonic-photonic cavity*

FENG PAN (Presenter), RANDALL H. GOLDSMITH, University of Wisconsin - Madison — Control of light-matter interactions is important to a number of advances in quantum communication, information and sensing. Tailoring coupling strength relative to loss rates is central to exert control over the interactions. Recently we have demonstrated we could pin down a high dynamic range of system parameters in a coupled plasmonic-photonic cavity. Embedding the coupled cavity with an index-matching polymer matrix allows plasmonic and photonic modes to be largely overlapped and thus lifts up $g$ to the same order of magnitude as dominant nonradiative loss rate, potentially leading to a strongly coupled cavity. After the coupled cavity is embedded by polydimethylsiloxane (PDMS). Plasmonic resonance of a gold nanorod (AuNR) is red-shifted due to change of local dielectric environment around the AuNR. Decreasing the aspect ratio blue-shifts its plasmon resonance back to our spectral window and then we observe a splitting spectral feature that signifies strong coupling. This demonstration provides an avenue for tailoring weak-to-strong coupling, which foreshadows the potential of entangling multiple plasmonic systems through photonic mode for protection against decoherence in quantum communication.

Strong coupling beyond the light-line*

KISHAN MENGHRAJANI (Presenter), WILLIAM L BARNES, University of Exeter — Many experiments on strong coupling of molecules make use of metal-clad microcavities. Coupling is usually investigated between the excitonic or vibronic molecular resonance (as appropriate) and the lowest order cavity mode. However, metal-clad microcavities also support a coupled surface plasmon mode, something that appears to have been ignored in previous work, probably because it exists beyond the light-line. Here we show that this coupled plasmon mode also interacts with molecular resonances to produce hybrid polariton modes.

We use a vibrational resonance in the polymer PMMA, incorporated into a microcavity with gold mirrors. Although the asymmetrically coupled surface plasmon (TM$_{1}$) mode has no cut-off, it lies outside the air light-line, we bring that mode inside the air light line by incorporating a grating structure into the lower gold mirror. The grating-scattered coupled plasmon mode is observed to strongly couple with the vibrational resonance. Our results indicate that this coupled plasmon mode should be taken into account when looking at how strong coupling may be used to alter/create molecular properties via strong coupling.

10:00AM L05.00007: Modified excited states dynamics in the nanoparticle plasmon – molecular exciton hybrids under strong coupling regime [Invited] TIMUR SHEGAI (Presenter), Physics, Chalmers University of Technology — Strong light-matter interactions in microcavities have been long known to provide means to alter optical and nonlinear properties of the coupled system. As a result of this interaction, one typically observes the emergence of new polaritonic eigenstates. These states are of hybrid nature and possess both light and matter characteristics, which is reflected in vacuum Rabi splitting, observed in the absorption or transmission spectra. Because of the hybrid nature of these states, the excited state temporal dynamics can be significantly altered in comparison to the uncoupled system dynamics. This, in turn, can have profound effects on the emission and photochemical processes.

Here, we show that individual plasmonic nanoantennas can strongly couple to molecular J-aggregates, resulting in splitting up to 400 meV, i.e. ~20% of the resonance energy. Moreover, we observe mode splitting not only in elastic scattering response but also in photoluminescence of individual hybrid nanosystems, which manifests a direct proof of strong coupling in plasmon-exciton nanoparticles. This situation is drastically different from the photoluminescence of uncoupled molecules, which signals the involvement of polaritonic states into the relaxation pathways of the hybrid system. We also discuss how the involvement of these pathways can modify excited state dynamics, including such important photochemical processes as photobleaching.

10:36AM L05.00008: Cavity Induced Non-adiabatic Effects and Modifications of the Spin-orbit Coupling* DOMINIK SIDLER (Presenter), MICHAEL RUGGENTHALER, HEIKO APPEL, ANGEL RUBIO, Max Planck Inst Structure & Dynamics of Matter — A numerically exact diagonalisation of the non-relativistic Pauli-Fierz Hamiltonian is performed for quantized three-body problems coupled to one cavity mode in 3D. The resulting 10-dimensional setup can be transformed into an effectively five dimensional problem, which is fully diagonalisable with state-of-the-art computers. This allows to investigate polaritonic effects for real systems (e.g. He or HD+) with high accuracy, potentially giving access to cavity induced non-adiabatic effects. Modifications of the fine-structure arising from the coupling to a quantized cavity mode can be treated perturbatively.

Protecting a bosonic qubit with autonomous quantum error correction I – Theory

CHEN WANG (Presenter), JEFFREY GERTLER, Univ of Mass - Amherst — Existing demonstrations of quantum error correction are based on an active schedule of measurement and recovery operations which is hardware intensive and incurs additional error overhead. It is theoretically possible to correct quantum errors with dissipation in a continuous and autonomous fashion, without a classical controller. While dissipative confinement of a quantum system to a two-state manifold had been demonstrated, so far it has remained challenging to achieve a dissipation operator that counters the dominant natural errors in order to extend the lifetime of an encoded qubit. Here we present an autonomous error correction scheme for a bosonic qubit in a superconducting cavity, which directly corrects the dominant error channel of the system: single photon loss. In this Part I of the talk, we discuss this dissipative error correction protocol, its design considerations, as well as its expected performance and limitations.

8:24AM L07.00003: All-Gaussian universality and fault tolerance with the Gottesman-Kitaev-Preskill code*  
BEN Q BARAGIOLA, GIACOMO PANTALEONI, Center for Quantum Computation and Communication Technology, School of Science, RMIT, RAFAEL ALEXANDER (Presenter), Center for Quantum Information and Control, University of New Mexico, ANGELA KARANJAI, Centre for Engineered Quantum Systems, School of Physics, The University of Sydney, NICOLAS C MENICUCCI, Center for Quantum Computation and Communication Technology, School of Science, RMIT — The Gottesman-Kitaev-Preskill (GKP) encoding of a qubit within an oscillator is particularly appealing for fault-tolerant quantum computing with bosons because Gaussian operations on encoded Pauli eigenstates enable Clifford quantum computing with error correction. We show that applying GKP error correction to Gaussian input states, such as vacuum, produces distillable magic states, achieving universality without additional non-Gaussian elements. Fault tolerance is possible with sufficient squeezing and low enough external noise. Thus, Gaussian operations are sufficient for fault-tolerant, universal quantum computing given a supply of GKP-encoded Pauli eigenstates.

8:36AM L07.00004: Stabilization of finite-energy Gottesman-Kitaev-Preskill bosonic codes*  
BAPTISTE ROYER (Presenter), SHRADDHA SINGH, STEVEN GIRVIN, Department of Physics, Yale University — Due to their large Hilbert space and their high quality factors, microwave cavities are an attractive candidate for the encoding of logical quantum information. One promising choice of encoding in these cavities is the Gottesman-Kitaev-Preskill (GKP) code which allows to protect against small displacements in phase space. However, in their ideal form, GKP codewords contain an infinite amount of energy and, consequently, their experimental implementation cannot be exact. Nevertheless, recent experiments [Flühmann et al., Nature (2019), Campagne-Ibarcq et al., arXiv:1907.12487] have demonstrated that it is possible to obtain long coherence times for GKP logical qubits. In this talk, we investigate improved stabilization strategies tailored specifically for finite-energy GKP codes and study how these protocols perform in a superconducting implementation with realistic parameters.

Path-independent gates for error-corrected quantum computing: Theory

WEN-LONG MA (Presenter), Pritzker School of Molecular Engineering, University of Chicago, PHILIP REINHOLD, SERGE ROSENBLUM, ROBERT SCHOELKOPF, Departments of Applied Physics and Physics, Yale University, LIANG JIANG, Pritzker School of Molecular Engineering, University of Chicago — Universal control of a quantum system can usually not be achieved by direct control of the system. To realize the missing unitary gates for universal control, we can couple an ancilla system with more complete functionality to the logical system and jointly control both systems. However, the ancilla often suffers much stronger noise than the logical system. Here, we propose a general class of quantum gates on the logical system that is path independent (PI) of Markovian ancilla error trajectories, including both ancilla relaxation and dephasing errors. By fixing the initial and final ancilla states, the designed gates can be PI of infinite-order ancilla dephasing errors, finite-order ancilla relaxation errors, and the combination of both. The PI gates can also be made error-transparent to the first-order logical system errors. As an example, we show that the photon-number selective arbitrary phase (SNAP) gates in circuit QED belong to such a class of PI gates. This proposal provides a hardware-efficient approach toward fault-tolerant quantum computation with system-specific error models.

Path-independent gates for error-corrected quantum computing: Experiment

SERGE ROSENBLUM (Presenter), PHILIP REINHOLD, Departments of Applied Physics and Physics, Yale University, WEN-LONG MA, Pritzker School of Molecular Engineering, University of Chicago, LUIGI FRUNZIO, Departments of Applied Physics and Physics, Yale University, LIANG JIANG, Pritzker School of Molecular Engineering, University of Chicago, ROBERT SCHOELKOPF, Departments of Applied Physics and Physics, Yale University — In future fault-tolerant quantum computers, errors resulting from noise and decoherence must be detected and corrected in real-time. This is particularly important while applying logical gates, which can cause errors to quickly spread throughout the system. Here, we present an error-corrected construction for a logical gate set [1] enacted by a multilevel transmon ancilla on a cavity-encoded logical qubit. We show that the logical information is maintained by detecting ancilla errors and applying the appropriate corrections to the logical qubit. The error-corrected operation is path-independent of dominant ancilla errors, leading to a sixfold suppression of the gate error with increased energy relaxation, and a fourfold suppression with increased dephasing noise. The results support the viability of hardware-efficient bosonic quantum computation by showing that bosonic qubits can be controlled by error-prone ancillas without inheriting their inferior performance.

*This research was supported by the Army Research Office (W911NF-18-1-0212), and the Air Force Office of Scientific Research (FA9550-14-1-0052 and FA9550-15-1-0015).
9:12AM L07.00007: Error-transparent operations on a logical qubit protected by quantum error correction
YUWEI MA (Presenter), YUAN XU, XIANGHAO MU, WEIZHOU CAI, LING HU, WEITING WANG, XIAOXUAN PAN, HAIYAN WANG, YIPU SONG, Tsinghua University, CHANGLING ZOU, USTC, LUYAN SUN, Tsinghua University — Universal quantum computation is striking for its unprecedented capability in processing information, but its scalability is challenging in practice because of the inevitable environment noise. Although quantum error correction (QEC) techniques have been developed to protect stored quantum information from leading orders of errors, the noise-resilient processing of the QEC-protected quantum information is highly demanded but remains elusive. Here, we demonstrate phase gate operations on a logical qubit encoded in a bosonic oscillator in an error-transparent (ET) manner. The ET gates are extended to the bosonic code and are able to tolerate errors during the gate operations, regardless of the random occurrence time of the error. With precisely designed gate Hamiltonians through photon-number-resolved AC-Stark shifts, the ET condition is fulfilled experimentally. We verify that the ET gates outperform the non-ET gates with a substantial improvement of the gate fidelity after an occurrence of the single-photon-loss error. Our ET gates in the superconducting quantum circuits are readily for extending to multiple encoded qubits and a universal gate set is within reach, paving the way towards fault-tolerant quantum computation.

9:24AM L07.00008: High-impedance circuits for parity measurements of cat qubits
CLARKE SMITH (Presenter), MARIUS VILLIERS, RAPHAËL LESCANNE, ANTOINE MARQUET, Ecole Normale Supérieure, CAMILLE BERDOU, MINES ParisTech, TAKIS KONTOS, Ecole Normale Supérieure, MAZYAR MIRRAHIMI, INRIA, ZAKI LEGHTAS, MINES ParisTech — Encoding a qubit in the two degenerate steady states of an oscillator—which only exchanges pairs of photons with its environment—can exponentially suppress the bit-flip rate for large phase-space separations. The unsuppressed phase flips of these so-called "cat qubits" correspond to a change in the photon number parity of the oscillator, and they could be corrected using redundant encoding. In such a scheme, errors are detected via measurements of the joint parity between cat qubits, which could be implemented at the Hamiltonian level using effective parity-type couplings. We show that a parity-type Hamiltonian emerges from the conventional Josephson potential in the limit of high oscillator impedance. Here, the high impedance guarantees large fluctuations of the superconducting phase, which translates into large displacements in oscillator phase space. We present the design of a superconducting circuit that effectively realizes the parity-type Hamiltonian, as well as the status of its experimental implementation.

9:36AM L07.00009: Experimental implementation of fault-tolerant error syndrome measurement for pair-cat code (1/2)*  AKSHAY KOOTTANDAVIDA (Presenter), IOANNIS TSIOUTSIOS, SHANTANU O MUNDHADA, LUIGI FRUNZIO, MICHEL H. DEVORET, Yale University — Stabilized quantum manifolds of a bosonic system can encode error-protected qubits. In particular, a single-mode manifold spanned by cat states can exponentially suppress against phase-flip errors. However, errors due to photon loss cannot be corrected without stopping the stabilization process, using existing microwave superconducting circuit technology. Phase-flip suppression can also be achieved by stabilizing a manifold spanned by pair-cat states, which are superpositions of the two-mode states called Barut-Girardello/pair-coherent states. Moreover, it is now possible to detect, in a fault-tolerant manner, photon-loss errors in either mode, simultaneously with the manifold stabilization, by monitoring the photon-number difference between them. In this talk, we will present an experimental implementation of cavities and superconducting devices that is compatible with such encoding. We will also report on techniques of continuous monitoring of the photon number difference between the modes. Part-one of this two-part presentation will introduce the basic theoretical concepts of pair-cat codes and the design parameters of our experimental implementation.

*ARO, ONR, NSF, AFOSR, and YINQE

9:48AM L07.00010: Experimental implementation of fault-tolerant error syndrome measurement for pair-cat code (2/2)*  IOANNIS TSIOUTSIOS (Presenter), AKSHAY KOOTTANDAVIDA, SHANTANU O MUNDHADA, LUIGI FRUNZIO, MICHEL H. DEVORET, Department of Applied Physics, Yale University — Stabilized quantum manifolds of a bosonic system can encode error-protected qubits. In particular, a single-mode manifold spanned by cat states can exponentially suppress against phase-flip errors. However, errors due to photon loss cannot be corrected without stopping the stabilization process, using existing microwave superconducting circuit technology. Phase-flip suppression can also be achieved by stabilizing a manifold spanned by pair-cat states, which are superpositions of the two-mode states called Barut-Girardello/pair-coherent states. Moreover, it is now possible to detect, in a fault-tolerant manner, photon-loss errors in either mode, simultaneously with the manifold stabilization, by monitoring the photon-number difference between them. In this talk, we will present an experimental implementation of cavities and superconducting devices that is compatible with such encoding. We will also report on techniques of continuous monitoring of the photon number difference between the modes. Part-two of this two-part presentation will present our most recent experimental progress.

10:00AM L07.00011: Progress on fault-tolerant quantum computing with concatenated bosonic-qubit codes* ARNE GRIMSMO (Presenter), STEFANUS EDGAR TANUARTA, JULIETTE SOULE, Univ of Sydney, BEN Q BARAGIOLA, RMIT University, JOSHUA L. A. COMBES, University of Queensland — In this talk I will discuss ongoing work to quantify the performance of bosonic error correcting codes concatenated with conventional qubit codes. There are two questions we are trying to answer: 1. When does using a bosonic code at the ground level of a concatenated scheme outperform using two-level systems? 2. How do different bosonic codes compare to each other. We would like to answer both of these questions in a fault-tolerant setting that includes state preparation and measurement noise, as well as noise during the error correction circuit.

10:12AM L07.00012: Fault-Tolerant Bosonic Quantum Error Correction with the Surface-GKP Code KYUNGJOO NOH (Presenter), Yale University, CHRISTOPHER CHAMBERLAND, IBM Thomas J. Watson Research Center — Bosonic quantum error correction is a viable option for realizing error-corrected quantum information processing in continuous-variable bosonic systems. Here, we consider the concatenation of the bosonic Gottesman-Kitaev-Preskill (GKP) code with the surface code, namely, the surface-GKP code. In particular, we thoroughly investigate the performance of the surface-GKP code by assuming realistic GKP states with a finite squeezing and noisy circuit elements due to photon losses. By using a minimum-weight perfect matching decoding algorithm on a 3D space-time graph, we show that fault-tolerant bosonic quantum error correction is possible with the surface-GKP code if the squeezing of the GKP states is higher than 11.2dB in the case where the GKP states are the only noisy elements. We also show that the squeezing threshold changes to 18.6dB when both the GKP states and circuit elements are comparably noisy. At this threshold, each circuit component fails with probability 0.69%. Finally, if the GKP states are noiseless, fault-tolerant quantum error correction with the surface-GKP code is possible if each circuit element fails with probability less than 0.81%.
10:24AM L07.00013: Majorana dimer models of holographic quantum error correction

ALEXANDER JAHN (Presenter), MAREK GLUZA, FERNANDO PASTAWSKI, JENS EISERT, Dahlem Center for Complex Quantum Systems, Free University of Berlin — Holographic quantum error-correcting codes have been proposed as toy models describing key aspects of the AdS/CFT correspondence. In this talk, we introduce a versatile framework of Majorana dimers capturing the intersection of stabilizer and Gaussian Majorana states. This picture allows for an efficient contraction with a simple diagrammatic interpretation and is amenable to analytical study of holographic quantum error-correcting codes. Equipped with this framework, we revisit the recently proposed hyperbolic pentagon code (HyPeC) and demonstrate efficient computation of boundary state properties for generic logical bulk input. We show that the dimers characterizing boundary states of the HyPeC follow discrete bulk geodesics. From this geometric picture, properties of entanglement, quantum error correction, and bulk/boundary operator mapping immediately follow, offering a fresh perspective on holography. We also elaborate upon the emergence of the Ryu-Takayanagi formula from our model, which shares many properties of the recent bit thread proposal.

Our work thus elucidates the connection between bulk geometry, entanglement, and quantum error correction in AdS/CFT, and lays the foundation for new models of holography. We close with an outlook on the boundary symmetries of holographic Majorana dimer models and discuss the connection to the strong disorder renormalization group.

Session L08 DQI: Superconducting Qubits: Materials, Fabrication and Coherence II 104 - Martin Weides, Univ of Glasgow

8:00AM L08.00001: PAMBE grown NbTiN-AlN-NbTiN Josephson junction heterostructures for superconducting quantum circuits

CHRISTOPHER RICHARDSON (Presenter), AUSTIN THOMAS, ASHISH ALEXANDER, CHRISTOPHER WEDDLE, ALAN KRAMER, Laboratory for Physical Sciences, MATTHEW OLSZTA, BRUCE AREY, Pacific Northwest National Laboratory — Plasma assisted molecular beam epitaxy (PAMBE) is used to grow niobium titanium nitride alloys (Nb$_x$Ti$_{1-x}$N) superconductors and wide bandgap nitride (AlN) trilayers directly on c-plane sapphire wafer. This combination of nitride materials provides sufficient degrees of freedom that synthesis of an epitaxial Josephson junction may be possible. Using a structure first approach to design optimization, the structural, surface topology, bonding, and interface characteristics will be described. Superconducting characteristics including microwave loss and work towards IV transport through Josephson junction devices will be discussed.
As the lifetime of superconducting qubits has increased, large temporal fluctuations in the relaxation time $T_1$ of the excited state have been observed by different groups. We have measured such fluctuations in several Al/AlOx/Al transmons mounted in 3-D aluminum cavities. Our longest lived device showed $T_1$ that varied from 100 to 300 μs at 20 mK. Comparing with shorter lived transmons, we find that the size of the fluctuations in $T_1$ appears to scale with $T_1$. Measurements of $T_1$ versus temperature from 20 to 300 mK reveal that the fluctuations depend on temperature and support the idea that non-equilibrium quasiparticles are the dominant source of dissipation in these devices.

*This work was supported by the Maryland Quantum Materials Center, the Joint Quantum Institute, and the Laboratory for Physical Sciences.

Protecting superconducting qubits from low-frequency noise is important for advancing superconducting quantum computation. We present a protocol for engineering dynamical sweet spots protecting against 1/f noise, using a periodic drive. The position and strength of dynamical sweet spots can be obtained analytically in the framework of Floquet theory. For the example of fluxonium biased slightly away from half a flux quantum, we predict an improvement in pure-dephasing time from less than 1 μs to over 1 ms. Using the Floquet eigenstates as the computational basis, we show that high-fidelity single-qubit gates can be implemented at dynamical sweet spots. We further confirm that qubit readout can be performed by adiabatically mapping the qubit's Floquet states to the static qubit states, and subsequently employing standard measurement techniques.

*Army Research Office Grant No. W911NF1910016
8:36AM L08.00004: Investigating the mechanisms of charge-parity switching in offset-charge-sensitive transmons* SPENCER DIAMOND (Presenter), Department of Applied Physics, Yale University, KYLE SERNIAK, MIT Lincoln Lab, MAX HAYS, VALLA FATEMI, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Department of Applied Physics, Yale University, GIANLUIGI CATELANI, Forschungszentrum Julich, MANUEL HOUZET, CEA Grenoble, LEONID GLAZMAN, MICHEL H. DEVORET, Department of Applied Physics, Yale University — Charge-parity switches in superconducting qubits contribute to decoherence and limit qubit performance. In the past, such decoherence was exclusively attributed to pre-existing non-equilibrium quasiparticles tunneling across Josephson junctions and exchanging energy with the qubit. However, it was recently predicted that high-frequency photons can be efficiently absorbed at transmon Josephson junctions and cause charge-parity switches. This process requires no pre-existing quasiparticles, but in fact generates two quasiparticles and can likewise change the qubit state. These two types of charge-parity switches are distinguishable by their relative rates of qubit excitation and relaxation, which have been measured in single-junction offset-charge-sensitive transmons. The transition rates were found to be inconsistent with a thermal distribution of quasiparticles in the superconductor tunneling across the junction, but may be explained by photon-assisted tunneling events. Here, we will present experimental results demonstrating that adding flux-tunability to our device can further distinguish between these charge-parity switch-induced decoherence mechanisms.

8:48AM L08.00005: Effect of external high-energy radiation on coherence of superconducting qubits ANTTI VEPSALAINEN (Presenter), AMIR KARAMLOU, Massachusetts Institute of Technology MIT, JOHN LAURENCE ORRELL, Pacific Northwest National Laboratory, AKSHUNNA S DOGRA, FRANISICA VASCONCELOS, Massachusetts Institute of Technology MIT, BEN LOER, Pacific Northwest National Laboratory, BETHANY NIEDZIELSKI, ALEXANDER MELVILLE, DAVID KIM, MOLLIE SCHWARTZ, JONILYN YODER, MIT Lincoln Laboratory, BRENT A VANDEVENDER, Pacific Northwest National Laboratory, SIMON GUSTAVSSON, WILLIAM OLIVER, Massachusetts Institute of Technology MIT — There is an anomalously high density of broken Cooper pairs in superconductors, which has been universally seen in experiments. It has been shown that external radiation can break Cooper pairs in superconducting circuits, causing elevated quasiparticle densities. The origin of the radiation has been a source of extensive research over several decades, but no conclusive answer has been found. It is known that thermal effects cause a finite quasi-particle density, but the observed densities are several orders of magnitudes higher than predicted by thermal equilibrium model. In superconducting devices infrared photons have shown to contribute to non-equilibrium quasi-particle densities through connected microwave lines. We propose that in addition to this effect, gamma-rays from radioactive decays in the environment are also a significant source of quasi-particle breaking radiation. We have measured the strength of the external radiation in our laboratory and demonstrated the effect of the high-energy radiation on qubit coherence using a Cu64 source with time-varying intensity. We show that proper shielding from gamma-rays is required for reaching high coherence times in transmon qubits.
9:00AM L08.00006: Synchrotron X-ray studies of superconducting qubit materials*  IGNACE JARRIGE (Presenter), National Synchrotron Light Source II, Brookhaven National Laboratory, ANJALI PREMKUMAR, Department of Electrical Engineering, Princeton University, CONAN R WEILAND, Materials Measurement Science Division, National Institute of Standards and Technology, JACK BERTHOLD, ALEXANDER PLACE, Department of Electrical Engineering, Princeton University, IRA WALUYO, ADRIAN HUNT, ANDREW M. KISS, YONG CHU, VALENTINA BISOGNI, JONATHAN PELLICIARI, ABDUL K RUMAIZ, National Synchrotron Light Source II, Brookhaven National Laboratory, MIKE MILLER, PAULA RUSSO, Angstrom Engineering Inc., DAVID I SCHUSTER, Department of Physics and the James Franck Institute, University of Chicago, ANDREW HOUCK, Department of Electrical Engineering, Princeton University — Despite dramatic improvements in the coherence times of superconducting qubits over the past decade, further progress is still needed to push quantum computers towards reality. Recent breakthroughs highlighted the paramount role played by the defect-prone native surface oxide layers in limiting the coherence of qubits. However, very little is known about the defects and their mechanism of coupling to the qubit degree of freedom, in part due to the lack of suitable probes for defects in thin amorphous layers. Here, we report on the combined use of synchrotron X-ray scattering and spectroscopic tools to probe the surface electronic and bulk structural properties of Nb thin films deposited on sapphire, which emulate qubit capacitor pads. The thin films were deposited using four different techniques yielding varying film qualities and densities. Material properties, including crystalline grain sizes and surface oxide layer thicknesses and compositions, will be discussed in light of the coherence times obtained for transmon qubits using Nb capacitor pads deposited with the same four techniques. We will discuss possible scenarios for the correlations between the material properties and the qubit performance.

*AP, BJ, & AP thank ARO, NSF GRF, Humboldt Foundation, & NDSEG.

9:12AM L08.00007: Highly uniform submicron junction arrays and applications to next generation photodetectors*  JOHN MARK KREIKEBAUM (Presenter), University of California, Berkeley, KEVIN O'BRIEN, Massachusetts Institute of Technology, BAPTISTE ROYER, Universite de Sherbrooke, ARNE GRIMSMO, University of Sydney, ALEXANDREblaís, Universite de Sherbrooke, IRFAN SIDDIQI, University of California, Berkeley — Josephson junctions are an ubiquitous circuit element in cQED experiments. In complex devices with many such junctions, such as state-of-the-art microwave photon detectors, precise control over each junction's critical current is often required, and thus variations of the junction area and tunnel barrier thickness must be sufficiently minimized. Analyzing junction array resistance distributions from many wafers, we have identified several key processing variables to improve uniformity. Using this optimized recipe, we have fabricated and benchmarked a single microwave photon detector utilizing four identical transmons to mediate cross-Kerr coupling between a photon input waveguide and a readout resonator. Plans to increase detector performance by distributing the coupling over 1000's of junctions will be discussed; a very challenging device to build without the uniformity improvements presented.

9:24AM L08.00008: Loss Characterization in Superconducting Resonators  
ALEXANDER MELVILLE (Presenter), GREG CALUSINE, WAYNE WOODS, KYLE SERNIAK, EVAN GOLDEN, ARJAN SEVI, JONILYN YODER, WILLIAM OLIVER, MIT Lincoln Laboratory — Uniquely characterizing loss from two-level systems (TLS) in dielectric materials in coplanar waveguide resonators is challenging due to the nearly proportional scaling of the electric field participation in response to changes in geometry and anisotropic trench depth [1]. We tailor our resonator design and fabrication process to focus the participation into specific dielectric regions such that we can characterize the specific loss tangent of each dielectric [2]. In this talk, we characterize the change in overall quality factor and dielectric-specific loss tangent arising from specific changes to the fabrication process.

*This material is based upon work supported by the Department of Defense under Air Force Contract No. FA8721-05-C-0002. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the Department of Defense.

9:36AM L08.00009: Modeling geometric dependence of dielectric losses in superconducting coplanar-waveguide resonators  
VALTTERI LAHTINEN (Presenter), MIKKO MOTTONEN, Aalto University — Superconducting coplanar-waveguide (CPW) resonators are essential devices in circuit quantum electrodynamics (cQED). Their performance is limited by dielectric losses in the substrate and in the thin lossy oxide layers on the material interfaces. Reliable modeling is required to aid in the design of low-loss CPW structures for cQED. We analyze the geometric dependence of the dielectric losses in CPW structures using finite-element modeling of the participation ratios of the lossy regions. Material and device specific parameters of these regions are generally not known accurately enough, introducing uncertainty in the simulations. To this end, we carry out simulations on a range of CPW geometries and parameters. Combining the simulations with measured two-level-system-limited Q factors of CPW resonators, we solve an inverse problem to find optimal model parameters producing these values. Utilizing this model and our geometric-dependence analysis, we predict high Q factors obtainable by optimizing the cross-sectional geometries of the measured CPW structures. Our results guide the fabrication of low-loss CPW resonators for cQED.

Reducing dephasing for flux control of superconducting qubits

NICOLAS DIDIER (Presenter), Rigetti Quantum Computing — Scaling up superconducting quantum processors with optimized performance requires sufficient flexibility in the choice of operating points for single and two qubit gates to maximize their fidelity and cope with imperfections. Flux control is an efficient technique to manipulate the parameters of tunable qubits, in particular to activate entangling gates. It however suffers from enhanced dephasing, induced by the ubiquitous 1/f flux noise at flux sensitive points of operation. We consider how flux pulses can protect a tunable qubit from slow flux noise for a range of frequencies in the tunability band. Preserving long coherence times during qubit interactions could furthermore alleviate the constraints on coupling strength and unlocks high fidelities for both single and two qubit gates in a scalable architecture based on static couplings.

Characterizing noise for capacitively-shunted flux qubits

VINAY TRIPATHI (Presenter), MOSTAFA KHEZRI, HUO CHEN, DANIEL A LIDAR, Univ of Southern California — Capacitively-shunted flux qubits (CSFQs), due to their high anharmonicity together with reduced persistent currents allow for relatively fast control pulses and long coherence times. This makes them a suitable candidate for both gate model quantum computing and quantum annealing. We report a joint theoretical-experimental study of 1/f noise in CSFQs using Macroscopic Resonance Tunneling (MRT). MRT has been used for flux qubits to characterize low-frequency flux noise using well established theoretical models. A detailed theoretical explanation of higher order MRT with correction of junction asymmetry is important for our understanding of noise in CSFQs. We carry out analyses of different theoretical models that account for relaxation and dephasing to explain experimental $T_1$ and $T_2$ results obtained from studies of CSFQs.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.
Hexagonal boron nitride (hBN), an insulating 2-D(van der Waals) material that features an essentially defect-free bulk and atomically flat surfaces through mechanical exfoliation, may be used to build high-quality Josephson elements and qubit capacitors. We study hBN in the microwave regime via lateral capacitive coupling and parallel plate capacitors. In the single-photon limit, the extracted quality factor of hBN is bounded below at ~ 200,000. Beyond hBN, this measurement technique can also be used to explore new material platforms for superconducting technologies.

10:24AM L08.00013: Loss Mechanisms in Superconducting Quantum Transmission Line Metamaterials* TAMIN TAI (Presenter), JINGNAN CAI, STEVEN ANLAGE, Physics Department, University of Maryland, College Park — Superconducting quantum bits (qubits) coupled with resonators are widely utilized for applications in quantum computing. Efforts are under way to scale up the numbers of qubits, but there are many recurring issues of dielectric loss of substrate materials, two level systems, and quasi-particles loss, all leading to decoherence of superconducting qubits. In order to understand different loss mechanisms, our group is fabricating many high-quality aluminum half wavelength transmission line resonators by e-beam deposition and photo-lithography methods. Through the investigation of power dependence and temperature dependence of these transmission line resonators, and comparison with different theoretical models, the dominant loss mechanism in our half wavelength transmission line can be identified. This transmission line will later host many flux qubits to study the collective behavior of a quantum metamaterial system.

10:36AM L08.00014: Over-100µs tunable planar transmons: epitaxial Josephson Junctions and design optimization* ANASTASIYA PISHCHIMOVA, DMITRIY MOSKALEV, ALEKSEI MATANIN (Presenter), FMN Laboratory, Bauman Moscow State Technical University, ALINA DOBRONOSOVA, Dukhov Automatics Research Institute, (VNIIA), DARIA EZENKOVA, FMN Laboratory, Bauman Moscow State Technical University, ELIZAVETA IL'INICHNA MALEVANNAYA, Dukhov Automatics Research Institute, (VNIIA), ILYA BESEDIN, National University of Science and Technology, OLGA SOROKINA, LUCIA ALMIROVNA GANIEVA, Dukhov Automatics Research Institute, (VNIIA), ANDRONIC MICHAEL, VLADIMIR VLADIMIROVICH ECHEISTOV, FMN Laboratory, Bauman Moscow State Technical University, ALEXANDER VYACHESLAHOVICH ZVEREV, Dukhov Automatics Research Institute, (VNIIA), DMITRIY SERGEEVICH YAKOVLEV, Institute of Solid State Physics, Russian Academy of Sciences, ILYA RODIONOV, FMN Laboratory, Bauman Moscow State Technical University — Since superconducting qubits discovery over twenty years ago energy relaxation times has been improved by several orders. Josephson junctions, a crucial nonlinear component of superconducting qubits, are still fabricated from two aluminum polycrystalline electrodes with lossy amorphous aluminum oxide in between. Here we demonstrate our results in reducing two-level states (TLS) in amorphous oxides by means of Josephson Junctions optimization, thus reducing the participation of the lossy materials and interfaces. We carry out a comparative analysis of tunable X-mon qubit lifetimes based on various Josephson Junctions design types, demonstrating several times coherence improvement. From the other hand, we propose novel superconducting qubits fabrication technique based on Josephson junction epitaxial growth with inorganic masks. To experimentally test the proposed approaches we demonstrate tunable X-mon qubits with coherence over 100 microseconds.

*Devices were fabricated at the BMSTU Nanofabrication Facility (Functional Micro/Nanosystems, FMNS REC, ID 74300).
8:00AM L09.00001: Breakdown of phenomenological Lindblad master equations in the strong coupling regime*  
BRUNO TAKETANI (Presenter), Univ Federal de Santa Catarina, J. MAURICIO TORRES, Instituto de Física, Benemérita Universidad Autónoma de Puebla, RALF BETZHOLZ, School of Physics and International Joint Laboratory on Quantum Sensing and Quantum Metrology, Huazhong University of Science and Technology — The Lindblad form of the master equation has proven to be one of the most convenient ways to describe the impact of an environment interacting with the quantum systems of interest. For single quantum systems, the jump operators that characterize this interaction usually take simple forms, with clear experimental/physical interpretation. However, for coupled quantum systems the jump operators can take significantly different forms and in general the total Lindbladian for the system cannot be described by separate Lindbladians acting on the individual quantum systems. In this talk we investigate the effects of such separate, phenomenological description in optomechanical and spin-boson systems, which are particularly pronounced in the strong coupling regime and compare the results with a more realistic microscopic derivation of the master equation. We show that these approaches, phenomenological and microscopic, lead to different solutions to the model and we explore the parameter regime and conditions where these differences manifest themselves in an experiment. We propose an experiment with superconducting systems to investigate these issues and the breakdown of the phenomenological approach with increasing coupling strength.

Entanglement classifier in chemical reactions*  
JUNXU LI (Presenter), SABRE KAIS, Department of Chemistry and Physics, Purdue Univ — The Einstein, Podolsky, and Rosen (EPR) entanglement, which features the essential difference between classical and quantum physics, has received wide theoretical and experimental attentions. Recently, the desire to understand and create quantum entanglement between particles such as spins, photons, atoms, and molecules is fueled by the development of quantum teleportation, quantum communication, quantum cryptography, and quantum computation. Although most of the work has focused on showing that entanglement violates the famous Bell's inequality and its generalization for discrete measurements, few recent attempts focus on continuous measurement results. Here, we have developed a general practical inequality to test entanglement for continuous measurement results, particularly scattering of chemical reactions. After we explain how to implement this inequality to classify entanglement in scattering experiments, we propose a specific chemical reaction to test the violation of this inequality. The method is general and could be used to classify entanglement for continuous measurement results.

Concurrence and Discord measurements in a Kitaev type 1D Spin chain  
VIMALESH VIMAL (Presenter), IIT Kanpur — We present the study of concurrence and quantum discord in the ground state of 1D spins. The spins have the nearest neighbor Kitaev type interaction with the external transverse magnetic field. The system with periodic boundary condition gives the translation symmetry which simplifies the study to pairwise concurrence and discord at the odd and the even pair of sites separately. The correlation measures do not depend on the direction of the external field. They show dependence on spin length in the smaller chain but saturate quickly. The concurrence and the discord show the peak structure in the critical region but their derivatives do not show pronounced singularity to trace the phase transition of the system. The discord quantifies the correlation better as it gives finite correlation in the region where concurrence goes to zero.

8:36AM L09.00004: Triangle Nonlocality: genuine quantum nonlocality and quantum Finner inequality* [Invited] Marc-Olivier Renou (Presenter), ICFO Barcelona, Salman Beigi, IPM Theran, Nicolas Brunner, Nicolas Gisin, Sadra Boreiri, University of Geneva, Yuyi Wang, Computer Science, ETH Zurich, Elisa Bäumer, ETH Zurich — Network nonlocality extends standard Bell nonlocality to networks, where several independent sources are distributed to several parties according to the network structure. Contrary to standard Bell Nonlocality, this problem is non convex: no efficient systematic way to tackle it is known, either for local or quantum correlations. It is only partially understood for the simplest scenarios of bilocality (extended to star-locality and nonlocality on a line). However, for scenarios with loops, e.g. the triangle network, nothing is known except examples directly deduced from the usual form of quantum nonlocality (via the violation of a standard Bell inequality). This can even be done without using inputs. The question of finding a genuine quantum violation of triangle network locality was open the last years.

In this talk, we first present a novel example of quantum nonlocality without inputs in the triangle network, which we believe represent a new form of quantum nonlocality, genuine to the triangle network. It involves both entangled qubit states and joint entangled measurements. We generalize it to qutrits shared states and any odd-cycle networks.

Then, we move to the question of the characterization of local and quantum correlations. We derive a bound, the quantum Finner inequality (already known to hold for local resources), which we also demonstrate to hold when the sources are arbitrary no-signaling boxes which can be wired together. We generalize this bound to all networks involving bipartite sources. We discuss it as an application for the device-independent characterization of the topology of a quantum network.

We conclude with some open questions related to quantum network nonlocality.

This talk is based on the two letters arXiv:1905.04902 and arXiv:1901.08287.

9:12AM L09.00005: Evolution of entanglement in collective excitations in linear atomic chains Emily Townsend (Presenter), Garnett Bryant, National Institute of Standards and Technology, Abhikbrata Sarkar, Indian Institute of Technology, Kharagpur, India. — Quantum simulation of small physically realizable systems (e.g. chains of precision placed dopant atoms in silicon) provides an opportunity to learn about many-body physics at larger scale. Electrons in 1-D atomic chains with a long range coulomb interaction support plasmonic excitations of various modes and occupations of these modes, as linear superpositions of single particle excitations. We examine the time evolution of entanglement following plasmonic excitation due to coupling between the atomic chain and dipole emitters. We compare the results for a wide range of interaction strength between the electrons, from non interacting to strongly coupled and for pumping various plasmonic modes.
9:24AM L09.00006: Entanglement and impropriety*  BRIAN LA COUR (Presenter), THOMAS YUDICHAK, University of Texas at Austin — We describe a classical model of quantum entanglement corresponding to spontaneous parametric downconversion. Specifically, we consider the interaction of classical stochastic vacuum modes from the zero-point field and a high intensity pump with a nonlinear optical medium. The vacuum modes are treated as proper complex Gaussian random variables and are the sole source of randomness in the model. Phase matching conditions mimic the quantum mechanical energy and momentum conservation laws and result in outgoing classical fields of maximum intensity. The resulting transformation resembles the Bogoliubov transformation for multi-mode squeezed light, albeit with operators replaced by random variables, and yields a vector of improper complex Gaussian random variables. Using an amplitude threshold detection and post-selection measurement scheme, the degree of impropriety is found to correspond to the degree of entanglement in the corresponding quantum description.

9:36AM L09.00007: Tripartite information, scrambling, and the role of Hilbert space partitioning in quantum lattice models*  OSKAR SCHNAACK, NIKLAS BÖLTER, SEBASTIAN PAECKEL, SALVATORE MANMANA (Presenter), STEFAN KEHREIN, University of Gottingen, MARKUS SCHMITT, University of California, Berkeley — For the characterization of the dynamics in quantum many-body systems the question how information spreads and becomes distributed over the constituent degrees of freedom is of fundamental interest. The delocalization of information under many-body dynamics has been dubbed scrambling and out-of-time-order correlators were proposed to probe this behavior. In this work we investigate the time evolution of tripartite information as a natural operator-independent measure of scrambling, which quantifies to which extent the initially localized information can only be recovered by global measurements. Studying the dynamics of quantum lattice models with tunable integrability breaking we demonstrate that in contrast to quadratic models generic interacting systems scramble information irrespective of the chosen partitioning of the Hilbert space, which justifies the characterization as scrambler. Without interactions the dynamics of tripartite information in momentum space reveals unambiguously the absence of scrambling.

9:48AM L09.00008: Tsirelson Polytopes and Randomness Generation* PETER BIERHORST (Presenter), Mathematics, University of New Orleans, YANBAO ZHANG, NTT Corporation, EMANUEL H KNILL, National Institute of Standards and Technology — We classify the extreme points of polytopes of probability distributions in the (2,2,2) Bell-CHSH setting that are induced by a single Tsirelson bound. We also do the same for a parametrized family of polytopes obtained from two Tsirelson bounds that interact non-trivially. Such constructions can be applied to device-independent random number generation using the method of probability estimation factors (PRA 98:040304(R) (2018), arXiv:1812.07786, arXiv:1806.04553). We demonstrate a meaningful improvement in certified randomness applying the new polytopes characterized here.

10:00AM L09.00009: Experimental Certification of a Minimal Informationally Complete Positive Operator-Valued Measure in a Device-Independent Protocol* MASSIMILIANO SMANIA (Presenter), Stockholm University, PIOTR MIRONOWICZ, Gdansk University of Technology, MOHAMED NAWAREG, Stockholm University, MARCIN PAWLOWSKI, University of Gdansk, ADAN CABELLO, Universidad de Sevilla, MOHAMED BOURENNANE, Stockholm University — Minimal informationally complete positive operator-valued measures (MIC-POVMs) are a special kind of measurements in quantum theory that have the property that the statistics of their $d^2$-outcomes are enough to reconstruct any $d$-dimensional quantum state. For this reason, MIC-POVMs are referred to as "standard" measurements for quantum information, and are of the utmost interest in quantum information theory and applications, where they have been shown to be the ultimate tools for quantum state tomography [1], quantum key distribution [2] and randomness certification [3], among other fields.

We report on an experiment with entangled photon pairs that certifies for the first time a MIC-POVM for qubits following a device-independent protocol. That is, modeling the state preparation and the measurement devices as black boxes and using only the statistics of the inputs and outputs.

Many-particle interference and entanglement controlled by undetected particles  MAYUKH LAHIRI (Presenter), Department of Physics, Oklahoma State University — Creating and manipulating entangled states are essential for performing various tasks in quantum information science. We present a unique interferometric scheme that allows us to generate many-particle entangled states. The unique feature of the scheme is that the entangled states can be manipulated without interacting with the entangled particles [1]. We illustrate the scheme by two special cases in which Bell states and GHZ-class states are produced. The scheme also emphasizes the connection between interference and entanglement, a connection that has been of interest in fundamental physics [2-4].

Quantum State Reduction: Generalized Bipartitions from Algebras of Observables*  OLEG KABERNIK, JASON POLLACK, Department of Physics and Astronomy, University of British Columbia, ASHMEET SINGH (Presenter), Walter Burke Institute for Theoretical Physics, California Institute of Technology — Reduced density matrices are a powerful tool in the analysis of entanglement structure, coarse-grained dynamics, decoherence, and the emergence of classicality. While one often uses the partial trace map to produce a reduced density matrix, in many natural situations (such as limited resolution experiments) this reduction may not be achievable. We investigate the general problem of identifying how the quantum state reduces given a restriction on the observables where the appropriate state-reduction map can be defined via a generalized bipartition, which is associated with the structure of irreducible representations of the algebra generated by the restricted set of observables. One of our main technical results is a general algorithm for finding irreducible representations of matrix algebras. We demonstrate the viability of this approach with two examples of limited-resolution observables. The definition of quantum state reductions can also be extended beyond algebras of observables by a more flexible notion of bipartition, the partial bipartition, which describes coarse-grainings preserving information about a limited set (not necessarily algebra) of observables.

L09.00012: Optimality in Quantum Data Compression using Dynamical Entropy
GEORGE ANDROULAKIS (Presenter), Univ of South Carolina — In this joint work with Duncan Wright we study lossless compression of strings of pure quantum states of indeterminate-length quantum codes which were introduced by Schumacher and Westmoreland. Past work has assumed that the strings of quantum data are prepared to be encoded in an independent and identically distributed way. We introduce the notion of quantum stochastic ensembles, allowing us to consider strings of quantum states prepared in a more general way. For any identically distributed quantum stochastic ensemble we define an associated quantum Markov chain and prove that the optimal average codeword length via lossless coding is equal to the quantum dynamical entropy of the associated quantum Markov chain.

L09.00013: Experimental Test of Leggett's Inequalities with Solid-State Spins
XIANZHI HUANG (Presenter), XIAOLONG OUYANG, WENGANG ZHANG, XIN WANG, HUILI ZHANG, YEFEI YU, DONGLING DENG, LUMING DUAN, Center for Quantum Information, IIIS, Tsinghua University, Beijing 100084, P. R. China — Bell's theorem states that no local hidden variable model is compatible with quantum mechanics. Surprisingly, even if we release the locality constraint, certain nonlocal hidden variable models, such as the one proposed by Leggett, may still be at variance with the predictions of quantum physics. Here, we report an experimental test of Leggett's nonlocal model with solid-state spins in a diamond nitrogen-vacancy center. We entangle an electron spin with a surrounding weakly coupled $^{13}$C nuclear spin and observe that the entangled states violate Leggett-type inequalities by more than 6.4 and 10.1 standard deviations for six and eight measurement settings, respectively. Our experiment results are in full agreement with quantum predictions and render Leggett's nonlocal hidden variable model disputable with a high level of confidence.

8:00AM L10.00001: Propellant Quantity Gauging in Microgravity Using Radio Frequency Tank Modes*  
GREGORY ZIMMERLI (Presenter), NASA Glenn Research Center, MARIUS ASIPAUSKAS, Universities Space Research Association, CAMERON DONG, NASA Glenn Research Center — The Radio Frequency Mass Gauge (RFMG) is a novel propellant quantity gauging technique developed at NASA for the purpose of gauging cryogenic propellant tanks in low-gravity. The RFMG operates by sensing several resonant electromagnetic modes of a tank and comparing the measured tank mode frequencies to a lookup table of results from several thousand numerical simulations. The numerical simulations are performed in advance in order to predict the electromagnetic eigenmode frequencies at different propellant fill levels, liquid configurations, and temperatures. A best match between measured and simulated eigenmode frequencies is used to gauge the fluid mass inside the tank. An RFMG instrument flew on the International Space Station (ISS) and was used to gauge the mass of liquid methane in a 50 L tank as part of the Robotic Refueling Mission 3 (RRM3) payload operations. Shifts to the measured tank RF spectra during the mission indicated significant changes to the fluid configuration as a result of various ISS maneuvers and payload tests. During the four months of RRM3 cryogenic payload operations the RFMG produced a mean gauged mass of 19.0 kg, in agreement with the expected value, with a one-sigma error distribution of ±2% of the full-scale mass.

8:12AM L10.00002: Stretching the bandwidth of physical measurements by compressed sensing  
SHUNSUKE FUJISAWA (Presenter), SUSUMU FUKATSU, Graduate School of Arts and Sciences, University of Tokyo — The bandwidth limit is an issue in any class of physical measurements. To restore the original full-band spectrum from the available data sets that have been severely bandwidth-limited due to measurement is a challenge. Compressed sensing (CS), which is essentially an estimation based on L1 norm minimization, is a powerful technique to retrieve signals using a small number of clues on the assumption of sparsity. Here we attempt the CS in frequency domain to restore the otherwise lost part of the spectrum with good fidelity. The proof-of-concept experiment was done on a model system with bandwidth-limiting properties by first acquiring the prior knowledge of its step response in the form of discretized impulse response function. The original input waveform was mixed with random signal to spread the spectrum over the entire frequency range, i.e., omni-frequency heterodyne. Then the CS was implemented by using repetitive interleaved random sampling over the captured signals that are linearly coupled with the random mixing signals through the step response. Successful recovery of the original full-band spectrum with well over 70%-fidelity holds promise for high-Z and the many strongly bandwidth-limiting measurements. Single-shot and real-timeliness issues will also be discussed.
The Role of Noise in \textit{PT}-Symmetric Systems*  

BAHAR JAFARI ZADEH (Presenter), FRED M ELLIS, Wesleyan Univ — \textit{PT}-symmetric systems have provided a remarkable variety of phenomena related to signal manipulation ranging from unconventional state management to enhanced sensitivity at exceptional points. Although ideal models have been proposed for many different systems, the role of noise has typically not been the focus of previous papers. In this study, we compare the consequences of noise, both internally generated and externally received, between a non-\textit{PT} regenerative resonator and a \textit{PT} resonator pair. We show that, in general, there is no advantage of the \textit{PT} system from a signal-to-noise perspective.

*We acknowledge partial support from the National Science Foundation through awards DMR-1420451 and CMMI-1925543, and from Wesleyan University

Characterization of Acoustic Standing Waves Surrounding A Cylindrical Inertia Block in an Ultra-Low Vibration Facility*  

JULIET NWAGWU UME-EZEOKE (Presenter), YU LIU, JENNIFER E. HOFFMAN, Harvard University — In facilities working with scanning tunneling microscopes (STM), it has been found that the vibrations of the surface on which the STM is placed can significantly alter results. To mitigate this issue, more research is being done into low-vibration laboratories. The low-vibration facility at Harvard University employs a massive cylindrical inertia block mounted on pneumatic isolators. The block has been made cylindrical to avoid coupling of acoustic standing waves between the walls of the room and the inertial block. We have used COMSOL Multiphysics to perform finite element analysis to simulate coupling of the acoustic standing waves in the room to the resonant modes of the inertial block. To check the results of the simulation, a speaker is used to generate a range of frequencies in order to excite the block. We then measure the acoustic standing waves using a microphone.

*This work was funded by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4536, the STC Center for Integrated Quantum Materials, NSF Grant No. DMR-1231319, and NSF MRI Grant No. DMR-1828569.

Optimizing mechanical resonator sensitivity for thin film internal friction and shear modulus measurements*  

THOMAS METCALF (Presenter), XIAO LIU, BATTOGTOKH JUGDERSUREN, United States Naval Research Laboratory — The double-paddle oscillator is a mechanical resonator with an extremely high quality factor at liquid helium temperatures, enabling sensitiv measurements of the internal friction and shear modulus of thin film materials. Since its development more than twenty years ago, several energy loss mechanisms that establish its background quality factor have been identified and quantitatively modeled, including thermoelastic dissipation and attachment loss. Building on work that led to the successful design of a companion resonator (one that measures Young’s modulus), here we use Finite Element Modeling (FEM) of variations on resonator geometry to seek lower thermoelastic and attachment losses as well as to increase the frequency-space separation of resonant modes. Four candidate resonator geometries were identified and fabricated. We compare measurements of these designs to that of the standard resonator geometry.

*Work supported by the Office of Naval Research
9:00AM L10.00006: Progress on the Detection of Single Free Helium Atoms through Field Ionization for a Dark Matter Detector* DAVID OSTERMAN (Presenter), HUMPHREY J MARIS, GEORGE M SEIDEL, DEREK STEIN, Physics, Brown University —
We describe recent progress on the detection of free helium atoms by field ionization, which is a key element of a new liquid helium-based method of dark matter detection proposed by Maris, Seidel and Stein [1]. When a dark matter particle collides with a liquid He atom it produces phonons and rotons which propagate through the superfluid, eventually arriving at the surface. These excitations can then evaporate a He atom, which can then be detected through field ionization, the process of ionizing them in a strong electric field using sharp, metal nanotips. The ability of field ionization to detect even a single helium atom, combined with the < 1 meV binding energy of a He atom to the superfluid surface, could potentially allow for the detection of dark matter particles with masses down to 1 MeV/c².

9:12AM L10.00007: Digitizer nonlinearity correction with an AC Josephson Voltage Standard JASON M UNDERWOOD (Presenter), BRYAN C WALTRIP, Physical Measurement Laboratory, National Institute of Standards and Technology — High-fidelity conversion of physical measurement data to the digital domain is desirable in many fields of science. Numerous techniques are available for the correction of nonlinearities in analog-to-digital converters (ADCs). However, implicit in these methods is the availability of a source with a higher resolution and/or lower nonlinearity than that of the ADC under test, which is challenging to realize for ADCs with resolutions exceeding 20 bits. An AC Josephson Voltage Standard (ACJVS) is capable of generating pure tones with distortion below 1 part per billion and amplitude accuracies in the single parts per million. These characteristics make it an ideal source for evaluating nonlinearities in high-resolution digitizers commonly used in audio and dynamic force measurements. In this talk I will describe the framework for performing such nonlinearity corrections with the ACJVS, share results and limitations, and discuss possible ways that this technique can be used to account for phase distortion.
9:24AM L10.00008: Effect of chiral dopant and nanoparticles on liquid crystal based microlenses  
KELUM PERERA (Presenter), AHLAM NEMATI, TORSTEN HEGMANN, ANTAL ISTVAN JAKLI, Kent State Univ - Kent — Microlenses apply to optical devices such as biomimetic optical systems, optical fiber switches, light deflection devices, solar concentrators, etc. [1,2]. Piotr et al. [1] demonstrated and characterized chiral nematic liquid crystal (LC) films suspended in the transmission electron microscope (TEM) grids that form converging spherical microlenses when immersed in water. Here we report on the tunability of the focal length of the TEM grids suspended 4-cyano-4-pentylbiphenyl (5CB) microlenses by adding different concentrations chiral dopant CD1 (ZLI 811) and mixing chiral nanoparticles with 5CB to detect various sources of chirality and make various shapes of microlenses with tunable focal lengths. Additionally, the effects of chiral dopants on the hybrid alignment of LC microlenses is also presented.

8:00AM L15.00001: Observation of broad-band water wave guiding in shallow water*  
CLAUDIO FALCON (Presenter), FABIÁN SEPULVEDA, DIEGO GUZMÁN, RODRIGO VICENCIO, Univ de Chile — We report on the observation and characterization of broad-band wave guiding of surface gravity waves in an open channel in the shallow water limit. The wave guide is constructed by changing locally the depth of the fluid layer, which creates conditions for surfaces waves to propagate along the guide. We present experimental and numerical results of this shallow water wave guiding, which can be straightforwardly matched to the one-dimensional wave equation of shallow water waves. Furthermore, we also probe the possibility of wave guiding in curve guides and measure how this changes wave propagation.

8:12AM L15.00002: Designing an All-Carbon Membrane for Water Desalination* DAVID TOMANEK (Presenter), Michigan State University, ANDRII KYRYLCHUK, National Academy of Sciences of Ukraine — We design an all-carbon membrane for the filtration and desalination of water. A unique layered assembly of carbon nanostructures including graphite oxide (GO), buckypaper consisting of carbon nanotubes, and a strong carbon fabric provides high mechanical strength and thermal stability, resilience to harsh chemical cleaning agents and electrical conductivity, thus addressing major shortcomings of commercial reverse osmosis membranes. We use ab initio density functional theory calculations to obtain atomic-level insight into the permeation of water molecules in-between GO layers and across in-layer vacancy defects. Our calculations elucidate the reason for selective rejection of solvated Na\(^+\) ions in an optimized GO membrane that is structurally stabilized in a sandwich arrangement in-between layers of buckypaper, which are protected on both sides by strong carbon fabric layers.

8:24AM L15.00003: Separation and collision dynamics in biomimetic wind-driven fog harvesting AIDA SHAHROKHIAN (Presenter), Polymer Science, University of Akron, FAN KIAT CHAN, University of Illinois at Urbana-Champaign, JIANSHE FENG, Polymer Science, University of Akron, MATTIA GAZZOLA, University of Illinois at Urbana-Champaign, HUNTER KING, Polymer Science, University of Akron — In regions where foggy days are recurrent and other water sources scarce, harvesting fog is a practical solution. Physical and behavioral techniques developed over eons by plants and animals in these regions can provide useful insight to do it better. O.unguicularis, a Namib desert beetle, goes to the top of the sand dunes on foggy days and uses its forewings to intercept the inertial microdroplets carried by the wind. Adaptation of this beetle has been extensively studied through the lens of surface wettability and its role in transporting accumulated water. Yet, how the interaction between flow dynamics and surface topography of beetle elytra can induce collision of droplets and increase accumulation of water has not been considered. Here, we show in careful experiments accompanied by numerical flow simulations that surface morphology, independent of wettability, plays a dominant role in deposition efficiency of beetle-like geometries. Furthermore, we investigate the potential role of hydrodynamic forces in near collision dynamics where surface mechanics and texture can limit the possibility of collision. The results suggest that manipulation of the collision mechanism via geometry and mechanics can be an alternative driver of the physical adaptation of the fog basking beetles.
8:36AM L15.00004: Pair interaction between sedimenting polar objects in the Stokes regime*

ALYSSA CONWAY (Presenter), NARAYANAN MENON, RAHUL CHAJWA, SRIRAM RAMASWAMY, Univ of Mass - Amherst — We study triangles placed in a quasi-two-dimensional container and sedimented at low Reynolds number as a model of the stokesian sedimentation of polar objects. Individual polar objects, unlike non-polar axisymmetric objects, rotate as they sediment due to coupling between the orientational and translational degrees of freedom and ultimately reorient into stable orientations [Jayaweera, Mason, J. Fluid Mech. 22 (1965)]. In order to study the pair interaction between polar objects, we sediment pairs of triangles with initial conditions that include both stable and unstable orientations of the individual triangles. Surprisingly, none of the periodic motions observed [Chajwa, Menon, Phys. Rev. Lett. 122 (2019)] with non-polar object pairs are seen with pairs of triangles. Instead, we observe that triangles reorient and translate away from each other until both objects achieve a stable orientation. As a special case, we also observe that equilateral triangle pairs (which have three-fold, rather than polar, symmetry) continuously rotate in their steady state.

*We acknowledge funding from NSF DMR 1905698.

8:48AM L15.00005: Sedimenting disk arrays: waves and transient growth*

RAHUL CHAJWA (Presenter), RAMA GOVINDARAJAN, International Centre for Theoretical Sciences TIFR, Survey no. 151 Shivakote, Bengaluru 560089, NARAYANAN MENON, Physics Department, University of Massachusetts Amherst MA 01003, SRIRAM RAMASWAMY, Department of Physics, Indian Institute of Science, Bengaluru 560 012 — We study experimentally the Stokesian sedimentation (Re \(\sim 10^{-4}\)) of one-dimensional lattice of disks in a quasi two-dimensional geometry with trajectories of disk centres lying in a plane. We induce initial positional perturbations over a uniformly spaced configuration of disks with their separation vectors and normals aligned, and perpendicular to gravity. For various perturbation wavenumbers \(q\) and interparticle separations \(d\), we find two classes of behaviour: (i) wavelike propagation of orientations coupled with number-density fluctuations and (ii) clumping instability resembling that of spheres, decorated with orientations. We construct equations of motion using pairwise addition of forces and torques in an array of spheroids. Linear stability analysis of the dispersion relation predicts non-modal transient growth, which we observe experimentally; and a phase boundary in the \(q-d\) plane separating neutrally stable and unstable regimes, consistent with our experimental observations. We predict a critical density of the lattice of spheroids below which all wavenumbers are asymptotically linearly stable, showing that orientable particles need not be subject to the inevitable clumping instability of spheres.

Session L16 DQI: Quantum Annealing and Optimization II 201 - Yudong Cao, Zapata - Tag(s): Focus
Adaptive measurement approach towards controlling non-adiabatic transitions in quantum annealing

SALIL BEDKIHAL (Presenter), MEHMET CANTURK, YONGCHAO TANG, ANTONIO MARTINEZ, ADRIAN LUPASCU, University of Waterloo, SONG ZHANG, JUAN ATALAYA, BIRGITTA K WHALEY, University of California, Berkeley — Non-adiabatic transitions arising from extremely small energy gaps present a challenge to quantum annealing and adiabatic quantum computing. In realistic quantum annealing scenarios, one does not have a priori knowledge of the energy-spectrum and hence the location of minimum energy gaps; thereby making it difficult to design strategies that will slow down close to the points of enhanced transition probability out of the ground state. In this work, we present an adaptive annealing protocol based on measurement of the energy-level curvature. Numerical results are presented for a random transverse field Ising model. We also discuss the relationship between the measurement operator and the fidelity-susceptibility, a measure allowing analysis of quantum phase transitions in many-body systems.

Elucidating the interplay between non-stoquasticity and the sign problem

LALIT GUPTA (Presenter), ITAY HEN, Univ of Southern California — The sign problem is a key challenge in computational physics, encapsulating our inability to properly understand many important quantum many-body phenomena in physics, chemistry and the material sciences. Despite its centrality, the circumstances under which the problem arises or can be resolved as well as its interplay with the related notion of ‘non-stoquasticity’ are often not very well understood. In this study, we make an attempt to elucidate the circumstances under which the sign problem emerges and to clear up some of the confusion surrounding this intricate computational phenomenon. To that aim, we make use of the recently introduced off-diagonal series expansion quantum Monte Carlo scheme with which we analyze in detail a number of examples that capture the essence of our results.

8:24AM L16.00003: All-optical Ising machine by spatial light modulation  
DAVIDE PIERANGELI (Presenter), GIULIA MARCUCCI, CLAUDIO CONTI, Univ of Rome La Sapienza — A broad class of computationally intractable problems maps to the search of the ground state of a spin system. Quantum and classical setups that evolve according to an Ising Hamiltonian are thus emerging as novel computing architectures for solving combinatorial optimizations that cannot be tackled on large scales by conventional hardware. Among these, photonic platforms can process data at light speed and in parallel, through multiple spatial or frequency channels. However, the realized photonic Ising machines either involve a limited number of spins or electronic spin couplings or lack of scalability.

Here, we make use of optical spins that are encoded and controlled by spatial light modulation to realize a large-scale all-optical Ising machine [1]. We implement photonic spin configurations with an unprecedented number of interacting nodes that settle in the corresponding Ising ground state. The setup, which is based on the sole spatial coherence of light, suggests a scalable and efficient approach for optical computing. Our results open the route to Ising machines that exploit spatial degrees of freedom of light for parallel spin processing.

8:36AM L16.00004: Is Fault Welcoming Quantum Computing Realistic?*  
ELIOT KAPIT (Presenter), Physics, Colorado School of Mines, VADIM OGANESYAN, Physics, City University of New York — An error-corrected, fault tolerant quantum computer is one of the most important long term goals of quantum computing research. In these systems random noise is an obstacle that must be overcome through error correction. Here we explore a new possibility, fault-welcoming quantum computing, where a system can not only maintain a quantum speedup for a given (likely non-universal) class of quantum algorithms against realistic noise, but actually performs better than an idealized copy with no noise. We modify flux qubit quantum annealing by including random, coherent low-frequency oscillations in the directions of the transverse field terms during evolution. Through analytical and numerical calculations, we show that this produces a quantum speedup for finding ground states in the Grover problem and quantum random energy model, and thus should be widely applicable to other hard spin glass problems. Further, we show that this speedup should be resilient to two realistic noise channels, and that another channel, bath-assisted phase transitions, accelerates optimization and may outweigh the others, thus potentially making the system fault welcoming. The modifications we consider could be explored with current technology.

8:48AM L16.00005: Schrieffer-Wolff Methods for Annealing Qubits* RUDOLPH MAGYAR (Presenter), DAVID GEORGE FERGUSON, Northrop Grumman - Mission Systems — A robust method for characterizing the low-energy Pauli decomposition of coupled superconducting qubits is based on a generalization of Bravyi et al's Schrieffer-Wolff transformation but applied in infinitesimal steps [1]. This method has several desirable properties. The effective Hamiltonian remains block diagonal so that the computational subspace is completely decoupled from the non-computational one. The adiabatic connection terms generated by the time-dependence of the computational subspace are block off-diagonal and thus do not generate any terms within the computational subspace. This work is a continuation of work described last year focused on the readout of single flux qubits. Subsequent numerical advances now permit the extension of the method to interacting tunable flux qubits including novel flux qubits capable of implementing strong non-stoquastic interactions.

*This material is supported by the Intelligence Advanced Research Projects Activity (IARPA) through the Army Research Office (ARO) Contract No. W911NF-17-C-0050.

9:00AM L16.00006: Beyond Standard Quantum Annealing* [Invited] TAMEEM ALBASH (Presenter), University of New Mexico — Quantum annealing is typically studied (and experimentally realized) in terms of an interpolation between a driver and a problem Hamiltonian, often taken to be a uniform transverse field and an Ising Hamiltonian respectively. Nothing restricts the time-dependent Hamiltonian to take such a simple form, and greater control of experimental systems has revived the study of more exotic interpolations. We review recent work exploring new quantum annealing protocols, including adiabatic reverse annealing and the introduction of catalyst Hamiltonians. While providing an exponential improvement in performance for solving certain highly symmetric toy models, no recipe is known for how to use these new proposals to give performance enhancements more generally. This highlights the need for dramatically new insights and methods but also more experimental capabilities to further explore the performance of non-standard quantum annealing.

9:12AM L16.00007: A real-time path integral representation of driven quantum algorithms*

FRANK WILHELM, Univ des Saarlandes, DAVID K HEADLEY (Presenter), Group Research, Future Technologies, Daimler AG, Stuttgart, Germany, PETER SCHUHMACHER, Univ des Saarlandes — Both adiabatic quantum computing / quantum annealing and the quantum approximate optimization algorithm combine a problem Hamiltonian with a non-commuting driver Hamiltonian in order to efficiently explore the complete state space of an optimization problem. We develop a representation of such algorithms as a real-time path integral that directly and rigorously implements the otherwise colloquial idea that quantum algorithms follow all possible computations at the same time. We apply path integral techniques such as eikonals and semiclassics in order to provide a way to better understanding under which conditions we can expect these algorithms to reliably converge.

*Funded in parts by IARPA under the QEO program

9:24AM L16.00008: Updates to Hybrid Quantum-Classical Annealing*

PETER SCHUHMACHER (Presenter), ADITI MISRA, Univ des Saarlandes, SALIL BEDKIHAL, XI DAI, ADRIAN LUPASCU, University of Waterloo, FRANK WILHELM, Univ des Saarlandes — Last year. we proposed an efficient gap-independent cooling scheme for a quantum annealer that benefits from finite temperatures. We chose a system based on superconducting flux qubits as a prominent example of current quantum annealing platforms and proposed coupling the qubit systemtransversely to a coplanar waveguide to counter noise and heating that arise from always-present longitudinal thermal noise. We provide a schematic circuit layout for the system and showed we achieve global performance enhancements. However, the work covered only single-qubit annealing. In this work, we discuss different strategies to generalize HQCA to larger qubit numbers.

*The research is based upon work (partially) supported by the Office of the Director of National Intelligence(ODNI), Intelligence Advanced Research Projects Activ-ity (IARPA), via the U.S. Army Research Office con-tract W911NF-17-C-0050. 9:36 AM L16.00009: Non-stoquastic interactions of superconducting circuits in the low frequency regime* MARIUS SCHÖNDORF (Presenter), FRANK WILHELM, Univ des Saarlandes — Non-stoquastic interactions are hard to realize in experimental setups using superconducting qubits. On the other hand they are important or even necessary for the construction of adiabatic quantum computers which show a real quantum speedup. In ArXiv:1903.06139, Ozfidan et al. show that they can realize non-stoquastic qubit-qubit interactions in a superconducting circuit architecture. The non-stoquastic nature only appears when the system is restricted to the low energy qubit subspace, since the full circuit Hamiltonian itself is stoquastic. Here we study the origin of these non-stoquastic interactions arising when projecting stoquastic Hamiltonians to the low energy spectrum. For this we use different theoretical tools, e.g. renormalization group techniques.

*This work was funded by IARPA in connection with the quantum enhanced optimization (QEO) program.

9:48 AM L16.00010: Oscillatory quantum optimization methods applied to problems with large ground state bands* ZHIJIE TANG (Presenter), ELIOT KAPIT, Colorado Sch of Mines — RFQA is a promising new quantum method for solving optimization problems, where by adding local oscillations to transverse fields, it can provide a polynomial quantum speedup over traditional quantum annealing methods. Inspired both by the performance of RFQA in trial problems with few ground states, and by the phenomenology of NP-complete problems, we consider RFQA applied to problems with exponentially many ground states, but where these states are an exponentially small fraction of the total configuration space. We explore how accelerated thermalization in low energy bands can provide a potentially noise tolerant quantum speedup for optimization and machine learning.

*NSF grant (PHY-1653820)

10:00 AM L16.00011: How Quantum is the Speedup in Adiabatic Unstructured Search?* ITAY HEN (Presenter), Univ of Southern California — In classical computing, analog approaches have sometimes appeared to be more powerful than they really are. This occurs when resources, particularly precision, are not appropriately taken into account. While the same should also hold for analog quantum computing, precision issues are often neglected from the analysis. I will discuss in the above context the sensitivity of the quantum adiabatic unstructured search algorithm [Roland and Cerf, Phys. Rev. A 65, 042308 (2002)] against various types of imperfections and show that the speedup associated with the algorithm is generally not robust against the presence of finite precision. In addition, I will present a classical analog algorithm for unstructured search that can be viewed as analogous to the quantum adiabatic unstructured search algorithm and which provides a quadratic speedup over standard digital unstructured search.

*The research is based upon work (partially) supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office contract W911NF-17-C-0050.
Recent advances in adiabatic quantum computing and quantum annealers has centered around using more advance and novel Hamiltonians to solve optimization problems. One of these advances has centered around the development of driver Hamiltonians that commute with the constraints of an optimization problem. This approach has been shown to be able to use sparser connectivity to embed several practical problems on quantum devices in comparison to other methods. Designing the driver Hamiltonians that successfully commute with several constraints has largely been based on strong intuition for specific problems and with no general algorithm for arbitrary constraints. In this work, we develop an algebraic framework for reasoning about the commutation of Hamiltonians with linear constraints - one that allows us to classify the complexity of finding a driver Hamiltonian for a set of constraints as NP-Hard through a reduction to the Subset Equal Sums problem as well as design a simple algorithm to solve the problem for Hamiltonians with bounded number of higher body interaction terms.

8:00AM L17.00001: Strong photon coupling to the quadrupole moment of an electron in a triple quantum dot* [Invited] JONNE KOSKI, ANDREAS LANDIG, ETH Zurich, MAXIMILIAN RUSS, Department of Physics, University of Konstanz, JOSE CARLOS ABADILLO-URIEL, Department of Physics, University of Wisconsin-Madison, PASQUALE SCARLINO, BENEDIKT KRATOCHWIL, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zurich, GUIDO BURKARD, Department of Physics, University of Konstanz, SUSAN NAN COPPERSMITH, Department of Physics, University of Wisconsin-Madison, ANDREAS WALLRAFF, KLAUS ENSSLIN, THOMAS IHN (Presenter), ETH Zurich — We experimentally couple the photonic excitations of a superconducting microwave resonator to a single electron hosted in a quantum dot charge qubit. The two qubit states with a 4.3 GHz separation arise in a four-electron triple quantum dot formed by locally gating a two-dimensional electron gas in GaAs. We demonstrate strong electron-photon coupling via the quadrupole moment in a parameter regime with negligible dipole coupling. The quadrupolar qubit-photon coupling strength is estimated from the vacuum Rabi mode splitting to be $g_0/2\pi = 150$ MHz. The qubit can also be tuned into a regime where it operates as a conventional double quantum dot charge qubit dipole coupled to the resonator. The experiment is motivated by a recent proposal [1,2] which aims at avoiding decoherence by distant charge fluctuations. Using spectroscopy measurements we determine the decoherence rate of the quadrupolar qubit to be $\gamma_2/2\pi = 32$ MHz. Comparing the coupling of charge noise to the conventional dipolar qubit and the quadrupolar qubit, we find that the coherence of the system is limited by short-range charge noise originating from noise sources residing near the triple quantum dot.

8:36AM L17.00002: Efficient orthogonal control of tunnel couplings in a quantum dot array

TZU-KAN HSIAO (Presenter), CORNELIS VAN DIEPEN, UDITENDU MUKHOPADHYAY, Delft University of Technology, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zurich, LIEVEN M VANDERSYPEN, Delft University of Technology — Electrostatically defined semiconductor quantum dot arrays offer a promising platform for quantum computation and quantum simulation. However, crosstalk of gate voltages to dot potentials and inter-dot tunnel couplings complicates the tuning of the device parameters. To date, cross-talk to the dot potentials is routinely and efficiently compensated using virtual gates, but cross-talk to the tunnel barriers is currently compensated through a slow iterative process, due to exponential dependence of tunnel couplings on gate voltages. Here we show that the crosstalk on tunnel barriers can be compensated using a linear combination of gate voltages, since the exponential dependence applies to all gates. We demonstrate efficient calibration of crosstalk in a quadruple dot and define a set of virtual barrier gates as linear combinations of physical gate voltages. We then demonstrate orthogonal control of tunnel couplings in the quadruple dot using these virtual barrier gates. Our method marks a key step forward in the scalability of the tuning process of large-scale quantum dot arrays.

8:48AM L17.00003: Barrier-Controlled Multi-Qubit Exchange

HAIFENG QIAO (Presenter), YADAV KANDEL, University of Rochester, SAEED FALLAHI, GEOFF C GARDNER, MICHAEL MANFRA, Purdue University, JOHN NICHOL, University of Rochester — Heisenberg exchange coupling between neighboring electron spins in semiconductor quantum dots provides a powerful tool for coherent qubit manipulation in spin-based quantum computing and quantum information processing. Various other phenomena such as many body localization and time crystals in semiconductor quantum dots also require tunable exchange couplings. However, controlling multiple exchange couplings in large quantum dot arrays proves to be challenging, due to non-linear and non-local dependence of the exchange couplings on the confinement gate voltages. In this work we demonstrate simultaneous control of multiple barrier-induced exchange couplings in a four-qubit processor. We model the dependence of the exchange couplings on all barrier gate voltages, which provides a means of precisely and simultaneously controlling multiple exchange couplings. We demonstrate two-, three-, and four-qubit exchange oscillations, and compare the experimental data to the simulated predictions.

9:00AM L17.00004: Coherent Spin-State Transfer via Heisenberg Exchange*  YADAV KANDEL  
(Presenter), HAIFENG QIAO, University of Rochester, SAEED FALLAHI, GEOFFREY C. GARDNER, MICHAEL MANFRA, Purdue University, JOHN NICHOL, University of Rochester — Spin qubits in semiconductors are a promising scalable architecture for quantum computing. Long chains of spin qubits have already been realized in different semiconductor platforms but transferring quantum information throughout such chains is still a challenge. Here we present the first experimental demonstration of the coherent transfer of electron spin states back and forth across a chain of four quantum-dot spin qubits using Heisenberg exchange coupling between neighboring electrons, which arises from the overlap of their wavefunctions. We swap the spin states of a pair of electrons via precisely-controlled exchange pulses. Successive SWAP operations between different pairs can transfer a quantum spin state to a distant qubit, without moving any electrons. Because this method is scalable to long chains of spin qubits, coherent spin-state transfer using Heisenberg exchange will be useful in multi qubit operations, measurement-based entanglement swapping and gate teleportation, and error correction in spin-based quantum computers.

*This research was funded by the University of Rochester, ARO/LPS through Grant No. W911NF-17-1- 0260, and the DARPA DRINQS program through Grant No. D18AC00025.

9:12AM L17.00005: Noise-resilient driven exchange gate for quantum dot spin qubits*  
STEPHAN PHILIPS (Presenter), MAXIMILIAN RUSS, LIEVEN M VANDERSYPEN, Delft University of Technology — Spin qubits in silicon quantum dots are a promising candidate for high-fidelity quantum computation due to long decoherence times and fast operations. Demonstrations of single qubit gates with fidelities up to 99.9% have been shown [1,2]. Recent demonstrations of two-qubit gates show fidelities of 92-98% [2,3]. These two-qubit gate implementations are not robust against low-frequency charge noise, which couples in via the exchange interaction, causing a limited fidelity. We propose a simple yet effective scheme that is resilient against low-frequency charge noise. We use a combination of analytic calculations and numerical simulations under realistic conditions to obtain estimated gate fidelities greater than 99%, which allow for fault-tolerant two qubit gates. We directly compare these realizations with existing proposals and will present our experimental efforts towards achieving this goal.

*We acknowledge financial support from the Marie Sklodowska-Curie actions—Nanoscale solidstate spin systems in emerging quantum technologies—Spin-NANO, grant agreement number 676108 and from the European Research Council (ERC-Synergy).
**9:24AM L17.00006: Interplay of exchange and superexchange in triple quantum dots**

KUANGYIN DENG (Presenter), EDWIN BARNES, Virginia Tech — Recent experiments on semiconductor quantum dots have demonstrated the ability to utilize a large quantum dot to mediate superexchange interactions and generate entanglement between distant spins. This opens up a possible mechanism for selectively coupling pairs of remote spins in a larger network of quantum dots. We will describe our theoretical efforts to understand the controllability of superexchange interactions in these systems. We focus on a triple-dot system arranged in a triangular configuration and use configuration interaction calculations to investigate the interplay of superexchange and nearest-neighbor exchange interactions as the geometry and detuning of the mediating dot are varied. We also study how the strength and sign of the superexchange coupling depends on the number of electrons in the mediator. Our results can be used as a guide to assist further experimental efforts towards scaling up to larger, two-dimensional quantum dot arrays.

*This work is supported by the Army Research Office (W911NF-17-0287).

**9:36AM L17.00007: Coherent manipulation of three-spin states in a Si/SiGe triple quantum dot**

KENTA TAKEDA (Presenter), AKITO NOIRI, TAKASHI NAKAJIMA, JUN YONEDA, TAKASHI KOBAYASHI, SEIGO TARUCHA, RIKEN — Quantum dot arrays provide a promising platform for quantum information processing. In Si-based devices, recent technological advances make it possible to implement single- and two-qubit operations with high fidelities. A three-qubit system is a next step toward scaling up and it is particularly important for realizing a quantum error-correcting code. In this work, we demonstrate coherent manipulation of three individual spins in a Si/SiGe triple quantum dot by site-selective electric dipole spin resonance. Spins in the left and right dots are read out by a spin-selective tunneling technique while the center spin is measured by reading out the left spin subsequently to a controlled-rotation operation. We also report our recent progress on controlled-controlled-rotation where the resonance frequency of the center spin depends on both left and right spin states.

*This work was supported financially by Core Research for Evolutional Science and Technology (CREST), Japan Science and Technology Agency (JST) (JPMJCR15N2 and JPMJCR1675) and MEXT Quantum Leap Flagship Program (MEXT Q-LEAP) grant No. JPMXS0118069228.
9:48AM L17.00008: Full Permutation Dynamical Decoupling in an Encoded Triple-Dot Qubit
BO SUN (Presenter), HRL Laboratories, LLC — Dynamical decoupling (DD) sequences can mitigate decoherence induced by slowly varying interactions between a qubit and a bath by using appropriately timed qubit rotations. For an exchange only qubit encoded in the spins of three electrons, dynamical decoupling can be achieved by applying a series of full-SWAP operations on the constituent spins which fully permute their locations across the three dots [1]. Using gate-defined quantum dots in an enriched Si/SiGe device, we demonstrate that repeated applications of the full permutation sequence can echo low frequency charge and magnetic noise, resulting a dynamically decoupled coherence time of 100s of microseconds. We find that the first order DD sequence is susceptible to rotations about the Y-axis of the Bloch sphere, driven by either real magnetic field gradients or spin-orbit pseudo-gradients. Initializing the qubit along the Y axis renders the experiment insensitive to these errors, as implied by measurements of qubit leakage in this configuration. The resulting experiment is only sensitive to high-frequency noise sources and is similar to noise spectroscopy. We compare our results to simulations which include various types of high-frequency charge noise.

10:00AM L17.00009: Highly tunable exchange-only singlet-only qubit in a GaAs triple quantum dot
ARNAU SALA (Presenter), JØRGEN HOLME QVIST, JEROEN DANON, NTNU — Quantum-dot based exchange-only spin qubits offer fast manipulation and full electric control but decohere rapidly in the presence of Zeeman field gradients, such as those resulting from the hyperfine interaction with randomly polarized nuclear-spin ensembles in the dots. A solution is to encode the qubit in the decoherence-free subspace spanned by two four-particle singlet states in a quadruple-dot setup [1].

Here we propose an implementation of this singlet-only qubit in a triple quantum dot with a (1,4,1) charge occupation. In the central multi-electron dot, the interplay between Coulomb interaction and an out-of-plane magnetic field creates an energy spectrum with a tunable singlet-triplet splitting and this feature can be exploited to create a six-particle singlet-only qubit with a qubit splitting that can straightforwardly be tuned over several μeV by adjusting the external magnetic field. We confirm the full exchange-based electric control of the qubit and demonstrate its superior coherence properties due to its singlet-only nature.

10:12AM L17.00010: Correcting Distortion of Base-band Exchange Pulses in Quantum Dot Qubits  DAVID BARNES (Presenter), HRL Laboratories, LLC — Repeatedly identical control waveforms are necessary for high fidelity qubit control. In triple-dot exchange-only spin qubits, full Bloch-sphere control is achieved via baseband voltage pulses alone. This makes them sensitive to the effects of pulse distortion extending from kHz to GHz frequencies. Here we present a technique to correct the known distortion of our arbitrary waveform generators. The application of this correction lead to a reduction of single qubit infidelity from 0.5% to 0.2% as measured by the “blind randomized benchmarking” protocol [1]. Additionally, we will cover an extension to this routine where we are able to estimate and potentially correct residual pulse distortion using coherent qubit control experiments.

10:24AM L17.00011: Long-Distance Charge Transport in a Single Electron Conveyor Device in (Al,Ga)As  MATTHIAS KUENNE (Presenter), JARA-FIT Institute for Quantum Information, Forschungszentrum Juelich GmbH and RWTH Aachen University, D-52074 Aachen, Germany, STEFAN TRELLenkAMP, Helmholtz Nano Facility, Forschungszentrum Juelich GmbH, D-52425 Juelich, Germany, JULIAN RITZMANN, ARNE LUDWIG, ANDREAS WIECK, Lehrstuhl für angewandte Festkoerperphysik, Ruhr-Universität Bochum, D-44801 Bochum, Germany, HENDRIK BLUHM, JARA-FIT Institute for Quantum Information, Forschungszentrum Juelich GmbH and RWTH Aachen University, D-52074 Aachen, Germany — For the realization of scalable quantum computing architectures enabling topological error correction, a transfer of the qubit information over distances of at least a few microns is required for making space for signal vias and allowing for tiling of qubit registers with classical control-circuits. Instead of coupling qubits by employing surface acoustic waves, we chose a one-dimensional, gate-defined conveyor belt-like device layout where electrons are moved between qubit sites by translating the potential minima in which the electrons are trapped. Here, the direction and the velocity of the electron transport are not limited by the crystal’s properties.

In this talk, I will present a device designed to allow the shuttling of electrons over 7 µm with only four voltage signals, whereby in principle arbitrary distances are feasible. We employed high-yield, multi-layer electron beam lithography in order to fabricate the required 100 metallic gates. I will show results on pumping charges from one reservoir to the other by filling each potential minimum in the conveyor with up to five electrons. We observed charge transport which is independent of a bias voltage and linear in frequency.
10:36AM L17.00012: Computer-automated tuning procedures for semiconductor quantum dot arrays* ADAM MILLS (Presenter), MAYER M FELDMAN, Princeton University, CARA MONICAL, PHILLIP J LEWIS, KURT W LARSON, ANDREW M MOUNCE, Sandia National Laboratories, JASON PETTA, Princeton University — As with any quantum computing platform, semiconductor quantum dot devices require sophisticated hardware and controls for operation. The increasing complexity of quantum dot devices necessitates the advancement of automated data collection and control software. By automating the analysis of charge stability diagrams, we can easily create tools to tune charge occupancy and interdot tunnel couplings in our quantum dot arrays. We use an image analysis toolbox developed in Python to automate the calibration of virtual gates, a process that previously involved a large amount of user intervention. Moreover, we show that straightforward feedback protocols can be used to simultaneously tune multiple tunnel couplings in a triple quantum dot1.

10:48AM L17.00013: Designing CPHASE Gates with Arbitrary Phase by Structural Modification of the Fong-Wandzura Sequence DANIEL ZEUCH (Presenter), Peter Grünberg Institut, Forschungszentrum Jülich, NICHOLAS EVANS BONESTEEL, Department of Physics, Florida State University and NHMFL — We design efficient arbitrary CPHASE gates for exchange-only spin-based quantum computation in which quantum gates are carried out by sequences of exchange pulses acting on qubits encoded using three or more spins. The construction we present is motivated by our analytic derivation [1] of the Fong-Wandzura sequence [2], the shortest known pulse sequence for an exact CNOT gate (for a linear array of spins). This earlier derivation is based on a type of elevation of a simple five-pulse sequence consisting only of SWAP or trivial pulses, which captures the essential structure of the Fong-Wandzura sequence. In the present construction, we introduce and evaluate a modified simple five-pulse sequence consisting of four SWAP pulses and one pulse of arbitrary duration. We then show how this sequence can be elevated in a fashion similar to that of our Fong-Wandzura derivation, to yield a leakage-free entangling two-qubit sequence that carries out a gate operation locally equivalent to arbitrary CPHASE.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM
8:00AM L18.00001: New experimental approaches for exploring condensed matter physics
[Invited] AMIR YACOBY (Presenter), Harvard University — The magnetic fields generated by spins and currents provide a unique window into the physics of correlated-electron materials and devices. Proposed only a decade ago, magnetometry based on the electron spin of nitrogen-vacancy (NV) defects in diamond is emerging as a platform that is exceptionally suited for probing condensed matter systems: it can be operated from cryogenic temperatures to above room temperature, has a dynamic range spanning from DC to GHz, and allows sensor-sample distances as small as a few nanometers. As such, NV magnetometry provides access to static and dynamic magnetic and electronic phenomena with nanoscale spatial resolution.

While pioneering work focused on proof-of-principle demonstrations of its nanoscale imaging resolution and magnetic field sensitivity, now experiments are starting to probe the correlated-electron physics of magnets and superconductors and to explore the current distributions in low-dimensional materials. In this talk, I will review some of our recent work that uses NV center magnetometry to image skyrmions in thin magnetic films, measure the spin chemical potential in magnetic insulators, and image hydrodynamic electron flow in graphene.

8:36AM L18.00002: Virginia O Lorenz Invited Talk
[Invited] —

9:12AM L18.00003: Hybrid sensing approaches for quantum spin sensors* [Invited] MICHAEL FLATTÉ (Presenter), Univ of Iowa — Quantum sensing, for example using diamond NV spin centers, has been effectively demonstrated for magnetic and electric fields as well as to measure the local temperature. Novel methods using hybrid sensing modalities, in which auxiliary entities are exploited to interact with the quantum sensor, are now under intense investigation. These include using a nearby ferromagnetic particle with a freely orientable magnetization, which amplifies the magnetic field of a sensed object to the point where it can be detected by a quantum spin sensor. Here I will describe two recent proposals for hybrid sensing modalities. In the first proposal the magnetic field of the NV spin itself is used to generate a magnetic response from a nearby material, and the resulting magnetic field is detected by the spin center. This extends quantum sensing to diamagnetic materials, for which the magnetic susceptibility is the desired metric. In the second proposal single-photon detection by a photoreceptive molecule, which changes its conformation in response to the absorption of a photon, can be measured using quantum sensing of the resulting electric dipole change due to the new shape of the molecule. These results suggest many new hybrid modalities are possible based on current quantum spin sensors. This work done in collaboration with J. van Bree and N. J. Harmon.

9:48AM L18.00004: Defect spins in two-dimensional materials for quantum sensing and nanophotonics* [Invited]  LEE BASSETT (Presenter), University of Pennsylvania — Optically addressable spin defects like the diamond nitrogen-vacancy center enable versatile applications in precision sensing and nanoscale imaging. Related defects in other materials, especially two-dimensional materials such as hexagonal boron nitride (hBN), offer potential advantages and novel sensing capabilities. Van der Waals materials like hBN can host defects in a precise two-dimensional layer, at a surface that is potentially cleaner than that three-dimensional semiconductors. This talk will introduce the properties of optically active defects in hBN, focusing in particular on their room-temperature optical and spin properties [1,2]. We will also discuss the role of new materials and defects more broadly for use in quantum sensing and other applications in quantum science [3].

*This work was supported by the Army Research Office (W911NF-15-1-0589) and the National Science Foundation (DMR-1922278).

10:24AM L18.00005: What would you do with a quantum-limited torque magnetometer?* [Invited]  JOHN DAVIS (Presenter), Physics, University of Alberta — In the past decade, cavity optomechanics has demonstrated its awesome potential to bring quantum mechanics into the study of mechanical systems. Yet little work has been done to use cavity optomechanics for sensing applications, such as the study of condensed matter systems. At the University of Alberta, we have focused on harnessing cavity optomechanical detection to measure ever smaller moment of inertia resonators, thereby improving torque sensing. Combining this with low temperature operation, we have reached torque sensitivities on the order of $10^{-24}$ N m/√Hz, just ten times the device’s standard quantum limit. To date, we have used such cavity optomechanical torque sensors to explore nanomagnetic vortices, collective spin dynamics, and phase-shift keying applications, but potential quantum sensing applications are numerous. Looking forward, it will also be possible to use the toolbox of quantum optics such as single photon detectors and squeezed states, along with cavity optomechanics, to enable new frontiers of quantum sensing and to push beyond the standard quantum limit.

Light induced phase transitions in charge density waves

GEDIK (Presenter), Massachusetts Institute of Technology MIT — Upon excitation with an intense laser pulse, materials can undergo a non-equilibrium phase transition through pathways different from those in thermal equilibrium. The mechanism underlying these photoinduced phase transitions has long been researched, but many details in this ultrafast, non-adiabatic regime still remain to be clarified. To this end, we studied light induced phase transitions in two different charge density wave (CDW) systems. First, we investigated the photo-induced melting of a unidirectional CDW in LaTe$_3$. Using a suite of time-resolved probes, we independently track the amplitude and phase dynamics of the CDW. We find that a fast (approximately 1 picosecond) recovery of the CDW amplitude is followed by a slower re-establishment of phase coherence dictated by the presence of topological defects in CDW. Furthermore, after the suppression of the original CDW by photoexcitation, a different, competing CDW along the perpendicular direction emerges. The timescales characterizing the relaxation of this new transient CDW and the reestablishment of the original CDW are nearly identical, which points towards a strong competition between the two orders. Secondly, I will also report the realization of optical chiral induction and the observation of a gyrotropically ordered CDW phase in 1T-TiSe$_2$. Our results provide a framework for understanding other photoinduced phase transitions and for unleashing novel states of matter that are “trapped” under equilibrium conditions.

Quantum Beats by Lightwave Acceleration of Broken-Symmetry Supercurrents

JIGANG WANG (Presenter), Department of Physics and Astronomy, Iowa State University & Ames Laboratory — Light-induced supercurrents chart a path forward for the electromagnetic design of emergent materials phases and collective modes for quantum engineering applications. In this talk, I will discuss our recent progress towards applying this new tuning knob, enabled by using single- and few-cycle THz pulses, to reveal some distinguishing features of quantum systems: Anderson pseudo-spin precessions and higher harmonics forbidden by equilibrium symmetry, hidden emergent phases that are difficult to be accessed by other tuning methods, Higgs modes in unconventional superconductors. We will also discuss how to extend THz light-driven coherence and subcycle symmetry breaking for quantum control of other complex systems including topological matter, with implications on quantum gate and sensing applications.

*The author is grateful for collaborations with Ilias E. Perakis and Chang-Beom Eom. Work at Iowa State University was supported by the National Science Foundation.
Local Symmetry Breaking and Spin Momentum Locking in Cuprates Superconductors [Invited] ALESSANDRA LANZARA (Presenter), University of California, Berkeley — The 20th century has been dominated by the realization that symmetry and symmetry breaking are keys to much of the novel phenomena observed in physics today. Superconductivity for example requires both time-reversal and inversion symmetry, and the removal of one of these (e.g. time reversal through a magnetic field) leads to the suppression of the superconducting order. Recently however it has been realized that, even if the global symmetry of the system is retained, a local symmetry breaking can still induce a variety of novel fascinating behaviors. In this talk I will present the effect of local breaking of inversion symmetry in cuprates superconductors and show that this leads to unusual phenomena and the appearance of a non-zero spin polarization with a well-defined spin momentum locking, that is strictly linked to the Fermi surface topology.

These results were enabled by the combination of UV laser with a state-of-the-art time of flight spectrometer combined with exchange scattering, allowing to perform spin and angle resolved photoemission spectroscopy experiments with unprecedented spin, time, energy and momentum resolution.

Femtosecond Covariance Spectroscopy to Control Multimode Quantum Correlations* [Invited] DANIELE FAUSTI (Presenter), Università di Trieste e Elettra Sincrotrone Trieste — The vast majority of nonlinear optical spectroscopies work in an integrated mode, namely they use the mean-value signal, properly averaged over several stroboscopic repetitions. While ensuring an adequate signal-to-noise ratio, this approach relies strongly on pulse-to-pulse consistency and has thus motivated significant efforts in pursuit of perfect experimental stability. By contrast, we have developed a fundamentally different approach, named Femtosecond Covariance Spectroscopy (FCS), which identifies noise as a powerful and unique asset to access information that standard mean-value experiments miss. FCS is based on covariance rather than mean-value observables and relies on the study of multimode quantum correlations imprinted on stochastic ultrashort pulses by light-matter interactions. As a proof of principle, we have successfully applied such approach to the study of Raman-active vibrational modes excited through Impulsive Stimulated Raman Scattering (ISRS) in crystalline quartz. Nevertheless, the impact of FCS is not only limited to the field of condensed matter physics. Indeed, given the formal analogy between the quantum description of ISRS and optomechanical experiments, FCS could pave the way to a new generation of experiments in which the coupling between the electromagnetic field and the mechanical oscillator, could be reproduced by the interaction between light pulses and phonon modes.

Mariano Trigo Invited Talk [Invited] —

Wednesday, March 4, 2020 8:00 AM - 10:48 AM
8:00AM L20.00001: Tubulin shape controls the kinetics and mechanism of microtubule depolymerization*  
JONATHAN BOLLINGER (Presenter), ZACHARY IMAM, MARK STEVENS, GEORGE BACHAND, Sandia National Laboratories — Microtubules exhibit alternating phases of growth and shrinkage thought to be controlled by the conformation of tubulin dimers. Specifically, compression of tubulin due to the hydrolysis of GTP has been suggested to generate stress and drive catastrophic depolymerization. We use molecular dynamics simulations and ex vivo experiments to investigate how depolymerization is affected by the presence of uncompressed (unhydrolysed) dimers in the microtubule lattice. Both methods reveal exponential decay in the kinetics of depolymerization corresponding to the relative number of uncompressed dimers. This slowdown is accompanied by a morphological change from ram's horns to blunt-ended dissociation. Collectively these data show that uncompressed dimers can alter depolymerization consistent with promoting rescue events.

*This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the U.S. DOE's National Nuclear Security Administration under contract DE-NA0003525.
8:12AM L20.00002: Stutter: a Transient Microtubule Dynamic Instability Phase that is Strongly Associated with Catastrophe* [invited] SHANT MAHSEREJIAN, Pacific Northwest National Lab, JARED SCRIPTURE, AVA MAURO, University of Notre Dame, ELIZABETH LAWRENCE, MARIJA ZANIC, Vanderbilt, MARK ALBER, University of California, Riverside, HOLLY GOODSON (Presenter), University of Notre Dame — Microtubules (MTs) are dynamic polymers with critical roles in processes ranging from membrane transport to chromosome separation. Central to MT function is dynamic instability (DI), a behavior typically assumed to consist of growth and shortening, with sharp transitions in between. However, this two-state assumption disregards details in MT behavior that are evident in high-resolution data. For example, MTs exhibit growth rate variability, and pinpointing where transitions begin can be difficult when viewed at high spatiotemporal resolution. These observations suggest that MT behavior is more complicated than implied by standard quantification methods. To address these problems, we developed STADIA (Statistical Tool for Automated Dynamic Instability Analysis). STADIA’s methods are rooted in machine learning to objectively analyze and quantify macro-level DI behaviors exhibited by MTs. Applying STADIA to MT length-history data revealed a transient, intermediate phase that we term ‘stutter’, during which the rate of MT length change is smaller in magnitude than growth or shortening phases. Significantly, most catastrophe events in both simulations and experiments are preceded by stutters, suggesting that this newly recognized phase is mechanistically involved in catastrophes. Consistent with this idea, a MT anti-catastrophe factor (CLASP2γ) increases the likelihood of growth following a stutter phase in experiments. We conclude that STADIA enables unbiased identification of DI phases including stutters, producing more complete and accurate DI measurements than possible with classical analysis methods. Identifying stutters as a distinct and quantifiable phase provides a new target for mechanistic studies regarding DI phase transitions and their regulation by MT binding proteins.

8:48AM L20.00003: Molecular dynamics study of Katanin oligomers: A MT-severing enzyme* MANGESH DAMRE (Presenter), ROHITH ANAND VARIKOTI, RUXANDRA I DIMA, Univ of Cincinnati — Microtubule (MT) severing enzymes, such as katanin, belong to the AAA ATPases family and play an important role in meiosis and mitosis through their cutting action on MTs. The severing action is driven by ATP hydrolysis, which induces transitions between distinct conformations of the oligomeric state of the severing enzyme. Two of these oligomeric structures, one in a spiral and the other in a closed ring arrangement, have recently been solved using cryo-EM. ATP is present in all the chains from the spiral conformation, while there is only partial occupancy of ATP in the ring conformation. At the same time, reports from the literature suggest that such high-order oligomeric states of severing enzymes are stable only in the presence of nucleotides and the substrate. We will describe our all-atom molecular dynamics simulations performed on the apo, the ATP bound, and minimal substrate-bound states of katanin. Our results help identify the factors that account for the stability of the oligomeric states and characterize the allosteric transitions that underlie the action of severing enzymes.

9:00AM L20.00004: Role of substrate cooperativity and motor concentration in microtubule severing*  ROHITH ANAND VARIKOTI (Presenter), Univ of Cincinnati, JENNIFER L ROSS, Department of Physics, Syracuse University, RUXANDRA I DIMA, Univ of Cincinnati — Microtubules (MTs) associated proteins (MAPs) regulate the dynamic behavior of MTs during cellular processes. Severing enzymes are MAPs which destabilize MTs by removing subunits from the filament. Because severing enzymes belong to the AAA+ unfoldases family, we probed the severing mechanism characterized by the enzymes applying pulling forces on the C-terminal regions of MT subunits. Due to the large size of the system, we employed coarse grained molecular simulations of different MT lattices and at varying concentration of severing enzymes. Comparison of results from our simulations with data from in-vitro severing assays shows that the cooperative removal of protofilament fragments, at increased concentration of severing enzymes, is a likely MT destabilization scenario. Moreover, we found that optimization of energetics is not a strong requirement if severing proceeds entirely by an unfoldase mechanism.

9:12AM L20.00005: Dynamic stability of actin cytoskeletal networks with mixed geometries  PASHA TABATABAI (Presenter), LAURA LANIER, MICHAEL MURRELL, Yale University — Cells dynamically remodel their cytoskeleton while simultaneously utilizing it to carry out vital tasks such as migration and division. In cells, multiple distinct actin structures coexist, and it is unclear how this coexistence of multiple dynamic networks affects the stability of each network. To this end, we re-engineer a dynamic cytoskeletal system using a minimal set of purified proteins to simultaneously nucleate filamentous actin networks containing mixtures of both branched Arp2/3 and linear formin networks. With this system, we investigate the effect of coexistence of networks with different geometries and growth rates on steady-state structure. Additionally, we explore the influence of both filament severing activity and molecular motor activity on network stability.

9:24AM L20.00006: Actin crosslinking controls mobility, microtubule crosslinkers control co-localization in a composite cytoskeletal network*  LEILA FARHADI (Presenter), Physics, University of Massachusetts Amherst, MICHAEL RUST, Department of Molecular Genetics and Cell Biology, University of Chicago, MOUMITA DAS, School of Physics and Astronomy, Rochester Institute of Technology, RAE M ROBERTSON-ANDERSON, Department of Physics and Biophysics, University of San Diego, JENNIFER L ROSS, Physics, Syracuse University — Actin and microtubule filaments are cytoskeletal biopolymers with various vital roles in the cell. Despite decades of studying them separately, they have recently been shown to interact in networks mechanically and chemically. Here, we are interested in the composite network mechanics and mobility as the actin and microtubules are increasingly crosslinked. We use biotin-NeutrAvidin crosslinkers to irreversibly crosslink actin and MAP65, an antiparallel microtubule crosslinker to bundle microtubules. Cytoskeleton networks are imaged over time using fluorescent microscopy and the mobility characteristics are measured. We find that actin crosslinkers tune the mobility of this composite network, while microtubule crosslinkers can control the co-localization of actin and microtubules.

**Avalanches in simulations of branched actomyosin networks with the Arp2/3 complex**

JAMES LIMAN (Presenter), Department of Bioengineering, Rice University, CARLOS BUENO, Systems, Synthetic, and Physical Biology, Rice University, YOSSI ELIAZ, Department of Physics, University of Houston, NICHOLAS SCHAFTER, Center for Theoretical Biological Physics, Rice University, NEAL WAXHAM, Department of Neurobiology and Anatomy, McGovern Medical School at The University of Texas Health Science Center at Houston, PETER G WOLYNES, Center for Theoretical Biological Physics, Rice University, HERBERT LEVINE, Department of Physics, Northeastern University, MARGARET CHEUNG, Department of Physics, University of Houston — Actomyosin networks are ubiquitous in biology. They provide structure to cells and are involved in cell movement, growth, and division. The dynamics of actomyosin networks are active processes and are greatly influenced by actin binding-proteins (ABPs). These ABPs include both motor proteins (non-muscle myosin IIA heavy chain (NMIIA)) and cross-linker proteins (α-actinin). Another important ABP, the Arp2/3 complex, nucleates branched filaments thereby influencing the topology of the network. In this work, we simulate the spatiotemporal configurations of actomyosin networks with and without the Arp2/3 complex. The simulations show that the branched actomyosin networks that include the Arp2/3 complex exhibit sporadic convulsive movements, which we call avalanches, that release built-up stress in the network. We then identify and characterize these avalanches. The characteristics of these avalanches observed in the simulations are consistent with the recent experimental observation of “cytoquakes.”

**A dynamic contractile F-actin network reconstituted in Xenopus egg extract**

JIANGUO ZHAO (Presenter), CHRISTOPH F. SCHMIDT, Department of Physics and Soft Matter Center, Duke University — The actin cytoskeleton in most animal cells is a highly dynamic multi-component network that rapidly turns over, adapts, generates forces and moves. The continuous remodelling of the cytoskeleton and spontaneous flows have been extensively visualized in a variety of cellular processes, including intracellular transport, cell migration and division. It remains unclear how the spatiotemporal interactions of the various components self-organize to give rise to global F-actin flows. We reconstituted a fully active model cytoskeleton in water-in-oil emulsion droplets containing xenopus egg extract. We observed steady state directed flows and non-equilibrium phase separation. We analysed the flow and examined the contractile stress generated by actin-myosin interactions.
10:00AM L20.00009: Controlling ‘cell’ size and shape to elucidate the mechanics of microtubule aster positioning* [Invited]  
JAY GATLIN (Presenter), TAYLOR SULERUD, ABDULLAH SAMI, ZACH GEISTERFER, Molecular Biology, University of Wyoming, JOHN OKEY, Chemical Engineering, University of Wyoming — The microtubule (MT) cytoskeleton plays critically important roles in numerous eukaryotic cellular functions, and it does so across a functionally diverse and morphologically disparate range of cell types. In these roles, MT assemblies must adopt distinct cell cycle-dependent morphologies and physical dimensions to perform specific functions. During interphase, the MT network takes the form of a radial astral array (aster) that functions to center the nucleus, a by proxy the mitotic spindle, which ultimately dictates the position of the cell division plane. The mechanical underpinnings of this positioning phenomenon remain elusive despite its fundamental importance to both symmetric and asymmetric vision and intensive study. To address this gap in our collective understanding, we have combined photo-labile hydrogels with cell-free extracts in a new experimental platform that affords exquisite control of “cell” shape and volume. By observing the behavior/dynamics of MT asters confined in hydrogel micro-containers of different geometries, we have elucidated the relative contribution of MT-based pushing forces to aster positioning and have begun to characterize the length scales over which they operate.

10:36AM L20.00010: Active Composites of Actin and Kinesin-driven Microtubules*  
JOHN BEREZNEY (Presenter), SETH FRADEN, Brandeis Univ, ZVONIMIR DOGIC, Physics, University of California, Santa Barbara — Two major structural proteins, actin and microtubules, form multiple co-existing and interpenetrating filamentous protein networks within the cell cytoplasm. The out-of-equilibrium active reorganization of these structures by molecular motors is necessary for basic physiological processes such as cell division, cell motility, and environmental sensing. While the passive structure and mechanics of such materials have been well documented, the effects of their steady-state out-of-equilibrium reorganization is a site of current research. To demonstrate some of the mechanics governing the active reorganization of these materials, we have built a polymer blend of kinesin-driven microtubule networks which reorganize a passive entangled actin network. We find both the mechanics of the actin network as well as its initial structure can have dramatic effects on the steady-state behavior of the system. To capture the range of behaviors, we build a state diagram which captures the non-equilibrium phenomena we observe.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

8:00AM L21.00001: Development of a Machine-Learned Density Functional Tight Binding for TiH₂ Bulk and Surface Chemistry* NIR GOLDMAN (Presenter), Lawrence Livermore Natl Lab — Knowledge of chemical defect energies and kinetics is essential for assessing potential hydrogen storage materials like TiH₂, where hydrogen point defects need to be assessed accurately and efficiently. The Density Functional Tight Binding (DFTB) method is a highly efficient semi-empirical quantum approach that can accurately probe these properties, but can be challenging to parameterize for each system of interest due to the different bonding types that can occur. Here, we have created a machine learning-based approach for determining the DFTB models which is both rapidly optimized, systematically improvable, and highly transferable. Our method leverages the Chebyshev Interaction Model for Efficient Simulation (ChIMES), a reactive many-body molecular dynamics force field where interactions are represented by linear combinations of Chebyshev polynomials. In this work, we discuss our ChIMES/DFTB models for TiH₂, and show its accuracy for both bulk and surface properties. Our approach is easy to implement and can yield accurate DFTB models for a number of challenging materials and conditions where chemical events can be difficult to model with standard quantum approaches alone.

*Prepared by LLNL under Contract DE-AC52-07NA27344.

8:12AM L21.00002: Molecular Dynamics Modeling of Plasma Material Interactions using Machine Learned Interatomic Potentials* MARY ALICE CUSENTINO (Presenter), MITCHELL WOOD, AIDAN THOMPSON, Sandia National Laboratories — Multiple materials, namely tungsten and beryllium, will be present in future fusion reactors as plasma facing components. Experiments of beryllium implantation in tungsten indicate the formation of W-Be intermetallics on the surface, which can affect the performance of the tungsten divertor. Molecular dynamics (MD) can provide insight into physical processes related to experimental observations. However, MD is limited by the accuracy of the interatomic potential used. Recently, machine learning methods are being used to develop more accurate, quantum-informed potentials. In this work, we have developed a machine learned Spectral Neighbor Analysis Potential (SNAP) for W-Be and used this potential to study beryllium implantation in tungsten. An amorphous W-Be layer forms within the first 50 ns that is limited to the near surface region and an exchange mechanism that allows tungsten to migrate from the substrate into the amorphous layer was observed. Ordered structures similar to expected intermetallic configurations were seen within the amorphous layer. These results show the early stages of a surface W-Be layer that can provide further insight into the formation of the intermetallics observed in experiments.

*SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525
8:24AM L21.00003: Machine learning modeling of the Curie temperature for ferromagnetic intermetallics*

HONGBIN ZHANG (Presenter), TENG LONG, NUNO FORTUNATO, YIXUAN ZHANG, OLIVER GUTFLEISCH, Technische Universität Darmstadt — Magnetic materials play an essential role in green energy and informatics applications, such as efficient energy harvesting and conversion and low energy cost spintronic devices. Currently the key challenge is how to optimize the performance of existing systems and to design novel materials for broader applications. In this talk, a random forest model is trained to classify ferromagnetic and antiferromagnetic orderings and to predict the transition temperature ($T_C$) of the ferromagnets, using 2805 known intermetallic compounds. The resulting accuracy is 86% for classification and 92% for regression (with a mean absolute error of 58K), comparing favourably with first-principles methods. We apply these models to 5183 intermetallic compounds found in the Materials Project database, predicting their magnetic ordering and $T_C$. This enables us to make reliable predictions, particularly by combing high throughput and machine learning methods, paving the way to accelerate the discovery of novel magnetic compounds for technological applications.

*We thank the financial support from European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (Grant No. 743116-project Cool Innov) and the Chinese Scholarship Council.

8:36AM L21.00004: Comparison of Classical Molecular Dynamics and Ab initio Molecular Dynamics with Different Equilibration Methods for Modeling Solvent - Lithium Salt Systems in Lithium Air Batteries*

EMILY CRABB (Presenter), ARTHUR FRANCE-LANORD, GRAHAM MICHAEL LEVERICK, Massachusetts Institute of Technology MIT, RYAN STEPHENS, Shell International Exploration & Production Inc., YANG SHAO-HORN, JEFFREY C GROSSMAN, Massachusetts Institute of Technology MIT — Lithium-air batteries are an active area of research because of their potential to have a much higher energy density than traditional lithium-ion batteries. However, they are not yet commercially viable due to poor efficiency, high charging voltages, and low cycle lifetimes. In Li-air batteries, $O_2$ reduction starts when superoxide forms in solvent and reacts with $Li^+$ to form lithium superoxide ($LiO_2$). Solid $Li_2O_2$ then forms as the final discharge product on the cathode. Recent experimental work suggests that the choice of solvent and the presence of lithium salts in the system may have a large impact on how the discharge product forms at the cathode. We therefore modeled the clustering of lithium salt molecules in solvent without $LiO_2$ present with explicit solvent calculations using both classical and ab initio molecular dynamics simulations. For each ab initio simulation, we also used one of two equilibration procedures: (1) performing a classical molecular dynamics simulation or (2) performing shorter ab initio simulations at higher temperatures. A comparison of these computational approaches for properties such as coordination numbers will be presented.

*This work is supported by a grant from Shell, as well as partial support from a DOE fellowship.
8:48AM L21.00005: Benchmarking SCAN functional for two-dimensional crystal structures*
GRACIE CHANEY (Presenter), DANIEL WINES, JARON KROPP, FATIH ERSAN, CAN ATACA, Univ of Maryland-Baltimore County — It has recently been reported that the strongly constrained and appropriately normed (SCAN) meta-GGA functional has performed exceptionally well for density functional theory (DFT) calculations involving molecular and crystalline systems. In addition, the computational cost of SCAN is argued to be much less than that of the highly demanding hybrid functional methods with comparable accuracy. SCAN has been applied to several three-dimensional systems, but has not been widely used for two-dimensional materials such as transition metal (M) monochalcogenides (MX), M dichalcogenides (MX₂), and M trichalcogenides (MX₃). In this study, we provide a comprehensive set of data obtained by SCAN, hybrid functionals (HSE), and PBE. Specifically, we compare lattice constants, band gaps, electronic/thermal transport and magnetic properties, and computational cost. We also study optical properties with GW approximation, using DFT orbitals obtained from SCAN and PBE. Our goal is to benchmark results from SCAN, PBE, HSE, PBE+GW, and SCAN+GW and to create a detailed picture of how SCAN performs compared to other well established DFT functionals. This work is the terminal paper for benchmarking different DFT functionals and will guide further theoretical studies involving 2D materials.

*NDF DMR-1726213

9:00AM L21.00006: Theoretical study on the electric-double layer formed at interlayer of transition-metal-carbide MXene by quantum-classical hybrid interface simulation
YASUNOBU ANDO (Presenter), CD-FMat, AIST, MASASHI OKUBO, The University of Tokyo, MINORU OTANI, CD-FMat, AIST, ATSUO YAMADA, The University of Tokyo — Two-dimensional transition-metal carbide MXene has been known as a promising material of high-performance electrode for energy storage applications with both non-aqueous and aqueous electrolytes because it has electronic conductivity, ion capability in interlayer nanospace, and the redox activity of Ti. Here, we performed a microscopic theoretical analysis of the electric-double layer capacitance in the interlayer nanospace of the MXene electrode by combining first-principles calculations and implicit solvation theory named 3D-RISM method[1]. As a result, we found that hydration shell of Li⁺ and Na⁺ overscreens the electric field, or shows “negative dielectric constant”, and enhances its electronic-double layer capacity[2, 3].

First-principles analysis of band offsets, phase stability, and alkali incorporation in (Ag,Cu)(In,Ga)Se$_2$ solar cells*  KOSTIANTYN SOPIHA (Presenter), JES LARSEN, JAN KELLER, MARIKA EDOFF, CHARLOTTE PLATZER-BJÖRKMAN, Ångström Solar Center, Division of Solid State Electronics, Uppsala University, CLAS PERSSON, Department of Physics/Centre for Materials Science and Nanotechnology, University of Oslo, JONATHAN SCRAGG, Ångström Solar Center, Division of Solid State Electronics, Uppsala University — Over the years, thin-film photovoltaics based on Cu(In,Ga)Se$_2$ (CIGS) have undergone continuous improvements, with recent efficiency records indicating that CIGS is yet to unleash its full potential. Ag-alloying (forming ACIGS) is emerging as an exciting focus area, since ACIGS demonstrates better crystallinity and lower $V_{OC}$ losses than CIGS alone. In this work, we investigate the fundamental origin of these improvements by performing detailed first-principles analysis of ACIGS alloys. Based on the computed electronic properties, we establish a correlation between the composition and conduction band minimum, which allows rational tuning of band offsets at ACIGS/buffer (CdS or Cd-free) interface with a desired band gap of the absorber. From a thermodynamic analysis, we reveal the existence of a miscibility gap that can induce phase separation and Ag grading during thin film growth. Furthermore, from a defect analysis, we show that Ag promotes solubility of alkalis during post-deposition treatment. The obtained results are verified by measuring device and material characteristics for different ACIGS films, which showed a good agreement with the theoretical predictions.

*We thank Swedish Foundation for Strategic Research and Research Council of Norway for their financial support.

Accelerated Discovery of Efficient Solar Cell Materials Using Quantum and Machine-Learning Methods  FRANCESCA TAVAZZA (Presenter), KAMAL CHOU DHARY, Materials Measurement Lab, National Institute of Standards and Technology — Solar energy plays an important role in solving serious environmental problems and meeting the high energy demand. However, the lack of suitable materials hinders further progress of this technology. Here, we present the largest inorganic solar cell material search till date using density functional theory (DFT) and machine-learning approaches. We calculated the spectroscopic limited maximum efficiency (SLME) using the Tran–Blaha-modified Becke–Johnson potential for 5097 nonmetallic materials and identified 1997 candidates with an SLME higher than 10%, including 934 candidates with a suitable convex-hull stability and an effective carrier mass. Screening for two-dimensional-layered cases, we found 58 potential materials and performed $G_0W_0$ calculations on a subset to estimate the prediction uncertainty. As the above DFT methods are still computationally expensive, we developed a high accuracy machine-learning model to prescreen efficient materials and applied it to over a million materials. The data and tools are publicly distributed at: https://www.ctcms.nist.gov/~knc6/JVASP.html, https://www.ctcms.nist.gov/jarvisml/, https://jarvis.nist.gov/, and https://github.com/usnistgov/jarvis.
9:36AM L21.00009: Electrical property dominated promising half-Heusler thermoelectrics through high-throughput material computations*  SHUPING GUO (Presenter), TIANTIAN JIA, Institute of Solid State Physics, Chinese Academy of Sciences, SHASHWAT ANAND, Department of Materials Science and Engineering, Northwestern University, YONGSHENG ZHANG, Institute of Solid State Physics, Chinese Academy of Sciences, JEFF SNYDER, Department of Materials Science and Engineering, Northwestern University — Half-Heusler (HH) compounds are one of the state-of-the-art thermoelectric materials with high electrical properties. Here, we carry out high-throughput computations on 95 HH compounds. Using the thermoelectric properties of NbFeSb and ZrNiSn as the screening criterion, we filter out nine p-type and six n-type promising candidates with environmentally friendly elements. Scrutinizing their electronic structures, we find that the cooperative effects of high band degeneracy, small deformation potential, light band, and large phonon velocity contribute to the large power factor. It is interesting to notice that the electrical properties dominate the thermoelectric performance in HH compounds. Balancing the excellent electrical properties and relatively low thermal conductivities, three HH compounds are predicted to be promising thermoelectric candidates. Our work not only provides novel promising materials for future experimental investigation but also offers insights into understanding the underlying physical nature of high thermoelectric performance.

*We acknowledge supports from the National NSF of China (grant no. 11774347), the “Designing Materials to Revolutionize and Engineer our Future” program of the NSF under Award No. 1729487 and the U.S. DOE, Office of EERE.

9:48AM L21.00010: Computational Discovery of an Enormous Class of Stable Quaternary Chalcogenides with Very Low Lattice Thermal Conductivity  KOUSHIK PAL (Presenter), CHRISTOPHER MARK WOLVERTON, Northwestern University — The development of efficient thermal energy management devices such as thermoelectrics, barrier coatings, and thermal data storage disks relies on compounds which possess low lattice thermal conductivity ($\kappa_l$). Here, we present an enormous class of thermodynamically stable quaternary chalcogenides $\text{AMM'}\text{Q}_3$ (A=Alkali, alkaline earth, post transition metals; M,M'=transition metals, lanthanides; Q= chalcogens) that possess intrinsically low $\kappa_l$ using high-throughput DFT calculations. Leveraging the computed energetics of hundreds of thousands of multinary compounds in the Open Quantum Materials Database (OQMD), we discovered a large number (nearly 1000) of thermodynamically stable chalcogenides through successive screening based on the calculations on multiple crystallographic prototypes of the experimentally known $\text{AMM'}\text{Q}_3$ compounds. We validate the low-$\kappa_l$ in this family of compounds by calculating the lattice thermal conductivity taking several representative compounds using the highly accurate anharmonic lattice dynamics methods. Our predictions suggest new experimental research opportunities in the synthesis and characterization of these stable, low-$\kappa_l$ compounds.
10:00AM L21.00011: Electron-phonon scattering effects on the transport properties of ZrS$_2$

HITOSHI MORI (Presenter), MASAYUKI OCHI, KAZUHIKO KUROKI, Osaka Univ — Multi-valley structure is known as one of the favorable band structures for enhancing thermoelectric efficiency. N-type TiS$_2$ has electronic structure with multi-valley character, and its power factor is relatively high: ~40 μW/cmK$^2$ at room temperature. In previous experimental studies, the electrical resistivity of TiS$_2$ has been found to exhibit strong temperature dependence of ~T$^2$. One of the previous studies indicated that inter-valley scattering among conduction band valleys may be related to the peculiar temperature dependence of the electrical resistivity [1].

Since understanding the inter-valley scattering effect on the transport properties may provide a clue toward designing materials with higher thermoelectric efficiency, in the present study, we perform DFT calculations and calculate the electronic transport properties by considering the electron-phonon scattering effect using the EPW code [2]. As a target material in this study, we consider not TiS$_2$, but instead its analogous compound ZrS$_2$. We will discuss the role of the inter-valley scattering played in the electronic transport properties of ZrS$_2$.

10:12AM L21.00012: Li and Na migration in Guest-free, type I clathrates evaluated via ab initio methods*

XIHONG PENG (Presenter), ANDREW DOPILKA, CANDACE CHAN, Arizona State Univ — Open, cage-like clathrates Tt$_{46}$ (Tt = Si, Ge, Sn) has a potential as anodes in Li/Na-ion batteries. Density-functional theory calculations were performed to explore ionic mobility of Li/Na through clathrate crystals. Local energy minima of Li/Na locations inside the clathrates were determined, the Li/Na migration paths/barriers were calculated using nudged elastic band method. It was found that it is favorable for Li to occupy the Tt$_{20}$ cage center while preferring the off-center positions in larger Tt$_{24}$ cages. The lowest Li migration barriers were found to be 0.35, 0.13 and 0.37 eV for Si$_{46}$, Ge$_{46}$, and Sn$_{46}$, respectively. In contrast, Na shows preference for the cage centers and higher migration barriers than Li. In general, the Tt$_{24}$ channels in the guest-free, type I clathrates are ideal for fast Li diffusion, while Na is too large to migrate effectively between cages. The energy landscape for Li inside the clathrates is uniquely different than that in diamond allotropes, leading to significantly lower energy barriers for Li migration. These results suggest that open frameworks of intermetallic clathrates may enable facile Li migration and have potential as anodes in Li-ion batteries.

**10:24AM L21.00013: Effect of Bulk Diffusivities of Co-solvents on the Microscopic Dynamics of an Ionic Liquid**  
NARESH C OSTI (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, RAY MATSUMOTO, MATTHEW THOMPSON, PETER THOMAS CUMMINGS, Chemical and Biomolecular Engineering, Vanderbilt University, MADHUSUDAN TYAGI, NIST Center for Neutron Research, National Institute of Standards and Technology, EUGENE MAMONTOV, Neutron Scattering Division, Oak Ridge National Laboratory — Room temperature ionic liquids (RTILs) are considered superior over organic electrolytes in terms of their thermal stability, volatility, voltage window, and device life expectancy, making them promising electrolyte materials for electrical double layer capacitors. However, pure RTILs often exhibit high viscosity, low conductivity, and poor diffusivity, which can affect the charging and discharging rates, impacting device performances. The addition of co-solvents is found to change the viscosity of RTILs, leading to improved physico-chemical characteristics that affect their bulk and interfacial properties. Even though a direct correlation of co-solvent polarity with cation diffusivity has been established, an impact of co-solvent bulk diffusivity on the cation dynamics of RTILs has never been explored. Here, using different neutron scattering spectrometers and molecular dynamics simulation, we showed a presence of a phase separation into an ionic liquid-rich and a solvent-rich phase of 1-butyl-3-methyl-imidazolium bis(trifluoromethylsulfonyl)imide, [Bmim$^+$][TFSI$^-$], mixed with four different co-solvents of nearly the same dipole moment, where we observed a scaling of long-range translational mobility of the [Bmim$^+$] cation with the bulk diffusivities of the organic solvents.

**10:36AM L21.00014: Properties of V$_2$O$_5$ polymorphs from first principles**  
SAKTHI KASTHURIRENGAN (Presenter), HARTWIN PEELAERS, Univ of Kansas — V$_2$O$_5$ is a very promising battery electrode material that can intercalate not only Li, but also more abundant alkaline metals such as Na and K, and even multivalent ions such as Mg, Ca, Zn, and Al. V$_2$O$_5$ can occur in several polymorphs, with at least 5 different polymorphs observed. During intercalation phase transitions can take place, and such phase transitions can be detrimental to battery performance. Understanding these transitions requires knowledge of the energetics and structural properties of the various V$_2$O$_5$ polymorphs.

We provide such understanding by employing density functional theory (DFT) calculations based on hybrid functionals. Since several of the polymorphs are layered, van der Waals interactions are important. However, this interaction is not included in standard DFT calculations. We therefore tested several approaches to include these interactions in combination with hybrid functionals. Based on our results we discuss the structural and electronic properties of the various polymorphs, and show the role polarons play in electronic transport. The obtained insights can be used to optimize future V$_2$O$_5$-based battery electrodes.
Computational Design and Study of Small D-A Type Organic Molecule with Ambipolar Characteristics and Rich Linear and Non-Linear Optical Properties

DWAIPAYAN CHAKRABORTY (Presenter), PRIYA JOHARI, Shiv Nadar Univ — Push-pull type small organic molecule has recently gained a huge scientific research owing to their remarkable charge transfer properties, high non-linear optical response, reduced HOMO-LUMO gap and hence broad range of absorption spectrum, air stability etc. which collectively promotes this class of molecules as potential candidate for non-linear optical devices, OFETs and organic solar cells. In this effort, we therefore rationally designed a promising Donor(D)-π-Acceptor(A) (i.e, push-pull) type molecule NNDM-NH$_2$, a trans-stilbene derivative. We predicted its crystal structure starting from the experimental crystal structure of another stilbene derivative and calculated the charge transport properties, electronic band structure, gas-phase linear and non-linear optical properties. We also did the Hirshfeld surface analysis and plotted the molecular electrostatic potential to get insight into the structure-property correlation. We found that this new organic semiconductor owns a high charge carrier mobility for hole and electron, together with desirable electronic and linear and non-linear optical properties revealing NNDM-NH$_2$ as a potential candidate for the opto-electronic devices.

8:00AM L22.00001: Filament Nucleation Tunes Mechanical Memory in Active Polymer Networks* [Invited] VIKRANT YADAV, Yale University, DEB BANERJEE, Physics, University College London, ALAN TABATABAI, Yale University, DAVID KOVAR, Division of Biological Sciences, University of Chicago, TAEGYOON KIM, Biomedical Engineering, Purdue University, SHILADITYA BANERJEE, Physics, University College London, MICHAEL MURRELL (Presenter), Yale University — Incorporating growth into contemporary material functionality presents a grand challenge in materials design. The F-actin cytoskeleton is an active polymer network which serves as the mechanical scaffolding for eukaryotic cells, growing and remodeling in order to determine changes in cell shape. Nucleated from the membrane, filaments polymerize and grow into a dense network whose dynamics of assembly and disassembly, or ‘turnover’, coordinates both fluidity and rigidity. Here, we vary the extent of F-actin nucleation from a membrane surface in a biomimetic model of the cytoskeleton constructed from purified protein. We find that nucleation of F-actin mediates the accumulation and dissipation of polymerization-induced F-actin bending energy. At high and low nucleation, bending energies are low and easily relaxed yielding an isotropic material. However, at an intermediate critical nucleation, stresses are not relaxed by turnover and the internal energy accumulates 100-fold. In this case, high filament curvatures template further assembly of F-actin, driving the formation and stabilization of vortex-like topological defects. Thus, nucleation coordinates mechanical and chemical timescales to encode shape memory into active materials.

8:36AM L22.00002: Bioinspired materials with self-adaptable mechanical behaviors* SANTIAGO ORREGO, Temple University, ZHEZHI CHEN, URSZULA KREKORA, DECHENG HOU, SEUNG-YEOL JEON, MATTHEW PITTMAN, Johns Hopkins University, CAROLINA MONTOYA, Temple University, YUN CHEN, SUNG KANG (Presenter), Johns Hopkins University — Nature produces outstanding biomaterials for structural applications such as bones and woods that can adapt to their surrounding environment. However, it is a challenge for synthetic materials to change and adapt their structures and properties to address the changes in loading conditions. To overcome the issue, we have investigated synthetic materials inspired by bone that trigger mineral syntheses from ionic solutions on scaffolds upon mechanical loadings so that they can self-adapt to mechanical loadings. For example, we observed a 30-180% increase in the modulus of the material upon different magnitudes of periodic loadings. Moreover, the mechanism allows a one-step route for making graded materials by controlling stress distribution along the scaffold. The findings can contribute to addressing the current challenges of synthetic materials for load-bearing applications from self-adaptive capabilities.

8:48AM L22.00003: The continuum of allosteric behavior in mechanical networks  JASON ROCKS (Presenter), Physics, Boston University, ANDREA JO-WEI LIU, ELENI KATIFORI, Physics and Astronomy, University of Pennsylvania — Allosteric regulation in proteins is often accompanied by conformational transitions, facilitating the transmission of mechanical signals between distant ligand binding sites. Analyses of allosteric proteins have revealed a variety of archetypal motions ranging from hinge-like or shear mechanisms to allosteric strain pathways connecting different binding sites. Here we investigate the range of possible motions that can be achieved in mechanical networks tuned to perform allostery. Using an analysis based on persistent homology, we develop a description of allosteric motion which quantifies and unifies all mechanisms into a single framework. We show that while some networks fall into distinct classes of archetypal designs, most fall along a continuum consisting of combinations of hinges, strain pathways and isostatic architectures. We apply this analysis to a collection of proteins, allowing us to identify potential sets of residues that are important for facilitating allosteric communication between different binding sites.

9:00AM L22.00004: A microfluidic model of periarterial spaces in the glymphatic system* KEELIN QUIRK (Presenter), KERSTIN N. NORDSTROM, Mt Holyoke Coll, DOUGLAS H KELLEY, University of Rochester — In the glymphatic system, cerebrospinal fluid enters through periarterial spaces and removes metabolic waste from the brain's interstitial spaces. Previous experiments in live mice have found that a wave along artery walls produced by the heartbeat induces flow in the surrounding perivascular space. However, the mechanisms driving the flow are still not well understood, as many mechanisms may be acting simultaneously. We have designed microfluidic devices to serve as two-dimensional models of periarterial spaces. Using particle tracking velocimetry, we analyze induced flow driven by a peristaltic wave at the frequency range representative of human heartbeats. We find the overall bulk flow induced by the membrane wave travels in the same direction as the wave and increases with frequency. However, during an individual pump cycle, we observe both forward and backwards flow. We also measure the phase shift of the induced flow.

9:12AM L22.00005: Ultrafast Finger Snap is Mediated by a Frictional Skin Latch  RAGHAV
ACHARYA (Presenter), ELIO CHALLITA, SAAD BHAMLA, Chemical and Biomolecular Engineering, Georgia
Institute of Technology — The snap of a finger is a ubiquitous motion that has been seen across
cultures and times. Using high-speed imaging, we analyze finger snap dynamics for the first time.
We find that the mechanics of the snap are strongly mediated by human skin friction, which acts
as a latch to generate rapid motion. The skin frictional latch is optimally tuned to enable
maximum kinematic performance as the angular accelerations observed during a snap are one
of the fastest human motions known. A simple scaling relationship is found that links the latch
geometry to the performance of snapping motion across multiple organisms from termites to
humans. Ultimately, our work reveals how friction between surfaces can be harnessed as tunable
and scalable latching mechanism, with applications ranging from increasing grip in biomedical
prosthetic surfaces to generating high force and accelerations in tiny robots.

9:24AM L22.00006: Unveiling Interfacial Properties of Surfactant Assemblies Mimicking
Healthy and Diseased States in Lung Membranes*  MARILYN PORRAS-GOMEZ (Presenter),
CECILIA LEAL, University of Illinois at Urbana-Champaign — Lipid-protein complexes conform the
basis of pulmonary surfactants covering the respiratory surface and mediating gas exchange in
lungs, yet how they contribute to alveoli membrane functions in healthy and diseased conditions
is not sufficiently understood. Alveolar stability appears to be controlled by the passive elastic
properties of the pulmonary tissue as well as the mechanical performance of the surfactant
membranes and an unbalance of these is associated with different respiratory dysfunctions and
pathologies. Cardiolipin is a mitochondrial lipid overexpressed in mammalian lungs infected by
bacterial pneumonia, likely to play a role in alveolar stability. We performed structural and
mechanical characterization by GISAXS, AFM and Fast Force Mapping on lipid-based mimicking
pulmonary membranes in healthy and diseased states. Our preliminary results unveiled that
pulmonary membranes suffer structural transformations induced by cardiolipin and calcium
ions. Membrane contacts, or stalks, might induce a significant increase in oxygen gas permeation
that can lead to imbalance in alveoli gas exchange.

9:36AM L22.00007: Hybrid active matter: particles and cellular aggregates*  FRANCOISE BROCHARD-WYART (Presenter), PhysicochimieCurie, Institut Curie — We investigate the collective migration of cell on adhesive substrates, using 3D cellular aggregates as a model system. Aggregates spread by expanding outwards a cell monolayer, which may dewet, causing the aggregates to move as “Giant Keratocytes”. We interpret this motion by a symmetry-breaking of cell polarity in analogy to active droplets.

We then describe mixture of dead and living matter and how microparticles play with cells. The size of the particles is varied from nanometers to few microns. Nanoparticles (size 20nm) can be used as a glue “nanostickers” to stick cells together and have important applications for cellular therapy and cancer treatment. Micro-particles MiPs (size ≈ micron) are used to study the spreading of cell aggregates on substrates decorated with MiPs. A cell monolayer expands around the aggregate. Cells at the periphery uptake the microparticles “gluttonous cells” by phagocytosis, forming an aureole of cells full of particles. Macro-particles MaPs (size ≈10 microns) are too big to be eaten and they are put into active motion “dancing”. We study also phase separations in hybrid particles -cells aggregate versus beads volume fraction.

9:48AM L22.00008: The role of heterogeneous environments and docetaxel gradients in the emergence of polyploid, mesenchymal and resistant prostate cancer cells.*  ROBERT AUSTIN (Presenter), Princeton University — The ability of a population of PC3 prostate epithelial cancer cells to become resistant to docetaxel therapy and progress to a mesenchymal state remains a fundamental problem. The progression towards resistance is difficult to directly study in heterogeneous ecological environments such as tumors. In this work, we use a micro-fabricated “evolution accelerator” environment to create a complex heterogeneous yet controllable in-vitro environment with a spatially-varying drug concentration. With such a structure we observe the rapid emergence of a surprisingly large number of polyploid giant cancer cells (PGCCs) in regions of very high drug concentration, which does not occur in conventional cell culture of uniform concentration. This emergence of PGCCs in a high drug environment is due to migration of diploid epithelial cells from regions of low drug concentration, where they proliferate, to regions of high drug concentration, where they rapidly convert to PGCCs. Such a mechanism can only occur in spatially-varying rather than homogeneous environments.

10:00AM L22.00009: Predicting Pericellular Matrix Structure from Simple Models of Hyaluronan Secretion* JAN SCRIMGEOUR (Presenter), Clarkson Univ — The synthesis and release of hyaluronan (HA) from the surface of living cells is essential to the maintenance of living tissues and fluids. HA synthesis is controlled by the hyaluronan synthase enzyme, which assembles the polymer chain, and extrudes it through the cell membrane before it is released into the extracellular space. This enzymatic process forms a critical link between the state of the cellular system (protein expression, metabolism, etc) and the properties of cellular interfaces, the extracellular matrix and many biofluids. I present a simple kinetic model that allows an examination of the secretion process. This model enables simulation of the synthesis and release process, enabling prediction of the molecular weight distributions of HA that are tethered to, and released from the cell surface. In so doing this model offers direct insight into the structure of the pericellular matrix, a cell tethered, hyaluronan-rich interface that mediates many cell processes such as adhesion and cell surface access. In addition, the simulations suggest that time-resolved analysis of the hyaluronan molecular weight distributions produced by living cells after PCM digestion can reveal critical details of hyaluronan synthase function.

10:12AM L22.00010: Electrical detection of Hachimoji nucleobases via a nanopore device incorporated in a graphene/h-BN heterostructure* GANESH SIVARAMAN, Argonne Leadership Computing Facility, Argonne National Laboratory, FABIO ARTHUR LEAO DE SOUZA, Instituto Federal do Espírito Santo, MARIA FYTA, Institute for Computational Physics, University of Stuttgart, RALPH HENDRIK SCHEICHER, Department of Physics and Astronomy, Uppsala University, WANDERLA L. SCOPEL, Department of Physics, Universidade Federal do Espírito Santo, RODRIGO G. AMORIM (Presenter), Department of Physics, ICEx, Universidade Federal Fluminense - UFF — Solid-state nanopores based on 2D materials have been proposed as a candidate for next generation sequencing (NGS) to achieve high throughput, label-free DNA and protein sequencing at low costs. A recent endeavor in synthetic biology resulted in the creation of stable DNA/RNA systems based on 8 (`hachi`) letter (`moji`) building blocks (i.e. 4 synthetic and 4 natural nucleobases) [1]. Although mutations and methylations of the natural nucleobases have been extensively investigated, synthetic nucleobases reported in the hachimoji system remain unexplored with such NGS methods. Hence in this talk, we propose a computational study based on density functional theory and non-equilibrium Green’s function formalism, to unravel the electrical read-out of synthetic and natural nucleobases. To this end, we propose a hybrid 2D nanopore formed in a graphene nanorod embedded within hexagonal boron nitride to perform the electrical read. We will go on to show that the proposed hybrid 2D nanopore can qualitatively discriminate natural and synthetic nucleobases.

10:24AM L22.00011: Modeling the rheology of dense biological tissues JUNXIANG HUANG
(Presenter), DAPENG BI, Northeastern University — Shear forces in tissues are prevalent in many important biological processes including embryonic development, organogenesis and tumor invasion. However, the intercellular transmission of shear forces and the rheological response of a tissue remains poorly understood. In this work, we use a minimal vertex-based model to investigate the rheology of confluent epithelial tissues. We systematically probe the effects single-cell stiffness, polarized cell motility and the strain rate on the monolayer stress. We also elucidate how the interplay of these parameters affect the cellular rearrangements such as T1 transitions and the statistics of cell shapes in the tissue.

Session L23 DBIO GSNP: Physics of the Brain: Structure and Dynamics

8:00AM L23.00001: A structured representation of odors in the fly mushroom body* [Invited] JIE-YOON YANG, ELIZABETH J HONG (Presenter), Division of Biology & Biological Engineering, California Institute of Technology — The mushroom body (MB) is a third-order olfactory area in the insect brain required for adaptive olfactory behaviors, such as learning odor associations, and is loosely analogous to olfactory cortex in mammals. In the vinegar fly Drosophila melanogaster, the chemical selectivity of each of the ~2200 principal neurons of the MB, called Kenyon cells (KCs), is determined by the pooling of odor information from a small random subset of the ~50 channels of olfactory input. The random integration of olfactory inputs in KCs contrasts with connectivity rules in other third-order olfactory areas, such as the lateral horn, where feature selectivity is determined by the invariant integration of specific combinations of olfactory inputs. The distinct connectivity statistics in different third-order olfactory areas has led to the idea that odor representations in the MB are “unstructured” and individualized in every brain, and must acquire meaning through learning, whereas invariant, chemotopic representations in the lateral horn support innate behaviors. We present a method using genetically enabled, in vivo two-photon functional imaging to measure near complete population representations of odors in KCs. We find that the relationship among neural representations of odors in the MB is invariant across individual brains. Furthermore, we apply a simple computational model of MB odor responses to illustrate that sparse, random connectivity can result in invariant relationships among odor representations, the structure of which is at least partially dictated by the correlational structure of the peripheral olfactory code. However, the experimentally observed structure of MB representational space deviates significantly from the predictions of the model for some regions of odor space. We discuss possible reasons for this discrepancy and future experimental directions to distinguish among these possibilities.

8:36AM L23.00002: Inferring causality in highly-synchronized dynamics*  JOSUAN CALDERON (Presenter), GORDON BERMAN, Emory University — The brain is a complex system with intricate neural dynamics, exhibiting interactions that are thought to be crucial for emergent cognitive functions. Causality methods provide a powerful tool for the characterization of these functional circuits by identifying directed functional interactions from time-series data. A frequently-stated hypothesis is that synchronization of oscillatory activity plays a key role for the communication of information between distant sites of the brain. However, quantitatively assessing the strength and the direction of these interactions has proven difficult, especially in the highly-synchronized states that are often observed. Here we explore how synchronization affects the capability to mathematically measure causal interactions in both artificial systems and data. Performing a comparative analysis of often-used causality metrics, we show how synchronization introduces biases. These results suggest a new framework that could be used to assess causality across a wide range of synchronization states in the brain and elsewhere.

*HFSP (RGY0076/2018)

8:48AM L23.00003: Modularity allows classification of human brain networks during music and speech perception*  MELIA BONOMO (Presenter), Department of Physics and Astronomy, Rice University, CHRISTOF KARMONIK, Magnetic Resonance Imaging Core, Center for Performing Arts Medicine, Houston Methodist Research Institute, ANTHONY K BRANDT, Shepherd School of Music, Rice University, J TODD FRAZIER, Center for Performing Arts Medicine, Houston Methodist Hospital — Therapeutic music engagement is effective for improving cognitive health in patients suffering from neurological disease or trauma, however, little is known about the mechanism of action. Here, we investigated a means to quantify individual differences in functional brain activity while subjects listened to a variety of auditory pieces. Modularity was used to measure the degree to which functional activity within a group of brain regions was more highly correlated than activity between groups. We found consistent modules of the brain regions responsible for auditory processing among subjects, but differing whole-brain connection patterns and co-activation of regions responsible for autobiographical memory, prospection, and processing emotion ultimately led to differing modular structure. Significant trends were seen for individuals with higher or lower modularity during their self-selected musical piece. The use of modularity as a classifier of functional brain activity during auditory processing paves the way for creating personalized music therapy interventions and understanding how music benefits the brain.

Synchronization, waves and stochasticity in spatially structured neuronal networks

JONAS RANFT, IBEIN, Ecole Normale Superieure, ANIRUDH KULKARNI, Institut de la Vision, Inserm, VINCENT HAKIM (Presenter), Ecole Normale Superieure — Synchronization between distant brain regions, in the 20-30 Hz frequency range, has been observed in areas such as V1 or in the motor cortex during movement preparation. In order to shed light on these data, we have revisited the synchronization properties of distinct oscillating local Excitatory-Inhibitory (E-I) modules induced by distance-dependent long-range excitation. First, focusing on the sparsely synchronized oscillation regime which prevails in vivo, we have developed a rate model that accurately describes the stochastic oscillations of a single spiking E-I module. Second, we have considered the case of a chain of E-I modules with long-range excitation that decreases with distance. For modules of large sizes, complex dynamical regimes are observed in a sufficiently long chain, when long-range excitation mainly targets excitatory neurons. Synchronization of the module oscillations is otherwise observed. For modules with a moderate and biologically realistic size, stochasticity plays an important role in the observed dynamics. We show that its effect can be quantitatively described by modifications of the well-known Edwards-Wilkinson or KPZ equations. We analyse the resulting stochastic dynamics and discuss their relations to observed experimental observations.

Searching for emergent long time scales without fine tuning

XIAOWEN CHEN (Presenter), WILLIAM S BIALEK, Princeton University — Most of animal and human behavior occurs on time scales much longer than the response times of individual neurons. In many cases it is plausible that these long time scales emerge from the recurrent dynamics of electrical activity in networks of neurons. In linear models, time scales are set by the eigenvalues of a dynamical matrix whose elements measure the strengths of connections between neurons. It is not clear to what extent connection strengths need to be tuned in order to generate sufficiently long time scales; in some cases, one needs not just a single long time scale but a whole range. For a system with random symmetric connections, random matrix theory allows us to show that imposing a global stability constraint is sufficient to generate a diverging density of arbitrarily slow modes. But as soon as the detection mechanism for stability is set to be biologically plausible, these modes disappear for all system sizes. We will give a progress report on the more realistic, and challenging, case of asymmetric interactions.

*This work was supported in part by the National Science Foundation, through the Center for the Physics of Biological Function (PHY-1734030).
Neurons in the brain receive inputs from thousands of afferents. The high dimensionality of neural input spaces is tightly linked to the ability of neurons to realize difficult classification tasks through simple decision surfaces. However, this advantage of high dimensional neural representations comes at a price: Learning is difficult in high dimensional spaces. In particular, a neuron's ability to generalize from a limited number of training examples can be impaired by overfitting when the number of free parameters, i.e. synaptic efficacies, is large.

Constituting a major breakthrough in machine learning, learning in high-dimensional spaces has been greatly improved by margin techniques that maximize the minimal distance between available training examples and the learned decision boundary. Maximal margin techniques have been applied successfully in artificial neural networks with graded responses where standard metrics apply. By contrast, the use of margin learning has been much less straightforward in networks of spiking neurons that consist of neuron models that (like nerve cells in the brain) respond to inputs by eliciting trains of discrete all-or-nothing events (action potentials).

Recently, we have introduced the spike-threshold-surface to define a continuous distance between the responses of spiking neurons. Here we extend this notion to capture the margins between responses of spiking neurons. We show that a family of gradient-based learning rules that operate on these margins strongly improves the learning capabilities of spiking neurons. We discuss their biologically plausible implementation through empirically observed synaptic learning rules. This work transfers powerful margin-based learning concepts from machine to neurobiological learning.

Randomly connected networks generate emergent selectivity and predict decoding properties of large populations of neurons* AUDREY SEDERBERG (Presenter), ILYA M NEMENMAN, Emory University — Modern recording methods enable sampling of thousands of neurons during the performance of behavioral tasks, raising the question of how recorded activity relates to theoretical models. In the context of decision making, functional connectivity between choice-selective cortical neurons was recently reported[1]. The straightforward interpretation of these data suggests the existence of selective pools of inhibitory and excitatory neurons. Computationally investigating an alternative mechanism for these experimental observations, we find that a randomly connected network of excitatory and inhibitory neurons generates single-cell selectivity, patterns of pairwise correlations, and indistinguishable excitatory and inhibitory readout weight distributions, as in experimental observations. We predict that, for this task, there are no anatomically defined subpopulations of neurons representing choice, and that choice preference of a particular neuron changes with the details of the task. We suggest distributed stimulus selectivity and functional organization in population codes are emergent properties of randomly connected networks.

Impact of correlated connections in large recurrent networks with mesoscopic structure ALEXANDER KUCZALA (Presenter), TATYANA OLEGIVNA SHARPEE, Salk Inst — Random recurrent networks serve as a useful tool for the tractable analysis of large neural networks. The spectrum of the connectivity matrix determines the network's linear dynamics as well as the stability of the nonlinear dynamics. Knowledge of the onset of chaos helps determine the networks computational capabilities and memory capacity. However, fully homogeneous random networks lack the non-trivial structures found in real world networks, such as cell types and plasticity induced correlations in neural networks. We address this deficiency by investigating the impact of correlations between forward and reverse connections, which may depend on the neuronal type. Using random matrix theory, we derive a set of self consistent equations that efficiently compute the eigenvalue spectrum of large random matrices with block-structured correlations. The inclusion of structured correlations distorts the eigenvalue distribution in a nontrivial way; the distribution is neither a circle nor an ellipse. We find that layered networks with strong interlayer correlations have gapped spectra. For antisymmetric layered networks, oscillatory modes dominate the linear dynamics. In simple cases we find analytic expressions for the support of the eigenvalue distribution.
10:24AM L23.00009: Relationships Between Lognormal Distributions of Neural Properties and Connectivities

PETER ROBINSON (Presenter), XIAO GAO, YINUO HAN, Physics, Univ of Sydney — Relationships between convergence of inputs onto neurons, divergence of outputs from them, synaptic strengths, nonlinear firing properties, and randomness of axonal ranges are systematically explored by interrelating means and variances of synaptic strengths, firing rates, and soma voltages. Imposition of self-consistency yields broad distributions of synaptic strength as a necessary concomitant of the massive convergence of inputs to individual neurons, and widths of lognormal distributions of synaptic strength and firing rate are explained. The strongest individual synapses are shown to have an effect on soma voltage comparable to the standard deviation of all others combined. Remarkably, inclusion of moderate randomness in axonal ranges accounts for the observed ~10^3-fold variability in two-point connectivity at a given separation, and ~10^5-fold overall when the known mean exponential fall-off is included, consistent with observed near-lognormal distributions.

10:36AM L23.00010: Directed effective connectivity of in vitro neuronal networks revealed from electrophysiological recordings

CHUMIN SUN, K.C. LIN, Department of Physics, Chinese Univ of Hong Kong, YU-TING, HUANG, Institute of Physics, Academia Sinica, EMILY S.C. CHING (Presenter), Department of Physics, Chinese Univ of Hong Kong, PIK-YIN LAI, Dept. of Physics and Center for Complex Systems, National Central University, C.K. CHAN, Institute of Physics, Academia Sinica — Studying connectivity of in vitro neuronal network revealed from electrophysiological recordings can provide insights for understanding the brain network. Existing methods focus on estimating functional connectivity defined by statistical dependencies between neuronal activities but it is effective connectivity that captures the relevant direct casual interactions. We present a method that makes explicit use of a theoretical result that effective connectivity is contained in the relation between time-lagged cross-covariance and equal-time cross-covariance. Applying this method to data recorded by multi-electrode arrays of over 4000 electrodes, we estimate the directed effective connectivity and synaptic weights of neuronal cultures at different days in vitro. Our analyses show that the neuronal networks are highly nonrandom with a fraction of inhibitory nodes close to the values measured in monkey cerebral cortex, have small-world topology and feeder hubs of large outgoing degree and the distributions of the average incoming and outgoing synaptic strength are non-Gaussian with long tails.

Session L24 GSNP DSOFT: Jamming, Criticality, and the Gardner Transition 401 - Corey O'Hern, Yale University - Tag(s): Focus
Pressure-dependent shear response of jammed packings of frictionless, spherical particles* [Invited] KYLE VANDERWERF (Presenter), ARMAN BOROMAND, Yale University, MARK SHATTUCK, The City College of New York, COREY SHANE O’HERN, Yale University — The mechanical response of packings of purely repulsive, spherical particles to athermal, quasistatic simple shear near jamming onset is highly nonlinear. Previous studies have shown that, at small pressure $p$, the ensemble-averaged static shear modulus $<G>G_0$ scales with $p^\alpha$, where $\alpha \approx 1$, but above a characteristic pressure $p^{**}$, $<G>G_0$ scales with $p^\beta$, where $\beta \approx 0.5$. However, we find that the shear modulus $G_i$ for an individual packing typically decreases linearly with $p$ along a geometrical family where the contact network does not change. We resolve this discrepancy by showing that, while the shear modulus does decrease linearly within geometrical families, $<G>$ also depends on a contribution from discontinuous jumps in $G_i$ that occur at the transitions between geometrical families. For $p > p^{**}$, geometrical-family and rearrangement contributions to $<G>$ are of opposite signs and remain comparable for all system sizes. $<G>$ can be described by a scaling function that smoothly transitions between two power-law exponents $\alpha$ and $\beta$. We also demonstrate the phenomenon of compression unjamming, where a jammed packing unjams via isotropic compression.

Gardner physics in three-dimensional structural glasses* CAMILLE SCALLIET (Presenter), DAMTP, Univ of Cambridge, LUDOVIC BERTHIER, L2C, University of Montpellier, FRANCESCO ZAMPONI, Laboratoire de Physique, ENS Paris — The discovery of Gardner phases in structural glasses has profound consequences for their physical behavior, e.g. elasticity, rheology, low-temperature transport. It is therefore crucial to understand which type of materials, and under which physical conditions, are in the Gardner phase. Based on mean-field results [1], we present a comprehensive numerical study of 3d glasses. By changing external parameters, we explore regimes relevant to granular, colloidal, and molecular glasses. We delimit two separate regimes. We find that glasses close enough to jamming present a hierarchical landscape [2], and rejuvenation and memory effects expected in a Gardner phase [3]. In the regime far from jamming, relevant to atomic glasses, no Gardner physics is observed. Our study reveals instead the presence of localised excitations, whose role in low-temperature transport is analyzed. Our results suggest that Gardner physics should be observed in colloidal and non-Brownian particles near jamming.

8:48AM L24.00003: Dimensional Dependence of Scaling Prefactors in Overjammed Systems
JAMES SARTOR (Presenter), ERIC CORWIN, Univ of Oregon — Granular materials express universal properties regardless of the material properties of the individual grains. This universality of granular packings is a direct consequence of the statistics of contact forces between grains. When packing fraction changes, material properties are governed by the creation and destruction of new contacts. The number of excess contacts, packing fraction, and pressure all characterize distance to the jamming transition and are related by scaling theory made possible by the universality of granular materials. While the scalings between these parameters follow simple power laws, the prefactors to these scalings are not universal. We present measurements of these prefactors in dimensions 2-10. These prefactors depend nontrivially on dimension and differ from the asymptotic high dimensional values predicted by mean field theory.

9:00AM L24.00004: Vibrational Properties of Hard and Soft Spheres are Unified at Jamming
FRANCESCO ARCERI (Presenter), ERIC CORWIN, Physics, University of Oregon — Glasses and granular materials are characterized by the appearance of amorphous rigidity at the jamming point. While grains described as soft spheres jam in the limit of zero pressure, in a thermal hard sphere glass jamming is only achieved at infinite pressure when all the available space is filled and particles are in enduring contact with one another. The criticality near jamming has been largely explored from the soft side of the transition both in theory and numerics. The study of the vibrational properties in hard spheres has proven to be challenging to measure numerically because no analytic interaction is defined. Recently, an effective interaction between hard spheres at zero temperature has been proposed, of which minimization is able to produce typical configurations of low temperature colloidal glasses. This protocol ensures a proper definition of the vibrational spectrum near and at jamming. We observe a variety of low frequency modes which, for a certain range of density, agree with those found in jammed soft spheres. Therefore, the vibrational properties of hard and soft spheres near jamming are fully governed by the geometry of the system and the critical point represents a smooth joining between the two descriptions.
Effect of annealing on the nature of the yielding transition of amorphous solids

SRIKANTH SASTRY (Presenter), HIMANGSU BHAUMIK, Jawaharlal Nehru Ctr Adv Sci, GIUSEPPE FOFFI, LPS, Université Paris-Sud, France — Recently it has been demonstrated employing athermal quasi-static cyclic shear that an atomistic model glass former exhibits a sharp yielding transition across a sharply defined critical amplitude [1], which is further characterized by strain localization at the post yield regime [2], and the attainment of low energy structures approaching the yielding point. Here, we study the applicability of these results to a model of silica, and further, study the effect of annealing on the nature of yielding in both the model systems. We analyse the manner in which the discontinuous nature of the transition changes with annealing and compare our results with recent results analysing the effect of annealing in glasses [4].

Universal non-mean-field scaling in the density of states of amorphous solids

HARUKUNI IKEDA (Presenter), Ecole normale supérieure — Amorphous solids have excess soft modes in addition to the phonon modes described by the Debye theory. Recent numerical results show that if the phonon modes are carefully removed, the density of state of the excess soft modes exhibit universal quartic scaling, independent of the interaction potential, preparation protocol, and spatial dimensions. We hereby provide a theoretical framework to describe this universal scaling behavior. For this purpose, we extend the mean-field theory to include the effects of finite-dimensional fluctuation. Based on a semiphenomenological argument, we show that mean-field quadratic scaling is replaced by the quartic scaling in finite dimensions. Furthermore, we apply our formalism to explain the pressure and protocol dependence of the excess soft modes.

A jamming plane of sphere packings*  
YULIANG JIN (Presenter), Institute of Theoretical Physics, Chinese Academy of Sciences, HAJIME YOSHINO, Cybermedia Center, Osaka University — The concept of jamming has attracted great research interest due to its broad relevance in soft matter such as liquids, glasses, colloids, foams, and granular materials, and its deep connection to the sphere packing problem and phase transitions. Here we show numerically that the phase space of frictionlessly jammed states can be extended from the well-known jamming-point along the density axis to a jamming plane spanned by the density and shear-strain axes. We discuss how this jamming plane can be explored by standard athermal and thermal jamming protocols, and relate the protocol-dependence of the explored phase space to the reversibility of the routes to the jammed states. While all jammed states are isostatic and in the same universality class, their anisotropies and amorphous orders depend on the density and the shear strain. Among all points on the jamming plane, the jamming-point is special: it sets a sharp lower bound in the thermodynamic limit for the jamming density of all frictionless random packings, and the configurations there have the minimum amorphous order.

Out-of-equilibrium jamming of liquids and glasses: memory and criticality*  
PETER MORSE (Presenter), PATRICK CHARBONNEAU, Duke University — The emergence of memory in glass-forming liquids has recently been described by mean-field theory. Liquids equilibrated below the onset packing fraction (or above the onset temperature) share the same set of inherent states, while on the other side of that onset the set of inherent states depends on the equilibrated liquid properties. The resulting jammed states then have memory of the original liquid. In this talk, we present a new method to jam hard sphere liquids efficiently, which enables us to reliably detect this onset and relate its value with the mean-field prediction. This jamming algorithm also exhibits a signature of an out-of-equilibrium Gardner transition, corresponding to the point at which the roughness of the optimization landscape becomes algorithmically notable. Taken together these results will help inform a theory of out-of-equilibrium liquids and glasses.

*This research is supported by a grant from the Simons Foundation (#454937, Patrick Charbonneau).
10:00AM L24.00009: Creating ultra-stable jammed packings by training on pressure  VARDA FAGHIR HAGH (Presenter), Physics, University of Chicago, ERIC CORWIN, Physics, University of Oregon, M. LISA MANNING, Physics, Syracuse University, ANDREA JO-WEI LIU, Physics, University of Pennsylvania, SIDNEY ROBERT NAGEL, Physics, University of Chicago — Disordered materials are highly trainable because of their rugged energy landscapes. The idea of training is to evolve the physical properties of the microscopic constituents in a given system until a macroscopic state with desired emergent properties is achieved. Here, we train packings of soft harmonic spheres based on their per-particle pressures. First, the pressure on each particle is measured and then the radius of each particle is changed proportional to the inverse of its pressure, (i.e. particles with larger pressure get slightly smaller and particles with smaller pressure grow slightly larger). This process is repeated iteratively until pressure fluctuations disappear from the system. The final trained packings have a much lower energy and are mechanically ultra-stable regardless of original (untrained) packings' distance from the instability. This training process moves the critical packing fraction to a higher value and engraves a memory of training in the system that does not disappear under decompression.

10:12AM L24.00010: Intruder dynamics in granular flow  SCOTT NEWLON (Presenter), Southern Illinois University Carbondale, LEO SILBERT, Department of Physics, Central New Mexico Community College — The dynamics and kinematics of a single intruder particle in two dimensional, disordered packings of frictionless bidisperse discs interacting through linear and non-linear contact forces are investigated using computer simulations. To initiate motion of the intruder requires a threshold force to be exceeded which depends on the pressure of the packing. Beyond this critical force, for a given driving force, the average intruder velocity scales with the excess driving force. The velocity curves for different pressures are found to obey an universal scaling relation that depends on the initial packing pressure. We also find that the critical, threshold force is related to the shear modulus, thereby connecting the microrheological properties of the intruder at the grain scale to the bulk, macroscopic mechanical properties of the packing.

10:24AM L24.00011: One-step replica-symmetry-breaking phase in low-dimensional spin glasses*  JUDITH HOELLER (Presenter), NICHOLAS READ, Yale University — It is long known that mean-field theory of an Ising spin glass predicts a second-order phase boundary in the temperature–magnetic field plane between a paramagnet and a replica-symmetry-breaking phase. Here, we show that at nonzero magnetic fields and just above six dimensions, this phase diagram is modified by the appearance of a one-step replica symmetry-breaking phase below the transition, and a tricritical point beyond which the transition becomes quasi-first-order. These results may explain the reported absence of a diverging correlation length in the presence of a magnetic field in less-than-six-dimensional spin glasses in simulations and high-temperature series expansions.

10:36AM L24.00012: Origin of Two-Step Glass Transition in 2D Colloidal Suspension of Rods*

XINZHUO LIU, HUAGUANG WANG, ZEXIN ZHANG, Institute for Advanced Study, Soochow University, XINSHEING LING (Presenter), Brown University — We report an experimental study of monolayers of colloidal rods which exhibits a two-step glass transition with no appearance of nematic domains. Instead, it was found that rods tend to align with each other randomly in two preferred configurations, parallel, or perpendicular. We argue that the bi-modal distribution of the relative angles of the rods in the glassy phase is due to the existence of an activation barrier separating two local free energy minima in the configurational space. This barrier increases significantly when the first transition is approached, thereby freezing out the rotational motion while the translational motion remains diffusive. The results suggest that the activation barrier for rods rotating relative to each other is the key to the two-step glass transition.

Session L25 GSNP DSOFT DCP: Physics of Liquids III 402 - Fausto Martelli, IBM TJ
Watson Research Center - Tag(s): Focus

8:00AM L25.00001: Energy landscapes: from molecules and nanodevices to glasses and machine learning [Invited] DAVID WALES (Presenter), University of Cambridge — The potential energy landscape provides a conceptual and computational framework for investigating structure, dynamics and thermodynamics in atomic and molecular science. This talk will highlight connections between glassy systems and emergent phenomena in clusters, biomolecules and soft matter. Applications will be presented to illustrate new approaches for global optimisation, quantum dynamics, enhanced sampling of systems exhibiting broken ergodicity, and rare event dynamics. The key aim is to explain how the energy landscape perspective can unify our understanding of apparently disparate systems. A range of applications will be presented, from spectroscopy, biomolecules, and structural glass-formers, along with coarse-grained models and some recent results for machine learning landscapes.

Effects of random pinning on the potential energy landscape of a supercooled liquid, JCP, 149, 114503, 2018.
Defining and quantifying frustration in the energy landscape, JCP, 146, 124103, 2017.
8:36AM L25.00002: Nanoscale dynamics of liquids: $S(Q,\omega)$ with 0.8 meV resolution using x-rays    ALFRED Q. R. BARON (Presenter), DAISUKE ISHIKAWA, Materials Dynamics Laboratory, RIKEN SPring-8 Center — We describe a new instrument for measuring the dynamic structure factor of liquids, $S(Q,\omega)$, at the RIKEN SPring-8 Center in Japan using inelastic x-ray scattering (IXS) (see https://arxiv.org/abs/1504.01098). A long, 15m, insertion device provides unprecedented x-ray intensity, making practical experiments possible with sub-meV resolution at sub nm$^{-1}$ momentum transfers. This allows new insight into the mesoscale crossover regions between hydrodynamic and atomistic behavior of liquids. The performance will be illustrated with examples, including new results from liquid water [Ishikawa & Baron, submitted] and liquid iron [Baron, Inui, Ishikawa, et al, work in progress], demonstrating the range of the instrument and its applicability to even rather difficult experiments.

8:48AM L25.00003: The formation of nanoripples by ultra-low energy ion irradiation reveals the liquidus nature of metallic glass surface    PENG LUO (Presenter), CAMILO JARAMILLO CORREA, JESSICA CRYSTAL SPEAR, University of Illinois at Urbana-Champaign, JEAN PAUL ALLAIN, The Pennsylvania State University, YANG ZHANG, University of Illinois at Urbana-Champaign — We report an experimental investigation of ion irradiation on metallic glasses (MGs), with extremely low ion energy of 50–225 eV, orders of magnitude lower than that often used in previous studies. Highly periodic ripples with a wavelength of 20 nm and an amplitude of 0.5 nm were developed on MG surfaces under irradiation. With increasing irradiation time, we can identify three regimes: appearance of initial random islands, coarsening of the pattern through annihilation reactions of mobile defects, and finally saturation of the ripples. No change is observed for the devitrified counterparts with the same treatment. These findings reveal the liquidus nature of glass surface even far below the glass transition temperature and provide new clues for surface modification of amorphous materials.

9:00AM L25.00004: Study of Mesoscale Structure and Dynamics of Associated Liquid 2-propanol by Neutron Scattering and Molecular Dynamics Simulations    YANQIN ZHAI (Presenter), Nuclear, Plasma, and Radiological Engineering, University of Illinois at Urbana-Champaign, ANTONIO FARAOINE, NIST Center for Neutron Research, National Institute of Standards and Technology, YANG ZHANG, Nuclear, Plasma, and Radiological Engineering, University of Illinois at Urbana-Champaign — Monohydroxy alcohols are good model systems for studying the impact of hydrogen bonding on the structure and dynamics of liquids and on the macroscopic transport properties such as viscosity. We investigated 2-propanol by static and quasielastic neutron scattering experiments on a series of partially and fully deuterated samples at temperatures ranging from the liquid, the deeply supercooled, to the glassy state. Corresponding Molecular Dynamics (MD) simulations are performed to further understand the collective dynamics of the system. We focus on the mesoscale structures associated to the structure factor pre-peak at wavevector $Q \sim 0.8$ Å$^{-1}$. The dynamics of these molecular associates is at least one order of magnitude slower than the dynamics at the structure factor peak, at $Q \sim 1.4$ Å$^{-1}$. MD simulations show that 2-propanol molecules prefer to form chain-like structures with approximately 10% of the rings although the hydroxyl group is located in a non-terminal position. The emergence of multiple relaxation processes as the system is cooled towards the melting temperature and below is observed, which could be related to the non-Arrhenius increase of the viscosity.
TIMOTHY PRISK (Presenter), National Institute of Standards and Technology, SCOTT HANNA, Winston Churchill High School, RICHARD AZUAH, National Institute of Standards and Technology — Quantum zero-point motion plays an important role in determining the properties and behavior of liquid hydrogen. For example, by comparing the predictions of classical molecular dynamics with centroid molecular dynamics, several theoretical studies have suggested that the self-diffusion constant of liquid para-hydrogen is dominated by zero-point motion. In this presentation, we report quasi-elastic neutron scattering measurements of liquid normal hydrogen under saturated vapor pressure. Our empirical estimates of the self-diffusion constant and Arrhenius activation energy are in good agreement with accepted values obtained by nuclear magnetic resonance. As previous theoretical work has generally focused upon temperatures near the triple point, we will argue that further development in this area would be useful.

YADU KRISHNAN SARATHCHANDRAN (Presenter), University of Tennessee, Knoxville, YUYA SHINOHARA, EUGENE MAMONTOV, Oak Ridge National Laboratory, WOJCIECH DMOWSKI, TAKESHI EGAMI, University of Tennessee, Knoxville — Water exhibits an anomalously high dielectric constant, $\varepsilon=78$, at ambient temperature. This is caused by a Debye peak in the dielectric spectrum with a maximum at ~20 GHz. It is reported that this Debye peak reflects some hydrogen bond mediated, collective dipolar dynamics in water. However, a clear microscopic description of this phenomenon is lacking. We report our study on the microscopic picture of water's dielectric relaxation using the time-dependent pair-distribution function, the Van Hove function. The dynamic structure factor of water, $S(Q, E)$, is measured using quasi-elastic neutron scattering over a wide momentum transfer range by making use of recent advances in analyzer crystal options at BASIS, SNS. $S(Q, E)$ is double Fourier transformed to obtain the Van Hove function, $g(r, t)$, to investigate the temporal evolution of molecular correlations in real-space up to 10 picoseconds. Our findings align with previous studies on the time-scale of the Debye process and the higher frequency excess Debye process, although significantly differ in the microscopic description.

9:36AM L25.00007: Atomic dynamics of liquid Hg studied by high-resolution inelastic x-ray scattering

DAISUKE ISHIKAWA (Presenter), Japan Synchrotron Radiation Research Institute, ALFRED Q. R. BARON, RIKEN SPring-8 Center — High-resolution Inelastic X-ray Scattering (IXS) is a powerful tool for measuring the dynamic structure factor, S(Q,ω), in liquids. Very recently, we began to operate a new instrument that allows practical measurements on liquids of the most interesting low Q region at BL43LXU of the RIKEN SPring-8 Center in Japan. Liquid dynamics in this region is important since this region corresponds to transition from hydrodynamic to solid-like elastic regimes. Liquid metals are particularly interesting since they behave quite differently from molecular liquids due to strong atomic interactions. We use the new setup to investigate liquid Hg with energy resolution >0.8 meV at temperature near the melting point T_m = 234.3 K. We will discuss details of transition of the speed of sound in liquid Hg, the quasi-elastic line-width, and a new approach to fitting dynamical spectra.

9:48AM L25.00008: Isotope effect in liquid water explored by X-ray absorption spectroscopy

CHUNYI ZHANG (Presenter), Temple University, LINFENG ZHANG, Princeton University, JIANHANG XU, FUJIE TANG, XIFAN WU, Temple University — The X-ray absorption spectra (XAS) of both liquid H_2O and D_2O are computed using our recently developed approximate computational approach in solving Bethe-Salpeter equation. In the above, the molecular structures are obtained from the well-equilibrated trajectories generated by path-integral deep potential molecular dynamics (DPMD). In particular, the DPMD force field is constructed from ab initio path-integral molecular dynamics based on the strongly constrained and appropriately normed (SCAN) density functional. Our preliminary results indicate that the experimentally observed isotope effects in the XAS spectra are qualitatively reproduced by our theoretical prediction. The H-bond network in heavy water is slightly more structured than that in light water, which is consistent with the less prominent pre-edge and main-edge of theoretical XAS spectrum of D_2O than that of H_2O.

*This work was primarily supported by National Science Foundation through Awards No. DMR-1552287.
10:00AM L25.00009: The Long-range Ordering of Ions in Aqueous Salt Solutions  EVGENII FETISOV (Presenter), JOHN L FULTON, SHAWN MICHAEL KATHMANN, CHRISTOPHER J MUNDY, GREGORY K SCHENTER, Pacific Northwest National Laboratory — The importance of understanding the long-range structure in aqueous salt solutions has recently come to the forefront when it was suggested that the ordering of water in the presence of ions possibly reaches length scales up to 10 nm. A much more important question regards the long-range ordering of the ions themselves since their arrangement critically affects processes such as nucleation/crystallization and the solution energetics related to activity coefficients and osmotic pressure. We use a combination of molecular dynamics and X-ray diffraction to correlate experimentally measured long-range structure to the precise spatial distribution of species in aqueous solutions of alkali and alkali earth halides. For the first time, we quantitatively differentiate and explain a separate region in the fluid structure factor containing diffraction-like features at low Q values (“pre-peaks”) that lead to the oscillatory behavior in the ion-ion and ion-water pair distribution functions. These features are shown to be due to a combination of correlated (e.g., cation-cation and cation-water) and anti-correlated (cation-anion and anion-water) atomic positions. In addition, we also explore the influence of salt concentration on the position and magnitude of the pre-peaks.

10:12AM L25.00010: Influence of ionic species on water broadband electrodynamics  VASILY G. ARTEMOV (Presenter), HENNI OUERDANE, Skolkovo Institute of Science and Technology — Proton exchange plays a central role in modern electrochemical systems. While it is well described for times larger than milliseconds [1], it is an important process not fully understood on nanoscale distances and subpicosecond timescales. Here, we discuss the dynamical structure of water from femtoseconds to seconds time intervals using a combination of broadband dielectric spectroscopy and infrared spectroscopy methods. Accounting for dielectric properties [2], isotopic effects [3] and confinement effects [4], we present a model of water based on the time-dependence of the ionic species concentration, over the whole time interval between the intermolecular direct current (below microseconds) and intramolecular infrared vibrations (sub-picoseconds), which so far was hardly achievable. Our approach provides a new vision on the hydrogen bonding in water taking into account the role of ionic species on the intermolecular interactions; and we discuss how this paves the way to innovative design of electrochemical energy storage devices.

HOSSAM FARAG (Presenter), Department of Nuclear, Plasma, and Radiological Engineering, University of Illinois at Urbana-Champaign, ILYA A SHKROB, LU ZHANG, LEI CHENG, Chemical Sciences and Engineering Division, Argonne National Laboratory, YANG ZHANG, Department of Nuclear, Plasma, and Radiological Engineering, University of Illinois at Urbana-Champaign — Non-aqueous electrolytes enable batteries to operate at higher cell potentials compared to its aqueous counterpart due to the wider electrochemical stability window of the former. Super-concentrated electrolytic solutions are emerging as a new class of liquid electrolytes with various unusual functionalities beneficial for advanced Li battery applications. However, a desired high ionic conductivity is missing in the high-concentrated regime due to a reduction in ionic mobility. Reduced ionic motility is ascribed to an increase in solution viscosity whose mechanism is still not fully understood. We hypothesize that we could tune the solution viscosity via modulating the supramolecular interactions enabling a groundbreaking solution for fast recharging rate of these batteries. We carried out MD simulations to investigate the mechanism by which the ionic conductivity decreases. We first observed a reduction in the number free-ion carriers via formation of contact ion pair in this high concentration regime. Further investigation of the mechanism by which viscosity increases is still undergoing. Herein, we present the simulation results and relative analysis.

10:36AM L25.00012: Local Dynamics in Metallic Liquids Studied by Inelastic Neutron Scattering*  
ZENGQUAN WANG (Presenter), HUI WANG, WOJCIECH DMOWSKI, University of Tennessee, Knoxville, KENNETH F KELTON, Washington University, St. Louis, TAKESHI EGAMI, University of Tennessee, Knoxville — Local dynamics in liquid metals has been poorly understood when compared to their crystalline counterparts. For instance, the atomistic origin of the viscous behavior is not well elucidated, even though viscosity is one of the most basic properties for liquids. In this research, inelastic neutron scattering (INS) experiments were carried out on various metallic liquid droplets (including single, binary, and complex BMG forming liquids), using an electro-static levitator, at different temperatures at SNS. The dynamic structure function $S(Q, E)$ and the Van Hove correlation function $G(r,t)$ were then obtained. Compared with Molecular Dynamics (MD) simulation results, the local configuration change was analyzed based on distinct $G(r,t)$ and proved as the elementary excitation in high temperature metallic liquids, thus controlling their shear viscosity. Also, self diffusion behaviors were analyzed based on self $G(r,t)$. A comprehensive understanding of the local dynamics was made in various metallic liquids.

High-resolution neutron imaging study of kinetics of H$_2$O water vapor uptake from air into sessile heavy water droplets

JAE KWAN IM (Presenter), LEEKYO JUNG, Physics, Ulsan Natl Inst of Sci & Tech, JAN CRHA, PAVEL TRTIK, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, JOONWOO JEONG, Physics, Ulsan Natl Inst of Sci & Tech — At the surface of a liquid, the liquid molecules escape and enter the encompassing air as a gas, and the gas molecules join the liquid concurrently. Here we report the neutron imaging of a sessile heavy water (D$_2$O) droplet that absorbs light water (H$_2$O) vapor from the ambient air. A quantitative image analysis utilizing the Beer-Lambert law enables us to measure the attenuation coefficient of the specimen and estimate H$_2$O content within the droplet. We double-check this result with a quantitative Fourier-transform infrared spectroscopy and conclude that small D$_2$O droplets with a large surface-to-volume ratio can be very hygroscopic, e.g., the 15 percent of a D$_2$O droplet of 10 microliters can be replaced with H$_2$O in 10 minutes.

The neutron imaging was performed at the ICON beamline of SINQ at Paul Scherrer Institut, Switzerland, under the proposal-number 20180136. The authors acknowledge support from the 2018 Research Fund (1.180069.01) of UNIST (Ulsan National Institute of Science and Technology) and IBS-R020-D1 funded by the Korean Government.

Session L26 DBIO DSOFT GSNP DPOLY: Mechanics of Cells and Tissues Across Scales V

How does extracellular matrix rigidity affect the fluidity of an embedded spheroid?

AMANDA PARKER (Presenter), Physics, Syracuse University, M CRISTINA MARCHETTI, Physics, UC Santa Barbara, M. LISA MANNING, J M SCHWARZ, Physics, Syracuse University — The extracellular matrix (ECM) that surrounds a tissue, such as a cancer spheroid, is known to regulate spheroid behavior, with stiffer ECM promoting invasion. Using a computational model, we explore how a simple mechanical interaction between a spheroid and its ECM promotes changes in the spheroid's rigidity, morphology and the shapes of its constituent cells, as well as the ECM's rigidity and structure. We model the spheroid using a vertex model and the ECM using a spring network model, with an additional term describing the interfacial tension between the spheroid and ECM. Both vertex and spring network models transition between rigid and floppy phases, depending on their respective tuning parameters (cell shape and spring rest length) and imposed strain. Therefore, we expect, and find, that by mechanically coupling the two systems, changes to the phase of one system can drive changes to the phase of the other. We identify two regimes of interest—one in which compression of the spheroid dominates and one in which stretching dominate. We find that isotropic compression promotes fluidity of tissue and preserves the relationship between cell shape and tissue phase, while stretching by the ECM results in rather different behavior.

8:12AM L26.00002: Self-organized vasculogenesis in 3D printed mixed cell populations
SARAH ELLISON (Presenter), THOMAS ANGELINI, University of Florida — In the process of vasculogenesis during embryotic development, endothelial cells create blood vessel networks necessary for the survival and function of tissues. In tissue engineering, creating functional vasculature remains among the largest impediments to achieving healthy tissues. Deeper understanding of cell self-organization during vasculogenesis could therefore have impacts in developmental biology and tissue engineering. To fabricate 3D multicellular systems of designed consistency, we 3D print structures made from mixtures of hepatocytes, endothelial cells, and extracellular matrix. These structures are fabricated directly in a 3D growth medium made from jammed microgels. By observing cellular spatial organization and testing biological markers, we investigate how endothelial cells and hepatocytes self-organize into co-continuous interpenetrating networks, resulting in vasculature and improved overall cellular function. Preliminary data and analysis will be presented.

8:24AM L26.00003: Interrogating collagen mechanics at the single-molecule level* NANCY R. FORDE (Presenter), Department of Physics, Simon Fraser University — Collagen is the fundamental structural protein in vertebrates, forming a variety of hierarchical material structures. In spite of its prevalence and mechanical importance in biology, its mechanics at the molecular level – where it possesses a unique triple-helical structure – are surprisingly controversial: its flexibility is unresolved, as is its response to stress. My research group has been investigating these properties through single-molecule experiments. To do so, we have developed imaging algorithms to use in atomic-force microscopy (AFM), developed a model for polymers with inherent curvature (the curved worm-like chain model - cWLC), and built an instrument for high-throughput single-molecule force spectroscopy, the mini-radio centrifuge force microscope (MR.CFM). I'll describe what we have learned about collagen's flexibility and stress response, how local sequence context matters, and how our work resolves some of the many contentious findings regarding collagen's mechanics.

*This work was supported by the Natural Sciences and Engineering Research Council of Canada (NSERC).

8:36AM L26.00004: Mechanical response of the vitreous gel in our eyes: Results from an inhomogeneous two-fluid model* PANCY LWIN (Presenter), SCOTT V FRANKLIN, GEORGE THURSTON, DAVID ROSS, MOUMITA DAS, Rochester Institute of Technology — The vitreous gel is a viscoelastic gel present between the eye lens and the retina. It is made up of a composite network of stiff collagen fibers and softer hyaluronic acid (HA) polymers, and water. Its mechanical properties are critical to proper functioning of the eye, and undergo changes with aging and disease. We study rheological properties of this gel by simulating it as a two-fluid model made of an inhomogeneous polymer network interacting with a fluid. Our results relate the time-varying mechanical response of the gel to the composition of the network, the material properties of the network and the fluid, and the strength of the coupling of between the network and the fluid. These results may provide insights into changes in mechanical-structure function properties of the vitreous gel in vitreous disorders.

8:48AM L26.00005: Kinetics of Cell Adhesion Through Biomimetic Glycocalyx*  
YU JING, SHLOMI COHEN, JESSICA FAUBEL, JENNIFER CURTIS (Presenter), School of Physics, Georgia Institute of Technology — Giant polysaccharides grafted to the external cell surface interfere with receptor-ligand binding and can strain molecular bonds. This is relevant in cell-matrix interactions during cell migration as well as in cell-cell interactions, such as T-cell immune response. We introduce a biomimetic glycocalyx platform to investigate the kinetics of cell adhesion in the presence of sugar-rich interfaces. With this approach, we study the mechanisms by which cells penetrate the thick polymer brush-like interface and how this process depends on initial brush thickness.

*The authors gratefully acknowledge funding from NSF DMR #1709897.

9:00AM L26.00006: Length regulation of epithelial cell junctions  
MICHAEL STADDON (Presenter), University College London, KATE E CAVANAUGH, EDWIN M MUNRO, MARGARET GARDEL, University of Chicago, SHILADITYA BANERJEE, University College London — Morphogenesis of epithelial tissues involve precise spatiotemporal coordination of cell shape changes. In vivo, many morphogenetic events are driven by pulsatile contractions of intercellular junctions, producing irreversible deformations at tissue scales. The biophysical functions of these oscillatory contractions and the significance of their temporal structure remain unknown. Here, we combine theory and experiments to demonstrate that pulsatory contractions serve as a mechanical ratchet to guide directed morphogenesis. We propose a new theory for epithelial tissue mechanics that highlights two essential properties of intercellular junctions. First, epithelial junctions must overcome a critical strain threshold to trigger irreversible tension remodelling and junction length changes. Second, continuous relaxation of junctional strain promotes gradual loss of mechanical memory from the system, which makes the system refractory to continuous input, enabling frequency-dependent modulation of cell shape changes via junctional ratcheting. Taken together, the combination of mechanosensitive tension remodelling and strain relaxation provides a robust mechanism for directed tissue morphogenesis and the maintenance of tissue homeostasis in response to small amplitude contractions.
The physics of lipid bilayer in cell membranes is one of the most exciting topics in modern science. We have investigated the molecular dynamics of complex phospholipid membranes in their fluid phases by neutron spin echo spectroscopy. Our study reveals the origin of anomalous motions in different phospholipids that leaves a generalized fingerprint in their mean square displacement (MSD). It shows a $t^{0.26}$ dependence in the pico- to nanosecond region that indicates a new localized motion that is related to the tail group of the lipid. At longer times, $t > 3$ ns, the MSD shows a $t^{0.66}$ dependence describing membrane undulation, followed by a translational diffusion ($t^1$), that is visible at the edge of instrumental resolution. The analysis reveals the range in which we can analyze the membrane fluctuations to determine the membrane rigidity. Our study reveals the existence of the complex dynamic organization of the lipid bilayer in terms of localized anomalous motions. In biological cell membranes, these anomalous motions would imply a substantial difference in cellular signaling and regulatory processes.

In vitro characterization and numerical simulations of red blood cell transmigration through splenic inter-endothelial slits

During their circulation through the spleen, red blood cells (RBCs) are forced to squeeze through gaps between endothelial cells that are ~8 times narrower than its diameter. The ensuing squeezing motion causes large RBC deformations that remove old and diseased cells from the circulation. There is limited data about the deformation and stress experienced by RBCs. To study the mechanics of RBC splenic filtration, we designed and characterized a family of microfluidic devices where a suspension of human RBCs flows through an array of channels of controlled length (L), width (W) and height (H). We varied these geometrical parameters ($0.75 < W < 3$, $4.5 < H < 10$ and $1 < L < 5$ um) and imaged the time-evolving RBC shape while crossing each channel, as well as the flow field through the channel by μ-PIV. We also investigated this process computationally by coupling a multiscale model of the RBC membrane with a boundary integral formulation of the fluids. The computationally flow field and cell deformation are consistent with experiments. In wider channels RBCs reorient into the direction of less constrain, whereas in narrower channels, cells fold (U shape) experimenting large deformations. We examined computationally the mechanics of folded cell shapes under different flow rates and slit geometries.
Nucleation and Formation of a Primary Clot in Insect Blood Probed by Magnetic Rotational Spectroscopy

KONSTANTIN KORNEV (Presenter), PAVEL APRELEV, PETER ADLER, ARTIS BRASOVS, Clemson University — Blood clotting at wound sites is critical for preventing blood loss and invasion by microorganisms in multicellular animals, especially small insects vulnerable to dehydration. The mechanistic reaction of the clot is the first step in providing scaffolding for the formation of new epithelial and cuticular tissue. The clot, therefore, requires special materials properties. We have developed and used nano-rheological magnetic rotational spectroscopy with nanorods to quantitatively study nucleation of cell aggregates that occurs within fractions of a second. Using larvae of Manduca sexta, we discovered that clot nucleation is a two-step process whereby cell aggregation is the time-limiting step followed by rigidification of the aggregate. Clot nucleation and transformation of viscous blood into a visco-elastic aggregate happens in a few minutes, which is hundreds of times faster than wound plugging and scab formation. This discovery sets a time scale for insect clotting phenomena, establishing a materials metric for the kinetics of biochemical reaction cascades.

Microfluidic platform for label-free viability cell sorting

FATIMA EZAHRA CHRIT (Presenter), ABHISHEK RAJ, NICK STONE, TODD SULCHEK, ALEXANDER ALEXEEV, Georgia Inst of Tech — Cell biomechanical properties often change in predictable ways with important cell phenotypes changes, such as cell loss of viability. We propose a biophysical approach for cell viability sensing, enumeration, and purification that is label-free and continuous. Using microfluidics, we show that we can separate viable cells from nonviable cells based on the difference in their stiffness with an enrichment factor of >5 and an overall recovery of 95%. The technology consists of a microchannel with diagonal ridges that direct cells along different paths in a manner dependent on cell biomechanical properties. As a result, the sorted viable and nonviable cells are collected at different microchannel outlets. To investigate the sorting process, we use a tracking algorithm that tracks cells moving through the microchannel. Sorting outcomes are correlated with the tracking metrics such as the cell deflection per ridge and the interaction time with ridges in the channel. The approach can be used for cell characterization and purification either in-line with cell bioreactors or after cell manufacture and prior to administration to improve outcomes.

**10:00AM L26.00011: Simultaneous Measurement of Electrical and Mechanical Properties of Biological Cells Using a Tuning Fork-Coupled Conductive Probe**  
MARK SCHILLER (Presenter), 
Physics, Boston College, ALEXANDRA M IVANOV, MEGI MACI, Biology, Boston College, EVA K PONTRELLI, Physics, Boston College, JUAN MERLO, Physics and Astronomy, Vassar College, TIMOTHY CONNOLLY, Biology, Boston College, MICHAEL NAUGHTON, Physics, Boston College — AFM-style probes have commonly been used to measure mechanical properties of materials such as their Young's Modulus. This technique has also been implemented to further explore biological cells\(^1\). Differentiation, pluripotency, and other attributes have been linked to certain mechanical properties of cells as well their membrane potential\(^2,3,4\). Simultaneous measurements of these quantities can help determine their inter-relation and inform on their relationship(s) with other properties. We have devised a conductive tip tuning fork probe, which is intended to simultaneously measure mechanical properties and membrane potential of a cell. We discuss fabrication and preliminary experimental results using conductive tip tuning forks to probe HeLa cells.

**10:12AM L26.00012: Brain Mechanics Drive Cavitation and Fracture Response**  
CAREY DOUGAN (Presenter), SUALYNETH GALARZA, Chemical Engineering, University of Massachusetts, CHRISTOPHER BARNEY, Polymer Science and Engineering, University of Massachusetts, YUE ZHENG, SHENGQIANG CAI, Department of Mechanical and Aerospace Engineering, University of California San Diego, ALFRED J CROSBY, Polymer Science and Engineering, University of Massachusetts, SHELLY PEYTON, Chemical Engineering, University of Massachusetts — Roughly 1.7 million cases of Traumatic Brain Injury occur in the U.S. every year. It has been suggested that impact injuries and non-impact injuries due to explosive blasts result in “cavitation-related damage.” This cavitation event is the formation of bubbles in the brain that can lead to fracture upon collapse. Therefore, it is essential to understand how brain mechanics contributes to the propagation of cavitation and fracture related damage \textit{in vivo}. Needle-induced cavitation (NIC) is a useful technique to study localized deformation within brain tissue and how modulus and strain rate contribute to fracture. Utilizing the techniques of NIC and indentation we observe a significant correlation between modulus and strain rate. This strain rate dependency for NIC can result in visible fracture of specific brain regions of varying moduli at large strains. With the help of modeling, we use the NIC measurements to understand the fracture properties of brain tissue. By understanding the strain rate deformation of specific areas of the brain, we aim to gain further insight into how cavitation-related events lead to irreversible damage.

Rheological properties of cellular aggregates formed by pilus mediated interactions

HUI-SHUN KUAN (Presenter), Friedrich-Alexander Uni Erlangen-Nürnberg & Max-Planck-Zentrum für Physik und Medizin, FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems, VASILY ZABURDAEV, Friedrich-Alexander Uni Erlangen-Nürnberg & Max-Planck-Zentrum für Physik und Medizin — Aggregates of living cells are an example of active materials with unconventional material properties. The rheological properties of cellular aggregates can, therefore, be markedly different from those exhibited by passive soft systems. Motivated by colonies of *Neisseria gonorrhoeae* bacteria, we develop a continuum theory to study cellular aggregates formed by attractive pili mediated intercellular interactions. We find that the formation of cellular aggregates is an active phase separation process and we discuss the activity-induced viscoelastic properties of such aggregates. By studying the behaviour of aggregates under oscillatory shear, we can link the loss and storage moduli of the aggregates to the dynamics of the active intercellular forces. Due to the turnover of pili, the aggregates show a liquid-like behaviour at large times and strong shear-thinning effect under the large amplitude oscillatory shear. Our theory provides an important insight on how pilus mediated intercellular forces in cellular aggregates govern their material properties which in the future could be tested experimentally.

Optical tweezer application with Autofocusing Airy-Bessel beams

YI LIANG (Presenter), Guangxi Key Lab for Relativistic Astrophysics, Center on Nanoenergy Research, School of Physical Science and Technology, Guangxi University, YINXIAO XIANG, West Virginia Univ, FAN SHI, Tianjin University of Technology — We proposed a new autofocusing beams named autofocusing Airy-Bessel beams (AABB). Compared with traditional circular autofocusing beams (CAB), autofocusing Airy-Bessel beams exhibited a shorter autofocusing propagation distance and two times stronger peak intensity at the focusing point. We adopted this new kind of autofocusing beams as an optical tweezer to trap particles and red blood cells. This kind of optical tweezer presented a larger trapping stiffness, which corresponded a stronger trapping force as compared with conventional autofocusing beams. In other words, it could reduce the photodamage on sample especially some biological sample such as different kind of cells at realizing a same trapping. Generally, the trapping ability of this kind of optical tweezer was found to be proportion to the laser power. This new type of tweezer may find new applications in optical manipulation and biomedical research.

**8:00AM L27.00001: Highly Efficient Vertical SnS₂ Nanoflake Photodetector Decorated with PbS Colloidal Quantum Dots**  
BINOD GIRI (Presenter), PRATAP RAO, Worcester Polytech Inst — Tin disulfide (SnS₂) is a 2D material with excellent optoelectronic properties suitable for various solar conversion and sensing applications. SnS₂ has been used in photodetectors due to its high carrier mobility and bandgap of 2.2eV. In applications where the detection of longer wavelengths of light is desired, other materials such as lead sulfide quantum dots (PbS QDs) with tunable band gaps are used together with SnS₂ to maximize light absorption and charge collection. Although several reports have demonstrated high sensitivity and responsivity of few-layer-SnS₂/PbS QDs photodetectors, their large scale production has not been addressed. These devices are often made by mechanically exfoliating bulk SnS₂ and depositing narrow metal contacts using e-beam lithography, which are both not scalable. In this work, we have fabricated photodetectors from vertical SnS₂ nanoflakes grown by a scalable close space sublimation and decorated by colloidal PbS QDs. The SnS₂/PbS QD device is fabricated on SiO₂/Si substrates with gold contacts patterned using standard photolithography. These devices exhibit excellent responsivity, on-off ratios and transient response critical for a photodetector. Our work presents a scalable method of fabricating photodetectors from SnS₂ nanoflakes and PbS QDs.

**8:12AM L27.00002: Fundamental limits on the performance of electromagnetic devices**  
RAHUL TRIVEDI (Presenter), GUILLERMO ANGERIS, Electrical Engineering, Stanford University, LOGAN SU, Applied Physics, Stanford University, SHANHUI FAN, JELENA VUCKOVIC, Electrical Engineering, Stanford University — Formulating the design of electromagnetic devices as an optimization problem has opened up the possibility of achieving performance metrics that have eluded common design techniques. However, since these optimization problems can only be approximately solved, it is not clear what performance metrics (e.g. transmission and cross-talk) are achievable for an optical device, subject to constraints on device footprint, refractive index contrast, and feature size. In this work, we show how to efficiently calculate provable bounds on performance metrics that are expressible as a quadratic form in the electric field for a general class of linear-optical devices using Lagrangian duality and convex relaxations. We illustrate these techniques by calculating bounds on some representative 1D and 2D electromagnetic design problems: the reflectivity of a 1D mirror and the focusing efficiency of a 2D lens.

8:24AM L27.00003: Optical sensor development for toxic elements detection in liquids*  
C BHATT (Presenter), DANIEL HARTZLER, DUSTIN MCINTYRE, National Energy Technology Lab — Laser induced breakdown spectroscopy (LIBS) based sensor methodology was developed for the detection of three toxic elements; As, S, and Se in liquid. This concept will be used to develop a sensor for the in-situ analysis of coal power plant wastewater. Real time probe for the monitoring of the EPA regulated species is needed to control effluent streams in the power plants. Single and double pulse LIBS systems with 1064 nm Nd:YAG lasers were utilized to generate micro plasma from the surface of liquid jet containing these elements in ppm levels. Plasma emission was collected at 45 degree with the laser beam for As and Se emission lines detection in UV range while that was collected in collinear mode with laser beam for S line detection in near IR. Atomic emission lines at wavelengths 274.4 nm, 278.0 nm for As, 921 nm for S, and 196.09 nm, 203.9 nm, and 206.32 nm for Se were detected in LIBS spectra.

8:36AM L27.00004: Cryogenic Operation of Silicon Photonic Electro-Optic Modulators based on DC Kerr Effect*  
UTTARA CHAKRABORTY (Presenter), JACQUES CAROLAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, GENEVIEVE CLARK, MITRE Corporation, DARIUS BUNANDAR, JELENA NOTAROS, MICHAEL R. WATTS, DIRK R. ENGLUND, Research Laboratory of Electronics, Massachusetts Institute of Technology — Scalable photonic integrated circuits operating at cryogenic temperatures are essential for quantum information processing and supercomputing. The silicon-on-insulator platform is highly promising for its compactness and CMOS compatibility. However, efficient electro-optic modulation in silicon at cryogenic temperatures remains an outstanding challenge, owing to carrier freeze-out at cryogenic temperatures in conventional plasma-dispersion-based modulators [1]. The generation of an induced second-order nonlinearity in silicon with an applied DC electric field has been demonstrated at room temperature [2]. In this work, we demonstrate DC Kerr-based modulation in silicon at a temperature of 5K at GHz speeds, showing the potential of DC Kerr modulators for use in large-scale silicon photonic integrated circuits for cryogenic computing.

Pump-probe experiment in a non-linear chaotic photonic cavity: modulation of a Physically Unclonable Function*  
SAMUEL METAIS, AMY C. FOSTER (Presenter), MARK A FOSTER, Johns Hopkins University — How to design a PUF, physically unclonable function[1], is a recurrent problem in information theory and cryptography. In our group, we use a non-linear truncated disk of silicon in a silicon dioxide background as a semi-chaotic cavity[2]. Silicon waveguides show non-linear effect during the propagation of high-amplitude pulses, which further complexifies the underlying physics of our device. From known results and performances of actual devices[3], we will first show here how one can enhance the photon lifetime in such a cavity to increase the information content in our operating bandwidth, and in a second part use a co-propagating laser pump in order to locally modulate the refractive index, allowing us to control the cavity’s response.

*The author recognizes funding from the IARPA under the contract number # 2018-18041100006.

Large emission enhancement and emergence of strong coupling with plasmons in nanoassemblies: Role of quantum interactions and finite emitter size.*  
RIYA DUTTA (Presenter), Indian Institute of Science - Dept of Physics, KRITIKA JAIN, MURUGESAN VENKATAPATHI, Computational and Statistical Physics Laboratory, INDIAN INSTITUTE OF SCIENCE, JAYDEEP BASU, Indian Institute of Science - Dept of Physics — Next-generation photonic devices, optical quantum communication, and information processing will rely on generating Quantum Emitter assemblies with high photonic efficiencies, that can be coupled to sources of localized radiation typically enabled by plasmons in ultrasmall metal nanoparticles. The Purcell effect has been the basis for several decades in understanding enhancement of photonic efficiency and decay rates of emitters through their coupling to cavity modes and metal nanostructures. However, it is not clear whether this regime of radiative enhancements can be extended to ultrasmall nanoparticle sizes or interparticle distances. Here we report large radiative enhancements of quantum dot assemblies with extremely small metal nanoparticles and emitter-particle separations R of a few nanometers, where Purcell effect would lead to either no enhancements or quenching. We invoke a new regime of radiative enhancements to explain the experimental data and also correctly predict the emergence of strong coupling below certain R, as observed in experiments. In addition, we show that the widely used point emitter approximations diverge from actual observations in the case of finite size emitters at such small separations. REF- PHYSICAL REVIEW B 100, 155413 (2019)

9:12AM L27.00007: Multiscale electrothermal simulation of quantum cascade lasers

MICHELLE KING (Presenter), Materials Science and Engineering, University of Wisconsin-Madison, SINA SOLEIMANIKAHNOJ, IRENA KNEZEVIC, Electrical and Computer Engineering, University of Wisconsin-Madison — Quantum cascade lasers (QCLs) are high-power, coherent light sources that emit at midinfrared and terahertz frequencies. The active core of these devices is a periodic multiple-quantum-well heterostructure where the electronic and lattice systems exist far from equilibrium and are strongly coupled. Heat generated in the active core (the part responsible for light emission) diffuses throughout the rest of the device. Coupled charge and heat transport in QCLs present a multiscale and multiphysics problem that governs device properties observed in experiment, such as the current-voltage characteristics, gain, and internal quantum efficiency. We present a strategy for simulating coupled heat and charge transport in QCLs, which occur on drastically different spatial scales, that employs a coupled ensemble Monte Carlo for electrons and phonons in a stage-level simulation of the active core and couples to a device-level heat diffusion simulation.

9:24AM L27.00008: Selectively launching propagating surface plasmon from designed symmetric plasmonic structures

YU GONG (Presenter), College of Charleston, ALAN G. JOLY, PATRICK Z. EL-KHOURY, WAYNE P. HESS, Pacific Northwest National Laboratory — The next generation signal processing technology demands high speed and energy efficient information carriers. Surface plasmon polaritons (SPPs) can be one of the most promising candidates since they propagate at almost the speed of light, and can be confined to sub-wavelength dimensions using designed nanostructures. In our studies, we show the intensity of propagating SPPs launched from opposing edges of a symmetric trench structure can be controlled by the linear polarization of the optical field. Through the FDTD simulations, we reveal that the coupling efficiency of the propagating SPPs is inversely proportional to that of the localized surface plasmon excited at the trench edges. We also explored the generation of propagating SPPs from a protruded silver cap structure with s-polarized femtosecond laser excitation. Surprisingly, our results show the SPPs propagate with a bifurcated spatial structure with an antisymmetric mirror plane and may be regarded as two spatially distinct, temporally phase-locked wave packets. Our findings can facilitate the design of plasmonic devices/components in nanophotonic circuits.

*The authors acknowledge support from the US Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences.
9:36AM L27.00009: Fundamental thermal noise limits for high-Q/V optical microcavities
CHRISTOPHER PANUSKI (Presenter), RYAN HAMERLY, DIRK R. ENGLUND, Massachusetts Institute of Technology MIT — Thermo-refractive noise — refractive index perturbations driven by fundamental thermal fluctuations — have recently been identified as a limiting noise source in various optical microcavities. Here, we present a theoretical and experimental characterization of this thermal noise in high quality factor \((Q)\), small mode volume \((V)\) photonic crystal cavities. The theory reveals a mode volume-dependent maximum “effective” \(Q\)-factor due to thermal dephasing. We quantify the implications for quantum optical devices operating in the qubit limit of cavity nonlinear optics and compare these results to calibrated frequency stability measurements of common 2D silicon photonic crystal cavities. The results highlight the importance of considering thermal noise in state-of-the-art high-Q/V optical resonators, but also inform design choices which minimize its impact on device performance.

9:48AM L27.00010: Cryogenic electro-optic interconnect for superconducting circuits
ITAY SHOMRONI (Presenter), AMIR YOUSSEFI, NATHAN R BERNIER, YASH JOSHI, Ecole Polytechnique Federale de Lausanne, PHILIPP JOHANN UHRICH, University of Heidelberg, TOBIAS J. KIPPENBERG, Ecole Polytechnique Federale de Lausanne — Encoding information onto optical fields is the backbone of modern telecommunication networks. Optical fibers offer low loss transport and vast bandwidth compared to electrical cables, and are currently also replacing copper cables for short-range communications. Optical fibers also exhibit significantly lower thermal conductivity, making optical interconnects attractive for interfacing with superconducting circuits and devices. Yet little is known about modulation at cryogenic temperatures. Here we demonstrate a proof-of-principle experiment, showing that currently employed Ti-doped LiNbO modulators maintain the Pockels coefficient at 3K—a base temperature for classical microwave amplifier circuitry. We realize electro-optical read-out of a superconducting electromechanical circuit to perform both coherent spectroscopy, measuring optomechanically-induced transparency, and incoherent thermometry, encoding the thermomechanical sidebands in an optical signal. Although the achieved noise figures are high, approaches that match the lower-bandwidth microwave signals, use integrated devices or materials with higher EO coefficient, should achieve added noise similar to current HEMT amplifiers, providing a route to parallel readout for emerging quantum or classical computing platforms.
10:00AM L27.00011: Photon Mediation of Electron Transitions in Quantum Cascade Lasers

SINA SOLEIMANIKAHNOJ (Presenter), MICHELLE KING, IRENA KNEZEVIC, University of Wisconsin - Madison — Quantum cascade lasers (QCLs) are unipolar coherent light sources emitting in the terahertz and midinfrared portion of the electromagnetic spectrum. The active region of a QCL consist of periodic stacks of alternating semiconductor materials forming quantum wells which confine electrons in space and ensure they have desired discrete energy levels. Lasing is achieved by electron transition between these energy levels. In QCLs with the so-called diagonal design, this transition involves quantum tunneling between states with a small spatial overlap, separated by a potential barrier. This electron tunneling is mediated by photons present in the active region of the QCL and is referred to as photon-assisted (PA) tunneling. So far, theoretical studies dedicated to PA tunneling in QCLs have been limited to simple rate equations accompanied by empirical or phenomenological scattering rates. In this work, we present a quantum-transport study of PA tunneling in QCLs based on a Markovian master equation for the density matrix and investigate the effect of PA tunneling on electron dynamics and state lifetime.

*Funding: DOE BES DE-SC0008712; AFOSR FA9550-18-1-0340

10:12AM L27.00012: Extreme laser background suppression for resonance fluorescence in semiconductor nanostructures

MERYEM BENELAJLA (Presenter), attocube systems AG, MERYEM BENELAJLA, CNRS/INSA Toulouse, ELENA KAMMANN, KHALED KARRAI, attocube systems AG — Semiconductor nanostructures are promising candidates for developing single photon technologies. Relevant demonstrations in this field has been carried out by resonantly coupling a laser beam to a quantum emitter. Such challenging measurements require the suppression of laser background by several order of magnitudes. One way to do that is to use cross polarization confocal microscopy. Normally, high quality commercial crossed polarizers allows a laser suppression down to 5 to 6 orders of magnitudes. Surprisingly, when used in combination with a confocal microscope, the extinction ratio is boosted up to 9 order of magnitudes. This unexpected but very welcome enhancement finds its origin in the Imbert-Fedorov effect, now commonly referred to as Spin Hall effect of light, which manifests itself in the reflectivity of a Gaussian laser beam off a mirror. In this presentation, we will discuss in details the physics and optics of such a remarkable effect, which we mapped in details for the first time.
Quantized Microwave Faraday Rotation

VISHNUNARAYANAN SURESH (Presenter), EDOUARD PINSOLLE, CHRISTIAN LUPIEN, Universite de Sherbrooke, TALIA MARTZ-OBERLANDER, Department of Physics, McGill University, MICHAEL P LILLY, JOHN RENO, Center for Integrated Nanotechnologies, Sandia National Laboratories, GUILLAUME GERVAIS, Department of Physics, McGill University, THOMAS SZKOPEK, Electrical and Computer Engineering, McGill University, BERTRAND M REULET, Universite de Sherbrooke — The phenomenon of rotation of polarization in the presence of static magnetic field known as Faraday rotation [1] is very well known. Here we present the quantitative observation of microwave Faraday rotation conducted with GaAs/AlGaAs semiconductor heterostructure. The microwave Faraday rotation observed in high mobility two-dimensional electron gas arises as a result of cyclotron motion of charge carriers. The Faraday rotation induced can be understood by Fresnel analysis for the transmission of right and left handed circularly polarized microwaves. As with the Hall effect, a continuous classical as well as quantized Faraday rotation is observed. In the quantum Hall regime, the Faraday rotation is quantized in units of fine structure constant. The dielectric response of the semiconductor host, and the modification of the wave impedance and field distribution by a wave guide [2] will lead to a modification of the quantized Faraday rotation away from the vacuum fine structure constant, $\alpha \approx 1/137$. The effect of frequency dependent electromagnetic confinement can be accounted with an effective fine structure constant $\alpha^*$. 

In-chip laser nano-structuring inside silicon with spatially modulated beams

ONUR TOKEL (Presenter), AQIQ ISHRAQ, RANA ASGARI SABET, Bilkent Univ — Recently, we demonstrated a laser-writing method that exploits nonlinear interactions to form subsurface (in-chip) modifications, created deep inside silicon [1]. This single-step, maskless method introduced a new capability, i.e., controlled 3D microfabrication capability at 1-µm resolution inside Si [1]. Here, we expand the technique for demonstrating, to the best of our knowledge, the first nanofabrication capability in Si, realized without damaging the wafer surface. In order to achieve this, we exploit the ‘non-diffracting’ nature of Bessel beams, which offer better spatial control in comparison to Gaussian beams. The laser pulses of ~5 ns, 1.55 µm and a few-microjoules energy are modulated with a spatial light modulator, before directed with a lens system, forming Bessel pattern inside the sample. The crystal structure is disrupted in the form of rod-like structures that have high aspect-ratios > 500, with structure-widths that are on the order of 250 nm, and of roughness ~30 nm. These in-chip nano-structures can potentially lead to novel infrared photonic elements for phase and polarization control at the nanoscale.

L27.00015: Visible quantum dot light-emitting diodes with simultaneous high brightness and efficiency*  

HUAI BIN SHEN, Hua University, Kaifeng, China, QIANG GAO, University of Science and Technology of China, Hefei, China, YANBIN ZHANG, Henan University, Kaifeng, China, YUE LIN, University of Science and Technology of China, Hefei, China, QINGLI LIN, ZHAOHAN LI, LING CHEN, ZAIPING ZENG, Henan University, Kaifeng, China, XIAOGUANG LI, Shenzhen University, Shenzhen, China, YU JIA, SHUJIE WANG, ZULIANG DU, LIN SONG LI, Henan University, Kaifeng, China, ZHENYU ZHANG (Presenter), University of Science and Technology of China, Hefei, China — Quantum dot light-emitting diodes are promising light sources for applications in displays. However, to date, there have been no reports of devices that simultaneously offer both high brightness and high external quantum efficiency. Here, we report red, green and blue quantum dot light-emitting diodes based on CdSe/ZnSe core/shell structures that have these attributes. We demonstrate devices with maximum external quantum efficiencies of 21.6%, 22.9% and 8.05% for red, green and blue colours with corresponding brightness of 13,300 cd m^{-2}, 52,500 cd m^{-2} and 10,100 cd m^{-2}. The devices also offer peak luminance of 356,000 cd m^{-2}, 614,000 cd m^{-2} and 62,600 cd m^{-2}, respectively. We postulate that this high performance is due to the use of Se throughout the core/shell regions and the existence of alloyed bridging layers at the core/shell interfaces. This study suggests that in the future visible quantum dot light-emitting diodes will also be suitable for lighting applications.

Session L28 FIAP GERA: Seeing the Energy Future 405-407 - Carlos Gutierrez, Sandia National Laboratories - Tag(s): Industry, Invited, Undergrad Friendly

8:00AM L28.00001: Robert Andosca Invited Talk [Invited] —
ANDREW SPECK (Presenter), Schlumberger — Over the last few years, the Oil & Gas Industry has increasingly been driven to provide the most cost-effective and reliable supply of energy possible in order to continue providing over half of the world’s energy mix sustainably. This has required service providers for the industry to relentlessly optimize their technology performance and service delivery to improve asset economics both in existing fields as well as in new developments. A key location for optimization is in the multi-billion-dollar investments in subsea fields which require continual operational expenditures for services such as Inspection, Maintenance, and Repair (IMR) to ensure asset integrity.

IMR service providers currently utilize remotely operated vehicles (ROV) tethered to a surface vessel and piloted in real-time. Recent progress in underwater perception, maritime autonomy, and artificial intelligence can disrupt this old method and allow developing a leaner service model that significantly reduces the costly vessel and personnel support while improving data quality. uROV (untethered ROV) is unique in its approach to this problem. Around producing subsea fields, a higher level of supervision than “launch and forget” is needed. Thus, the uROV platform is based around supervised autonomy wherein a “person in the loop” has real-time feedback from onboard sensors and is then able to update the operation.

This talk will present the novel sensor architecture embedded on the uROV platform to enable this vision. Results include a first demonstration of remote acoustic visualization and control of subsea LiDAR during a high-resolution scan of a P-38 wreck. Extensions under development will enable remote mapping of infrastructure surface temperatures as well as detection and localization of potential hydrocarbon leaks. I will lastly present progress towards utilizing the data generated by these sensors for localization and cluttered environment navigation to safely approach high value assets.

ROSS KONINGSTEIN (Presenter), Research, Climate and Energy, Google — Tentative notional abstract. Work in progress.

Opening up the future of energy requires making bold advances in stationary and mobile power production.

In energy, more so than in most industries, most of the resources go into incremental advances. History teaches us that the marked differences between the past and today are due to fundamental changes.

So let’s look at what some fundamental changes could look like, and why this field could be the most exciting one to place revolutionary bets in.
In an increasingly electrified technology driven world, power electronics is central to the entire manufacturing economy. Silicon (Si) power devices have dominated power electronics due to their low cost volume production, excellent starting material quality, ease of processing, and proven reliability. Although Si power devices continue to make progress, they are approaching their operational limits primarily due to their relatively low bandgap and critical electric field that result in high conduction and switching losses, and poor high temperature performance.

In this presentation, the favorable material properties of Silicon Carbide (SiC) devices, which allow for highly efficient power electronic systems with reduced form factor and reduced cooling requirements, will be highlighted. Emphasis will be placed on high impact application opportunities where SiC devices are expected to displace their incumbent Si counterparts. These include “more electric aerospace” with weight, volume, and cooling system reductions contributing to energy savings and low emissions; automotive power electronics with reduced losses and relaxed cooling requirements; more efficient, flexible, and reliable grid applications with reduced system footprint; variable frequency drives for efficient high power electric motors at reduced overall system cost; and novel data center topologies with reduced cooling loads and higher efficiencies. Cost reduction strategies will be outlined elucidating the path to the projected $1.9 billion SiC device market by 2024.

8:00AM L29.00001: Coarse-grained theory for motion of solitons and skyrmions* CHENG LONG (Presenter), JONATHAN SELINGER, Kent State Univ - Kent — Recent experiments have found that applied electric fields can induce motion of skyrmions in chiral nematic liquid crystals [1]. To understand the magnitude and direction of the induced motion, we develop a coarse-grained approach to describe dynamics of skyrmions, similar to our group’s previous work on the dynamics of disclinations [2]. In this approach, we represent a localized excitation in terms of a few macroscopic degrees of freedom, including the position of the excitation and the orientation of the background director. We then derive the Rayleigh dissipation function, and hence the equations of motion, in terms of these macroscopic variables. We demonstrate this theoretical approach for 1D motion of a sine-Gordon soliton, and then extend it to 2D motion of a skyrmion. Our results show that skyrmions move in a direction perpendicular to the induced tilt of the background director. When the applied field is removed, skyrmions move in the opposite direction but not with equal magnitude, and hence the overall motion may be rectified.

8:12AM L29.00002: Energy dependence of resonant x-ray scattering for the twist bend nematic phase, a helix of liquid crystals* YU CAO, State Key Laboratory for Mechanical Behavior of Materials, Shaanxi International Research Center for Soft Matter, School of Materials Science and Engineering, Xi’an Jiaotong, JUN FENG, Advanced Light Source, Lawrence Berkeley National Laboratory, ASRITHA NALLAPANENI, Department of Polymer Engineering, University of Akron, YUKI ARAKAWA, Department of Applied Chemistry and Life Science, Toyohashi University of Technology, KEQING ZHAO, College of Chemistry, Sichuan Normal University, FENG LIU, State Key Laboratory for Mechanical Behavior of Materials, Shaanxi International Research Center for Soft Matter, School of Materials Science and Engineering, Xi’an Jiaotong, CHENHUI ZHU (Presenter), Advanced Light Source, Lawrence Berkeley National Laboratory — We examined the manifestation of resonance effects in twist bend nematic (NTB), smectic A (SmA) and crystalline phases via tender resonant X-ray scattering (TReXS) at sulfur K-edge. While SmA layering peak is partially resonant, scattering peak of NTB is purely resonant visible only near S K-edge. The difference is attributed to the periodic molecular orientation variation with weak electron density modulation. We further demonstrate that the energy-dependence of such scattering peak arising from pure orientation variation scales with the sum of $f_1(E)^2$ and $f_2(E)^2$, corresponding to the real and imaginary parts of dispersion correction respectively, while the resonant contribution in sulfur-containing SmA scales with $f_1(E)$, and is a first order perturbation to the relatively strong non-resonant peak from electron density modulation.

8:24AM L29.00003: Behavior of Superparamagnetic Microbeads in Smectic Films*
EMMANUEL BAMIDELE (Presenter), Material Science and Engineering Program and Soft Materials Research Center, University of Colorado, XI CHEN, JACKSON DURM, CHEOL PARK, JOSEPH E MACLENNAN, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado — We investigate the behaviour and magnetic response of superparamagnetic, silica-coated iron oxide microbeads embedded in freely suspended films of the smectic A liquid crystal 8CB. The microbeads, which are 5 mm in diameter, are mixed into the liquid crystal material at the edge of the film holder before the films of a few smectic layers are spread. Small aggregates and short chains of beads are observed in the film a few minutes after spreading, with longer chains forming along layer steps and at the heavily dislocated meniscus. The microbeads appear to affect the line tension of the layer steps, resulting in an increased tendency for thicker material to sweep in from the meniscus onto the initially thin film and causing islands to shrink much more rapidly than in films of neat 8CB. Moderate applied magnetic fields can be used to translate the beads on the film and to change the rate of island shrinkage.

8:36AM L29.00004: Dynamics of magnetically induced defect walls in Nematic Lenses
ZOLTAN KARASZI (Presenter), HAUMED RAHMANI, Kent State Univ - Kent, VIKTOR KENDERESI, PETER SALAMON, AGNES BUKA, Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, ANTAL ISTVAN JAKLI, Kent State Univ - Kent — We studied nematic liquid crystal (NLC) droplets with lens-shaped free surface placed on solid substrates under magnetic field applied parallel to the solid substrate. Both the solid substrate and the air pose homeotropic anchoring of the NLC director. At low magnetic-fields, the director field with a small radial in-plane component becomes distorted toward the field. At moderate fields it transforms into two regions with opposite tilt direction, separated by a wall. Polarizing optical microscopy (POM) with monochromatic light illumination reveals two sources of magnetic field driven fringe generation. At high fields, a Helfrich-type inversion defect wall arises normal to the magnetic field and moves outward. In addition to the experimental POM results, we present a simple theory and computer simulations that explain the magnetic field dependence of the director field and the time dependence of the outward motion of the inversion wall at constant magnetic fields.
8:48AM L29.00005: Dynamic pattern generation of topological defect arrays in nematic liquid crystals*  MINSU KIM (Presenter), FRANCESCA SERRA, Johns Hopkins University — Some photonic devices use the periodic nature of repeating lattices to modulate light.[1] Here we create tunable patterns of topological defect arrays in nematic liquid crystals (LCs) that can be simply controlled by electrical waveforms.[2,3] The refractive index of LCs is spatially modulated owing to the presence of the topological defect arrays. The symmetry and regularity of patterns is controllable thanks to micro-pillars created by photolithography. Adjusting the frequency and amplitude of electrical waveforms changes the defect spacing. Where the defect spacing is reduced, the number density of defects increases, compatibly with the presence of the pillars. The patterns are in two dimensions and this opens up more possibilities for the arrangement of the defects. When a laser beam propagates through the spatially modulated refractive index LC layer, the direction of the wave front changes and the beam can be split and steered. We utilize these complex patterns as a diffraction grating, which can change both diffraction (polar) angle and azimuthal angles.

9:00AM L29.00006: Elongation of Tactoids in the presence of an electric field*

MOHAMMADAMIN SAFDARI (Presenter), University of California, Riverside, PAUL VAN DER SCHOOT, Physics, Eindhoven University of Technology, ROYA ZANDI, University of California, Riverside — Tactoids are spindle-shaped droplets of a nematic phase suspended in the co-existing isotropic phase. They are found in dispersions of a wide variety of elongated colloidal particles, including actin, fd virus, carbon nanotubes, vanadium peroxide, and chitin nanocrystals. Recent experiments on tactoids of chitin nanocrystals dispersed in water show that electrical fields can strongly elongate tactoids, but only if the tactoids have a sufficiently large volume. We explain this by extending the Oseen-Frank elastic model of Kaznacheev et al. [1] and Prinsen et al. [2] to partially bipolar tactoids and evaluate the level of elongation of the tactoids as a function of the surface tension, elastic constants, volume, and electric field strength. By invoking a free-energy-based relaxational dynamics, we also describe the time evolution after switching on the electric field, confirming that, counterintuitively, large tactoids take more time to elongate to their equilibrium value in an electric field than small ones do.

9:12AM L29.00007: Observation of Ferroelectricity in a Thermotropic Nematic Liquid Crystal Using its Spectacular Electro-Optics* XI CHEN (Presenter), Department of Physics, University of Colorado, Boulder, EVA KORBLOVA, Department of Chemistry, University of Colorado, Boulder, RENFAN SHAO, LEO RADZIHOVSKY, MATTHEW GLASER, JOSEPH E MACLENNAN, Department of Physics, University of Colorado, Boulder, DAVID M. WALBA, Department of Chemistry, University of Colorado, Boulder, NOEL ANTHONY CLARK, Department of Physics, University of Colorado, Boulder — We have synthesized and studied the literature compound RM734 [1], a polar rod shaped molecule exhibiting a typical nematic phase and a second nematic phase assigned to be a "splay nematic" state [2]. We find that the second phase is rather a thermotropic ferroelectric nematic, an identification based on the first observation in a nematic of the defining characteristics of ferroelectricity: (1) the formation, in absence of applied electric field, of spontaneously polar domains of opposite sign of polarization separated by distinct domain boundaries; and (2) field-induced polarization reversal mediated by movement of these domain boundaries. A truly remarkable feature of this phase is the magnitude of its spontaneous polarization, saturating at 6 μC/cm², the largest ever reported for an organic material or for any fluid, and larger than that of all but a few crystalline ferroelectrics.

9:24AM L29.00008: Ferromagnetic Fréedericksz transition in ferromagnetic nematic filaments* MIN SHUAI (Presenter), XI CHEN, NATHAN COBASKO, JOSEPH E MACLENNAN, MATTHEW A. GLASER, NOEL ANTHONY CLARK, University of Colorado, Boulder — Barium hexaferrite nanoplates at sufficiently high concentrations in 1-butanol spontaneously form a ferromagnetic nematic phase due to the interplay between Onsager excluded volume effects and magnetic dipole-dipole interactions [Nat Comm, 7: 10394, 2016]. We have discovered a rich variety of ferromagnetic structures, such as droplets, toroids, and filaments, which form in the isotropic background when the concentration of the nanoplates is within the isotropic-nematic phase coexistence region. Here, we demonstrate a Fréedericksz transition in such ferromagnetic filaments. In the absence of applied magnetic field, the local magnetization direction of the filaments is parallel to their long axes. When a magnetic field is applied parallel to the magnetization direction, the existing alignment of the nanoplates is reinforced and the shape of the filaments remain unchanged. However, when a sufficiently strong magnetic field is applied antiparallel to the magnetization direction, an undulation instability sets in and the filaments form wavy structures. A simple model was developed to describe the deformation of the filaments close to the transition points.

**9:36AM L29.00009: Electrostatically controlled surface boundary conditions in hybrid molecular-colloidal liquid crystals**

HARIDAS MUNDOOR (Presenter), BOHDAN SENYUK, MAHMOUD ALMANSOURI, SUNGOH PARK, BLAISE FLEURY, University of Colorado, Boulder, HENRICUS WENSINK, Laboratoire de Physique des Solides, Université Paris-Sud, IVAN I SMALYUKH, University of Colorado, Boulder — In fundamental studies of liquid crystal (LC) colloids, surface interactions define the boundary conditions for molecules on particle surfaces and ultimately determine the induced defects and interactions. We study the influence of surface charge and ions on surface anchoring properties, with a focus on defining the behavior of anisotropic colloids dispersed in a nematic LC. We demonstrate a systematic variation of boundary conditions through controlling the competing aligning effects of surface functionalization and electric field arising from surface charging and bulk counterions. The control of ionic content in the bulk and at surfaces allows for tuning the equilibrium orientations of charged colloidal particles with respect to the far-field director \( \mathbf{n} \). When dispersed in high concentration, the charged colloids form biaxial nematic, columnar, and crystalline assemblies with tunable symmetries and ordering enabled by the anisotropic elastic and electrostatic interactions.

**9:48AM L29.00010: Cellulose Nanocrystal well alignment with addition magnetic nanoplates in weak gradient magnetic field**

MINGFENG CHEN (Presenter), ZHENGDONG CHENG, DALI HUANG, Texas A&M University — Rod like Cellulose nanocrystal (CNCs) are emerging nanomaterials that form chiral nematic liquid crystals and the controlling of orientation of formed liquid crystal phased has attracted broad attention. To enhance the response of CNC rods in the magnetic field, barium hexaferrite (BF) nanoplates, with positive magnetic susceptibility and mean nanoplatelet magnetization is \( m_0 = 2 \times 10^{-18} \) A m\(^2\), were introduced. Here, we investigated the effect of addition BF nanoplatelets on the phase transition and orientation of CNCs suspension in a weak external gradient magnetic field (Several hundred Gauss) . We observed the nematic phase prefer to move to the lower magnetic field region and a floating nematic phase is formed when the direction of magnetic field is contrast with the gravity field. We also demonstrate the gradient magnetic field can accelerate the phase separation. Based on these, we establish a method to control the phase separation speed and the position of nematic phase, since the movement of nematic phase depends on the competition of magnetic and gravity field. Moreover, the nematic phase were nearly perfect alignment along the magnetic field, which indicate with the BF magnetic nanoplates, the CNCs can be aligned by very weak magnetic field.
10:00AM L29.00011: Application of monolayer WSe\textsubscript{2} as the planar-alignment agent in an electro-optic liquid crystal device*  
RAJRATAN BASU, LUKAS J ATWOOD (Presenter), US Naval Academy — Two-dimensional (2D) tungsten diselenide (WSe\textsubscript{2}) nanosheets were transferred onto indium tin oxide (ITO) coated glass slides. Two such 2D WSe\textsubscript{2}-covered ITO glass slides were placed together to fabricate a liquid crystal (LC) cell. A nematic LC inside this WSe\textsubscript{2}-based cell exhibits uniform planar-alignment. This planar-alignment at the molecular scale is achieved due to the coherent overlay of the LC molecules along the selenium (Se) array on the WSe\textsubscript{2} lattice. This WSe\textsubscript{2}-based LC device shows the typical electro-optical effect when an electric field is applied via ITO electrodes. This electro-optical effect also reveals a standard Fréedericksz transition of the LC, confirming that the 2D WSe\textsubscript{2}, as the planar-alignment agent, supplies adequate planar anchoring energy—which can be overcome by the Fréedericksz threshold voltage.

10:12AM L29.00012: Topographical variations in thin liquid crystal films*  
TIM ATHERTON (Presenter), Physics and Astronomy, Tufts University, ANDREW FERRIS, CHARLES ROSENBLATT, Physics, Case Western Reserve University — A thin film of isotropic fluid with a free interface is always perfectly flat far away from boundaries and inclusions. In contrast, liquid crystals can, in principle, sustain a surface topography because elastic distortions in the bulk can be relaxed by deformation(s) of the surface. In practice, surface tension tends to dominate over elastic forces and so boundary deformations are usually neglected. (However, these have been observed in smectics and in nematics, as De Gennes famously predicted, where defects are confined to the boundary.) Here we present a different scenario: Topography at the free interface is induced by surface patterning of the substrate in a thin, hybrid-aligned nematic liquid crystal. The proposed mechanism requires finite anchoring at the free interface leading to modulation of the nematic orientation; deformation of the surface then allows the nematic to better satisfy the anchoring condition. We present analytical and numerical theory for several surface patterns, which are compared with our experimental actualizations.

10:24AM L29.00013: Microscopic look at mesogen interactions with two-dimensional nanosheets*  
PAUL BROWN (Presenter), ASEE Fellow for Naval Research Laboratory, SEAN A FISCHER, JAKUB KOLACZ, CHRISTOPHER SPILLMANN, DANIEL GUNLYCKE, United States Naval Research Laboratory — Recent interest surrounding the combination of liquid crystals (LC) and two-dimensional (2D) nanosheets has shown when 2D nanosheets are utilized liquid crystal-optical refractors obtain faster response times, smaller device dimensions, and the replacement of mechanical components that suffer from deterioration. Additionally, 2D materials can operate as an electrode and alignment agent simultaneously. In this talk, we use density functional theory to focus on the microscopic origins of recent observations where liquid crystals are combined with two-dimensional nanosheets. We highlight the origins of critical interactions between 5CB and graphene, boron nitride, and phosphorene. We demonstrate qualitatively different band structures among the substrates, and, in particular, boron nitride shows an alignment dependence for 5CB. The effect associated with the 5CB orientations on boron nitride will be discussed in more detail, where the possibility of edge modes form. Finally, we discuss the influence of point defects in the crystal lattice of each substrate.

XIAO LI (Presenter), Univ of North Texas, KANGHO PARK, Korea Advanced Institute of Science and Technology, JOSE MARTÍNEZ-GONZÁLEZ, Universidad Autónoma de San Luis Potosí, ORLANDO GUZMAN, Universidad Autonóma Metropolitana, JUAN DE PABLO, PAUL F NEALEY, University of Chicago — In condensed matter, the correlation length is an essential parameter for describing the distance over which a material maintains its structural properties. In liquid crystals, such a characteristic length is of the order of 10 µm while in solid crystals it can be extent up to macroscopic dimensions. Here, we report how to measure the correlation length of blue-phases (BPs), which are chiral liquid crystals with long-range 3D-crystalline structures and submicron-sized lattice-parameters. We design patterned substrates made of a binary array of regions with different anchoring, which facilitate a uniform nucleation and growth of BP-crystals with (100)-lattice orientation and a simple cubic symmetry. Our results indicate that this simple cubic blue-phase (BPII), forms first on the patterned surface, thereby setting the growth of domains in directions that can be parallel or perpendicular to the patterned regions. These results are used to understand the emergence of a surface anchoring assisted BPII-coherence length in terms of time and pattern characteristics. We found that BPII single crystals can be achieved on patterned regions whose lateral dimensions are equal or larger than 10 µm, which is consistent with our measurements of the BPII-coherence length.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM
8:00AM L30.00001: Conformal elasticity of two-dimensional dilational maximally auxetic materials [Invited]  

ZEB ROCKLIN (Presenter), Georgia Tech — The elastic response of a structure depends not only on its material, but on its geometry, as when the thinness of a sheet gives rise to out-of-plane bending fundamentally distinct from the response of a thick slab. Such thinness is similarly exploited in mechanical metamaterials which permit counter-rotations of stiff adjoining elements, ranging from corner-sharing square or triangular pieces to disordered networks. Such behavior can be described via a micromorphic theory which includes these abrupt local rearrangements, giving rise to a long-wavelength elastic theory which resembles conventional Cauchy elasticity with a dramatically reduced bulk modulus. The low-energy deformations consist predominantly of local rotations, translations and dilations without shears and are hence exactly the conformal maps of complex analysis, which admit a simple analytical theory extending even into the nonlinear regime. Despite finite-size effects, bending resistance and disorder, this theory accurately captures response in both finite-element simulations and experimental systems, opening new avenues for shape-changing, programmability and nonlinear response.

8:36AM L30.00002: Control and design of response in disordered networks: Geometry and self-stresses.*  

ANWESA BOSE, STEVEN A. VAN DUIJNHOVEN, MATTHIJS F.J. VERMEULEN, WOUTER G ELLENBROEK, CORNELIS STORM (Presenter), Applied Physics, Eindhoven University of Technology — The mechanical response of elastic networks is not only controlled by the elastic properties of its constituents, but also by their architecture. This is evident for crystalline structures, but equally true for random networks. I share two recent examples where we use geometry to elicit nonstandard mechanical response from disordered networks. In the first, we design freestanding frames that are mechanically overconstrained, and demonstrate that by engaging their states of self stress (i.e., applying internal loads that produce no strain) we can tune the overall mechanical response and induce softness, bi- and instabilities of purely geometric origin [1]. In the second example, we design random periodic lattices and structurally optimize them to exhibit specific responsiveness manifested, f.i., by extreme auxeticity (deeply negative Poisson's ratios). Together, these examples illustrate that the power of geometry may be harnessed to coax tailored, highly non-generic response even out of fully disordered materials.

8:48AM L30.00003: Coulomb Floppy Networks: from soft to hard matter.* ALEXEI TKACHENKO (Presenter), IGOR ZALIZNYAK, Brookhaven National Laboratory — Floppy Networks (FNs) play a prominent role in soft condensed matter physics, from polymeric gels and rubber to biomolecules, glasses, and granular materials. We demonstrate how the very same concept emerges in the context of a family of open-framework ionic solids, e.g. ScF$_3$, which can be conceptualized as Coulomb FNs. They exhibit unusual properties, including quantum structural phase transition near ambient pressure and negative thermal expansion (NTE). We connect these phenomena to FN-like crystalline architecture, stabilized by the net electrostatic repulsion, playing a role similar to the osmotic pressure in a polymeric gel. Our theory provides an accurate quantitative description of NTE and structural transition. Entropic stabilization of criticality explains the observed phase behavior. In addition, a significant entropic contribution to elasticity accounts for the marked discrepancy between numerical and experimentally observed compressibilities.

*The work was performed at Brookhaven National Laboratory under DOE contract DE-SC0012704. It used resources of the Center for Functional Nanomaterials (CFN), a user facility of the Office of Basic Energy Sciences (BES), and was partially supported Division of Materials Sciences and Engineering of BES.

9:00AM L30.00004: Emergence of rigidity, microscopic rearrangements and viscoelastic response in soft particle gels EMANUELA DEL GADO (Presenter), Georgetown University, BAVAND KESHAVARZ, Mechanical Engineering, MIT, MINASPI BANTAWA, Georgetown University, MICHELA GERI, Mechanical Engineering, MIT, MEHDI BOUZID, LPTMS, Universite Paris Sud, THIBAUT DIVOUX, CNRS, MIT, GARETH H MCKINLEY, Mechanical Engineering, MIT — We have investigated the connection between the structural and mechanical heterogeneities of soft particulate gels and their viscoelastic spectrum in a 3-D microscopic numerical model, using large scale simulations with Optimally Windowed Chirp (OWCh) signals. In the model, particles spontaneously self-assemble into disordered, stable porous networks (even at low volume fractions) that feature extended relaxation spectra, microscopic dynamics, and mechanics consistent with several observations in colloidal and protein gels. To recapitulate the basic features of the particle contacts in those systems, the main ingredients of the model are short-range attractive interactions and bending stiffness for the inter-particle bonds. We have analyzed the emergence of rigidity, the shape of the frequency-dependent dynamic modulus G*(ω) and its dependence on the gel connectivity, and the distribution of microscopic non-affine rearrangements the network experiences under small-amplitude oscillatory deformation. We show how the viscoelastic response of different gels can be captured in a unique master curve through a fractional constitutive model and discuss how the underlying microscopic dynamical processes determine the rheological response.

9:12AM L30.00005: Pseudomomentum balance in thin structures JAMES HANNA (Presenter), University of Nevada, Reno, HARMMEET SINGH, École Polytechnique Fédérale de Lausanne — The balance of pseudomomentum is associated with material symmetry in continua. We will employ it in the context of thin, flexible structures, to explain conserved quantities in rotating conical membranes and propulsive forces on confined elastic rods.
9:24AM L30.00006: Asymptotic isometry and wrinkle-to-fold transition in a simplified Lamé problem*  ANSHUMAN PAL (Presenter), THOMAS WITTEN, University of Chicago — Azimuthal wrinkling in the annular (Lamé) geometry serves as an archetype for understanding geometry-influenced elastic response in thin sheets. In most experiments, the annulus is subjected to radial tension at both the inner and outer boundaries, generating compression and wrinkling in the azimuthal direction ([1]). In our work, we study an even simpler version of this problem, using theory and simulations, where the annulus is subjected to only a radial pull at the inner boundary. This creates azimuthal wrinkling with a simpler, one-dimensional phase space spanned by the dimensionless 'bendability' parameter, $\varepsilon^{-1}$. We focus on the large $\varepsilon^{-1}$ (small thickness and/or large load) limit — here, in contrast to previous experiments, the sheet becomes asymptotically isometric, and the wavenumber coarsens and hits a lower limit set by the geometry of the sheet and the boundary conditions. If we now loosen the boundary condition, the wrinkles transition to a single fold that consumes all the excess length. Although purely numerical, to the best of our knowledge, this is the first realisation of a wrinkle-to-fold transition ([2]) on an unsupported membrane.

9:36AM L30.00007: Geometry, mechanics, and dynamics of leaves, flowers, and sea slugs KENNETH YAMAMOTO (Presenter), SHANKAR VENKATARAMANI, Univ of Arizona — Why are there intricate, self-similar wrinkles along the edges of growing leaves, blooming flowers, torn plastic sheets, and frilly sea slugs? We argue that the mechanics and dynamics of these non-Euclidean elastic sheets are governed by interacting non-smooth geometric defects in the material. I will describe novel ideas stemming from characterizing and analyzing these defects using discrete differential geometry in order to uncover fundamental insights into the elastic behavior and properties of thin hyperbolic bodies. New theories based on the mechanics of non-smooth defects may (i) explain biological phenomena, from the morphogenesis of leaves, flowers, etc. to the biomechanics of sea slugs, as well as (ii) introduce new paradigms for materials design and actuation in a variety of new technologies, e.g., soft robotics.
9:48AM L30.00008: Mechanics and geometry of soft beams and shells
DANIELE BATTISTA (Presenter), MICHELE CURATOLO, PAOLA NARDINOCCHI, Univ of Rome La Sapienza — We investigate swelling-induced morphing in thin soft polymer based plates and shells. Starting from flat geometries, sphere-like and nearly developable shapes are realized and the ability to control a specific shaping, shifting from one shape to another, under anisotropic swelling is investigated. Starting from nearly developable shapes, the effects on the geometry of swelling and shrinking is also studied. The mathematical model accounts for both diffusion and nonlinear mechanics (stress-diffusion model). It is implemented in a finite element code and a campaign of numerical experiments is planned. Reduced analytical or semi-analytical approaches will be used to catch the experimental results above.

The Authors thank PRIN 2017 "Mathematics of active materials: From mechanobiology to smart devices", project n. 2017KL4EF3, for financial support.

10:00AM L30.00009: Capture of particles by a flexible granular envelope
KATHARINE BANCROFT (Presenter), THEODORE ANTHONY BRZINSKI, Haverford College — The capture of small particles by a flexible envelope can model many common phenomena. For example, in the rotating environment of a commercial dryer, large, flexible, non-convex objects like fitted sheets and duvet covers often capture smaller items like socks that fail to dry as a result. Amoeba exploit a similar process for prey capture by extruding pseudopodia in which smaller organisms become trapped. We have developed a quasi-2D granular system with qualitatively similar dynamics: a granular chain envelope composed of custom ball chain in a background dispersion of spherical grains inside a rotating drum. The particle-scale geometry of the granular chain determines the available conformations of the envelope, leading to a biased convexity. We share the results of our investigation of the kinetics of particle capture for this novel model system.

10:12AM L30.00010: Predicting the onset of disclination defects on curved open surfaces
SIDDHANSH AGARWAL (Presenter), SASCHA HILGENFELDT, University of Illinois at Urbana-Champaign — Ordered structures on surfaces with Gaussian curvature are topologically constrained to contain a finite defect charge, while the positioning of these defects is determined by optimization of the surface’s elastic energy. Open surfaces of sufficiently small curvature minimize energy without defects in the bulk, while stronger curvature favors the appearance of a disclination in the ground state; the presence of a boundary adds subtlety to the local screening of Gaussian curvature by defects. We find that, in contrast to previous heuristic arguments, the onset of transition is governed neither by local values of Gaussian curvature nor by its global integral. Starting from stringent energy minimization, we instead propose a weighted integral Gaussian curvature as an improved predictor for the transition - one that is universally valid for a large class of bounded rotationally symmetric surfaces. Our formalism also allows for analysis of the first or second order character of the transition, and how it is modified by boundary stresses and/or breaking symmetries of shape or material properties. These findings are of practical and fundamental importance in both engineering and biological cellular systems, such as the pattern of visual processing in invertebrate eyes.
10:24AM L30.00011: Facets and Folds: A model for fragmentation kinetics of crumpled thin sheets

JOVANA ANDREJEVIC (Presenter), LISA M LEE, SHMUEL RUBINSTEIN, CHRISTOPHER RYCRFT, Harvard University — As a confined thin sheet crumples, a unique arrangement of sharp ridges emerges, delineating approximately flat facets. Viewed collectively, this mosaic of ridges and facets exhibits striking statistical reproducibility - the total length traced out by ridges, for instance, has been shown to grow logarithmically with the number of crumpling and unfolding repetitions. Here, we explore the correspondence between crumpling and a general fragmentation process. We identify a physical model for the evolution of facet area distribution in crumpled sheets that captures a wide range of data samples with a single variable parameter. We then demonstrate the capacity of this model to reproduce experimental observations such as the characteristic logarithmic scaling of total ridge length, thereby supplying a missing physical basis for the observed phenomenon.

10:36AM L30.00012: Stress Relaxation of Drying Colloids

ZHIYU JIANG (Presenter), CHONG SHEN, LANFANG LI, Physics, Lehigh University, MEGAN VALENTINE, Mechanical Engineering, University of California, Santa Barbara, YE XU, Mechanical Engineering, Beihang University, H DANIEL OU-YANG, Physics, Lehigh University — Stress relaxation during the drying of coatings is of interest due to its importance in the thin film-formation process that dictates the final properties of coatings. Using drying colloidal suspensions as a model system, this study examines how stresses in the colloidal matrix relax when particles are compacted during uniaxial drying in a microfluidics. Microscopic oil droplets co-suspended in the colloids are used as probes for local stresses and strains as these droplets are deformed by the changing matrix of particles. Balance of the interfacial stress of the oil in the colloids and the stress produced by the compacting colloids dictates the shape evolution of the droplets. The evolution of the deformations of multiple droplets is recorded by confocal fluorescence microscopy. Images of the time evolutions of the droplet shapes and the positions of fluorescent tracer particles nearby the droplets are analyzed by digital image correlation. The talk will address questions on the roles of the viscous damping, interfacial tension between the oil and colloidal matrix, the anisotropy of the strain and stress distributions and the mechanical properties of compacting colloidal particles before the coating is fully dried.
Physics Behind the Snapping of a Twisted Balloon

YU-CHUAN CHENG (Presenter), HUNG-CHIEH FAN CHIANG, HSIN-HUEI LI, WEI-CHIH LI, TZAY-MING HONG, Physics, National Tsing Hua University — It is childhood experience to twist balloons and turn them into dogs and flower. In this talk we investigate the process that leads up to the snap of a cylindrical balloon. For a twisted short balloon (1<\(L/D\)<7 where \(L\), \(D\) : length and diameter), its phase transits from (1) being sheared and wrinkle-free while torque (\(t\)) is linear to \(\theta\), (2) appearance of a neck without wrinkles, while radius and shear angle are found to obey \(r^3\!d\theta/dx=\text{const}\), (3) development of parallel wrinkles whose number \(\sim 12\) is insensitive to \(L\), \(D\), and thickness. \(\tau\) increases concavely with \(\theta\), to (4) wrinkles cross one another eventually and are followed by a sudden snap into two segments, as for a bended drinking straw. For a medium-size balloon (7<\(L/D\)<15), (a) similar to (1), (b) skip (2, 3) to become curled with a low-amplitude oscillation in \(\theta\), (c) similar to (4). When the balloon is long (15<\(L/D\)), (i) similar to (1) (ii) similar to (b), but develop a supercoil while accompanied by a suddenly drop in \(\tau\), (iii) repeat (i, ii). Heuristic models are proposed to understand the physics behind different phases. MD simulation is also performed to reveal energetics. Furthermore, to verify whether the above properties are unique to a quasi-1D object (balloons), a thread (real 1D) and ribbon (2D) are also studied.

Session L31 DSOFT: DSOFT Early Career Award and Directed Assembly
8:00AM L31.00001: Early Career Award for Soft Matter Research talk* [Invited] STEFANO SACANNA (Presenter), New York Univ NYU — Colloidal self-assembly today is increasingly focused on the development of particles that mimic atomic properties. Atoms serve as inspiration for what simple but ideal building blocks are capable of, and through the mastery of relatively few design principles, such as directionality, valence, and well-defined bonds, many target architectures become rationally accessible. A colloidal diamond lattice, for example, theoretically operates as an exotic semiconductor for light, and is just now becoming available through molecular mimetic routes. Myriad syntheses have been developed to accomplish this by targeting specific geometries and surface patterns, which serve to direct assembly. In this talk, I will break down and categorize the wide selection of colloidal reactions available by using an analogy to synthetic chemistry, helping to index and navigate the ever-expanding colloidal toolbox. Beginning with elementary colloidal particles, I will define the set of directions synthetic routes can take, firstly, through inter-particle reactions, which combine disparate particles into new well-defined units and secondly through intra-particle reactions, which occur through a particle’s internal transformation. I will also discuss the most prominent colloidal interactions available for assembly, and which are most useful for a given synthetic route. Today, long-sought-after target structures are just coming to fruition, so it is an ideal time in the colloidal community to examine the most efficient ways to generate particles and how to make them assemble. Drawing from many fields including colloid and surface chemistry, supramolecular chemistry, biochemistry, and photonics, molecular mimetic colloids represent a point of interest for any materials scientist.

8:36AM L31.00002: Colloidal Diamond Crystals MINGXIN HE (Presenter), Department of Chemical and Biomolecular Engineering, New York University, JOHNATHON GALES, ETIENNE DUCROT, Department of Physics, New York University, ZHE GONG, Department of Chemistry, New York University, GI-RA YI, School of Chemical Engineering, Sungkyunkwan University, STEFANO SACANNA, Department of Chemistry, New York University, DAVID J PINE, Department of Chemical and Biomolecular Engineering, New York University — Self-assembling colloidal diamond has been a longstanding goal because of the structure’s potential for photonic applications. Because particles in a diamond lattice are tetrahedrally coordinated, one approach has been to self-assemble spherical particles with tetrahedral sticky patches. Difficulties persist, however, because the patchy particles possess no mechanism to select the proper staggered orientation of tetrahedral bonds on nearest-neighbor particles, a necessary requirement for cubic diamond. Here, we show that by using partially compressed clusters with retracted sticky patches, colloidal cubic diamond can be self-assembled using patch-patch adhesion together with a steric interlock mechanism that selects the proper staggered bond orientation. Colloidal particles in the self-assembled diamond structure are highly constrained and mechanically stable, which makes it possible to dry the suspension and retain the diamond structure. The inverse lattice exhibits promising photonic properties, including a complete photonic bandgap.
8:48AM L31.00003: Colloidal Diamond Photonic Bands  JOHNATHON GALES (Presenter), MINGXIN HE, DAVID J PINE, New York Univ NYU — We have designed a new set of patchy tetrahedral colloidal clusters that can self-assemble into a diamond lattice. Like the conventional colloidal diamond of spheres, we find that the diamond lattice of clusters we have assembled exhibits a strong photonic band gap for appropriate parameters. Inverting the lattice leads to a particularly strong band gap after optimizing a few geometric parameters. We also provide a method for achieving the inverse lattice.

9:00AM L31.00004: Photonic band gaps in self-assembled colloidal structures  DUANDUAN WAN (Presenter), Wuhan Univ, SHARON C GLOTZER, University of Michigan — An intriguing feature of colloids is their ability of self-assembly, i.e., colloidal particles arrange themselves into an ordered structure. Using computer simulations, we explore the effect of thermal disorder on the photonic band gap in a self-assembled photonic crystal. We find that photonic band gaps can exist over a large range of intermediate packing fractions and that the widest gap does not necessarily appear at the densest packing fraction. Further, we show that with judicious choices of particle shape, packing fraction, and particle internal structure, self-assembly can be a promising method to make photonic crystals with large band gaps despite the presence of disorder.

9:12AM L31.00005: Rational Design of Patchy Colloids Capable of Self-Assembling into Open Crystal Lattices with Complete Photonic Bandgaps*  YUTAO MA (Presenter), ANDREW L FERGUSON, University of Chicago — Patchy colloids equipped with anisotropic interactions are promising building blocks whose self-assembly provides a powerful tool for forming many complex functional materials. A main challenge in the self-assembly of patchy colloids is the design of colloidal geometry and chemistry that favor the formation of target structure thermodynamically and kinetically. We have previously developed a rational design protocol, called landscape engineering, in which we recover the free energy surface governing colloidal self-assembly process by combining molecular simulation with nonlinear dimensionality reduction technique and sculpt the free energy surface by modifying the colloidal design using genetic algorithm to make target structure thermodynamically favorable. We have applied this protocol to successfully design patchy colloids capable of self-assembling into pyrochlore lattice and cubic diamond lattice consisting of tetrahedral clusters via two-stage temperature control. Both structures are defect-free and possess complete photonic bandgaps. Our method may be extended to the rational design of self-assembling colloidal molecules and other systems such as peptides.

9:24AM L31.00006: Nanoparticle Superlattices with Polymer Ligands*  ALEX TRAVESSET  
(Presenter), Physics and Astronomy, Iowa State University and Ames Lab, NATHAN R HORST, Ames Lab, JIANSHE XIA, HONGXIA GUO, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100190, China — We provide a study of the assembly of single component nanocrystals (nanoparticles) NCs capped with polystyrene by solvent evaporation. We investigate regimes from the colloidal $R_G/R_C<<1$ with $R_C$ (core radius) and $R_G$ (ligand gyration radius) to the polymer limit $R_G/R_C>>1$. We show that for increasing chain length, there is the emergence of a ```cascade effect```, i.e. an abrupt drop in internal energy with the resulting potential of mean force dominated by configurations wherein the chains bend over the core in order to maximize contacts with the other NC, which accounts for the large magnitude of the many body effects in the superlattice free energy. Interestingly, the Orbifold Topolgical Model (OTM) that successfully characterizes the nanocrystal interaction in the colloidal limit, quantitatively describes the polymer limit as well. Our results establish that bcc is the equilibrium phase. Implications for recent and future experiments are discussed.

9:36AM L31.00007: Binary colloidal compounds with depletants*  ALI EHLEN (Presenter), HECTOR MANUEL LOPEZ RIOS, MONICA OLVERA DE LA CRUZ, Northwestern University — We study the effects of depletants on binary size-asymmetric colloidal crystals. Specifically, we discuss the mechanism that leads to two types of systems: 1) stable compound crystals of large repulsive particles with smaller particles; and 2) crystals of large repulsive particles stabilized by a mobile sublattice of small particles. This talk will address the impact of the presence of depletants in both the compounds and in the sublattice-melted crystals, as well as the relative significance of the attractive interaction between the particles and the depletion forces.

*We acknowledge the support of the Sherman Fairchild Foundation for this work.
9:48AM L31.00008: Phase Diagram and Structure Map of Binary Nanoparticle Superlattices from a Lennard-Jones Model*  SHANG REN (Presenter), Department of Physics and Astronomy, Rutgers University, YANG SUN, FENG ZHANG, Ames Laboratory, ALEX TRAVESSET, CAI-ZHUANG WANG, KAI-MING HO, Department of Physics and Astronomy, Iowa State University — In this work, we show that a binary system interacting through Lennard-Jones (LJ) potential predicts all phases reported in experiments in which nanoparticles are effectively described as quasi hard spheres. Furthermore, we show that binary lattices may be described as combinations of a small number of particle clusters, motifs, which generalize the four Z-N that describe Frank Kasper phases. We report a phase diagram consisting of 53 equilibrium phases, whose stability is quite insensitive to the microscopic details of the potentials, thus giving raise to some universality. Our results show that meta-stable phases share the same motifs as equilibrium phases. Connections with packing models, phase diagrams with repulsive potentials and the prediction of new superlattices in experiments are thoroughly discussed.

10:00AM L31.00009: Novel mesophase behavior in two-dimensional binary solid solutions*  PRAJWAL BANGALORE PRAKASH (Presenter), FERNANDO A ESCOBEDO, Cornell University — Towards the goal of designing new complex materials, Monte Carlo simulations were used to study the entropic-driven assembly of binary mixtures of hard polygons and disks. Two distinct types of mixtures were studied, such that individual components either form distinct crystal lattices, like squares and disks, or similar crystal lattices, like hexagons and disks. Our focus was the 2D phase behavior of mixtures where the components have size ratios that optimize their co-assembly into solid solutions, and over the full range of compositions and concentrations to further detect any partially ordered phases (mesophases). Besides the enhanced regions with solid miscibility, a novel mosaic/polycrystalline phase was found for the disk+square mixtures and a rotator-plastic solid phase for the disk+hexagon mixtures. The mosaic phase has interspersed clusters of locally ordered 4-fold squares and 6-fold disks, distributed throughout the domain with random orientations. The plastic-solid rotator mesophase of hexagons and disks exhibits long-range translational and short-range orientational order. Changes in phase behavior for different component size ratios were also investigated to assess the importance of the optimal size ratio in promoting mesophase behavior.

*NSF award CBET-1907369
10:12AM L31.00010: Diffusion of DNA-coated colloids on DNA coated surface* JEANA(AOJIE) ZHENG (Presenter), New York Univ NYU, SOPHIE MARBACH, MIRANDA HOLMES-CERFON, Courant Institute of Mathematical Sciences, New York University, DAVID J PINE, New York Univ NYU — DNA-coated colloids can self-assemble and crystalize into a wide variety of structures. In order for DNA-coated colloids to anneal and form crystals, they must roll and diffuse while attached to each other. Here we report on the diffusion of DNA-coated colloidal spheres on a flat DNA-coated substrate. Near the DNA-melting temperature, the mean square displacement is linear in time as expected for normal diffusion, but the diffusion coefficient is much smaller than for free diffusion. As the temperature is lowered, the motion becomes sub-diffusive, which suggests the presence of random free energy barriers in the DNA-mediated interactions. We have found that DNA induced interactions are highly sensitive to the density and homogeneity of the DNA distribution. As we reduce the DNA density, the DNA coated colloids diffuse slower. Here we also report the modeling of melting curve for particle - substrate binding, allowing to understand and predict how binding properties depend on parameters of the DNA-coated colloids (salt concentrations, DNA sequence, etc.) This study is important for designing and optimizing self-assembly structure of DNA coated colloids.

*MRSEC Program of the National Science Foundation under Award Number DMR-1420073

10:24AM L31.00011: 3D self-replication of DNA nanostructures* FENG ZHOU (Presenter), HENG NI, RUOJIE SHA, NADRIAN C SEEMAN, PAUL M CHAIKIN, New York Univ NYU — Self-replication is a natural process that can generate materials and pass along information. We have seen several examples of artificial self-replication in which the template assembles, organizes and directs formation of the target nanostructure. However, the self-assembly procedure increases the template's dimensionality, which makes it challenging to template and replicate a 3D object. Here, we report the direct self-replication of a 3D object. First, we fabricate a three face cube corner as our template. The replication proceeds by self-assembling three daughter origami tiles to three edges of the cube corner. DNA single strands on each cube face and daughter tile hybridize to fold the tiles inward and complete the cubic box. The daughter tiles are then cross-linked into a new cube corner. Heating releases the two complementary cube corners. This method provides a general approach for conducting high-order self-replication by organizing the materials via folding. Considering that the 3D DNA nanostructure is a functional platform, this type of 3D self-replication can produce new materials, such as chiral plasmonic nanomaterials, by passing the steric information through successive generations.

10:36AM L31.00012: Self-assembled helical structures of ABCD star tetrablock copolymer within cylindrical confinement  PARESH CHOKSHI (Presenter), SUPRIYA GUPTA, Department of Chemical Engineering, Indian Institute of Technology Delhi — Physical confinement of block copolymers plays an important role in generating a rich variety of novel ordered phases not seen in bulk systems. These novel ordered microstructures, arising mainly out of structural frustration and confinement-induced entropy loss, provide ideal templates to self-assemble nanoparticles. In order to generate novel multicomponent helical structures, we investigate the four-armed ABCD star tetrablock copolymers for their equilibrium states under cylindrical nanopore confinement with the help of self-consistent field theory. The ABCD star tetrablock copolymer exhibits rich self-assembly behaviour with myriads of three-dimensional ordered phases ranging from one-component, two-components and three-components helices to honeycomb-like structures depending upon the individual block fractions and the size of cylindrical nanopore. Such chiral structural motifs generated from achiral polymeric molecules are fascinating due to superior performance in sophisticated optical functions. The comprehensive understanding of the self-assembly behaviour enables one to design novel nanostructured materials with desired material properties.

10:48AM L31.00013: Toward generating colloidal cubic phases: Shape sensitivity of the Ia(-3)d gyroid phase in hard pear-shaped particle systems  PHILIPP SCHÖNHÖFER (Presenter), University of Michigan, GERD SCHROEDER-TURK, Murdoch University — The ambition to mimic highly complex and functional nanostructures found in living organisms marks one of the pillars of today's research in bio- and soft matter physics. Here, self-assembly has evolved into a prominent strategy in nanostructure formation. However, it is still a challenge to design and realise particle properties such that they self-organise into the desired target configuration. One key design parameter is the (effective) shape of the constituent particles.

We address the entropically driven colloidal self-assembly of tapered ellipsoids, reminiscent of "pear-shaped" particles, including the formation of structures based on triply periodic minimal surfaces (TPMS) such as the gyroid. Using computational simulations, we investigate the influence of variations in shape on the stability of the gyroid phase. We show that the formation of the gyroid reported earlier in the so-called pear hard Gaussian overlap (PHGO) approximation, is due to small non-additive properties of that potential. This phase does not form in pears with a "true" hard pear-shaped potential. In particular, the slight differences in shape favour the formation of interdigitated bilayers in the PHGO particle ensemble, which indicates a two-step hierarchical mechanism to generate TPMS phases.

Session L32 DPOLY DSOFT DCP: Dynamics of Glassy Polymers Under Nanoscale Confinement II  504 - Biao Zuo, Zhejiang Sci-Tech University - Tag(s): Focus
8:00AM L32.00001: Measuring dynamic mechanical properties of thin polymer films [Invited]
YUNLONG GUO (Presenter), PEI BAI, Shanghai Jiao Tong Univ — Polymer dynamics under confinement on nanoscale exhibits substantial deviation from the bulk and has received a great deal of research interests in the past two decades. To date, some representative physical properties of confined polymers such as glass transition temperature and structural relaxation, have been studied extensively. Despite milestone progress in measuring Young's modulus, creep, and stress-strain curves of thin polymers, mechanical properties of confined polymers are still far from well understood, and remain to be elucidated in many other aspects. Here we demonstrate an experimental apparatus for direct measurement of dynamic mechanical response of thin polymer films. We utilize a sinusoidal pressure wave on a polymer film to induce vibration, and the response of the material is record by a high-speed digital camera. By analyzing the data on stress, strain, and the phase difference in between, we obtained dynamic mechanical properties of polymer films with various thickness.

8:36AM L32.00002: An explanation of how nanoconfinement affects the control of local dynamic relaxation*  
JANE E LIPSON (Presenter), RONALD WHITE, Dartmouth Coll — The dynamics of local segmental relaxation in glass forming systems is linked to fundamental material properties and control variables that reflect the influence of thermodynamics on the relaxation time, tau. In the Cooperative Free Volume (CFV) model the key variables are temperature (T) and free volume (V_{free}), which is related to density. The general CFV result is that \( \log \tau \sim (1/V_{\text{free}}) \times f(T) \). We find that our result for \( f(T) \) works equally well for the bulk under highly varying pressure conditions, and for all types of confinement. The presence of \( V_{\text{free}} \) in the CFV expression for \( \log \tau \) results in a sensitivity to density changes that becomes strong at low T, and also reflective of the presence of interfaces, whether in film or nanocomposite. In this talk these CFV features will be illustrated through extensive connection with experimental data on a variety of systems.

*NSF DMR-1708542
8:48AM L32.00003: Is there a general compensation rule governing the relaxation dynamics of polymeric surface patterns?  SONAL BHADAURIYA, Department of Polymer Engineering, University of Akron, CHRISTOPHER M STAFFORD, JACK DOUGLAS, Materials Science and Engineering Division, National Institute of Standards and Technology, ALAMGIR KARIM (Presenter), Department of Chemical and Biomolecular Engineering, University of Houston — Understanding the mechanism and decay kinetics of patterned polymeric surfaces is a pertinent issue in nanotechnology. Herein, we present the relaxation behaviour of nanoparticle-brush filled imprinted and wrinkled polymer films showing similar compensation effect. Entropy-enthalpy compensation (EEC) effect signifies a linear correlation between the activation parameters of a relaxation process and is routinely observed in the relaxation dynamics of many condensed materials such as molecular additives and glass-forming materials. For the first time, we experimentally observed a full mapped out transition of pattern decay kinetics as a function of temperature (below and above the glass transition of the matrix) and additive concentration by utilizing decay of polymeric surface wrinkles. We observe EEC effect for an athermal and a favorable interacting composite system, thereby ensuring the robustness of the observed phenomenon. As a consequence of this compensation effect, relaxation kinetics for composite wrinkled films is faster than the neat polymer film below the characteristic compensation temperature, $T_{comp}$ and faster above the $T_{comp}$. EEC proves itself to be the underlying mechanism for patterned polymer decay, governing the kinetics of any polymeric surface with patterns.

9:00AM L32.00004: A simulation study on nonlinear mechanical responses of glassy polymer nanofibers*  TAEJIN KWON (Presenter), BONG JUNE SUNG, Sogang Univ — The confined polymer glasses, such as glassy polymer fibers, exhibit unique glassy behaviors that differ from bulk polymer glasses. We perform molecular dynamics simulations and study nonlinear mechanical responses of glassy polymer nanofibers under uniaxial deformation. We investigate not only nonlinear mechanical responses but also the dependence of mechanical properties on the strain rates of typical polymer glasses, which were also observed in previous experiments. We find from our simulations that the local stress in the surface regions of fibers is greater than that in the core region of fibers, for which the stress of glassy polymer fibers is greater than that of bulk polymer glasses in our simulations. The distance between monomers in glassy polymer fibers are more stretched than that in bulk polymer glasses. Also, the non-affine displacements in the surface regions of glassy polymer fibers are greater than those in bulk polymer glasses. These results indicate that the microscopic events during deformation relate closely to the mechanical responses of polymer glasses.

*This work was supported by the Samsung Science and Technology Foundation under Project Number SSTF-BA1502-07.
9:12AM L32.00005: Gradient overlap effects in the thin films

ASIEH GHANEKARADE (Presenter), DAVID SIMMONS, Univ of South Florida — The dynamics of polymer and other glass-forming liquids can exhibit massive gradients in the nanoscale vicinity of interfaces – an effect that is not locally correlated with microscopic changes in structure. A major outstanding question is how these gradients behave in extremely thin films, where gradients emanating from distinct interfaces can interact. Here we report on the results of ultra-thin film simulations probing dynamics and glass formation locally and globally in this gradient-overlap regime. Results point to three general regimes of thin film behavior: one when the film thickness is greater than twice the gradient range; one in which the gradients overlap but do not individually span the film; and an ultra-thin-film limit in which each gradient span fully to the other interface. We report on distinct behaviors in these regimes in terms of the form of the gradients, the presence or absence of a bulk-like domain, and the breadth of the overall film glass transition. These findings have implications for the interpretation of dynamical data in ultra-thin films and for the underlying origin of alterations in dynamics in the nanoscale vicinity of interfaces.

*This material is based upon work supported by the National Science Foundation under Grant No. CBET1705738.

9:24AM L32.00006: Dynamical gradients, barrier factorization and interface coupling in thick and thin films of glass-forming liquids

KENNETH SCHWEIZER (Presenter), University of Illinois at Urbana-Champaign, ANH D. PHAN, Phenikaa University, Hanoi, Vietnam — We have developed a microscopic theory for the spatially heterogeneous dynamics of glassy polymer liquids near a vapor interface. The key activated event involves cage scale hopping facilitated by a collective elastic distortion of the surrounding medium. Three coupled physical effects enter for thick films: reduction of neighbors and weakened caging constraints nucleated very near the surface, dynamical transfer of weakened constraints in a layer-by-layer manner into the bulk, and modification of the collective elastic barrier both near and far from the interface. Predictions include an exponential spatial variation of caging constraints and the local glass transition temperature, the near factorization of the temperature and spatial location dependences of the total activation barrier, a double exponential form of the alpha time gradient characterized by a nearly constant correlation length, and position-dependent power law decoupling of the relaxation time from its bulk analog. Generalization of the ideas to thin films predicts nonadditive dynamical gradient interference effects resulting in a further enhancement of relaxation and reduction of the film averaged effective barrier with decreasing film thickness. Comparisons to simulation and experiment will be presented.
The surface glass transition temperature \(T_{g_{\text{surf}}}\) of polystyrene (PS) films supported by silica was studied for film thickness, \(h\), from 7 nm to 100 nm by time-of-flight secondary ion mass spectrometry (ToF-SIMS). The width of the surface glass transition, \(\Delta T_{g_{\text{surf}}}=(T_{g_{\text{surf}+}}-T_{g_{\text{surf}-}})\) and \(T_{g_{\text{surf}}}=(T_{g_{\text{surf}+}}+T_{g_{\text{surf}-}})/2\) were extracted from the end group intensity as a function of temperature. We found that \(T_{g_{\text{surf}}}\) decreases with decreases \(h\) and is \(~20\) K lower than the glass transition temperature \((T_g)\) of the film for any given \(h\). We attribute this observation to effects of the free surface. On the other hand, \(\Delta T_{g_{\text{surf}}}\) increases with decreasing \(h\) starting from large \(h\ (>\sim60\text{nm})\). We explore possible origins for the noted broadening in surface glass transition of thin films.

*We acknowledge supports of the Research Grant Council of Hong Kong through the Projects 16303418 and 16302917.

Despite more than two decades of study, there remain many fundamental unanswered questions about the dynamics of glass-forming materials confined to thin films. In particularly, several experiments show evidence of a qualitative change in behavior upon confinement to sufficiently thin films. For example, the viscosity of amorphous thin films has been shown to exhibit a sharp transition from glassy to liquid-like behavior when film thickness is reduced below 30 nm [Y. Zhang et al., J. Chem. Phys. 145, 114502 (2016)]. Here, we provide evidence that this transition is due to the films inability to support an inactive, low-mobility, dynamic phase near a free surface. Active to inactive dynamical phase transitions have been found for a number of bulk glassy systems by biasing trajectories to low-mobility states using a field \(s\). For a model polymer system, we find that thin films require a dramatically larger field strength than the bulk to reach the inactive phase suggesting that it may be inaccessible for thin enough films. This sheds light on why the dynamics on the surface of amorphous materials is so different from bulk behavior.

*Funded by NSF grants MRSEC/DMR-1720530.
10:00AM L32.00009: Modeling the Glass Transition in Polymers using a Mean-Field “TS2” Model: Bulk and Thin Films* VALERIY GINZBURG (Presenter), Dow Chemical Co — A phenomenological model is proposed to describe the equilibrium dynamic behavior of amorphous, glass-forming polymers. We postulate that a material can be represented by a lattice of cooperatively re-arranging regions (CRR), with each CRR having two states, the low-temperature “Solid” and the high-temperature “Liquid”. At low temperatures, the material exhibits two characteristic relaxation times, corresponding to the slow large-scale motion involving multiple “solid” CRRs (α-relaxation) and the faster local motion within individual CRRs (β-relaxation). At high temperatures, the α- and β-relaxation times merge, as observed experimentally and suggested by the “Coupling Model” framework. This approach is labeled “Two-state, two (time)scale model” or TS2. We show that the TS2 treatment can successfully describe the low-temperature Arrhenius a-relaxation time behavior described in several recent experiments. We also apply TS2 to describe the molecular-weight dependence of the glass transition temperature in bulk polymers, as well as its dependence on film thickness in thin films.

*This work was supported by Dow.

10:12AM L32.00010: Tuning the Effective Viscosity of Random Copolymer films of Styrene and 4-Methoxystyrene by Varying the Copolymer Composition* JIANQUAN XU (Presenter), Hong Kong University of Science and Technology, CHAO LV, BINYANG DU, Zhejiang University, OPHELIA TSUI, Hong Kong University of Science and Technology — We show that thickness dependence of effective viscosity, $\eta_{\text{eff}}(h_0)$, of random copolymer films of styrene (St) and 4-methoxystyrene (MeOS) supported by silica (SiOx) can be easily tuned by using different MeOS concentrations, $X_{\text{MeOS}}$. When $X_{\text{MeOS}}$ is increased from 0% to 100%, $\eta_{\text{eff}}$ of nanometer films changes steadily from suppressed to enhanced. At $X_{\text{MeOS}} = 10\%$, $\eta_{\text{eff}}(h_0)$ displays a non-monotonic variation. We explain our results by suggesting that MeOS interacts more strongly with SiOx than St does and the behavior of $\eta_{\text{eff}}(h_0)$ is due to competitions between substrate effect and free surface effect. If substrate effect is stronger, $\eta_{\text{eff}}$ of nanometer films is enhanced. If free surface effect is stronger, $\eta_{\text{eff}}$ reduction occurs. When the two effects are comparable, our $X_{\text{MeOS}} = 10\%$ data suggests that substrate effect dominates in nanometer films but free surface effect dominates in thicker films, resulting in a non-monotonic $\eta_{\text{eff}}(h_0)$ dependence.

*We acknowledge supports of the Research Grant Council of Hong Kong through the Projects 16302917 and 16303418. B.D. acknowledges support of the National Science Foundation of China through the Projects 21674097 and 21875214.
10:24AM L32.00011: The Glass Transition Behavior and Structural Recovery of 2D Stacked Polystyrene Nanorods  MADHUSUDHAN REDDY PALLAKA, SINDEE L SIMON (Presenter), Texas Tech Univ —

The behavior of glass-forming materials confined at the nanoscale has been of considerable interest over the past two decades with conflicting results sparking debate. Here the focus is on the glass transition and associated structural relaxation kinetics of 20 and 350 nm stacked polystyrene nanorods using the Mettler Toledo Flash differential scanning calorimeter (DSC). The $T_g$ of 20 nm stacked polystyrene nanorods is depressed by 20 K and 10 K at cooling rates of 0.1 and 1000 K/s, respectively, whereas bulk-like behavior is observed for 350 nm stacked polystyrene nanorods. Structural recovery is also performed on 20 and 350 nm stacked polystyrene rods as a function of aging time and temperature, and the evolution of the enthalpy is followed. The structural recovery rate is found to be enhanced in the case of 20 nm stacked polystyrene rods when compared to the 350 nm stacked rods. The effect of spatial dimensionality on $T_g$ and structural recovery is also evaluated; in addition, a relaxation time map is constructed to better understand the glass transition and structural recovery kinetics. The results will also be discussed in the context of current controversies in the field.

10:36AM L32.00012: The Importance of Density in Segmental Dynamics: Applications of the Cooperative Free Volume Rate Model and Connections with the Density Scaling Approach*
RONALD WHITE (Presenter), JANE E LIPSON, Dartmouth College — A focus in our work is to make predictive connections with real experimental systems. For example, while segmental relaxation data is sometimes collected only at atmospheric pressure, deeper insight is only possible by accounting for pressure-dependent dynamics. This enables the analysis of the contributions due to independent changes in temperature ($T$) and volume ($V$), which gives a much deeper representation of the experimental system. It also leads to natural connections with that system’s dynamics under confinement. In this talk we discuss our recent work in modeling and predicting alpha relaxation times, $\tau(T,V)$, using the cooperative free volume rate model (CFV), in which the system's (well-defined and thermodynamically quantified) free volume controls the molecular cooperativity, and thus the activation energy. In addition to presenting our analysis of experimental systems, we will also feature connections and comparisons with the widely applied density scaling approach. We will show how the key parameters of the two approaches are connected and contrast their predictive power. A strength of the CFV model is its more efficient use of the same thermodynamic information to characterize the form of the corresponding dynamics.

Session L33 DPOLY DSOFT: Hierarchical Structural Emergence in Elastomer Nanocomposites: Dispersion, Dynamics, Structure, Modeling, and Simulation I  505 - Anne-Caroline Genix, Université de Montpellier - Tag(s): Focus
8:00AM L33.00001: Rheological and Electrical Percolation Behavior of Carbon Black Suspended in Propylene Carbonate  JEFFREY RICHARDS (Presenter), Northwestern University, JULIE HIPP, NORMAN J. WAGNER, Chemical and Biological Engineering, University of Delaware — In this work, the microstructural origin of the rheo-electric behavior of carbon black gels and suspensions is studied. These materials find widespread use as conductive fillers in composites and slurry-based electrochemical energy storage technologies. In these applications, both the viscosity and electrical conductivity are key design parameters. We use microstructural, rheological and electrical measurements to understand the origin of percolation in these suspensions and rationalize the results using a fluid-cluster-gel transition. The results of these studies explain many emerging observations of the macroscopic behavior of filled carbon black suspensions and guide the way toward improving their rheological and electrical performance.

8:12AM L33.00002: Dielectric & Dynamic response of emergent hierarchical filler networks in polymer nanocomposites*  KABIR RISHI (Presenter), Univ of Cincinnati, ASHISH GOGIA, University of Dayton, GREG BEAUCAGE, Univ of Cincinnati, VIKRAM KUPPA, University of Dayton, ANH TANG, Univ of Cincinnati — Commercial nanocomposites such as tire compounds are composed of dispersions of carbon black/silica mass fractal aggregates in an elastomer/oil blend, the performance of which is related to the nano-aggregate network structure, the interfacial chemical affinity and extent of dispersion based on accumulated strain. These composites display a complex hierarchical structure intimately tied to their inherent incompatibility and processing history. On the nanoscale carbon black displays primary particles aggregated into mass fractal aggregates that percolate locally above about 5wt.% into a network cluster. In the linear viscoelastic regime, this network dictates the high-frequency response.\textsuperscript{1} At higher concentrations near 20wt.% the local aggregated clusters agglomerate into a micron-scale mass fractal network associated with electrical conductivity that influence the gel-like dynamic response at low frequencies.\textsuperscript{2} The impact of the inherent particle structure, the attributes of the nano-scale and meso-scale networks on the dynamic and electrical moduli of these systems was explored using different industrial grade carbon blacks.

8:24AM L33.00003: Rheology and Shear-Induced Structural Evolution in Model Conductive Carbon Black Suspensions  JULIE HIPP (Presenter), Chemical and Biomolecular Engineering, University of Delaware, JEFFREY RICHARDS, Chemical & Biological Engineering, Northwestern University, NORMAN J. WAGNER, Chemical and Biomolecular Engineering, University of Delaware — Carbon black is commonly used in many technological applications ranging from tire rubbers and inks to electrochemical energy storage devices. In these applications, shear plays an important role in determining end performance due to the shear-induced structural changes and resulting change in properties that occur during mixing, processing, and application steps. To understand this shear-dependent behavior, the microstructure of carbon black suspensions is directly measured by performing Rheo-USANS (Ultra-Small Angle Neutron Scattering) experiments at a range of applied shear rates for suspensions with varying interaction strength, particle loading, and building block characteristics. These experiments show that a dramatic structural transformation from large, dense agglomerates to small, open agglomerates is predictable using the inverse Bingham number, which compares the measured stress to the yield stress of the suspension. Additionally, at high shear rates, the self-similar breakdown of agglomerates is shown to be dependent on the Mason number, which compares shear forces to interparticle attractions. This structural evolution explains many behaviors that are not well understood such as apparent shear-thickening and tunability of yield stress and elasticity.

8:36AM L33.00004: Polyisoprene silica nanocomposites and its structure property relationship*  DEBOLEENA DHARA (Presenter), ANDREW JIMENEZ, Columbia Univ, ZAID M ABBAS, Department of Chemistry and Biochemistry, University of South Carolina, MORTON M DENN, The City College of New York, BRIAN C BENICEWICZ, Department of Chemistry and Biochemistry, University of South Carolina, SANAT KUMAR, Columbia Univ — Recently, tire companies have sought to improve their fuel economy to meet the demand for a higher fuel efficiency and environmental sustainability. To achieve this goal, tire technologies have looked to improving the tire rolling resistance. In this talk, we investigate the structure-property relationship of polymer grafted nanoparticles, where the grafted polymer provides a better control over the dispersion of the particles in a polymer matrix. The dispersion and resulting morphologies of various systems were studied and followed by rheology and dynamic mechanical testing to probe the impact of the various structures on the mechanical properties, in the melt and the crosslinked forms. Using small amplitude oscillatory shear, we found that increasing nanoparticle loading significantly contributed to mechanical reinforcement. Reduction in tan delta that accompanies this reinforcement indicates an improvement in rolling resistance. In addition, creep measurements help us to expand the frequency window of our study, allowing access to the lower frequencies that are relevant to the operating frequencies of a tire.

8:48AM L33.00005: Microscopic Origins of Dynamic Mechanical Properties of Filled Rubber Investigated with X-ray Photon Correlation Spectroscopy*  
DILLON PRESTO (Presenter), Polymer Science, University of Akron, SURESH NARAYANAN, Advanced Photon Source, Argonne National Laboratory, BRYCE MEYER, Mathematics, University of Akron, JOHN MEYERHOFER, Polymer Science, University of Akron, SERGIO MOCTEZUMA, Dynasol Elastómeros, MARK SUTTON, Physics, McGill University, MARK FOSTER, Polymer Science, University of Akron — The mechanical properties of nanoparticle filled rubber are largely determined by the structure of the filler network and filler/polymer interactions. These reinforced rubbers have broad commercial utility, such as use in tire tread technology. The dynamic mechanical properties of these systems have a major impact on tire safety and fuel economy. Despite their importance, the connections between microscale filler behavior and macroscale performance are not well understood. Recent developments in X-ray photon correlation spectroscopy (XPCS) allow us to probe the microscale dynamics of filler particle networks and determine how this influences macroscale properties. We have used in-situ XPCS on styrene-butadiene rubber (SBR) filled with silicas of different surface chemistries under dynamic strain to probe the rearrangement of the filler network. We draw connections between the filler/polymer interaction and the resulting network structure, filler dynamics, and macroscopic properties.

*We thank Dynasol Group for funding and sample preparation. This research used resources of the Advanced Photon Source, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.

9:00AM L33.00006: Probing dynamics and crosslink morphology of thermosets during cure via XPCS*  
EDWARD TRIGG (Presenter), HILMAR KOERNER, Air Force Research Lab - WPAFB — Epoxy-based systems have been widely used for decades, from aircraft parts to consumer goods. However, there are still gaps in the fundamental understanding of their crosslinking (curing) behavior, specifically heterogeneities in crosslink topology depending on cure cycle rates. Optimization of cure cycles is key to agile polymer matrix processing in industry and government. Here, we use X-ray photon correlation spectroscopy (XPCS) to study the crosslinking of epoxies in real time, with dilute nanoparticles as tracers to study the effect of the progressing crosslink topology as it confines the dynamics of the tracer. A series of six epoxy systems are presented, wherein the ratio of two curing agents is systematically varied. The fully cured systems range from linear polymers to densely crosslinked resins, enabling a deeper understanding of their cure mechanisms and crosslink topologies. XPCS shows diffusive motion at low degrees of cure, and a sharp transition to ballistic motion at higher cure, which depends on composition. DSC, in situ near-FTIR, and MC simulations complement the XPCS data. XPCS can be used as a tool to interpret crosslinking mechanisms without dynamically perturbing the system as is done in rheology.

9:12AM L33.00007: Influence of Graft Density on Dynamically Coupled Polymer Grafted Nanocomposites* ANDREW EHLERS (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical Engineering and Materials Science, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — The viscoelastic behavior of polymer grafted nanocomposites (PGNs) with significantly different glass transition temperatures ($T_g$s) between the graft and matrix polymers is investigated with molecular dynamics simulations. These types of PGNs have been shown to have reversible and repeatable stiffening behavior upon heating (Senses, E.; Isherwood, A.; Akcora, P. ACS Appl. Mater. Interfaces 2015, 7, 14682). This unique thermal stiffening behavior was attributed to the dynamic coupling of the high-$T_g$ adsorbed chains and the low-$T_g$ matrix chains. The PGN studied in the current work consists of a nanoparticle with grafted high-$T_g$ polymer chains in a low $T_g$ polymer matrix. The effect of the dynamic coupling of the grafted and matrix polymer chains is studied by molecular dynamics (MD) simulations. Results of MD simulations indicate that grafted chains drastically slow down matrix chain dynamics and also form a percolated network at high nanoparticle concentrations. The influence of the graft density on viscoelastic properties is investigated to identify the mechanism of the observed stiffening in these types of PGNs.

9:24AM L33.00008: The emergence of quasi-sinusoidal nonlinearity in particle-filled polymer solutions WENTAO XIONG (Presenter), XIAORONG WANG, School of Chemical Science and Engineering, Tongji University — Systematic rheometric measurements are carried out to explore the nonlinear responses of carbon black-filled polyisoprene/squalene solutions with the polymer concentrations $f$ in the matrix ranging from the coil overlapping state ($\Phi = \Phi^*$) to the melt state ($\Phi = 1$). At the coil overlapping state when $\Phi \ll 1$, the system shows the classic nonlinearity, where the storage modulus $G'$ decreases as strain amplitude increases and the resulting stress responses are deviated from sinusoidal waves. At the melting state when $\Phi = 1$, the system displays a new nonlinearity, where the stress responses are surprisingly sinusoidal regardless the reduction of $G'$. Between the two states when $\Phi^* < \Phi < 1$, the system exhibits a complex nonlinear behavior throughout a wide range of $\Phi$. The ratio of the third to the first harmonics $I_3/I_1$ in the stress responses first decreases rapidly reaching a minimum when $\Phi \approx 0.1$, then increases to a maximum when $\Phi \approx 0.3$, after which it decreases again as $\Phi$ approaches 1. Remarkably, the filler flocculation in the system also displays the corresponding minimum and maximum values. The quasi-sinusoidal response in a system is apparently due to the restoration of broken filler network requiring longer than the time scale of a typical dynamic perturbation.
9:36AM L33.00009: Single Particle Tracking of Sticky and Non-Sticky Nanoparticles in Polymer Melts  JINSEOK PARK (Presenter), ERIC BAILEY, RUSSELL COMPOSTO, KAREN WINEY, University of Pennsylvania — While nanoparticle (NP) diffusion in polymer melts is important to the fabrication and applications of polymer nanocomposites, the influence of the NP/polymer interaction is poorly understood. Investigation of the weak NP/polymer interactions is experimentally challenging tendency for nanoparticle aggregation. Here, the diffusion coefficients of weakly attracting (methyl capped, CH$_3$ QDs) and strongly attracting (carboxylic acid capped, COOH QDs) nanoparticles (radius ~ 6.5 nm) in poly(propylene glycol) (PPG) melts were measured by single particle tracking (SPT). The mean-squared displacements and van Hove distribution of nanoparticle motion show Brownian motion of non-aggregated nanoparticle, in the long-time diffusion regime (~1s). For weakly interacting CH$_3$ QDs, the effective nanoparticle radius is independent of PPG $M_W$ due to the absence of a bound layer. For strongly interacting COOH QDs, the effective radius of the nanoparticle increases with the PPG molecular weight as $M_W^{0.5}$, indicating a long-lived bound layer. By obtaining spatial and temporal diffusion behavior of single nanoparticles, SPT provides previously inaccessible information on the nanoparticle diffusion in polymer melts.

9:48AM L33.00010: A Coarse Grained Model for the Simulation of dynamic Properties of Filled Elastomers  MARIIA VIKTOROVA, REINHARD HENTSCHKE (Presenter), School of Mathematics and Natural Sciences, Bergische Universitaet, Wuppertal, Germany, HOSSEIN ALI KARIMI-VARZANEH, Continental Reifen Deutschland GmbH, D-30419 Hannover, Germany — The properties of rubber are strongly influenced by the distribution of filler within the polymer matrix. We describe a modelling approach to the calculation of dynamic moduli of filled elastomers based on filler morphologies derived from the experimental interface tensions of the material's components. A Monte Carlo-based morphology generator, developed previously [1], is used to build model compounds on the µm-scale. Subsequently the Monte Carlo morphologies are mapped onto on a coarse grained model, allowing to obtain the amplitude and frequency dependence of the dynamic moduli during cyclic deformations. This combination of models ties the experimental surface tensions, characterizing the individual components, to the dynamic behavior of the macroscopic material. We consider selected examples of binary polymer blends containing a single type of filler at variable concentration. In addition to the dynamic moduli we also compute attendant transmission micrographs, wetting envelopes and work of adhesion plots.

10:00AM L33.00011: The influence of shear rate and adsorbed polymer chain flexibility on thermally stiffening nanocomposites*  
CHEN GONG (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical and Materials Engineering, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — The novelty of the nanocomposite used in the current work is that it thermally stiffens with increasing temperature. It consists of a low glass transition temperature ($T_g$) polymer matrix incorporating silica nanoparticles that contain an adsorbed high-$T_g$ polymer. Although the unique thermal-stiffening property has great application potential, the weak interactions between the adsorbed polymer and nanoparticles make it vulnerable to severe shear stresses that are prevalent in standard processing operations. In the current study, a laboratory mixing extruder was used to process nanocomposites that were initially solution blended, as a function of shear rate and adsorbed polymer chemistry. The extrudates were characterized via multiple methods such as electron microscopy, small angle X-ray scattering, and rheometry. Results indicated that the extrusion process altered the dispersion and distribution of nanoparticles, thereby, leading to changes in the mechanical properties depending on the adsorbed polymer chain flexibility – systems with flexible adsorbed chains recovered most of their mechanical performance. The effect of adsorbed chain flexibility provides an insight into designing thermally stiffening nanocomposites with better processability.

*Supported by NSF Grant 1825254.

10:12AM L33.00012: Understanding the Dispersion and Aggregation of fillers in Polymer Nanocomposites using Dissipative Particle Dynamics (DPD) Simulations of Polymer-Filler Blends*  
ASHISH GOGIA (Presenter), University of Dayton Research Institute, University of Dayton, 1700 Curran Place, Dayton, OH 45409-0170, KABIR RISHI, ALEX M MCGLASSON, GREG BEAUCAGE, Dept. Chem. and Mat. Eng., University of Cincinnati, VIKRAM KUPPA, University of Dayton Research Institute, University of Dayton, 1700 Curran Place, Dayton, OH 45409-0170 — Enhancing the properties of polymeric systems such as natural rubber by the addition of suitable additives provides for interesting applications, both mundane and novel. Such nanocomposites contain nanoscale fillers of varying miscibility, including carbon black, silica, metal oxides, pigments, and/or various combinations thereof. These complex systems exhibit rich phase behavior resulting from thermodynamic interactions and kinetic history. In this research, we perform Dissipative Particle Dynamics (DPD) simulation of polymer chains with aggregated and free filler particles, varying polymer-polymer, filler-filler, and polymer-filler interaction energy, to understand the hierarchical structure and dispersion over multiple length and time-scales. Our results demonstrate the role of concentration, temperature and interaction strength on the clustering of fillers, investigated via their fractal dimension, the radius of gyration, mesh size and population distributions, and are compared with small-angle x-ray scattering data.

*NSF CMMI - 1635865, 1636036.
FRANÇOIS BOUÉ (Presenter), Laboratory Léon Brillouin CNRS-CEA-UPSay — We review work from Laboratory Léon Brillouin and associated groups, on the structure of polymer-nanoparticles composites, under deformation, in relation with mechanical properties improvement of plastics. First, the nanoparticles: depending on preparation, but also on composition (non grafted or grafted particles), and on the matrix chains molecular weight, they can show individually dispersion, fractal aggregation, compact aggregation (1), or initially anisotropic aggregates. These conditions can be created by physicochemical ways, like solution casting, or combined with an external field, or by industrial protocols like in tyre industry... We will review how to obtain the different cases, and their response to deformation (2). For this we will use first different chemical synthesis, including chain grafting on the particles; second, physical characterization: Small Angle Scattering, mostly from X Rays (SAXS), complemented by Electronic Transmission Microscopy to help us for interpretation of the scattering.

Second, the polymer chains: we will observe them in the matrix (non-crystalline), as well as the grafted ones, combining now X Rays with neutron radiation (SANS), in nanocomposites at rest, and under deformation (3). This leads to striking comparison with measured stress-strain curves. We will compare and harmonise with results of other groups (4), for a more global view.

Tunable thermal transport and reversible thermal conductivity switching in topologically networked bio-inspired materials

John Tomko (Presenter), University of Virginia, ABDON PENA-FRANCESCH, HUIHUN JUNG, Pennsylvania State University, MADHUSUDAN TYAGI, Center for Neutron Research, NIST, BENJAMIN ALLEN, MELIK DEMIREL, Pennsylvania State University, PATRICK HOPKINS, University of Virginia

The dynamic control of thermal transport properties in solids must contend with the fact that phonons are inherently broadband. Thus, efforts to create reversible thermal conductivity switches have resulted in only modest on/off ratios, since only a relatively narrow portion of the phononic spectrum is impacted. Here, we report on the ability to modulate the thermal conductivity of topologically networked materials by nearly a factor of four following hydration, through manipulation of the displacement amplitude of atomic vibrations. By varying the network topology, or crosslinked structure, of squid ring teeth-based bio-polymers through tandem-repetition of DNA sequences, we show that this thermal switching ratio can be directly programmed. This on/off ratio in thermal conductivity switching is over a factor of three larger than the current state-of-the-art thermal switch, offering the possibility of engineering thermally conductive biological materials with dynamic responsivity to heat.

A Thermal Resistance Network Model for Heat Conduction of Amorphous Polymers

Jun Zhou, Qing Xi, Tongji University, Jixiong He, North Carolina State University, Nakayama Tsuneyoshi, Hokkaido University, Yuanyuan Wang, Shanghai Second Polytechnic University, Jun Liu (Presenter), North Carolina State University

Thermal conductivities (TCs) of the vast majority of amorphous polymers are in a very narrow range, 0.1 ~ 0.5 W m⁻¹ K⁻¹, although single polymer chains possess TC of orders-of-magnitude higher. Entanglement of polymer chains plays an important role in determining the TC of bulk polymers. We propose a thermal resistance network (TRN) model for TC in amorphous polymers taking into account the entanglement of molecular chains. Our model explains well the physical origin of universally low TC observed in amorphous polymers. The empirical formulae of pressure and temperature dependence of TC can be successfully reproduced from our model not only in solid polymers but also in polymer melts. We further quantitatively explain the anisotropic TC in oriented polymers.

We acknowledge funding from NC State University Faculty Research and Professional Development Fund, National Key R&D Program of China (No. 2017YFB0406004), National Natural Science Foundation of China (No. 11890703), and Shanghai Key Laboratory of Special Artificial Microstructure Materials and Technology (2019 ~2022).
8:24AM L34.00003: Improving ductility of glassy semicrystalline polymers by pre-deformation*  TRAVIS SMITH, MASOUD RAZAVI, SHIQING WANG (Presenter), Univ of Akron — Having developed some elementary understanding of how glassy polymers gain ductility [1, 2], we have begun to explore molecular mechanics of semicrystalline polymers whose Tg > ambient, to which poly(L-lactic acid) (PLLA), poly(ethylene terephthalate) (PET), and syndiotactic polystyrene (sPS) belong. Our objective is to explain why crystallization can turn a ductile glassy polymer to a brittle material, as is the case for PLLA [3]. Based on PET and s-PS, the present study will show how the ductility of such polymers can be predicted to improve upon introducing predeformation effect that alters the morphology and network structure. In doing so, we are able to further advance our theoretical understanding of factors that influence polymer ductility.

8:36AM L34.00004: Low, high, and switchable thermal conductivity in soft materials [Invited] DAVID CAHILL (Presenter), University of Illinois at Urbana-Champaign — A century of experiment and theory have produced a thorough understanding of heat conduction by phonons in simple inorganic crystals. By contrast, basic understanding of heat conduction by molecular vibrations in soft materials (amorphous and crystalline polymers, small molecule solids, biological materials) is much less mature. Complex, non-periodic structures spanning multiple length scales are difficult to characterize and model. Low thermal conductivity, fiber morphologies, poor control of defects, and anisotropy created by molecular order create daunting challenges for experiment. I will discuss our past work on the thermal conductivity and elastic constants of a wide variety of polymeric materials in the form of thin films and fibers that span a factor of 300 in thermal conductivity, 0.06 to 20 W/m-K. Time-domain thermoreflectance (TDTR) provides a common experimental platform for these studies; varying the thickness and modulation frequency changes the relative sensitivities of the TDTR measurement to thermal conductivity and heat capacity. Our recent work has employed light-activated changes in the morphology azo-polymers to switch by a factor of 3 between a low conductivity amorphous form and higher thermal conductivity crystalline form. We are developing frequency-domain probe beam-deflection and optical-fiber-based TDTR measurements to provide new capabilities for measurements of the thermal conductivity, effusivity and diffusivity of small volumes of soft materials.
9:12AM L34.00005: Making transparent, super-ductile and heat-resistant semi-crystalline polymers*  MASOUD RAZAVI (Presenter), SHIQING WANG, Univ of Akron — Based on our recent molecular picture [1], chain networking is a key factor that affords ductility for polymer glasses during tensile deformation. Therefore, it is essential, when considering the mechanics of semicrystalline polymers, that crystallization does not disrupt the chain network, which is typically not the case for semicrystalline polymers that crystallize slowly. We explore a molecular strategy to avoid depletion by crystallization of the polymer entanglement associated with the interchain uncrossability. The present study will characterize the conditions for producing such a new crystalline state and examine its mechanical behavior using class B semicrystalline polymers such as PLA and PET whose Tg is above room temperature.

*This work is supported by NSF (DMR-1905870) and ACS PRF# 60897-ND7.

9:24AM L34.00006: Estimation of mechanical properties of interfaces in polymer nanocomposites using molecular dynamics*  ABHISHEK SHANDILYA (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, PRAJAKTA PRABHUNE, CATHERINE BRINSON, Mechanical Engineering and Materials Science, Duke University, RAVISHANKAR SUNDARARAMAN, Materials Science and Engineering, Rensselaer Polytechnic Institute — Polymer nanocomposites are candidates for the next-generation of cable insulation and capacitor dielectrics. Nanoscale fillers, due to their high surface area, drastically increase the interfacial region which improves the dielectric permittivity and breakdown strength of the nanocomposites. Understanding the role of these interfaces in mechanical response of nanocomposites is crucial for their robust design. Modelling them at the molecular scale can capture the nanoscale features of the filler surface, the amorphous nature of the polymer and the interaction between them, while keeping the computational cost low. Using molecular dynamics, we calculate mechanical response of an ensemble of composites where polymer chains are grafted on a filler surface. We study the role of graft density and filler surface curvature on the stress and displacement field near the interface. We use an iterative finite-element-based approach to extract elastic modulus variation near the interface from the molecular dynamics stress and displacement profiles, which provides a starting point for large-scale modeling of composite nanostructures from first principles.

*This work was supported by the National Science Foundation under Grant No. 1729452.
A grand challenge in designing polymeric materials is to tune their properties by macromolecular engineering. Here, applications of polymers are often hindered by their low thermal conductivity $k$. While low $k$ values are highly desirable for thermoelectric materials, they create severe problems when used under the high temperature conditions. Going from the polymers dictated by weak Van der Waals to hydrogen-bonded interactions, $k$ varies between 0.1-0.4 W/Km. Using molecular dynamics simulations, we study thermal transport and its links to the elastic response of polymers and polymer blends in their solid states. We find that there exists a maximum attainable stiffness, thus providing an upper bound of $k$ for solid polymers. The specific chemical structures and the glass transition temperature play no role in controlling $k$, especially when the microscopic interaction is hydrogen bonded. These results are consistent with the minimum thermal conductivity model and existing experiments.

Employing Boltzmann transport equation coupled with Density-Functional Theory and non-equilibrium molecular dynamics simulation, we developed a combined scheme of calculating the thermoelectric property for polymeric materials. In the case of PEDOT doped with PSS, theory can give optimal carrier density for the power factor. It is found that the ideal crystalline polymer leads to a tiny thermoelectric figure of merit because of the extremely high thermal conductivity. Thus, engineering of disordered structure at nanoscale is essential.

We find that the formation of polaron band upon doping is essential to understand the "abnormal Seebeck effect", namely, for the potassium doped nickel-coordinated polymer, the Seebeck coefficient first increases with temperature and then suddenly drops. We proposed a two-band transport model to explain such exotic behavior.

10:36AM L34.00010: Effect of polymer architecture on the gas separation performance of PIM-1 membranes  VENKAT PADMANABHAN (Presenter), Tennessee Tech Univ — Molecular simulations are used to demonstrate the effects of chain architectures on the gas separation performance of PIM-1 membranes. Four different architectures (linear, H-shape, star, and dendritic) are considered to investigate the transport properties of four industrially relevant gases (CO₂, CH₄, O₂, and N₂). The simulations indicate that it is possible to tune the free volume morphology of PIM-1 membranes by choosing the appropriate architecture. An inverse relationship between the density and fractional free volume was observed as expected, with the highest density and lowest FFV obtained for the dendritic PIM-1. While the linear PIM-1 showed larger pores that enhanced the diffusivity of all small gases, the branched architectures (H-shape, star and dendritic) showed smaller interconnected pores with several bottle-neck morphologies. The observed modifications resulted in significant differences in the diffusivity of mid-range size gas molecules such as N₂, pushing the performance of CO₂/N₂ and O₂/N₂ separation performance beyond the Robeson’s 2008 upper bound.

10:48AM L34.00011: Surface Segregation of Branched Chain-ends in PDMS  MONICA MARKS (Presenter), School of Materials Science and Engineering, Georgia Institute of Technology, KYRIAKI KALAITZIDOU, George W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, WILL GUTEKUNST, School of Chemistry and Biochemistry, Georgia Institute of Technology — It is well known that polymeric materials reorganize at their surfaces in order to minimize surface tension and free energy. This reorganization, driven by enthalpic and/or entropic forces, creates surface properties that can dramatically differ from the bulk. Enthalpically driven reorganization allows low energy groups to surface segregate and dominate the surface properties of the material. This is the case with polydimethylsiloxane (PDMS), where low surface energy pendant methyl groups accumulate at the surface. However, in some cases, higher energy groups can surface segregate when incorporated into branched or bulky polymer chain-ends. This process is entropically driven, in order to maximize polymer configurations in the bulk, despite increasing the enthalpy of the system. This research aims to study the surface segregation behavior of high energy, branched chain-ends within a PDMS network. Novel Silicone additives consisting of linear PDMS polymers, chain-end functionalized with branched polyester dendrimers containing quaternary ammonium cations (QACs) have been synthesized. The QACs provide the observable property of antimicrobial activity, which will be used to probe the surface segregation of the additive chain-ends.

Session L35 DPOLY: Sustainable Biopolymers for Enhanced Applications 507 - John Dutcher, Univ of Guelph - Tag(s): Focus
8:00AM L35.00001: Dendrimeric Morphology and Mechanical Modulus of Soft Phytoglycogen Nanoparticles Revealed by AFM Force Spectroscopy  BENJAMIN BAYLIS (Presenter), ERIN SHELTON, JOHN DUTCHER, Univ of Guelph — Phytoglycogen is a naturally occurring glucose polymer that is produced in the form of highly branched, compact nanoparticles by sweet corn. The deformability, unique hydration and inherent safety of the particles makes them desirable for applications in personal care, nutrition and biomedicine. We have used atomic force microscopy (AFM) force spectroscopy to measure the size, morphology, and stiffness of the phytoglycogen nanoparticles in both water and air. For measurements in water, we were successful in covalently bonding isolated phytoglycogen particles to gold using an intermediate layer of 4-mercaptophenylboronic acid. We used the Quantitative Imaging mode of our JPK AFM to collect high resolution force-distance maps of a large number of individual phytoglycogen particles, which revealed the inner dendrimeric morphology of the particles at the largest applied forces and allowed us to quantify the increase in the elastic modulus in going from the outer to the inner regions of the particles. We also observed large increases in the modulus for dry particles in air, quantifying the effect of hydration on the mechanical stiffness of the particles.

8:12AM L35.00002: Structure of Native and Hydrophobically Modified Phytoglycogen Nanoparticles Using Small Angle Neutron Scattering  JOHN H ATKINSON (Presenter), Univ of Guelph, JONATHAN NICKELS, Univ of Cincinnati, MICHELLE MICHALSKI, MICHAEL GROSSUTTI, ADRIAN SCHWAN, Univ of Guelph, JOHN KATSARAS, Oak Ridge National Laboratory, JOHN DUTCHER, Univ of Guelph — Phytoglycogen is a highly branched polymer of glucose produced as soft, compact nanoparticles by sweet corn. Properties such as softness, porosity and mechanical integrity, combined with nontoxicity and biodegradability, make phytoglycogen nanoparticles ideal for applications involving the human body. We describe small angle neutron scattering (SANS) measurements of native phytoglycogen and phytoglycogen that was hydrophobically modified using octenyl succinic anhydride (OSA) in both its hydrogenated (hOSA) and deuterated (dOSA) forms. The data for the native particles was well described by a core-coil model, in which the outer surfaces of the particles are covered by short chains. The data for highly modified hOSA-phytoglycogen was consistent with a “raspberry” model, in which the outermost chains decorated with hOSA collapsed to form “seeds” with a well-defined size and separation. For lower DS values for both hOSA and dOSA-phytoglycogen, the data was well described using a core-shell particle geometry in which the composition of the shell was consistent with measured DS values. The results of the present study offer new insights into the morphology of phytoglycogen nanoparticles and the physical nature of their modification with OSA.
8:24AM L35.00003: Hydration water structure, hydration forces, and mechanical properties of polysaccharide films  
MICHAEL GROSSUTTI (Presenter), JOHN DUTCHER, Univ of Guelph — We have used ellipsometry at controlled relative humidity (RH) to measure the equilibrium swelling of ultrathin films of polysaccharides, including native and modified phytoglycogen nanoparticles as well as dextran and hyaluronic acid. At high humidities (RH > 70%), the RH-driven swelling of hydrophilic polymers can be described by exponentially decaying interstitial hydration forces. We have used two complementary approaches to analyse this high RH swelling regime to measure the length scale $\lambda_0$ that characterizes exponentially decaying hydration forces and to quantify the associated bulk modulus $K_p$ of the films. We further probe this swelling regime using attenuated total reflection infrared (ATR-IR) spectroscopy to investigate the hydrogen bond structure of the hydration water in the polysaccharide films. By combining ellipsometry and ATR-IR spectroscopy we find that the structuring of the hydration water hydrogen bond network in this regime correlates with both the hydration force decay length and film mechanical stiffness. These measurements provide insight into the relationship between the hydration water structure, hydration forces, and mechanical properties of polysaccharides, and suggest that a more ordered water hydrogen bond network leads to a smaller $\lambda_0$ and larger $K_p$.

8:36AM L35.00004: Carbohydrate-Based Polymers and Nanomaterials for Advanced Technologies* [Invited]  
MAREN ROMAN (Presenter), KEVIN EDGAR, Department of Sustainable Biomaterials, Virginia Tech, ALAN ROGER ESKER, Department of Chemistry, Virginia Tech — Carbohydrate-based polymers, termed polysaccharides, are ubiquitous in Nature. They perform a wide range of functions, including providing structural support in plant cell walls, generating swelling pressure in mammalian tissues, protecting microbes from dehydration and toxins, storing solar energy, and regulating binding events on cell surfaces. Owing to their diverse structures and properties, polysaccharides have found numerous industrial and medical applications. For example, they are used to increase the viscosity of food products and drilling fluids, stabilize emulsions, suspensions, and foams, form gels, prevent ice crystal formation, and protect wounds during healing. This presentation will showcase recent efforts at Virginia Tech toward the development of polysaccharide-based advanced technologies with biomedical and drug delivery applications.

**9:12AM L35.00005: Structure-Property Mappings for Bio-Advantaged Polyhydroxyalkanoate (PHA)-based Polymers**

KARTEEK BEJAGAM (Presenter), CARL N. IVerson, BABETTA L. MARRONE, GHANSHYAM PILANIA, Los Alamos National Laboratory — A steady increase in the consumption and rapid disposal of plastic products is currently imposing a stringent burden on the environment—translating into a range of severe problems from destruction of ecosystems to climate change. As a potential solution, biosynthetic and biodegradable polymers, such as Polyhydroxyalkanoates (PHAs), have emerged as a possible alternative material that can help drive the transition of our society to a more sustainable future. The underlying large combinatorial chemical space, however, poses a significant bottleneck towards identification of application-specific promising PHA-based candidate polymers. While a direct experimental-based exploration is impractical in this vast space, data-enabled screening approaches rely on our ability to accumulate accurate databases of key polymer properties. Towards this end, we are currently involved in an effort that employs molecular dynamics simulations—in a close coupling with experiments—to understand and establish accurate structure-property relationships for this bio-advantaged polymer class. In addition to providing molecular-level insights into the mechanistic origins of polymer functionalities, the generated data is expected to serve as an input for further informatics-based analysis.

**9:24AM L35.00006: Enabling Circular Polymer Chemistry Through Computation**

ALEXANDER EPSTEIN (Presenter), Materials Science and Engineering, University of California, Berkeley, PETER CHRISTENSEN, The Molecular Foundry, Lawrence Berkeley National Laboratory, TREVOR SEGUIN, Energy Technologies Division, Lawrence Berkeley National Laboratory, BRETT HELMS, The Molecular Foundry, Lawrence Berkeley National Laboratory, KRISTIN PERSSON, Materials Science and Engineering, University of California, Berkeley — Monomer-to-monomer recycling is a promising solution to the global plastic pollution crisis. However, most conventional plastics are difficult to depolymerize due to the large energy input required to degrade a carbon-carbon backbone. Instead, one can design polymers to incorporate bonds that are reversible in specific processes. This work demonstrates how quantum chemistry tools can be used to develop design rules for bonds that enable monomer-to-monomer recycling. Specifically, design rules were discovered for an exciting new polymer platform, called poly(dikeotenamine)s, which has been shown to display chemical circularity with >90% monomer yield. Design rules were developed from analysis of the simulated reaction pathway for the acid-catalyzed hydrolysis of the polymer with several heteroatom substitutions of the basic platform. Considering the ubiquity of the addition-elimination reaction in depolymerization processes, this analysis can inform design of a wide variety of monomer-to-monomer recycling techniques.

9:36AM L35.00007: Compression of Acid Hydrolyzed Phytoglycogen Nanoparticles at High Packing Densities  HURMIZ SHAMANA (Presenter), JOHN DUTCHER, Univ of Guelph — Phytoglycogen is a natural polysaccharide produced in the form of compact, 44 nm diameter nanoparticles in the kernels of sweet corn. Its highly branched, dendrimeric structure leads to interesting and useful properties that make the particles ideal as unique additives in personal care, nutrition and biomedical formulations. The properties of phytoglycogen nanoparticles can be altered through chemical modifications such as acid hydrolysis, which not only reduces their diameter but also produces significant changes to the interactions between particles in highly concentrated dispersions. At sufficiently small concentrations ($C < 30\% \text{ w/w}$), the acid hydrolyzed particles exhibit typical soft sphere behaviour characterized by an increase in the zero-shear viscosity with concentration, reaching a value that exceeds that of water by a factor of $\sim 10^3$ at $C \sim 30\% \text{ w/w}$. As the concentration is increased beyond 30% w/w (the concentration at which the particles begin to be compressed against one another), the dependence of zero-shear viscosity versus concentration data shows a pronounced kink, with increases beyond 30% w/w significantly more gradual. This result is consistent with a reduction in stiffness for acid hydrolyzed phytoglycogen nanoparticles.

9:48AM L35.00008: Tunable Yield Stress of Aqueous Dispersions of Hydrophobically-Modified Phytoglycogen Nanoparticles  CARLEY MIKI (Presenter), HURMIZ SHAMANA, JOHN DUTCHER, Univ of Guelph — Phytoglycogen is a natural polysaccharide produced in the form of compact, 44 nm diameter nanoparticles in the kernels of sweet corn. Its highly branched, dendrimeric structure leads to interesting and useful properties that make the particles ideal as unique additives in personal care, nutrition and biomedical formulations. The properties of phytoglycogen can be readily altered through chemical modification. We consider a hydrophobic modification of phytoglycogen by covalently attaching charged, hydrophobic octenyl succinic anhydride (OSA) chains to the weakly charged, hydrophilic surface of phytoglycogen. When dispersed in water at moderate concentrations ($C \sim 20\% \text{ w/w}$), the OSA-modified particles form a shear-sensitive gel with a low shear viscosity that exceeds by a factor of $\sim 10^6$ that of native phytoglycogen dispersions of the same concentration. Furthermore, the dispersions exhibit a well-defined yield stress, as measured using different rheology techniques. The yield stress vanishes as the pH of the dispersions is reduced below the pKa of the acidic group of OSA, with the material transitioning from a shear-sensitive gel to a flowing liquid. This pH-sensitivity suggests new applications for OSA-modified phytoglycogen.
10:00AM L35.00009: Binding of Proteins to a Phytoglycogen-Functionalized Surface Plasmon Resonance Sensor Surface  
KATHLEEN CHARLESWORTH, NICHOLAS VAN HEIJST (Presenter), AIDAN MAXWELL, MICHAEL GROSSUTTI, JOHN DUTCHER, Univ of Guelph — Phytoglycogen is a highly branched polymer of glucose produced as soft, compact nanoparticles by sweet corn. Properties such as softness, porosity and mechanical integrity, combined with nontoxicity and biodegradability, make phytoglycogen nanoparticles ideal for applications involving the human body. Many of these applications rely on the binding of small molecules onto phytoglycogen nanoparticles. Surface Plasmon Resonance (SPR) is a sensitive experimental technique, based on the resonant absorption of light within an ultrathin gold film, that can be used to measure the binding kinetics and affinities of small molecules. We have successfully created a stable phytoglycogen-functionalized SPR sensor surface, using 4-mercaptophenylboronic acid as a linker between the gold layer and phytoglycogen. This has allowed us to use SPR to measure the association constant between phytoglycogen and Concanavalin A (ConA) to be $2.87 \pm 0.44 \times 10^5$ M$^{-1}$ by fitting the data to the Langmuir adsorption model. By measuring the amide bands of ConA bound to phytoglycogen using infrared spectroscopy, we find that ConA maintains a large amount of its native beta-sheet content, suggesting that phytoglycogen helps to preserve its bioactivity.

10:12AM L35.00010: Plastic Resins for the Circular Economy: from Wind Turbines to Gummy Bear Candy and Beyond.*  
JOHN DORGAN (Presenter), BIN TAN, HARSHAL BAMBHANIA, Michigan State Univ — Plastics and composites have concerning sustainability metrics including high embedded energy and associated greenhouse gas emissions, low recyclability rates, and generation of microplastics pollution. Composites are notoriously difficult to recycle but are critical for wind turbine, lightweight vehicle, and other sustainable technologies. An economically viable, fully recyclable, composite resin is demonstrated; physical properties of composites produced from the reclaimed resin show true “turbine-to-turbine” recycling is possible. Various end-of-use options are established; regrinding produces short fiber moldable materials. Base catalyzed digestion produces poly(methyl methacrylate) or the superabsorbent poly(methacrylic acid). Distillation of the digestate produces methanol, water, and food grade potassium lactate; the resulting lactate has been incorporated into gummy bear candies. Judicious formulation of polymer resins enables complete circularity in low-embedded energy materials; exploitation of triggerable degradation provides varied and intriguing end-of-use recycling options.

10:24AM L35.00011: Performance-advantaged bioproducts from biomass* [Invited]  GREGG BECKHAM (Presenter), NREL — Chemical intermediates accessible from selective processing of lignocellulose, namely carbohydrates from polysaccharides and aromatic oxygenated compounds from lignin, offer the potential for atom-efficient biological and catalytic transformations to new building blocks for biopolymers that are difficult to access from petroleum-derived, hydrocarbon intermediates. To that end, this talk will cover several new biopolymers via biological and catalytic transformations of carbohydrates and lignin-derived aromatic compounds that exhibit performance-advantaged properties relative to existing petroleum-based polymers. Performance-advantaged bioproducts, such as those described here, could potentially incentivize the development of a viable bioeconomy alongside biofuels production.

Session L36 FED DCOMP: {$PICUP}: Integrating Computation in Introductory and Upper-Level Physics Courses 601/603 - Amy Liu, Georgetown University - Tag(s): Education, Invited, Undergrad Friendly

8:00AM L36.00001: Integrating computation using materials from the PICUP collection in Introductory Physics* [Invited] MARIE LOPEZ DEL PUERTO (Presenter), University of St. Thomas — The Partnership for Integrating Computation into Undergraduate Physics (PICUP, www.gopicup.org) runs workshops, hosts an online collection of curricular materials, and supports a growing community of interested faculty with the goal of making it easier for faculty to integrate computation into their courses. In this talk, I will share my experience integrating computation into the introductory physics sequence. I will highlight materials in the PICUP collection that I adapted, discuss how those materials fit into and enhance the course, and talk about how I integrate computation into a workshop-style course. I will then present different approaches used by faculty who integrate computation into introductory physics courses in a variety of institutional settings, so attendees can see how they might integrate computation in their own introductory courses.

*This work is supported in part by NSF grant DUE-1525062.
8:36AM L36.00002: Enhancement of Student Experience and Content Coverage in Physics Courses Through Integration of Computation* [Invited]  KELLY ROOS (Presenter), Bradley University — Integrating computational activities into undergraduate physics courses adds educational value to the physics curriculum through providing deeper conceptual understanding of physical principles, introducing marketable skills, enhancing problem-solving, and expanding topical coverage. In this presentation, I shall provide a few examples of these computational activities that add educational value to the undergraduate physics curriculum in introductory and upper level courses, and offer suggestions (based on more than 25 years of “trying things”) on how to effectively implement such activities into the traditional course format, i.e. the conventional lecture-lab mode of physics instruction.

*Support from the National Science Foundation, grants NSF-1525525, NSF-1524963, NSF-1525062, NSF-1524128, and NSF-1524493, is gratefully acknowledged.

9:12AM L36.00003: Title: Upper-Division Computational Physics at Syracuse and its Lasting Impact on Students [Invited]  WALTER FREEMAN (Presenter), Syracuse University — The value of incorporating computational physics into the undergraduate curriculum is now widely accepted, both because it facilitates student learning of core physical concepts and because computational skills are needed in graduate research and industry. However, computation doesn't just let us train the same sort of physicists more efficiently; students with computation as a core part of their training develop a richer, more insightful, more fundamentally grounded, and ultimately more fruitful perspective on physics as a discipline. In short, they become a different sort of physicist -- one with a clearer view of what physics shows us about the world and with more freedom to apply their knowledge to understand physical phenomena.

I will present case studies of students from Syracuse University who have studied computational physics as part of their upper-division and graduate training, and argue that their outlook on the physical world and approach to physics as a whole has benefited from this experience.

9:48AM L36.00004: Modern Computer Applications in the Advanced Laboratory [Invited]  DANIEL BORRERO-ECHEVERRY (Presenter), Willamette University — While computers have long played an important part in Physics laboratory instruction, the scope of their use is often limited to relatively simple data processing tasks like fitting experimental data to well-established analytical models. While these applications are obviously important, they are not representative of the full range of ways that computers are used in modern physics research laboratories. In this talk, I will discuss how the Physics department at Willamette University has created engaging laboratory experiences that tightly integrate experiment, theory, and computational modeling and incorporate modern computational tasks like data visualization, simulation of experimental systems, and computer-aided design of experimental apparatus. These activities have reduced the time that faculty spend training undergraduates to work in their labs allowing students to make more significant research contributions, while also helping them acquire crucial computation skills that they will need as they join the 21st century workforce.
10:24AM L36.00005: Normalizing computation through continuous student engagement in the undergraduate physics curriculum* [Invited]  YOGESH JOGLEKAR (Presenter), GAUTAM VEMURI, ANDREW D GAVRIN, Indiana University - Purdue University Indianapolis — Physics is, by definition, the most fundamental empirical science. Broadly construed, the laws of physics allow us to explain phenomena and predict outcomes on scales that range from astronomical to the microscopic. And yet, anecdotal surveys show that high-school and undergraduate students largely perceive physics as “theoretical” with little to no day-to-day consequences. This gap between the reality and the perception is fueled, in part, by undergraduate curriculum where majority of the courses mostly focus on examples that have the distinct advantage of being analytically solvable. In this talk, I will present a department-wide initiative to normalize computation across the physics curriculum – an intervention that is designed to bridge the gap by enabling students to explore realistic physics and engineering examples. It consists of a meta-course comprising computational modules developed by the departmental faculty for every course in the undergraduate curriculum, a redesigned “Introduction to Computational Physics” course, and a sustained engagement of students through assignments and exams that involve computational problems. I will present preliminary results of surveys from each semester under intervention.

*This work was supported IUPUI SEIRI seed grant.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L37 GIMS: Nanoscale Characterization of Correlated and Entangled Quantum Phenomena 605 - Stephen Jesse, Oak Ridge National Laboratory - Tag(s): Invited

8:00AM L37.00001: Markus B. Raschke Invited Talk [Invited]  MARKUS B. RASCHKE (Presenter), University of Colorado, Boulder — TBD
8:36AM L37.00002: Revealing topological quantum states with STM-based spectroscopy*

[Invited] AN-PING LI (Presenter), Oak Ridge National Lab — Topological insulators possess a massless Dirac dispersion with spin–momentum locking at the surface. The onset of a spontaneous magnetization or a broken time-reversal symmetry leads to the formation of an exchange gap in the Dirac band dispersion. In this work, we will present two examples to show how STM spectroscopy can be used to detect these signatures of topological quantum states. (1), Spin helical states on Bi2Te2Se. A multi-probe STM with spin-polarized tips allows us to perform in situ transport measurement to differentiate surface conductance from the bulk and spin-up chemical potential from the spin-down. As a result, a spin-momentum-locked current is revealed which shows ultra-high mobility and polarization. (2), Gapped surface states on MnBi2Te4. Quasiparticle interference patterns are used to probe local dispersions of both surface and bulk electronic structures. The theoretically predicted gapped surface states are evaluated with high spatial resolution. It is expected that tuning of the Fermi level in the exchange gap will result in the emergence of a quantum anomalous Hall effect.

*This research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.
9:12AM L37.00003: Atomic precision advanced manufacturing for electronic devices* [Invited]  
DAN R. WARD, TZU-MING LU, LISA A TRACY, XUJIAO GAO, ANDREW D. BACZEWSKI, AARON KATZENMEYER, SCOTT W SCHMUCKER, EVAN ANDERSON, JEFFREY IVIE, DENIS MAMALUY, EZRA BUSSMANN, SHASHANK MISRA (Presenter), Sandia National Laboratories — Since the advent of atomic manipulation with the scanning tunneling microscope (STM), a significant challenge for atomic scale fabrication has been to build structures large enough to exhibit emergent system-level phenomena that can be understood at a macroscopic level. Using fabrication to build a bridge between atomistic details and macroscopic properties promises to deepen our understanding of physical phenomena that are otherwise understood only in a coarse-grained way. STM-based hydrogen lithography on silicon can be used to place individual donor atoms comprising a device, a process we refer to as atomic precision advanced manufacturing (APAM). Although this capability promises to bolster our semiclassical understanding of electron transport in electronic devices, application of this technique has been held back by two factors that are the focus of this talk. In this talk, I will detail our efforts to make more atomically perfect devices, attempting to control both the precision placement of dopants and also their surroundings, and more complex devices, incorporating metal-oxide-semiconductor (MOS) gates. In the future, advanced devices could open the door to understanding the limitations of some fundamental assumptions in device physics including semiclassical approximations and linear response.

*This work was supported by the Laboratory Directed Research and Development Program at Sandia National Laboratories and was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, for the U.S. Department of Energy's National Nuclear Security. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government.

9:48AM L37.00004: Interrogating Entangled Matter with Entangled Probes [Invited]  
PATRICK BLACKSTONE (Presenter), ABU ASHIK MD. IRFAN, GERARDO ORTIZ, Indiana University - Bloomington — We developed an Entangled Scattering theory that extends the scope of standard scattering approaches to study entangled matter, such as unconventional phases of strongly correlated systems. Our presentation will focus on a neutron beam probe that is entangled in spin and path, although similar ideas also apply to photon probes. Our theory generalizes the ubiquitous van Hove Theory whereby the differential cross-section is written as a particular linear combination of two-point correlation functions. Controlling the degree of entanglement of the neutron probe (e.g., the microscopic spin-echo length) allows us to identify the relevant entangled excitations of the investigated target material. This theory and future experiments that it informs may shed light on complex phases exhibited by novel materials such as multiferroics, unconventional superconductors, quantum spin liquids, and frustrated magnets.
Toward practical quantum-enhanced microscopies* [Invited]  

BENJAMIN J LAWRIE (Presenter), RAPHAEL POOSER, Oak Ridge National Laboratory — Quantum light sources are increasingly essential to the development of the next generation of sensors and microscopes. While squeezed light exhibiting quantum noise reduction has been leveraged to enable quantum-enhanced measurements of microcantilever beam displacement [1], substantial further improvements are required to enable realistic quantum-enhanced scanning probe microscopy. We will discuss an approach to scanning probe microscopy based on truncated nonlinear interferometry that enables minimum photon back-action noise while also operating below the photon shot noise limit [2]. Further, we will explore photon correlation measurements in cathodoluminescence microscopies as a path toward the sub-diffraction-limited characterization of single color centers and excitons in nanostructured and 2D materials.

*This research was supported by the U. S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division. The experimental concept was conceived and initial experiments were performed as part of the Laboratory-Directed Research and Development Program of Oak Ridge National Laboratory, managed by UT-Battelle, LLC for the U.S. Department of Energy.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L38 COM: TEAM-UP: The Time is Now for Systemic Changes to Increase the Number of African American Bachelor’s in Physics and Astronomy  

607 - Garfield Warren, Indiana University Bloomington - Tag(s): Diversity

8:00AM L38.00001: Philip W Hammer Invited Talk [Invited] —
8:15AM L38.00002: The TEAM-UP Report: Major Findings and Recommendations [Invited]
MARY B JAMES (Presenter), Reed College — The TEAM-UP task force collected quantitative and qualitative data from over 250 undergraduate physics students and 40 physics departments to examine and assess the reasons for the persistent under-representation of African American (AA) students in physics and astronomy at the bachelor's level. The task forces embraced social science research methods and perspectives to investigate four key questions:
1. How does physics culture enhance or diminish AA students’ success?
2. What are the key experiences that lead to AA student persistence or failure to persist in undergraduate physics and astronomy programs?
3. What programmatic factors lead to the persistence of AA students in obtaining B.S./B.A. degrees in Physics/Astronomy?
4. What impedes or promotes culture change in the physics and astronomy community necessary to increase the persistence of AA students in Physics and Astronomy?

In this talk we describe the major findings and evidence-based recommendations for AIP Member Societies, physics and astronomy departments, and other stakeholders to increase the number and percentage of African American students obtaining bachelor's degrees in physics and astronomy.

8:45AM L38.00003: TEAM-UP’s Recommendations on Systemic Change [Invited] EDMUND BERTSCHINGER (Presenter), Massachusetts Institute of Technology — The TEAM-UP report identifies the structural and systemic causes explaining why African Americans have not experienced the growth in bachelor's degrees in physics the way they have in other fields or as other minority groups have experienced in physics over the past two decades. Solving these problems requires changing not only the way physicists train students, but how they think about training students. Research on change in higher education suggests the need for physicists and astronomers to recognize and question the norms, values, and culture of their fields. The TEAM-UP report’s highest priority recommendations provide a guide to cultural transformation in the profession. The evidence and theories presented in this report call for a new way of thinking by physicists, much as the Davisson-Germer experiment did nearly a century ago.

9:45AM L38.00005: Maria Ong Invited Talk [Invited] —

10:15AM L38.00006: PANEL DISCUSSION [Invited] —

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L39 DCOMP GDS DMP: Machine Learning for Quantum Matter
I 703 - Miles Stoudenmire, Simons Foundation - Tag(s): Focus
ANNABELLE BOHRDT (Presenter), Tech Univ Muenchen, CHRISTIE S. CHIU, GEOFFREY JI, MUQING XU, DANIEL GREIF, MARKUS GREINER, EUGENE DEMLER, Physics Department, Harvard University, FABIAN GRUSDT, MICHAEL KNAP, Tech Univ Muenchen — Quantum gas microscopes for ultracold atoms provide real-space snapshots of complex many-body systems with single site resolution. We use machine learning techniques to analyse and classify such snapshots of ultracold atoms. Specifically, we study the two-dimensional Fermi-Hubbard model, which is believed to capture the rich physics of high-temperature superconductivity and other phases such as the strange metal, stripe, antiferromagnet, or pseudo-gap phase. While a large number of theories exist to describe this system, each with its own merits, a unifying analytic understanding is still lacking. We compare the data from an experimental realization of the two-dimensional Fermi–Hubbard model to two theoretical approaches: a doped quantum spin liquid state of resonating valence bond type, and the geometric string theory, describing a state with hidden spin order. This method considers all available information without a potential bias towards one particular theory by the choice of an observable and can therefore select the theory that is more predictive in general. Up to intermediate doping values, our algorithm tends to classify experimental snapshots as geometric-string-like, as compared to the doped spin liquid. Our results demonstrate the potential for machine learning in processing the wealth of data obtained through quantum gas microscopy for new physical insights.

ELMER GUARDADO-SANCHEZ, BENJAMIN M SPAR, Princeton University, JUAN CARRASQUILLA, Vector Institute for Artificial Intelligence, RICHARD THEODORE SCALETTAR, University of California, Davis, WASEEM S BAKR, Princeton University, EHSAN KHATAMI (Presenter), San Jose State University — Quantum gas microscopes for ultracold atoms in optical lattices have transformed quantum simulations of many-body Hamiltonians. Statistical analysis of atomic snapshots can produce expectation values for various charge and spin correlation functions and has led to new discoveries for the Fermi-Hubbard model in two dimensions. Here, we enlist the help of artificial intelligence to look for possible patterns in the snapshots not captured by conventional indicators. We try this unbiased approach on images taken in the non-Fermi liquid phase of the Hubbard model around optimal doping.

*E.K. acknowledges support from the NSF under Grant No. DMR-1609560.
8:48AM L39.00003: Unsupervised machine learning of topological phase transitions*
JOAQUIN RODRIGUEZ NIEVA, MATHIAS SCHEURER (Presenter), Department of Physics, Harvard University — In the traditional theory of phase transitions, pioneered by Landau, different phases are characterized by the symmetries they break. However, physical systems can also exhibit phase transitions between two states that share the same symmetries, but can be sharply distinguished by their “topological” properties. While symmetry-breaking phase transitions are readily captured with machine learning, topological phase transitions are significantly more difficult, which is related to their non-local nature. In this talk, I will discuss an unsupervised machine-learning approach that we propose [see Nature Physics 15, 790-795 (2019)], which is capable of “learning” topological invariants from raw, unlabeled data. The success of the approach is demonstrated on several different models and we also discuss a mapping of the output of the machine learning to the eigenvalues and wavefunctions of an auxiliary quantum problem. This will allow us to use physical intuition of quantum mechanics to understand how the machine-learning algorithm performs the topological classification.

*JRN: support from AFOSR-MURI: Photonic Quantum Matter (award FA95501610323); MSS: support from the German National Academy of Sciences Leopoldina, grant no. LPDS 2016-12, and from the NSF under grant no. DMR-1664842.

9:00AM L39.00004: Classification of optical quantum states using machine learning
SHAHNAWAZ AHMED (Presenter), MC2, Chalmers University of Technology, CARLOS SÁNCHEZ MUÑOZ, Physics, Oxford University, FRANCO NORI, Theoretical Quantum Physics, Riken, ANTON FRISK KOCKUM, MC2, Chalmers University of Technology — Machine-learning techniques for quantum state tomography can give significantly faster results, e.g., by using adaptive measurements to avoid redundant data acquisition, or by finding efficient parameterizations of a quantum state to escape the "curse of dimensionality". Here, we explore a similar idea for optical quantum states by using deep neural networks (DNNs). We train a DNN to classify different optical quantum states, e.g., cat or thermal states, with a high accuracy. Our DNN can also predict interesting physical properties, such as Wigner negativity, directly from measurement data without requiring a full reconstruction. We study the influence of various factors such as noise, Hilbert-space cutoff, and measurement settings on the predictions and show that the DNN approach is robust. We also apply standard methods for analyzing neural network predictions, such as Grad-CAM, to determine the features used by the network to make its predictions. To benchmark our method, we compare with a naive classifier using maximum likelihood estimation. Our results indicate that the DNN can be a fast and efficient real-time classifier to distinguish various optical quantum states in the lab.
9:12AM L39.00005: Unsupervised learning of quantum phase transitions using nonlinear
dimension reduction methods  ALEXANDER LIDIAK (Presenter), ZHEXUAN GONG, Physics,
Colorado School of Mines — Quantum simulators have reached a complexity that understanding
measurement data they generated has become a daunting task for traditional data analysis
methods. To make scientific discoveries based on experimental data where theoretical
understanding is lacking, unsupervised machine learning can be a powerful tool. However,
existing approaches to unsupervised learning of quantum many-body states are largely focused
linear dimension reduction methods such as principle component analysis (PCA), or
generalizations such as kernel PCA. These methods often fail when order parameters of the
states are nonlinear functions, i.e. states with valence-bond order, topological order, many-body
localization, etc. This motivates us to investigate nonlinear dimension reduction methods such as
diffusion maps and autoencoders. By studying a 1D chiral Z3 clock model (experimentally a chain
of Rydberg atoms), we find PCA detects only the Z3 phase while diffusion maps detects the full
phase map including a incommensurate phase. In addition, diffusion maps directly detect the Z3
symmetry of model and predict the number of clusters. We find these nonlinear dimension
reduction methods also useful in learning valence-bond order and Gaussian-type topological
phase transitions in quantum spin systems.

9:24AM L39.00006: Machine learning the Mattis glass transformation  DANIEL LOZANO-
GOMEZ (Presenter), DARREN PEREIRA, MICHEL J P GINGRAS, University of Waterloo — Machine
learning techniques are being actively explored to ascertain their usefulness in many areas of
physics. Within condensed matter physics, one of the goals these techniques are being
investigated for is per their ability to identify the different phases of a system. As such, the
identification of a system's symmetries and underlying gauges is taken as a crucial step to
accomplish this endeavor. In this context, we consider classical spin models in which we
introduce a so-called Mattis gauge transformation. This transformation turns the standard
ferromagnetic Ising model into a non-frustrated random bond Ising model, and the
ferromagnetic XY model into an XY model with random Dzyaloshinskii-Moriya interactions. We
show through a simple unsupervised method, the Principal Component Analysis (PCA), that PCA
is able to expose the introduced, albeit hidden, gauge transformation for both models. For the
Ising Mattis-model, the original Ising model structure is recovered by PCA, and a rough estimate
of the gauge distribution is extracted. For the XY gauge model, we show that while the gauge
transformation is `hidden'' in the clustering structure for the full data set, it is nevertheless
uncovered when studying a specific component of the spins.
9:36AM L39.00007: Augmenting machine learning algorithms with the addition of a physics based intelligence prior  CHRISTOPHER SINGH (Presenter), MATTHEW REDELL, Physics, Binghamton University, MOHANNAD ELHAMOD, JIE BU, ANUJ KARPATNE, Computer Science, Virginia Tech, WEI-CHENG LEE, Physics, Binghamton University — Improving the predictive power of machine learning models is one of the greatest challenges to the science of learning. Here we demonstrate with the simplest of neural networks that the addition of an intelligence prior can drastically improve the learning capabilities. We outline this simple mechanism to decrease the number of exposures, and enhance the predictive power with a number of examples relevant to the study of quantum phase transitions. We find that guided networks are uniquely capable to identify key features of quantum phases where unguided models fail, and that while the mean square error of topologically equivalent models may be commensurate, the structure of the predictions produced by the models is qualitatively very different. In many situations where knowledge of a physical system is available, but direct sampling of the entire phase space is computationally intractable, this approach offers a superior learning alternative.

9:48AM L39.00008: Adversarial machine learning for modeling the distribution of large-scale ultracold atom experiments*  CORNEEL CASERT (Presenter), Ghent University, KYLE MILLS, Ontario Tech University, TOM VIEIJRA, JAN RYCKEBUSCH, Ghent University, ISAAC TAMBLYN, National Research Council of Canada — Directly generating microstates with desired properties from the configuration space of many-body systems is infeasible due to its high-dimensional nature. Instead, traditional generation methods rely on computationally costly algorithms or carefully controlled experimental setups, which limits the number of particles that can be investigated. We present how artificial neural networks allow for the direct and targeted generation of large-scale microstates, while restricting the time-consuming simulations or measurements to a small number of particles. Their potential is illustrated on a data set of experimental snapshots of a doped Fermi-Hubbard model realized by ultracold atoms trapped in an optical lattice. The adversarial machine learning method we develop here is broadly applicable and can also be used for speeding up computer simulations of both equilibrium and nonequilibrium physical systems.

*This research is supported by an NVIDIA hardware grant.
10:00AM L39.00009: Using Convolutional Neural Networks to analyze phase transitions and calculate critical exponents  NISHAD MASKARA (Presenter), EVERT VAN NIEUWENBURG, MANUEL ENDRES, Physics, California Institute of Technology — Identifying phase transitions and their corresponding order parameters is a central problem in physics, but estimation of order parameters from experimental measurements is difficult. In this work, we present an alternative framework for analyzing phase transitions by using neural networks to learn order parameters directly from data. By introducing a type of convolutional architecture, we show how these methods can be made more robust by systematically increasing the convolutional window size. We investigate the extraction of correlation length critical exponents by performing finite-size scaling on the network, and use this to analyze the 1D TFIM phase transition from measurements in different bases. This work is a step towards a machine learning toolkit for characterizing phase transitions without prior knowledge.

10:12AM L39.00010: Unsupervised learning of topological indices  OLEKSANDR BALABANOV (Presenter), MATS GRANATH, University of Gothenburg — I will present an unsupervised protocol for learning topological indices of quantum systems [1]. The idea is to produce ensembles of topologically equivalent data and then train a specially designed neural-network-based regressor for classifying them. The datasets of topologically equivalent samples are derived by continuously deforming some selected parent systems and this procedure does not require any knowledge of the topological numbers or how they are constructed. I will explicitly illustrate the protocol with two examples: It will be employed for classifying 1d band insulators in symmetry class AIII, characterized by a winding number, and 2d band insulators in symmetry class A, characterized by a Chern number.

10:24AM L39.00011: Machine Learning based BCS superconductivity Predictor from Normal State Properties  FEI HAN (Presenter), NINA ANDREJEVIC, THANH NGUYEN, QUYNH NGUYEN, SHREYA PARJAN, Wellesley College, MINGDA LI, Massachusetts Institute of Technology MIT — BCS theory is the widely accepted microscopic mechanism for conventional superconductivity. However, despite decades’ research effort, it is still challenging to judge that whether a material is superconducting or not, not to mention a faithful estimation on the superconducting critical temperature $T_c$. In this study, we employed a few deep learning architectures to correlate the normal state properties to superconductivity. A few normal state properties are found to be closely related to the formation of superconductivity with further link to $T_c$. Our work might offer an alternative avenue to rapidly identify superconducting materials.
Unlocking quantum critical phenomena with physics guided artificial intelligence

CHRISTOPHER SINGH, MATTHEW REDELL (Presenter), Binghamton University, MOHANNAD ELHAMOD, JIE BU, Virginia Tech, WEI-CHENG LEE, Binghamton University, ANUJ KARPATNE, Virginia Tech — Breakthroughs in cold atom experiments, advances in quantum computing, developments in spin liquids, and the proliferating importance of quantum critical phenomena compel the application of machine learning techniques to difficult quantum problems. In an age where data can drive unparalleled discoveries, expensive-to-acquire data such as measurements of quantum computer states or cold atom chains can be used by the community to distill new information. Thus, more effective ways of prediction and distillation are required to efficiently identify the criticality. While many have done this using a classification algorithm, we have pioneered a method to predict quantum critical phenomena using machine learning in the absence of direct exposure to states on either side of the transition by directly predicting the ground state wavefunction. By analyzing the predictions for the total phase space, we can confidently identify the location of criticality from the evolution of the predicted wavefunctions. Through further development, this type of machine could help researchers quickly, and cheaply, identify regions of the phase space that are of the utmost interest.

Neural-Network Approach to Dissipative Quantum Many-Body Dynamics

MICHAEL HARTMANN (Presenter), Univ Erlangen Nuremberg, GIUSEPPE CARLEO, Flatiron Institute — In experimentally realistic situations, quantum systems are never perfectly isolated and the coupling to their environment needs to be taken into account. Often, the effect of the environment can be well approximated by a Markovian master equation. However, solving this master equation for quantum many-body systems becomes exceedingly hard due to the high dimension of the Hilbert space. Here we present an approach to the effective simulation of the dynamics of open quantum many-body systems based on machine-learning techniques. We represent the mixed many-body quantum states with neural networks in the form of restricted Boltzmann machines and derive a variational Monte Carlo algorithm for their time evolution and stationary states. We document the accuracy of the approach with numerical examples for a dissipative spin lattice system.

Session L40 DCOMP DMP: Matter in Extreme Environments III: Warm Dense Matter
Warm and extremely dense matter, having densities ranging from tens to millions of grams per cubic centimeters and temperatures of 104 to 106 K, widely exist in the universe such as giant planet cores and white dwarfs. Thanks to advances in technology, such extreme conditions can now be created in laboratories by powerful lasers or pulsed-power machines. Experimental advances have certainly helped us to unravel how matter behaves under warm and superdense conditions. On the theory and computation side, first-principles tools such as thermal density-functional theory (DFT) are often used to reveal novel properties of warm and extremely dense matter. Many new phenomena, for example, unusual K-edge shifting,[1] dynamical Ka-line movement,[2] and interspecies radiative transition,[3] have been predicted by ab-initio DFT calculations. Some of them have recently been confirmed by experimental measurements. In this talk, we will cover the recent progress in understanding the physics of matter in such extreme environments through both computational and experimental studies. This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003856.

8:36AM L40.00002: Ultrafast electron-ion coupled dynamics of iron nano-foil in warm dense matter (WDM) conditions studies by time resolved XANES and ab-initio simulations*

AMALIA FERNANDEZ (Presenter), ALFREDO A. CORREA, SEBASTIEN HAMEL, Lawrence Livermore Natl Lab, DAVID PRENDERGAST, Lawrence Berkeley Nationa Laboratory, SRI CHAITANYA DAS PEMMARAJU, PHILIP HEIMANN, SLAC, ROGER WIRTH FALCONE, University of California Berkeley, JON HENRY EGGERT, YUAN PING, TADASHI OGITSU, Lawrence Livermore Natl Lab — In recent years, significant progresses have been made in both ultrafast experimental measurements techniques as well as in computational modeling that allow us to access to fundamental properties such as electron-phonon coupling under electron-ion non-equilibrium conditions. In this presentation, we will discuss how a combination of time-resolved XANES experiment and ab-initio derived two-temperature model coupled with XANES simulation is used to study the spatiotemporal electron-ion relaxation behavior of nano-meter thin iron foil that is exposed to femto second laser pulse. We show that the current level of experimental time resolution is already sufficient to constraint thermophysical properties under non-equilibrium WDM conditions within a few tens of percent, however, for the optimal sensitivity, which depends strongly on the choices of geometrical design of target as well as corresponding laser fluence.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344 with support from DOE OFES Early Career program.

8:48AM L40.00003: First-principles Stopping Power in Warm Dense Matter*  

ATTILA CANGI (Presenter), ANDREW BACZEWSKI, STEPHANIE B HANSEN, Sandia National Laboratories — Recent experiments provide measurements of fusion-product stopping powers in warm dense targets [1, 2]. State-of-the-art numerical modeling complements these critical advances in our empirical knowledge and phenomenological understanding of transport properties in this thermodynamic regime. In anticipation of future experiments, we assess the ability of real-time time-dependent density functional theory (TDDFT) to reproduce these results and compare its predictions with linear response TDDFT and average-atom models.

*Sandia National Laboratories is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.
9:00AM L40.00004: Thermoelectric properties from time-dependent density functional theory*  ALICIA WELDEN (Presenter), XAVIER ANDRADE, ALFREDO A. CORREA, Lawrence Livermore Natl Lab — The goal of this work is to develop computational methods to predict electrical and thermal transport properties from ab-initio quantum simulations. We apply a microscopic theory of quantum transport to obtain conductivities from first principles. The new methods, based on simulating real time electron dynamics, are able to access larger systems than the standard Kubo-Greenwood approach and are also applicable in non-linear regimes. We investigate liquid metallic hydrogen at 1400 K and 400 GPa, in order to see if there is nonlinear behavior under conditions that are typically accessible by experiments.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344." LDRD: Quantum Non-Equilibrium Dynamics of Electronic Transport in Nonlinear Regimes [18-ERD-031 2018] RELEASE:LLNL-POST-773049

9:12AM L40.00005: Thermal gradient effect on the transport properties of helium and intrinsic defects in tungsten*  ENRIQUE MARTINEZ SAEZ (Presenter), Theoretical Division, Los Alamos National Laboratory, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts, BRIAN WIRTH, Department of Nuclear Engineering, University of Tennessee — Plasma-facing materials (PFMs) in a fusion reactor are expected to withstand stringent conditions, with high heat and particle fluxes that modify the materials microstructure. These fluxes create strong gradients of temperature and concentration of diverse species. Besides the He ash, neutron particles will create intrinsic point defects, such as vacancies and self-interstitials atoms (SIAs), and their clusters. These species will then migrate in the presence of the afore-mentioned gradients. In this work, we use nonequilibrium molecular dynamics simulations to study the transport properties of He, vacancies, and SIAs in the presence of a thermal gradient in tungsten. In all cases, the defects and impurity atoms tend to migrate toward the hot regions of the material. The resulting concentration profiles are in agreement with irreversible thermodynamics. We compute a negative heat of transport for all species, which indicates that the respective driven species fluxes are directed opposite to the heat flux. We demonstrate that, when the mass-heat transport coupling is considered, the resulting steady-state profiles vary significantly from those when species transport is decoupled from heat transport.

Electronic structure approach to compute Dark Matter-Electron scattering cross-sections in Direct Detection experiments

CHENG ZHEN (Presenter), ROUVEN ESSIG, MARIVI FERNANDEZ SERRA, State Univ of NY - Stony Brook — The existence of dark matter in the Universe is nowadays overwhelming. Numerous direct detection experiments are currently on going or planned all around the world. As the mass of these dark matter particles is unknown, these experiments explore different mass ranges, with a large majority being sensitive to masses above the GeV range. In these experiments dark matter is assumed to scatter from the nuclei and background models are built upon a combined theoretical and experimental characterization of nuclear recoils in the detectors. Recently, however, dark matter in the sub-GeV mass range has received much attention, and several well-motivated theoretical models exist for candidates in this mass range. The traditional method of detecting the nuclear recoil does not apply for sub-GeV dark matter because the recoil energy falls below the detector threshold. However, the scattering of dark matter with atomic electrons can produce observable ionization signals. In this talk we present the theoretical model to estimate the dark matter-electron scattering event rate using first principle methods. We will show how this rate estimation depends on the underlying theoretical approximations. We also show results for different systems like liquid Xe, Si and Ge.

Accurate Calculations of a Solid State Test Set with Quantum Monte Carlo Methods

CODY MELTON (Presenter), Sandia National Laboratories, JARON KROGEL, Oak Ridge National Laboratory, FIONN MALONE, MIGUEL A MORALES, Lawrence Livermore National Laboratory, LUKE SHULENBURGER, Sandia National Laboratories — Quantum Monte Carlo (QMC) methods serve as some of the most promising techniques for studying correlated materials across large spans of system size. Here, we revisit a solid state test set for QMC ranging from ionic, metallic, covalent, and van der Waals materials.

Using the familiar fixed-node Diffusion Monte Carlo (DMC) and the more recent auxiliary field quantum Monte Carlo (AFQMC), we examine the bulk ground state properties from ambient conditions up to nearly 300 GPa. One of the key limitations to the accuracy of previous DMC calculations for this set was the quality of the effective core potentials utilized. In this work, we use the recently developed correlation consistent effective core potentials and compare to previous calculations to quantify the size of the pseudopotential errors in DMC on the calculated structural properties. Additionally, we directly compare AFQMC to DMC in order to understand the relative strengths and weaknesses of the two methods for these calculations.

This work was supported by the Center for Predictive Simulation of Functional Materials, a DOE-BES center. SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525
Materials Informatics for Dark Matter Detection

RICHARD GEILHUFE (Presenter), BART OLSTHOORN, NORDITA, ALFREDO FERELLA, Stockholm University, TIMO KOSKI, KTH Royal Institute of Technology, FELIX KAHLHÖFER, RWTH Aachen, JAN CONRAD, Stockholm University, ALEXANDER V BALATSKY, NORDITA — Dark Matter particles are commonly assumed to be weakly interacting massive particles (WIMPs) with a mass in the GeV to TeV range. Recent interest has shifted toward lighter WIMPs, which are more difficult to probe experimentally. A detection of sub-GeV WIMPs requires the use of small gap materials in sensors. Using recent WIMP mass estimates, we identify the relevant target space toward small gap materials (100 to 10 meV). Dirac Materials, a class of small- or zero-gap materials, emerge as natural candidates Dark Matter sensors. We propose the use of informatics tools to rapidly assay materials band structures to search for small gap semiconductors and semimetals, rather than focusing on a few preselected compounds. As a specific example of the proposed strategy, we use the organic materials database (https://omdb.mathub.io) to identify organic candidate materials. We outline a novel and powerful approach to search for dark matter detection sensor materials by means of a rapid assay of materials using informatics tools.

We acknowledge support from VILLUM FONDEN via the Centre of Excellence for Dirac Materials (Grant No. 11744), the European Research Council under the European Unions Seventh Framework ERS-2018-SYG 810451 HERO, and the Knut and Alice Wallenberg Foundation.

Extreme Electric Fields in DFT

MICHAEL ASHTON (Presenter), CHRISTOPH FREYSOLDT, JOERG NEUGEBAUER, Max Planck Inst fuer Eisenforschung GmbH — Strong (10^10 V/m) electric fields can be used to trigger chemical processes with extreme precision by selectively stabilizing or weakening bonds to initiate reactions which are otherwise slow or do not proceed at all. The ability to manipulate electric fields to tailor and stimulate bond-breaking events is a powerful experimental control knob, but one whose effects are difficult to predict due to a lack of suitable tools to probe its associated atomic-scale mechanisms. Here we introduce a novel approach, which we term the Generalized Dipole Correction (GDC), that enables the direct study of ultra-high fields effecting bond-breaking and desorption at the level of single atoms using Density Functional Theory (DFT). As a prototype application, we consider field evaporation from a kinked W (110) surface. We reveal two qualitatively different competing mechanisms that can be switched by the applied field.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L41 GMAG: Magnetic dynamics and magnetic switching

Yabin Fan, Massachusetts Institute of Technology MIT - Tag(s): Focus
The coupling between electronic and magnetic phenomena was one of the riddles propelling the development of modern electromagnetism. Today, the fully controlled electric field evolution of ultrashort laser pulses permits the direct and ultrafast control of electronic properties of matter and is the cornerstone of light-wave electronics. In sharp contrast, because there is no first order interaction between light and spins, the magnetic properties of matter can only be affected indirectly on the much slower tens-of-femtosecond timescale in a sequence of optical excitation followed by the rearrangement of the spin structure.

I will discuss an experiment recording an orders of magnitude faster magnetic switching with sub-femtosecond response time by initiating optical excitations with near-single-cycle laser pulses in a ferromagnetic layer stack. The unfolding dynamics are tracked in real-time by a novel attosecond time-resolved magnetic circular dichroism (atto-MCD) detection scheme revealing optically induced spin and orbital momentum transfer (OISTR) in synchrony with light field driven charge relocation. In tandem with ab-initio quantum dynamical modelling, we show how this mechanism provides simultaneous control over electronic and magnetic properties that are at the heart of spintronic functionality. This first incarnation of attomagnetism observes light field coherent control of spin-dynamics in the initial non-dissipative temporal regime and paves the way towards coherent spintronic applications with Petahertz clock rates.
8:36AM L41.00002: Unification of ultrafast demagnetization and switching* GUOPING ZHANG (Presenter), M MURAKAMI, Y. H. BAI, Indiana State University, THOMAS F GEORGE, University of Missouri-St. Louis, XIAOSHAN WU, Nanjing University — All-optical spin switching and demagnetization are two sides of the same physics. We find a way to unify them through the same model that takes into account the Heisenberg exchange between spins and spin-orbit coupling. We include both the kinetic energy term and potential energy term, so that we can account for the realistic interaction between the laser and the system. To have efficient spin switching, the electron initial momentum direction must closely follow the spin's orientation, so that the orbital angular momentum is transverse to the spin, and consequently the spin-orbit torque lies in the same direction as the spin. Both left and right circularly polarized light have stronger but different effects in both uniform spin domains and The demagnetization can be understood from the spin-orbit coupling-mediated spin-wave excitation. The efficiency of laser-induced demagnetization is very high. We also observe the collapse of the spin-spin correlation length within 20 fs, consistent with the experimental findings.

8:48AM L41.00003: Ultrafast Magnetic Spectroscopy, Scattering and Full-Field Imaging Using Tabletop High Harmonic Sources* PETER JOHNSEN (Presenter), CHRISTIAN GENTRY, ROBERT M KARL, SINEAD RYAN, JEREMY THURSTON, HENRY KAPTEYN, MARGARET MURNANE, JILA — The observation and manipulation of spin dynamics on the nanoscale is a crucial ability in our quest to engineer quantum materials. We present spectroscopy, scattering, and full field imaging of magnetic nanostructures using EUV high harmonic sources. Our control of EUV polarization, spin and orbital angular momentum, along with high spatial and temporal coherence, allows us to uniquely control and probe spin dynamics on few-femtosecond timescales on up.

*STROBE NSF Science and Technology Center

9:00AM L41.00004: Revealing angular momentum transfer channels and timescales in the ultrafast demagnetization process of ferromagnetic semiconductors  ZHANGHUI CHEN (Presenter), Lawrence Berkeley National Laboratory, JUN-WEI LUO, Chinese Academy of Sciences, LIN-WANG WANG, Lawrence Berkeley National Laboratory — Ultrafast control of magnetic order by light provides a promising realization for spintronic devices beyond Moore's Law. Here, we unravel the laser-induced demagnetization mechanism of ferromagnetic semiconductor GaMnAs, using an efficient time-dependent density functional theory approach that enables the direct real-time snapshot of the demagnetization process. Our results show a clear spin-transfer trajectory from the localized Mn-d electrons to itinerant carriers within 20 fs, illustrating the dominant role of \( sp-d \) interaction. We find that the total spin of localized electrons and itinerant carriers is not conserved in the presence of spin-orbit coupling (SOC). Immediately after laser excitation, a growing percentage of spin-angular momentum is quickly transferred to the electron orbital via SOC in about 1 ps, then slowly to the lattice via electron–phonon coupling in a few picoseconds. The spin-relaxation time via SOC is about 300 fs for itinerant carriers and about 700 fs for Mn-d electrons. These results provide a quantum-mechanical microscopic picture for the long-standing questions regarding the channels and timescales of spin transfer, as well as the roles of different interactions underlying the GaMnAs demagnetization process.

9:12AM L41.00005: Magnetic Entropy Dynamics in Ultrafast Demagnetization  SAHAR GOHARSHENASANESFAHANI (Presenter), SERBAN SMADICI, Univ of Louisville — Development of femtosecond laser sources and magneto-optical pump-probe techniques enabled measurements of ultrafast demagnetization in ferromagnets. It is necessary to measure two quantities to thermodynamically describe a magnetic state. In particular, measuring the magnetic entropy dynamics of a material in addition to its magnetization dynamics is crucial for fully understanding the transient magnetic state.

Time-resolved magneto-optical Kerr effect measurements of magnetization and magnetic entropy dynamics were made for ferromagnetic Co/Au/glass thin films. An intense 1030 nm pump pulse excited the film and a weak 515 nm time-delayed probe pulse was detected after reflecting off the sample. An external magnetic field was applied along the film surface. Different powers of the pump were used, increasing the film temperature to Curie temperature. Measurements revealed unexplored properties of the magnetic state at ultrafast timescales. Results will be compared to predictions of the Landau model and computer simulations.
9:24AM L41.00006: Analytic modeling of switching time dynamics of monodomain ferromagnets with biaxial energy landscape* ANKIT SHUKLA (Presenter), Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, ARUN PARTHASARATHY, Electrical and Computer Engineering, New York University, SHALOO RAKHEJA, Electrical and Computer Engineering, University of Illinois at Urbana-Champaign — Assuming the macrospin model, we develop analytic models to describe the magnetization dynamics of an in-plane-anisotropy ferromagnet driven by spin-transfer-torque with spin polarization collinear to the easy axis orientation. Thus far, the physics of in-plane magnets has been analyzed using numerical solution of the Landau Lifshitz Gilbert (LLG) equation, while analytic expressions of switching time probability, which are needed for memory design and optimization, are lacking. In the limit of small torque, low damping and zero temperature, we construct an average energy flow equation to describe the dynamics of the in-plane magnet. We approximate the elliptic integrals in the flow equation with rational functions and obtain the switching time of the magnetization as a function of energy landscape, material parameters, and input spin current. We also evaluate analytical expressions for switching time probability and cumulative distribution functions assuming a Boltzmann equilibrium distribution of magnetization in the initial energy basin. Good agreement between the model and numerically evaluated results based on Monte Carlo simulations of the LLG equation is demonstrated.

*This work is supported by the National Science Foundation Grant no. 1930620

9:36AM L41.00007: Elastic Properties of Encapsulation Epoxy for Vanadium Tetracyanoethylene Devices Measured Using Brillouin Light Scattering (BLS)* KATHERINE E. NYGREN (Presenter), Department of Physics, Colorado State University, ANDREW FRANSON, SETH KURFMAN, EZEKIEL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University, KRISTEN S. BUCHANAN, Department of Physics, Colorado State University — The organic-based ferrimagnetic coordination compound vanadium tetracyanoethylene (VTCNE) shows promise for microwave applications because it has low damping, similar to that of yttrium iron garnet (YIG), it exhibits conformal deposition on a variety of substrates, and the deposition process does not require high temperatures, which allows for simple integration into large scale semiconductor fabrication processes. Like many organic materials, however, it is sensitive to oxygen. The use of organic-friendly epoxy for encapsulation is a common method for protecting the organic that can easily be integrated into device fabrication processes on a large scale, and epoxies that protect the VTCNE without compromising the damping have been identified. Recent measurements suggest, however, that the magnetic properties, particularly the anisotropy, of VTCNE may be sensitive to strain. Consequently, understanding the mechanical properties of the encapsulating epoxy under typical device conditions is important. Here, we have used Brillouin light scattering (BLS) spectroscopy to probe the elastic properties of the cured encapsulating epoxy via phonon spectra measurements as a function of the angle of incidence and light polarization.

Overcoming the spectroscopic limitations of inelastic light scattering by sub-diffraction light confinement

RYAN M FREEMAN (Presenter), Department of Physics, Emory University, VLADISLAV DEMIDOV, SERGEJ DEMOKRITOV, Institute for Applied Physics and Center for Nonlinear Science, University of Muenster, JINJUN DING, MINGZHONG WU, Department of Physics, Colorado State University, HAYK HARUTYUNYAN, SERGEI URAZHDIN, Department of Physics, Emory University — The small momentum of light strongly limits inelastic light scattering techniques. For instance, only long-wavelength spin waves are accessible to Brillouin light spectroscopy (BLS) widely utilized in studies of magnetic materials and nanostructures [1,2]. We overcome this limitation by utilizing a nanoscale metallic antenna on yttrium iron garnet (YIG) film. The antenna facilitates sub-diffraction confinement of light, generating momentum significantly larger than that of free-space light, and simultaneously enhances the local field due to a combination of geometric phase matching and optical reflection. We also present evidence for the plasmonic effects further enhancing the sensitivity and the spectral range. Our approach can be extended to other types of excitations and light scattering techniques. The demonstrated momentum enhancement can also facilitate light absorption in indirect-gap semiconductors, improving the efficiency of solar cells and optical detectors.

10:00AM L41.00009: Terahertz emission from circular photogalvanic effect in bismuth thin films* YOSHUA HIRAI (Presenter), NAOTAKA YOSHIKAWA, HANA HIROSE, MASASHI KAWAGUCHI, MASAMITSU HAYASHI, Department of Physics, University of Tokyo, RYO SHIMANO, Cryogenic Research Center and Department of Physics, University of Tokyo — When circularly polarized light is shined onto a sample, optical selection rules lead to spin-dependent excitations. This can cause helicity-dependent spin-polarized photocurrents within the sample, referred to as the circular photogalvanic effect (CPGE). Bismuth is a highly expected material to host spin-dependent photocurrents, due to its large spin Hall angle and Rashba-like surface states. Recently, helicity dependent photocurrents have been demonstrated in bismuth/copper heterostructures by dc transport measurements [1]. Correspondingly, ultrafast transient photocurrents are expected to occur under the illumination of femtosecond laser pulses, resulting in the emission of terahertz (THz) pulse radiation. Here, we present the observation of THz emission from bismuth thin films under near-infrared (800 nm, 1.55 eV) pulse excitation. A polarization dependent THz emission is observed in both bismuth thin films and bismuth/metal heterostructures. The opposite polarities of the emitted THz pulse with the left/right-hand circular polarized excitation evidences the transient photocurrent with the opposite direction due to CPGE.

10:12AM L41.00010: Ultrafast Spin Seebeck Measurements on Rare-Earth Iron Garnets* VICTOR ORTIZ (Presenter), Physics and Astronomy, University of California, Riverside, MICHAEL J GOMEZ, Mechanical Engineering, University of California, Riverside, YAWEN LIU, MOHAMMED ALDOSARY, JING SHI, Physics and Astronomy, University of California, Riverside, RICHARD WILSON, Mechanical Engineering, University of California, Riverside — Understanding the thermal generation of spin currents in magnetic materials is an important goal for the field of spin caloritronics. Among magnetic materials, rare earth iron garnets (REIG) display intriguing magnetic transport properties as result of strong antiferromagnetic exchange interactions and low magnetic damping. We report on ultrafast longitudinal spin Seebeck effect (LSSE) experiments on thin film REIG / heavy metal (HM) heterostructures (RE: Y, Tm, Eu, Tb; HM: Au). We use time-resolved magneto optic Kerr effect measurements to directly observe the transfer of magnetization from the REIG into the HM on femto-second timescales, allowing us to selectively probe the interfacial SSE. We observe a factor of 4 difference in the magnitude of the LSSE among the different REIG samples. Our results provide insight regarding the different contributions to the spin current from the different REIGs and the relevance of the interface between the REIG and the HM layers.

*This work was supported by the U.S. Army Research Laboratory and the U.S. Army Research Office under contract/grant number W911NF-18-1-0364; and SHINES, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award SC0012670.
10:24AM L41.00011: Controlled nonlinear magnetic damping in spin-Hall nano-devices*
BORIS DIVINSKIY (Presenter), Institute for Applied Physics and Center for Nonlinear Science, University of Muenster, SERGEI URAZHDIN, Department of Physics, Emory University, SERGEJ DEMOKRITOV, VLADISLAV DEMIDOV, Institute for Applied Physics and Center for Nonlinear Science, University of Muenster — One of the fundamental dynamical phenomena in magnetic systems is the nonlinear damping enhancement, which imposes strict limitations on the operation and efficiency of magnetic nanodevices. For instance, nonlinear damping prevents coherent magnetization auto-oscillations driven by the spin injection into spatially extended magnetic regions [1].
We utilize micro-focus Brillouin light spectroscopy (BLS) to demonstrate that nonlinear damping can be controlled by the ellipticity of magnetization precession. By balancing the demagnetizing field with the magnetic anisotropy in a Pt/Co/Ni heterostructure, we minimize ellipticity and achieve coherent magnetization oscillations in a microscopic CoNi disk, driven by spatially extended injection of spin current generated in Pt by the spin Hall effect. Micromagnetic simulations show that the mechanism responsible for the nonlinear damping is non-resonant parametric pumping enabled by the precession ellipticity. Our results provide a novel route for the implementation of efficient active spintronic and magnonic devices driven by spin current.

*Supported by the NSF award #ECCS-1804198

10:36AM L41.00012: Conductivity-Like Gilbert Damping due to Intraband Scattering in Epitaxial Iron*
BEHROUZ KHODADADI, Virginia Tech, ANISH RAI, ARJUN SAPKOTA, ABHISHEK SRIVASTAVA, BHUWAN NEPAL, University of Alabama, YOUNGMIN LIM, DAVID SMITH, Virginia Tech, CLAUDIA K.A. MEWES, SUJAN BUDHATHOKI, ADAM JOSEPH HAUSER, University of Alabama, MIN GAO, JIE-FANG LI, DWIGHT D VIEHLAND, ZIJIAN JIANG, JEAN J HEREMANS, Virginia Tech, PRASANNA V BALACHANDRAN, University of Virginia, TIM MEWES, University of Alabama, SATORU EMORI (Presenter), Virginia Tech — Confirming the origin of Gilbert damping by experiment has remained a challenge for many decades, even for some of the simplest ferromagnetic metals. Here, we experimentally identify Gilbert damping that increases with decreasing electronic scattering in thin films of BCC Fe. The observed conductivity-like damping, which cannot be accounted for by classical eddy current loss, is in excellent quantitative agreement with theoretical predictions of Gilbert damping due to intraband scattering. These results resolve the longstanding question since the 1970s about the role of intraband scattering in Gilbert damping. Our results also indicate that – somewhat counterintuitively – disorder can reduce intrinsic damping at low temperatures in ferromagnetic metals, such that optimally disordered films may be well suited for cryogenic spintronic and quantum applications.

Manipulation of terahertz spectrum using microfabricated magnetic heterostructures*  WEIPENG WU (Presenter), SERGI LENDINEZ, MOJTABA TAGHIPOUR KAFFASH, Department of Physics and Astronomy, University of Delaware, RICHARD D SCHALLER, Department of Chemistry, Northwestern University, HAIDAN WEN, Advanced Photon Source, Argonne National Laboratory, MATTHIAS BENJAMIN JUNGFLEISCH, Department of Physics and Astronomy, University of Delaware — Terahertz (THz) radiation with sub-micrometer wavelength falls in the gap between the optical and radio frequency range. Conventional THz emitters rely only on the electron's charge. However, recently it was found that spin-based effects occur on the ultrafast time scale. Upon excitation with a femtosecond laser pulse a diffusive spin current is created in a ferromagnet that leads to THz transients in an adjacent heavy metal layer due to a conversion by the inverse spin Hall effect. Here, we demonstrate generation and control of THz radiation from microstructured Fe/Pt bilayers. We compare the THz spectrum of different patterns and an extended film using time-domain THz spectroscopy. The microstructures are fabricated using optical lithography and sputtering deposition. The THz spectrum is experimentally observed and interpreted in terms of a simplified multi-slit diffraction model, which captures the main experimental features. Our results show an efficient control of the emitted THz light. This is a crucial step forward for the design and realization of directional spin-based THz sources.

Session L42 GMAG DMP FIAP DCOMP: Spin Phenomena in Nonmagnetic 2D Materials 709/711 - Brian Zhou, Boston College - Tag(s): Focus

Extracting spin-orbit coupling strength using realistic device simulations  BAS NIJHOLT, Kavli Institute for Nanoscience, Delft University of Technology, P.O. Box 4056, 2600 GA Delft, The Netherlands, GEORG WINKLER (Presenter), JUKKA VAYRYNEN, Microsoft Quantum, Microsoft Station Q, University of California Santa Barbara, Santa Barbara, CA 93106, USA, GUANZHONG WANG, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands, GIJS DE LANGE, Microsoft Quantum Lab Delft, 2628 CJ, Delft, The Netherlands, LUCA BINCI, ALBERTO BORDIN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands, ROMAN LUTCHYN, Microsoft Quantum, Microsoft Station Q, University of California Santa Barbara, Santa Barbara, CA 93106, USA — We do realistic device simulations of semiconductor nanowires and calculate the weak antilocalization correction. We match our numerical simulation to magnetoconductance measurements and accurately extract the spin-orbit coupling strength from experiment. Unlike analytic approaches, our approach considers the electrostatic potential, works for arbitrary wire cross sections, and arbitrary finite mean free paths, including the complicated cross over regime where mean free path is comparable to wire width. After verifying our technique against known analytical results, we extract the spin-orbit coupling strength of semiconductor nanowires produced by selective area growth.
Far out-of-equilibrium spin populations trigger giant spin injection into atomically thin MoS$_2$  

EE MIN CHIA (Presenter), Nanyang Tech Univ — Injecting spins from ferromagnetic metals into semiconductors efficiently is a crucial step towards the seamless integration of charge- and spin-information processing in a single device. However, efficient spin injection into semiconductors has remained an elusive challenge due to the extremely low injection efficiencies originating from impedance mismatch, or technological challenges due to stability and cost issues. In Co/MoS$_2$, by making use of the strongly out-of-equilibrium character of the injected spins, we demonstrate a highly-efficient spin injection from a ferromagnet (Co) into a semiconductor (MoS$_2$), thus overcoming the crippling problem of impedance mismatch. Astonishingly, we measure a giant spin current that is orders of magnitude larger than typical injected spin current densities using currently available techniques. Our result demonstrates that technologically relevant spin currents can be driven by ultralow-intensity laser pulses, finally enabling ultrashort spin-current pulses to be a technologically viable information carrier for terahertz spintronics. *Nature Physics*, DOI:10.1038/s41567-018-0406-3 (2019).

*A*STAR PHAROS Programme on Topological Insulators (SERC Grant No. 152 74 00026) and 2D Materials (SERC Grant No. 152 70 00012 and 152 70 00016).

Introducing CVD WS$_2$ in Magnetic Tunnel Junctions  

VICTOR ZATKO (Presenter), MARTA GALBIATI, CNRS/THALES, SIMON MUTIEN-MARIE DUBOIS, Université Catholique de Louvain, Institute of Condensed Matter and Nanosciences, MAURO OCH, CECILIA MATTEVI, Department of Materials, Imperial College London, PIERRE BRUS, ODILE BEZENCENET, MARIE-BLANDINE MARTIN, BERNARD SERVET, Thales Research and Technology France, JEAN-CHRISTOPHE CHARLIER, Université Catholique de Louvain, Institute of Condensed Matter and Nanosciences, FLORIAN GODEL, FRÉDÉRIC PETROFF, ALBERT FERT, BRUNO DLUBAK, PIERRE SENEOR, CNRS/THALES — The use of the spin variable as the vector of information has been largely applied from hard drives read-heads to MRAMs, with novel propositions beyond spin-logics for neuromorphic, stochastic and quantum calculations. While very recent, the introduction of 2D materials such as graphene and the 2D insulator h-BN in Magnetic Tunnel Junctions (MTJs) vertical spin valves has already shown some promising properties[1]. The advent of the 2D semiconductors families opened new opportunities for further tailoring of spintronics properties[2]. Here, we will present results on the scarcely studied WS$_2$ 2D semiconductor for spintronics. We will detail a protocol to fabricate spin valves based on CVD grown WS$_2$, with step by step characterizations in support (Raman spectroscopy, photoluminescence, AFM). We will then present our spin transport measurements obtained in a CVD WS$_2$ based MTJ. Our measured MR signals, above state of the art for 2D semiconductor based MTJs, validates our fabrication approach. These results open the way to the integration of different members of the very large 2D semiconductor families, TMDC and beyond, in order to reveal their spin transport properties in MTJs.

Defect induced magnetism in monolayer semiconducting PtSe$_2$  

AHMET AVSAR (Presenter), CHEOL-YEON CHEON, MICHELE PIZZOCHERO, ALBERTO CIARROCCHI, OLEG V. YAZYEV, ANDRAS KIS, Ecole Polytechnique Federale de Lausanne — Intrinsic disorders such as metal vacancies and antisites in 2D TMDCs are generally accompanied by local magnetic moments which could induce long range magnetic ordering if disorder concentration is sufficient. Towards this, we have recently shown that platinum (Pt) vacancy defects located at the surfaces of multilayer metallic PtSe$_2$ act as magnetic centers [1]. For both fundamental studies and technological applications, it is critical to explore magnetism in ultra-thin PtSe$_2$ as this material shows a complete switching from a metal to a semiconductor as its thickness is reduced [2]. Here, we will present our magneto-transport measurements together with first-principles calculations which clearly demonstrate that Pt vacancy defect yields an antiferro- (ferro-)magnetic ordering in mono (bi-)layer PtSe$_2$. We will also demonstrate that these air-stable crystals can be employed as a magnetic substrate to induce novel proximity phenomena into adjacent nonmagnetic layers. Our findings broaden the horizon of 2D magnets to include normally nonmagnetic stable materials by defect engineering.

Weak anti-localization in undoped Ge/GeSn heterostructures*  

JIUN-YUN LI, CHIA-TSE TAI (Presenter), CHENG-YU LIN, CHIA-YOU LIU, TZU-MING WANG, Natl Taiwan Univ, CHARLES HARRIS, TZU-MING LU, Sandia National Laboratories — In this work, we demonstrate weak anti-localization (WAL) in undoped Ge/GeSn heterostructures. We used gated Hall-bar devices to induce two-dimensional hole gases (2DHGs) in strained GeSn quantum wells for magnetotransport experiment at 1.2 to 10 K. Transition from weak localization to WAL is observed as the density increases due to density dependent spin-orbit coupling. By fitting to the HLN formula, phase coherence and spin-orbit times of 2DHGs as well as the spin-orbit splitting energy in undoped Ge/GeSn heterostructures are extracted. Our data show that the scattering lifetime is shorter than the spin-orbit time at all densities, indicating that the system is in the spin-diffusive regime.

**9:00AM L42.00006: Magnetic order and anisotropy at 3d ferromagnet/2D material heterojunctions**

DER-HSIN WEI (Presenter), Scientific Research Division, National Synchrotron Radiation Research Center, CHUN-I LU, Department of Physics, National Taiwan Normal University, CHIH-HENG HUANG, International PhD Program for Science, National Sun Yat-sen University, YANNWEN LAN, Department of Physics, National Taiwan Normal University, CHIEN-CHEN KUO, Department of Physics, National Sun Yat-sen University, TZU-HUNG CHUANG, Scientific Research Division, National Synchrotron Radiation Research Center — Layered (opto-)electronic devices integrated with two dimensional (2D) materials is an exciting research field that packs with new possibilities and challenges. For example, a high spin injection efficiency from ferromagnetic (FM) electrode to 2D-materials is thought possible, but it needs to work with the complex orbital hybridization and proximity effect at heterojunctions. Here we report the magnetic properties of two 3d ferromagnet/2D material heterojunctions; Co/MoS$_2$ and Fe/graphene. Both macroscopic magnetic orders and microscopic magnetic configurations of these two heterojunctions are examined. In addition, the interplay between FM materials and 2D materials are studied with the X-ray micro-spectroscopy. We find a heterojunction can exhibit the magnetic anisotropy, but it seems crystalline structure of FM layer is not responsible for it. I will present the experimental data followed by a brief discussion.

*Supported by MOST 107-2112-M-213-003-MY3, and National Synchrotron Radiation Research Center

**9:12AM L42.00007: Spin-to-charge interconversion in van der Waals heterostructures** [Invited]

CK SAFEER (Presenter), CIC NanoGUNE, San seanstan, Spain — Graphene has been known as an excellent material for long-distance spin transport due to its weak spin-orbit coupling (SOC). However, the same reason makes graphene an adverse candidate for different spintronics applications in which strong SOC is required, such as the Datta and Das proposal or spin-charge interconversions. It has recently been predicted theoretically that SOC can be induced in graphene so that exotic spin-orbit phenomena such as spin Hall effect (SHE) or Rashba-Edelstein effect can be obtained. In our work, by using van der Waals heterostructure-based lateral spin valves, we experimentally demonstrate spin-to-charge conversion (SCC) due to SHE in graphene via spin-orbit proximity with MoS$_2$, a transition metal dichalcogenide (TMD)$^1$. The combination of long-distance spin transport and large spin-to-charge conversion in a van der Waals heterostructure gives rise to a hitherto unreported efficiency for the spin-to-charge voltage output. Using a similar approach, we observed large multidirectional SCC in Weyl semimetal MoTe$_2$. Here, due to the low symmetry of MoTe$_2$ crystal, we detect, along with the conventional SCC, an unconventional SCC where the spin polarization and the charge current are parallel. Our finding enables the simultaneous conversion of spin currents with any in-plane spin polarization in one single experimental configuration. All in all, these exceptional effects obtained by the unique properties of 2D materials open exciting opportunities in a variety of future spintronic applications.

Two-dimensional spin-valley locking spin valve

LINGLING TAO (Presenter),
EVGENY Y TSYMBAL, Department of Physics and Astronomy, University of Nebraska-Lincoln —

Valleytronics is an emerging field of research which employs energy valleys in the band structure of two-dimensional (2D) electronic materials to encode information. A special interest has been triggered by the associated spin-valley coupling which reveals rich fundamental physics and enables new functionalities. Here, we propose exploiting the spin-valley locking in 2D materials with a large spin-orbit coupling and electric field reversible valley spin polarization, such as germanene, stanene, a 1T' transition metal dichalcogenide (TMDC) monolayer, and a 2H-TMDC bilayer, to realize a valley spin valve (VSV). The valley spin polarization in these materials can be switched by an external electric field, which enables functionalities of a valley spin polarizer or a valley spin analyzer. When placed in series, they constitute the proposed VSV—a device whose conductance state is ON or OFF depending on the relative valley spin polarization of the polarizer and the analyzer. Using quantum-transport calculations based on an adequate tight-binding model, we predict a giant VSV ratio of nearly 100% for both germanene- and stanene-based VSV devices. Our results demonstrate the implication of the spin-valley coupling in 2D materials for the novel device concept promising for valleytronics.

Group-IV tellurides as a route towards all-in-one spin transistors

JAGODA SLAWINSKA (Presenter), FRANK T CERASOLI, PRIYA GOPAL, Univ of North Texas, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, Univ of North Texas —

Simple displacive ferroelectrics GeTe and SnTe have been studied for decades but their intriguing physics based on spin-orbit coupling remained unexplored until few years ago. In particular, they are prototype examples of ferroelectric Rashba semiconductors, a class of materials in which the unique coupling between spin and polar degrees of freedom enables the electrical manipulation of spins. Such a property, combined with a sizable spin Hall effect recently predicted in these materials opens a perspective to integrate different functionalities and construct ferromagnets-free spin devices. Here, we reveal even more intriguing phenomena emerging at the limit of the monolayer. More specifically, we explore the persistent spin texture intrinsically present in the ferroelectric phase which protects the spin from decoherence and supports extraordinarily long spin lifetime. Our first-principles calculations followed by symmetry arguments revealed that such a spin wave mode can be externally detuned by perpendicular electric field, leading to spin randomization and decrease in spin lifetime. We propose this mechanism as an operation principle of an all-in-one spin transistor, in which spin injection/detection can be accomplished via spin Hall effects.
10:12AM L42.00010: Atomically-resolved theory of the magnitude of the bulk Rashba effect* CARLOS MERA (Presenter), University of Colorado, Boulder, ELTON OGOSHI, ABC university, Santo Andre, SP, Brazil, ADALBERTO FAZZIO, Brazilian Nanotechnology National Laboratory, Campinas, SP, Brazil, GUSTAVO M. DALPIAN, ABC university, Santo Andre, SP, Brazil, ALEX ZUNGER, University of Colorado, Boulder — Rashba effect based-mechanisms to control and generate spin-polarized states have been one of the cornerstones of spintronics. A strong Rashba effect -- as measured by the Rashba coefficient $\alpha_R$ -- is required for applications. However, the physical mechanism defining the $R$ scale, i.e., the magnitude of $\alpha_R$, is unknown. We find an intrinsic separation between strong Rashba effect associated with anti-crossing bands, and weak Rashba effect associated with no anti-crossing bands. As an application of the proposed theory, we use this design principle to guide the selection of strong Rashba compounds. First, we illustrate that since topological insulators (TIs) intrinsically have anti-crossing bands, strong Rashba compounds could then be identified almost effortlessly by isolating TIs that are non-centrosymmetric, thus establishing a case for cross-functionality of topological Rashba materials. Second, we predict 34 strong Rashba materials by performing DFT calculations for ~800 potential Rashba compounds and filtering those with anti-crossing bands. This reveals rationally designed cases including known GeTe and BiTeI, and compounds that were previously made but unnoticed as Rashba compounds BiTeCl ($P6_3mc$) and BaCdK2Sb2 ($Pmc2_1$).

*Supported by NSF-DMR-CMMT and FAPESP (Grant 19/03663-7).

10:24AM L42.00011: All-electrical creation and control of giant spin-galvanic effect in 1T’-MoTe$_2$/graphene heterostructures at room temperature MD ANAMUL HOQUE (Presenter), DMITRII KHOKHRIAKOV, BOGDAN KARPIAK, SAROJ DASH, Chalmers Univ of Tech — The ability to engineer new states of matter and to control their electronic and spintronic properties by electric fields is at the heart of the modern information technology and driving force behind recent advances in van der Waals (vdW) heterostructures of two-dimensional materials. Here, we exploit a proximity-induced Rashba-Edelstein (REE) effect in vdW heterostructures of Weyl semimetal candidate MoTe$_2$ and CVD graphene, where an unprecedented gate-controlled switching of spin-galvanic effect emerges due to an efficient spin-to-charge conversion at room temperature [1]. The magnitude of the measured spin-galvanic signal is found to be an order of magnitude larger than the other systems, giving rise to a giant REE. The magnitude and the sign of the spin-galvanic signal are shown to be strongly modulated by gate electric field near the charge neutrality point, which can be understood considering the spin textures of the Rashba spin-orbit coupling-induced spin-splitting in conduction and valence bands of the heterostructure. These findings open opportunities for utilization of gate-controlled switching of spin-galvanic effects in spintronic memory and logic technologies.

10:36AM L42.00012: Highly tunable nonlinear Hall effects induced by spin-orbit couplings in strained polar transition-metal dichalcogenides* CHENG-PING ZHANG (Presenter), TONG ZHOU, KAM TUEN LAW, Hong Kong University of Science and Technology — Recently, signatures of nonlinear Hall effects induced by Berry curvature dipoles have been found in atomically thin 1T'/T_d-WTe_2. In this work, we show that in strained polar transition-metal dichalcogenides (TMDs) with 2H-structures, Berry curvature dipoles created by spin degrees of freedom lead to strong nonlinear Hall effects. Under easily accessible uniaxial strain of order ~ 0.2%, strong nonlinear Hall signals, characterized by Berry curvature dipole in the order of ~ 1Å, arise in electron-doped polar TMDs such as MoSSe, which is easily detectable experimentally. Moreover, the magnitude and sign of the nonlinear Hall current can be easily tuned by electric gating and strain. These properties can be used to distinguish nonlinear Hall effects from classical mechanisms such as ratchet effects. Importantly, our system provides a potential scheme for building electrically switchable energy harvesting rectifiers.

L42.00013: Research on the valley-related properties based on multilayer transition metal dichalcogenides HONGMING GUAN (Presenter), NING TANG, XIAOYUE ZHANG, XINGCHEN LIU, WEIKUN GE, BO SHEN, State Key Laboratory of Artificial Microstructure and Mesoscopic Physics, School of Physics, Peking Univ — Monolayer transition metal dichalcogenides (TMDCs), owing to the unique valley-related phenomena, have aroused great attention. However, in multilayer TMDCs, for the presence of the spatial-inversion symmetry, the valley-related phenomena are absent, which limits the developments of valleytronics. In this report, by utilizing the ionic liquid (IL) covering on top of the multilayer TMDC samples, the spatial-inversion symmetry is broken by the out-of-plane electric field induced by IL. The valley-related properties are therefore induced. Firstly, we investigated the circular photogalvanic effect (CPGE) in multilayer MoS_2. Upon the electric field induced by IL, the valley-coupled CPGE signals emerge. Via the wavelength-dependent measurements, it is confirmed only with resonant excitation of K (K') valley can the CPGE signals be detected. Furtherly, we studied the circular photon assisted valley Hall effect in multilayer WSe_2. With the application of IL, a Hall-oriented photocurrent signal in proportional to the drain-source voltage is detected, illustrating the valley Hall effect is successfully observed. These results imply the valley degree of freedom could be reborn in multilayer TMDCs.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L43 DCOMP DMP DCP: First-principles modeling of excited-state phenomena in materials VII: Electronic excitations: DFT and Beyond 702 - Michiel van Setten, IMEC - Tag(s): Focus
Transition to metallization in warm dense helium-hydrogen mixtures using stochastic density functional theory* [Invited] YAEL CYTTER, The Hebrew University of Jerusalem, ERAN RABANI (Presenter), University of California, Berkeley, DANIEL NEUHAUSER, University of California, Los Angeles, MARTIN PREISING, RONALD A. REDMER, University of Rostock, ROI BAER, The Hebrew University of Jerusalem — The Kubo-Greenwood (KG) formula is often used in conjunction with Kohn-Sham (KS) density functional theory (DFT) to compute the optical conductivity, particularly for warm dense matter. For applying the KG formula, all KS eigenstates and eigenvalues up to an energy cutoff are required and thus the approach becomes computationally expensive, especially for high temperatures and large systems, scaling cubically with both system size and temperature.

In this talk, I will review our recent developments to calculate the KS conductivity within the stochastic DFT framework, which requires knowledge only of the KS Hamiltonian but not its eigenstates and values. The method allows for an accurate description of the entire spectrum, including the high-frequency range, unlike the deterministic method which is compelled to introduce a high-frequency cutoff due to memory and computational time constraints. The computational effort associated with the method scales linearly with system size and reduces in proportion to the temperature, unlike the cubic increase with traditional deterministic approaches.

We applied the method to helium-hydrogen mixtures in the warm dense matter regime at temperatures of \( \sim 60,000 \) K and find that the system displays two conductivity phases, where a transition from nonmetal to metal occurs when hydrogen atoms constitute \( \sim 0.3 \) of the total atoms in the system.

*Work supported in part by the Center for Computational Study of Excited State Phenomena in Energy Materials (C2SEPEM) at the Lawrence Berkeley National Laboratory, which is funded by the U.S. Department of Energy, Office of Science, Basic energy Sciences, Materials Sciences and Engineering Division under Contract No. DEAC02-05CH11231 as part of the Computational Materials Sciences Program.
Towards a systematic multi-scale method for excitations in molecular materials in the BigDFT code

MARTINA STELLA (Presenter), LAURA E RATCLIFF, Imperial College London, LUIGI GENOVESE, CEA Grenoble Center, France — Understanding excitations is critical in spectroscopy as well as in technological applications, e.g. identifying where excited states lay for molecules in crystals is crucial for guiding experimentalists in locating excitation sources. Another example is thermally activated delayed fluorescence (TADF), a mechanism for designing the next generation of OLEDs (Organic Light Emitting Diodes materials) that are less environmentally harmful than the previous generation. Excitations in TADF materials exhibit an intricate mixture of charge-transfer and local nature and can be strongly influenced by the host material.

Modelling TADF (e.g identifying the best performing material) or locating excited states, thus, requires an accurate methodology that explicitly includes environmental effects. We are developing a multi-scale approach in the BigDFT code where high accuracy is combined with the ability of treating big systems to eventually go beyond implicit models. BigDFT runs on parallel architectures and can treat large systems with high, controllable precision. As a first step towards a robust methodology, we assess the performance of a promising new constrained-DFT approach recently developed in our group for various classes of excitations in comparison to standard methods (TDDFT).

MuST: An integrated ab initio framework for the study of disordered structures

YANG WANG (Presenter), Pittsburgh Supercomput Ctr, Carnegie Mellon University, MARKUS EISENBACH, XIANGLIN LIU, Oak Ridge National Laboratory, KHORGOLKUHU ODBADRAKH, University of Tennessee Knoxville, HANNA TERLETSKA, Department of Physics, Middle Tennessee State University, KA-MING TAM, Department of Physics, Louisiana State University, YI ZHANG, University of the Chinese Academy of Sciences, LIVIU CHIONCEL, Institute of Physics, University of Augsburg — The effect of disorder in materials is of great fundamental and technological interest. In this presentation, I will introduce a new public software package, called MuST, designed for enabling first principles investigation of disordered materials. MuST is developed based on full-potential multiple scattering theory with Green function approach, and is built upon decades of development of research codes that include Korringa-Kohn-Rostoker Coherent Potential Approximation (KKR-CPA), a highly efficient ab initio method for the study of random alloys, and Locally Self-consistent Multiple Scattering (LSMS) method, a linear scaling ab initio code capable of treating extremely large disordered systems from the first principles using the largest parallel supercomputers available. Strong disorder and localization effects can also be studied in real system within the LSMS formalism with cluster embedding in an effective medium with the Typical Medium Dynamical Cluster Approximation (TMDCA), which enables a scalable approach for first principles studies of quantum materials.

*This work is jointly supported by the NSF OCA and DMR under award number 1931525/1931367/1931445, and is supported in parts by the Office of Science of DOE and the LDRD Program of ORNL.
9:00AM L43.00004: Understanding the chemical enhancement mechanism of 2D substrate enhanced Raman Spectroscopy (2D-SERS). KANCHAN ULMAN (Presenter), SU YING QUEK, Natl Univ of Singapore — Surface-enhanced Raman spectroscopy (SERS) is a well established field which utilizes the enhancement of Raman signals for molecules on metal substrates, resulting in applications of this phenomena for detection and identification of trace concentrations of molecules. In recent years, two-dimensional (2D) materials like graphene, h-BN and MoS$_2$ are being used as substrates for SERS, giving rise to rapidly growing field of 2D-substrate enhanced Raman spectroscopy (2D-SERS). In conventional SERS, the enhancement factor is dominated by an electromagnetic enhancement mechanism, as compared to the smaller chemical enhancement effect. In 2D-SERS however, this chemical enhancement effect (which stems from electron-phonon coupling within the molecule and substrate) is thought to play a dominating role. Yet, the detailed understanding of the chemical enhancement effect in 2D-SERS is still lacking. Using first principles calculations, we study the chemical enhancement mechanism using typical probe molecules such as pyridine and pthalocyanine on 2D substrates, highlighting the role of electron-phonon coupling and charge-transfer excitons in the chemical enhancement mechanism of 2D-SERS.

9:12AM L43.00005: Local mixing in modified Becke-Johnson potential for low-dimensional systems TOMAS RAUCH (Presenter), IFTO, FSU Jena, Germany, MIGUEL MARQUES, Institute of Physics, MLU Halle-Wittenberg, Germany, SILVANA BOTTI, IFTO, FSU Jena, Germany — We propose an extension to the modified Becke-Johnson potential [1] that enables its use to study both heterogeneous and low-dimensional systems. This is achieved by using a coordinate-dependent expression for the $c$ parameter, in contrast to the original global formulation. Our functional builds on the excellent description of bulk band gaps of the modified Becke-Johnson potential and preserves its modest computational effort. Furthermore, it yields with one single calculation band-diagrams and band-offsets of heterostructures, interfaces, and surfaces. We exemplify the usefulness and efficiency of our local functional by testing it for a series of semiconductor interfaces, surfaces, two-dimensional systems, and molecules.

9:24AM L43.00006: Periodic Electronic Structure Calculations With Density Matrix Embedding Theory*  
HUNG Q PHAM, MATTHEW R HERMES, LAURA GAGLIARDI (Presenter), University of Minnesota — We developed a periodic version of density matrix embedding theory, DMET, with which it is possible to perform electronic structure calculations on periodic systems, and compute the band structure of solid-state materials. Electron correlation can be captured by means of a local impurity model using various wave function methods, like, for example, full configuration interaction, coupled cluster and multiconfigurational methods. The method is able to describe not only the ground-state energy but also the quasiparticle band picture via the real-momentum space implementation. We investigate the performance of periodic DMET in describing the ground-state energy as well as the electronic band structure for one-dimensional solids. Our results show that DMET is in good agreement with other many-body techniques at a cheaper computational cost. We anticipate that periodic DMET can be a promising first principle method for strongly correlated materials.

*This research is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences and Biosciences under Award DEFG02-17ER16362.

9:36AM L43.00007: Density Functional Theory-based study of charge transfer in doped silicon nanowire with gold leads: A toy model for the p-n junction photovoltaic device  
NATHAN WALKER (Presenter), DMITRI KILIN, ANDREI KRYJEVSKI, North Dakota State Univ — We analyze a toy model for p-n junction photovoltaic devices by simulating photoexcited state dynamics in silicon nanowires doped with aluminum and phosphorus atoms and capped with gold leads. We use Boltzmann transport equation (BE) that includes phonon emission, carrier multiplication (CM), and exciton transfer. BE rates are computed using non-equilibrium finite-temperature many-body perturbation theory (MBPT) based on Density Functional Theory simulations, including excitonic effects from Bethe-Salpeter Equation (see A. Kryjevski, D. Mihaylov, and D. Kilin, J. of Phys. Chem. Lett., 9(19) (2018), A. Kryjevski, D.Mihaylov, S. Kilina, and D. Kilin, J. of Chem. Phys., 147, 154106 (2017)). We compute total charge transfer amount generated from the initial photoexcitation and find an enhancement when CM is included.
**9:48AM L43.00008: Hj-Aggregate Theory Applied to Interacting SP³-Hybridization Defects in Carbon Nanotubes**  
BRADEN WEIGHT (Presenter), Department of Physics, North Dakota State University, ANDREW E SIFAIN, US Army Research Laboratory, BRENDAN J GIFFORD, Center for Nonlinear Studies, Los Alamos National Laboratory, SVETLANA KILINA, Department of Chemistry and Biochemistry, North Dakota State University, SERGEI TRETIAK, Center for Nonlinear Studies, Los Alamos National Laboratory — Single-walled carbon nanotubes (CNTs) have been recently studied in greater depth due to their promise of superior electronic properties for tunable emission of infrared energies. Optical features of functionalized CNTs (via SP³-hybridization defects) have been narrowed to only a few main parameters: (I) chirality, (II) defect configuration, and (III) defect electronegativity. Previous theoretical studies have been directed at single defects (comprised of a pair of functional groups) attached to the CNT surface, and, until recently, no literature has discussed the effects of defect concentration on CNTs in any depth [1,2]. In this work, we aim to model the interactions between nearby defects using density functional theory (DFT) and, extending to excited states, time-dependent DFT (TD-DFT) in order to fit these interactions to a well-known descriptor of analogous systems known as Hj-aggregate theory.

*Los Alamos National Laboratory LDRD Program*

**10:00AM L43.00009: Identifying sources of error in finite temperature calculations for molecules and solids using density matrix quantum Monte Carlo**  
HAYLEY PETRAS, SAI RAMADUGU, JAMES SHEPHERD (Presenter), Department of Chemistry, University of Iowa — Density matrix quantum Monte Carlo (DMQMC) calculates exact-on-average finite temperature electronic energies in a finite basis. This method has shown promise when applied to model systems like the electron gas (Phys. Rev. Lett. 117, 115701) but it is not well understood whether these findings are transferrable to real systems and to what extent strong correlation can affect our ability to run calculations on a system. Calculations on small molecules and solids (in a periodic basis set) will be presented including a resolution to previous convergence issues for the H10 chain. Finally, the computational cost scaling of DMQMC will be identified.

*We acknowledge the University of Iowa for funding.*
10:12AM L43.00010: Dynamical configuration interaction study of free base porphyrin*
MARC DVORAK (Presenter), PATRICK RINKE, Aalto University — We apply the recently developed dynamical configuration interaction (DCI) theory to study the low-lying excited states of free base porphyrin. In DCI [1,2], we diagonalize the exact many-body Hamiltonian in the strongly-correlated active space with the wave function technique of configuration interaction (CI). Additionally, the effects of the surrounding degrees of freedom are downfolded onto an energy-dependent correction added to the bare CI Hamiltonian. These corrections are approximated with many-body Green's function theory in the GW approximation. Free-base porphyrin is the largest system studied with DCI so far and serves as an important test of the numerical implementation, scalability, and size consistency of the theory. Our DCI results for excitation energies of porphyrin are in good agreement with past work.

10:24AM L43.00011: Light driven Non-Thermal Amorphization Mechanism of Phase Change Material*
SUBODH TIWARI (Presenter), AIICHIRO NAKANO, Univ of Southern California, FUYUKI SHIMOJO, Department of Physics, Kumamoto University, RAJIV KALIA, PAULO BRANICIO, PRIYA VASHISHTA, Univ of Southern California — Phase-change materials (PCM) are exploited in modern electronics due to the extreme electro-optical contrast between crystalline and amorphous states. However, atomistic mechanisms governing photoexcitation-induced athermal amorphization processes are still unknown. We perform excited-state dynamics within the framework of density functional theory to understand the mechanism behind such crystalline-to-amorphous transition for Germanium Telluride (GeTe). Amorphous phase induced due to excited-state dynamics was characterized by computing diffraction pattern. Further analysis of bond-overlap population shows charge transfer of electron from Ge-Te bonding orbitals to Ge-Ge antibonding orbitals. Such charge transfer process leads to the destabilization of GeTe crystals, eventually leading to amorphization. Rapid heat extraction during excited-state simulation does not lead to amorphous phase. Since structural transformation limits the lifetime of PCM-based devices, a complete understanding behind mechanism may allow us to a new avenue to design better devices.

First Principles Simulations of Hg$_x$Cd$_{1-x}$(S,Se) Optical Properties*  
ERICK HERNANDEZ ALVAREZ (Presenter), ANDREW MICHAEL SMITH, ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Mercury cadmium chalcogenide alloy quantum dots (QDs) are a promising material to meet the rapidly growing need for materials with emission in the biological near-infrared (NIR) window (700-2,000 nm) where tissue transparency is high and autofluorescence noise is low. Cation exchange-mediated alloying is an effective way to tune the QD emission wavelength continuously across the entire visible and NIR spectra without altering the QD’s physical dimensions. Here we describe the optical properties of zinc blende Hg$_x$Cd$_{1-x}$S and Hg$_x$Cd$_{1-x}$Se alloys from first principles simulations across the compositional space. We use density functional theory to compute electronic band structures of the binary mercury and cadmium chalcogenide systems and their intermediate ternary alloys. We then compute the corresponding optical spectra and describe the extent of the effect of spin-orbit coupling on the calculated photophysical properties. Comparison to measured absorption spectra of mercury cadmium chalcogenide alloy QDs provides insights into how photophysical parameters can be achieved with specific compositions and nanocrystal sizes.

DFT: the lore of smoothing and tetrahedra is wrong*  
JEREMY JORGENSEN (Presenter), GUS HART, Brigham Young Univ - Provo — Smoothing and tetrahedron methods in density functional theory (DFT) codes were developed to improve the robustness and efficiency of DFT codes. Tests we have performed demonstrate that both methods fail to accomplish either assertion. We have run ~20,000 DFT calculations in VASP and Quantum Espresso with various types and amounts of smoothing on 12 metals. The rate of convergence of the total energy for calculations with smoothing is often worse than those without smoothing, and smoothing does not result in a reduction in the number of self-consistency cycles when compared to runs without smoothing. We obtained similar results in comparisons involving tetrahedron methods.

8:00AM L44.00001: Beyond Fourier's law: viscous heat equations [Invited] ANDREA CEPELLOTTI (Presenter), School of Engineering and Applied Sciences, Harvard University — Heat hydrodynamics is undergoing a renewed wave of interest, after it has been theoretically proposed to take place in 2D materials and recent experimental observations in graphite. In particular, heat hydrodynamics emerges when the momentum carried by phonons is weakly dissipated, making it possible, for example, to observe second-sound, a wave-like propagation of heat. The macroscopic description of this regime, however, is still object of investigations, as the commonly used Fourier’s law isn’t capable of describing hydrodynamic transport.

In this talk, we will first introduce a first-principles formalism to compute the thermal viscosity, the transport coefficient determining the diffusion of momentum (as opposed to thermal conductivity, which describes energy diffusion). Using an exact solution of the phonon Boltzmann transport equation (BTE) based on relaxons, the eigenvectors of the scattering matrix, we show how the thermal viscosity is fully determined by the even part of the relaxon spectrum, whereas the odd part describes thermal conductivity.

Next, we show that thermal conductivity and viscosity parametrize a set of viscous heat equations, the thermal counterpart of the Navier-Stokes equations in the linear and laminar regime, with heat transport being described in terms of temperature and drift-velocity fields. These equations reduce to Fourier’s law in the limit of strong momentum dissipation, yet, if momentum dissipation is weak, can also describe second sound. These equations can be parametrized with first-principles calculations, and then solved at a similar complexity of Fourier’s law. We test the formalism on silicon, diamond and graphite, replicating for graphite the experimental observations of a hydrodynamic window and suggesting the existence of hydrodynamic transport in diamond. These equations pave the way to the description of heat transport in devices at the mesoscale.

8:36AM L44.00002: Quantum thermal transport in glasses: the role of anharmonicity
MICHELE SIMONCELLI (Presenter), Ecole Polytechnique Federale de Lausanne, FRANCESCO MAURI, Physics, Sapienza University of Rome, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne — Thermal transport in glasses is often described by the harmonic theory introduced by Allen and Feldman [Phys. Rev. Lett., 62(6) (1989)], where heat is carried by couplings between vibrational modes and disorder limits the thermal conductivity. Hitherto, the effects of anharmonicity on heat conduction in glasses have been investigated using molecular simulations, combined with empirical quantum corrections to address discrepancies with experiments at low temperature. Recently, a unified theory of thermal transport in crystals and glasses has been formulated [Simoncelli, Marzari, and Mauri, Nat. Phys., 15 (2019)], allowing to account rigorously for quantum and anharmonic effects also in glassy or disordered systems. Here, we show that quantum effects and anharmonicity are crucial to explain the increasing non-saturating trend of the thermal conductivity with temperature observed in silica glass --- and not explained by the saturating Allen-Feldman harmonic theory. We analyze amorphous silica as a prototypical glass and provide recipes to perform first-principles quantum thermal conductivity calculations in glasses, which are accurate over a wide temperature range.

8:48AM L44.00003: Thermal transport modeling of nanoscale graphene devices using a Peierls-Boltzmann treatment  ALI KEFAYATI (Presenter), State Univ of NY - Buffalo, PHILIP ALLEN, Department of Physics and Astronomy, Stony Brook University, VASILI PEREBEINOS, State Univ of NY - Buffalo — In nonmagnetic insulators, phonons are the carriers of heat. If heat enters in a region and temperature is measured at a point within a phonon mean free paths of the heated region, ballistic propagation causes a nonlocal relation between local temperature and heat insertion. Our work focuses on the solution of the Peierls-Boltzmann equation (PBE) for nanoscale graphene devices. We use a realistic anharmonic scattering potential and examine different approximations such as the relaxation time approximation and the definition of local temperature. The results illustrate the expected local (diffusive) response for minimum phonon mean free path \(\lambda_{\text{min}} \ll L\), and a diffusive to ballistic crossover as \(\lambda_{\text{min}}\) increases toward the scale of the device size \(L\).

9:00AM L44.00004: Heat transport in resonant condensed systems: Thermal conductivity reduction by coherent mechanisms* [Invited]  MAHMOUD I. HUSSEIN (Presenter), CHIA-NIEN TSAI, HOSSEIN HONARVAR, University of Colorado, Boulder — The notion of a locally resonant metamaterial—widely applied to light and sound—has recently been introduced to heat, whereby the thermal conductivity is reduced primarily by intrinsic localized atomic vibrations (vibrons) rather than scattering mechanisms. The localized vibration modes manifest by the introduction of intrinsic nanoresonators within, or attached to, a host crystalline material, ideally a semiconductor. The phonon band structure under such conditions exhibit a myriad of horizontal bands representing each resonant degree of freedom. These bands hybridize with the underlying phonon modes carrying the heat in the host medium, which leads to significant reductions in the phonon group velocities and to mode localizations within the nanoresonators. Moderate reductions in the phonon lifetimes also occur. The nature of nanoscale thermal conduction under such conditions is fundamentally transformed due to these effects. A key requirement for the realization of phonon-vibron couplings and the subsequent effects mentioned above is the presence of a sufficient level of coherent wave behavior, which is only possible when there is a relatively wide distribution of the phonon mean free path. An example of a “nanophononic metamaterial” is a silicon membrane with nanopillars distributed on the surface. In this work, we provide predictions—by theory and simulations—of the thermal transport properties of this system.

Minimizing Heat Transport by Ballistic Confinement in Phononic Metalattices

WEINAN CHEN (Presenter), DISHA TALREJA, DEVIN GOODLING, PRATIBHA MAHALE, NABILA NOVA, HIU CHENG, JENNIFER RUSSELL, SHIHYING YU, NICOLAS POILVERT, GERALD D MAHAN, SUZANNE MOHNEY, VINCENT CREPSI, THOMAS MALLOUK, JOHN BADDING, BRIAN FOLEY, VENKATRAMAN GOPALAN, ISMAILA DABO, Pennsylvania State University — We study the thermal conductivity of phononic metalattices, a class of newly synthesized nanostructures exhibiting long-range periodicity commensurate with the mean free paths of the phonons. In this work, we present a computational approach that is capable of computing the ballistic phonon mean free paths in periodic metamaterials by embedding an explicit model of phonon radiation into a continuum density of scatters, closing the gap between existing analytical models and numerical simulations. Our computational predictions supported by sensitive measurements indicate that the thermal conductivity minimum of metalattices can be as low as 0.15 W/m/K, which is among the smallest lattice conductivities reported for two- and three-dimensional silicon-based materials. This exceptional reduction in the heat conductivity establishes metalattices as a useful platform to achieve order-of-magnitude tunability in the thermal response of crystalline semiconductors.

Thermal boundary conductance of beyond graphene two-dimensional materials

CAMERON FOSS (Presenter), ZLATAN AKSAMIJA, Univ of Mass - Amherst — An ongoing concern for 2D materials is their ability to thermally couple with an underlying substrate which acts as the primary pathway for heat removal in 2D devices. The thermal pathway from the 2D layer to substrate has been studied rigorously in graphene and various transition metal dichalcogenides. However, the literature still lacks a comprehensive analysis of thermal boundary conductance (TBC) for beyond-graphene materials. Previously [2D Mater. 6 (2019) 025019] we have shown that the TBC depends strongly on the overlap of available phonon modes in the long-wavelength regime and found selection criteria for choosing the best substrate for TBC. Here we use first-principles calculations and phonon interface transport modeling to calculate the TBC of beyond-graphene 2D materials, such as; silicene, germanene, BAs, InAs, and blue and black phosphorene, on amorphous and crystalline substrates. Our results show the TBC for these 2D materials on amorphous SiO$_2$ (a-SiO$_2$) falls between 20-50 MW.m$^{-2}$K$^{-1}$. A trend emerges that 2D materials with lower ZA branch frequencies have higher TBCs when placed on a-SiO$_2$. Our results provide selection criteria for 2D materials that improve interfacial heat transport in 2D devices with amorphous and crystalline substrates.
Spatially-Resolved Phonon Hydrodynamic Flow from First Principles

GEORGIOS VARNAVIDES (Presenter), Massachusetts Institute of Technology MIT, ADAM JERMYN, Center for Computational Astrophysics, Simons Foundation, Flatiron Institute, POLINA ANIKEEVA, Massachusetts Institute of Technology MIT, PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Material hydrodynamic regimes are characterized by numerous scattering events, each of which conserves quasi-momentum and thus doesn't oppose the flow of carriers. Recent observations of non-resistive carrier transport in two-dimensional materials suggest that hydrodynamic flow can occur over a wide range of temperatures. In thermal transport, hydrodynamic flow manifests itself in two separate phenomena: the wavelike propagation of heat, termed second sound, and parabolic heat profiles, reminiscent of classical incompressible fluid pipe flow. Theoretical efforts to characterize and predict such phenomena are often restricted to momentum-space, effectively assuming spatial homogeneity. However, hydrodynamic flow exhibits strong real-space signatures. In this talk, we extend previous work and solve the phonon Boltzmann Transport Equation using both spatial and momentum resolution. We present ab initio calculations of hydrodynamic phenomena in real-space in experimentally-realizable geometries.

Microscopic thermal transport mechanisms in Tl$_3$VSe$_4$: lattice phonons or localized oscillators?

YI XIA (Presenter), KOUSHIK PAL, JIANGANG HE, Northwestern University, VIDVUDS OZOLINS, Applied Physics, Yale University, CHRISTOPHER MARK WOLVERTON, Northwestern University — Recently, crystalline Tl$_3$VSe$_4$ was experimentally reported to exhibit an ultralow lattice thermal conductivity ($\kappa_l$) of 0.3±0.05 W/mK at 300 K [Science 360, 1455 (2018)]. Understanding of the underlying thermal transport mechanism has been deemed nontrivial, which requires a complex scenario that involves two channels: lattice phonons and localized oscillators. However, the observed Raman spectra, specific heat, and temperature dependence of $\kappa_l$ only reveal features characteristic of phonons in an ordered crystalline compound. To resolve this conundrum, we investigate the heat transfer in Tl$_3$VSe$_4$ by combining a first-principles density-functional theory based framework of anharmonic lattice dynamics with the Peierls-Boltzmann transport equation for phonons. Specifically, we include contributions of the three- and four-phonon scattering processes to the phonon lifetimes as well as the temperature-dependent anharmonic renormalization of phonon energies. We reveal the dominant thermal transport mechanism by explicitly evaluating both diagonal (particle-like propagation) and off-diagonal (wave-like tunneling) terms of the heat current operator.

10:24AM L44.00009: Violation of the Wiedemann-Franz law in graphene: plasmon contribution to the heat conductivity  LARS FRITZ (Presenter), Physics, Utrecht University — It is well established that close to the Dirac point in graphene the Wiedemann-Franz law is violated. Using a microscopic Boltzmann approach we first show that a theory of electrons and holes cannot quantitatively account for the heat conductivity observed in experiment. We argue that the missing heat conductivity is due to plasmons which make a sizeable contribution in the vicinity of the Dirac point.

10:36AM L44.00010: Influence of Adsorbed Liquid Monolayer Ordering on the Kapitza Resistance at Solid/Liquid Interfaces*  HIROKI KAIFU (Presenter), SANDRA TROIAN, Applied Physics, Caltech — Applications ranging from small scale avionics control to AI computing platforms are ever more reliant on high density integrated chips prone to thermal runaway. Thermal extraction is now the limiting factor in information processing and so conventional air cooling is being displaced by microscale liquid cooling systems, which are more efficient due to the higher heat capacity of liquids. In this work, we use non-equilibrium MD simulations to examine thermal transport across solid/liquid (S/L) interfaces in quiescent fluids, as quantified by the Kapitza resistance. While previous studies have focused on interfacial behavior mediated by liquid density stratification, wettability and solid crystalline symmetry, we instead examine the influence of in-plane ordering within the first few liquid monolayers adsorbed at the solid surface. The characteristics of these proximal layers are tuned by varying the depth and repulsive distance characterizing the intermolecular potential. Our results, some intuitive and some not, yield general correlations between the Kapitza jump and measures of interfacial commensurability influenced by the structure and collective response of such monolayers.

Session L45 DCOMP GDS DSOFT DPOLY: Emerging Trends in Molecular Dynamics Simulations and Machine Learning II  706 - Ken-ichi Nomura, University of Southern California - Tag(s): Focus

8:00AM L45.00001: Deep Learning for molecular simulation and spectra calculation* [Invited] LINFENG ZHANG (Presenter), Princeton University — I will discuss some mathematical perspectives of model representation and exploration of \textit{ab initio} data for generating reliable deep learning-based models that represent the interatomic potential energy surface and electronic information of complex systems. This gives us an unprecedented opportunity to perform large-scale molecular simulation and extract direct experimental observables, such as the infrared and Raman spectra. I will show how these methodologies help us understand the complex nature of water in a large region of its thermodynamic phase diagram.

*This work is partially supported by the Center Chemistry in Solution and at Interfaces (CSI) funded by the DOE Award DE-SC001934.
Molecular dynamics (MD) simulations rely on accurate numerical integrators such as Verlet method to model the equations of motion to generate a set of trajectories for a finite ensemble of particles. The design of MD simulations are constrained by the available computation power and must use small enough timestep to avoid discretization errors. Multiple timestep methods have been developed to mitigate this situation but are generally constrained by specific applications.

We introduce and develop recurrent neural networks (RNN) based Integrators (“surrogate”) for learning MD dynamics of physical systems generally simulated with Verlet solvers. The RNN surrogate, trained on trajectories generated using Verlet integrator, learns to propagate the dynamics of few-particle systems with multiple timestep values that are orders of magnitude higher compared to the typical Verlet timestep. Different pair interaction potentials including spring potential and Lennard-Jones potential are investigated. Prospects for extending the approach to simulate a large number of particles are outlined.

*This work is supported by the National Science Foundation through award 1720625.

Correlated quantum-chemical methods for condensed matter systems, such as the random phase approximation (RPA), hold the promise of reaching a level of accuracy much higher than that of conventional density functional theory approaches. However, the high computational cost of such methods hinders their broad applicability, in particular for finite-temperature molecular dynamics simulations. We propose a method that couples machine learning techniques with thermodynamic perturbation theory to estimate finite-temperature properties using correlated approximations [1]. We apply this approach to compute the enthalpies of adsorption in zeolites and show that reliable estimates can be obtained by training a machine learning model with as few as 10 RPA energies. This approach paves the way to the broader use of computationally expensive quantum-chemical methods to predict the finite-temperature properties of condensed matter systems.

9:00AM L45.00004: Neural Network Potentials for Twisted Few-Layer Materials*  EMINE KUCUKBENLI (Presenter), EFTHIMIOS KAXIRAS, Harvard University — Few-layer materials twisted at small angles are experimentally shown to host non-trivial electronic structure such as superconductivity or strongly-correlated insulating state. It is also theoretically demonstrated that in twisted bilayer graphene, the prototypical system for this class of materials, characteristics of the band structure is significantly affected by the atomic relaxation that occurs due to the twist. Since small twist angles result in large Moiré patterns, atomistic simulation of these systems from first principles is computationally costly, and empirical potentials are needed. However, the development of such interatomic potentials is also challenging due to the very different energy and length scales of inter- and intralayer interactions. Furthermore, the changes in atomic positions and energy due to the twist is only a small fraction of the typical length and energy scales, imposing a tight accuracy requirement on the potential design. In this talk we present our attempt at developing such a potential via neural networks, and how the challenges highlighted above translate into practical steps during training and testing. Finally we examine the performance of the neural network potential and its transferability.

*This work is supported by DoE Award DE-SC0019300.

9:12AM L45.00005: Development of reliable neural network potential for metal–semiconductor interface reaction: case study for Ni silicidation  WONSEOK JEONG (Presenter), DONGSUN YOO, KYUHYUN LEE, SEUNGWU HAN, Seoul National University — Molecular dynamics using classical interatomic potentials can provide valuable information at the atomistic scale. However, when the simulation involves chemical reactions of bond breaking and forming along with mixed bonding characters, it is challenging to develop an accurate force field for the system and sometimes practically impossible. In this respect, the machine-learning potentials are highly anticipated since they are based on flexible mathematical structures with no pre-fixed form. In this presentation, we discuss the process of constructing a reliable neural network potential (NNP) for a challenging metal–semiconductor interface reaction, with example of thermally activated Ni silicidation. We present a systematic way to build up the training set that can describe the interface reaction. We also introduce some of the techniques we utilized for higher reliability and efficiency, including Gaussian density function weighting, principle component analysis training etc. In order to obtain the prediction uncertainty for certain local configurations, we adopt replica NNPs that are trained directly on the atomic energy of the reference NNP. Finally, we suggest the underlying mechanism of abnormal crystal phase growth from ultra-thin Ni film silicidation.
9:24AM L45.00006: Linearized machine learning potential with high-order rotational polynomial invariants for multi-component systems  ATSUTO SEKO (Presenter), ISAO TANAKA, Kyoto Univ — Machine-learning potential (MLP) providing an accurate description of the structure-energy relationship and its potential applications are of growing interest. Such an approach is based on a linearized MLP framework, which was successful in constructing accurate MLPs in a variety of elemental metals [1]. Also, the introduction of group-theoretical high-order rotational polynomial invariants can contribute to systematically derive MLPs with high predictive power for a wide range of structures, including extreme structures [2]. The present study proposes a formulation of linearized MLP extended to multi-component systems involving high-order rotational invariants. We also show its applications to several binary alloy and ionic systems such as Ti-Al system. For each system, we obtain MLPs with high predictive power and Pareto frontier MLPs for the computational cost versus the accuracy.

9:36AM L45.00007: Transfer learning of neural network potentials for reactive chemistry* JASON GOODPASTER (Presenter), University of Minnesota — Large, condensed phase, and extended systems impose a challenge for theoretical studies due to the compromise between accuracy and computational cost in their calculations. Machine learning methods are an approach to solve this trade-off by leveraging large data sets to train on highly accurate calculations using small molecules and then apply them to larger systems. In this study, we are developing a method to train a neural network potential with high-level wavefunction theory on targeted system of interest that are able to describe bond breaking. We combine density functional theory calculations and higher level ab initio wavefunction calculations, such as CASPT2, to train our neural network potentials. We first train our neural network at the DFT level of theory. Using an adaptive active learning training scheme, we retrained the neural network potential to a CASPT2 level of accuracy. We demonstrate the process as well as report current progress and performance of this neural network potential for molecular dynamic simulations.

9:48AM L45.00008: Insights about accelerated dynamics calculations of the acid $pK_a$ beyond biasing the coordination number collective variable  CARLOS WEXLER (Presenter), JIASEN GUO, Univ of Missouri - Columbia, ALBERTO ALBESA, Univ Nacional de La Plata — Knowing the dissociation constant $K_a$ of a weak acid is fundamental to understand many chemical and physical processes. Theoretical calculation of the $K_a$ remains a challenge. The use of accelerated methods such as metadynamics has shown promise for numerical computation of $K_a$ with explicit solvent molecules. In the most common approach, a single collective variable (CV) representing the coordination number of the proton donor group yields results that are in reasonable agreement with experiments, however there remains questions as to whether the configuration space of the deprotonated state was sufficiently sampled given the small typical simulation box. We studied the deprotonation of acetic acid using the ReaxFF in simulation boxes of varying sizes and observed significant size dependence of $\Delta G$ when biasing with a single CV representing the coordination number of the acetate oxygen atoms. However, biasing with an additional CV describing the $H_3O^+$ and acetate anion distance results in a virtual elimination of the size dependence. The improvement is due to accelerated sampling of the deprotonated configuration state.

10:00AM L45.00009: Multitask machine learning of collective variables for enhanced sampling of reactive molecular dynamics*  LIXIN SUN (Presenter), SIMON BATZNER, JONATHAN VANDERMAUSE, YU XIE, BORIS KOZINSKY, School of Engineering and Applied Science, Harvard University — Ability to discover reactions and predict their rates is key to understanding many computational physics, biology and chemistry problems. Enhanced sampling techniques, such as metadynamics and umbrella sampling, use a low-dimensional reaction coordinate / collective variable (CV) space to accelerate sampling for slow reactions. However, their efficiency relies on the choice of CVs, which requires intuition and many trial-and-error tests.

In this work, we propose a multi-task machine learning algorithm to learn collective variables (CVs) from short MD trajectories and transition path sampling, which preserves the information on state labels and potential energies. We show that the algorithm can accurately measure reaction progress and identify the slow motion of the system. It offers a unified dimensionality reduction framework that integrates different learning objectives and can be applied to a wide variety of reactive systems, including Muller-Brown potential model and alanine dipeptide.

10:12AM L45.00010: Exploring Cucurbituril-Fentanyl Binding (and Beyond) with Parallel Biasing Methods*  
ANNE LEONHARD (Presenter), JONATHAN K. WHITMER, University of Notre Dame — The physics underlying drug delivery, molecular separation, and detection of harmful agents relies in many cases on microscopic binding events. There is a critical need for information about these processes, in particular from molecular simulations which can be used to pre-screen molecules and materials. Binding events can be simple, such as gas molecules adsorbing onto surfaces, or complex, such as protein-ligand interactions. Here, we discuss new techniques for computing the binding free energy of small organic molecules to cucurbituril (CB) macrocycles (specifically, cucurbit[7]uril with fentanyl) as both a test case of intermediate complexity, and one of great potential application in sensing and remediation platforms. The system exhibits multiple potential binding conformations, rendering computational study of CB–fentanyl binding difficult with standard methods. Parallel biasing metadynamics is used to enhance sampling in this system along multiple important structural and dynamic degrees of freedom, without restricting the movement between bound states. We compare our results to experiment and discuss the general applicability of the parallel biasing scheme to alternate systems.

*ACL would like to acknowledge funding from a NSF-GRFP fellowship.

10:24AM L45.00011: Neural Network Interatomic Potentials for Water*  
ALBERTO TORRES (Presenter), Instituto de Física Teórica, Universidade Estadual Paulista (UNESP), LUANA PEDROZA, Centro de Ciências Naturais e Humanas, Universidade Federal do ABC, ALEXANDRE R ROCHA, Instituto de Física Teórica, Universidade Estadual Paulista (UNESP) — Water is the most important liquid on Earth. And difficult to describe theoretically, due to a delicate balance of weak and strong interactions tuned by entropic effects. High level ab initio calculations, such as Coupled Cluster (CC), can do the job, but albeit highly accurate their application is limited to systems with a few molecules due to their computational cost, not being amenable to simulate liquid water. Recent developments in density functional theory (DFT), i.e. new functionals and better description of van der Waals interactions, have made it possible to describe water with reasonable accuracy, and a good cost/accuracy compromise. Yet, even with DFT it is difficult to perform simulations on large systems at long time scales. Artificial Neural Networks (ANN) force fields have been shown to be able to yield accurate (on par with the method they were fitted to) results with low cost. In this work we employ ANNs to represent the water potential surface with DFT- and CC-quality, and compare ANNs trained at different levels of theory to discuss the accuracy of different methods in describing macroscopic properties of water under different conditions including nuclear quantum effects.

10:36AM L45.00012: Anharmonicity in a linear chain of Lennard-Jones atoms  ADRIAN DE LA ROCHA (Presenter), JORGE MUNOZ, University of Texas, El Paso — Atoms in solids move in the force fields of their vibrating neighbors and these vibrations give rise to thermodynamics. In many systems it is enough to use the Taylor expansion of the potential energy up to second order to derive most of their thermodynamic properties, but higher order (anharmonic) terms are necessary to predict quantities that depend on scattering rates, such as thermal conductivity. Here we present a study of the anharmonicity that arises from atoms in a linear chain interacting via the Lennard-Jones potential and a test run of a dynamic mean field theory in which the atoms only see a harmonic potential but the stiffness of the potentials depends on the configuration of the system which is determined using a machine learning classifier.

10:48AM L45.00013: Hunting FOX: Using Fragments to Sniff Out Drug Leads for Antibiotic Discovery*  RACHAEL MANSBACH (Presenter), Los Alamos National Laboratory, INGA V LEUS, JITENDER MEHLA, University of Oklahoma, CESAR A LOPEZ, Los Alamos National Laboratory, JOHN K WALKER, Saint Louis University, VALENTIN V RYBENKOV, University of Oklahoma, NICOLAS W HENGARTNER, Los Alamos National Laboratory, HELEN I ZGURSKAYA, University of Oklahoma, S GNANAKARAN, Los Alamos National Laboratory — Drug discovery faces a potential crisis. Due a dwindling "obvious" search space, productivity is declining. This has led to the idea of "drug repurposing," in which data on drugs that have failed clinical trials are reused. We approach drug repurposing by introducing an algorithm—which we term "Hunting FOX" for "Hunting Fragments Of X"—that combines a fragment-based representation with traditional machine learning to identify the most important submolecules correlating with an activity of interest. We validate our approach on the problem of drug permeation through the highly-impermeable outer membrane of P. aeruginosa. We show that Hunting FOX is able to recapitulate a set of relevant fragments with understandable physicochemical properties. By using coarse-grained molecular dynamics, we show a possible mechanism behind fragment-based permeation enhancement. We also fit a predictive classifier using the identified fragments and verify its predictions experimentally. Overall, we have developed a novel algorithm of great use in improving outcomes for drug discovery and validated it as applied to the design of antibiotics that can permeate Gram-negative bacteria.

Session L46 GMAG DCOMP DCMP: Magnetism and Magnetoelectrics: Molecule-Based and 2D Materials  708 - Vivien Zapf, Los Alamos Natl Lab - Tag(s): Focus
8:00AM L46.00001: σ-Dimerization of organic radicals as mechanism for strongly hysteretic magneto-structural phase transitions* [Invited] MICHAEL SHATRUK (Presenter), Florida State Univ — In this contribution, we present a few systems of σ-dimerizing organic radicals, which provide examples of magneto-structural phase transitions that occur with a large thermal or photochemical hysteresis window. In each case, the dimerization causes drastic structural changes that underlie a substantial energy barrier for the conversion between the diamagnetic σ-dimer phase and the paramagnetic π-radical phase. We demonstrate that in the case of dithiazolyl radicals the existence of such energy barrier allows photo-generation of paramagnetic state with remarkable thermal stability. In the case of N-oxyl radicals that exist as a rotationally disordered plastic crystalline phase at room temperature and dimerize into a long-range ordered crystalline phase upon cooling, the barrier to the intra-dimer bond breaking causes a large thermal hysteresis, which exhibits high sensitivity to applied pressure. We will also discuss general requirements for observing such transitions for other organic radicals.

8:36AM L46.00002: Controlling the Kinetics of Spin Transitions through Heterostructure Elasticity* JOHN CAIN (Presenter), WANHONG HE, Chemistry, University of Florida, JERRY L. ZHANG, Physics, University of Florida, DANIEL R. TALHAM, Chemistry, University of Florida, MARK W MEISEL, Physics and NHMFL, University of Florida — An often overlooked feature of spin transitions is the significant volume change associated with altered metal-ligand bonding between the two spin states. Recent examples of exploiting the strain developed during a spin transition include integration into hybrid materials to influence electrical, optical, or magnetic properties. These applications all require the spin transition material to physically couple to other components; however, an interface with another material can strongly influence the behavior of the spin transition material, especially as sizes approach the nanoscale. Our lab has shown these interfaces can dramatically influence the kinetics of solid-state spin transitions. For example, the rate of the light-induced spin transition in Rb$_x$Co[Fe(CN)$_6$]$_y$ (RbCoFe-PBA) increases by several orders of magnitude when RbCoFe-PBA is used as the core of a core-shell particle, relative to uncoated RbCoFe-PBA. A theoretical electroelastic model was used to guide chemical alterations, allowing the mechanism to be probed experimentally with nuclear inelastic scattering.

*Supported by the NSF via DMR-1904596 (DRT) and DMR-1708410 (MWM). A portion of this work was performed at the MagLab, which is supported by NSF DMR-1644779 and the State of Florida.
8:48AM L46.00003: Microscopic theory of spin-crossover phase transition and magnetolectric coupling* JIE-XIANG YU (Presenter), DIAN-TENG CHEN, JIE GU, JIA CHEN, JUN JIANG, LONG ZHANG, XIAOGUANG ZHANG, Department of Physics, Center for Molecular Magnetic Quantum Materials and Quantum Theory Project, University of Florida, VIVIEN ZAPF, National High Magnetic Field Lab, Los Alamos National Lab, HAI-PING CHENG, Department of Physics, Center for Molecular Magnetic Quantum Materials and Quantum Theory Project, University of Florida — The molecular magnet Mn(taa) is one of the earliest studied spin-crossover system where the spin can transit from a low-spin state to a high-spin state around 45 K. Very recently, the magnetolectric coupling was observed in Mn(taa) and a microscopic theory is needed. Here, we investigated the atomistic origin of the phase transition and magnetolectric coupling in spin-crossover system Mn(taa) via first-principles calculations and Monte Carlo simulations. By constructing a molecular-scale Hamiltonian, we discovered that the Jahn-Teller-induced intermolecular strain interaction is the key factor in both the spin-crossover phase transition and magnetolectric behaviors. Our work leads to a first theory that goes beyond the mean field approximation.

*This work was supported as part of M2QM, an EFRC funded by the U.S. DOE, BES under Award No. DE-SC0019330. Computations were done using the utilities of NERSC, XSEDE under Grant No. TG-PHY170023, and UFRC.

9:00AM L46.00004: Observation of magnetolectric, spin-lattice, and electron-phonon coupling in multiferroic (NH$_4$)$_2$[FeCl$_5$(H$_2$O)] KENDALL HUGHEY, University of Tennessee, Knoxville, JISOO NAM, MINSEONG LEE, Ulsan National Institute of Science and Technology, AMANDA CLUNE, KENNETH R O’NEAL, AVERY BLOCKMON, University of Tennessee, Knoxville, WEI TIAN, Oak Ridge National Laboratory, MYKHAYLO OZEROV, National High Magnetic Field Laboratory, VIVIEN ZAPF, Los Alamos National Laboratory, JUN HEE LEE, Ulsan National Institute of Science and Technology, JANICE LYNN MUSFELDT (Presenter), University of Tennessee, Knoxville — We bring together pulsed-field polarization techniques, magnetoinfrared spectroscopy, and lattice dynamics calculations to uncover the high magnetic field coupling mechanism of polarization and magnetic field in (NH$_4$)$_2$[FeCl$_5$(H$_2$O)] and to explore the structural distortions that this system undergoes through various magnetic phases and across the magnetic quantum phase transition. High-field polarization is quenched by the quasicollinear to collinear sinusoidal magnetic transition. Strikingly, spin-lattice coupling across the magnetic quantum phase transition reveals that nearly all low-frequency vibrations modulate magnetic exchange via hydrogen- and halogen-bonding interactions. An analysis of combined techniques demonstrates that magneto-infrared is sensitive to both spin-phonon and electron-phonon coupling.
Magneto-optical Detection of Chirality Induced Spin Selectivity in 2D Chiral Hybrid Organic-Inorganic Perovskites*  
ZHENGJIE HUANG (Presenter), Physics, North Carolina State University, BRIAN BLOOM, ZHENI NIKOLAEVA GEORGIEVA, Chemistry, University of Pittsburgh, ERIC VETTER, Physics, North Carolina State University, DAVID WALDECK, Chemistry, University of Pittsburgh, DALI SUN, Physics, North Carolina State University — The Chirality-Induced Spin Selectivity (CISS) effect, an appealing 'spin filtering' effect arising from the chirality of materials has been demonstrated in various organic systems. The recent convergence of chiral molecules with metal halide frameworks gives rise to a new family of chiral systems: 2D chiral hybrid organic-inorganic perovskites (2D-chiral-HOIPs). This class of materials possesses both the implanted chirality and the excellent photovoltaic properties, making it a promising platform that bridges opto-spintronic studies and the CISS effect. Here we show the observation of light-induced CISS effect in the 2D-chiral-HOIPs detected by a magneto-optical measurement. It shows that the incident light changes the Kerr response of the ferromagnetic layer attached to the chiral-HOIP layer. The change of Kerr signal follows a linear relation with respect to the applied magnetic field, of which the sign of the slope depends on the chirality of the HOIPs. Our results pave a new route for employing 2D-chiral-HOIPs for future opto-spintronic applications.

Theoretical design of two dimensional magnetoelectrics*  
SHUAI DONG, LING-FANG LIN (Presenter), Southeast University — Achieving magnetoelectric two-dimensional (2D) materials should enable numerous functionalities in nanoscale devices. Until now, however, predicted 2D magnetoelectric materials are very few and with coexisting yet only loosely coupled (type-I) ferroelectricity and magnetism [1]. Based on physical analysis and by using density functional theory calculations, a type-II multiferroic MXene Hf$_2$VC$_2$F$_2$ monolayer is predicted. For multiferroic MXene Hf$_2$VC$_2$F$_2$ monolayer, its ferroelectricity originates directly from its magnetism [2]. The noncollinear 120° Y-type spin order generates a polarization perpendicular to the spin helical plane. Remarkably, the multiferroic transition is estimated to occur above room temperature. Our investigation should open the door to a new branch of 2D materials in the pursuit of intrinsically strong magnetoelectricity.

Gate tunability of 2D antiferromagnet magnon modes

XIAO-XIAO ZHANG (Presenter), University of Florida, LIZHONG LI, KIN FAI MAK, JIE SHAN, Cornell University — The recently discovered atomically-thin magnetic crystals provide a unique playground to develop new approaches to manipulate magnetism. Rapid progresses have been made that demonstrate the potentials of utilizing 2D magnets to construct novel spintronics devices. However, their spin dynamics, which are crucial for microscopic understanding and determine the fundamental limit of spin manipulation, still remain elusive due to the difficulty to characterize these micron-sized samples with conventional microwave techniques. In this talk, we will show how we can access and probe the collective spin-wave excitations in an antiferromagnetic bilayer CrI3, which allows us to extract magnetic anisotropy and exchange energy. In particular, we will demonstrate the gate tunability of magnon frequencies, which is unique for the 2D magnet system.

2D ferromagnetism in porphyrin-based semiconductors

*ARTEM PIMACHEV, ROBERT D NIELSEN, Univ of Wyoming, ANRI KARANOVICE, Virginia Tech, YURI DAHNOVSKY (Presenter), Univ of Wyoming — We study an environmentally stable 2D ferromagnetic semiconductor with applications in biomedicine, solar cells, spintronics, and energy and hydrogen storage. We describe the electronic, transport, optical, and magnetic properties of a π-conjugated micropore polymer with three iron atoms placed in the middle of an isolated pore. We study how these properties change when bonded with CO, CO$_2$, and O$_2$. This material exhibits strong Fe-localized d$_{z^2}$ bands with a direct bandgap of 0.28 eV. The material is a ferromagnet of an Ising type with long-range exchange interactions with a very high magnetic moment per unit cell, m = 6 μB. The estimated exchange integral is calculated to be about J$_{nn}$ = 25 meV. The binding of CO, CO$_2$, and O$_2$ modifies the d$_{z^2}$ bands of the Fe ions with varying indirect bandgaps with values between 0.269 - 0.626 eV, 0.039 - 0.434 eV, and 0.291 - 0.347 eV for CO, CO$_2$, and O$_2$, respectively. Both the absorption coefficient and conductivity have large modifications to the xy-components. The material remains ferromagnetic with the magnetic moment per unit cell decreasing to 4, 2, and 0 μB for gases attached to one, two, and three Fe ions per unit cell, respectively.

*This acknowledge a grant (No. DMR-1710512) from the US National Science Foundation
10:00AM L46.00009: Low-Damping Ferromagnetic Resonance in Electron-Beam Patterned, High-Q Vanadium Tetracyanoethylene Magnon Cavities* ANDREW FRANSON (Presenter), Physics, The Ohio State University, NA ZHU, Electrical Engineering, Yale University, SETH KURFMAN, MICHAEL CHILCOTE, Physics, The Ohio State University, DENIS CANDIDO, Physics and Astronomy, University of Iowa, KRISTEN S. BUCHANAN, Physics, Colorado State University, MICHAEL FLATTÉ, Physics and Astronomy, Yale University, HONG X TANG, Electrical Engineering, Yale University, EZEKIEL JOHNSTON-HALPERIN, Physics, The Ohio State University — Integrating patterned, low-loss magnetic materials into microwave devices and circuits presents many challenges due to the specific conditions that are required to grow ferrite materials, driving the need for flip-chip and other indirect fabrication techniques. The low-loss ($\alpha=3.98 \times 10^{-5}$), room-temperature ferrimagnetic coordination compound vanadium tetracyanoethylene ($V[\text{TCNE}]_x$) is a promising new material for these applications that is potentially compatible with semiconductor processing. Here we present the deposition, patterning, and characterization of $V[\text{TCNE}]_x$ thin films with lateral dimensions ranging from 1 micron to several millimeters. We employ electron-beam lithography and liftoff using an aluminum encapsulated PMMA/P(MMA-MAA) copolymer bilayer on sapphire. Growth occurs in an argon atmosphere at 30 mTorr and 50 °C. Films patterned via this method maintain low-loss characteristics down to 25 microns with only a factor of 2 increase down to 5 microns. A manifold of thickness and radial confined spin wave modes reveals the quality of the patterned films. This work establishes the versatility of $V[\text{TCNE}]_x$ for applications requiring highly coherent magnetic excitations ranging from microwave communication to quantum information.

10:12AM L46.00010: Two-dimensional magnetic coordination polymers: tuning the surface and the magnetic properties. SAMUEL MAÑAS-VALERO (Presenter), EUGENIO CORONADO, Univ de Valencia — Magnetic two-dimensional (2D) materials have emerged recently with examples of inorganic monolayers like antiferromagnets (FePS$_3$) [Nano Letters 16, 7433, 2016; 2D Materials 3, 031009, 2016] and highly unstable ferromagnets such as CrI$_3$ [Nature 546, 270, 2017] or Fe$_3$GeTe$_2$ [Nature Materials 17, 778. 2018].

To overcome the present unstabilities of 2D magnetic materials, we take advantage of layered molecular magnets since, thanks to the chemical design, it is feasible to bring new magnetic scenarios as well as to overcome the present unstabilities of 2D magnetic materials. Here [Nature Chemistry 10, 1001, 2018 and unpublished data] we present a pre-synthetic method based on coordination chemistry that affords the isolation of crystalline molecular monolayers. The concept is illustrated using layered coordination polymers formed by reacting various benzimidazole derivatives with ferrocene. By the election of the proper ligand and the metal source, it is possible to tune the surface properties as well as the magnetism. Moreover, the magnetic order of the flakes is probed by its integration into membranes. Therefore, these new 2D molecular materials are exceptional candidates for studying the magnetism in the 2D limit, as well as for developing membranes for selective molecular sensing.
A New Mercury-based Cation Radical Salt: α-(BEDT-TTF)$_2$Hg(SeCN)$_2$Cl$^*$

ALYSSA HENDERSON (Presenter), KAYA WEI, JOHAN VAN TOL, RACHAEL RICHARDSON, KOMALAVALLI THIRUNAVUKKUARASU, THEO SIEGRIST, Natl High Magnetic Field Lab, JOHN A SCHLUETER, National Science Foundation — BEDT-TTF [BEDT-TTF = bis(ethylenedithio)tetrathiafulvalene, henceforth referred to as ET] cation radical salts continue to serve as important physical representations of various theoretical quantum systems. The arrangement of ET radical cations in these materials have dramatic effects on their physical properties. Here we report the synthesis of the new α-(ET)$_2$Hg(SeCN)$_2$Cl salt. Single crystals, crystallizing in the monoclinic space group $P2_1/n$, were prepared through the use of electocrystallization.\(^1\) The two dimensional crystal structure is characterized by layers of ET radical cations separated by dimerized Hg(SeCN)$_2$Cl$^-$ anions. The synthesis, structure, and magnetization, heat capacity, electron-spin-resonance, and Raman measurements are reported.

10:36AM L46.00012: Magneto-elastic coupling in multiferroic metal-organic framework [(CH$_3$)$_2$NH$_2$]Co(HCOO)$_3$  KOMALAVALLI THIRUNAVUKKURASU (Presenter), RACHAEL RICHARDSON, Florida A&M University, ZHENGGUANG LU, National High Magnetic Field Laboratory, NAN HUANG, Department of Materials Science and Engineering, University of Tennessee Knoxville, DMITRY SMIRNOV, National High Magnetic Field Laboratory, DAVID MANDRUS, Department of Materials Science and Engineering, University of Tennessee Knoxville — Metal-organic frameworks (MOFs) are a class of nanoporous compounds where organic groups are used in combination with transition metal ions to obtain multifunctional materials. The family of MOFs comprised of methylammonum (A= (CH$_3$)$_2$NH$_2$) and metal (B=Co, Cu, Fe, Mn, Ni) cations with a formate (X=HCOO$_3$) anion are very interesting because of their multiferroic properties [1]. Therefore, several efforts have been made to understand the exchange interactions in these materials including magnetization at magnetic fields up to 60 T and infrared spectroscopy at fields up to 35 T [2,3]. Concurrently, we performed Raman spectroscopy on [(CH$_3$)$_2$NH$_2$]Co(HCOO)$_3$ at magnetic fields up to 31T to probe the magneto-elastic coupling. Also, the effect of hydrostatic pressure on the magnetic-elastic coupling in this system was explored. We will discuss our investigations and its implications.

L46.00013: High throughput ab initio screening for magnetic two dimensional materials
XUE JIANG (Presenter), Dalian University of Technology — Quantum information and spintronics devices, based on searching and manipulating magnetism, open up new questions in the studies of two dimensional materials. In this talk, I will present our theoretical design on few new types of 2D ferromagnetic materials (MBene, CrSBr, K2N, and 2D MOFs). They are shown robust ferromagnetism coupling, high Curie temperature (Tc), and large magnetic anisotropy energy (MAE). Many strategy have also been introduced to tailor their magnetic behavior, such as chemical functionalization, isoelectronic substitution, non-stoichiometry, strain, and metal decoration.

**8:00AM L47.00001: Strain effects on bulk α-RuCl$_3$ and α-RuCl$_3$/graphene bilayer**  SANANDA BISWAS (Presenter), YING LI, DAVID KAIB, KIRA M. RIEDL, STEPHEN WINTER, Goethe University Frankfurt, JOHANNES KNOLLE, Department of Physics, Technical University Munich, ROSER VALENTÍ, Goethe University Frankfurt — α-RuCl$_3$ has gained considerable attention recently, being the ‘proximate’ Kitaev spin liquid candidate. We discuss the effect of electronic proximity of α-RuCl$_3$ to graphene which gives rise to an insulator to metal transition in α-RuCl$_3$ with the Fermi energy located close to the bottom of the upper Hubbard band of the t$_{2g}$ manifold. These results suggest the possibility of realizing metallic and even exotic superconducting states. Moreover, we show that in the strained α-RuCl$_3$ monolayer, the Kitaev interactions are enhanced compared to the unstrained bulk structure. Furthermore, we investigate the thermal expansion and magnetostriction coefficients of bulk α-RuCl$_3$ via *ab initio* based methods.

*This project was supported by the Deutsche Forschungsgemeinschaft (DFG) through grant VA117/15-1.

**8:12AM L47.00002: Magneto-oscillations in the Thermal Conductivity of Kitaev Magnet RuCl$_3$**  PETER CZAJKA (Presenter), TONG GAO, JINGJING LIN, Princeton University, MAX HIRSCHBERGER, RIKEN, ARNAB BANERJEE, PAULA LAMPEN-KELLEY, JIAQIANG YAN, DAVID MANDRUS, STEPHEN E NAGLER, Oak Ridge National Laboratory, N. PHUAN ONG, Princeton University — RuCl$_3$ has been the subject of much intrigue and controversy due to it’s status as a possible realization of Kitaev’s honeycomb model and it’s exotic physics. Much of this attention has focused on the half-integer quantized thermal hall conductivity reported by Kasahara et al [1]. Here, we report a striking new observation in the system’s thermal transport physics. When cooled below 4K, RuCl$_3$ exhibits strong magneto-oscillations in its longitudinal thermal conductivity. Additionally, the thermal conductivity follows a butterfly-shaped hysteresis loop that also displays oscillations. We discuss possible explanations for this surprising effect and provide updates on our attempts to reproduce the half-integer quantized thermal hall conductivity reported by Kasahara et al.

8:24AM L47.00003: Kitaev-Γ-Heisenberg exchange in Ni$^{3+}$ honeycomb magnet NaNi$_2$BiO$_{6-δ}$

ALLEN SCHEIE (Presenter), Oak Ridge National Lab, COLLIN LESLIE BROHOLM, Physics and Astronomy, Johns Hopkins University, KATE ROSS, Physics, Colorado State University, PANAGIOTIS PETER STAVROPOULOS, Physics, University of Toronto, ELIZABETH SEIBEL, Chemistry, Princeton University, JOSE RODRIGUEZ-RIVERA, National Institute of Standards and Technology, JOEL TANG, Chemistry, Johns Hopkins University, YI LI, Physics and Astronomy, Johns Hopkins University, HAE-YOUNG KEE, Physics, University of Toronto, ROBERT J. CAVA, Chemistry, Princeton University — We present experimental and theoretical evidence for bond-dependent Kitaev-Γ-Heisenberg exchange in honeycomb Ni$^{3+}$ magnet NaNi$_2$BiO$_{6-δ}$. Heat capacity and neutron diffraction reveal a low-temperature ordered magnetic state for $T < 4.8$ K with $(1/3, 1/3, 0.15(1))$ order. In-plane magnetic correlations match the 120° ordered state of the Kitaev-Γ-Heisenberg exchange. Electron spin resonance and density functional theory reveal a uniform 3+ valence in Ni intermediate between a $S=3/2$ and $J=1/2$ state. DFT shows that covalent bonding between oxygen and Bi produces an enhanced spin orbit coupling in Ni$^{3+}$, which allows for strong bond-dependent exchange. The ordering wave vector, in-plane magnetic correlations, missing entropy, spin state, and superexchange pathways are all consistent with bond-dependent Kitaev-Γ-Heisenberg exchange interactions in NaNi$_2$BiO$_{6-δ}$.

8:36AM L47.00004: Intermediate magnetic phase of the proximate Kitaev system in the in-plane magnetic field

BEOM HYUN KIM (Presenter), Korea Institute for Advanced Study, SHIGETOSHI SOTA, TOMONORI SHIRAKAWA, RIKEN Center for Computational Science, YOUNG-WOO SON, Korea Institute for Advanced Study, SEIJI YUNOKI, RIKEN Center for Computational Science — a-RuCl$_3$ is the antiferromagnetic insulator with a zigzag order which is believed to be proximate to the Kitaev spin liquid. Its magnetic continuum excitation likely resulted from fractionalized Majorana fermions has been evidently observed in recent experiments. The zigzag long-range order can be suppressed and an intermediate phase, a possible quantum spin liquid, can emerge in between the zigzag phase and parallelly polarized phase when the magnetic field is applied. A few theories have attempted to explain the origin of intermediate magnetic phase in the presence of magnetic field. However, they have failed to manifest the intermediate phase in the in-plane external field observed by some experiments.

In the study, we verify that a simple magnetic model with a ferromagnetic Kitaev interaction and antiferromanetic third nearest neighbor Heisenberg interaction ($K$-$J_3$ model) can give successfully the intermediate phase in the in-plane magnetic field. Based on both exact diagonalization and density matrix renormalization group methods, we investigate the magnetic phase diagram of $K$-$J_3$ model in the in-plane magnetic field and demonstrate that the intermediate phase can occur when the field direction is perpendicular to the displacement vector between the nearest neighboring spins.
8:48AM L47.00005: Analysis of the high-field evolution of magnetic excitations in α-RuCl₃*

DAVID KAIB (Presenter), STEPHEN WINTER, ROSER VALENTI, Goethe University Frankfurt — The antiferromagnetic order of α-RuCl₃ can be suppressed by an in-plane magnetic field of approximately 7.5 tesla. Above this critical field, a rather unconventional field-dependence of the magnetic excitations has been reported. More recent Raman and terahertz spectroscopy experiments went up to significantly higher fields [1, 2]. We theoretically analyze these and compare the response of realistic anisotropic models. To this end we discuss different scattering mechanisms for the Raman response. We find that the Fleury-Loudon mechanism (usually discussed as the “two-magnon mechanism”) can explain the strikingly strong intensity of the single-magnon in the Raman spectra, as a consequence of strong Kitaev and anisotropic couplings. Our study firmly establishes the partially-polarized quantum disordered character of the high-field phase.

9:00AM L47.00006: Half-integer quantized thermal Hall conductance without out-of-plane magnetic field in a chiral spin liquid state of α-RuCl₃

YUICHI KASAHARA (Presenter), TAICHI YOKOI, SIXIAO MA, SHIGERU KASAHARA, Department of Physics, Kyoto University, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo, NOBUYUKI KURITA, HIDEKAZU TANAKA, Department of Physics, Tokyo Institute of Technology, JOJI NASU, Department of Physics, Yokohama National University, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo, CIARAN HICKEY, SIMON TREBST, Institute for Theoretical Physics, University of Cologne, YUJI MATSUDA, Department of Physics, Kyoto University — Kitaev quantum spin liquid (QSL) displays the fractionalization of quantum spins into Majorana fermions. In magnetic fields, the emergence of Majorana edge current is predicted to manifest itself in the form of half-integer quantized thermal Hall plateau, which has recently been reported for two-dimensional honeycomb material α-RuCl₃ [1]. While the conventional electronic Hall effect requires a perpendicular magnetic field, we find that the thermal Hall plateau appears even for a magnetic field with no out-of-plane components. In addition, the topological Chern number determined by the sign of the quantized thermal Hall conductance is consistent with that expected in the pure Kitaev spin liquid. These results demonstrate that the Kitaev interaction is primarily responsible and that the non-Abelian topological order persists even in the presence of non-Kitaev interactions in α-RuCl₃.

New Kitaev Magnet with Compelling Thermodynamic Evidence of Proximity to the Kitaev Spin-Liquid*  
FARANAK BAHRAMI (Presenter), Boston College, WILLIAM LAFARGUE-DIT-HAURET, University of Liège, OLEG I. LEBEDEV, Laboratoire CRISMAT, ROMAN MOVSHOVICH, Los Alamos National Laboratory, HUNG-YU YANG, DAVID BROIDO, Boston College, XAVIER ROCQUEFELTE, Chemistry, University of Rennes 1, FAZEL TAFTI, Boston College — Kitaev magnets are widely studied in search of quantum spin-liquid (QSL) ground states and Majorana excitations. Recent theoretical studies predict two potential signatures of a QSL at finite temperatures: a scaling behavior of thermodynamic quantities and a two-step release of the magnetic entropy. Here, we successfully synthesized a new Kitaev magnet, Ag$_3$LiIr$_2$O$_6$ with both signatures in our AC magnetic susceptibility, magnetization and heat capacity measurements. In this new quaternary oxide, despite the existence of a large Weiss temperature, there is no evidence of long-range order in our DC magnetic susceptibility and heat capacity measurements. Based on our DFT calculations, a mixing between silver d and oxygen p orbitals enhances the spin-orbit coupling within the honeycomb layers suggesting a closer proximity to the QSL in Ag$_3$LiIr$_2$O$_6$ compared to known Kitaev magnets, α-Li$_2$IrO$_3$ and Na$_2$IrO$_3$.

*NSF-DMR-1708929

Quasiparticle Relaxation Dynamics in the Kitaev Hyperhoneycomb β-Li$_2$IrO$_3$*  
PETER KISSIN (Presenter), ALEJANDRO RUIZ, PETER KIM, MAX POORE, ANANYA RAI, University of California, San Diego, MAYIA A VRANAS, JAMES ANALYTIS, University of California, Berkeley, ALEX FRANO, RICHARD AVERITT, University of California, San Diego — We study quasiparticle relaxation dynamics in single crystals of the three dimensional Kitaev hyperhoneycomb β-Li$_2$IrO$_3$ (LIO) using time-resolved optical pump-probe spectroscopy (OPPS). OPPS is extremely sensitive to subtle changes in the low energy electronic structure and the emergence of new quasiparticles, which can be missed with other probes. For LIO, we show that the photoinduced change in reflectivity is sensitive to several distinct phases upon varying temperature, photoexcitation intensity, and magnetic field applied along the crystallographic b axis. We observe large differences in the relaxation dynamics in the incommensurate spiral phase at low applied fields as compared to the field-induced zig-zag phase at fields above 2.8 Tesla. In addition, OPPS is sensitive to the recently discovered bulk high temperature phase transition at approximately 100 Kelvin. By tracking the evolution of quasiparticle dynamics within this new phase as a function of temperature and field, our results shed light on the nature of this phase as well as its relationship to the known low temperature phases.

9:36AM L47.00009: A rare-earth Kitaev material candidate YbCl$_3$*  

EVE EMMANOUILIDOU (Presenter), JIE XING, Department of Physics and Astronomy and California Nano Systems Institute, University of California, Los Angeles, CA 90095, USA, HUIBO CAO, Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, CHAOWEI HU, JINYU LIU, Department of Physics and Astronomy and California Nano Systems Institute, University of California, Los Angeles, CA 90095, USA, DAVID E GRAF, National High Magnetic Field Laboratory, 1800 E. Paul Dirac Drive, Tallahassee, FL 32310, USA, ARTHUR RAMIREZ, Department of Physics, University of California, Santa Cruz, CA 95064, USA, GANG CHEN, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China, NI NI, Department of Physics and Astronomy and California Nano Systems Institute, University of California, Los Angeles, CA 90095, USA —

Most of the searches for Kitaev materials deal with 4d/5d magnets with spin-orbit-coupled $J = \frac{1}{2}$ local moments such as iridates and $\alpha$-RuCl$_3$. Here we propose a new Kitaev material candidate YbCl$_3$. We perform thermodynamic, ac susceptibility and angle-dependent torque measurements on a YbCl$_3$ single crystal. We find that the Yb$^{3+}$ ion exhibits a Kramers doublet ground state that gives rise to an effective spin $J_{\text{eff}} = \frac{1}{2}$ local moment with likely strong anisotropic exchange interactions. The compound exhibits short-range magnetic ordering at around 1.20 K followed by long-range ordering at 0.60 K. These orderings can be suppressed by in-plane and out-of-plane magnetic fields, resulting in a quantum critical point at around 6 and 10 T, respectively. Furthermore, the non-monotonic decrease of Neel temperature under out-of-plane magnetic fields and the 99.8% of ground state entropy release across the short-range ordering, strongly suggest that YbCl$_3$ is a close realization of a Kitaev system.

Field-angle-resolved specific heat measurements in the Kitaev material α-RuCl₃

OHEI TANAKA (Presenter), RYUHEI HARASAWA, YUTA MIZUKAMI, Department of Advanced Materials Science, University of Tokyo, MARCIN KONCZYKOWSKI, Laboratoire des Solides Irradiés, Ecole Polytechnique, NOBUYUKI KURITA, HIDEKAZU TANAKA, Department of Physics, Tokyo Institute of Technology, EUN-GOOK MOON, Department of Physics, KAIST, YUICHI KASAHARA, YUJI MATSUDA, Department of Physics, Kyoto Univ, KENICHIRO HASHIMOTO, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo — Recently, 4d⁵ or 5d⁵ honeycomb materials with strong spin-orbit coupling have attracted great attention as a candidate for realizing a Kitaev quantum spin liquid (QSL). However, most of the candidate materials show magnetic orders at low temperatures. Indeed, α-RuCl₃, one of the most promising candidates, also exhibits a zigzag antiferromagnetic order below \( T_N \) (~ 7 K). However, the magnetic order of this material can be suppressed by applying a critical magnetic field \( H^* \) of 7.5 T parallel to the honeycomb plane. Recent thermal transport measurements, as well as spectroscopic studies such as inelastic neutron scattering, suggest the emergence of spin fractionalization into Majorana fermions in the field-induced QSL phase. Here, we report specific heat measurements under in-plane magnetic fields up to 7 T on electron-irradiated α-RuCl₃ single crystals, in which a systematic suppression of \( T_N \) and \( H^* \) was observed. We find a remarkable six-fold oscillation in the field-angle dependence of the specific heat at low temperatures above \( H^* \). This result is consistent with the field-angle dependence of the Majorana gap expected in the Kitaev QSL.

Ruthenium Substitution in Beta-Lithium Iridate

MAYIA VRANAS (Presenter), University of California, Berkeley, ALEJANDRO RUIZ, Physics, Univ of California - San Diego, BENJAMIN FRANDSEN, Physics, Brigham Young University, ARANI ACHARYA, VIKRAM NAGARAJAN, GILBERT LOPEZ, NITYAN NAIR, University of California, Berkeley, NICHOLAS BREZNAY, Physics, Harvey Mudd College, ZAHRUL ISLAM, Physics, Argonne National Laboratory, ALEX FRANO, Physics, Univ of California - San Diego, JAMES ANALYTIS, University of California, Berkeley — In the Kitaev model, orthogonal bond-directional exchange interactions have been proposed to give rise to quantum spin liquid ground state with fractional Majorana excitations. However, the candidate honeycomb materials described by this model order at low temperatures. Nonetheless, external perturbations, such as applied magnetic field, pressure, and chemical substitution, have been shown to change the strengths of the magnetic interactions and alter their ground state. Additionally, recent work in beta-lithium iridate has shown a hidden magnetic anomaly at T~100K which may be connected to the Kitaev-like behavior in the material. In this work, we present thermodynamic, resonant X-ray diffraction, and muon spin relaxation studies on ruthenium-doped beta-lithium iridate (\( \beta-Li_2Ru_xIr_{1-x}O_3 \)). We describe how the addition of magnetic impurities on the iridium sites suppresses the incommensurate phase and gives rise to an anisotropic spin glass. Additionally, we discuss the impact that these impurities have on the high-temperature phase.

10:12AM L47.00012: Confinement of fractional excitations in the 3D Kitaev magnet β-Li$_2$IrO$_3$  
YIPING WANG (Presenter), Boston College, ALEJANDRO RUIZ, Physics, university of California San Digo, JAMES ANALYTIS, Physics, University of California Berkerley, KENNETH BURCH, Boston College — Kitaev quantum spin liquid (QSL) is a highly frustrated state in topological magnets with excitations from fractional particles. In candidate materials like RuCl$_3$ and A$_2$IrO$_3$ (A = Na, Li), there is always an ordered state below Tc. However, the transition from spin liquid like fractional excitations to the magnons of the ordered state is still unclear. Here, we report the Raman scattering result on three-dimensional magnet β-Li$_2$IrO$_3$. We identified the polarization and temperature dependence of the magnons and fractional excitations in Raman. This provides first direct evidence for confinement of fractional excitations into magnons in a kitaev system, which so far has only been observed in quasi-1d systems.

10:24AM L47.00013: Evolution of magnetic phases in beta-Li2IrO3 under high magnetic fields*  
VIKRAM NAGARAJAN (Presenter), University of California, Berkeley, KIMBERLY MODIC, Max Planck Institute, JOHN SINGLETON, MUN K. CHAN, Los Alamos National Laboratory, KEVIN WANG, JAMES ANALYTIS, University of California, Berkeley — The Kitaev model describes a honeycomb net of Ising spins where each bond direction exchange-couples an orthogonal component of spin. Remarkably, this model is exactly solvable and predicts a quantum spin liquid ground state. Within the past decade, several materials have been theorized to realize the Kitaev model in their magnetic interactions. One of these materials is beta-Li2IrO3, which crystallizes in a 3D "hyperhoneycomb" structure. While this material does not possess a quantum spin liquid ground state, it contains a variety of interesting magnetic phases that coexist at intermediate temperature. In this talk, we describe how these phases evolve under strong magnetic fields using the state-of-the art technique of resonant torsion magnetometry.

High-resolution RIXS as a probe of Kitaev Magnetic Excitations in β-Li$_2$IrO$_3$

ALEJANDRO RUIZ (Presenter), ANTHONY ALLEN, University of California, San Diego, VIKRAM NAGARAJAN, Argonne National Lab, JAKE KORELEK, SLAC National Accelerator Laboratory, MARY UPTON, JONGHO KIM, Argonne National Lab, NICHOLAS BREZNAY, Physics, Harvey Mudd College, JAMES ANALYTIS, Physics, University of California Berkeley, DIEGO M CASA, Argonne National Lab, ALEX FRANO, University of California, San Diego — Spin-orbit entangled Mott insulators with strong bond-directional interactions have been proposed as a possible venue for the realization of the Kitaev honeycomb model. Most candidate materials, however, order at low temperatures due to the presence of additional spin coupling interactions. Nonetheless, a wealth of theoretical and experimental work has shown that the Kitaev term is the dominant magnetic exchange. The 3D Kitaev material β-Li$_2$IrO$_3$ hosts nearly degenerate states below 38K when a magnetic field is applied along a Kitaev direction: an incommensurate spiral (INC) and a commensurate field-induced ‘zig-zag’ phase (FIZZ). Most recently, a high-temperature magnetic anomaly was revealed at 100K using thermodynamics and muon relaxation techniques. In this work, we used a high-resolution RIXS spectrometer (FWHM=10meV) to measure the low-energy spin excitations in β-Li$_2$IrO$_3$ under a 2T applied field. We have identified magnon branches near each q-vector and the closing of a gap at the FIZZ q-position with the applied field. More importantly, we have observed a broad continuum of magnetic excitations centered around 35meV, which is unaffected by the low-temperature ordered states, and whose integrated intensity is constant up to 100K and continuously decreases above that.

Anomalous, Anisotropic and Extended Nonlinear Susceptibility in a-RuCl$_3$

BELLAVE SHIVARAM (Presenter), LUDWIG FW HOLLEIS, Univ of Virginia, JOSEPH PRESTIGIACOMO, Naval Research Laboratory, ZHIJE FAN, Univ of Virginia, SATOSHI NISHIMOTO, IFW Dresden, Germany, JIAQIANG YAN, ARNAB BANERJEE, Oak Ridge National Laboratory, MICHAEL OSOFSKY, Naval Research Laboratory, JEROEN VAN DEN BRINK, IFW Dresden, Germany, GIA-WEI CHERN, Univ of Virginia, DAVID MANDRUS, University of Tennessee, STEPHEN E NAGLER, Oak Ridge National Laboratory — In proximate Kitaev a-RuCl$_3$, we establish a radically new behavior of the nonlinear susceptibility hitherto not established. For T < T$_c$ and B || ab-plane, a dual nonlinear response is observed. The high field response above 2 T yields a third order nonlinear susceptibility which peaks near T$_c$ = 7.5 K, reminiscent of behavior in a classical 2D antiferromagnet, but with a large positive value for lowest T. The low field response, for B less than 2T - on the other hand, is positive quadratic and shows a rapid rise below T$_c$. This dual response vanishes for T beyond T$_c$ where the nonlinear response is dominated by only the cubic term. This term is significantly > 0 and turns negative only for a temperature T > 50 K >> T$_c$. Classical Monte Carlo (CMC) simulations capture the observed quadratic response, albeit only near T$_c$. The CMC however fail to reproduce the large quadratic term at low T.. This discrepancy indicates inadequacy of current models and points to the importance of multi-spin correlations in a-RuCl$_3$. For B || c-axis, we measure no dual response with only the cubic term being apparent. We also compare our results with exact diagonalization calculations performed on 16 x 16 cluster.

*The work at ORNL and the University of Tennessee were supported by the Department of Energy.
Motivated by recent discoveries of the coexistent phenomena of superconductivity and ferroelectricity in doped SrTiO$_3$ [1,2], we investigated the feasibility of ferroelectric (FE) superconductivity in which superconductivity coexists with a FE-like order. By analyzing an electron-lattice coupled model for a two-dimensional superconductor, we show that the FE superconductivity is realized through two different mechanisms that rely on the intrinsic spin-orbit coupling [3]. First, the FE superconducting state is stabilized by the ferroelectricity-induced Lifshitz transition in low carrier density regimes. Second, the FE superconducting state is stabilized under a Zeeman magnetic field owing to the suppression of the Pauli depairing effect in the FE phase. Furthermore, we show that the FE superconductivity in SrTiO$_3$ is strongly affected by the multiorbital effect of $t_{2g}$ electrons [4]. Then, we predict a topological Weyl superconducting state in the FE superconducting phase of bulk SrTiO$_3$.

8:12AM L48.00002: Capillary waves on ferroelastic domain walls as a pairing mechanism in strontium titanate*

DAVID PEKKER, Physics and Astronomy, University of Pittsburgh, C STEPHEN HELLBERG, Naval Research Laboratory, ANTHONY TYLAN-TYLER, JEREMY LEVY (Presenter), Physics and Astronomy, University of Pittsburgh — While it has long been known that strontium titanate is a superconductor, with a transition temperature of ~300 mK, the pairing mechanism that leads to superconductivity remains a mystery. We gather insight from recent experiments on superconductivity in the two-dimensional gas formed in lanthanum aluminate/strontium titanate heterostructures. These experiments provide evidence that superconductivity is localized to the edge of the electron gas, which is also associated with a ferroelastic domain wall between an out-of-plane deformation associated with the high electron density region and an in-plane deformation associated with the electron poor region. While the energy scales associated with bulk ferroelastic domains are quite large, on the order of 100 K, we show that capillary waves on domain walls can have much lower energy scales. Further, we argue that these capillary waves are strongly coupled to charge, making them a compelling candidate for an intermediate boson that mediates pairing interaction. We put these notions together in a model of ferroelastic domain walls that supports electron pairing.

8:24AM L48.00003: Unconventional High Temperature Superconductivity in Cubic Zinc-blende Transition Metal Compounds*

QIANG ZHANG (Presenter), KUN JIANG, YUHAO GU, JIANGPING HU, Institute of Physics, Chinese Academy of Sciences — Recently, we have identified a key character, called high temperature superconductivity "gene", which separates the cuprates and iron-based superconductors from other transitional metal compounds, and proposed some candidates for unconventional superconductivity. All of them are quasi-two dimensional. Here we propose a three dimensional candidate, transition metal compounds in a cubic zinc-blende lattice with electronic filling d^7. We argue that upon doping, this electronic environment can be one of `genes" to host unconventional high temperature superconductivity with a time reversal symmetry broken d+id pairing symmetry. With gappless nodal points along the diagonal directions, this state is a direct three dimensional analogue to the two dimensional B1g d-wave state in cuprates. We suggest that such a case may be realized in electron doped zinc-blende CoN.

Superconducting pairing in non-pseudospin electron bands

KIRILL SAMOKHIN (Presenter), Brock University — We develop the symmetry classification of superconducting gap functions in electron bands that do not transform like the pure spin-1/2 states under the crystal point group operations. Generalizing the commonly used Ueda-Rice prescription, we define the Bloch bases in twofold degenerate bands with spin-orbit coupling in a way which satisfies all symmetry and continuity requirements. These bases are used to construct general multiband pairing Hamiltonians in centrosymmetric crystals. Focusing on single band pairing, several exceptional cases are identified in which the triplet superconducting gap function does not transform under the point-group operations as a pseudovector, with a significant impact on the nodal structure.

A microscopic picture of pseudogap phase related to charge fluxes

XIN LI (Presenter), Harvard University — Pseudogap phase in unconventional superconductors is mysterious. Previously, our work disclosed a new relation that the strength of apical charge flux in different families of cuprate superconductors obtained from our computation is correlated with the superconducting transition temperatures reported in previous experiments [1]. A microscopic picture about how such flux can further modulate the in-plane hopping of individual charge carrier was also proposed [1].

In this talk we further discuss an important emergent behavior of such charge fluxes in cuprate superconductors [2]. We use a combination of DFT simulations and theoretical modeling to quantitatively describe how such emergent behavior controls the hopping of charge carriers to give the observed pseudogap phenomena. Simulations of ARPES and resistivity are further compared with experiments. We hope that this new picture of pseudogap phase will shed light on the understanding of more complicated phenomena in the phase diagram of unconventional superconductors.

9:00AM L48.00006: Multiband Superconductivity: Anisotropy, Scattering and Bound States

TOM SAUNDERSON (Presenter), Univ of Bristol, GABOR CSIRE, Catalan Institute of Nanoscience and Nanotechnology (ICN2), JAMES F ANNETT, Univ of Bristol, BALAZS UJFALUSSY, Hungarian Acad. of Science, MARTIN GRADHAND, Univ of Bristol — First principles modeling of phonon mediated s-wave superconductors has been largely successful for bulk crystals [1], however, the incorporation of impurities in such theories will be much harder. This problem becomes particularly relevant as impurities affect the superconducting state and magnetic impurities are pair breaking and lead to bound states [2]. Such states are a possible source of Majorana Fermions [3]. Here we present the implementation of the Bogoliubov-de Gennes (BdG) equation into a Green's function (KKR) first principles method [4]. This method is ideal to model impurities and interfaces without the need of artificial supercells. We parameterize the pairing potential but solve the BdG equation self-consistently incorporating microscopic electronic properties of real materials. Our method allows us to investigate the rich complexity of gap anisotropy on the Fermi surface and also how real magnetic and non-magnetic impurities interfere with the superconducting state.

9:12AM L48.00007: Using unsupervised machine learning to predict critical temperatures of superconductors

BENJAMIN ROTER, SASA DORDEVIC (Presenter), Univ of Akron — We use the superconductors from the SuperCon database to construct element vectors and then perform unsupervised learning of critical temperatures. Only the chemical composition of superconductors is used in this procedure. No physical predictors (neither experimental nor numerical) of any kind are used. We archive $R^2=0.93$ which is comparable and in some cases higher than similar estimates using other artificial intelligence techniques. Based on this machine learning model, we predict several new superconductors with high critical temperatures. We also discuss the factors that impede the learning process and suggest possible ways to fix them.
9:24AM L48.00008: Superconducting Neural Networks for Faster Machine Learning
ALEXANDRA DAY (Presenter), ALEXANDER WYNN, EVAN GOLDEN, Massachusetts Institute of Technology MIT — Next-generation neural networks have the potential to deliver advanced performance and higher processing speeds for applications in machine learning and artificial intelligence. MIT Lincoln Laboratory is investigating the feasibility of a superconducting neural network to support faster and lower-energy computing. We will present a conceptual framework for a superconducting neural network and its related benchmarks, along with simulation results for simple circuits.

9:36AM L48.00009: Novel Magnetoelectric Effects in Gyrotropic Superconductors and a Case Study of Transition Metal Dichalcogenides*  
WENYU HE (Presenter), KAM TUEN LAW, Hong Kong University of Science and Technology — In this work, we classify superconductors according to their magnetoelectric response. Among all the noncentrosymmetric superconductors, only superconductors with gyrotropic point groups have non-zero magnetoelectric response such that a supercurrent can induce a finite spin magnetization. We call these superconductors gyrotropic superconductors. Importantly, the general form of the magnetoelectric response is dictated by the point group symmetry and lead to novel magnetoelectric effects. Novel magnetoelectric effects of several noncentrosymmetric superconductors, including superconductors with chiral lattice symmetry and atomically thin superconducting transition metal dichalcogenides are discussed. Using a newly discovered monolayer 2H-structure NbSe2 as an example, we further show that how an unconventional magnetoelectric response can be induced by strain in superconductors with non-gyrotropic point groups.

9:48AM L48.00010: Resonant study of the vortex state in LSCO cuprates up to 35 T.*
ARKADY SHEKHTER (Presenter), ALI BANGURA, Natl High Magnetic Field Lab, ANDREAS RYDH, stockholm university, KIMBERLY MODIC, Max Planck Dresden, GREGORY SCOTT BOEBINGER, Natl High Magnetic Field Lab, BRAD J RAMSHAW, Cornell, ROSS MCDONALD, Los Alamos Natl. Lab — We used a newly developed resonant probe of elastic moduli to explore the phase diagram of the vortex state in LSCO cuprates near critical doping x=0.20, up to 35 T. The elastic anomaly at the vortex melting transition—jump down upon entry into the vortex solid—is consistent with a second order phase boundary. The magnitude of the jump, ~0.1 GPa at 20 T is consistent with expected magnitude $\sim H^2/8\pi$ of elastic moduli of the vortex lattice. We also observe a second thermodynamic anomaly at around 5T in the vortex-solid state that is weakly dependent on temperature and field orientation that appears to have dynamic origin. Finally, we will discuss magnetotrophic coefficient measurements in the same system.

10:00AM L48.00011: Four-fold anisotropy of the parallel upper critical magnetic field in a layered d-wave superconductor at T = 0  
ANDREI LEBED (Presenter), Univ of Arizona — It is well known that a four-fold symmetry of the parallel upper critical magnetic field disappears in the Ginzburg-Landau (GL) region in quasi-two-dimensional (Q2D) d-wave superconductors. Therefore, it has been accurately calculated so far as a correction to the GL results, which is valid close to superconducting transition temperature and is expected to be stronger at low temperatures. As to the case T=0, some approximated methods have been used, which are good only for closed electron orbits and inappropriate for the open orbits which exist in a parallel magnetic field in Q2D superconductors. For the first time, we accurately calculate the four-fold anisotropy of the parallel upper critical magnetic field in a Q2D d-wave superconductor at T=0, where it has the highest possible value. Our results are applicable to Q2D d-wave high-Tc and organic superconductors.
Recently we discovered three laws [1] of electronic thermal conductivity (ETC) in HTSCs via dipolon theory [2-5]. Previously, the dipolon theory predicted first of all two new high energy kinks which were observed later on experimentally. Here we present three corollaries to the three laws of ETC. First corollary: For HTSCs for which \( \Delta(0) = \alpha T_C \), the peak of the ETC is at \( T^{(p)} = 0.4\alpha T_C \). Second corollary: If the superconducting energy gap is destroyed, the peak of the ETC disappears. Third corollary: The peak of the ETC is not due to the reduction of the scattering rate though it enhances the ETC and shifts the peak dependent on the variation of the scattering rate with temperature. These along with three laws [1] explain clearly the origin and behavior of ETC in HTSCs.

**10:24AM L48.00013: Detecting superconductivity out-of-equilibrium**

SEBASTIAN PAECKEL
(Presenter), Insitut fuer Theoretische Physik, Georg-August Universitaet Goettingen, BENEDIKT FAUSEWEH, Theoretical Division, Los Alamos National Laboratory, ALEXANDER OSTERKORN, Insitut fuer Theoretische Physik, Georg-August Universitaet Goettingen, THOMAS KOEHLER, Department of Physics and Astronomy, Uppsala University, DIRK MANSKE, Quantum Many-Body Theory, Max-Planck-Institut für Festkörperforschung, SALVATORE MANMANA, Insitut fuer Theoretische Physik, Georg-August Universitaet Goettingen — Recent pump-probe experiments on underdoped cuprates and similar systems suggest the existence of a transient superconducting state above \( T_c \). This poses the question how to reliably identify the emergence of long-range order, in particular superconductivity, out-of-equilibrium. We investigate this point by studying a quantum quench in an extended Hubbard model and by computing various observables, which are used to identify (quasi-)long-range order in equilibrium. Our findings imply that, in contrast to current experimental studies, it does not suffice to study the time evolution of the optical conductivity to identify superconductivity. In turn, we suggest to utilize time-resolved ARPES experiments to probe for the formation of a condensate in the single- and two-particle channel.

**10:36AM L48.00014: Computational Simulations of the Cooling of Type II Superconductors Using a Material Specific Formulation of the Ginzburg Landau Equations**

AIDEN HARBICK
(Presenter), William & Mary College, ALDEN PACK, BRAEDON JONES, MARK TRANSTRUM, Brigham Young University — Superconducting Radio Frequency (SRF) cavities play a fundamental role in particle accelerators. Efficient operation depends on expelling magnetic flux from the cavity, and any residual flux that remains trapped after cooling below the critical temperature can have a significant impact on performance. Experimental evidence suggests that cooling protocols can have a strong impact on subsequent performance. To better understand this phenomenon, we use time-dependent Ginzburg-Landau theory implemented as finite-element simulations. We adapt the theory to allow spatial variation of material-specific parameters along with realistic temperature dependencies. We report on numerical experiments for different configurations of pinning sites and cooling protocols and discuss implications for SRF cavity design and operation.

10:48AM L48.00015: Hall anomalies and vortex charge in layered superconductors*  DANIEL AROVAS (Presenter), University of California, San Diego, ASSA AUERBACH, Physics, Technion, Israel Institute of Technology — The Hall anomalies in the flux flow regime are associated with moving vortex charge (MVC) in the superconducting layers, which are screened by immobile charges in neighbouring dopant layers. The MVC depends on the logarithm of the magnetic field, and proportional to the doping dependent superfluid stiffness and interlayer dielectric constant. The MVC is shown to add to the Hall conductivity by reformulating Flux Flow transport theory as a current response to applied electric and magnetic field, without the use of vortex forces or complex relaxation rates. MVC curves are extracted from experimental resistivities of hole and electron doped cuprates. These are fit to theory using measured London penetration depths, and a reasonable value of interlayer dielectric constant.

8:24AM L49.00003: Radio-frequency response of a graphene Josephson junction based superconducting oscillator circuit*  
SUBHAMOY GHATAK, JOYDIP SARKAR (Presenter), PRATAP ADAK, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research (TIFR), BISWAJIT DATTA, Materials Department, University of California, Santa Barbara, SUPRIYA MANDAL, LUCKY N. KAPOOR, KISHOR V SALUNKHE, SUMAN KUNDU, R VIJAY, MANDAR M DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research (TIFR) — Ballistic transport in a graphene-based Josephson junction provides a great opportunity to realize different superconducting quantum circuits. Such circuits are tunable by various externally controllable knobs like - doping, electric field, magnetic field; hence, they can have the potential to be used as superconducting qubits over the existing ones which do not have such variety of tunability. We have devised a superconducting oscillator circuit, employing graphene-based Josephson junction. The analogous electrical circuit is a simple parallel LC oscillator, where the oscillator frequency is tunable through magnetic flux variation and carrier density modulation in graphene. The response of a Josephson junction as an inductor and its non-linearity is vital. The readout of the device involves coupling of an external RF signal to the oscillator through a reflection based measurement. Such a response can be promising for the future direction of graphene-based quantum devices.

*We acknowledge funding support from the Department of Atomic Energy and the Department of Science and Technology of India.
8:36AM L49.00004: Gate Controlled Anomalous Phase Shift in Al/InAs Josephson Junctions*
WILLIAM MAYER (Presenter), MATTHIEU DARTAILH, JOSEPH YUAN, KAUSHINI S WICKRAMASINGHE, Center for Quantum Phenomena, New York University, ENRICO ROSSI, Department of Physics, William & Mary, JAVAD SHABANI, Center for Quantum Phenomena, New York University — In a standard Josephson junction the current is zero when the phase difference between superconducting leads is zero. This condition is protected by parity and time-reversal symmetries. However, the combined presence of spin-orbit coupling, and in-plane magnetic field breaks these symmetries, which can lead to a finite supercurrent even when the phase difference is zero. This is the anomalous Josephson effect which can be characterized by the corresponding anomalous phase shift. We report the observation of a tunable anomalous Josephson effect in Al/InAs Josephson junctions measured via a superconducting quantum interference device. By gate controlling the density of InAs, we are able to tune the spin-orbit coupling in the Josephson junction. This gives us the ability to tune the anomalous phase using both in-plane magnetic field and gate voltage. We observe anomalous phase shifts larger than expected from theory for our material parameters. These results open new opportunities for superconducting spintronics, and new possibilities for realizing and characterizing topological superconductivity.

8:48AM L49.00005: Superconductivity induced in InSb nanowires from new thin film superconductors
BOMIN ZHANG (Presenter), Physics, Univ. of Pittsburgh, MIHIR PENDHARKAR, IEE, UC Santa Barbara, PO ZHANG, HAO WU, AZARIN ZARASSI, Physics, Univ. of Pittsburgh, CONNOR DEMPSEY, JOON SUE LEE, SEAN HARRINGTON, IEE, UC Santa Barbara, GHADA BADAWY, SASA GAZIEGOVIC, ROY OP HET VELD, JASON JUNG, MARCEL VERHEIJEN, Applied Physics, Eindhoven Univ. of Technology, MOIRA HOCEVAR, Institute Neel, CEA Grenoble, ERIK BAKKERS, Applied Physics, Eindhoven Univ. of Technology, CHRIS J PALMSTROM, IEE, UC Santa Barbara, SERGEY M FROLOV, Physics, Univ. of Pittsburgh — Previous research on superconductor-semiconductor nanowire devices focused heavily on aluminum and niobium alloys. Here we study superconductivity from new thin film superconductors in InSb nanowires. We observe hard superconducting gap and quantized conductance plateau at zero field. The magnetic field evolution of superconducting gap and of supercurrent are studied. New super-semi hybrid structures offering larger critical field and increased energy gap, as compared to aluminum, are interesting as they provide a powerful platform to study topological superconductivity, spin-orbit and Zeeman effects in Superconductor-Semiconductor Josephson Junctions.
9:00AM L49.00006: Magnetic field and flux driven 0-π phase transition in a spinful Josephson junction  ALEXANDER WHITICAR (Presenter), ANTONIO FORNERI, FELIX PASSMANN, ABHISHEK BANERJEE, ASBJORN DRACHMANN, Center for Quantum Devices, Microsoft Quantum Lab – Copenhagen and Niels Bohr Institute, University of Copenhagen, TIANTIAN WANG, CANDICE THOMAS, SERGEI GRONIN, GEOFF C GARDNER, MICHAEL MANFRA, Department of Physics and Astronomy and Station Q Purdue, Purdue University, CHARLES MARCUS, Center for Quantum Devices, Microsoft Quantum Lab – Copenhagen and Niels Bohr Institute, University of Copenhagen — The coexistence of magnetism and superconductivity in a Josephson junction can lead to a 0-π phase transition. Quantum dots (QDs) can serve as spin impurities that can be controllably coupled to a superconductor (S). Here, we probe the Andreev spectrum of a hybrid S-QD-S Josephson junction by performing tunneling spectroscopy with a weakly coupled normal lead. We identify a gate-voltage-induced transition from singlet to doublet ground state, where the Andreev spectrum develops a π-phase shift. We demonstrate control of the 0−π transition using superconducting phase difference across the junction and an external magnetic field. We identify parity transitions by measuring zero-bias crossings induced by a magnetic field, phase difference, and gate voltage. This research was supported by Microsoft and the Danish National Research Foundation.

9:12AM L49.00007: A Mesoscopic Spectrometer Based on the Josephson Effect*  JOËL GRIEßMAR, FABIEN LAFONT, RAMIRO RODRIGUEZ (Presenter), VINCENT BENZONI, LÉO PEYRUCHAT, JEAN-LOUP SMIRR, CAGLAR GIRIT, Flux Quantum Lab, CNRS USR 3573, Collège de France, Paris, France — A key element of mesoscopic topological systems, such as hybrid semiconductor-superconductor circuits, are Andreev Bound States, single quasiparticles localized at superconducting weak links. The characteristic transition energy of these states is twice the superconducting gap (90 GHz in Al). Conventional microwave techniques allow probing these states but only in a limited bandwidth. We implement a new broadband spectrometer operating at frequencies up to 180 GHz, with a 2 MHz linewidth and a minimal theoretical sensitivity of 5 kHz, based on the Josephson effect which converts a DC voltage to microwave oscillations at a frequency proportional to this voltage. Conveniently the absorption of the emitted photons is measured in the spectrometer DC current-voltage characteristic. Using a symmetrical SQUID biased at half a flux quantum allows decoupling the spectrometer from parasitic environmental modes. We demonstrate this spectroscopy technique by detecting the plasma frequency, near 100 GHz, of an RF-SQUID, fabricated both on- and off-chip, inductively coupled to the spectrometer.

Graphene Josephson junctions in high in-plane magnetic field

TOM Dvir (Presenter), QuTech, Delft University of Technology, Ayelet Zalic, The Racah Institute of Physics, The Hebrew University of Jerusalem, Kenji Watanabe, Takashi Taniguchi, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba 305-0044, Japan, Hadar Steinberg, The Racah Institute of Physics, The Hebrew University of Jerusalem — In recent years, there is a growing interest in graphene as the main ingredient in Josephson junctions (JJs). The ability to control the concentration and the sign of the charge carriers allows the fabrication of bipolar JJ with critical currents that can be varied in three orders of magnitude in the same device. Also, using clean graphene allows studying the interplay between quantum Hall effect and superconductivity. The study of graphene JJs in high magnetic fields was so far limited by the response of the host superconductor to the application of field. We fabricate JJs using ultra-thin NbSe$_2$ as the superconductor, allowing us to apply very high in-plane magnetic fields without significantly affecting the superconducting gap. We show that such JJs, NbSe$_2$-graphene-NbSe$_2$, are highly transparent, and survive to in-plane fields up-to 8T. Due to the two-dimensional nature of the system, the interaction of the in-plane field with the system occurs only with the spin degree of freedom, imitating S-ferromagnet-S JJs, with effective exchange energy determined by the external field.

Interference of chiral Andreev edge states in a multi-terminal Josephson junction

Lingfei Zhao (Presenter), Ethan Arnault, Andrew Seredinski, Trevyn Larson, Duke University, Hengming Li, Appalachian State University, Kenji Watanabe, Takashi Taniguchi, Advanced Materials Laboratory, NIMS, Francois Amet, Appalachian State University, Gleb Finkelstein, Duke University — We study the interference effects of chiral Andreev edge states (CAES) in a multiterminal Josephson junction operated in the quantum Hall regime. On well quantized QH plateaus, we observe CAES interference in the form of voltage fluctuations downstream from the grounded superconducting contact. We have previously attributed this interference to successive electron-hole conversion along the quantum Hall-superconducting interface. Here, we show that these fluctuations also exist in the Hall voltage, indicating a second order effect whereby the downstream particle experiences an additional electron-hole conversion along more than one superconducting contact. These observations indicate the potential for coherent control of the chiral Andreev edge states.

9:48AM L49.00010: Proximity effects in superconducting heterostructures*  
BALAZS UJFALUSSY (Presenter), GABOR CSIRE, Wigner Research Centre for Physics, KYUNGWHA PARK, Virginia Tech — The overlayer of metallic thin films on top of an s-wave superconducting substrate is studied by the numerical solution of the fully relativistic Kohn-Sham-Bogoliubov-de Gennes equations via multiple scattering methods. We briefly describe the methodology which allows for a material-specific calculation of the Andreev band structure. We discuss the relation of the effective pair interaction, the anomalous charge density and the induced superconducting gap in heterogeneous systems. Taking Au/Nb films as an example, we also show how surface and interface states behave in such systems and study the formation of the superconducting gap in one-dimensional impurity systems.

10:00AM L49.00011: Visibility of a topological qubit quantum dot measurement  
ALEKSEI KHINDANOV (Presenter), University of California, Santa Barbara, DMITRY I. PIKULIN, Microsoft Research — Topological superconductor-quantum dot-topological superconductor (TS-QD-TS) system is of current interest for topological quantum computing, being a proposed platform for detecting Majorana zero modes (MZMs) and for measuring a topological qubit state. Here, using perturbation theory we derive expression for Josephson energy in this system, with a particular emphasis on a term associated with a coupling of the QD to quasiparticle continuums in each TS, arising in the fourth order. Furthermore, we study how 1/f flux noise, typical for SQUID-type devices, interferes measurement visibility of the qubit. We find that even though coupling of the QD to quasiparticle continuums does not directly affect measurement outcomes, the flux noise might considerably decrease the signal to noise ratio. We calculate experimental parameter values for which the effect is minimized and a best signal to noise ratio can be achieved.

10:12AM L49.00012: Domain wall based spin-triplet Josephson junction and SQUID  
EKTA BHATIA (Presenter), NISER, ANAND SRIVASTAVA, JAMES DEVINE STONEMAN, NADIA A STELMASHENKO, ZOE BARBER, JASON ROBINSON, Material Science and metallurgy, University of Cambridge, KARTIK SENAPATI, NISER — Spin-singlet Cooper pairs convert to spin-triplet Cooper pairs on passing through a magnetic non-collinear structure at superconductor(S)/ferromagnet(F) interface [1]. In this context, the generation of triplet supercurrents through intrinsic ferromagnetic domain walls, which are naturally occurring non-collinear magnetic structure, was proposed theoretically in the last decade [2]. However, an experimental demonstration has been lacking in the literature, particularly due to the difficulty in accessing a single domain wall which is typically buried between two domains in a ferromagnetic material. In this report, by pinning a magnetic domain wall at the barrier of a nanoscale S/F/S planar junction, we have been able to demonstrate the predicted long-range triplet supercurrent due to a domain wall. The spin-triplet current was measured over a ferromagnetic barrier width exceeding 70 nm. Using the same concept of domain wall pinning at the Josephson junction barrier, we have also demonstrated a planar Nb/Ni/Nb triplet SQUID device.

10:24AM L49.00013: Unconventional magnetic flux response of Josephson junctions with a weak link made from alternating normal and ferromagnetic interlayers*  IVAN P NEVIRKOVETS, MIKHAIL BELOGOLOVSKII (Presenter), Department of Physics and Astronomy, Northwestern University — We present the first systematic study of critical current-vs-external magnetic flux dependences in Josephson junctions with a weak link formed by alternating normal (N=Al) and ferromagnetic (F=Ni or Py) nominally identical nm-thick films coupled to superconducting (S=Nb) electrodes. In contrast to the well-known Fraunhofer-type behavior for conventional Josephson trilayers, the S/(NF)ₙ/S hybrids with n > 5 (with or without an ultra-thin Al-oxide barrier) have revealed anomalous patterns. In the most samples, with increasing magnetic flux, the supercurrent underwent periodic, constant-amplitude modulation resembling that in SQUIDs, see preliminary data [1]. The oscillatory pattern was superposed on a background supercurrent having much larger oscillation period in an externally applied magnetic field. We explain the origin of the non-Fraunhofer critical current curves as being associated with a special type of diffusive charge trajectories confined to the edges of the periodic (NF)ₙ weak link. The Josephson devices in the surface-dominated transport regime can be exploited for nanoscale low-field detection.

10:36AM L49.00014: Enhanced triplet pairing in magnetic junctions with s-wave superconductors  CHENGHAO SHEN (Presenter), State Univ of NY - Buffalo, THOMAS VEZIN, Ecole Polytechnique, JONG E HAN, IGOR ZUTIC, State Univ of NY - Buffalo — A common path to Majorana fermions and topologically-protected quantum computing relies on spin-triplet superconductivity[1]. While spin-triplet pairing is elusive in nature and even common spin-triplet candidates, such as Sr₂RuO₄, could support alternative explanations[2], proximity effects in heterostructures can overcome these limitations. Specifically, a common expectation is that robust spin-triplet superconductivity in magnetic junctions should rely on highly spin-polarized magnets or complex magnetic multilayers[3]. Instead, we predict that the interplay of interfacial spin-orbit coupling and the barrier strength in simple magnetic junctions with s-wave superconductors can lead to nearly complete spin-triplet superconducting proximity effects when magnets have only a small spin polarization[4]. We show that this enhanced spin-triplet regime is characterized by a huge increase in conductance magnetoanisotropy[4-6], orders of magnitude larger than in the normal state.

The current-phase relationship of Josephson junctions is often assumed to be a sinusoid. However, this is not always the case. In order to directly measure the current-phase relationship of junctions with a range of characteristics, including both SIS and SNS junctions, we fabricated Josephson junctions having $\text{Nb}_x\text{Si}_{1-x}$ barriers with varied Nb concentration. We constructed a superconducting SQUID-sensor-based circuit to extract their current-phase relationships. SIS-like junctions had the expected near-sinusoidal current-phase relationship, but the current-phase relationship gained additional harmonics as the barriers became less insulating. Thus, SNS-like junctions with normal barriers and high Nb content had sawtooth-like current-phase relationships. This deviation is likely due to additional Andreev reflections. The effects of this non-sinusoidal current phase relationship were observed in current-voltage characteristics through the appearance of non-integer Shapiro steps. Additionally, the same techniques were applied to Si-Mn nanocluster junctions to measure the changes in the current-phase relationship caused by the dynamic tuning of the critical currents of these junctions.

*This work is partially funded by NIST and the IARPA SuperTools Program.
8:00AM L50.00001: Late time dynamics of dynamical correlation functions and out of time ordered correlators* JONATHON RIDDELL (Presenter), McMaster Univ, ÁLVARO ALHAMBRA, Perimeter Institute, LUIS GARCIA-PINTOS, University of Maryland, ERIK SORENSEN, McMaster Univ — In this talk we study the universal properties of different types of dynamical quantities in time, for large classes of systems. First we investigate two-point correlation functions—also known as dynamical response functions in closed non-integrable many-body quantum systems. We show that for a large class of models these correlation functions factorize at late time, proving dissipation emerges from unitary dynamics. We similarly show that the fluctuations around the late time are bounded by the purity of the thermal ensemble. For auto-correlation functions we provide an upper bound on the timescale for which they equilibrate to this late time factorization. We then move onto study the late time dynamics of fermionic models in the presence of disorder for out of time ordered correlators. Focusing on the Aubry-André model we derive universal late time behavior for the OTOC in the extended regime of the model. These fermionic results are then used to extend the discussion to equilibration in finite time for all quadratic models in the extended regime.

8:12AM L50.00002: Self-averaging in many-body quantum systems out of equilibrium* LEA SANTOS (Presenter), MAURO SCHIULAZ, Yeshiva Univ, E. JONATHAN TORRES HERRERA, Benemérita Universidad Autónoma de Puebla,., FRANCISCO PÉREZ-BERNAL, Universidad de Huelva — Despite its importance to experiments, numerical simulations, and the development of theoretical models, self-averaging in many-body quantum systems out of equilibrium remains underinvestigated. Usually, in the chaotic regime, self-averaging is just taken for granted. The numerical and analytical results presented here force us to rethink these expectations. They demonstrate that self-averaging properties depend on the quantity and also on the time scale considered. We show analytically that the survival probability in chaotic systems is not self-averaging at any time scale, even when evolved under full random matrices. We also analyze the participation ratio, Rényi entropies, the spin autocorrelation function from experiments with cold atoms, and the connected spin-spin correlation function from experiments with ion traps. We find that self-averaging holds at short times for the quantities that are local in space, while at long times, self-averaging applies for quantities that are local in time. Various behaviors are revealed at intermediate time scales.

**Measurement-induced entanglement dynamics in many-body localizable systems**

OLIVER LUNT (Presenter), ARJEET PAL, Univ Coll London — In this work we explore the interplay of two types of entanglement transition: the many-body localization (MBL) transition, where eigenstates go from volume law to area law, and measurement-induced transitions, where recent work has demonstrated that the late-time entanglement entropy of random circuits can collapse from volume to area law above a finite critical measurement rate [1-3]. Whereas previous studies have focused mainly on random quantum circuits, here we focus on Hamiltonian dynamics. Many-body localizable systems exhibit at least two phases with distinct dynamical properties: the thermal and the localized phases. In this work, we investigate the effect of measurements on the entanglement dynamics of these phases.

**Quantum Impurity Far from Equilibrium: Quantum Transport Through a Dissipative Resonant Level Using DMRG**

XIN ZHANG (Presenter), THOMAS BARTHEL, HAROLD U BARANGER, Duke University — Using time-dependent matrix product state techniques, we study the quantum transport properties of a dissipative resonant level model, in which a quantum impurity is coupled to two leads and a bosonic bath. Experimentally, this model can be realized by coupling a quantum dot with resistive leads [1]. We focus on the far-from-equilibrium steady states. The non-linear I-V curves and their scaling behavior are presented for different dissipation strengths in the case of both symmetric and asymmetric coupling. In the symmetric setup, a quantum critical point of the two-channel Kondo class is present [2]. To probe properties of the quasiparticle excitations, which can be measured with tunneling spectroscopy, we study the spectral function and shot noise.

8:48AM L50.00005: Role of non-linear susceptibilities in non-equilibrium transport through an N-level Anderson impurity model away from half-filling

YOSHIMICHI TERATANI (Presenter), AKIRA OGURI, Osaka City Univ — We study non-equilibrium SU(N) Kondo effect that occurs in quantum impurity systems at low-temperatures T and low-bias voltages eV. We expand the differential conductance up to terms of order T^2 and (eV)^2 at arbitrary electron fillings, using an extended version of the Fermi-liquid theory for the Anderson impurity model. The coefficients for these terms are determined by the linear and non-linear susceptibilities defined with respect to the equilibrium ground state [1,2]. We calculate these susceptibilities using the NRG for N=2, 4, and 6 in a wide range of electron fillings N_d, varying the impurity level position ε_d. The results show that contributions of the three-body susceptibilities on the transport coefficients increase as N_d deviates away from half-filling, especially near the fillings of N_d = 1 and N_d = N-1. We also employ a large N approach, i.e., the 1/(N-1) expansion with a scaling that keeps (N-1)U constant [3]. We find that the 1/(N-1) results and NRG results are in good already at N=4 and 6.

9:00AM L50.00006: Hamiltonian dynamics of a sum of interacting random matrices*

MATTEO BELLITTI (Presenter), SIDDHARDH MORAMPUDI, CHRISTOPHER LAUMANN, Boston Univ — In ergodic quantum systems, physical observables have a non-relaxing component if they "overlap" with a conserved quantity. In interacting microscopic models, how to isolate the non-relaxing component is unclear.

We compute exact dynamical correlators governed by a Hamiltonian composed of two large interacting random matrices, H=A+B.

We analytically obtain the late-time value of 〈A(t)A(0)〉; this quantifies the non-relaxing part of the observable A.

The relaxation to this value is governed by a power-law determined by the spectrum of the Hamiltonian H, independent of the observable A.

For Gaussian matrices, we further compute out-of-time-ordered-correlators (OTOCs) and find that the existence of a non-relaxing part of A leads to modifications of the late time values and exponents.

Our results follow from exact resummation of a diagrammatic expansion and hyperoperator techniques.

9:12AM L50.00007: Universal Dynamics of Stochastically Driven Quantum Impurities*
WILLIAM BERDANIER (Presenter), University of California, Berkeley, JAMIR MARINO, Harvard University, EHUD ALTMAN, University of California, Berkeley — We show that the dynamics of a quantum impurity subject to a stochastic drive on one side and coupled to a quantum critical system on the other display a universal behavior inherited from the quantum critical scaling. Using boundary conformal field theory, we formulate a generic ansatz for the dynamical scaling form of the typical Loschmidt echo and corroborate it with exact numerical calculations in the case of a spin impurity driven by shot noise in a quantum Ising chain. We find that due to rare events the dynamics of the mean echo can follow very different dynamical scaling than the typical echo for certain classes of drives. Our results are insensitive to irrelevant perturbations of the bulk critical model and apply to all the microscopic models in the same universality class.

9:24AM L50.00008: Non-Equilibrium Dynamics of the SYKq=∞ Model  STEFAN KEHREIN
(Presenter), Institute for Theoretical Physics, University of Goettingen — The Sachdev-Ye-Kitaev model is a paradigm for quantum many-body systems without a quasiparticle description. Its non-equilibrium dynamics after a quench was investigated in Ref. [1], where certain quenches to the q=∞ model could even be solved analytically. In this talk these analytical results are extended to arbitrary quenches to the q=∞ SYK model. Remarkably one always finds instant thermalization.

9:36AM L50.00009: Using charge- and spin-specific local integrals of motion to explore entanglement growth in the disordered Fermi Hubbard model*  RACHEL WORTIS (Presenter), BRANDON LEIPNER-JOHNS, Trent University — The Fermi Hubbard model has both charge and spin degrees of freedom at each site. We explore the coupling of the dynamics in these two channels in the presence of disorder. In particular, we write the Hamiltonian in terms of charge- and spin-specific local integrals of motion, and compare the strengths of the coupling constants linking integrals of motion of the same species (charge-charge and spin-spin) with those linking charge and spin. This provides an avenue to understanding the wide range of time scales which appear in the dynamics.

*Supported by NSERC of Canada.
9:48AM L50.00010: Scalable probes of measurement-induced phase transitions* DAVID HUSE (Presenter), MICHAEL GULLANS, Princeton University — Measurement-induced phase transitions are a recently uncovered class of critical phenomena that occur when many-body unitary dynamics are interspersed with measurements at a tunable rate. We uncover a local order parameter for such measurement-induced criticality (MIC) equal to the average entropy of a single reference qubit initially entangled with the system. Using this order parameter, we identify scalable probes of MIC that are immediately applicable to advanced quantum computing platforms. We test our proposal on a 1+1-dimensional stabilizer circuit model that can be classically simulated in polynomial time. We determine bulk and surface critical exponents of MIC for such models and find that they are very close, or equal to those of 2+0-dimensional critical percolation. Developing scalable probes of MIC in more general models may be a useful application of noisy-intermediate scale quantum (NISQ) devices, as well as point to more efficient realizations of fault-tolerant quantum computation.

*Research supported in part by the DARPA DRINQS program. D.A.H. was supported in part by a Simons Fellowship.

10:00AM L50.00011: Higher-order and fractional discrete time crystals in clean long-range interacting systems* ANDREA PIZZI (Presenter), Univ of Cambridge, JOHANNES KNOLLE, Technical University Munich, ANDREAS NUNENKAMP, Univ of Cambridge — Discrete time crystals are periodically driven systems characterized by a response with periodicity $nT$, with $T$ the period of the drive and $n>1$. Typically, $n$ is an integer and bounded from above by the dimension of the local (or single particle) Hilbert space, the most prominent example being spin-1/2 systems with $n$ restricted to 2. Here we show that a clean spin-1/2 system in the presence of long-range interactions and transverse field can sustain a huge variety of different 'higher-order' discrete time crystals with integer and, surprisingly, even fractional $n>2$. We characterize these non-equilibrium phases of matter thoroughly using a combination of exact diagonalization, semiclassical methods, and spin-wave approximations, which enable us to establish their stability in the presence of competing long- and short-range interactions. Remarkably, these phases emerge in a model with continuous driving and time-independent interactions, convenient for experimental implementations with ultracold atoms or trapped ions.

10:12AM L50.00012: Time dependent, external perturbations of Hubbard clusters with explicit many electron interactions and their implications  GAYANATH FERNANDO, ADIL-GERAI KUSSOW (Presenter), Univ of Connecticut - Storrs, KALUM PALANDAGE, Physics, Trinity College — We examine the effects of harmonic and other time dependent external perturbations on a many electron system using exact diagonalization and Lanczos method for Hubbard clusters in our search for time crystal and other behaviors such as precursors to superconducting states. It is possible to open time dependent breathing modes of the Hubbard Hamiltonian by exposing the cluster to electromagnetic radiation. The analysis based on exact solutions of the Heisenberg equation demonstrates that it is possible to reach highly populated states with localized pairs of electrons having opposite spins (related to possible superconductivity). Since the system is principally time dependent in the pre-thermalization regime, it can be treated as an example of a time crystal.

10:24AM L50.00013: Flow Renormalization and Prethermal Regimes of Periodically-Driven Quantum Systems  MARTIN CLAASSEN (Presenter), Center for Computational Quantum Physics, Simons Foundation Flatiron Institute — One of the most fascinating aspects of non-equilibrium physics is that a quantum system pushed out of equilibrium can exhibit markedly different dynamics when probed on different time scales. We develop a flow renormalization approach for periodically-driven quantum systems, for which a rigorous relation between "flow time" and real time can be established. In this formalism, the dynamical problem is recast in terms of a flow towards an attractive thermal fixed point, while narrowly avoiding a series of unstable fixed points that determine distinct transient dynamical regimes at intermediate times. We show that a unique choice of flow permits relating flow-time and real-time evolution via analytic continuation, and study the appearance of long-lived prethermal regimes in Floquet Hubbard models and spin chains.
10:36AM L50.00014: Flow equation approach to periodically driven quantum systems*
MICHAEL VOGL (Presenter), University of Texas at Austin, PONTUS LAURELL, Oak Ridge, AARON BARR, GREGORY A FIETE, University of Texas at Austin — We present a theoretical method to generate highly accurate time-independent Hamiltonians governing the finite-time behavior of time-periodic systems. The method exploits infinitesimal unitary transformation steps, from which renormalization group-like flow equations are derived to produce effective Hamiltonians. The method has a range of validity reaching into frequency regimes that are usually inaccessible by high frequency expansions. Our approach is demonstrated for many-body Hamiltonians and offers an improvement over the more well-known Magnus expansion and the rotating frame approximation. We show how the method relates to the rotating frame approximation and how it can be used to approximately transform to a rotating frame when the exact transformation isn't tractable. We compare our approximate results to those found via exact diagonalization.

10:48AM L50.00015: Fermi-liquid corrections to non-equilibrium Keldysh vertex functions for an Anderson impurity model. AKIRA OGURI (Presenter), YOSHIMICHI TERATANI, Department of Physics, Osaka City Univ, RUI SAKANO, ISSP, The university of Tokyo — We study in detail the residual interaction between quasi-particles that plays an essential role in the non-equilibrium transport through quantum dots under finite bias voltage $eV$. Specifically, Fermi-liquid corrections to the vertex functions, which can be related to the collision integral for the Anderson impurity model, are calculated away from half-filling up to linear terms with respect to $\omega$, $\omega'$, and $eV$ at zero temperature $T=0$. Here, $\omega$ and $\omega'$ correspond to the energies of two interacting quasi-particles. The expansion coefficients are obtained by extending the recent developments [1,2], using the Ward-Takahashi identity for the Keldysh current vertex functions. We also discuss low-energy behavior of nonlinear current noise in the Fermi-liquid regime using the numerical renormalization group approach.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L51 DCMP: Optical Spectroscopy of 2D Materials Mile High Ballroom 1D -
Yunqiu (Kelly) Luo, Cornell University
Monolayer transition metal dichalcogenide (TMD) semiconductors have garnered interest due to their direct band gap, strong excitonic effects, and valley optical selection rules. Organic semiconductors also host strongly bound excitons and allow for broadly tunable emission energies. Together, heterointerfaces of a molecular semiconductor adsorbed on a monolayer TMD are characterized by interesting effects including enhanced Raman scattering. These Raman enhancements are poorly understood but are attributed to different charge transfer mechanisms [1], [2], [3]. Here, we study a system of monolayer 3,4,9,10-perylene tetracarboxylic dianhydride (PTCDA) on WSe₂, chosen for its type-II band alignment. We performed low temperature Raman and photoluminescence spectroscopy and observe a large enhancement of the PTCDA Raman signal compared to monolayer PTCDA on SiO₂. The behavior of this Raman scattering is explored through electrostatic doping of the TMD and excitation energy dependence. Control over the Raman enhancement would yield new understanding of the Raman enhancement phenomena in these systems.

**8:12AM L51.00002: Dark Excitons in Monolayers of Molybdenum based Transition Metal Dichalcogenide**  
CEDRIC ROBERT (Presenter), Institut National des Sciences Appliquees de Toulouse, PIOTR KAPUSCINSKI, Institute of Experimental Physics, Faculty of Physics, University of Warsaw, ALEX DELHOMME, LNCMI Grenoble, BO HAN, Institut National des Sciences Appliquees de Toulouse, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, BERNHARD URBASZEK, XAVIER MARIE, Institut National des Sciences Appliquees de Toulouse, CLEMENT FAUGERAS, MAREK POTEMSKI, LNCMI Grenoble — Excitons with binding energies of a few hundreds of meV drive the optical properties of Transition Metal Dichalcogenide (TMD) monolayers. One can expect that the optoelectronic properties will change drastically whether the spin-forbidden dark excitons lie below or above the bright excitons. This exciton fine structure splitting was accurately determined recently for WS2 and WSe2 monolayers using various experimental techniques [1-5]. In contrast the energy of the dark exciton in MoS2 ML has not been measured yet though this was the first member of the TMD family to be established as a direct gap semiconductor in the monolayer form. Here we have performed magneto-photoluminescence experiments on MoS2 monolayers encapsulated in hexagonal Boron Nitride (hBN) with a magnetic field oriented along the monolayer plane. The high quality of the investigated samples allowed us to determine accurately the bright-dark energy splitting. We have performed similar measurements for other MoX2 monolayers (X=Se or Te) encapsulated in hBN. The different contributions to the exciton fine structure will be discussed.

**8:24AM L51.00003: Effect of many-body interactions on the valley-selective optical Stark in WS2**  
PAUL CUNNINGHAM (Presenter), United States Naval Research Laboratory, AUBREY T. HANBICKI, Laboratory for Physical Sciences, University of Maryland, THOMAS L REINECKE, KATHLEEN M MCREARY, BEREND THOMAS JONKER, United States Naval Research Laboratory — Breaking the valley degeneracy in monolayer transition metal dichalcogenides through the valley-selective optical Stark effect can be exploited for quantum valleytronic operations such as coherent manipulation of valley superposition states. The strong light-matter interactions that give rise to the optical Stark effect have historically been described by a two-level dressed-atom model, which assumes non-interacting particles. While this model works well far from resonance where the Rabi frequency is larger than the exciton formation rate, here we show experimentally that it does not apply for excitation near resonance in monolayer WS2. Instead, our observations are well described by an excitonic model of the optical Stark effect that includes many-body Coulomb interactions. We observe a blue-shift due to the valley-selective optical Stark effect for excitation both below and above resonance, confirming the prediction from this theory that repulsion between virtual excitons dominates the light-matter interactions for photoexcitation detuned from resonance by less than the exciton binding energy. We expect our findings to be general to low-dimensional semiconductors that support bound excitons and other many-body Coulomb interactions.
8:36AM L51.00004: Direct Observation of Gate-Tunable Dark Trions in Monolayer WSe$_2$*

TIANMENG WANG (Presenter), ZHIPENG LI, Rensselaer Polytechnic Institute, ZHENGUANG LU, Natl High Magnetic Field Lab, MANDEEP KHATONIAR, The City College of New York, ZHEN LIAN, Rensselaer Polytechnic Institute, YUZE MENG, Nanjing University, MARK BLEI, Arizona State University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, STEPHEN A MCGILL, Natl High Magnetic Field Lab, SEFAATTIN TONGAY, Arizona State University, VINOD M MENON, The City College of New York, DMITRY SMIRNOV, Natl High Magnetic Field Lab, SUFEI SHI, Rensselaer Polytechnic Institute — Spin-forbidden intravalley dark excitons in tungsten-based transition-metal dichalcogenides (TMDCs) have attracted intense research interest. It has been discovered that tungsten-based TMDCs such as WSe$_2$ and WS$_2$ have a unique bandstructure, in which the spin-orbit coupling also induces the splitting of the conduction band. The resulted ground state of the exciton, however, is a spin-triplet state as the spin-forbidden dark exciton. We show that we can control the dark exciton electrostatically by dressing it with one free electron or free hole, forming the dark trions. The existence of the dark trions is suggested by the unique magneto-photoluminescence spectroscopy pattern of the monolayer WSe$_2$ device. And the existence of the dark trions is unambiguously demonstrated by directly resolving the radiation angle of the dark trions through back focal plane imaging. The dark trions possess binding energy of $\sim$15 meV, and inherit the long lifetime and large g-factor from the dark exciton. The dark trions open the door to new possibilities of valleytronics and excitonic applications.

*We thank Dr. Lei Shi and Shengnan Miao for helpful discussions. We acknowledge support from AFOSR, through Grant No. FA9550-18-1-0312. and support from ACS PRF, through Grant No. 59957-DNI10.

8:48AM L51.00005: Spin-allowed quantum emission from strain confinement in monolayer semiconductors

LEO YU (Presenter), MINDA DENG, JINGYUAN LINDA ZHANG, Stanford Univ, SVEN BORGHARDT, BEATA KARDYNAL, Peter Grünberg Institute, Forschungszentrum Jülich, JELENA VUCKOVIC, TONY F HEINZ, Stanford Univ — Here we demonstrate quantum emitter behavior from strained monolayer MoSe$_2$. Exciton confinement has been achieved using strain associated with causing the monolayer to conform to a nanoscale indentation prepared in the substrate. By sufficiently reducing the lateral scale of the confinement, we have achieved single quantum emitter behavior, with the A exciton feature showing a drop in linewidth to below 0.2 meV at cryogenic temperatures, in an emission 70-meV redshifted from the bulk A exciton feature of the unstrained monolayer. The quantum emitter characteristics of these confined excitons has been demonstrated directly by $g(2)$ measurements. Unlike recent demonstrations of quantum emitters in monolayer WSe$_2$, the exciton involved for our MoSe$_2$ samples has a spin aligned configuration. This was demonstrated by Zeeman measurements indicating a g factor of 4, and was also reflected in the relatively short, 0.2 ns measured photoluminescence lifetimes. Our approach has the potential for creating spin-allowed quantum emitters that can be arbitrarily located laterally and tuned by the engineered strain properties.
Propagation of excitons in TMDC monolayers with suppressed disorder
KOLOMAN WAGNER (Presenter), JONAS ZIPFEL, JONAS D. ZIEGLER, University of Regensburg, RAUL Perea causin, Roberto Rosati, Samuel Brem, Chalmers University of Technology, MARVIN KULIG, University of Regensburg, Takashi Taniguchi, Kenji Watanabe, National Institute for Material Science, Tsukuba, Ermin Malic, Chalmers University of Technology, Mikhail Glazov, Ioffe Institute Saint Petersburg, Alexey Chernikov, University of Regensburg — Coulomb-bound electron-hole pairs, or excitons, dominate the electro-optical properties in single layers of semiconducting transition metal dichalcogenides (TMDCs) and their heterostructures. In these 2D systems, excitons can move freely across large distances. We study exciton propagation by directly monitoring their spatial behavior in single layers of TMDCs by spatially- and time-resolved photoluminescence microscopy. In high-quality boron nitride encapsulated samples with strongly suppressed disorder, we find very efficient diffusion at low excitation densities and a strongly non-linear behavior at high densities. Single layers of encapsulated TMDCs provide a highly promising platform to explore exciton transport phenomena, including low-temperature conditions with suppressed phonon-scattering and manipulation of spin-valley polarized excitations.

9:24AM L51.00008: Polarizability of finite-bandwidth two-dimensional electron gas  KAVEH KHALIJ (Presenter), University of Minnesota, TOBIAS STAUBER, ICMM, CSIC, Madrid, TONY LOW, University of Minnesota — The two-dimensional electron gas (2DEG), characterized by its parabolic electron energy dispersion, has been the subject of intense research for more than half a century. The main fuel to this interest has been its simplicity and physical relevance to describe the low energy behavior of most known 2D electronic systems, up to a point where any deviation from a 2DEG behavior (such as what was observed in graphene) has been pinpointed as anomalous and receives extra attention. Following this, here, we ask what would happen to the polarizability if we restrict the parabolic energy dispersion to a finite bandwidth (FBW), for which the 2DEG behavior would then be a natural limit (i.e. allowing for the bandwidth to be infinite). We discuss the polarizability of the FBW-2DEG, in dynamical and static limits, as the key physical quantity to obtain elementary excitation spectra, collective modes, charged impurity-limited transport properties, and spin-spin exchange interaction.

9:36AM L51.00009: Quasiparticle and optical properties of monolayer C$_3$N*  ZHAO TANG (Presenter), WEIYI XIA, State Univ of NY - Buffalo, YABEI WU, WENQING ZHANG, Department of Physics, Southern University of Science and Technology, PEIHONG ZHANG, State Univ of NY - Buffalo — Highly ordered honeycomb structure carbon nitride (C$_3$N) is an emerging 2D material that has attracted much interest recently. The (indirect) band gap of this material has recently be predicted to be about 1.5 eV [1]. In this work, we present fully converged GW+BSE results for monolayer C$_3$N. The calculated the GW band gap of monolayer C$_3$N is about 1.5 eV, an ideal value for electronics applications. Detailed investigations of the band-edge electronic states suggest a strong band edge absorption. Our fully converged GW+BSE calculation predicts an optical gap about 1.9 eV, with an excitonic binding energy of 0.7 eV.

Hyperbolic plasmon polaritons are uncommon light-matter modes in materials at the extreme of anisotropy — where metallic and dielectric characters coexist along different crystallographic directions. Using Kramers-Kronig analysis and finite-difference time-domain simulations, we have identified a new quasi-two-dimensional material, palladium cobaltate ($\text{PdCoO}_2$), that is expected to support low-loss hyperbolic plasmon polaritons at infrared frequencies. Simulations are consistent with the polariton dispersion calculated from the complex reflection coefficient. The large optical anisotropy can be recognized by the order of magnitude difference between the in-plane and out-of-plane plasma frequencies. Scanning near-field optical microscopy can be used to study these light-matter modes. However, because hyperbolic polaritons travel inside the material and reflect off the surfaces, observing them requires a thin layer (50-150 nm) of $\text{PdCoO}_2$ with smooth surfaces. This presents a challenge to an experimental demonstration of hyperbolic modes in $\text{PdCoO}_2$ since the material does not exfoliate readily from flux-grown single crystals and forms twin domains in films grown by molecular beam epitaxy. Efforts to isolate flat, thin flakes of $\text{PdCoO}_2$ for near-field measurements will be presented.

Directional shift current and dipole selection rules in the layered semiconductor $\text{BC}_2\text{N}^*$

We study the shift-current optical response in a noncentrosymmetric polytype of the quasi-2D layered semiconductor $\text{BC}_2\text{N}$ [1]. Employing a recently developed first-principles Wannier-interpolation technique [2] implemented in the latest release of Wannier90 [3], we find that the photoconductivity exhibits two distinctive features at the band edge. First, it ranks among the largest bulk nonlinear responses reported to date, and peaks in an energy range suitable for optical manipulation. Secondly, it is strongly anisotropic, due to the vanishing of particular tensor components not foretold by phenomenological symmetry arguments; this is a consequence of dipole selection rules imposed by mirror symmetry, which imply that the relative parities between valence and conduction bands are key for determining the directionality of the band-edge response. The implications of the dipole selection rules should apply to a broad class of nonlinear responses.

10:12AM L51.00012: First-principles calculations for high-harmonic generation in two-dimensional materials: from single atomic layer to thin films* SHUNSUKE YAMADA (Presenter), KAZUHIRO YABANA, Center for computational sciences, University of Tsukuba — We present first-principles studies on high-harmonic generation (HHG) in thin materials using the time-dependent density functional theory (TDDFT). HHG in reflected and transmitted waves from a thin film exposed to intense light pulses is modulated from the bulk optical response by light propagation effect and surface effect. We have developed a real-time simulation method combining the time-dependent Kohn-Sham and the Maxwell equations for describing the microscopic dynamics of electrons and electromagnetic field in a thin film. This method can take into account both the propagation and surface effects. Using our method, we investigate the dependencies of HHG on the light intensity, polarization, and film thickness for semiconductor films. We discuss the mechanism of HHG signal growth in reflected and transmitted waves.

*This research was supported by JST-CREST under grant number JP-MJCR16N5.

10:24AM L51.00013: Quasiparticle and optical properties of hexagonal boron nitride: from monolayer to bulk* WEIYI XIA (Presenter), State Univ of NY - Buffalo, WEIWEI GAO, University of Texas at Austin, PEIHONG ZHANG, State Univ of NY - Buffalo — Hexagonal boron nitride (h-BN), an emerging building block for van der Waals heterostructures, has become a research focus in recent years. Interesting, some of the most fundamental aspects of this material are still not fully understood. For example, there are still debates on whether the fundamental band gap is direct or indirect, for both monolayer and bulk h-BN. To the best of our knowledge, the quasiparticle band gap of few-layer h-BN has not been accurately determined. In this talk, we will present fully converged GW+BSE results for monolayer, bilayer and bulk h-BN, aiming to resolve some of the controversies and illustrate the effects of dielectric screening and interlayer interaction on the quasiparticle and optical properties of this material.

*This work is supported in part by the NSF (Grant Nos. DMR-1506669 and DMR-1626967).

10:36AM L51.00014: Optical Absorption and Emission of Two-Dimensional Tetracene Crystals SEONGHYUN KOO (Presenter), SUNMIN RYU, Pohang Univ of Sci & Tech — Organic crystals have received much attention because of their unique properties different from inorganic crystals such as mechanical flexibility and high quantum yield of luminescence. Although various organic solids are used in many industrial applications, the electronic structures of low-dimensional forms are far from being understood not only because their van der Waals interactions between molecules are intractable but also because it has been a challenge to prepare such crystalline systems with sufficient stability. In this work, we present absorption and emission spectroscopy on single and few-layer tetracene (Tc) layers sandwiched between two-dimensional (2D) inorganic crystals including graphene and hexagonal BN. Tc deposited by thermal evaporation formed flat films with thickness of multiples of its minimum (~1.3 nm) and long-range order confirmed by polarized spectroscopy. Vibrational progressions and Davydov splitting observed in the absorption and emission spectra revealed significant deviation from their bulk counterparts, which suggests distinctive crystalline structures and dielectric environments of 2D Tc. We will also discuss structural details and excitonic dynamics probed by time-resolved spectroscopy.
**10:48AM L51.00015: Low efficiency of the exciton-phonon scattering involving large momentum transfer in 2D-TMDC**  HANZ YECID RAMÍREZ (Presenter), School of Physics, Universidad Pedagógica y Tecnológica de Colombia (UPTC) — Atomically thin transition metal dichalcogenide sheets are among the most promising systems for efficiently controlled emission of quantum light. However, like in all solid-state based emitters, temperature is a critical parameter to have into account, because of the ever present decoherence induced by phonons. In this theoretical work, the effects of the transferred momentum on the exciton-phonon interaction is studied. As a main result, the inefficiency of this coupling for scattering involving large phonon momentum is found, as consequence of the localization of the exciton wave function in the reciprocal space. This feature may favor robustness of the high quality optical activity of these low dimensional systems, along significant temperature ranges.

*This work was funded by the Research Division of Universidad Pedagógica y Tecnológica de Colombia, and the Ministry of Science and Technology of Taiwan.

**8:00AM L52.00001: A novel surface reconstruction of the TiO₂ Anatase (001) surface from machine learning**  MAXIMILIAN AMSLER (Presenter), ULRICH ASCHAUER, University of Bern — Surfaces of semiconductors often exhibit reconstructions that can significantly influence their physical and chemical properties. Especially for catalysts, studying the surface structures at the atomic scale is crucial to gain a better understanding of the catalytic activity and, ultimately, to design improved materials. Atomistic simulations can provide insight, but *ab initio* structure predictions are rather challenging due to the large supercells required to model 2D surfaces. To alleviate this issue, we use a machine-learned interatomic potential trained on DFT data in conjunction with a sophisticated structure prediction method to explore low-energy reconstructions of the TiO₂ Anatase (001) surface. We identify a new surface reconstruction that is comparable in energy with the well-known (001)-1x4 ad-molecule model and could explain the recently discovered experimental structures from STM imaging.
8:12AM L52.00002: Theoretical investigation of the GaN (0001) surface reconstruction

FATIMA ALQUAITI (Presenter), ALEXANDER DEMKOV, University of Texas at Austin — Using density functional theory we study the surface reconstruction of GaN (0001). We compare energetics of the 2x2 and root 3 by root 3 R30 GaN (0001) surface structures and find them to be energetically equivalent. In addition, we systematically compare the results found when using the local density approximation and the generalized gradient approximation. We also consider Ga and La ad-atoms on Ga (0001), and determine the corresponding potential energy surfaces and diffusion rates and compare them with those previously computed for Eu, Ce, and Gd. In addition, similarly to the cases of Eu, Ce, and Gd, the La ad-atom exchange with a surface Ga atom is found energetically favorable and with a much smaller barrier of 0.15 eV. This may indicate a path to forming intermetallic LaGa$_2$ through the surface exchange reaction.

*The work at the University of Texas at Austin is supported by the National Science Foundation under grant DMR-1507970.

8:24AM L52.00003: Two-dimensional overlayers of Au and Ag on the Ge(111) surface: insights from first-principles calculations

SHREE RAM ACHARYA (Presenter), Physics, Univ of Central Florida, SHIRLEY CHIANG, Physics, University of California, Davis, TALAT S. RAHMAN, Physics, Univ of Central Florida — Experimental observations using low-energy electron microscopy (LEEM) of Au overlayers on the Ge(111) surface have revealed two-dimensional Ge(111)-Au(√3×√3)R30° structure as the only ordered structure being irrespective of Au coverage and sample temperature [1] while Ag overlayers form a number of structures on the same range of coverages and temperatures [2]. The charge density distribution analysis is performed using the density functional theory to see the variation in binding of Ag and Au on the Ge surface taking the thermodynamically stable √3 structures which shows that the Au atoms form strong covalent bond with Ge atoms (height = 0.56 Å) than bond between Ge atoms whereas the Ag atoms does not share charge with the Ge atoms indicating that they are trapped at height 0.73 Å inside the cage of the strong Ge-Ge bond. We will compare the electronic and vibrational structures of additional overlayer structures and strain on those systems to trace the reason behind such a difference in observed structures.

8:36AM L52.00004: 3D atomic mapping of rutile-TiO2(110) supported Vanadium oxide catalyst using X-ray Standing Wave excited XPS*  
ANUSHEELA DAS (Presenter), YANNA CHEN, Northwestern University, TIEN-LIN LEE, Diamond Light Source Limited is United Kingdom's national synchrotron and is a leading scientific facility in the world. They host facilities supporting cutting edge research, KVLV NARAYANACHARI, MICHAEL J BEDZYK, Northwestern University — XSW excited XPS was used to study atomic-scale structure of 1/2 monolayer vanadium oxide catalyst supported on rutile TiO2(110) single crystal. The experiments were performed at I09 beamline at the Diamond Light Source. Collecting V 2p, O 1s and Ti 2p XPS signals as we scanned across a Bragg peak at different stages of a redox reaction allowed tracking of surface sites for chemically distinct V atoms, important for understanding their catalytic behaviour. V5+ and V4+ 2p XPS peaks were found to be separated by 1.4 eV and were found to have different XSW coherent fraction and position. Summation of these Fourier components for 5 symmetry inequivalent hkl Bragg peaks generates a chemical state sensitive 3D atomic map of vanadium. These results give us unique insights into this as well as other related oxide supported catalysts.

8:48AM L52.00005: Combinatorial Synthesis of a New II-IV-N2: MgSnN2*  
ANN GREENAWAY (Presenter), AMANDA L LOUTrIS, KAREN HEINSELMAN, National Renewable Energy Laboratory, CELESTE MELAMED, REKHA SCHNEPF, Colorado School of Mines, MARSHALL TELLEKAMP, National Renewable Energy Laboratory, RACHEL WOODS-ROBINSON, University of California, Berkeley, RACHEL SHERBONDY, Colorado School of Mines, DYLAN BARDGETT, STEPHAN LANY, STEVEN CHRISTENSEN, ADELE TAMBOLI, National Renewable Energy Laboratory — Nitrides with novel compositions are an emerging research topic in basic energy science, with applications in optoelectronics, catalysis, and magnetism. Ternary semiconductors are underexplored and have unique properties, such as transitions between cation ordered and disordered structures, which may be exploited to modify properties in a single composition. We demonstrate combinatorial co-sputtering of a new II-IV-N2, MgSnN2, in a phase-pure wurtzite structure across a range of cation compositions and from 200 to 400 °C. Below 200 °C, a metastable rocksalt phase is observed which is a potential wide bandgap, high dielectric constant material. Ellipsometry reveals an optical absorption onset at ~2 eV for the wurtzite phase, suggesting tuning via cation disorder from the predicted bandgap of 2.5 eV; disorder is confirmed by synchrotron x-ray diffraction. Finally, we demonstrate epitaxial growth via combinatorial co-sputtering on GaN. Based on this work, MgSnN2 is a target for fundamental exploration of novel nitride properties as well as a candidate for future device applications.

*Work funded by a Director’s Postdoctoral Research Fellowship (LDRD) at NREL and by the Office of Science, Basic Energy Sciences, Material Sciences and Engineering Division.
9:00AM L52.00006: Temperature-Dependent Spectroscopy of Rutile Tin Dioxide*  
HAWAZIN ALGHAMDI (Presenter), Physics Department, Howard University, BENJAMIN CONCEPCION, Physics Department, George Mason University, SUGATA CHOWDHURY, PRABHAKAR MISRA, Physics Department, Howard University — The present spectroscopic investigation focuses on rutile tin dioxide (SnO₂) in powder form. Raman spectroscopy with laser excitation at 780 nm has been used to characterize the different vibrational modes of SnO₂. Thermal effects on the vibrational features in the Raman spectrum have been studied in the range 30 – 170 °C. We have demonstrated a red-shift in the Raman spectra as the temperature increases for both A₁g (634 cm⁻¹) and B₂g (775 cm⁻¹), while E₉ (475 cm⁻¹) exhibited little change. FT-IR spectra have been obtained in order to study the IR-active vibrational modes for tin dioxide: Sn-O stretching vibration at 467.36 cm⁻¹ and Sn-O-Sn asymmetric vibration at 569.37 cm⁻¹. X-ray diffraction (XRD) spectra have been recorded to confirm the rutile structure of tin dioxide. Scanning Electron Microscope (SEM) images have provided information regarding the size of the spherical grain particles. Molecular Dynamic simulation (MD) has been utilized to study the various vibrational modes at different temperatures using the LAMMPS software.

*Financial support from the REU Site in Physics at Howard University (NSF Award# PHY-1659224) is gratefully acknowledged.

9:12AM L52.00007: First-Principles Theory for Schottky Barrier Height*  
DMITRY SKACHKOV (Presenter), XIAOGUANG ZHANG, HAI-PING CHENG, University of Florida — The physics of Schottky contact is very challenging and there are exist only simple empirical models for Schottky barrier. In current work we are developing the first-principles theory for the Schottky barrier height. Our method based on density functional theory and consists of calculation of evanescent states in the gap of the semiconductor based on complex band structure of the semiconductor surface, following by calculation of the induced charge in the bulk of semiconductor. Next we find iteratively an equilibrium between the induced charge and the electrostatic potential. The method is tested on the GaAs(111) – graphene system.

*US Department of Energy Basic Energy Sciences Energy Frontier Research Centers under Grant No. DE-SC0019330
**9:24AM L52.00008: Targeted High-Throughput Growth and Automated Phase Mapping of the Novel Semiconductor Zn$_2$SbN$_3$ Using the Analysis Package COMBItgor**

ALLISON MIS (Presenter), Colorado School of Mines, ELISABETTA ARCA, Lawrence Berkeley National Laboratory, GEOFF BRENNECKA, Colorado School of Mines, ADELE TAMBOLI, National Renewable Energy Laboratory — High-throughput materials discovery has boomed in the past decade through the pairing of combinatorial growth methods and automated characterization routines. However, much of the data collected must still be processed manually, creating a bottleneck, notably for phase identification and phase space mapping. In this work, we will present semi-automated phase identification and targeted sputter growth of the novel semiconducting material Zn$_2$SbN$_3$, to date the only reported crystalline antimony nitride in which Sb functions as a cation with a positive oxidation state. This ternary nitride has a predicted effective electron mass of (0.15-0.19m$_e$) and direct band gap of 1.7 eV that may be tunable with cation disorder. X-ray diffraction patterns were run through an automated fitting routine, the fit parameters of which were fed into routines for the creation of phase maps, tracking thin-film texturing, and directed growth through the use of fit variables as proxies for properties like optical absorption. This work will present an expanded understanding of this unique and promising material as well as a widely-applicable add-on to the free, open-source data handling and analysis package COMBItgor.

*Funding provided by the CoorsTek Fellowship program.

**9:36AM L52.00009: Transition-metal nitride semiconductors**

BAIWEI WANG (Presenter), Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, POOMIRAT NAWARAT, KIM LEWIS, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, PANOS PATSALAS, Department of Physics, Aristotle University of Thessaloniki, DANIEL GALL, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — Semiconducting transition-metal nitride alloys emerge as a new category of semiconductors that are stable in hostile environments and are compatible with conventional semiconductor device processing. We report on the epitaxial growth and the electrical and optical properties of Ti$_{1-x}$Mg$_x$N, Ti$_{1-x}$Mg$_x$C$_{0.2}$N$_{0.8}$, and (Ti$_{0.5}$Mg$_{0.5}$)$_{1-x}$Al$_x$N on MgO(001) and (Ti$_{1-x}$Mg$_x$)$_{0.25}$Al$_{0.75}$N on Al$_2$O$_3$(0001). X-ray diffraction reciprocal space mapping is used to quantify composition dependent lattice parameters and critical thicknesses for strain relaxation. Ti$_{0.5}$Mg$_{0.5}$N is a new semiconductor with a bandgap of 0.7-1.7 eV. Reducing the Mg-content in Ti$_{1-x}$Mg$_x$N to $x < 0.5$ leads to a tunable plasmonic response that extends from infrared to visible (930 - 470 nm). The substitutional addition of Al and C on anion and cation sites, respectively, reduces the free carrier density: (Ti$_{0.5}$Mg$_{0.5}$)$_{1-x}$Al$_x$N layers show a negligible density of states at the Fermi level and a blue-shift of the absorption edge from 1.8 to 2.1 eV for $x = 0 - 0.4$. Ti$_{1-x}$Mg$_x$C$_{0.2}$N$_{0.8}$ exhibits a metal to semiconductor to insulator transition as $x$ increases from 0.3 to 0.4 to 0.5. Wurtzite-structure (Ti$_{1-x}$Mg$_x$)$_{0.25}$Al$_{0.75}$N(0001) layers have a measured bandgap that increases from 5.1 to 5.2 to 5.9 eV for $x = 0.0, 0.5$ and $1.0$. 
9:48AM L52.00010: Unpinning the relationship between pinning factor and electronegativity by calculating Schottky barrier heights from first principles* NICOLE HALL (Presenter), ISMAILA DABO, Pennsylvania State University — We calculate the Schottky barriers that develop at the interface between a metal and semiconductor. These barriers govern the current-rectification ability of Schottky diodes and the electrical response of metal-semiconductor field effect transistors. A model that accounts for the alignment of the electronic levels across the metal-semiconductor interface and the long-range polarization within the space charge region enables us to predict the heights of the barriers as a function of the electronic offsets, including the effects of charge trapping and Fermi-level pinning. We validate our computational predictions against experimental measurements [1], providing a detailed understanding of trends in the pinning factor, i.e., the change in the Schottky barrier height as a function of the metal work function. The resulting model provides a comprehensive first-principles approach to simulate the characteristics of semiconductor-metal junctions under bias.

*The authors acknowledge support from NSF (grant number DMR-1654625), the Computational Materials Education and Training (CoMET) program (grant number DGE-1449785), and the Pennsylvania State University's Institute for CyberScience Advanced CyberInfrastructure (ICS-ACI).

10:00AM L52.00011: Ultrafast Electron Diffraction of Monoclinic GaTe and the Dynamic Breaking of Friedel's Law* QINGKAI QIAN (Presenter), Department of Electrical Engineering, The Pennsylvania State University, University Park, PA 16802, United States, XIAOZHE SHEN, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA, LANXIN JIA, School of Physics, Nanjing University, Nanjing 210046, China, RENKAI LI, JIE YANG, DUAN LUO, XIJIE WANG, SLAC National Accelerator Laboratory, Menlo Park, CA 94025, USA, SHENGXI HUANG, Department of Electrical Engineering, The Pennsylvania State University, University Park, PA 16802, United States — GaTe is a low-symmetry layered materials with strong anisotropy, which has been widely studied in recent years. Various applications, such as photodetectors, nonlinear optics and thermoelectric devices, have been demonstrated based on GaTe. Here the electron-phonon coupling and the lattice dynamics of GaTe are studied by ultrafast electron diffraction (UED). Besides the Debye-Waller effect caused by the incoherent electron-phonon coupling, we observed a coherent breathing phonon mode in GaTe. Different from the LA breathing modes of high-symmetry 2D materials, the displacement direction of the LA breathing phonon modes in GaTe has deviated incommensurately from the stacking lattices. In-phase and out-of-phase oscillations of diffraction intensities are observed for each Friedel pairs, which in fact break the Friedel's law dynamically. This dynamic breaking of Friedel's law can be explained by the wobbling of the crystal lattice and the Ewald sphere, and the related study can be used as a reference for UED characterization of other low-symmetry thin films.

*The UED work was conducted at SLAC MeV- UED, which is supported in part by the DOE BES SUF Division Accelerator & Detector R&D program, the LCLS Facility, and SLAC under contract Nos. DE-AC02-05-CH11231 and DE-AC02-76SF00515.
Temperature dependent X-ray studies of negative thermal expansion (NTE) ScF$_3$ thin films under strain

AMANI JAYAKODY (Presenter), ZHIWEI ZHANG, Univ of Connecticut - Storrs, ZHIHAI ZHU, Massachusetts Institute of Technology, HOPE R WHITELOCK, University of Colorado, JOSEPH I BUDNICK, JASON N HANCOCK, BARRETT O WELLS, Univ of Connecticut - Storrs —

Bulk Scandium trifluoride (ScF$_3$) is known for a pronounced negative thermal expansion (NTE) over a wide range of temperature, from 10 K to 1100 K. The structure of ScF$_3$ can be described as an ABX$_3$ perovskite with an empty A-site. Growing films of ScF$_3$ allows for tuning the lattice constant, the thermal expansion, and the construction of devices based upon differential thermal expansion. We have investigated the growth of ScF$_3$ films on oxide and fluoride substrates using pulsed laser deposition (PLD). We have found growth routes for producing films with very good epitaxy and stability. Curiously, diffraction studies show narrow Bragg peaks along the principal crystallographic directions but substantial broadening for peaks along other directions, presumably associated with accommodating drastic differentials in thermal expansion. This report describes the temperature dependent X-ray studies of epitaxial NTE ScF$_3$ thin films grown epitaxially on a strongly positive thermal expansion (PTE) substrate.

A revised three-dimensional electron gas model to describe surface plasmonic phenomena*

JIANTAO KONG (Presenter), Rutgers University, Camden — The long wavelength limit negative slope of the surface plasmon dispersion curve (for simple metals such as alkali) has been experimentally [1] and theoretically [2] investigated for a long time. Yet there is no universally accepted theory. On the other hand, the traditional 3D electron gas model such as Lindhard function [3] is successful in explaining many bulk properties, but not much attempt in literature has been made to account for the surface effects. We worked on the traditional 3D electron gas model, modifying the electron self-energy [4] with a correction due solely to surface, and produced the negative slope naturally from simple calculation. In other words, a revised 3D electron gas model can predict and describe surface plasmonic phenomena by itself.

*This work has been supported by the new faculty start-up fund of Rutgers, the State University of New Jersey, Camden.
L52.00014: Low energy excitons in GaN film under strong magnetic fields  YI WANG, School of Physics, Peking University, LIUYUN YANG, XINQIANG WANG, State Key Laboratory of Artificial Microstructure and Mesoscopic Physics, School of Physics, Peking University, CHANGLI YANG, Daniel Chee Tsui Laboratory, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, CAS, CHI ZHANG (Presenter), SKLSM, Institute of Semiconductors, CAS — We investigate magneto- far-infrared (FIR) transmission on a 100 μm thick GaN film, which is grown on a Si/HR-GaN substrate. Under zero magnetic (B) fields, we observe three absorption peaks, which are located at the energy of 30.6 meV (Peak I), 34.7 meV (II), and 40.0 meV (III), respectively. Under perpendicular B-fields, small energy shifts of the three absorption peaks (I, II, III) are all linear to B. Meanwhile, peak II splits into two distinct peaks, with a distance about 0.08 meV/T in between. And three distinct splits are observed around Peak III with a distance of about 0.11 meV/T between neighbor peaks. We propose that the patterns of the absorption can be attributed to the low energy excitons in GaN under strong magnetic fields.

Session L53 DMP DCOMP: 2D Semiconductors: Magnetism Mile High Ballroom

1F - Rui He, Texas Tech Univ - Tag(s): Focus

8:00AM L53.00001: Stacking dependent 2D magnetism [Invited] SHIWEI WU (Presenter), Fudan Univ — In van der Waals layered materials, the symmetries and functionalities could be controlled by modifying the stacking order through rotation and translation between the layers. Whereas most previous work has focused on the electronic and optical properties associated with the van der Waals stacking, the recent discovery of magnetism in 2D materials, achieved through both mechanical exfoliation and molecular beam epitaxy (MBE), provides an exciting opportunity to explore the effects of stacking order on a material's magnetic properties. In this talk, I will present two of our recent studies in this direction. 1) By discovering a giant nonreciprocal second harmonic generation from layered antiferromagnetism in mechanically exfoliated bilayer CrI3, we revealed the underlying C2h symmetry, and thus monoclinic stacking order in bilayer CrI3, providing crucial structural information for the microscopic origin of layered antiferromagnetism. 2) By using the molecular beam epitaxy to grow monolayer and bilayer CrBr3 and in situ characterization with a spin-polarized scanning tunneling microscopy and spectroscopy, we observed that while individual CrBr3 monolayer is ferromagnetic, the interlayer coupling in bilayer depends strongly on the stacking structure and can be either ferromagnetic or antiferromagnetic. Thus, the direct correlation between stacking order and interlayer magnetism pave the way for manipulating 2D magnetism.
8:36AM L53.00002: Electronic properties of magnetically ordered topological semimetals.*
[Invited] ADAM KAMINSKI (Presenter), Physics and Astronomy, Iowa State University — Magnetic topological semimetals are new and exciting field of research. In this talks we will present ARPES studies of several magentically ordered topological systems, where magnetic ordering allows to tune and control the topological features leading to observation of novel groundstates.

*Ames Laboratory is operated for the U.S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358. Research was partially supported by CEM, a NSF MRSEC, under Grant No. DMR-1420451.

9:12AM L53.00003: Probing magnetic orders and stacking patterns in bilayer CrI$_3$ by theoretical Raman scattering LIANGBO LIANG (Presenter), Oak Ridge National Lab — Chromium triiodide (CrI$_3$), a 2D van der Waals magnet, has been extensively studied due to its fascinating properties. Within each layer spins are ferromagnetically coupled with strong out-of-plane anisotropy, but between layers the spin ordering can be manipulated between ferromagnetic (FM) and antiferromagnetic (AFM) ordering by numerous ways, such as stacking pattern and applied electric/magnetic field. For bilayer CrI$_3$, the interlayer spin ordering is closely connected to the stacking configuration, such as the common hombohedral and monoclinic patterns. Using density functional theory, I carried out a systematic study on a variety of possible stacking patterns in bilayer CrI$_3$, where for each stacking both interlayer FM and AFM spin orders were considered. The calculations found that different stacking patterns and magnetic orderings lead to different symmetries and interlayer coupling strengths, which can alter Raman optical selection rules, phonon frequencies, and Raman intensities. This highlights the intricate interactions between stackings, spins, and phonons in 2D magnets. I will present a Raman spectra map of bilayer CrI$_3$ with different stacking patterns and spin orderings under both linearly and circularly polarized light for guiding experimental identification.
**9:24AM L53.00004: Imaging domains and defects in the stacking of few-layer and twisted CrI$_3$**

ARIANA RAY (Presenter), Physics, Cornell University, YU-TSUN SHAO, YANG XU, NIHIL SIVADAS, TINGXIN LI, ZEFANG WANG, Applied and Engineering Physics, Cornell University, JIE SHAN, Physics, Cornell University, KIN FAI MAK, DAVID ANTHONY MULLER, Applied and Engineering Physics, Cornell University — Different lateral shifts of the stacked monolayers in CrI$_3$ lead to different magnetic ground states, with a rhombohedral-symmetry stacking resulting in ferromagnetic layer ordering, and a monoclinic-symmetry stacking leading to antiferromagnetic layer ordering. Here we explore the structural arrangements found as the CrI$_3$ thickness is systematically reduced to the monolayer limit using 4D-STEM electron diffraction and atomic resolution imaging. We find that CrI$_3$ flakes from bilayer to 50 nanometer thickness remain in a monoclinic stacking when cooled to 95 K. However, the monoclinic group allows for multiple variants -- arising from 120 degree stacking rotations both in-layer and between neighboring CrI$_3$ layers -- and we observe a rich assortment of stacking orders and domains, as well as moirés. We show that these stacking rotations can change as a function of temperature. The observed vertical superposition of monoclinic variants in few-layer to bulk CrI$_3$ flakes may present as an overall three-fold symmetry to macroscopic-averaged measurement, but can be recognized by atomic resolution imaging.

**9:36AM L53.00005: Raman spectroscopy studies of spin-lattice coupling in bilayer CrI$_3$**

WENCAN JIN (Presenter), University of Michigan, HYUN HO KIM, University of Waterloo, ZHIPENG YE, GAIHUA YE, Texas Tech University, BOWEN YANG, University of Waterloo, SHANGJIE TIAN, HECHANG LEI, Renmin University of China, ADAM TSEN, University of Waterloo, RUI HE, Texas Tech University, LIUYAN ZHAO, University of Michigan — CrI$_3$ has been shown to be a layered antiferromagnet in its few-layer form. Upon the application of a moderate out-of-plane magnetic field, the layered antiferromagnetic state can be switched to a fully spin-polarized state. Among the few-layer CrI$_3$ system, bilayer CrI$_3$ is of particular interest because the coupling between its crystal structure and magnetic ordering can give rise to unique magneto-optical effects such as magnetic circular dichroism, nonreciprocal second harmonic generation, and deviation of Raman selection rules. In this talk, we will present Raman spectroscopic evidence of spin-lattice coupling in bilayer CrI$_3$. We will show that spin-lattice coupling in bilayer CrI$_3$ manifests itself in both first-order and higher-order Raman modes. The results of temperature and magnetic field dependence measurements will be discussed.

9:48AM L53.00006: Topological spin waves in 2D CrI$_3$: an itinerant fermion description*  
ANTONIO COSTA, International Iberian Nanotechnology Laboratory (INL), DANIEL LR SANTOS, CEFEDET, NUNO PERES, JOAQUIN FERNANDEZ-ROSSIER (Presenter), International Iberian Nanotechnology Laboratory (INL) — We present a theory of spin waves in ferromagnetic CrI$_3$ monolayers based on the calculation of the renormalized spin susceptibility, computed using an extended multi-orbital Hubbard model obtained from first-principles calculations. Our theory includes the multi-orbital nature of Cr and I atoms, as well as their spin orbit coupling and yield the spin waves as poles from the spin susceptibility tensor. For monolayers, theory reproduces the spin wave dispersion measured with inelastic neutron scattering, with a gap at the Dirac point compatible with a topological origin. We have computed the spin waves for a ribbon and find in-gap chiral edge states that provide further back-up to this scenario. Importantly, our approach goes does not require to define spin Hamiltonian, and can be applied to a wide class of magnetic 2D materials.

*JFR acknowledges funding from FCT UTAPEX/NTec/0046/2017

10:00AM L53.00007: Magneto-optical properties of CrI$_3$, CrBr$_3$ and CrCl$_3$ monolayers: chemical trends and excitonic effects*  
ALEJANDRO MOLINA-SANCHEZ (Presenter), GONÇALO CATARINA, International Iberian Nanotechnology Laboratory, DAVIDE SANGALLI, Istituto di Struttra della materia (ISM), CNR, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory — Chromium trihalides (CrI$_3$, CrBr$_3$ and CrCl$_3$) are a prominent family of isostructural insulating layered materials in which ferromagnetic order has been observed down to the monolayer. Here we provide a comprehensive computational study of the magneto-optical properties useful to probe ferromagnetic order of monolayers, magnetic circular dichroism and magneto-optic Kerr effect. We combine density functional theory calculations and many-body perturbation theory. We solve the Bethe-Salpeter to obtain the excitonic states and to calculate the optical absorption and Kerr angle spectra. We compare the magneto-optical response of the chromium trihalides series. We find strong excitonic effects on the optical response. Moreover, the Kerr angle spectrum is governed by the spin-orbit coupling of the ligand atoms (I, Br or Cl) and is a fingerprint of the degree of magnetic anisotropy of these compounds.

10:12AM L53.00008: Evidence of the polaronic character of excitons in a two-dimensional ferromagnet* ZHIPENG YE (Presenter), GAIHUA YE, RUI HE, Texas Tech University, HYUN HO KIM, BOWEN YANG, ADAM TSEN, University of Waterloo, Canada, WENCAN JIN, JASON SHIH AN HORNG, HUI DENG, KAI SUN, LIUYAN ZHAO, University of Michigan — Studies of exciton dynamics in two-dimensional (2D) transition metal dichalcogenide (TMDC) semiconductors have led to discoveries of a variety of fascinating properties for optoelectronic applications. It has been known that exciton dynamics can be strongly affected by lattice vibrations through electron-phonon (e-ph) coupling. The recently discovered 2D ferromagnetic semiconductor, CrI$_3$, provides a new platform to explore exciton physics beyond the well-studied 2D TMDC semiconductors because of its localized orbitals, intrinsic long-range ferromagnetic order, and strong e-ph coupling. Here we use linear absorption spectroscopy to identify the exciton resonance transitions in bilayer CrI$_3$. We further use resonant micro-Raman spectroscopy to explore the electron-phonon coupling in bilayer CrI$_3$. Temperature and magnetic field dependence of e-ph coupling in bilayer CrI$_3$ will be discussed.

*Supported by NSF CAREER Grants No. DMR-1760668 and No. DMR-1749774.

10:24AM L53.00009: Switching 2D Magnetic States via Pressure Tuning of Layer Stacking TIANCHENG SONG (Presenter), ZAIYAO FEI, MATTHEW A YANKOWITZ, ZHONG LIN, QIANNI JIANG, KYLE HWANGBO, QI ZHANG, BOSONG SUN, University of Washington, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, MICHAEL MCGUIRE, Oak Ridge National Laboratory, DAVID E GRAF, National High Magnetic Field Laboratory, TING CAO, JIUN-HAW CHU, DAVID COBDEN, University of Washington, CORY DEAN, Columbia University, DI XIAO, Carnegie Mellon University, XIAODONG XU, University of Washington — The physical properties of two-dimensional van der Waals crystals can be sensitive to the interlayer coupling. For 2D magnets, theory suggests that the interlayer exchange coupling strongly depends on layer separation, while the stacking arrangement can even change the sign of the interlayer magnetic exchange, thus drastically modifying the ground state. Here, we demonstrate pressure tuning of magnetic order in the 2D magnet CrI$_3$. We probe the magnetic states using tunneling and scanning magnetic circular dichroism microscopy measurements. We find that the critical field for the spin-flip transition can be more than doubled by hydrostatic pressure. In bilayer CrI$_3$, pressure induces a transition from layered antiferromagnetic to ferromagnetic phases. In trilayer CrI$_3$, pressure can create coexisting domains of three phases, one ferromagnetic and two antiferromagnetic. The observed changes in magnetic order can be explained by changes in the stacking arrangement. Such coupling between stacking order and magnetism provides ample opportunities for designer magnetic phases and functionalities.
10:36AM L53.00010: Uncovering two-dimensional intrinsic ferromagnetism from host antiferromagnet via super-exchange interaction modulation*  FANG ZHANG (Presenter), Institute of Applied Physics and Materials Engineering, University of Macau, XINGQIANG SHI, Department of Physics, Southern University of Science and Technology of China, STEVEN LOUIE, Department of Physics, University of California, Berkeley, ZI KANG TANG, Institute of Applied Physics and Materials Engineering, University of Macau — Two-dimensional ferromagnetic semiconductors have been gaining great attention as they incorporate low-dimensionality, ferromagnetism and semiconductivity, which are promising for next-generation multifunctional spintronics. Here, we report an effective strategy to design ferromagnetic single crystals based on our previous extended super-exchange theory for polyvalent anion materials, e.g. CrOCl. We reveal that the magnetic order of one specific super-exchange cation-anion-cation path in CrOCl prototype is directly related to all anions' valence state. Choosing suitable anions (A_1=VIIA, A_2=VA element) in sites, all super-exchange paths are tuned into strongly ferromagnetic, leading to designed materials are intrinsic ferromagnets companied with high Curie temperatures. On the basis of the explored strategy and first-principles calculations, two stable monolayers CrIP and CrIAs are predicted to be ferromagnetic half-metal and semiconductor, respectively. The Curie temperature, estimated by Monte Carlo simulation using Heisenberg model, is as high as 1050 K and 655 K.

10:48AM L53.00011: Exotic magnetism in 2D Ni-based halides  SILVIA PICOZZI (Presenter), DANILA AMOROSO, PAOLO BARONE, CNR-SPIN, Consiglio Nazionale delle Ricerche — Driven by the increasing enthusiasm towards long-range magnetic order in two-dimensional materials (2D) (such as CrI3 and CrGeTe3), we carry out simulations based on density functional theory (DFT) for halides, focusing in particular on Ni-(VII)2 (VII = Cl, Br, I) monolayers. In addition to standard analysis of structural and electronic properties, we put special emphasis on the magnetic properties, in terms of magnetic moments, Heisenberg exchange coupling (including anisotropic and off-diagonal terms in the exchange tensor) and magnetic anisotropy energy. Moreover, starting from DFT results and mapping total energies on model spin Hamiltonians, we perform Monte-Carlo simulations to investigate the ground-state magnetic ordering and trends at finite temperatures and upon magnetic fields. Our predictions suggest a particularly rich phase diagram for Ni iodide and bromide monolayers, with exotic non-collinear spin configurations and complex topological transitions.

Wednesday, March 4, 2020 8:00 AM - 10:36 AM

Session L54 DCMP: Computational Studies of Topological Materials Mile
High Ballroom 2A
8:00AM L54.00001: Time-reversal-invariant Weyl semimetals indicated by symmetry indicators and invariants  
YUTING QIAN, JIACHENG GAO, Chinese Academy of Sciences, Institute of Physics, ZHIDA SONG, Department of Physics, Princeton University, SI-MIN NIE (Presenter), Department of Materials Science and Engineering, Stanford University, ZHIJUN WANG, HONGMING WENG, ZHONG FANG, Chinese Academy of Sciences, Institute of Physics — For the time-reversal(TR)-breaking centrosymmetric systems, an odd number of all the even/odd parity occupied bands, at eight inversion-symmetry-invariant (ISI) momenta, indicates the appearance of Weyl points in the systems. Here, based on the first-principles calculations and symmetry analysis, we demonstrate that, for the TR-preversing noncentrosymmetric systems with S4 symmetry, the Weyl semimetal phase can be characterised by the nonequality between an invariant \( \eta \) and an S4 indicator \( z_2 \). By applying it, we find that some candidates can be ideal Weyl semimetals in a noncentrosymmetric space group with S4 symmetry. Our first-principles calculations show that four pairs of Weyl points are located in the \( k_{x,y} = 0 \) planes, being right at the charge neutrality level. An effective model has been built and captures the nontrivial topology in these materials. Our strategy to find the Weyl points by using symmetry indicators and invariants opens a new route to search for Weyl semimetals in TR-invariant systems.

8:12AM L54.00002: Topological crystalline insulator: from symmetry indicators to material discovery  
TAY-RONG CHANG (Presenter), XIAOTING ZHOU, National Cheng Kung University, CHUANG-HAN HSU, VITOR MANUEL PEREIRA, National University of Singapore, ARUN BANSIL, Northeastern University, SYUYANG XU, Harvard University, HSIN LIN, Academia Sinica, LIANG FU, Massachusetts Institute of Technology — Topological crystalline insulators (TCIs) are insulating electronic phases of matter in which the nontrivial topology is driven by crystalline symmetries. Recent theoretical advances have proposed new rotational-symmetry-protected TCI states that are expected to show unique topologically protected boundary modes. The surface normal to the rotational axis in these TCIs features "unpinned" Dirac surface states whose Dirac points are located at generic \( k \) points. Also, due to the "higher-order" bulk-boundary correspondence, such a 3D TCI supports 1D helical edge states. However, to date, rotational-symmetry-protected TCIs have remained elusive in real materials. We systematically examine the topological properties of the TCI states in \( \text{Ca}_2\text{As} \). On both the top and side surfaces, we show the presence of topological surface states protected independently by rotational and mirror symmetries [1]. We also discuss the van der Waals material \( \alpha\text{-Bi}_4\text{Br}_4 \) and the pristine bulk bismuth and show that these materials harbor TCI states protected purely by rotation symmetry [2,3], even though these materials have been long thought to be topologically trivial.

Emergent dual topology in the three-dimensional Kane-Mele Pt$_2$HgSe$_3$

ANTIMO MARRAZZO, NICOLA MARZARI, École Polytechnique Fédérale de Lausanne, MARCO GIBERTINI (Presenter), Department of Quantum Matter Physics, University of Geneva — Recently, the very first large-gap Kane-Mele quantum spin Hall insulator was predicted to be monolayer jacutingaite (Pt$_2$HgSe$_3$), a naturally-occurring exfoliable mineral. The stacking of quantum spin Hall monolayers typically leads to a (0;001) weak topological phase, which does not protect the existence of surface states on the (001) surface. Unexpectedly, recent ARPES experiments revealed the presence of surface states dispersing over large areas of the 001-surface Brillouin zone. Such 001-surface states have been shown to be topologically protected by a non-zero mirror Chern number, associated with a nodal line gapped by spin-orbit interactions. Here, we extend the two-dimensional Kane-Mele model to bulk jacutingaite and unveil the microscopic origin of the gapped nodal line and the emerging crystalline topological order. By using maximally-localized Wannier functions, we identify a large non-trivial second nearest-layer hopping term that breaks the standard paradigm of weak topological insulators. Complemented by this term, the predictions of the Kane-Mele model are in remarkable agreement with recent experiments and first-principles simulations, providing an appealing conceptual framework also relevant for other layered materials made of stacked honeycomb lattices.

Doping induced topological phase transition in Bi: The role of quantum electronic stress*

KYUNG-HWAN JIN (Presenter), University of Utah, HAN WOONG YEOM, Pohang University of Science and Technology, FENG LIU, University of Utah — Charge doping is an essential means to tailor materials' properties. However, besides moving the Fermi level, charge doping is generally not expected to induce topological phase transition (TPT). Surprisingly, using first-principles calculations, here we demonstrate an electron doping induced TPT in bulk Bi from a higher-order topological insulator (HOTI) to a TI. The underlying mechanism is revealed to be driven by an electron doping induced quantum electronic stress (QES), which in turn induces a highly anisotropic lattice expansion to close/reopen the small energy gap in Bi band structure. Our finding significantly resolves an outstanding controversy concerning the topological characterization of bulk Bi among existing experiments and theories, and explains the physical origin of the topologic order in Bi (111) thin films. It sheds new lights to fundamental understanding of topological properties of small band gap materials in relation to doping and QES.

*This work is supported by DOE-BES under Grant No DE-FG02-04ER46148.
Possibility of topological properties in 2D cadmium chalcogenide (CdX, X = S, Se, and Te) buckled honeycomb monolayer on substitutional doping*  

SUTAPA CHATTOPADHYAY, ANJALI KSHIRSAGAR (Presenter), Univ of Pune — Two-dimensional honeycomb monolayers doped with tin atoms are designed from (111) surface of bulk zinc blende structures of cadmium chalcogenides using first principles density functional theory based calculations. On relaxation the buckled honeycomb monolayer shows signature of band inversion between Sn and Cd orbital at the zone center (Γ point) deep in the valence band and high above in the conduction band. The band inversion, due to hybridization, stays even after inclusion of spin-orbit coupling. The systems were chosen with an intention to exploit the possibility of d-d band inversion. CdSnS has s-s band inversion but CdSnSe and CdSnTe monolayers do show band inversion involving d states. The calculated phonon spectra confirmed the stability of all the systems studied. The details of the electronic structure bring out the importance of s-d band inversion. We also report the topological invariants and analysis of edge state properties and band structure of these materials in ribbon geometry. Such systems can be useful for technological application in the Spintronic domain.

The electronic and topological properties of plumbene by first-principles calculations*  

YUE LI (Presenter), ZHONGQIN YANG, Fudan Univ — Combining tight-binding (TB) models with first-principles calculations, we investigate the electronic and topological properties of plumbene. “Constructive” coupling effects of topological states are found in the plumbene, causing the system being a normal insulator, opposite to topologically nontrivial states formed in the other group IVA monolayers. Based on this mechanism, several schemes are raised to produce a globally topological state in the plumbene. Interestingly, after the edge modification in the nanoribbon structure, the plumbene can own low-dissipation tunable edge states with good conduction performance despite the topologically trivial behavior.
