9:12AM L54.00007: Topological States in \(\beta\)-PbO\(_2\)?  SHARAD MAHATARA (Presenter), BORIS KIEFER, New Mexico State Univ — The electronic properties of \(\beta\)-PbO\(_2\), have been controversial for over a century. Experiments find metallic behavior, attributed to its defect structure, to indirect semiconducting for stochiometric samples, with a gap of 0.61 eV. Theory leads to similar ambiguities, and predicts this phase to be metallic (PBE, HSE06) or the opening of too small a bandgap (HSE06). An area where this inconsistency is significant, is when a material property depends on the electronic structure in the vicinity of the Fermi energy, such as topological states. In our work, we use a self-consistent DFT+U approach and find stochiometric \(\beta\)-PbO\(_2\) to be an indirect semiconductor with a band gap of \(\sim\)0.8 eV, similar to experiment. The larger bandgap requires strains of \(\sim\)4% to drive \(\beta\)-PbO\(_2\) into a nodal line semimetallic state, which is not protected under the application of spin-orbit-coupling. Moreover, our surface computations do not show any topologically protected states near the Fermi energy. Therefore, our results show that in contrast to previous computations \(\beta\)-PbO\(_2\) is a topologically trivial material, consistent with experiment. Differences to previous work can be attributed to our more accurate description of the optical properties of bulk \(\beta\)-PbO\(_2\).

9:24AM L54.00008: Mode-Selective Spontaneous Oscillation of Bandgap in Dirac Wedge Semimetals  ZHIGANG SONG (Presenter), Lawrence Berkeley National Laboratory —

This article studies the time-dependent behavior of semimetal \(\text{Zr}_3\text{AgX}_3\text{F}_{20}\) [\(X=\text{Cd and Hg}\)], \(\text{M(MoS)}_3\) and \(\text{M(MoSe)}_3\) [\(\text{M}=\text{Li, Na, K, Rb, Tl, In, I}\)] using time-dependent density functional theory. The results show half-occupied Dirac wedge bands. Due to the one-dimensional character, the materials oscillate in a selective mode at a finite temperature. The wedge bands couple to such a phonon mode, resulting in spontaneous oscillation in a rigid period. Especially, the bandgap periodically closes and opens in a large scale, supporting a pulsed current even under a constant biased voltage. Besides, these systems might be long sought time crystals in condensed matters.
9:36AM L54.00009: Application of Convolutional Neural Network to Quantum Percolation in Topological Insulators*  
TOMI OHTSUKI (Presenter), TOMOHIRO MANO, Phys. Division, Sophia Univ — Quantum material phases such as Anderson insulator, diffusive metal, Weyl/Dirac semimetal as well as topological insulators show specific wave functions both in real and Fourier spaces. These features are well captured by convolutional neural networks, and the phase diagrams have been obtained, where standard methods are not applicable. One of these examples are the cases of random lattices such as quantum percolation. Here we study the topological insulators with random vacancies, namely the quantum percolation in topological insulators, by analyzing the wave functions via convolutional neural network. The vacancies in topological insulators are especially interesting since peculiar bound states are formed around the vacancies. We show that only a few percent of vacancies derives topological phase transition. The results are confirmed by independent calculations of localization length, density of states, and wave packet dynamics.

9:48AM L54.00010: Predicting Topological Properties of Quantum Materials via Statistical Methods*  
THOMAS MERTZ (Presenter), KARIM ZANTOUT, ROSER VALENTI, Goethe University Frankfurt — We discuss the topological phases of correlated and non-correlated (insulating) quantum materials using a statistical method that explores the entire phase space. Based on model systems we draw fundamental conclusions and discuss the predictive power of this method when applied to real materials.

*We thank the German Research Foundation (Deutsche Forschungsgemeinschaft) for financial support.

10:00AM L54.00011: Strong-coupling superconductivity and pseudogap in topological flat bands: a quantum Monte Carlo study  
JOHANNES HOFMANN (Presenter), EREZ BERG, Weizmann Institute of Science, DEBANJAN CHOWDHURY, Physics, Cornell University — We study a two-dimensional model of an isolated narrow topological band at partial filling with local attractive interactions. Exact quantum Monte Carlo calculations show that the ground state is a superconductor with a critical temperature that scales linearly with the interaction strength. We also find a broad pseudogap regime at temperatures above the superconducting phase that exhibits strong pairing fluctuations and a tendency towards electronic phase separation. We discuss the possible relevance of superconductivity in this unusual regime to the Physics of flat band Moiré materials, and as a route to designing higher temperature superconductors.
Role of van der Waals interactions in topological insulators: bulk, surface and interfaces*  

KARUNYA SHAILESH SHIRALI (Presenter), WILLIAM A SHELTON, ILYA VEKHTER, Louisiana State University, Baton Rouge — It is well-known that van der Waals interactions (vdW) play an important role on structural properties of the prototypical 3D topological insulators Bi$_2$Se$_3$ and Bi$_2$Te$_3$. However, systematic investigations of different implementations of vdW interactions using density functional theory are lacking. We have performed a comprehensive comparison using both semi-empirical (DFT+D2, DFT+D3, Tkatchenko-Scheffler) and first principles (Langreth-Lundqvist DF, SCAN-rVV10) vdW methods in bulk and surface calculations for these materials, treating structural and electronic properties on equal footing. We find that semi-empirical methods, especially D2 produce structural parameters, electronic dispersion, and the Dirac velocity of the surface state close to the experimental values, while other methods exhibit serious problems when applied to Bi$_2$Se$_3$ and Bi$_2$Te$_3$. We attribute these differences to the importance of the long range $r^{-6}$ tail of the vdW interaction, and we discuss its relevance for the properties of topological interfaces.

Topological Phases in Hydrogenated Group 13 Monolayers  

RANJAN BARIK (Presenter), RITESH KUMAR, ABHISHEK SINGH, Indian Institute of Science — The topological phases of matters have been a rapid exposed field of research due to its possible applications in spintronics and fault-tolerant quantum computing. Recently, the 2D sheet of gallium (gallenene), a group 13 element, has been synthesized, for which topological properties remain undefined. Using an effective k.p model, symmetry analysis and group theoretical approach with first-principles calculations we studied the topological properties of hydrogenated gallenene (gallenane) and other group 13 elements. Without the inclusion of spin-orbit coupling (SOC) all hydrogenated group-13 sheets that are aluminane, gallenane, indinane and thallinane become nodal line semimetal (NLSM). Interestingly, gallenane under SOC and with 2.6% tensile strain evolves to quantum spin Hall insulator with an energy gap of 28 meV, which makes it promising for room temperature applications. Aluminane preserved its topology even in the presence of SOC due to feeble strength of it. Indinane and thallinane are trivial semimetals under SOC. These findings could offer a new direction in topological research.

**L54.00014: Robust descriptor for high-throughput discovery of alloyed topological insulators based on artificial intelligence**

GUOHUA CAO (Presenter), Wuhan University, RUNHAI OUYANG, LUCA GHIRINGHELLI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, HUIJUN LIU, Wuhan University, CHRISTIAN CARBOGNO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, ZHENYU ZHANG, ICQD, University of Science and Technology of China — Significant advances have been made in predicting new topological materials using high-throughput empirical descriptors or symmetry-based indicators. To date, these approaches have been applied to materials in existing databases, and are severely limited to systems with well-defined symmetries, leaving a much larger materials space unexplored. Using tetradymites as a prototypical class of examples, we uncover a novel two-dimensional descriptor by applying an artificial intelligence (AI) based approach for fast and reliable identification of the topological characters of a drastically expanded range of materials, without prior determination of their specific symmetries and detailed band structures. By leveraging this descriptor that contains only the atomic number and electronegativity of the constituent species, we have readily scanned over four million alloys in the tetradymite family. Strikingly, nearly two million new topological insulators are identified, revealing a much larger territory of the topological materials world. The present work also attests the increasingly important role of such AI-based approaches in modern materials discovery.

**8:00AM L55.00001: Mesoscopic Conductance Fluctuations in Class D Superconducting Wires**

DANIIIL ANTONENKO (Presenter), Skolkovo Institute of Science and Technology, PAVEL OSTROVSKY, Max Planck Institute for Solid State Physics, MIKHAIL SKVORTSOV, Skolkovo Institute of Science and Technology — We study disordered superconducting wires (length L) of class D via supersymmetric sigma-model approach in the critical regime between topological and trivial phases, where delocalization happens and average conductance scales as $G \sim L^{-1/2}$ [1]. In order to calculate the variance of conductance $\text{var } G$ in the diffusive regime we introduce $n=2$ sigma-model and apply the method of transfer-matrix Hamiltonian, studying Laplace-Beltrami operator on the rank two symmetric superspace. We use Iwasawa decomposition to construct eigenbasis on this supermanifold, which appears to consist of three-parametric and one-parametric subsets, with the latter closely related to the eigenfunctions on the $n=1$ sigma-model manifold. Our approach allows to find $\text{var } G$ at arbitrary lengths in the diffusive region with the crossover from the perturbative weak-localisation regime at $L \ll \xi$ to the regime of a very broad conductance distribution at $L \gg \xi$, where $\xi$ is the correlation length of the wire. Also, we account to the possible back/forward channels imbalance, which is described by a Wess-Zumino-Witten term in the sigma-model action.

Majorana bound states from textured chiral magnets* STEFAN REX (Presenter), IGOR GORNYI, ALEXANDER MIRLIN, Karlsruhe Institute of Technology — Non-collinear magnetism combined with superconductivity can support the formation of localized Majorana bound states.

We discuss a hybrid system consisting of a conventional superconductor exchange-coupled to a magnetic layer with Dzyaloshinskii-Moriya interaction (DMI). DMI systems are capable of developing complex magnetic textures spontaneously without a need for external microscopic control of the spin. Experimentally observed textures comprise skyrmions, spin spirals, and topological defects at domain walls.

We investigate theoretically in which cases Majorana modes can be expected in the hybrid system, and support our findings with numerical results. In particular, skyrmion-vortex pairs are highlighted as a candidate composite structure for the creation and individual control of localized Majorana bound states [PRB 100, 064504 (2019)]. Thus, the hetero-systems that we study represent an exciting new platform in the pursuit of topological braiding operations.

Topological Phases in a One-dimensional Majorana-Bose-Hubbard Model* ANANDA ROY (Presenter), JOHANNES HAUSCHILD, FRANK POLLMANN, TU Munich — Majorana zero modes (MZM-s) occurring at the edges of a 1D, p-wave, spinless superconductor, in absence of fluctuations of the phase of the superconducting order parameter, are quintessential examples of topologically-protected zero-energy modes occurring at the edges of 1D symmetry-protected topological phases. In this work, we numerically investigate the properties of the topological phase in the presence of phase-fluctuations using the density matrix renormalization group (DMRG) technique. To that end, we consider a one-dimensional array of MZM-s on superconducting islands at zero temperature. We show that the system can be in either a Mott-insulating phase, a Luttinger liquid (LL) phase of Cooper-pairs or another gapless phase. The latter phase can be viewed as a LL of charge-e bosons where nonlocal string correlation functions decay algebraically. These nonlocal correlation functions, together with correlation functions of the Cooper-pair creation operators, distinguish the different phases of the model. We map the system to an interacting model of spins coupled to rotors and use DMRG to characterize the different phases and the phase-transitions.

8:36AM L55.00004: Boundary-induced dynamics and quantum memory effect of 1D and 2D topological systems  CHIH-CHUN CHIEN (Presenter), University of California, Merced, YAN HE, Sichuan University — The dynamics after a change of the boundary condition for selected 1D and 2D topological systems are analyzed. We consider the 1D Su-Schrieffer-Heeger (SSH) model and Kitaev model transforming from periodic to open boundary condition and the 2D Chern insulator (CI) and topological quadrupole insulator (TQI) transforming from a cylinder or Mobius strip to open boundary condition. In all the cases, we found the occupation of the topological edge states reaches a steady-state value after the transformation is completed in absence of any external dissipation mechanism. The steady-state value depends on the ramping rate of the boundary condition. The dependence of the steady-state occupation of the topological edge states on the ramping rate thus exemplifies one kind of quantum memory effect, which originates from the trapping of excitations due to the localized nature of the edge states. The mechanism suggests that this type of quantum memory effect may be universal in topological systems with localized edge states.

8:48AM L55.00005: Interaction Driven Floquet Engineering of Topological Superconductivity in Rashba Nanowires  MANISHA THAKURATHI (Presenter), University of Waterloo, PAVEL ASEEV, DANIEL LOSS, JELENA KLINOVAJA, Department of Physics, university of Basel — We analyze, analytically and numerically, a periodically driven Rashba nanowire proximity coupled to an s-wave superconductor [1] using bosonization and renormalization group analysis in the regime of strong electron-electron interactions. Due to the repulsive interactions, the superconducting gap is suppressed, whereas the Floquet Zeeman gap is enhanced, resulting in a higher effective value of g-factor compared to the non-interacting case [2]. The flow equations for different coupling constants, velocities, and Luttinger-liquid parameters explicitly establish that even for small initial values of the Floquet Zeeman gap compared to the superconducting proximity gap, the interactions drive the system into the topological phase and the interband interaction term helps to achieve larger regions of the topological phase in parameter space.

9:00AM L55.00006: Almost strong 0, π edge modes in clean, interacting 1D Floquet systems*  DANIEL YATES (Presenter), New York Univ NYU, FABIAN H.L. ESSLER, University of Oxford, ADITI MITRA, New York Univ NYU — Certain periodically driven quantum many-particle systems in one dimension are known to exhibit edge modes that are related to topological properties and lead to approximate degeneracies of the Floquet spectrum. A similar situation occurs in spin chains, where stable edge modes were shown to exist at all energies in certain integrable spin chains. Moreover, these edge modes were found to be remarkably stable to perturbations. Here we investigate the stability of edge modes in interacting, periodically driven, clean systems. We introduce a model that features edge modes that persist over times scales well in excess of the time needed for the bulk of the system to heat to infinite temperatures.

9:12AM L55.00007: Rigorous results on topological superconductivity with particle number conservation* MATTHEW LAPA (Presenter), MICHAEL LEVIN, University of Chicago — Most theoretical studies of topological superconductors and their unpaired Majorana fermions rely on a mean-field (or Bogoliubov-de Gennes) approach to describe superconductivity, which violates particle number conservation (PNC). Recently, however, A.J. Leggett and others have argued that this violation of PNC may pose a serious conceptual problem for Majorana-based quantum computation. To resolve this issue, reliable results on number-conserving models of superconductivity are essential. As a first step in this direction, we use rigorous methods to study a number-conserving toy model of a topological superconducting wire. We prove that this model exhibits many of the desired properties of the mean-field models, including a finite energy gap in a sector of fixed total particle number, and the existence of long range “Majorana-like” correlations between the ends of the wire. These results show that many of the remarkable properties of mean-field models of topological superconductivity persist in more realistic models with number-conserving dynamics.

9:24AM L55.00008: Braiding Floquet Majorana Modes in One-Dimensional Topological Superconductors* BILL TRUONG (Presenter), TAMI PEREG-BARNEA, KARTIEK AGARWAL, McGill University — It is well-known that braiding Majorana zero modes in one-dimensional (1D) topological systems is a challenge since the modes hybridize when they are within proximity of each other. Recent developments have indicated that braiding in 1D can be accomplished through periodic driving. In our work, we study a 1D $p$-wave superconductor modelled as a Kitaev chain with the driving achieved by periodically modulating the parameters of the system. This Floquet system gives rise to Majorana edge modes of both zero and $\pi$ quasienergy. We numerically implement the adiabatic protocol developed in Ref. [1] to braid the Floquet Majorana zero modes, using the Floquet Majorana $\pi$ modes as an auxiliary degree of freedom. We consider the inclusion of interactions and disorder into the system and demonstrate the robustness of the protocol by examining quantities such as the exchange operator.

9:36AM L55.00009: Universal delocalization transition in 1D chiral Floquet topological insulators*  PRATIK SATHE (Presenter), ALBERT BROWN, FENNER HARPER, RAHUL ROY, University of California, Los Angeles — Periodically driven systems of non-interacting fermions, also known as Floquet topological insulators, exhibit novel topological characteristics distinct from those of static systems. In the case of 1D Floquet topological insulators with chiral symmetry (class AIII), the dynamical topological nature can be understood through studying the time evolution operator U(t) evaluated close to the midpoint of a driving period, i.e. U(T/2). We investigate the localization properties at this special point, for flat-band, two-step Floquet drives. Specifically, for topologically non-trivial disordered drives, we show that the localization length of eigenstates of U(T/2 - epsilon) diverges as epsilon approaches 0 as a power law with exponent nu = 2, and argue that this property is universal for this class of AIII models.

9:48AM L55.00010: Experimental study of 1D Su-Schrieffer-Heeger edge modes in a water-wave channel  ADAM ANGLART, PAWEL OBREPALSKI, KEI KUSUMI, Physique et Mecanique des Milieux Heterogenes (PMMH), AGNES MAUREL, Institut Langevin, ESPCI, PHILIPPE PETITJEANS, Physique et Mecanique des Milieux Heterogenes (PMMH), VINCENT PAGNEUX (Presenter), Laboratoire d'Acoustique de l'Universite du Maine — The main objective of this work is to experimentally investigate the topologically protected edge-states and band gaps in a water waveguide with periodic geometry. One of the representations of the topological states, provided by the Su–Schrieffer–Heeger model (SSH) [1], is applied to describe the observed phenomena [2]. A waveguide with step periodic width as well as corresponding rectangular tank with constant width are examined using Confocal Displacement Sensors allowing the measurement of water surface displacements. 2D numerical simulations are carried out in order to verify the SSH model and experimental data. The obtained results show that this very simple setup exhibits all the properties of the SSH model with an excellent agreement to the water-wave systems.

10:00AM L55.00011: Path integral for spin-1 chain in the entangled basis  JUNG HOON HAN
(Presenter), Physics, Sungkyunkwan University — We develop path-integral formulation of spin-1
Haldane chain in the entangled, matrix product state (MPS) basis. Whereas the conventional path
integral approach is founded on spin-based coherent states as the basis, we here adopt a new
basis consisting of bond-based coherent states. The Affleck-Kennedy-Lieb-Tasaki (AKLT)-type
ground state is obtained as the saddle point solution of the newly developed action. Small
fluctuations around the saddle point are developed in terms of conventional gradient expansion.
Ways to compute various correlation functions based on the effective action will be discussed.
While certain crude approximations have to be made to proceed with the calculation, it appears
that features of spin gap in the spin-1 chain seems nicely captured at the mean-field level by the
path integral written in the entangled basis. This work was done in collaboration with Jin-Tae Kim,
Rajarshi Pal, and Jin-Hong Park at SKKU.

10:12AM L55.00012: Detecting one-dimensional interacting topological phases by edge-
state pinning*  SHUN-CHIAO CHANG (Presenter), PAVAN HOSUR, Univ of Houston — In density
matrix renormalization group (DMRG) simulations, edge states are often identified by computing
edge-edge or bulk-edge two-point correlation functions. Since this approach involves computing
the square of the local order parameter, very large systems at high precision are required to
obtain reliable results when the order parameter is small, which is true, for instance, near a
phase boundary. Moreover, the computational cost of this method increases drastically with the
bulk entanglement. In this work, we propose and demonstrate an efficient method for detecting
the topological edge states with DMRG. That is, we study edge states by pinning one edge with
appropriate fields and observing the corresponding local order parameter of the other edge. The
method is validated here for antiferromagnetic Heisenberg model, the simplest realization of the
Haldane phase. It would be interesting to study other one-dimensional topological phases using
this method.

Mathematics and the University of Houston.

10:24AM L55.00013: Generalized bulk-edge correspondence for non-hermitian topological
phases*  KEN-ICHIRO IMURA (Presenter), YOSITAKE TAKANE TAKANE@HIROSHIMA-U.AC.JP,
Hiroshima Univ — In a recent paper [1] we have established that the idea of bulk-edge
correspondence in the hermitian limit can be generalized to non-hermitian topological systems.
But strictly speaking, the proof given there was limited to the regime of weak (perturbative) non-
hermiticity. Here, we deepen the idea of the generalized bulk-edge correspondence proposed in
Ref. [1] and give a more general proof valid also in the non-perturbative non-hermitian regime.

8:00AM L56.00001: Topology and the doped Kondo Heisenberg model** JULIAN MAY-MANN (Presenter), RYAN LEVY, EDUARDO FRADKIN, BRYAN CLARK, University of Illinois at Urbana-Champaign, RODRIGO B SOTO, Departamento de Física, Pontificia Universidad Católica de Chile, GIL YOUNG CHO, Korea Institute for Advanced Study — In previous works, it has been proposed that the doped Kondo Heisenberg model is topological and hosts Majorana zero modes. These Majorana zero modes correspond to solitons of the gapped spin sector of the model. We have investigated this claim on the lattice using DMRG, and found no evidence for these proposed zero modes. In light of this, we revisit the original claims that the model is topological using bosonization. We discuss how this continuum analysis fits with the numeric data and the lattice model.

**Julian May-Mann is supported by the National Science Foundation Graduate Research Fellowship Program under Grant No. DGE – 1746047

8:12AM L56.00002: Fermionic multichannel dynamical large-N approach to Kondo lattice model** JIANGFAN WANG, YUNG-YEH CHANG (Presenter), CHUNG-HOU CHUNG, Natl Chiao Tung Univ — We establish a novel theoretical framework to study the quantum phases and phase transitions of a two-dimensional Kondo Heisenberg lattice model based on the dynamical large-N approach to the multichannel pseudofermion representation of the model with $\text{Sp}(N) \times \text{SU}(K)$ symmetry with $N$ and $K$ being number of spin flavors and Kondo screening channels, respectively. This approach captures the heavy electron Fermi liquid state when $\text{SU}(K)$ symmetry is broken with Kondo hybridization in terms of Bose-condensed holons, and a spin-liquid metallic state with gaped fermionic spinons when the anti-ferromagnetic coupling dominates. A self-consistent Green’s function method is used. The global phase diagram and the thermodynamic properties of the spin liquid state share close resemblance to CePdAl, a heavy-fermion systems with magnetic frustration.

Kondo effect due to a hydrogen impurity in graphene: A multichannel Kondo problem with diverging hybridization*  ZHENG SHI (Presenter), Dahlem Center for Complex Quantum Systems and Physics Department, Freie Univ Berlin, EMILIAN NICA, Department of Physics, Arizona State University, IAN AFFLECK, Department of Physics and Astronomy and Stewart Blusson Quantum Matter Institute, University of British Columbia — We consider the Kondo effect arising from a hydrogen impurity in graphene. Approximating the C-H covalent bond as infinitely strong and the Hubbard interaction to be present only on the three nearest neighbors of hydrogen impurity, we obtain a Kondo model with three $Z_3$-symmetric impurity spins and three conduction channels, two of which support a diverging local density of states $\propto 1/|\omega| \ln^2(\Lambda/\omega)$ near the Dirac point $\omega \to 0$. When the particle-hole (p-h) symmetry breaking at the impurity is not too strong, numerical renormalization group shows that the ground state is either a p-h symmetric spin-1/2 doublet with ferromagnetic impurity spin correlations, or a p-h asymmetric spin singlet with antiferromagnetic impurity spin correlations. This behavior is inherited by the Anderson model containing the hydrogen impurity and all four carbon atoms in its vicinity.

Magnon Bose-Einstein Condensation and Superconductivity in a Frustrated Kondo Lattice*  JED PIXLEY (Presenter), PAVEL VOLKOV, Department of Physics and Astronomy, Center for Materials Theory, Rutgers University, SNIR GAZIT, Racah Institute of Physics, The Hebrew University, Jerusalem — Magnetically frustrated Kondo lattices are considered to be one of the most promising platforms for the realization of novel types of metallic quantum criticality. Motivated by the recent experiments on the heavy fermion compounds with a nonmagnetic valence bond solid (VBS) ground state of the localized spins, such as YbAl$_2$C$_3$, we study a one-dimensional two-leg spin ladder model with a VBS ground state doped with itinerant fermions. Using field theory techniques and precise density matrix renormalization group calculations, we provide a solution of the model as a function of the Kondo coupling and magnetic field. We demonstrate that the magnetic field-driven transition to an easy-plane antiferromagnet (known as magnon Bose-Einstein condensation (BEC) in the insulating limit) is stable in the presence of a Fermi sea and its universality class is unchanged, while the critical field decreases as a function of Kondo coupling. We also find that spin fluctuations in the VBS phase can drive unconventional superconducting correlations. Finally, we argue that, depending on the filling of conduction electrons, the magnon BEC transition can remain stable in a metal also in dimensions two and three.

8:48AM L56.00005: Magnetic Doublon Bound States in the Kondo Lattice Model* ROMAN RAUSCH (Presenter), University of Kyoto, MICHAEL POTTHOFF, I. Institute for Theoretical Physics, University of Hamburg, NORIO KAWAKAMI, University of Kyoto — We present a novel pairing mechanism for electrons, mediated by magnons. These paired bound states are termed magnetic doublons. Applying numerically exact techniques (exact diagonalization and the density-matrix renormalization group, DMRG) to the Kondo lattice model at strong exchange coupling J for different fillings and magnetic configurations, we demonstrate that magnetic doublon excitations exist as composite objects with extremely weak dispersion at excitation energies of the order of $3J/2$ above the ground state. They are highly stable, support a novel "inverse" colossal magnetoresistance and potentially other effects like metastable superconductivity, or cooling via quantum distillation.

9:00AM L56.00006: Competing Energy Scales and Quasiparticle Dynamics in a Driven Kondo Impurity System* CHEN-YEN LAI (Presenter), Los Alamos Natl Lab, QIMIAO SI, Rice University, JIAN-XIN ZHU, Los Alamos Natl Lab — The ultrafast pump-probe techniques are used to probe the elementary excitations and its energy scale in materials. Recent study [Nat. Phys. 14 1103 (2018)] shows the collapse and revival of the Kondo correlations from terahertz reflectivity measurement. Here we propose a model study as a proof of principle to first determine the corresponding Kondo energy scale by using the matrix product state to simulate the Fermi-Bose-Anderson impurity model, which is a good starting model for the study of Kondo lattice model. In equilibrium, the model displays a quantum critical point that captures the competition between RKKY interaction and Kondo coupling in the underlying system. As a laser pump pulse is applied to the system, our nonequilibrium simulations show that the driven system exhibits qualitatively different response, which is related to the competing energy scales. Our results benchmark the competing energy scales in a Kondo impurity system and provide new insight on the behavior of the critical quasiparticle in heavy fermion compounds.

9:12AM L56.00007: Universality in the ferromagnetic strong coupling regime of the Kondo model out of equilibrium*  
ADRIAN CULVER (Presenter), NATAN ANDREI, Rutgers University, New Brunswick — We present a nonperturbative method for calculating the time-dependent many body wavefunction following a local quench and use it to find new results in and out of equilibrium in the universal strong ferromagnetic regime of the Kondo model. The method addresses the general problem of calculating $e^{-iHt}\Psi$, where the initial state $\Psi$ is a free N-particle state (such as a Fermi sea) and $H$ is a many body Hamiltonian which is switched on at $t=0$. While the method may be of wider applicability, we have so far focused on one dimensional models of quantum dots attached to linearized leads. The method yields the exact many body wavefunction of the two lead Kondo model following the quench. In the strong ferromagnetic regime, we find a new universal scale $T_K = D \exp[3\pi^2 \rho J / 8]$ and the surprising result that the steady state conductance $dI/dV$ reaches the unitarity limit asymptotically at large voltage or temperature.

*Research supported by NSF Grant DMR 1410583.

9:24AM L56.00008: Comparing Different Refermionizations of Multichannel Kondo Hamiltonians  
ALEKSANDAR LJEPOLA (Presenter), Univ of Cincinnati, NAYANA SHAH, Washington University in St. Louis, C. J. BOLECH, Univ of Cincinnati — Following a critical revision of the procedures for bosonization and debosonization of theories with boundaries [1,2] we consider novel alternative schemes to arrive at refermionized Hamiltonians for the standard multichannel Kondo model. We compare them order by order using Green-function based perturbative expansions and discuss the results on the basis of symmetries and decoupled dynamical sectors of the original theory.

9:36AM L56.00009: Various Fermi liquid phases on the Kondo - Heisenberg model at quarter filling  
HEE SEUNG KIM (Presenter), HYEOK-JUN YANG, SUNGBIN LEE, KAIST — Motivated by exotic phases emerged from Kondo insulators, we study transport properties of electronic system under Kondo and Heisenberg interactions. Particularly, we focus on the Kondo - AF (antiferromagnetic) Heisenberg model on a honeycomb lattice at quarter filling. By using paraton mean-field theory, we construct generic mean-field phase diagram and investigate distinct Fermi liquid phases. In strong Kondo coupling limit, due to quarter filling condition, half of localized moments form Kondo singlet and the others develop triangular lattice with AF Heisenberg interaction which yields spin liquid phase. To investigate the low-energy excitation properties, we evaluate transport coefficients of mobile electrons and fractionalized quasiparticles respectively. Even though mobility of charge carriers is suppressed, Fermi liquid behavior is verified arose from neutral low-energy excitations.
9:48AM L56.00010: Emergent non-Fermi liquid phenomena in itinerant electron systems with multipolar local moments

ADARSH PATRI (Presenter), ILIA KHAIT, YONG-BAEK KIM, Univ of Toronto — Recent experiments on cubic heavy fermion systems with multipolar local moments offer a new avenue for the discovery of novel spin-orbital entangled quantum ground states. In this talk, we theoretically investigate the fate of the multipolar Kondo effect, where the local moment does not carry any dipole moment, but only quadrupolar and octupolar moments. Using perturbative renormalization group methods, we discover a number of non-Fermi liquid ground states, which are characterized by an absence of well-defined quasiparticles and singular power-law behaviours in physical properties. This work lays a novel ground for the identification of emergent non-Fermi liquid phases in many heavy fermion materials.

10:00AM L56.00011: Global phase diagram of a Kondo Hund impurity model and the destruction of Fermi-liquid theory

YILIN WANG (Presenter), Brookhaven National Laboratory, ELIAS WALTER, SEUNG-SUP LEE, KATHARINA M STADLER, JAN VON DELFT, Ludwig Maximilian University of Munich, ANDREAS WEICHESELBAUM, Brookhaven National Laboratory, GABRIEL KOTLIAR, Rutgers University, New Brunswick — In many correlated materials, notably the Hund metals, the Landau Fermi-liquid coherence scale $T_{FL}$ is found to be very small. In this Letter, we interpret its smallness in terms of proximity to quantum critical points (QCPs): We use the numerical renormalization group (NRG) to compute the global phase diagram of the simplest three-channel spin-orbital Kondo impurity model capturing the essential physics of Hund metals. When the spin or spin-orbital Kondo couplings are tuned into the ferromagnetic regimes, we find quantum phase transitions to a singular Fermi-liquid or a novel non-Fermi-liquid phase, signalling the existence of QCPs, while $T_{FL}$ is suppressed to zero. The new non-Fermi-liquid phase shows frustrated behavior involving alternating overscreenings in spin and orbital sectors, with universal power laws in the spin ($\omega^{-1/5}$), orbital ($\omega^{1/5}$) and spin-orbital ($\omega^1$) dynamical susceptibilities. These power laws, and the NRG eigenlevel spectra, can be fully understood using conformal field theory arguments, which also clarify the nature of the NFL phase.
Dynamical Kondo effect and Kondo destruction in effective models for quantum-critical heavy fermion metals

**Ang Cai** (Presenter), **Haoyu Hu**, Rice University, **Kevin Ingersent**, University of Florida, **Silke Buehler-Paschen**, Vienna University of Technology, **Qimiao Si**, Rice University — Kondo destruction that results in a sudden reconstruction of Fermi surface at the quantum critical point arises in certain heavy-fermion metals [1,2,3,4]. In the Kondo-destroyed phase, the static Kondo singlet amplitude vanishes and, thus, a well-defined Kondo resonance is lost, but the Kondo singlet correlations remain at nonzero frequencies. We elucidate the dynamical Kondo effect in Bose-Fermi Kondo/Anderson models which unambiguously exhibit a Kondo-destruction QCP [5]. We demonstrate that the dynamical Kondo effect is important for the stability of Kondo-destruction quantum criticality and provides understanding of the enhanced effective mass in the Kondo-destroyed phase.

Multiorbital Hund's coupled impurity in the mixed valence regime

**Victor Drouin-Touchette** (Presenter), **Elio Koenig**, **Yashar Komijani**, **Piers Coleman**, Rutgers University, New Brunswick — Motivated by the relevance of Hund's coupling in iron-based superconductors, we revisit the problem of a multiorbital Anderson impurity with Hund’s interaction. Using large-N and Schwinger boson techniques, we study the ground state and thermodynamic properties of this system in both integer and mixed valence regimes. The physics is characterized by the interplay of Hund's coupling, which tends to form large moments by aligning the spins of the impurity, and the Kondo effect, which leads to the low-temperature screening of the moments. In the integer valence regime, we confirm the formation of large moments, which eventually become screened at an exponentially reduced Kondo temperature due to the so-called Schrieffer effect, and compare to previous renormalization group studies [1]. In the mixed valence regime, the Hund's coupling gives rise to interesting physics: we explore the presence of a non-Fermi-liquid ground state and the possibility that the large moments can generate retarded on-site pairing correlations for the conduction electrons.

Numerical renormalization group method for computing four-point correlation functions

SEUNG-SUP LEE (Presenter), FABIAN KUGLER, JAN VON DELFT, Ludwig Maximilian University of Munich — Four-point correlation functions commonly appear in various contexts of the theory of strongly correlated systems, including diagrammatic extensions of dynamical mean-field theory (DMFT). Here we develop the numerical renormalization group (NRG) method for computing four-point correlation functions in quantum impurity systems. First, we derive the Lehmann representation for general four-point functions (i) in imaginary Matsubara frequencies, (ii) on the real-frequency axes at zero temperature, and (iii) on the Keldysh contour. By using the complete basis of energy eigenstates constructed within NRG, four-point functions can be computed at arbitrarily low temperatures. We present results for paradigmatic models, including the effective quantum impurity model arising in DMFT treatments of the Hubbard model.

Fractionalized Fermi liquid in square-lattice Kondo-Heisenberg model

YUNG-YEH CHANG (Presenter), CHUNG-HOU CHUNG, Natl Chiao Tung Univ, ALEXEI TSVELIK, Condensed Matter Physics and Materials Science Division, Brookhaven National Lab — The Kondo-Heisenberg model on a (un-frustrated) square lattice is studied via a controlled large-N (Sp(2N)) approach to demonstrate on a general ground the existence of a peculiar metallic state so-called “fractionalized Fermi liquid (FL*)” with unbroken translational symmetry and a Fermi surface volume not controlled by the total electron density. Close to half-filling, we show that the nesting of Fermi surface favors the Kondo hybridization to form between conduction electrons and local resonant-valence-bond spin-liquid fermions, which stabilizes FL* state with well-defined quasiparticle and gapped spinon excitations. The system develops an ordered phase at ground state (charge density wave or pair density wave superconducting). Our result generalizes the FL* state previously proposed in Phys. Rev. Lett. 90, 216403 (2003), which is restricted to frustrated Kondo lattice systems.

8:00AM L57.00001: Complementary logic inverters based on polarity-controllable MoS$_2$ fin-shaped and v-shaped field effect transistors* CHE-YU LIN, National Cheng Kung University, PO-CHUN CHEN, National Taiwan Normal Univ, MING-CHENG CHEN, MING-YANG LI, LAIN-JONG LI, Taiwan Semiconductor Manufacturing Company, KAI-SHIN LI, Taiwan Semiconductor Research Institute, YANNWEN LAN (Presenter), National Taiwan Normal Univ — Integration of high performance $n$-type and $p$-type field-effect transistors with complementary device operation in the same kind of layered materials is highly desirable for pursuing low power and flexible next-generation electronics. In this work, we show a well-mannered growth of MoS$_2$ between two electrodes on silicon oxide with fin-shaped and v-shaped structure. In the fin-shaped case, both $n$-type and $p$-type MoS$_2$ can be integrated by using a traditional implantation technique. In the v-shaped case, the device can alternately operate either as a $p$-type or an $n$-type semiconductor in the identical one. The proposed device is built with an adjustable threshold voltage ($V_{th}$), which can be varied by adding a layer of plasma-oxidized dielectric at the top gate structure. Consequently, the $V_{th}$ shifts and the top gate structure switch from the typical $n$-type to $p$-type while $n$-type behaviour remains in the application of bottom-gate voltages. In both cases, we have accordingly demonstrated the complementary logic inverters based on the polarity-controllable behavior. Our results provide evidence for complementary 2D materials operation in the same materials, a promising avenue for the development of high-density complementary 2D electronic devices.

8:12AM L57.00002: Device simulation study of ion-gated ambipolar transition-metal dichalcogenide transistors* AKIKO UEDA (Presenter), Spintronics Research Center, National Institute of Advanced Industrial Science and Technology (AIST), YIJIN ZHANG, Max Planck Institute for Solid State Research, HIROSHI IMAMURA, Spintronics Research Center, National Institute of Advanced Industrial Science and Technology (AIST), YOSHIHIRO IWASA, Department of Applied Physics and Quantum-Phase Electronics (QPEC) Center, The University of Tokyo — Ion gating is known as a powerful tool to access electronic functionalities with low voltage operation. Though many interesting experimental studies have been reported, the device simulation had never been performed before. In this work, we developed a two-dimensional layer transistor model based on the drift-diffusion method for an ionic liquid (IL) as a gate dielectric. We reproduced the transport characteristics of the ion-gated WSe$_2$ transistors reported in several experiments and explained the transport mechanism using the band profile and spatial distribution obtained by the calculation. In particular, the simulation explains the ambipolar behavior with the gate voltage comparable to the band gap energy, as well as the formation of p-n junctions in the channel reported in several experimental papers. The simulation clearly shows that the ambipolar behavior becomes possible by the dramatic change of the potential profile at the contacts. The developed model is highly advantageous for exploring the functionalities and design ideal devices for ion-gated transition-metal dichalcogenide transistors.

8:24AM L57.00003: Hybrid Transfer of 2D materials: An approach towards a wrinkle and contaminations free transfer of 2D materials grown on metallic substrates for van der Waals heterostructures and large scale industrial applications.*  SAJITH WITHANAGE (Presenter), THARANGA NANAYAKKARA, U. KUSHAN WIJEWARDENA, ANNIKA KRIISA, RAMESH MANI, Georgia State University — There has been much recent interest in transferring 2D materials on to non-conducting surfaces. One approach was to pick-up graphene grown by the CVD method using a flake of hexagonal boron nitride (hBN) to have a contamination-free dry transfer. [1] But this kind of transfer technique can be only used in small-scale device fabrication for laboratory use since the scale limitations of the hBN flakes and the limited supply of hBN flakes with low thicknesses. Here, we report a hybrid transfer technique that combines wet and dry transfer processes using polymer support resulting in wrinkle and contamination-free high mobility 2D materials. Thus, we detail the transfer process, conditions for a successful transfer and the quality of CVD grown graphene. The transferred graphene layers are characterized by various methods, and the results of the study are reported.

8:36AM L57.00004: Magnetotransport studies in hybrid 2D/0D nanostructures  ETHEL PEREZ-HOYOS (Presenter), YUNQIU (KELLY) LUO, ABHILASHA DEHANKAR, JINSONG XU, DANIEL PHARIS, ROLAND KAWAKAMI, JESSICA WINTER, EZEKIEL JOHNSTON-HALPERIN, Ohio State Univ - Columbus — We introduce a device fabrication strategy that takes advantage of stacking techniques developed for van der Waals heterostructures to construct hybrid 2D/0D composite magnetic nanostructures, with potential application in the study of spin and charge disorder as well as magnetic-proximity effects. The structures in this study are comprised of superparamagnetic iron oxide nanoparticles (SPIONs) and monolayer graphene. The SPIONs are deposited first using a Langmuir-Blodgett technique, yielding rafts of highly ordered nanoparticles (Fig.1b). Characterization via magnetic force microscopy (MFM) reveals magnetic order at multiple length scales and SQUID magnetometry identifies both glassy antiferromagnetic and ferromagnetic response. Single graphene monolayers are mechanically stacked on the SPIONs layer, and characterized via low temperature magneto-transport. Initial measurements show good electron mobility in the graphene layer and indications of exchange coupling between the graphene and the SPIONs layer. Measurements in the quantum Hall regime will be discussed.

ABRAR ALHAZMI (Presenter), MALAK ALBOGAMI, OALAIYAN ALOLAIYAN, MOHAMMED R AMER, King Abdulaziz City Sci & Tech — Layered 2D materials have recently attracted attention due to their unique electrical and optical properties. In particular, Germanium Sulfide (GeS) which has been predicted to exhibit high mobility. However, few research work reported in the literature on GeS devices and they exhibit high contact resistance. The origin of this contact resistance is still not clear. Here, we investigate the electron transport of pristine GeS field effect transistors. A high contact resistance was observed. Various methods were used to overcome this issue including thermal, electrical annealing, and 2D heterojunction contact. Both annealing methods did not yield any improvement in the measured $I/V_{ds}$. However, we observe an anomalous negative differential resistance (NDR) with low contact resistance and $n$-type conductivity when black phosphorus (BP) are deposited between GeS and S/D electrodes. This NDR is uncontrollable in ambient and insensitive to gate voltage. We believe this NDR is caused by chemical reaction between GeS and degraded BP where the measured electrical conductivity leads to chemical doping, causing the observation of conductivity switch from $p$-type for pristine GeS, to $n$-type for GeS with degraded BP contacts. Further investigations are needed to characterize the origin of this NDR.

**9:00AM L57.00006: Contact Doped Multi-layer Tungsten Diselenide Field Effect Transistors**

INYONG MOON (Presenter), SUNGWON LEE, Sungkyunkwan Univ., MINSUP CHOI, Columbia Univ., WON JONG YOO, Sungkyunkwan Univ. — According to the conventional transistor process including the silicon semiconductor device, it is the common practice to heavily dope contact regions under the metallic electrodes by using the ion implantation technique so as to minimize contact resistance. In this study, we demonstrate a contact doping technique applied to the ultra-thin (2~5 nm) tungsten diselenide (WSe$_2$) channel formed in field effect transistors (FET) by applying the selective oxidation process to the contact regions. Using our devices that underwent the contact doping, we were able to achieve high performance $p$-type FET electrical properties with an on/off ratio of $10^8$, a field effect mobility of 180 cm$^2$/Vs and a contact resistance of 1 kΩμm. Importantly, Schottky barrier heights (SBH) and Fermi level pinning factors of the contact doped WSe$_2$ FET were measured by employing various work function metals (In, Ti, Au, Pd) as the electrodes. We were able to derive the relationship between the Schottky barrier heights and the contact resistances very reliably.

The so-called Boltzmann Tyranny defines the fundamental thermionic limit of the subthreshold slope (SS) of a metal-oxide-semiconductor field-effect transistor (MOSFET) at 60 mV/dec at room temperature and, therefore, precludes the lowering of the supply voltage and the overall power consumption. Adding a ferroelectric dielectric as a negative capacitor to the gate stack of a MOSFET may offer a promising solution to bypassing this fundamental barrier. Meanwhile, two-dimensional (2D) semiconductors, such as atomically thin transition metal dichalcogenides (TMDs) due to their low dielectric constant, and ease of integration in a junctionless transistor topology, offer enhanced electrostatic control of the channel. In this talk, we will review the recent progress on negative capacitance field-effect transistors (NC-FET) and ferroelectric field-effect transistors (Fe-FET) using TMDs as the transistor channels. [1,2] More importantly, a new device concept, which we call as ferroelectric semiconductor field-effect transistor (FeS-FET), was proposed and experimentally demonstrated. [3] In this novel FeS-FET, a 2D ferroelectric semiconductor \( \alpha-\text{In}_2\text{Se}_3 \) is used to replace conventional semiconductor as channel. \( \alpha-\text{In}_2\text{Se}_3 \) is identified due to its proper bandgap, room temperature ferroelectricity, the ability to maintain ferroelectricity down to a few atomic layers and the feasibility for large-area growth.

**9:48AM L57.00008: 2D Heterostructure Devices** [Invited] ROMAN GORBATCHEV (Presenter), Manchester — Selected by Focus Topic Organizer (Deji Akinwande)
10:24AM L57.00009: New Approaches and Observations in Scaled Contacts for 2D FETs
ZHIHUI CHENG (Presenter), Duke University & Purdue University & NIST, HATTAN ABUZAID, Electrical and Computer Engineering, Duke University, YIFEI YU, Materials Science and Engineering, North Carolina State University, SHREYA SINGH, Electrical and Computer Engineering, Duke University, LINYOU CAO, Materials Science and Engineering, North Carolina State University, CURT RICHTER, Physical Measurement Laboratory, National Institute of Standards and Technology, AARON FRANKLIN, Electrical and Computer Engineering, Duke University — Atomically thin 2D crystals are promising channel materials for extremely scaled field-effect transistors (FETs). For devices at the scaled regime, both channel and contact length must be scaled, with channel length being the distance from source to drain contacts and contact length being the length of the source/drain covering the 2D semiconductor channel. Contacting 2D materials at these scaled contact lengths (< 30 nm) has rarely been pursued or studied in depth. Moreover, the device community has not yet determined how contacts can be scaled down without causing significant degradation in device performance; i.e., how long is the transfer length, below which current crowding effects appear? Here, we demonstrate new measurement approaches and results for determining the transfer length of MoS\textsubscript{2} FETs by physically scaling the contact length. We found that, contrary to previous reports, top contacts can be scaled to ~20 nm without obvious degradation in transistor performance. Our data from measurements of over 100 devices with different contact lengths statistically imply that contact resistance variation increases in the scaled contact regime. Our work illustrates the impact of current crowding in scaled contacts and the ultimate scalability of metal-2D contact interfaces.

10:36AM L57.00010: Ultrasensitive molecular interaction in MoS\textsubscript{2}-graphene hybrid structure via electrostatic control
RAHUL TRIPATHI (Presenter), ABHA MISRA, Indian Institute of Science — Following the discovery of graphene, other 2D materials such as TMDs offer great potential for future sensing devices because of the high surface-to-bulk ratio. Moreover, electronic transport in vertically stacked atomically thin heterojunctions of 2D materials are extremely sensitive to the surrounding atmosphere, thus allowing their exploration in molecular sensing applications. We report the fabrication of designed vdW interfaces of few-layer graphene and MoS\textsubscript{2} in vertical heterojunction and evaluation of electrical and molecular interaction. The few-layer MoS\textsubscript{2}-graphene with vertically stacked hybrid shows a non-linearity in the drain current due to barrier formation at the interface that can be modulated by an external electric field. The hetero p-n junction between MoS\textsubscript{2} on graphene reveals superior molecular interaction with a high sensitivity of 18\% at 10 ppb level of nitrogen dioxide in transfer characteristics near accumulation region at room temperature. We further observed that the recovery time of the device can be tuned using the switching behavior of the device depicting an overall superior sensing capability leading to an excellent advancement in sensing devices. Our findings offer significant insight into the MoS\textsubscript{2}-graphene heterostructure for molecular interaction.
10:48AM L57.00011: Monolayer-Bulk Black Phosphorus Natural Heterojunction Tunnel Field-Effect Transistor for Low Power Switches  
SEUNGHO KIM, SUNGJAE CHO, GYUHOMYEONG, WONGIL SHIN, HONGSIK LIM, BORAM KIM, TAEHYEOK JIN (Presenter), KAIST, SUNGJIN CHANG, NNFC, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS — Transistor down-scaling by Moore's law over fifty years enabled today's information technology, but fundamental limits have ended Moore's law [1]; Transistors require at least 60 mV switching voltage for each 10-fold current increase (subthreshold swing (SS) 60 mV/dec). Alternative tunnel field-effect transistors (TFETs) are widely studied to achieve a sub-thermionic SS and high I$_{60}$ (current where SS becomes 60 mV/dec) [2]. Heterojunction (HJ) TFETs bear promise to deliver high I$_{60}$, but experimental results do not meet theoretical expectations due to interface problems in the HJs constructed from different materials. Here, we report a natural HJ-TFET with spatially varying layer thickness in black phosphorus (BP) without interface problems. We achieved record-low average SS over 4–5 decades of current, SS$_{ave_{4dec}}$ ≈ 22.9 mV/dec and SS$_{ave_{5dec}}$ ≈ 26.0 mV/dec with record-high I$_{60}$ (= 0.65–1 μA/μm), paving the way for the application in low power switches.

8:00AM L58.00001: Quasiparticle Energies and Excitation Energies from Ground State DFT Calculations  
[Invited] WEITAO YANG (Presenter), Duke University — The perspectives of fractional charges and fractional spins provide a clear analysis of the errors of commonly used density functional approximations (DFAs). These errors, the delocalization and static correlation error, of popular DFAs lead to diversified problems in present-day density functional theory calculations. To achieve a universal elimination of these two errors, we developed a localized orbital scaling correction (LOSC) framework. The LOSC-DFAs lead to systematically improved results, including the dissociation of ionic species, single bonds, multiple bonds without breaking space or spin symmetry, the band gaps of molecules and polymer chains, the energy and density changes upon electron addition and removal, and photoemission spectra. Comparison of experimental quasiparticle energies for many finite systems with calculations from the GW Green function approach and LOSC shows that LOSC orbital energies achieve slightly better accuracy than the GW calculations with little dependence on the semilocal DFA, supporting the use of LOSC DFA orbital energies to predict quasiparticle energies. This leads the development of the Quasiparticle Energy DFT (QE-DFT) approach to the calculations of excitation energies of the N-electron systems from the ground state DFA calculations of the (N - 1)-electron systems. Results show good performance of QE-DFT for valence excitations with commonly used DFAs with or without LOSC, for Rydberg states only with the use of LOSC-DFA, and the accurate description of conical interactions. This highlights a new and simplest pathway to describe excited states.
We present an efficient self-consistent first-principles computational approach that extends the density functional theory plus on-site interaction (DFT+U) method further to include inter-site Hubbard Coulomb interaction (V). The extended DFT+U +V method is suitable to calculate electronic structures of periodic systems with various interactions with disparate spatial ranges. It has been known that typical computational methods for DFT+U and DFT+U+V require additional set of computations to obtain U and (or) V. In this presentation, we suggest a scheme to compute the Hubbard parameters self-consistently and ab initio without additional computations for a set of parameters of U and V. A few examples of calculations of energy bands for semiconductors and insulators will also be presented.

DFT calculations of defects in transition-metal oxides constitute a challenging task, often requiring advanced methods to ensure a reasonable description of the electronic structure and large supercells to mimic the dilute defect concentration. Several contradicting DFT results were reported for oxygen vacancies (V\text{O}) in SrTiO\text{3} (STO) and were often related to the peculiar properties of STO, which is a d\text{0} transition metal oxide with mixed ionic-covalent bonding. Here, for the first time, we apply the extended Hubbard DFT+U+V approach, including on-site (Ti-3d) as well as inter-site (Ti-3d and O-2p) electronic interactions, to study oxygen-deficient STO with Hubbard U and V parameters computed self-consistently via density-functional perturbation theory. The negligible additional cost of DFT+U+V compared to standard DFT enables the treatment of large supercells, yet the obtained structural and electronic properties agree well with hybrid-functional calculations and experiments. As such, DFT+U+V results in a bandgap and crystal field splitting for STO in good agreement with experiments. In turn, the description of the electronic properties of V\text{O} is improved, with formation energies much less dependent on the cell size compared to DFT+U and in excellent agreement with experiments.
9:00AM L58.00004: Spectral function database for correlated materials using beyond-DFT methods*  SUBHASISH MANDAL (Presenter), KRISTJAN HAULE, KARIN M RABE, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, United States — While DFT or DFT+U methods give quite accurate results for structural parameters in most materials, correct predictions of excited-state properties, even at a qualitative level, and other properties of correlated materials, usually require beyond-DFT methods. The existing materials databases, constructed in the spirit of the Materials Genome Initiative, are built almost exclusively by the DFT method and are thus very often making incorrect predictions for correlated materials. Various beyond DFT methods, such as meta-GGA, hybrid functionals, GW approximation, or dynamical mean-field theory have been developed to describe the electronic structure of correlated materials, but it is unclear how accurate these methods are when applied to a given strongly correlated solid. It is thus of pressing interest to compare their accuracy as applied to different categories of materials, and at the same time, to build the database of beyond-DFT calculations. We discuss a systematic study of these methods on a few training sets of correlated materials such as binary transition-metal oxides, Fe-pnictides & chalcogenides, and transition-metal dichalcogenides, and we compare theoretical predictions with experimental photoemission data, where available.

9:12AM L58.00005: Assessment of excited-state molecular geometries with optimally-tuned range-separated hybrid functionals  BERNHARD KRETZ (Presenter), DAVID ALEXANDER EGGER, Department of Physics, TU Munich — Computational modelling of photochemical processes (e.g., for photocatalysis) requires accurate descriptions of excited-state structural dynamics of the involved molecules. Often, the starting point of such investigations are geometries optimized for the lowest-lying excited state, as obtained in time-dependent density functional theory (TD-DFT) or high-level wave-function methods. While calculations based on TD-DFT are computationally very efficient, they often do not reach the accuracy of computationally more expensive wave-function methods[1]. However, the recently developed class of optimally-tuned range-separated hybrid (OT-RSH) functionals promises to reduce the gap in accuracy[2]. Here, we assess the precision of excited-state geometries obtained with TD-DFT and OT-RSH for a selection of organic molecules. Our focus lies on structural parameters (e.g., bond lengths, bond angles, etc.) of the lowest-excited singlet states, which we compare to high accuracy wave-function data from literature to benchmark our results.

9:24AM L58.00006: Kohn-Sham Density Functional Theory with Complex, Spin-Restricted Orbitals: Accessing a New Class of Densities without the Symmetry Dilemma  JOONHO LEE (Presenter), MARTIN P HEAD-GORDON, University of California, Berkeley — We show that using complex, spin-restricted orbitals in Kohn-Sham (KS) density functional theory allows one to access a new class of densities that is not accessible by either spin-restricted (RKS) or spin-unrestricted (UKS) orbitals [1]. We further show that the real part of a complex RKS (CRKS) density matrix can be nonidempotent when the imaginary part of the density matrix is not zero. Using CRKS orbitals shows significant improvements in the triplet-singlet gaps of a benchmark set, called TS12, for well-established, widely used density functionals. Moreover, it was shown that RKS and UKS yield qualitatively wrong charge densities and spin densities, respectively, leading to worse energetics. We demonstrate that representative modern density functionals show surprisingly no improvement even with a qualitatively more accurate density from CRKS orbitals. To this end, our work not only provides a way to escape the symmetry dilemma whenever there exists a CRKS solution, but also suggests a new route to design better approximate density functionals.

9:36AM L58.00007: "Implementation of imaginary time dependent density functional theory to periodic and noncollinear systems"*  JOHN MCFARLAND (Presenter), Florida State Univ — Recently an alternative to the SCF method for calculating the DFT electronic ground state was proposed that evolves the DFT wave function in imaginary time [1]. One benefit of this new method is that the DFT wave function is guaranteed to lower its energy and eventually reach the ground state with a sufficiently small time step. This avoids the problems in SCF that hinder convergence such as charge sloshing, which can necessitate fractional level filling. We extend imaginary time dependent density functional theory to periodic systems using a modification of the DFT package Quantum ESPRESSO, with the option of noncollinear and DFT+U calculations. We discuss some of the technical aspects of this as well as example systems which converge with this modification but have difficulty with standard implementations of SCF.

PyProcar: A Python library for electronic structure pre/post-processing

UTHPALA HERATH (Presenter), PEDRAM TAVADZE, Physics and Astronomy, West Virginia University, XU HE, ERIC BOUSQUET, Materials Theory, University of Liege, SOBHIT SINGH, Department of Physics and Astronomy, Rutgers University, FRANCISCO MUNOZ, Department of Physics, University of Chile, ALDO H ROMERO, Physics and Astronomy, West Virginia University — We present PyProcar, a Python package providing graphical representations for electronic structure calculations including band structures and Fermi surfaces as a function of atomic and/or s, p, d, f – orbital projected wavefunctions. This is compatible with DFT codes which output band and projection information in the PROCAR format, as done by the VASP and ABINIT codes. PyProcar is particularly suitable for studying atomic effects into the band structure, Fermi surface and spin texture. Aside from spin, orbital and atom projected band structures and Fermi surfaces, PyProcar plots Fermi surfaces which map colors to properties such as the electron velocity, electron-phonon mean path and effective mass. Another existing feature refers to the band unfolding of supercell calculations into predefined unit cells. PyProcar can be conveniently used in either a stand-alone command line mode or a library mode easily accessible through the Python packaging index (pip) and performs tasks with simple commands.

Session L59 DMP: MnBi2Te4 and Related Compounds: Bulk Properties

Mile High Ballroom 3C
Anti-site disorder and competing magnetic ground states of Mn$_{1-x}$Sb$_{0.67}$Te$_4^*$

YAOHUA LIU (Presenter), XIAOPING WANG, JIAQIANG YAN, Oak Ridge National Lab — Intrinsic magnetic topological insulators (TIs) provide a fertile playground to pursue exotic quantum states of matter at ambient conditions, such as the quantum anomalous Hall effect. MnBi$_2$Te$_4$, with the stacking of septuple-layers, has been recently predicted as the first instance of an antiferromagnetic TI, which has triggered intensive studies on related materials. The as-grown MnBi$_2$Te$_4$ is heavily electron-doped and substituting Bi with Sb is expected to fine-tune the Fermi level with little disturbance on the magnetic structure. Interestingly, we have found that the end compound MnSb$_2$Te$_4$, isostructural to MnBi$_2$Te$_4$ at room temperature, can host two dissimilar magnetic ground states with different magnetic wavevectors but similar ordering temperatures from magnetic measurements and single-crystal neutron diffraction (SCND) experiments. Energy-dispersive X-ray spectroscopy and SCND show Mn vacancies and Mn-Sb anti-site disorder in both cases. To explain the results, we consider a model where the sign of the effective inter-septuple-layer coupling becomes sensitive to the Mn-defect concentration on the Sb site.

Native defects in Antiferromagnetic Topological Insulator MnBi$_2$Te$_4^*$

ZENGLE HUANG (Presenter), Department of Physics and Astronomy, Rutgers University, New Brunswick, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, WEIDA WU, Department of Physics and Astronomy, Rutgers University, New Brunswick — The coupling of topological electronic states and magnetism can lead to various exotic phenomena such as quantum anomalous Hall effect, axion insulating state, etc. Recently, single crystals and thin films of MnBi$_2$Te$_4$ have been successfully synthesized and it has been shown to be a promising candidate of antiferromagnetic topological insulator [1, 2]. It is crucial to understand and control the defects in this material as they affect its electronic and magnetic properties. In this talk, I will present our study of the native defects in single-crystalline MnBi$_2$Te$_4$ using scanning tunneling microscopy (STM). We identify the dominant defects, Mn$_{Bi}$ antisites in the second layer of Bi, which may impact the magnetic properties of MnBi$_2$Te$_4$ [3, 4, 5]. In addition, we observe another interesting defects with pronounced defect states near the conduction band edge.

*This work is supported by NSF DMR-1506618.
Magnetism in MnBi$_2$Te$_4$ and related compounds

JIAQIANG YAN
(Presenter), ANDREW MAY, MICHAEL MCGUIRE, YAOHUA LIU, BRIAN SALES, Oak Ridge National Lab — MnBi$_2$Te$_4$ has been extensively investigated recently as the first intrinsic antiferromagnetic topological insulator. This compound also shows a strong correlation between structural, magnetic, and transport properties. In this talk, I will present our work on how the stacking of septuple (MnBi$_2$Te$_4$) and quintuple (Bi$_2$Te$_3$) layers, chemical doping, high pressure, and antisite defects affect the magnetic properties. I will also discuss how these results can guide us fine-tuning the magnetism for desired topological phenomena.

*Work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

MnBi$_{2n}$Te$_{3n+1}$: from intrinsic antiferromagnetic to ferromagnetic topological insulators

NI NI (Presenter), University of California, Los Angeles — Magnetic topological insulators provide an important materials platform to explore emergent quantum phenomena. Recently, MnBi$_2$Te$_4$ was discovered to be the first material realization of a van der Waals (vdW) antiferromagnetic topological insulator (TI). In the two-dimensional (2D) limit, at a record high temperature of 4.5 K, MnBi$_2$Te$_4$ manifests the QAH effect in the forced ferromagnetic state above 12 T [1]. To realize the QAH effect at lower fields or even zero field, it is essential to search for ferromagnetic TIs or antiferromagnetic TIs with lower saturation fields. By reducing the interlayer magnetic exchange interaction through our rational design of the natural heterostructure consisting of the building blocks of [MnBi$_2$Te$_4$] septuple layers and [Bi$_2$Te$_3$] quintuple layers, I will show that this family of materials can be tuned from antiferromagnetic to ferromagnetic, providing a superior material platform to investigate various emergent phenomena arising from the interplay between magnetism and band topology [2,3].

*Work at UCLA was supported by DOE, Office of Basic Energy Sciences under Award Number DE-SC0011978.
8:48AM L59.00005: Ferromagnetic van der Waals compound MnSb\(_{1.8}\)Bi\(_{0.2}\)Te\(_4\)  YANGYANG CHEN, YA-WEN CHUANG (Presenter), SENG HUAT LEE, YANGLIN ZHU, KEVIN HONZ, YINGDONG GUAN, YU WANG, KE WANG, ZHIQIANG MAO, Pennsylvania State University, COLIN HEIKES, PATRICK QUARTERMAN, National Institute of Standards and Technology, PAWEL ZAJDEL, University of Silesia, JULIE ANN BORCHERS, WILLIAM RATCLIFF, National Institute of Standards and Technology, JUN ZHU, Pennsylvania State University — The coexistence of topology and magnetism in the same material offers the possibility to realize novel quantum phenomena such as the quantum anomalous Hall effect. Van der Waals magnetic compounds in the form of MnSb\(_x\)Bi\(_{2-x}\)Te\(_4\) are promising candidates. In this work, we show that a Sb-rich composition MnSb\(_{1.8}\)Bi\(_{0.2}\)Te\(_4\) exhibits a ferromagnetic ground state below a Curie temperature of 26 K, in contrast to antiferromagnetic states found in previous studies of this compound family. Magneto-transport measurements are performed on flakes that are ~100 nm thick and prepared in an argon atmosphere. At low temperature, pronounced hysteresis is observed in magnetic field sweeps of \(R_{xy}\) and \(R_{xx}\). A remnant magnetization of \(M_0 = 0.6 \mu_B/Mn\), is extracted from bulk magnetization measurements. The presence of a major ferromagnetic phase is further confirmed by neutron diffraction studies. An excess signal beyond the conventional anomalous Hall effect is observed at \(T < 12\) K. We discuss the implications of our results.

9:00AM L59.00006: Stability subtlety of layered magnetic topological insulator MnBi\(_2\)Te\(_4\)*  JINLIANG NING (Presenter), Physics and Engineering Physics, Tulane University, YANGLIN ZHU, ZHIQIANG MAO, Department of Physics, Pennsylvania State University, JIANWEI SUN, Physics and Engineering Physics, Tulane University — Ab initio description of two dimensional magnetic materials (2DMM) thermodynamics faces great challenges, due to the coexistence of different kinds of chemical bonding, as well as coupling between charge, lattice, and spin degrees of freedom. As an illustration of such challenges, we investigated the metastability of a layered magnetic material MnBi\(_2\)Te\(_4\), which hosts the intrinsic quantum anomalous Hall effect but the crystal itself is hard to synthesize. We calculated the reaction free energy of Bi\(_2\)Te\(_3\)+MnTe→MnBi\(_2\)Te\(_4\), considering electron, vibration and magnetic contributions based on state-of-the-art SCAN+rVV10\(^1\) total energy calculations. We found MnBi\(_2\)Te\(_4\) to be stable only within a short high temperature range, consistent with experiments. Fundamental interactions including SOC effect, vdW interaction, 2D weak magnetism and lattice vibration all contribute subtly to the high-temperature stability of MnBi\(_2\)Te\(_4\), which exemplify that interplay of topology and magnetism can contribute to the stability of the material hosting it. These findings and methods pave a way for future high throughput discovery of novel 2DMM.

*This study was supported by DOE DE-SC0014208.
9:12AM L59.00007: Magnetic structure evolution in the Mn(Bi,Sb)$_2$Te$_4$ family of intrinsic magnetic topological insulators  COLIN HEIKES (Presenter), PATRICK QUARTERMAN, National Institute of Standards and Technology, YANGYANG CHEN, YA-WEN CHUANG, SENG HUAT LEE, YANGLIN ZHU, KEVIN HONZ, YINGDONG GUAN, YU WANG, Physics, The Pennsylvania State University, KE WANG, Materials Research Institute, The Pennsylvania State University, ZHIQIANG MAO, JUN ZHU, Physics, The Pennsylvania State University, PAWEL ZAJDEL, Institute of Physics, University of Silesia, JULIE ANN BORCHERS, WILLIAM RATCLIFF, National Institute of Standards and Technology — The Mn(Bi,Sb)$_2$Te$_4$ family of intrinsic magnetic topological insulators has been predicted to be an ideal platform to realize a high temperature quantum anomalous Hall state, an axion insulating state, as well as a variety of other non-trivial band topologies. The strong coupling between the magnetic ordering in these compounds and the details of their band structure makes understanding their magnetic structure and its evolution with chemistry and magnetic field critical for understanding these exotic states. Our prior work has demonstrated that the field driven spin canting in MnBi$_2$Te$_4$ drives the measured intrinsic anomalous Hall effect in that compound but there are many questions to be addressed about the details of the evolution of the magnetic phase diagram in this system as the Bi atoms are replaced with Sb [1]. Prior magnetometry and magnetotransport shows a clear bulk magnetic behavior change with increased Sb content, but the microscopic details of this evolution are unclear [2]. We will present structural and magnetic neutron scattering measurements and other magnetic characterization of the Mn(Bi,Sb)$_2$Te$_4$ family of compounds to clarify this evolution.

9:24AM L59.00008: Single Crystal Study of Magnetic Topological Material MnBi$_{2x}$Te$_{3x+1}$.  
JOSHUA WAKEFIELD (Presenter), TAKASHI KURUMAJI, TAKEHITO SUZUKI, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology MIT — MnBi$_2$Te$_4$ has emerged as the first stoichiometric antiferromagnetic topological insulator [1]. In thin flakes, MnBi$_2$Te$_4$ has shown remarkable properties including the quantum anomalous Hall (QAH) effect [2]. We investigate the single crystal growth and transport properties of other members of the MnBi$_{2x}$Te$_{3x+1}$ family and find both temperature and low field dependent crossovers from A-type antiferromagnetism to ferromagnetism in MnBi$_4$Te$_7$, suggesting MnBi$_4$Te$_7$ as another candidate for QAH effects in zero external field. We discuss the anomalous Hall response in relation to the magnetic structure, and dependence of the transport properties on angle of the external magnetic field.

MnBi$_{2n}$Te$_{3n+1}$

LEI DING (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, CHAOWEI HU, Department of Physics and Astronomy and California NanoSystems Institute, University of California, FENG YE, ERXI FENG, Neutron Scattering Division, Oak Ridge National Laboratory, NI NI, Department of Physics and Astronomy and California NanoSystems Institute, University of California, HUIBO CAO, Neutron Scattering Division, Oak Ridge National Laboratory — We present a systematic investigation of the crystal structure and magnetism of van der Waals topological insulators MnBi$_{2n}$Te$_{3n+1}$ (n = 1, 2) using single-crystal neutron diffraction, where emergent quantum phenomena have been recently observed. We show unambiguously that MnBi$_{2}$Te$_{4}$ orders antiferromagnetically below 24 K featured by a magnetic symmetry $R_f$-3c while MnBi$_{4}$Te$_{7}$ is antiferromagnetically below 13 K with a distinct magnetic space group $P_c$-3c1. They both present antiferromagnetically coupled ferromagnetic layers with spins along the c-axis. Further, we put forward a stacking rule for the crystal structure of an infinitely adaptive series MnBi$_{2n}$Te$_{3n+1}$ with the building unit of [Bi$_2$Te$_3$]. This enables us to draw that a two-dimensional magnetism limit might be realized in the derivatives. Our work may promote the theoretical predictions of exotic quantum states in the series of MnBi$_{2n}$Te$_{3n+1}$.

*The research at Oak Ridge National Laboratory (ORNL) was supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, Early Career Research Program Award KC0402010, under Contract DE-AC05-00OR22725 and the U.S. DOE, Office of Science User Facility operated by the ORNL.
Large intrinsic anomalous Hall effect in hole-doped ferromagnetic phase MnSb$_x$Bi$_{2-x}$Te$_4$*  

SENG HUAT LEE (Presenter), 2D Crystal Consortium, Materials Research Institute, Pennsylvania State University, University Park, Pennsylvania 16802, USA, YANGLIN ZHU, Department of Physics, Pennsylvania State University, University Park, Pennsylvania 16802, USA, LUJIN MIN, VERLINDE KATRINA, JINGYANG HE, Department of Materials Science and Engineering, Pennsylvania State University, University Park, Pennsylvania, 16802, USA, DAVID E GRAF, National High Magnetic Field Lab, Tallahassee, FL 32310, USA, RONALD REDWING, Department of Materials Science and Engineering, Pennsylvania State University, University Park, Pennsylvania, 16802, USA, ZHIQIANG MAO, Department of Physics, Pennsylvania State University, University Park, Pennsylvania 16802, USA — MnBi$_2$Te$_4$, an intrinsic magnetic topological insulator, has recently been predicted to possess a variety of topological quantum states, including quantum anomalous Hall insulator, axion insulator in its 2D thin layers and an ideal Weyl semimetal state in its bulk ferromagnetic (FM) phase$^{1,2}$. Although several interesting properties, including Chern insulator, axion insulator, and anomalous Hall effect (AHE) in its canted antiferromagnetic phase have been observed, the predicted FM Weyl state remains elusive$^{3-5}$. In this talk, we will report our magnetotransport studies on MnSb$_x$Bi$_{2-x}$Te$_4$. We will show when the Sb concentration is tuned to be close to a critical concentration where carrier density reaches a minimum, the FM phase under a high field range exhibits a large intrinsic AHE with the anomalous Hall angle reaching 5%. Moreover, the carrier mobility also reaches a maximum at the critical concentration. All these features are possibly associated with the long-sought ideal Weyl state.

10:00AM L59.00011: Quantum Oscillations in Intrinsic Magnetic Topological Insulator MnBi$_{2-x}$Sb$_x$Te$_4$*

QIANNI JIANG (Presenter), ZAIYAO FEI, TIANCHENG SONG, University of Washington, JIAQIANG YAN, Oak Ridge National Laboratory, PAUL MALINOWSKI, ZHAOYU LIU, University of Washington, DAVID E GRAF, National High Magnetic Field Laboratory, XIAODONG XU, JIUN-HAW CHU, University of Washington — The recently discovered first intrinsic antiferromagnetic (AFM) topological insulator (TI) MnBi$_2$Te$_4$ is expected to possess various exotic quantum states including axion insulator and quantum anomalous Hall effect. The band structure portrayed by ARPES measurements reveals nontrivial topology, but claims regarding the surface states are still controversial. When Bi is substituted by Sb, the material crosses a bulk charge neutrality point, from being electron-doped to hole-doped. By applying a magnetic field, it is possible to realize a magnetic Weyl semimetal phase by switching the AFM phase to the FM phase through a metamagnetic transition at B ~ 6T. Here, we present Shubnikov–de Haas oscillations of both electron and hole-doped MnBi$_{2-x}$Sb$_x$Te$_4$ in the FM state and trace its evolution as a function of chemical doping, providing the first measurement of the band structures of MnBi$_{2-x}$Sb$_x$Te$_4$ in the FM state.

*This work is supported as part of Programmable Quantum Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), under award DE-SC0019443.

10:12AM L59.00012: Optimization of the intrinsic magnetic topological insulator MnBi$_2$Te$_4$ and transport study

FENGQI SONG (Presenter), Nanjing Univ — Magnetic topological insulators (MTIs) offer a combination of topologically nontrivial characteristics and magnetic order and show promise in terms of potentially interesting physical phenomena such as quantum anomalous Hall (QAH) effect. However, the understanding of their properties and potential applications have been limited due to a lack of suitable MTIs. Here, we grow single crystals of Mn(Sb,Bi)$_2$Te$_4$ to search for intrinsic MTIs. We perform angle-resolved photoemission spectroscopy, transport measurements, and first-principles calculations to investigate the band structure, transport properties, and magnetism, as well as the evolution of their topological properties. We find that there exists an optimized MTI zone in the Mn(Sb,Bi)$_2$Te$_4$ phase diagram, which could possibly host a high-temperature QAH phase. We also report the reserved anomalous Hall effect (AHE) in the MnBi$_2$Te$_4$ thin film. By employing the top/bottom gate, a negative AHE loop gradually decreases to zero and changes to a reversed sign. The reversed AHE exhibits distinct coercive fields and temperature dependence from the previous AHE. It reaches the maximum inside the gap of the Dirac cone. The reversed AHE is attributed to the competition of intrinsic Berry curvature and extrinsic skew scattering.
Magnetotransport properties in MnBi$_{2n}$Te$_{3n+1}$

**CHAOWEI HU** (Presenter), JINYU LIU, SCOTT MACKEY, NI NI, University of California, Los Angeles — Recently, magnetic topological insulators MnBi$_{2n}$Te$_{3n+1}$ were discovered, where quantized anomalous hall resistance was observed in the two-dimensional limit of MnBi$_2$Te$_4$ at a record high temperature of 4 K under 12 T, providing an important material platform to explore emergent quantum phenomena such as quantized anomalous Hall effect and Majorana modes, etc. MnBi$_{2n}$Te$_{3n+1}$ family is made of alternating one septuple [MnBi$_2$Te$_4$] and (n-1) quintuple [Bi$_2$Te$_3$] layers, where the interlayer magnetic couplings are tuned systematically with increasing n. In this talk, we will show our recent results on the magnetotransport properties in MnBi$_{2n}$Te$_{3n+1}$, shedding light on the interplay between magnetism and band topology.

*Work at UCLA was supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0011978.

Intrinsic magnetic topological states in MnBi$_2$Te$_4$ family

**JING WANG** (Presenter), Fudan Univ — Here, we first predict the tetradymite-type compound MnBi$_2$Te$_4$ and its related materials host topologically nontrivial magnetic states. The magnetic ground state of MnBi$_2$Te$_4$ is an antiferromagnetic topological insulator state with a large topologically non-trivial energy gap (0.2 eV). It presents the axion state, which has gapped bulk and surface states, and the quantized topological magnetoelectric effect. It has several advantages over the previous proposals on realizing the topological magnetoelectric effect. The intrinsic magnetic and band inversion further lead to quantum anomalous Hall effect in odd layer MnBi$_2$Te$_4$ thin film with combined inversion and time-reversal symmetry breaking, which has been recently observed in experiments. The high quality intrinsic MnBi$_2$Te$_4$ together with other magnetic/superconducting 2D materials provides fertile ground for exploring exotic topological quantum phenomena.

Pressure-tuned interlayer coupling of the magnetic topological insulators MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ (n=1,2)

**JIFENG SHAO** (Presenter), XIAO-MING MA, JINGYUAN LI, YICHEN SUN, RUI'E LU, MENG ZENG, YIJIE HAO, CHANG LIU, QIHANG LIU, YUE ZHAO, Southern University of Science and Technology — Magnetic topological insulators with nontrivial topological band structure and broken time-reveal symmetry provide an ideal platform for exploring exotic quantum phenomena, such as quantum anomalous Hall effect (QAHE), axion insulator state and Majorana mode. Recently, MnBi$_2$Te$_4$ was discovered as the first intrinsic antiferromagnetic topological insulator. However, due to the large antiferromagnetic interlayer coupling, strong external magnetic field is needed to fully polarize the magnetic moment to achieve QAHE. By inserting one or two Bi$_2$Te$_3$ layers into the adjacent MnBi$_2$Te$_4$ septuple layers, the antiferromagnetic interlayer coupling can be greatly reduced. Using hydrostatic pressure to further modulate the interlayer interaction, we study the transport properties of the MnBi$_2$Te$_4$(Bi$_2$Te$_3$)$_n$ (n=1,2) bulk crystals and investigate the pressure tuned interlayer coupling in detail.
8:00AM L60.00001: Towards Material realizations of 2D Topological Superconductivities in \( \text{Pb}_{1-x}\text{Bi}_x \) Systems* [Invited] WEI QIN (Presenter), University of Science and Technology of China — New material realization of two-dimensional (2D) topological superconductors (TSCs) can provide new platforms for experimentally detecting and manipulating Majorana quasiparticles, which in pairs serve as an exotic entity for nonlocal encoding of quantum information [1]. In this talk, I will focus possibilities of realizing 2D intrinsic topological superconductivity in a new material family, namely atomic-layer-thin \( \text{Pb}_{1-x}\text{Bi}_x \) alloys. Based on first-principles calculations, three nearly energetically degenerate structural configurations of the prototypical system \( \text{Pb}_3\text{Bi} \) grown on a Ge substrate are identified and labeled respectively as \( T_1, H_3 \) and \( T_4 \) [2]. All three structures possess large Rashba energy band splittings and van Hove singularities (VHS) in the density of states. With proper tensile strains, \( H_3 \) and \( T_4 \) configurations are demonstrated to have nontrivial band topology characterized by topological edge states. To investigate the superconductivity, an effective formalism that respects hexagonal symmetry, Rashba splitting, VHS and electron-electron interactions is developed with parameters obtained from first-principles calculations. Our renormalization group analysis shows that a chiral \( p \)-wave superconducting phase dominates over other competing orders. Given these results, we identify hole-doped \( \text{Pb}_3\text{Bi}/\text{Ge}(111) \) as an appealing platform for realizing intrinsic 2D topological superconductivity [3].

*Supported by NSF of China

8:36AM L60.00002: Volkov-Pankratov states in two-dimensional topological superconductors DAVID ALSPAUGH (Presenter), DANIEL E SHEEHY, Louisiana State University, Baton Rouge, MARK OLIVER GOERBIG, PASCAL SIMON, Laboratoire de Physique des Solides, Université Paris-Sud — We study the in-gap states that appear at the boundaries of two-dimensional topological superconductors. While the massless chiral Majorana quasiparticles are guaranteed to arise by the bulk-edge correspondence, we find that they could be accompanied by massive Volkov-Pankratov (VP) states which are present only when the interface is sufficiently smooth. These predictions can be tested in an s-wave superconductor with strong Rashba spin-orbit coupling placed on top of a magnetic domain wall. We calculate the spin-resolved local density of states of the VP states about the band inversion generated by a magnetic domain wall and find that they are oppositely spin-polarized on either side of the topological phase boundary. We also demonstrate that the spatial position, energy-level spacing, and spin polarization of the VP states can be modified by the introduction of in-plane electric fields.
8:48AM L60.00003: Unconventional superconductivity in a doped quantum spin Hall insulator*  DOMENICO DI SANTE (Presenter), XIANXIN WU, MARIO FINK, WERNER R HANKE, RONNY THOMALE, Institut für Theoretische Physik und Astrophysik, University of Würzburg — A monolayer of jacutingaite (Pt$_2$HgSe$_3$) has recently been identified as a novel quantum spin Hall insulator. By first-principles calculations, we study its Fermiology in the doped regime and unveil a type-I and type-II van Hove singularity for hole and electron doping, respectively. We find that the common link between the propensity for a topological band gap at pristine filling and unconventional superconductivity at finite doping roots in the longer ranged hybridization integrals on the honeycomb lattice. In a combined effort of random phase approximation and functional renormalization group, we find chiral d-wave order for the type-I and odd-parity f-wave order for the type-II regime.

*This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – Project-ID 258499086 – SFB 1170 (Project B06) and by the Dresden-Würzburg Center for Topological Quantum Matter Research (ct.qmat).

9:00AM L60.00004: Majorana zero modes by engineering topological kink states in two dimensional electron gas  SHUGUANG CHENG, Department of Physics, Northwest University, China, JIE LIU, Department of Applied Physics, School of Science, Xi’an Jiaotong University, China, HAIWEN LIU, Center for Advanced Quantum Studies, Department of Physics, Beijing Normal University, China, HUA JIANG (Presenter), School of Physical Science and Technology, Soochow University, China, QING-FENG SUN, XINCHENG XIE, International Center for Quantum Materials, School of Physics, Peking University, China — Majorana zero modes (MZMs)–bearing potential applications for topological quantum computing are verified in quasi-one-dimensional (1D) Fermion systems, including semiconductor nanowires, magnetic atomic chains, planar Josephson junctions. However, the existence of multibands in these systems makes the MZMs fragile to the influence of disorder. Moreover, in practical perspective, the proximity induced superconductivity may be difficult and restricted for 1D systems. Here, we propose a flexible route to realize MZMs through 1D topological kink states by engineering a 2D electron gas with antidot lattices, in which both the aforementioned issues can be avoided owing to the robustness of kink states and the intrinsically attainable superconductivity in high-dimensional systems. The MZMs are verified to be quite robust against disorders and the bending of kink states, and can be conveniently tuned by varying the Rashba spin-orbit coupling strength. Our proposal provides an experimental feasible platform for MZMs with systematic manipulability and assembleability based on the present techniques in 2D electron gas system.
Transport properties of Majorana-Josephson interferometer

**CHANG-AN LI** (Presenter), **JIAN LI**, School of Science, Westlake University, **SHUN-QING SHEN**, Department of Physics, The University of Hong Kong — We study the transport properties of Majorana-Josephson interferometer, which is consisted of a two-terminal quantum anomalous Hall insulator strip with two superconducting bars grown over it, to showcase the interference nature of chiral Majorana modes. In this Majorana-Josephson interferometer, the interference effect is caused by a Majorana valve between two topological superconductors that form a Josephson junction. Its transport observables exhibit interference patterns depending on the Josephson phase as well as the junction length. We also show that the interference patterns are robust against weak disorder while strong dephasing effect destroys them. Interestingly, a Majorana-Josephson interferometer can work as two effectively separated Mach-Zennder interferometers, and it is even able to detect the Z2 phase of quantum vortices in topological superconductors. Experimental observation of these interference patterns will probe the topological superconducting phase in related systems and may pave a path for their further manipulations in topological quantum computation.

Josephson Interferometry of Zig-Zag Junctions Demonstrating Enhanced Localization

**ANDREW SAYDJARI** (Presenter), **ANDREW PIERCE**, **HECHEN REN**, **MICHAEL KOSOWSKY**, Harvard University, **CHRISTOPHER AMES**, **MARTIN STENHO**, **LAURENS W MOLENKAMP**, University of Wurzburg, **AMIR YACOBY**, Harvard University — Josephson junctions on mercury telluride quantum wells combine strong spin-orbit effects, s-wave superconductivity, and arbitrary lithographic design. This platform facilitates both the study of induced superconductivity in the quantum well and topological states in quasi-1D systems. While zero bias peaks have been observed in these quasi-1D systems, small topological gaps and poor confinement of the 0-D topological states makes their assignment as Majorana fermions challenging. Recent theoretical work suggests an order of magnitude enhancement in the topological gap and localization when the Josephson junction is fabricated in a zig-zag geometry [1]. In this work, we provide the first characterization of zig-zag geometry junctions and demonstrate enhanced localization of electrons within the junction.

9:36AM L60.00007: Magnetic Skyrmion Induced Topological Superconductivity
ERIC MASCOT (Presenter), DIRK KLAUS MORR, Univ of Illinois - Chicago — Magnetic skyrmions are a stable topological spin texture found in magnetic materials with Dzyaloshinskii-Moriya interactions. These skyrmions are highly controllable and can be written and deleted using spin polarized currents [1] and varied in size from 1 nm to 100 nm [2] by controlling material properties such as thickness or doping [3].

Here, we investigate magnet-superconductor heterostructures in which the presence of a magnetic skyrmion lattice gives rise to the emergence of topological superconductivity. We demonstrate that tuning between different topological phases can be achieved by varying the size of the skyrmions, the magnetic exchange coupling, and the chemical potential. We also show that the presence of magnetic skyrmions gives rise to a characteristic spatial structure of chiral Majorana edge modes, and of the induced superconducting triplet correlations, which can be probed experimentally.

*This work was supported by the U. S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-FG02-05ER46225.

9:48AM L60.00008: Tuning Shiba states hybridization on proximitized superconducting surface
HAO DING (Presenter), YUWEN HU, Princeton University, SILAS HOFFMAN, University of Basel, MALLIKA RANDERIA, Princeton University, OINDRILA DEB, JELENA KLINOVAJA, DANIEL LOSS, University of Basel, ALI YAZDANI, Princeton University — Magnetic atoms on a superconductor induce in-gap Shiba states that can be hybridized to create a topological superconducting phase when placed in one-dimensional chains, with Majorana zero modes (MZMs) localized at their ends. Here we study magnetic Gd adatoms deposited on the surface of epitaxially grown Bi(110) thin films on a superconducting Nb(110) surface using a dilution refrigerator scanning tunneling microscope (STM). Our spectroscopic measurements show a hard superconducting gap of 1.5 meV on Bi surface and the presence of Shiba states near Gd atoms. By manipulating Gd atoms with the STM tip, we find the Shiba states start hybridizing once two Gd atoms are closer than Fermi wavelength of Bi(110) surface states (~ 20 Å), which indicates the critical role of RKKY interaction mediated by Bi electrons. Through systematically changing the configurations of two Gd atoms, we show the hybridization can be dramatically strengthened as the distance between Gd atoms decreases. Our work provides a promising platform for realizing MZMs because it allows fine control over Shiba states hybridization.

10:00AM L60.00009: RKKY-induced magnetic transition for pairs of magnetic atoms on proximitized superconducting surface* YUWEN HU (Presenter), HAO DING, Department of Physics, Princeton University, SILAS HOFFMAN, Department of Physics, University of Basel, MALLIKA RANDERIA, Department of Physics, Princeton University, OINDRILA DEB, JELENA KLINOVAYA, DANIEL LOSS, Department of Physics, University of Basel, ALI YAZDANI, Department of Physics, Princeton University — An atomic chain with helical spin texture proximitized by an s-wave superconductor can harbor topological superconductivity that gives rise to Majorana zero modes (MZMs) localized at its both ends. Understanding the exchange interaction between magnetic atoms on a superconducting surface is the key to realizing helical spin chains and MZMs. Here we use atomic manipulation to build magnetic Gd dimers on proximitized superconducting Bi(110) surface with a dilution refrigerator scanning tunneling microscope (STM). By measuring the in-gap Shiba states induced by magnetism of Gd dimers, we find the magnetic ground state of Gd dimers changes from out-of-plane ferromagnetic to in-plane antiferromagnetic and then to in-plane ferromagnetic phase as a function of the distance between two Gd atoms. The Shiba states splitting behavior in the in-plane ferromagnetic state suggests the exchange interaction between two Gd atoms is dominated by RKKY interaction. Finally, by taking magnetic anisotropy, spin-orbit coupling and RKKY interaction into account, we propose a theoretical model that can describe this system.

10:12AM L60.00010: Topological superconductivity of adatom chains as probe for unconventional pairing ANDREAS KREISEL (Presenter), Institute for Theoretical Physics, University of Leipzig, TIMO HYART, International Research Centre MagTop, Institute of Physics, Polish Academy of Sciences, BERND ROSENOW, Institute for Theoretical Physics, University of Leipzig — Chains of magnetic atoms on the surface of s-wave superconductors, have been established as a laboratory for the study of Majorana bound states. In such systems, the breaking of time reversal due to magnetic moments makes the system a one-dimensional topological superconductor. However, in unconventional superconductors even non-magnetic impurities can induce in-gap states since scattering of Cooper pairs changes their momentum but not their phase. Here, we propose a novel paradigm for creating topological superconductivity, which is based on an unconventional superconductor with a chain of non-magnetic impurities on its surface. The system can be driven into the topological phase by tuning magnitude and direction of an external Zeeman field. We show that the topological energy gap can approach the minimum of the bulk energy gap. We develop a general mapping of films with impurity chains in multiband superconductors to one-dimensional lattice Hamiltonians. This allows us to illustrate the feasibility of our proposal in the case of the material Sr$_2$RuO$_4$, and to demonstrate that the study of impurity chains can be employed as a diagnostic tool for the nature of the pairing symmetry. This enables to distinguish competing proposals for the pairing symmetry in Sr$_2$RuO$_4$. 
10:24AM L60.00011: New classification of topological superconductors in 1D magnetic groups*  JINYU ZOU, Huazhong University of Science & Technology, ZHIDA SONG, Princeton University, GANG XU (Presenter), Huazhong University of Science & Technology — Topological superconductors (TSCs) with Majorana zero modes (MZMs) and their potential application in topological quantum computation have become an important area in condensed matter physics. Their topological classification with crystalline symmetries is an important and useful question for finding the possible TSC materials. We have classified the TSC phase in 1D system with local crystalline time reversal symmetry (LCTRS), where the time reversal symmetry (TRS) is broken, but the combination of TRS with some local crystalline symmetry is preserved. The LCTRS $M_x T$ or $C_{2z} T$ will lead to an effective BDI symmetry class which has a $Z$ classification. The case of LCTRS $C_{4z} T$ ($C_{6z} T$) are not included in the Altland and Zirnbauer (AZ) symmetry classes, and exhibit the $Z (Z + Z)$ classification TSC phase with the robust MZMs protected by the unitary chiral symmetry, which is different from the previously studied TSCs in BDI, DIII and D classes. We also present a minimal BdG Hamiltonian with $C_{4} T$ or $C_{6} T$ symmetry to illustrate the novel TSC phase.

10:36AM L60.00012: Topological Superconductivity Intertwined with Broken Symmetries*  HUI-KE JIN (Presenter), Zhejiang Univ, YI ZHOU, Institute of Physics, DONG-HUI XU, Department of Physics, Hubei University — Recently the superconductor and topological semimetal PbTaSe2 was experimentally found to exhibit surface-only lattice rotational symmetry breaking below Tc . We exploit the Ginzburg-Landau free energy and propose a microscopic two-channel model to study possible superconducting states on the surface of PbTaSe2 . We identify two types of topological superconducting states. One is time-reversal invariant and preserves the lattice hexagonal symmetry while the other breaks both symmetries. We prove that for a C3v lattice with spatial inversion symmetry breaking and strong spin-orbit coupling, the time reversal symmetry must be broken and the only way to lead a nematic superconductor is the mixing of 1D and 2D irreducible representation superconducting states.

**8:00AM L61.00001: Electronic Nematicity in FeSe** [Invited] MING YI (Presenter), Rice University — Superconductivity emerges in proximity to a nematic phase in most iron-based superconductors. It is therefore important to understand the impact of nematicity on the electronic structure. Orbital assignment and tracking across the nematic phase transition proved to be challenging due to the multiband nature of iron-based superconductors and twinning effects. Here we report a detailed study of the electronic structure of fully detwinned FeSe across the nematic phase transition using angle-resolved photoemission spectroscopy. We clearly observe a nematicity-driven band-reconstruction involving dxz, dyz and dxy orbitals. The nematic energy scale between dxz and dyz bands reach a maximum of 50meV at the Brillouin zone corner. We are also able to track the dxz electron pocket across the nematic transition and explain its absence in the nematic state. Our comprehensive data of the electronic structure provide an accurate basis for theoretical models of the superconducting pairing in FeSe.

**8:36AM L61.00002: Evolution of soft phonons in FeSe under pressure** ADRIAN MERRITT (Presenter), Physics, University of Colorado, Boulder, FRANK WEBER, ANNA BOEHMER, KAUSHIK SEN, JOHN-PAUL CASTELLAN, THOMAS WOLF, Institute for Solid State Physics, Karlsruhe Institute of Technology, SOFIA MICHAELA SOULIOU, European Synchrotron Radiation Facility, AHMET ALATAS, AYMAN SAID, Advanced Photon Source, Argonne National Laboratory, WENLI BI, University of Alabama - Birmingham, RAFAEL FERNANDES, University of Minnesota, DMITRY REZNIK, Physics, University of Colorado, Boulder — FeSe, as the simplest iron-based superconductor (Fe-SC), is of great interest for furthering our understanding of the Fe-SC materials. It shares a common tetragonal-to-orthorhombic phase transition at 90 K with many of the Fe-SCs, and becomes superconducting at 9 K, but in contrast displays no magnetic order. Previous studies have shown an enhancement of the superconducting transition temperature with increasing pressure, with a maximum of 37 K at approximately 6.3 GPa, and magnetic order concurrent with the structural transition above 1.6 GPa. Here we present IXS measurements of TA phonon dispersion from which we can extract the nematic correlation length. The phonon renormalization effects observed in our experiments have important implications for nematicity and superconductivity. This includes a significant reduction in the phonon softening at the high-pressure structural-magnetic transition and a new phonon hardening effect at the superconducting transition. We will discuss the implications of these results in the context of pressure- and doping-dependence in the Fe-SCs.

8:48AM L61.00003: Observation of intra-unit-cell nematic order in epitaxial bilayer FeSe films on SrTiO$_3$(001)  

HUIMIN ZHANG (Presenter), Department of Physics and Astronomy, West Virginia University, ZHUOZHI GE, Department of Physics, University of Wisconsin-Milwaukee, QIANG ZOU, Department of Physics and Astronomy, West Virginia University, MICHAEL WEINERT, Department of Physics, University of Wisconsin-Milwaukee, LIAN LI, Department of Physics and Astronomy, West Virginia University — Epitaxial FeSe thin films provide an ideal platform to probe the interplay of superconductivity and nematicity, due to the absence of long-range magnetic order. Here, we systematically investigate the nematic order in high quality bilayer FeSe/SrTiO$_3$ films grown by molecular beam epitaxy. Using low temperature scanning tunneling microscopy/spectroscopy, we observe features associated with Se atoms to be elongated along the Fe-Fe lattice direction within a specific energy window, demonstrating symmetry breaking from fourfold to twofold. Detailed analysis of Fourier transformation of the STM images reveals that the intensity of Fe Bragg peak breaks rotational symmetry within each Fe unit cell, indicative of an intra-unit-cell nematicity. Our results provide critical information on nematicity in Fe-based superconductors, an essential element in understanding superconducting transition in these materials.

9:00AM L61.00004: Phonon spectroscopy in FeSe using high-resolution inelastic x-ray scattering  

NAOKI MURAI (Presenter), Materials and Life Science Division, J-PARC Center, Japan Atomic Energy Agency, TATSUO FUKUDA, Materials Sciences Research Center, Japan Atomic Energy Agency, MASAMICHI NAKAJIMA, Department of Physics, Osaka University, MITSUAKI KAWAMURA, Institute for Solid State Physics, The University of Tokyo, DAISUKE ISHIKAWA, Japan Synchrotron Radiation Research Institute, SETSUKO TAJIMA, Department of Physics, Osaka University, ALFRED BARON, RIKEN SPring-8 Center — We report an inelastic x-ray scattering investigation of phonons in FeSe superconductor. Comparing the experimental phonon dispersion with density functional theory (DFT) calculations in the non-magnetic state, we found a significant disagreement between them. Improved overall agreement was obtained by allowing for spin-polarization in the DFT calculations, despite the absence of magnetic order in the experiment. This calculation gives a realistic approximation of the disordered paramagnetic state of FeSe, in which strong spin fluctuations are present. We will discuss the current state of our analysis relating magnetism to the phonon dispersion.
9:12AM L61.00005: Room temperature local nematicity in FeSe superconductor* ROBERT KOCH (Presenter), Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, TATIANA KONSTANTINOVA, Department of Physics and Astronomy, Stony Brook University, MILINDA ABEYKOON, Photon Science Division, Brookhaven National Laboratory, AIFENG WANG, CEDOMIR PETROVIC, YIMEI ZHU, EMIL BOZIN, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, SIMON J L BILLINGE, Columbia University, Department of Applied Physics and Applied Mathematics — We report pair distribution function measurements of the iron-based superconductor FeSe above and below the structural transition temperature. Structural analysis reveals a local orthorhombic distortion with a correlation length of about 4 nm at temperatures where an average tetragonal symmetry is observed. The analysis further demonstrates that the local distortion is larger than the global distortion at temperatures where the average observed symmetry is orthorhombic. Our results suggest that the low-temperature macroscopic nematic state in FeSe forms from an imperfect ordering of orbital-degeneracy-lifted nematic fluctuations which persist up to at least 300 K.

*This work was supported by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences (DOE-BES) under contract No. DE-SC0012704. X-ray PDF measurements were conducted on beamline 28-ID-1 of the National Synchrotron Light Source II, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Brookhaven National Laboratory under Contract No. DE-SC0012704.

9:24AM L61.00006: Observation of layer-dependent \(d_{xz}/d_{yz}\) band splittings in the nematic phase of FeSe/SrTiO\(_3\) films XILIANG PENG (Presenter), Institute of Physics, Chinese Academy of Sciences, KUN JIANG, Boston College, XIANXIN WU, University of Wurzburg, YONGHAO YUAN, Tsinghua University, YAOBO HUANG, Shanghai Synchrotron Radiation Facility, TIAN QIAN, Institute of Physics, Chinese Academy of Sciences, WEI LI, Tsinghua University, JIANGPING HU, Institute of Physics, Chinese Academy of Sciences, ZIQIANG WANG, Boston College, YUJIE SUN, HONG DING, Institute of Physics, Chinese Academy of Sciences — The effect of interlayer coupling on physical properties of layered materials such as iron-based superconductors is an interesting question. Here, we use angle-resolved photoemission spectroscopy to directly observe the electronic structure of FeSe films with different layers grown on SrTiO\(_3\)(001) substrates by \textit{in situ} molecular beam epitaxy. We find two distinct layer-dependent band splittings in the Brillouin zone center and corner, respectively. In the Brillouin zone corner, the band splitting caused by the nematic phase decreases with the increase in the number of layers. On the contrary, the degeneracy of \(d_{xz}/d_{yz}\) bands in double-layer FeSe is lifted in multi-layer films and the band splitting in the Brillouin zone center becomes larger with the increase of film thickness. The results of double-layer FeSe grown on SrTiO\(_3\) favor the proposal of \(d\)-wave nematic order. Our layer-dependent experiments provide limitations for the theoretical study of the nematic phase in FeSe and shed insights for the study of the interplay between nematicity and superconductivity.
9:36AM L61.00007: Nematicity from spin correlations in iron-based superconductors*
RONG YU (Presenter), YIMING WANG, Department of Physics, Renmin University of China, WENJUN HU, Department of Physics and Astronomy, University of Tennessee, Knoxville, QIMIAO SI, Department of Physics and Astronomy, Rice University — Electronic nematic order has been the topic of considerable interest in the area of iron-based superconductors. Motivated by recent experimental works, we study the connection between nematic order and magnetic fluctuations. We show, based on a symmetry analysis, that the spin correlations in the system allow for a variety of nematic orders, in particular an unusual $B_{2g}$ nematicity. Using qualitative considerations as well as microscopic calculations, we discuss the types of magnetic fluctuations that stabilize this $B_{2g}$ nematicity and how our proposed mechanism provides a natural understanding of the recent experimental observations in the heavily hole doped iron pnictides (Rb,Cs)Fe$_2$As$_2$. We also discuss the effects associated with the nematic transition.

Welch Foundation Grant No. C-1411 (W.H. and Q.S.)

9:48AM L61.00008: Spin nematicity in the local-moment Fe-chalcogenide KFe$_{0.8}$Ag$_{1.2}$Te$_2$ YU SONG (Presenter), University of California, Berkeley — Iron-based superconductors appear in the vicinity of a nematic quantum critical point, and due to the presence of spin, orbital and charge degrees of freedom, nature of the nematic order has been the focus of research in recent years. One route to address this question is to look for clues in related materials that exhibit similar physics. In semiconducting KFe$_{0.8}$Ag$_{1.2}$Te$_2$, an analogue of the archetypical iron pnictide BaFe$_2$As$_2$, we found simultaneous stripe-type magnetic order and nematic order below $T_{S,N}=$35 K, with striking similarities between the two systems. Above $T_{S,N}$, a sizable spin anisotropy develops under a small strain and increase upon cooling towards $T_{S,N}$, indicative of a divergent nematic susceptibility. Since the magnetic susceptibility of KFe$_{0.8}$Ag$_{1.2}$Te$_2$ is well described by the Curie-Weiss law with $S\approx$1, it is a local-moment magnet with orbital degeneracy. The similarities between nematic orders in KFe$_{0.8}$Ag$_{1.2}$Te$_2$ and BaFe$_2$As$_2$ suggest our findings to be relevant for iron-based superconductors, and establish KFe$_{0.8}$Ag$_{1.2}$Te$_2$ as a model system to investigate electronic nematicity in the localized limit.
Exploring the electronic structure of BaFe$_2$As$_2$ using resonant Raman scattering

RUDOLF HACKL (Presenter), ANDREAS BAUM, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, YING LI, Institute for Theoretical Physics, Goethe University Frankfurt, NENAD LAZAREVIC, Center for Solid State Physics and New Materials, Institute of Physics Belgrade, DANIEL JOST, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, JIUN-HAW CHU, Department of Physics, University of Washington, IAN FISHER, Geballe Laboratory for Advanced Materials & Dept. of Applied Physics, Stanford University, ROSER VALENTI, Institute for Theoretical Physics, Goethe University Frankfurt, IGOR MAZIN, Code 6393, Naval Research Laboratory — Iron-based materials are characterized by the competition of various phases including magnetism, nematicity, and superconductivity. The interrelation of these instabilities is a key question of both materials science and theoretical modelling. In this study we present light scattering data on twin-free BaFe$_2$As$_2$ as a function of the energy of the incident photons. The phonon intensities display an anisotropy for the polarizations oriented along either the ferro- or the antiferromagnetically ordered direction. This anisotropy makes the fully symmetric As phonon to appear in crossed polarizations. The anomalous intensity and the anisotropy of the spectral weight increase substantially in the blue-green spectral range. The experimental results are analyzed using density functional theory. Qualitative agreement between model calculations and experiment is found if the magnetic order is properly taken into account. The anomalies are fully developed only in the presence of long range magnetic order and are not directly linked to nematicity. Rather they are a high-energy phenomenon indicating that magnetism and nematicity are interrelated.

Hidden antiferro-nematic order in BaFe$_2$As$_2$ and NaFeAs above $T_S$

SEIICHIRO ONARI (Presenter), HIROSHI KONTANI, Physics, Nagoya University — In some Fe-based superconductors such as BaFe$_2$As$_2$ and NaFeAs, $C_4$ symmetry breaking emerges at $T^*$, which is tens of Kelvin higher than the structural transition temperature $T_S$ [1,2]. In this "hidden nematic state" below $T^*$, the orthorhombicity is very tiny. To explain this long-standing mystery, we propose the emergence of antiferro-bond order with antiferro wavevector $q=(0,\pi)$ at $T^*$, by solving the linearized density-wave equation based on the vertex correction theory [3,4]. This antiferro-bond order originates from the inter-orbital nesting between the $d_{xy}$-orbital hole-pocket and the electron-pocket, and naturally explains the pseudogap, band-folding, and tiny nematicity linear in $T^*-T$.

Quantum Critical Enhancement of Nematic-Resistivity Anisotropy in Underdoped Ba(Fe\textsubscript{1-x}Co\textsubscript{x})\textsubscript{2}As\textsubscript{2}\* SHUA SANCHEZ (Presenter), PAUL MALINOWSKI, University of Washington, JONG WOO KIM, PHILIP RYAN, APS, Argonne National Labs, JIUN-HAW CHU, University of Washington — The proportionality constant between the thermodynamic order parameter of a symmetry breaking phase and its associated transport coefficient often contains important information about the underlying electronic structure of a material. For instance, the anomalous Hall effect has been used to probe the Berry curvature of the band structures. Here we show how the proportionality constant between resistivity anisotropy and orthorhombicity in the nematic ordered phase is directly related to the elastoresistivity coefficient measured above the phase transition temperature. Using this relation, we discovered that this proportional constant increases significantly as doping approaches optimal, indicating the enhanced coupling between nematicity and conducting electrons near the quantum critical point.

*This work is supported by the Air Force Office of Scientific Research Young Investigator Program under Grant FA9550-17-1-0217.

Non-linear elasto-Hall measurements in iron-based superconductors\* PAUL MALINOWSKI (Presenter), QIANNI JIANG, ZHAOYU LIU, YUE SHI, SHUA SANCHEZ, JIUN-HAW CHU, University of Washington — It is well established that a rotational symmetry breaking electronic nematic phase is ubiquitous in the phase diagrams of iron-based superconductors and that anisotropic strain is a uniquely powerful in-situ probe of electronic anisotropy in these systems. In addition to the long-held belief that magnetic/nematic fluctuations are essential to understanding the pairing mechanism of the high $T_c$ superconductivity, they also drastically modify the normal state properties, evidenced by non-Fermi liquid behavior and strongly temperature dependent transport coefficients. In this work, we present the observation of the non-linear elasto-Hall effect in Co doped and P doped BaFe2As2. Our measurement reveals a large quadratic term of the Hall coefficient as a function of B2g anisotropic strain. For the optimally doped composition, the nonlinear elasto-resistivity diverges as temperature decreases. Combined with elastoresistivity, our result provides crucial insight into how nematicity and nematic fluctuations couple to conducting electrons.

Investigation of nematic phase in LaFeAsO

SOONSANG HUH, YOUNSIK KIM (Presenter), WONSHIK KYUNG, JONGKEUN JUNG, Seoul Natl Univ, SAICHARAN ASWARTHAM, BERND BUECHNER, IFW Dresden, CHENGXIAO DONG, JIANGPING HU, Beijing National Laboratory for Condensed Matter Physics, Chinese Academy of Sciences, SOOHYUN CHO, DAWEI SHEN, Shanghai Institute of Microsystem and Information Technology (SIMIT), Chinese Academy of Sciences, JONATHAN DENLINGER, Advanced Light Source, Lawrence Berkeley National Laboratory, CHANGYOUNG KIM, Seoul Natl Univ — The nematic phase is believed to play a key role in iron based superconductor (IBSC), but it is not fully understood. LaFeAsO, known to have nematic phase but its electronic structure is not well understood, is a good system to get new clues about the nematic phase. To investigate the electronic structure of LaFeAsO nematic phase, we performed angle resolved photoemission spectroscopy (APRES) experiment. We report temperature dependent band splitting behavior between $d_{xz}$ and $d_{yz}$ hole band near $\Gamma$ and $M$ point.

Session L62 DMP: Electron Transport in Nanostructures I — Mile High Ballroom 4C

- Jia Li, Brown University - Tag(s): Focus

Ultrafast and Cooperative Light-Matter Coupling [Invited] JUNICHIRO KONO (Presenter), Rice Univ — Recent experiments have shown that light and matter can mix together to an extreme degree, entering previously uncharted regimes of light-matter interactions [1]. This talk will summarize a series of experiments we have performed in such regimes. We will first describe our observation of ultrastrong coupling (USC) of a 2D electron gas with high-Q THz cavity photons in a quantizing magnetic field, demonstrating a record-high cooperativity [2]. The electron cyclotron resonance peak exhibited splitting into the lower and upper polariton branches with a magnitude that is proportional to the square-root of the electron density, a hallmark of cooperative vacuum Rabi splitting (VRS), known as Dicke cooperativity. Additionally, we have obtained evidence for the vacuum Bloch-Siegert shift [3], a signature of the breakdown of the rotating-wave approximation. The second part of this talk will present microcavity exciton polaritons in a thin film of aligned carbon nanotubes [4] embedded in a Fabry-Pérot cavity. This system exhibited cooperative USC with unusual continuous controllability over the coupling strength through polarization rotation [5]. Finally, we have generalized the concept of Dicke cooperativity to show that it also occurs in a magnetic solid in the form of matter-matter interaction [6]. Specifically, the exchange interaction of $N$ paramagnetic Er$^{3+}$ spins with an Fe$^{3+}$ magnon field in ErFeO$_3$ exhibited a VRS whose magnitude is proportional to $N^{1/2}$. Our results provide a route for understanding, controlling, and predicting novel phases of condensed matter using concepts and tools available in quantum optics. 1. P. Forn-Díaz, L. Lamata, E. Rico, J. Kono, and E. Solano, Revi. Mod. Phys. 91, 025005 (2019). 2. Q. Zhang et al., Nat. Phys. 12, 1005 (2016). 3. X. Li et al., Nat. Photon. 12, 324 (2018). 4. X. He et al., Nat. **8:36AM L62.00002: Anomalous Dirac Plasmons in 1D Topological Electrides**  JIANFENG WANG  (Presenter), Beijing Computational Science Res Ctr, XUELEI SUI, Tsinghua University, SHIWU GAO, Beijing Computational Science Res Ctr, WENHUI DUAN, Tsinghua University, FENG LIU, University of Utah, BING HUANG, Beijing Computational Science Res Ctr — Plasmon opens up the possibility to efficiently couple light and matter at sub-wavelength scales. In general, the plasmon frequency, intensity and damping are dependent of carrier density. These dependencies, however, are disadvantageous for stable functionalities of plasmons and render fundamentally a weak intensity at low frequency, especially for Dirac plasmon (DP) widely studied in graphene. Here we demonstrate a new type of DP, emerged from a Dirac nodal-surface state, which can simultaneously exhibit density-independent frequency, intensity and damping. Remarkably, we predict realization of anomalous DP (ADP) in 1D topological electrides, such as Ba$_3$CrN$_3$ and Sr$_3$CrN$_3$, by first-principles calculations. The ADPs in both systems have density-independent frequency and high intensity, and their frequency can be tuned from terahertz to mid-infrared by changing the excitation direction. Furthermore, the intrinsic weak electron-phonon coupling of anionic electrons in electrides affords an added advantage of low phonon-assisted damping and hence a long lifetime of the ADPs. Our work paves the way to developing novel plasmonic and optoelectronic devices by combining topological physics with electride materials.

**8:48AM L62.00003: Ultrafast terahertz microscopy down to the atomic scale**  TYLER COCKER  (Presenter), SPENCER AMMERMAN, VEDRAN JELIC, NICHOLAS J BRESLIN, Physics and Astronomy, Michigan State University — Recent developments have allowed terahertz (THz) scanning probe microscopy to achieve unprecedented simultaneous temporal and spatial resolutions. Included in the arsenal of THz microscopy techniques are terahertz scanning tunneling microscopy (THz-STM), which reveals the ultrafast response of a tunnel junction with atomic resolution [1-3], scattering-type scanning near-field optical microscopy (s-SNOM), which reveals the local dielectric function [4-6], and terahertz emission nanoscopy, which reveals local contrast in THz fields generated at the sample surface [7,8]. In this talk I will show examples of the types of experiments that can be done with each technique, including atomically resolved THz-STM snapshot imaging of local electron densities.

9:00AM L62.00004: Boltzmann treatment of nanoscale inhomogeneous electrical conduction  
RYAN MESCALL (Presenter), Physics, Yale, PHILIP ALLEN, State Univ of NY - Stony Brook —  
Small distance scales (e.g. boundaries of small samples) destroy the propagating electron quasiparticles that Boltzmann transport theory needs. Our model retains propagating single particle electrons, but generates nanoscale inhomogeneities by introducing nanoscale source terms in the Boltzmann equation of a macroscopic homogeneous metal. We solve the equations in Fourier space for electron distribution functions arising from charge input $\sim \exp(iqx)$. Fourier transformation allows computation of fields the $E(x)$, $V(x)$, and $n(x)$ corresponding to currents $j(x)$ derived from a realistic charge input from discrete electrodes. We study the ballistic to diffusive crossover as the sample size and electrode size are varied on distance scales comparable to the electron mean free path.

9:12AM L62.00005: Hydrodynamic effects of ballistic electron jets in high-mobility GaAs/AlGaAs  
ADBHUT GUPTA (Presenter), JEAN J HEREMANS, Virginia Tech, SAEED FALLAHI, GEOFF C GARDNER, MICHAEL MANFRA, Purdue University — The influence of a ballistic electron jet, injected through a lithographic aperture, is experimentally investigated through nonlocal resistance measurements over a distance $L$ from the injection point, in a 2D electron system in a high-mobility GaAs/AlGaAs heterostructure over a temperature range $4 \text{ K} < T < 40 \text{ K}$, at zero magnetic field. The geometry consists of various mesoscopic apertures separated by $L$ ranging from $1.3 \text{ μm}$ to $20.5 \text{ μm}$ such that the jet can be injected from any aperture and the nonlocal potential induced by the current distribution can be measured at any other aperture. The measured nonlocal resistance exhibits a non-monotonic behavior as $T$ is increased, leading to negative values (up to $L = 12.8 \text{ μm}$) in an intermediate $T$ range. This $T$ range lies in the hydrodynamic regime of transport where electron-electron interactions can lead to momentum exchange between the ballistic jet and the surrounding electron fluid, resulting in a depletion of electrons in vicinity of the main jet and extraction of electrons from the nearby detector aperture. The experimental results are compared to the predictions of theoretical models based on Boltzmann transport equations.

9:24AM L62.00006: On the Nonphysical Solutions to the Wigner Equation Used in Electronic Transport  
MAKBULE KUBRA ERYILMAZ (Presenter), SINA SOLEIMANIKAHNOJ, IRENA KNEZEVIC, Electrical and Computer Engineering, University of Wisconsin-Madison — The Wigner transport equation is gaining traction as a useful tool for modeling quantum electronic transport in semiconductors. However, nonphysical results are known to occur in numerical implementations and are often related to violation of the Heisenberg uncertainty principle when finite-difference techniques are employed. In this study, we analyze the role of boundary conditions in the behavior of the solutions to the Wigner equation for the example of a finite-sized one-dimensional nanostructure with a potential barrier in the middle and connected to reservoirs of charge. We discuss the cases in which artefacts occur and propose a boundary condition scheme that alleviates potential issues stemming from charge injection into a finite-sized simulation domain.

*DOE DE-FG02-08ER46532, DOE DE-SC0020138

9:24AM L62.00006: On the Nonphysical Solutions to the Wigner Equation Used in Electronic Transport

Quantum-dot–insulator–superconductor junctions coupled to a microwave resonator

VASILII SEVRIUK (Presenter), MATTI SILVERI, MIKKO MOTTONEN, QCD Labs, Aalto University — Quantum dots are finding more and more important applications in the modern electronics. Recent works related to the electron tunneling between a quantum dot and superconducting lead [1,2] inspired us to theoretically study the system consisting of quantum-dot–insulator–superconductor (QIS) junctions coupled to the microwave resonator. For this purpose, we adapted the theory developed before for the so-called quantum-circuit refrigerator [3-6], which is based on normal-metal–insulator–superconductor junctions. We demonstrate that the current running through the QIS junctions can lead to a negative damping rate at the microwave resonator and discuss the possibility to use such a system as a narrow-band amplifier and a microwave laser.

Multiple perfectly transmitting states of a discrete level at strong coupling

ÉTIENNE JUSSIAU (Presenter), University of Rochester, ROBERT S. WHITNEY, Univ. Grenoble Alpes, CNRS, LPMMC, ANDREW N JORDAN, University of Rochester — We analyze the transport properties of a discrete level between two reservoirs with a band structure. We focus on the case where the level is strongly coupled to the reservoirs, the coupling parameter is typically of the order of the energy scales of the band structures. In the absence of interactions, this system has an exact solution and the nonlinear Lamb shift can be derived. As expected, the Lamb shift has the effect of pushing the perfectly transmitting state (the reservoir state that flows through the discrete level without reflection) out of resonance with the discrete level, and can possibly turn it into a bound state. However, we show that additional pairs of perfectly transmitting states may appear due to the nonlinear Lamb shift when the coupling exceeds a critical value. The transmission function of the discrete level then resembles that of a multi-level system. Even in situations where the energy of the discrete level is outside the reservoirs' band, a perfectly transmitting state can be created inside the band if the coupling is strong enough. We propose observing the bosonic version of this physics in microwave cavities, and the fermionic version in the conductance of a quantum dot coupled to 1D or 2D reservoirs.
10:00AM L62.00009: Development of single-electron and single-electron-pair sources in LaAlO$_3$/SrTiO$_3$ nanostructures* YANG HU (Presenter), YUHE TANG, DENGYU YANG, YUN-YI PAI, JIANAN LI, Univ of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, CHANG-BEOM EOM, University of Wisconsin–Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — A source of single electrons can be realized by coupling quantum dots with tunnel barriers [1]. The 2D electron gas at the LaAlO$_3$/SrTiO$_3$ interface can be patterned using conductive atomic force microscope (c-AFM) lithography [2], which has been used to create quantum dots and single electron transistors [3]. We aim to use this technique to create an on-demand single-electron source by sketching quantum dots and applying out-of-phase excitation across the dot array. We discuss results for a triple-dot device and their associated electron tunneling phenomenon and issues related to the individual tunabilities of the dots. These devices may have application to quantum computation and simulation, and could also provide a robust standard for the electric unit ampere.

10:12AM L62.00010: Electron transfer in thermally heterogeneous environments GALEN CRAVEN (Presenter), Los Alamos National Laboratory, ABRAHAM NITZAN, University of Pennsylvania — Electron transfer is a fundamental process that drives many physical, chemical, and biological transformations, as well as playing a ubiquitous role in the development of electronics and technologies for energy conversion. Recent advances in temperature measurement and control at the nanoscale allow thermal gradients and heat flow to be addressed at the molecular level, making it possible to observe electron transfer across thermal gradients. In this talk, I will discuss the development of a theoretical framework to describe electron transfer between donor and acceptor sites, where each site has a different local temperature. The transfer of charge across the resulting thermal gradient is found to be coupled with an energy transfer mechanism that may alter heat conduction between sites. Application of the developed theory suggests that emergent relations connecting thermal and electronic currents can be utilized to control energy conversion between redox molecular motifs, at molecule-metal interfaces, and in molecular junctions.
10:24AM L62.00011: Suppression of ballistic effects in the ultra-pure delafossite PtCoO$_2$ via high-energy electron irradiation* PHILIPPA MCGUINNESS (Presenter), ELINA ZHAKINA, VERONIKA SUNKO, Max Planck Institute for Chemical Physics of Solids, MARCIN KONCZYKOWSKI, Ecole Polytechnique, SEUNGHYUN KHIM, MARKUS KOENIG, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids — PtCoO$_2$ is a layered oxide delafossite material which has a hexagonal, single-band Fermi surface. This ultrapure metal is extremely conductive, with a low-temperature mean free path of up to 5 μm [1]. Due to these properties, novel low-temperature ballistic effects have been demonstrated in the magnetoresistance of micron-scale ultrapure delafossite devices [2]. To determine the sensitivity of the ballistic behavior to disorder, we have used 2.5 MeV electron irradiation to introduce point-defect impurities into PtCoO$_2$ microstructures. This reduces the mean free path and therefore suppresses the ballistic phenomena. Surprisingly, these effects remain, in a weaker form, at an impurity level significantly higher than would be expected from the usual limits of the ballistic regime.

*The authors acknowledge support from the Max Planck Society. PM and VS thank EPSRC for PhD studentship support through grant number EP/L015110/1. The irradiation was performed at LSI at the Ecole Polytechnique and was supported by the EMIR network.

10:36AM L62.00012: Single electron occupation in a bilayer graphene double quantum dot
CHRISTIAN VOLK (Presenter), LUCA BANSZERUS, SAMUEL MÖLLER, EIKE ICKING, 2nd Institute of Physics, RWTH - Aachen, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CHRISTOPH STAMPFER, 2nd Institute of Physics, RWTH - Aachen — Graphene quantum dots (QDs) are an attractive platform for hosting spin qubits since the low nuclear spin densities and weak spin-orbit interaction in graphene promise long spin coherence times. Physically etched graphene QDs have been studied for about a decade. However, the influence of disorder, in particular the edge disorder prevented a precise control of the number of confined charge carriers.

We study an electrostatically gated bilayer graphene double QD (DQD) embedded in hexagonal boron nitride. Finger gates modulate the potential landscape along a one-dimensional channel confined by split gates and enable the formation of a DQD.

We control the number of charge carriers on each of the QDs from the few-electron regime down to the last. Tunnel coupling and capacitive interdot coupling increase with the QD occupation, leading eventually to the formation of a single QD. Furthermore, we can form a DQD in the low electron/hole occupation. Finite bias spectroscopy reveals the excited state spectrum of the first electrons in the DQD.

The precise control of the electron occupation is a key requirement for making such a device a suitable building block for spin qubit devices. The measured interdot tunnel coupling on the order of 2 GHz is in a regime compatible with spin qubits.
10:48 AM L62.00013: Coulomb drag between a carbon nanotube and monolayer graphene
SAMVEL BADALYAN (Presenter), Center for Graphene Research, Frisco, Texas 75035, USA, ANTTI-PEKKA JAUHO, Center for Nanostructured Graphene, Technical University of Denmark, 2800 Kongens Lyngby, Denmark — We study Coulomb drag in a system consisting of a carbon nanotube and monolayer graphene. Within the Fermi liquid theory we calculate the drag resistivity and find that the dimensional mismatch of the system components leads to a dependence of the drag rate on the carrier density, temperature, and spacing, which is substantially different from what is known for graphene double layers. We identify new features of the drag dependence on the electron density, which allows us to control their relative contribution to the drag resistivity.

Session L63 DMP DCMP FIAP: First Principles Approaches to Defects Mile
High Ballroom 4D - Joel Varley, Lawrence Livermore Natl Lab - Tag(s): Focus

8:00 AM L63.00001: First principles study of defect properties of II-VI photovoltaic materials
[Invited] SUHUAI WEI (Presenter), Beijing Computational Science Research Center — First-principles study of photovoltaic materials plays an important role in developing solar cell technologies because it can provide useful physical insights, fresh perspective and new design principles for developing innovative solar cell materials with high solar power conversion efficiency and reduced cost. Similar to other semiconductors, one of the most important issues in solar cell absorber materials are to control the defects, either for introducing charge carrier, improving charge transport, or reducing non-radiative carrier recombination. For example, a good solar cell material should have good defect properties, that is, it can be easily doped such that charge carriers can be created to generate the required electric field and has less defect-induced recombination centers such that it has high carrier life time and minority carrier mobility, so photo-generated charge can be easily collected. In this talk, using II-V thin-film solar cell absorber materials Cd(Te,Se), Cu(In,Ga)Se$_2$ (CIGS) and Cu$_2$ZnSnS$_2$ (CZTS) as examples, I will discuss how theoretical first-principles studies can be used to better understand and optimize the solar cell performance.
First-Principles Study on the Defect Physics of Ternary Chalcopyrite ZnGeP$_2$ through Hybrid Functional

MENGLIN HUANG (Presenter), SHANSHAN WANG, SHIYOU CHEN, East China Normal University — Zinc germanium diphosphide (ZnGeP$_2$) is a chalcopyrite semiconductor that can be used for infrared frequency conversion applications. It is believed that the intrinsic defects are responsible for the defect-related absorptions and emissions observed in experiments, and the performance of the corresponding device is also limited by those defects. Here we study the defect physics in ZnGeP$_2$ using the density functional theory (DFT) calculations with a hybrid functional. We will firstly present the result of phase stability, which differs significantly from the previous result calculated by semi-local DFT. Ge$_{Zn}$, Zn$_{Ge}$, Ge$_{P}$, P$_{Ge}$ antisites are the dominant point defects among all the Fermi level range and growth conditions. Under Zn-rich condition, the Fermi level is about 0.6 eV above valence band maximum (VBM), which shows the p-type conductivity, while under Ge-poor condition, the Fermi level is located at the middle of the band gap, consistent with the experiment results. We will also discuss the result of calculated optical transition that is related to photoluminescence peak and the possible impurities and defect complexes.

Dimensionality-suppressed chemical doping in 2D semiconductors: the cases of phosphorene, MoS$_2$, and ReS$_2$ from first-principles

JI-HUI YANG (Presenter), Department of Physics, Fudan University — In spite of great appeal of two-dimensional (2D) semiconductors for electronics and optoelectronics, to achieve required charge carrier concentrations by means of chemical doping remains a challenge, due to large defect ionization energies (IEs). Here by decomposing the defect IEs into the neutral single-electron defect level, the structural relaxation energy gain, and the electronic relaxation energy cost, we propose a conceptual picture that the large defect IEs are caused by two effects of reduced dimensionality. While the quantum confinement effect (QCE) makes the neutral single-electron point defect levels deep, the reduced screening effect (RE) leads to high energy cost for the electronic relaxation. The first-principles calculations for monolayer, few-layer, and bulk black phosphorus (BP), MoS$_2$, and ReS$_2$ do demonstrate the general trend. Based on the gained insight into defect behaviors, strategies can be envisaged for reducing defect IEs and improving charge carrier doping. Using BP monolayer either embedded into dielectric continuum or encapsulated between two h-BN layers, as practical examples, we demonstrate the feasibility of increasing the screening to reduce the defect IEs and boost carrier concentration.
9:00AM L63.00004: **First-principles study of defect physics in a photovoltaic semiconductor Cu$_2$ZnGeSe$_4$**  
LELE CAI (Presenter), SHIYOU CHEN, East China Normal University — Cu$_2$ZnGeSe$_4$ is of interest for the development of next-generation thin-film photovoltaic technologies. The additional number of elements in Cu$_2$ZnGeSe$_4$ increases the flexibility of material properties relative to binary and ternary semiconductors. However, a variety of intrinsic lattice defects are formed that have a significant impact on its photovoltaic performance. Here we study the intrinsic point defects in Cu$_2$ZnGeSe$_4$ using the density functional theory calculations with both the generalized gradient approximation and the hybrid functional. Examination of the thermodynamic stability of Cu$_2$ZnGeSe$_4$ shows that the stable chemical potential region for the formation of stoichiometric compound is small. Under Zn-poor condition, the shallow acceptor, Cu$_Zn$ antisite is the dominant defect with the lowest formation energy, accounting for the observed p-type conductivity, while in a Ge-rich condition, the Fermi level is close to the middle of band edge because of the lower formation energy of Zn$_{Cu}$. We will discuss the effects of these defects on the photoelectric properties of Cu$_2$ZnGeSe$_4$.

9:12AM L63.00005: **First principles calculations of phonons and Raman and infrared spectra in ZnGeGa$_2$N$_4$.**  
AMOL RATNAPARKHE (Presenter), WALTER LAMBRECHT, Case Western Reserve University — ZnGeN$_2$ is a semiconductor compound closely related to GaN. They have similar band gaps and are closely lattice matched but have a large band-offset, which enables new capabilities in heterostructure and alloy band structure engineering. Recently, a well-defined crystal structure with space group Pmn2$_1$ was proposed for the 50% compound ZnGeGa$_2$N$_4$ which satisfies the local octet rule around each N [PHYSICAL REVIEW MATERIALS2, 114602 (2018)]. Here, a first-principles study of the phonons in this material is presented. The calculations are performed using the density functional perturbation theory within the ABINIT software. The phonon frequencies at the Brillouin zone center and their symmetry analysis, as well as various associated parameters, will be presented: Born effective charge tensors, oscillator strength tensors, dielectric constants. The infrared and Raman spectra have been calculated for various scattering configurations. The phonon density of states and phonon dispersion curves will also be reported.

9:24AM L63.00006: Energy landscape of vacancy-related defects in silicon: a comprehensive picture from DFT and GW  GABRIELA HERRERO-SABOYA (Presenter), CEA de Bruyeres-le-Chatel, LAYLA MARTIN-SAMOS, CNR-IOM Democritos, ANNE HEMERYCK, LAAS-CNRS, NICOLAS RICHARD, CEA de Bruyeres-le-Chatel — Vacancy related point-like defects are one of the most common degrading centers in silicon-based technology. They have been the subject of extensive studies both experimental and theoretical. However, a comprehensive theoretical model capable of explaining experimental evidence is often missing. By means of first principles calculations we revisit structural, optical and electronic properties of these common point defects in silicon. Guided by simple theoretical models, we are able to perform accurate simulations, including many-body-perturbation corrections based on the GW approximation, in close quantitative agreement with the experiment. Going beyond the common total energy approach allows us to predict the electronic activity and the low temperature dynamics of such centers. At higher temperatures, vacancies become mobile centers, forming more complex systems and/or contributing to the diffusion of impurities. Starting from experimentally proposed mechanisms, we are able to theoretically characterize activation energies of such technologically relevant processes.

9:36AM L63.00007: Charged Defects in TiO$_2$ Anatase: A Comparative Study of Hybrid DFT, GW and BSE to Explore Optical Properties  POOJA BASERA, SASWATA BHATTACHARYA (Presenter), Indian Inst of Tech-New Delhi — Titanium dioxide (TiO$_2$) anatase is one of the most abundant, functionally versatile oxide materials. However, owing to its large bandgap, the photoabsorption efficiency is limited only in the UV region. Doping-mediated modulation is one of the most pragmatic approaches in the pursuit to improve the photocatalytic and solar energy conversion efficiencies of TiO$_2$. We report here using state-of-the-art hybrid density functional and \textit{ab initio} atomistic thermodynamics, the thermodynamic (meta-) stability of different non-metal dopants X (X= N, C, S, Se) as a function of charge state at realistic temperature and pressure. Knowing the most stable defects, we aim an accurate theoretical estimation of the optical properties of doped TiO$_2$. To do this, we have used many body perturbation theory viz. one particle Green's function (GW) method and higher order Green's function techniques Bethe-Salpeter Equation (BSE). Our calculations reveal the highly anisotropic nature of the doped TiO$_2$. The n-type doped TiO$_2$ is optically active in both x, z direction, whereas the p-type doped TiO$_2$ is optically inactive along z-direction. The most evident hallmark of the doped system is the appearance of absorption peaks at low energy below 3 eV, to give rise visible-light absorption.
**9:48AM L63.00008: The Barrier to the Small Polaron Formation in Metal Peroxides**

SHUAISHUAI YUAN (Presenter), ZI WANG, MAXIMILIAN L. F. BARON, KIRK H BEVAN, McGill Univ — Polaron formation is the process by which free electrons (or holes) in a material find a lower energy localized state by distorting their surrounding host lattice. Since polaron formation involves changes in both electronic and atomic coordinates, a deeper understanding of polaron formation promises to open up new avenues towards tailoring the physical properties of materials. Ab initio studies have predominantly focused on studying stabilized small polaron states and their hoping physics, while less investigation has been devoted to the equally important process of polaron formation. In this work, we provide ab initio insights into the polaron formation process and focus on exploring the physical origins of the barrier to polaron formation. We utilize the HSE06 hybrid functional to study small polaron formation in four similar metal peroxides, which exhibit a wide range of polaron formation barriers heights. Our results show that polaron hybridization with the conduction band minimum (CBM) plays a significant role in determining the magnitude of a polaron formation barrier. Moreover, by satisfying the generalized form of Koopmans’ theorem, we are able to show that the degree of hybridization is directly correlated with the electronic relaxation delay during polaron formation.

**10:00AM L63.00009: Machine learned defect and impurity levels in perovskite halides and CdTe**

ARUN KUMAR MANNODI KANAKKITHODI (Presenter), FATIH G SEN, MICHAEL TORIYAMA, MICHAEL J DAVIS, MARIA CHAN, Argonne Natl Lab — Electronic levels introduced by impurities and intrinsic defects in the band gap of semiconductors affect optoelectronic performance. Predictions of these defect levels are possible, but expensive, using first principles density functional theory (DFT), and chemical trends are often not easily available. In this talk, we will describe using machine learning (ML) trained on DFT data for defect levels in hybrid perovskite halides [1] and CdTe [2] photovoltaic materials. Relevant descriptors, relative performance of different ML approaches, and insight from resultant ML models will be discussed.

A quantitative understanding of the electronic excited states of point defects in semiconductors and insulators is crucial for identifying defects detrimental to device performance, as well as those that have attractive properties for quantum applications. In particular, transition metal impurities in semiconductors have been widely studied in both contexts. One of the key limitations for a first-principles description of such systems is that transition metal excited states often involve correlated low-spin multiplets that require a multideterminant treatment. This is beyond the capabilities of density functional theory (DFT), which is the workhorse for computational studies of point defects. Using Fe in GaN and AlN as an example, we address this issue by treating the defect as a correlated subspace embedded in the lattice. The defect structure is obtained from hybrid-functional DFT calculations, and the subspace is isolated via Wannierization. The dielectric screening effects from the surrounding lattice to the local defect Coulomb interactions is accounted for using the constrained RPA approach. Finally, the many-body problem within the subspace is solved exactly. We compare our results to previous calculations using constrained DFT, and experimental measurements.

We employed an experimentally motivated Monte Carlo simulation to calculate the conductance as a function of charged dopant concentration to investigate the non-linear evolution of the resistivity with annealing time in oxygen deficient thin films. The model consists of an N x N square lattice with hydrogenic atoms placed at each lattice site. The valence electrons are bound to their respective lattice site via a harmonic potential, and electrons at different sites are allowed to interact via a screened Coulomb potential. At each Monte Carlo step, electrons attempt to change their position slightly, and in addition attempt to transition between conducting and non-conducting states. We found nonlinear dependence of the resistance as a function of dopant concentration. The dopants act as electron traps where they lower the energy of nearby electrons and increase the energy requirement to transition to the conducting state. As more dopants are added, this effect increases, further suppressing the conductivity. This would indicate that the inclusion of the charged dopants advances the percolative evolution of such a phase transition.

10:36AM L63.00012: Formation energies of charged defects in 2D materials - a new perspective

ANDREW O'HARA (Presenter), Department of Physics and Astronomy, Vanderbilt University, BLAIR TUTTLE, Department of Physics, Penn State Behrend, XIAOGUANG ZHANG, Department of Physics, University of Florida, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — Formation energies of defects in semiconductors play a major role in understanding a wide range of properties. Supercell schemes have been widely used for calculations. For charged defects, a divergence in the potential arises from the periodic Coulomb interactions and, in the “jellium” approach, is removed by setting the average electrostatic potential to zero. A posteriori corrections are typically used to determine the infinite-supercell limit. For 2D materials, where unscreened Coulomb tails are present in the vacuum regions, additional complications arise. In this work, we present an alternative formalism based on statistical mechanics, which dictates that supercells are naturally neutral: “charged defects” are merely ionized, by trading carriers with the energy bands (charge neutrality of the crystal is an essential ingredient of the statistical mechanics of electrons in semiconductors). We show that the jellium approach can be derived from the statistical-mechanics-backed theory by invoking approximations with unknown consequences. We report density-functional-theory calculations showing that the differences between the two methods are especially large in 2D materials, e.g., h-BN, where they can be of order 1 eV. Convergence rates are excellent.

*DOE Grant DE-FG-02-09ER46554

10:48AM L63.00013: Origin of n-type conductivity of monolayer MoS2

AKASH SINGH (Presenter), ABHISHEK SINGH, Indian Institute of Science — Monolayer MoS2 is a promising two-dimensional material for electronic and optoelectronic devices. As-grown MoS2 is an n-type semiconductor, however, the origin of this unintentional doping is still not clear. Here, using hybrid density functional theory (DFT), we carried out an extensive study of often observed native point defects i.e., VS, VMo, VS2, VMoS3, VMoS6, MoS2, and S2Mo and found that none of them cause n-type doping. Specifically, S vacancy (VS), which has been widely attributed to n-type conductivity, turns out to be an electron compensating centre. We report that hydrogen, which is almost always present in the growth environments, is most stable in its interstitial (Hi) and H-S adatom forms in MoS2 and acts as a shallow donor provided the sample is grown under S-rich condition. Furthermore, they have high migration barrier (in excess of 1 eV), which would ensure their stability even at higher temperature and hence, lead to n-type conductivity.

*The authors thank Materials Research Centre and Supercomputer Education and Research Centre, Indian Institute of Science for the computational facilities. This work was supported by the India-Korea Joint Programme of Cooperation in Science and Technology. Akash Singh acknowledges the DST-Inspire fellowship (1F150954).
8:00AM L64.00001: Probing inhomogeneous superconductivity and magnetism in complex oxide heterostructures with scanning SQUID* [Invited]  HILARY NOAD (Presenter), Max Planck Institute for Chemical Physics of Solids — Complex oxide heterostructures offer unique opportunities for engineering electronic and magnetic systems, combining functionalities of their constituent materials and, in some cases, exhibiting emergent properties. The reduced dimensionality and broken inversion symmetry at interfaces can make them particularly sensitive to local variation in the crystal lattice. A key problem is to disentangle the intrinsic properties of heterostructures from those of ordered states stabilized by defects or other sources of inhomogeneity. I will discuss two studies which used scanning superconducting quantum interference device (SQUID) microscopy, a local magnetic probe, to investigate the effects of intrinsic or controlled inhomogeneity in complex oxide heterostructures. In the first, we imaged superconductivity in lanthanum aluminate/strontium titanate (LAO/STO) and delta-doped STO heterostructures. Spatial motifs in our measurements demonstrate that different orientations of structural domains with respect to the symmetry-breaking interface result in different superconducting transition temperatures. While LAO and STO are both nonmagnetic in the bulk, many experimental probes have found signatures of magnetism in LAO/STO heterostructures, with local measurements showing that magnetism, when present, is inhomogeneous. In our second study, we investigated oxygen vacancies as a proposed mechanism for the magnetism by measuring samples with differing oxygen content, placing tight limits on magnetism, even in the most strongly reduced samples.

*This work was supported by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract No. DE-AC02-76SF00515.
It is possible to reveal otherwise hidden electronic properties in 2D oxide interfaces, namely LaAlO$_3$/SrTiO$_3$, by using local probes instead of traditional bulk measurements. For example, scanning single electron transistor microscopy has shown enhanced transport along ferroelastic domain boundaries [1]. Furthermore, Frenkel et al. have demonstrated that the local application of pressure to the interface of LaAlO$_3$/SrTiO$_3$ can reveal ferroelastic domain boundaries [2]. Here we detail our efforts to reveal electron transport in “sketched” LaAlO$_3$/SrTiO$_3$ nanostructures [3] using a modified vacuum AFM at room and low (T < 25 K) temperatures.

8:48AM L64.00003: Dependence of LaAlO$_3$/SrTiO$_3$ Electron Pairing Strength on Crystallographic Orientation* ADITI NETHWEWALA (Presenter), Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, JIANAN LI, MEGAN BRIGGEMAN, YUZE ZHANG, TIANYI WANG, Department of Physics and Astronomy, University of Pittsburgh, JUNG-WOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Recently, it has been shown that superconductivity at the LaAlO$_3$/SrTiO$_3$ interface is essentially 1D in nature, and that the pairing mechanism appears to be linked to the boundaries of naturally formed X, Y and Z ferroelastic domains in SrTiO$_3$ [1]. Here, we investigate the nature of the pairing mechanism in LaAlO$_3$/SrTiO$_3$ nanostructures by examining the electron pairing strength with respect to the crystallographic direction. We write 1D, cross-shaped electron waveguides or “nanocrosses” [2] at the LaAlO$_3$/SrTiO$_3$ interface using conductive atomic force microscope (c-AFM) lithography. The c-AFM lithography and device geometry together defines the X, Y and Z domain boundaries across the nanocross at low temperatures. A sinusoidal dependence is observed as the nanocross is rotated with respect to the crystallographic direction. This characteristic angular dependence helps to constrain and sharpen our understanding of the pairing mechanism at the interface and the role of ferroelastic domain structure.

9:00AM L64.00004: Transport properties of non-reciprocal 1D quantum channels at the LaAlO$_3$/SrTiO$_3$ interface*  YUZE ZHANG (Presenter), TIANYI WANG, MEGAN BRIGGEMAN, Univ of Pittsburgh, HYUNGWOON LEE, JUNGHOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin - Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Abstract: Complex oxide heterostructures exhibit many interesting phenomena [1] that can be controlled on the nanoscale using a conductive atomic force microscope (c-AFM) lithography technique [2]. We create chiral 1D superlattices at the LaAlO$_3$/SrTiO$_3$ interface by adding a periodic modulation to an electron waveguide device. These nanostructures support quantized ballistic transport of electrons and electron pairs, as well as oscillatory transport behavior indicating an engineered spin orbit interaction [3]. These experiments represent a first step toward engineering properties in 1D quantum wires and can be regarded as a building block for more complex quantum systems.

*JL acknowledges a Vannevar Bush Faculty Fellowship (ONR N00014-15-1-2847) and NSF (PHY-1913034). C-BE acknowledges NSF DMREF (DMR-1629270), AFOSR (FA9550-15-1-0334), and AOARD (FA2386-15-1-4046).

9:12AM L64.00005: Nanoscale control of the metal-insulator transition in free-standing LaAlO$_3$/SrTiO$_3$ membranes*  MUQING YU (Presenter), Univ of Pittsburgh, KITAE EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, DENG YU YANG, Univ of Pittsburgh, JUNGHOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — By combining 2D materials such as graphene into layered van der Waals heterostructures, new types of designer materials with unique and emergent properties have been realized [1]. We describe a method for achieving free-standing single-crystal LaAlO$_3$/SrTiO$_3$ membranes by etching away a sacrificial SrRuO$_3$ layer underneath SrTiO$_3$. LaAlO$_3$/SrTiO$_3$ membranes are transferred to a sapphire substrate, and we use conductive AFM lithography [2] to achieve nanoscale control the insulator to metal transition at the LaAlO$_3$/SrTiO$_3$ interface. Nanoscale conductive channels created at room temperature remain conductive at two Kelvin. These results demonstrate the capacity to create LaAlO$_3$/SrTiO$_3$ membranes that can be integrated with other materials and reversibly patterned at nanoscale dimensions.

*JL acknowledges a Vannevar Bush Faculty Fellowship, funded by ONR (N00014-15-1-2847). C-BE acknowledges NSF DMREF (DMR-1629270), AFOSR (FA9550-15-1-0334), and AOARD (FA2386-15-1-4046)
9:24AM L64.00006: Influence of Temperature on LaAlO$_3$/SrTiO$_3$ Nanowire Lifetimes Under Ambient Conditions*

AARON GREENBERG (Presenter), PHILIP SHENK, JOSEPH ALBRO, MUQING YU, Univ of Pittsburgh, CHANG-BEOM EOM, University of Wisconsin - Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh —

The discovery of a tunable 2DEG at the interface of LaAlO$_3$/SrTiO$_3$ has spurred interest in LaAlO$_3$/SrTiO$_3$, which exhibits numerous interesting properties. Using a conductive AFM lithography technique, we can create novel devices at the interface of LaAlO$_3$/SrTiO$_3$ by locally confining the 2DEG to zero or one dimension [1]. However, in ambient conditions, an appreciable degradation of device lifetime occurs [2]. Previously, the decay rate of such devices was characterized as a function of humidity and pressure; however, its dependence on temperature has yet to be determined. Here we describe experiments detailing efforts to quantify the device lifetimes as a function of temperature under otherwise ambient conditions, which will aid in the creation of new, more complex devices.

9:36AM L64.00007: Surface Acoustic Wave Generation and Detection on LaAlO$_3$/SrTiO$_3$*

DENGYU YANG (Presenter), YUN-YI PAI, YUHE TANG, MUQING YU, YANG HU, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, KITAE EOM, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh —

We aim to generate and detect surface acoustic waves (SAW) in LaAlO$_3$/SrTiO$_3$ heterostructures. Using a well-developed conductive-AFM lithography technique [1], we “sketch” interdigitated transducers (IDT) on LaAlO$_3$/SrTiO$_3$ “canvases”, which convert electronic signals into SAW and vice-versa. Two sets of IDTs are written on the structure to function as a generator and detector. SAW can be used to generate dynamic potentials based on piezoelectric properties of LaAlO$_3$/SrTiO$_3$, and have the potential to drive electrons through nanostructures, a property that could be useful for quantum information applications.

Creating nano-scale “vias” in LaAlO$_3$/SrTiO$_3$ for integration of nanostructures

CARL WILSON (Presenter), ADITI NETHWEWALA, ERIN SHERIDAN, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — The 2D electron gas (2DEG) at the LaAlO$_3$/SrTiO$_3$ interface exhibits a wide range of gate-tunable properties like superconductivity, magnetism, and spin orbit coupling [1]. Furthermore, the interface can be patterned with nanoscale dimensions using c-AFM lithography [2] and integrated with other 2D materials such as graphene [3]. While the surface of LaAlO$_3$/SrTiO$_3$ is only 1.2 nm from the interface, improved coupling of particles on the surface with the interface requires closer proximity. Here, we discuss methods to create nanoscale holes or “nano vias” in LaAlO$_3$/SrTiO$_3$ with the goal of integrating nanomaterials directly to interface while maintaining interfacial conductivity. These nano vias will allow us to study the effect of local coupling between the 2DEG at LaAlO$_3$/SrTiO$_3$ interface and a wide variety of interesting nanomaterials such as colloidal quantum dots or graphene nanoribbons.

Interface band engineering in LaAlO$_3$/SrTiO$_3$ heterostructures

MICHAEL SING (Presenter), JUDITH GABEL, PHILIPP SCHEIDERER, MICHAEL ZAPF, MARTIN STÜBINGER, University of Wurzburg, Germany, CHRISTOPH SCHLUETER, Deutsches Elektronensynchrotron DESY, Hamburg, Germany, TIEN-LIN LEE, Diamond Light Source, UK, RALPH CLAESSEN, University of Wurzburg, Germany — Novel two-dimensional electron systems at the interfaces of oxide heterostructures such as LaAlO$_3$/SrTiO$_3$ recently have attracted much attention as they display intriguing properties which may be exploited in future electronic devices. A key requirement for such applications is the controllability of the electronic interface properties such as the valence band offset. We demonstrate that these properties can be effectively engineered in LaAlO$_3$/SrTiO$_3$ by virtue of the oxygen vacancy concentration. By angle-dependent hard x-ray photoelectron spectroscopy, we derive a complete band diagram of the heterostructure dependent on the oxygen vacancy concentration which is adjusted during the photoemission experiments by means of synchrotron light irradiation and simultaneous oxygen dosing. The dielectric constant of the SrTiO$_3$ substrates and its strong non-linear dependence on the electric field prove to be essential for the band arrangement of the LaAlO$_3$/SrTiO$_3$ heterostructures. The comprehensive analysis of the band situation at the LaAlO$_3$/SrTiO$_3$ heterointerface as a function of the oxygen vacancy concentration can reconcile the contradicting results of previous photoemission studies.
**10:12AM L64.00010: Character of the insulator-metal transition at the LaAlO$_3$/SrTiO$_3$ interface**  
DANIEL BENNETT, Univ of Cambridge, EMILIO ARTACHO (Presenter), Nanogune, DIPC, Ikerbasque & Univ of Cambridge, NICHOLAS C. BRISTOWE, Physical Sciences, Univ of Kent — Under a film of lanthanum aluminate (LAO) on strontium titanate (STO) a two dimensional metal appears after a critical thickness, as a response to the electrostatic energy build-up originated by the polar discontinuity at the interface. The character of the transition has not been much explored given the discrete character of the controlling parameter, the film thickness. However, an applied electric field across the film for a thickness close to the transition will drive the transition as well, the character of the transition becoming relevant, not only fundamentally but for possible applications, too. A phenomenological mean-field theory predicts a continuous transition, while a saturating discontinuous one has been assumed in other contexts. We will present a theoretical analysis showing a richer phenomenology than expected so far, with the possibility of either continuous or discontinuous transitions, including a situation in which there is a second discontinuous transition with a jump in carrier concentration after an earlier continuous metal-insulator one.

**10:24AM L64.00011: Giant nonreciprocal charge transport in noncentrosymmetric LaAlO$_3$/SrTiO$_3$ interfaces**  
DAESEONG CHOE (Presenter), MI-JIN JIN, Ulsan National Institute of Science and Technology, SHIN-IK KIM, HYUNG-JIN CHOI, Korea Institute of Science and Technology, JUNHYEON JO, INSEON OH, JUNGMIN PARK, HOSUB JIN, Ulsan National Institute of Science and Technology, HYUN CHEOL KOO, BYOUNG-CHUL MIN, SUK-MIN HONG, Korea Institute of Science and Technology, HYUN-WOO LEE, Pohang University of Science and Technology, SEUNG-HYUB BAEK, Korea Institute of Science and Technology, JUNG-WOO YOO, Ulsan National Institute of Science and Technology — Electrons confined at an interfacial quantum well of a LaAlO$_3$/SrTiO$_3$ associated with broken inversion symmetry show various exotic condensed matter phases and rich spin-orbitronic functionalities. This two-dimensional polar conductor may exhibit directional propagation of itinerant electrons, *i.e.* the leftward and rightward currents differ from each other, when time-reversal symmetry is further broken. This potential rectification effect generally was displayed to be very weak due to the fact that kinetic energy is much higher than energies related to symmetry breakings producing weak perturbation. Here, we present giant gate-tunable nonreciprocal charge transport in the LaAlO$_3$/SrTiO$_3$ conductive oxide interface, where the electrons are confined at two-dimension with low Fermi energy. The coefficient $\gamma$ indicating the magnitude of nonreciprocal response, was estimated to be as high as $\sim 10^2$ T$^{-1}$A$^{-1}$, which is about 3 order of magnitude higher than those reported for noncentrosymmetric conductors. The observed behavior of nonreciprocal response in LaAlO$_3$/SrTiO$_3$ is related to comparable energy scales among kinetic energy, magnetic field and spin-orbit interaction, which opens a promising route to improve nonreciprocal response and its functionalities in the emerging spin-orbitronics.
High-mobility two-dimensional hole gas at the SrTiO$_3$ interface formed by depositing an ultrathin metal film at room temperature*  

SHINGO KANETA (Presenter), Department of Electrical Engineering and Information Systems, The University of Tokyo, LE DUC ANH, Institute of Engineering Innovation, The University of Tokyo, MASASHI TOKUNAGA, Institute for Solid State Physics, The University of Tokyo, MUNETOSHI SEKI, HITOSHI TABATA, MASAAKI TANAKA, Department of Electrical Engineering and Information Systems, The University of Tokyo, SHINOBU OHYA, Institute of Engineering Innovation, The University of Tokyo — Despite intensive studies on the two-dimensional electron gas (2DEG) at the SrTiO$_3$ (STO) interface [1], forming a 2D hole gas (2DHG) at the STO interface is extremely difficult [2], although both are essential for the realization of high-speed oxide-based electronics. Here, we demonstrate a very simple method to realize a 2DHG with an ultrahigh mobility of 24,000 cm$^2$V$^{-1}$s$^{-1}$ at an STO interface. The 2DHG is obtained by depositing a sub-nm-thick Fe layer (thickness $t \leq 0.2$ nm) on STO substrates at room temperature in an ultrahigh vacuum chamber. The Fe layer is oxidized and becomes insulating amorphous FeO$_x$. Magnetotransport measurements reveal the existence of high-mobility carriers in the STO side, and the carrier type changes from a pure p-type ($t \leq 0.2$ nm) to n-type ($t > 0.3$ nm) by varying the Fe thickness. In a p-type sample ($t = 0.1$ nm), the Shubnikov - de Haas oscillation is clearly observed in out-of-plane magnetic field but disappears in in-plane field. These results clearly demonstrate the 2D nature of the high-mobility hole carriers.

Shubnikov-de Hass oscillations to the quantum limit in (111) oriented SrTiO$_3$ interface 2D electron gas*  

ZIQIAO WANG, AUTUMN B HELTMAN, SHALINI KUMARI, QI LI (Presenter), Pennsylvania State University, SHALINEE CHIKARA, ALEXEY SUSLOV, Florida State University, FEDOR BALAKIREV, JOHN SINGLETON, Los Alamos National Lab. — The (111) surface of perovskite oxide SrTiO$_3$ has a hexagonal structure, similar to topological insulator Bi$_2$Se$_3$. Existence of topological states has been predicted in this system and high mobility two-dimensional (2D) electron gases at interfaces provide a promising platform to study these properties. We created a 2D electron gas at SrTiO3 (111) interfaces with high mobility over 15000 cm$^2$V$^{-1}$s$^{-1}$ at low temperatures. Utilizing interface engineering, we have achieved relatively low carrier density of 1.3x10$^{13}$ cm$^{-2}$. Longitudinal magnetoresistance shows clear Shubnikov-de Hass (SdH) oscillations at low temperatures and high magnetic fields at both 35 T (DC field) and 60 T (pulsed field). In the low carrier density sample, we have observed the lowest Landau level at magnetic field around 20 T, which shifts to higher fields with higher carrier densities. More strikingly, a linear magnetoresistance (LMR) behavior appears at high magnetic field beyond the quantum limit. Temperature and angular dependence of the quantum oscillations as well as the LMR will be discussed.

8:00AM L65.00001: Stabilization of Crystalline Phase in Organo-metal Halide Perovskite Quantum Dots via Surface Manipulation*  WILLIAM DELMAS (Presenter), ALBERT DIBENEDETTO, University of California, Merced, EVAN VICKERS, JIN ZHANG, Department of Chemistry and Biochemistry, University of California Santa Cruz, SAYANTANI GHOSH, University of California, Merced — Size tunability of semiconducting quantum dots (QDs) is their most attractive characteristic, which allows modulation of their optical and electronic properties. In the case of organo-metal halide perovskite (OMHP) QDs, surface functionalization is one of the routes that offers a unique way to vary the size in a highly precise manner. In this study we use temperature dependent static and dynamic spectroscopy to investigate the effect of four different surface modification protocols on in CH$_3$NH$_3$PbBr$_3$ OMHP QDs using conductive aromatic ligands. Our results indicate that functionalization methods affect quantum yield (QY) based on how well the different ligands passivate the surface states, while simultaneously altering the contribution of those states to the energy landscape that allows us to arrest the structural phase transition of the QDs from tetragonal/cubic to orthorhombic at low temperatures. Further, these ligands allow charge delocalization around the benzoic positions, which improves inter-particle energy transfer efficiency in QD films based on the conjugation state of the ligands. The synthesis of phase stable and high QY QDs that form conducting films is a significant development that will find use in diverse applications.

8:12AM L65.00002: Advanced material system for the design of an intermediate band solar cell: type-II CdTe quantum dots in a ZnCdSe matrix*  

VASILIOS DELIGIANNAKIS (Presenter), GEHAN RANEPURA, The City College of New York, MILAN BEGLIARBEKOV, CUNY Graduate Center, IGOR KUSKOVSKY, Queens College, MARIA C TAMARGO, The City College of New York — Photovoltaics based on intermediate band (IB) absorption have the potential to overcome the Shockley-Quiesser limit and maintain a large $V_{oc}$. Quantum dots (QDs) or impurities can be used to form the IB. We propose a material system of submonolayer CdTe QDs embedded a ZnCdSe matrix that is optimum for the formation of an ideal IB and has other advantages to materials previously considered. Some unique attractive features of this material are its binary composition, simplifying growth; the absence of a deleterious interfacial layer, in spite of the lack of common ion; and the presence of strain, which allows for strain engineering of the IB. A superlattice structure of alternating QD and spacer layers is analyzed by X-ray diffraction (XRD) and photoluminescent (PL) spectroscopy. Simple arguments are used, following continuum elastic theory, to deduce the size of the dots and the strain within the superlattice from XRD data. Results of structural and optoelectronic characterization of both active layer and full device structures, using XRD, PL, photocurrent and contactless electro-reflectance measurements will be presented. The results suggest that the optimized materials are very well suited for potential high-efficiency IB solar cells.

8:24AM L65.00003: Photo-induced current enhancement in core-shell type quantum dot FET*  

SUNAO SHIMIZU (Presenter), CRIEPI, KEIICHIRO MATSUKI, Waseda University, KAZUMOTO MIWA, CRIEPI, DANIELE BRAGA, Fluxim AG, SHIMPEI ONO, CRIEPI — Low dimensional materials are promising candidates to provide unique electronic properties; among them, quantum dots (QDs) and their hybrid systems are considered highly feasible because of the tunability of physical and chemical properties by material design. Here we report the fabrication of CdSe/CdS core-shell QDs-based field effect transistors (FETs) and its application to photo FET operations under UV light irradiation. The thin films of CdSe/CdS QDs were fabricated on SiO2/Si substrates in order to perform field effect experiments. The UV light irradiation dramatically changed the transfer characteristics for the thin films, the thickness of which ranges from ~20 nm to ~200 nm. We will discuss the thickness and the gate voltage dependence of the photo-induced current enhancement in the core-shell QDs-based FET in detail.

8:36AM L65.00004: Infrared Optical-Field-Driven Luminescence in Quantum Dots  IBRAHIM BOULARES (Presenter), Combat Capabilities Development Command, US Army Research Laboratory, JIAOJIAN SHI, Department of Chemistry, Massachusetts Institute of Technology, BLAIR CONNELLY, Combat Capabilities Development Command, US Army Research Laboratory, KEITH ADAM NELSON, Department of Chemistry, Massachusetts Institute of Technology — A recent study on CdSe-CdS core-shell colloidal quantum dots (QDs) showed that extreme electric fields from ultrafast THz-frequency electromagnetic pulses alone can produce QD luminescence [1, 2]. Unlike multi-photon absorption, which occurs at much higher optical frequencies, such emission was shown to be associated with large energy shifts of the absorption edge (more than 25%) – much like electro-luminescence (EL) driven by a quasi-DC field. While details of the mechanism of THz driven-EL are still under investigation, the effects of high optical electric fields of mid- to long-wavelength infrared (IR) radiation on the optical properties of QDs remain largely unexplored. To expand our understanding of the responses of QDs to extreme optical fields, we investigated the interaction of visible bandgap QD materials with sub-picosecond infrared-frequency pulses in the 3.5 to 12 micron wavelength range, at electric field levels that exceeded 1 MV/cm. We observed significant luminescence, resulting in up-conversion of the IR light to visible wavelengths, throughout the IR range that we explored. Preliminary results suggests similar EL induced by strong THz and IR fields.

8:48AM L65.00005: Exciton Fine Structure in Lead Salt Quantum Dots  SERGUEI GOUPALOV (Presenter), Jackson State Univ, IVAN AVDEEV, MIKHAIL NESTOKLON, Ioffe Institute — Lead chalcogenide quantum dots (QDs) have attracted significant scientific and technological interest as their photoluminescence (PL) is tunable by the size change over a wide infrared wavelength range. Electron and hole states in bulk lead chalcogenides are highly degenerate leading to the 64-fold degenerate exciton states. In quantum dots (QDs), the 64-fold degeneracy of the excitons is lifted by the valley mixing and by the electron-hole exchange interaction. We thoroughly investigate the relative importance of the inter-valley, spin-orbit, and electron-hole exchange couplings for the splittings and calculate the resulting exciton fine structure in the framework of the empirical tight-binding method. The dependence of the exciton fine structure on QD size and shape is analyzed. The calculated exciton fine structure allows one to explain the temperature dependence of the PL lineshapes observed in recent single QD experiments on PbS/CdS core/shell colloidal nanocrystals.
9:00AM L65.00006: Atomic and Electronic Structure of Epitaxial Necking in Quantum Dot Super Lattice  MAHMUT SAMI KAVRIK (Presenter), University of California San Diego, WONHEE KO, JORDAN HACHTEL, Oak Ridge National Lab, CAROLINA QIAN, ALEX ABEISON, University of California Irvine, HARSHIL KASHYAP, SCOTT UEDA, University of California San Diego, AN-PING LI, JUAN IDROBO, Oak Ridge National Lab, MATT LAW, University of California Irvine, ANDREW KUMMEL, University of California San Diego — Quantum coupling between periodic nanocrystalline structures manifests novel mesoscale properties such as mini-band formation, which may induce high carrier mobility\(^1\). Colloidal PbSe quantum dots (QDs) can self-assemble into 3D superlattices and are a promising material system to realize these synergistic properties. In this work, the electronic structures of these systems are investigated with advanced metrology and the modulation of electronic band structure in QD epi-SL by the formation of epitaxial neck between the QDs were observed. Experiments revealed unexpectedly large zero conductance (band) gap formation (~1.1 eV) when the STS probe was located between the QDs, while a smaller band gap of ~0.7 eV was observed when probing the body of the QD, as expected. Monochromated STEM-EELS were performed on the monolayer epi-SL and the band gap modification as a function of the electron probe position studied which shown a high onset for the energy loss when the electron probe was positioned on the QD neck, while a smaller onset was observed when the probe was directly on the QD. It is hypothesized that the epitaxial necks between the QDs confines the electron (hole) wave functions, thereby forming large band gaps on the epitaxial necking regions.

9:12AM L65.00007: Advances in Colloidal Quantum Dot Superlattice Charge Transport*  HENRY TRAVAGLINI (Presenter), University of California, Davis —

Colloidal quantum dot (QD) superlattices are an attractive class of materials for next generation electronic devices due to the manifold methods to tune their fundamental properties, including atomic composition, size, shape, and surface functionalization. However, due to their massive surface area to volume ratio and various structural disorder, defects have prevented the realization of a QD superlattice that shows true band-like transport properties. We report on novel superlattice fabrication techniques and characterization techniques, which show a dramatic increase of mobility without the use of electrochemical gating. We use scanning photocurrent microscopy to provide a means of extracting accurate minority carrier diffusion lengths as a function of temperature. We show a significantly improved minority carrier diffusion length and external quantum efficiency compared to amorphous QD lattices. We conclude by discussing our results in the context of rigorous signatures of band-like transport in generic superlattices.

*This work was supported by the U.S. National Science Foundation Grant DMR-1710737 and the UC Laboratory Fees research program.
Zero field splitting of heavy-hole states in Ge quantum dots

GEORGIOS KATSAROS (Presenter), JOSIP KUKUCKA, LADA VUKUSIC, HANNES WATZINGER, Institute of Science and Technology Austria, FEI GAO, TING WANG, JIANJUN ZHANG, Institute of Physics, Chinese Academy of Sciences, KARSTEN HELD, Technical University of Vienna — Holes have gained increasing interest in the past few years as spin qubit candidates since their strong spin-orbit coupling allows full electrical control of the hole spins [1-4]. Despite the fact that a hole is simply a missing electron, their spins are behaving strikingly different than their electron counterparts. While the electron spin does not correlate with the direction of motion, for holes in semiconductors there is a strong coupling between the momentum and the hole pseudospin.

For heavy-hole (HH) states confined in two dimensions, the pseudospin points in the direction of strong confinement. This implies that such HHs should show a zero field splitting (ZFS). By performing cotunnelling spectroscopy, we measure a ZFS of up to 55μeV for the excited triplet states confined in a Ge hut wire quantum dot with an even hole occupation. The evolution of the triplet states both for perpendicular and parallel magnetic fields is in very good agreement with an anisotropic spin Hamiltonian.

Thermoelectric transport properties of coupled quantum dots

ROBERTO FRANCO PE?ALOZA (Presenter), Departamento de Física, Universidad Nacional de Colombia, Bogotá - Colombia, JOHN ALEJANDRO LANDAZABAL RODRIGUEZ, Departamento de Ciencias Naturales, Escuela Tecnológica Instituto Técnico Central, Bogotá-Colombia, JERESON SILVA VALENCIA, Departamento de Física, Universidad Nacional de Colombia, Bogotá - Colombia, EDWIN ER RAMOS, Departamento de Física, Universidad de los Andes, Bogotá - Colombia, MARCOS FIGUEIRA, Instituto de Física, Universidade Federal Fluminense, Niterói-RJ, Brazil — We study thermoelectric properties of coupled quantum dots (QDs), employing the impurity Anderson model (IAM), taking into account strong, but finite electronic correlation in each QD, and a Green's functions approximation with a many-body character [1,2]. We consider two geometrical configurations: two identical immersed QDs in a quantum wire (QW), taking the first QD in different regimes (different energy values) and the second one in the symmetric condition of the IAM; the second geometrical configuration describes a first QD side coupled to a QW for different QD energy values, a second QD in the symmetric condition is immersed in the QW.

Employing linear response theory we compute the electric (G) and thermal (K) conductances, thermopower (S), and the product between the thermoelectric figure of merit and the temperature (ZT) [2] for different temperatures and regimes of the first QD, studying too the validity of the Wiedemann-Franz law and the quantum scattering process and analysing its possible relation with the ZT improves conditions. We obtain specific conditions that enhance ZT (ZT >4) and that would be tested for experimental work.

9:48AM L65.00010: Entropy measurements in mesoscopic circuits: opportunities and limitations

TIM CHILD (Presenter), OWEN SHELLEY, Physics and Astronomy, University of British Columbia, NIKOLAUS GEORGE HARTMAN, Station Q, Purdue University, SILVIA LÜSCHER, JOSHUA FOLK, Physics and Astronomy, University of British Columbia, SAEED FALLAH, Physics and Astronomy, Purdue University, GEOFFREY C. GARDNER, Materials Engineering, Purdue University, MICHAEL MANFRA, Physics and Astronomy, Purdue University — Recently, Hartman et al. demonstrated the capability to measure the entropy of a quantum dot (QD) containing only a few electrons[1] by detecting shifts in the charge state of the dot with temperature, dN/dT. While the measurement technique in Hartman et al. achieved a high level of accuracy, it lacked versatility because it required the system to be in a weakly coupled state that is thermally broadened, and therefore that charge transitions have the standard cosh^2 line-shape of classic Coulomb blockade theory. Here, we show that integrating the dN/dT signal instead of fitting to a particular line-shape enables an entropy measurement of any transition[2], independent of the transition line-shape or even whether the entropy change occurs in the QD itself or another part of the system that is directly coupled to the dot. We demonstrate an entropy measurement for QDs throughout the range from weak to strong coupling to a reservoir. The QD is also sensitive to changes in entropy of other parts of the system, illustrating the potential for this method to be used to measure the entropy of more complex and interesting systems.

10:00AM L65.00011: Measured phase shift using quantum dot interferometer in Kondo regime

YUJIE ZHANG, Keio Univ, RUI SAKANO, Institute for Solid State Physics, University of Tokyo, MIKIO ETO (Presenter), Keio Univ — Phase measurement was reported by the transport through an Aharonov-Bohm ring with an embedded quantum dot, so-called quantum dot interferometer, with three terminals in the Kondo regime [1]. To evaluate how precisely the phase is measured, we theoretically examine the transport through a double quantum dot (DQD) in parallel, as a tractable model for the interferometer. One of the DQD is in the Kondo regime while the other is transparent with a large line width. We report (i) the formulation of transport through the DQD in terms of Keldysh Green functions for three-terminal setup. The conductance at zero temperature is exactly given using the Bethe Ansatz solution. We find that the Kondo temperature changes with a magnetic flux penetrating the ring. (ii) For the conductance as a function of gate voltage (Coulomb peaks), we show a crossover from an asymmetric shape of Fano-Kondo resonance to a symmetric Kondo plateau with an increase in the number of conduction channels in the leads. (iii) The phase locking at \( \pi/2 \) can be measured around the center of Kondo valley in some conditions for the tunnel couplings between the DQD and three leads, although the measured phase is slightly deviated from the Friedel sum rule.

10:12AM L65.00012: Evidence of quantum phase transition in double charge Kondo quantum dots* WINSTON POUSE (Presenter), DAVID GOLDHABER-GORDON, Stanford Univ, ANDREW MITCHELL, Physics, University College Dublin, GERGELY ZARAND, Theoretical Physics, Budapest University of Technology and Economics, CATALIN PASCU MOCA, Physics, University of Oradea, ULF GENNSER, Centre national de la recherche scientifique — The Kondo effect is one of the simplest many body phenomena, in which a single magnetic impurity couples to a continuum of states. Adding a second impurity coupled to the first has been suggested to provide insight into heavy fermion systems. Implementing such impurities in nanofabricated systems with tunable parameters has proven to be a powerful way to compare experiments to theoretical predictions. Recent experimental work demonstrated a new way to realize this type of physics: the charge on a hybrid metal-semiconductor quantum dot coupled to a quantum hall edge state acts as a pseudospin [1]. We build off this design to create a two impurity configuration, with a competition between a dot-dot Kondo interaction and a dot-lead Kondo interaction. We believe this yields a novel quantum critical state. In our device, we controllably tune the various interaction strengths to explore the distinct phases. We provide evidence of a phase transition via transport measurements, with an enhanced conductance when the interaction strengths are comparable.

10:24AM L65.00013: Majorana bound state in the continuum: Coupling between Majorana bound state and quantum dot mediated by continuum* JUAN RAMOS ANDRADE (Presenter), PEDRO ORELLANA, Physics Department, Federico Santa Maria Technical University, EDSON VERNEK, Physics Institute, Federal University of Uberlândia — In this work, we consider a single-level quantum dot (QD) and a Majorana bound state (MBS) placed at the end of a topological superconducting nanowire (TSW). Both are coupled to the continuum and do not have a direct connection between them. We addressed the behavior of MBS leaking phenomena and its consequences into the QD physics in the non-interacting and Coulomb blockade regime. By employing Green's function formalism via the equation of motion procedure, we calculate the physical quantities of interest. Our results show that the leakage of the MBS into the continuum state is achieved and can alter the physics of Coulomb blockade in the system through continuum-mediated coupling between MBS and QD. As a main consequence, we found a robust and non-trivial mechanism to accomplish a bound state in the continuum in the system.

10:36AM L65.00014: Spherical topological-insulator nanoparticles: Quantum size effects and optical transitions*  
LEI YANG (Presenter), Perimeter Inst for Theo Phys, MAX GOLDWATER CHRISTIE, ULRICH ZUELICKE, MICHELE GOVERNALE, ALEXANDER SNEYD, Victoria University of Wellington — We investigate the interplay between band inversion and size quantization in spherically shaped nanoparticles made from topological-insulator (TI) materials. A general theoretical framework is developed based on a continuum-model description of the TI bulk band structure subjected to a hard-wall mass confinement. Analytical results are obtained for the wave functions of single-electron energy eigenstates and the matrix elements for optical transitions between them. Quantized levels in TI nanoparticles can be labeled by angular momentum quantum numbers \( j \) and \( m = -j, -j+1, \ldots, j \). Additionally TIs possess a doubling of energy-level degeneracy due to different parity eigenstates with eigenvalues \((-1)^{j\pm1/2}\). The existence of energy eigenstates having the same \( j \) but opposite parity enables optical transitions where \( j \) is conserved, in addition to those adhering to the familiar selection rule where \( j \) changes by \( \pm 1 \). We treat intra- and inter-band optical transitions on the same footing and establish ways for observing unusual quantum-size effects in TI nanoparticles. Our theory also provides a unified perspective on multi-band models for charge carriers in semiconductors and Dirac fermions from elementary-particle physics.

10:48AM L65.00015: Flexible manipulation of quantum dots by single-pulse optical vortices*  
GUILLERMO FEDERICO QUINTEIRO (Presenter), Departamento de Física, Universidad Nacional del Nordeste, PABLO I TAMBORENEA, Departamento de Física, Universidad de Buenos Aires, M HOLTKEMPER, D. E. REITER, T. KUHN, Institut fur Festkörpertheorie, Universität Münster — Optical vortices (OV) are light fields with surprising properties, such as orbital angular momentum (AM), strong longitudinal components, and more, that can be exploited to control matter in new ways. Here we show that a single-pulse of an OV with the right parameters --degree of focusing, polarization, orbital AM, etc-- can precisely manipulate the electronic state of semiconductor quantum dots (QD) [1, 2]. Our models demonstrate the possibility of creating: i) heavy-hole excitons with arbitrary orbital AM, and ii) light-hole excitons with zero band+spin AM, with or without orbital AM. Such states can be named "envelope-forbidden" (i) or "spin-forbidden" (ii), since they cannot be excited by Gaussian light beams. In addition, we present potential applications to quantum technology: spin-forbidden states allow sub-picosecond spin flips of an extra electron charging the QD or the encoding of information on dark excitons, while envelope-forbidden states allow for the generation of currents that can produce magnetic fields at the nanoscale.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM
8:00AM L66.00001: Actuating and probing a single-molecule switch at femtosecond timescales*

DOMINIK PELLER, LUKAS Z KASTNER, THOMAS BUCHNER, CARMEN ROELCKE, FLORIAN ALBRECHT, RUPERT HUBER, JASCHA REPP (Presenter), Department of Physics, University of Regensburg, Germany — Accessing ultra-fast non-equilibrium phenomena is enabled by terahertz (THz) scanning tunneling microscopy [1] (THz-STM) through combining STM with lightwave electronics. In THz-STM, the electric field of a phase-stable single-cycle THz waveform acts as a transient bias voltage across an STM junction. These voltage transients may result in a net current that can be detected by time-integrating electronics. The recent development of this lightwave STM has enabled the combined femtosecond and sub-angstrom resolution in observing matter [2].

We now demonstrate the first combined femtosecond and sub-angstrom access in the control of matter. Ultrafast localized electric fields in lightwave STM enable exerting atom-scale femtosecond forces to selected atoms. By shaping atomic forces on the intrinsic timescale of molecules, coherent atomic motion can now be excited. Utilizing this coherent structural dynamics, we can modulate the quantum transitions of a single-molecule switch by up to 39%. We directly visualize the coherent excitation of the switch in the first femtosecond single-molecule movie [3].

To resolve the impact of coherent control of the single-molecule switch, alongside, we introduce single-shot action spectroscopy in lightwave STM as the first concept resolving individual path-selective reaction events of a single molecule in space and time. With this novel concept, we detect the outcome of every single laser shot and further separate the statistics of the two inverse reaction paths.

Our results open a new chapter in the control and observation of reactions of individual molecules directly on the relevant ultrafast and ultrasmall scales.

One major appeal of STM investigations is the unique combination of atomic scale manipulation capabilities with the excellent spectroscopic insight into the electronic structure of 2D materials; providing quasi-static information due to limited preamplifier bandwidth. However, access to the time-domain would enable additional measurement modalities, ranging from the investigation of charge and spin dynamics to the mechanical motion of nanostructures. Despite the early demonstrations by Nunes and Freeman, the widespread implementation of pump-probe methods has remained elusive due to instrumental hurdles. Here we introduce a versatile, straightforward, and affordable setup to achieve nanoseconds time-resolution with minimal changes to an existing STM system [1]. Our setup consists of a dual-channel arbitrary waveform generator, a transfer switch, and a lock-in amplifier. We demonstrate its plug-and-play capability on a field-trip, providing immediate access to the spin-excitation of a magnetic molecule. We further expand our setup to match requirements for pulsed ESR excitations.

9:12AM L66.00003: Single-atom qubits on a surface: pulsed electron spin resonance in a scanning tunneling microscope* [Invited]  KAI YANG (Presenter), IBM Research - Almaden — Recently, the ability to drive electron spin resonance (ESR) of individual atoms using a scanning tunneling microscope (STM) provides a major step forward in sensing and manipulating magnetism at the atomic scale. In the first part, I will describe the implementation of continuous-wave ESR in STM [1], which has allowed the measurement of the magnetic interaction between individual atoms [2–5] as well as the detection and control of nuclear spins [6, 7]. Next, I will talk about coherent spin rotations of individual atoms on a surface with control at the nanosecond timescale, using all-electric pulsed ESR in STM. By modulating the atomically-confined magnetic interaction between the STM tip and surface atoms [8, 9], the large oscillating electric field in the STM junction induces quantum Rabi oscillations between spin-up and spin-down states in as little as ~20 nanoseconds [10]. Ramsey fringes and spin echo signals allow us to understand and improve quantum coherence. I will also show the coherent operations on the coupled-spin states of engineered atomic dimers. Coherent control of spins arranged with atomic precision provides a solid-state platform for quantum simulation of many-body systems.

Resolving fast dynamics through measurement in the frequency domain* [Invited] RICCARDO BORGANI (Presenter), DAVID HAVILAND, KTH Royal Inst of Tech — The advent of multifrequency lock-in amplifiers has made possible the development of AFM methods that are explicitly designed to exploit the nonlinear nature of the tip-surface interaction. These methods capture information in the frequency domain with high signal-to-noise ratio through measurement of intermodulation between two or more drive tones.

Intermodulation electrostatic force microscopy (ImEFM) [1] is an open-loop alternative to Kelvin-probe force microscopy (KPFM), where the potential of the surface is obtained from a measurement of four frequency components of the force which fall within the cantilever resonance.

We have recently developed a time-resolved variant of ImEFM [2], where the cantilever drive intermodulates with a series of voltage pulses on the sample to produce force components at multiple frequencies around resonance. Measuring these force components we reconstruct dynamic processes in the material with time resolution of 30 nanoseconds, despite of the limited bandwidth (~500 Hz) of the cantilever resonance.

Intermodulation conductive AFM (ImCFM) [3] measures the current-voltage characteristic (IVC) at every pixel of an AFM scan with a speedup of four orders of magnitude in comparison to the traditional time-domain methods. Frequency-domain analysis allows for complete separation of the galvanic current from displacement current in the tip-sample capacitance. The technique also maps the voltage dependence of the tip-sample capacitance, allowing for the investigation of phenomena such as quantum capacitance.

Sebastian Loth Invited Talk [Invited] —

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Twisted bilayer graphene (TBG) with a rotational misalignment (twist) angle close to the magic value of 1.1°, features isolated flat electronic bands. These bands form a strongly correlated electronic system that exhibits a range of quantum phases, including superconductivity, ferromagnetism, and correlated insulating states. In this talk, I will present the latest results from our lab on magic-angle graphene obtained using scanning tunneling microscopy/spectroscopy (STM/STS) and transport measurements [1,2]. The local spectroscopy data shows that the flat bands get highly deformed when aligned with the Fermi level. Near half-filling of the bands, we observe the development of gaps originating from correlated insulating states, while near charge neutrality, we find a regime featuring an enhanced flat band splitting that can be described within a model predicting a strong tendency towards nematic ordering. In the second part of the talk, I will discuss transport measurements using novel stack geometry showing the existence of superconductivity in the absence of insulating states. Our findings provide a basis for a microscopic understanding of correlated quantum phases in twisted bilayer graphene.

We acknowledge support from NSF (DMR-1753306 and DMR-1744011) and the Gist-Caltech memorandum of understanding program.

[2] Superconductivity without insulating states in twisted bilayer graphene stabilized by monolayer WSe2
Van der Waals bilayers with an interlayer twist are an excellent platform towards achieving gate-tunable electronic flat bands. A number of emergent phases driven by electron-electron interactions have been observed when tuning the Fermi level through these flat bands. I will present atomically-resolved doping-dependent scanning tunneling spectroscopy studies of two graphene-based systems with emergent correlated phases due to flat bands – magic angle twisted bilayer graphene (tBG) and ABCA graphene, a simple system with a flat band without a moire potential. Our spectroscopy shows that magic angle tBG features two flat bands separated by 40-55 meV. Correlated states emerge when tuning the Fermi level through an individual flat band with minimized bandwidth suggesting the importance of maximized electronic correlations at the magic angle. We measure the correlated insulator gap at half filling and show evidence of nematicity near half-filling in magic angle tBG. I will then show that twisted double bilayer graphene (tDBG) features a fundamentally different moire pattern than tBG, hosting rhombohedral (ABCA) stacking sites. At tiny tDBG angles this creates micron-scale ABCA graphene domains, a robust platform to stabilize the ABCA graphene. Our spectroscopy reveals that ABCA graphene hosts a flat band of 3-4 meV half-width (versus 9-10 meV in magic angle tBG). The unprecedentedly narrow electronic band enhances electronic correlations inducing a correlated gap at charge neutrality making ABCA graphene a model graphene-based correlated system with no moire superlattice potential or integer fillings. Finally, I will show that ABCA graphene hosts topological surface helical edge states which can be turned on and off with gate voltage.
9:12AM L67.00003: Charge order and broken rotational symmetry in magic-angle twisted bilayer graphene* [Invited] JINHAI MAO (Presenter), YUHANG JIANG, University of Chinese Academy of Sciences, XINYUAN LAI, KRISTJAN HAULE, EVA ANDREI, Rutgers University — Bilayer graphene can be modified by rotating (twisting) one layer with respect to the other. The interlayer twist gives rise to a moiré superlattice that affects the electronic motion and alters the band structure. Near a ‘magic angle’ of twist, where the emergence of a flat band causes the charge carriers to slow down, correlated electronic phases including Mott-like insulators and superconductors were recently discovered by using electronic transport. These measurements revealed an intriguing similarity between magic-angle twisted bilayer graphene and high-temperature superconductors, which spurred intensive research into the underlying physical mechanism. Essential clues to this puzzle, such as the symmetry and spatial distribution of the spectral function, can be accessed through scanning tunnelling spectroscopy. Here we use scanning tunnelling microscopy and spectroscopy to visualize the local density of states and charge distribution in magic-angle twisted bilayer graphene. Doping the sample to partially fill the flat band, we observe a pseudogap phase accompanied by a global stripe charge order that breaks the rotational symmetry of the moiré superlattice. Both the pseudogap and the stripe charge order disappear when the band is either empty or full. The close resemblance to similar observations in high-temperature superconductors provides new evidence of a deeper link underlying the phenomenology of these systems.

9:48AM L67.00004: Spectroscopic signatures of many-body correlations in magic-angle twisted bilayer graphene* [invited] YONGLONG XIE (Presenter), Harvard University — The discovery of superconducting and insulating states in magic-angle twisted bilayer graphene (MATBG)\textsuperscript{1,2} has ignited considerable interest in understanding the nature of electronic interactions in this chemically pristine material. The transport properties of MATBG as a function of doping are similar to those of high-transition-temperature copper oxides and other unconventional superconductors\textsuperscript{1-3}, which suggests that MATBG may be a highly interacting system. However, there is no direct experimental evidence of strong many-body correlations in MATBG. In this talk, I will present the unusual spectroscopic characteristics found on MATBG, obtained using a scanning tunneling microscope, and describe how these correlated features allow us to establish a more concrete connection between MATBG and high-T\textsubscript{c} cuprates beyond the phenomenological resemblance of their transport phase diagrams\textsuperscript{4}.

Other support for the experimental work was provided by NSF-MRSEC programmes through the Princeton Center for Complex Materials DMR-142054, NSF-DMR-1608848, ExxonMobil through the Andlinger Center for Energy and the Environment at Princeton, and the Princeton Catalysis Initiative.

10:24AM L67.00005: Spectroscopy and Correlation Effect at Magic Angle [invited] BIAO LIAN (Presenter), Princeton University — The twisted bilayer graphene (TBG) near the magic angle develops topological flat electron bands at low energies, and exhibits both superconducting and correlated insulating phases at low temperatures. The STM spectroscopy measurements of magic angle TBG shows that the differential tunneling conductances dI/dV at both low and relatively high temperatures have a strong dependence on the doping density in the flat bands. We show that the Hartree Fock mean field theory with spontaneous spin/valley polarization and strain effect fails to capture the spectroscopy at the magic angle. Instead, we show that charge correlation effects beyond the mean field theory are significant for explaining the spectroscopy data, and can be demonstrated in the exact diagonalization of a phenomenological Hubbard model. We also discuss the possible effects of phonon-mediated electron interaction. Lastly, we talk about the effects of the TBG band topology on the Hofstadter butterfly and the interacting phases.

Session L68 DBIO: The Many Dimensions of Evolution Four Seasons 4 - Mikhail Tikhonov, Washington University, St. Louis - Tag(s): Invited, Undergrad Friendly
8:00AM L68.00001: The ecology and evolution of collective behavior [Invited] DEBORAH GORDON (Presenter), Biology, Stanford University — Ant colonies operate without central control, using feedback from simple olfactory interactions to regulate their activities. There are more than 14K species of ants in every habitat on Earth, using diverse stochastic algorithms, producing different feedback regimes, in different environments. These algorithms have evolved to fit the dynamics of particular environments, including energy flow, stability, and the threat of rupture. Harvester ants in the harsh but stable conditions of the desert, regulate foraging effort according to current food availability and humidity, using excitable dynamics based on the rate of contact inside the nest between returning and outgoing foragers. The feedback system sets a default of inactivity unless conditions are favorable. For turtle ants in the trees of the tropical forest, high humidity makes activity easy but competition is high. Their trail networks are constrained to follow the network of vegetation. They use the rate of deposition of a volatile pheromone to build and maintain a distributed routing network in heterogeneous environments, based on design principles that differ from the shortest paths commonly studied in ants and in network science. The feedback system sets a default of persistent activity unless conditions are unfavorable. The diversity of ants provides opportunities to learn how collective behavior evolves to fit diverse environmental dynamics.

8:36AM L68.00002: Attack of the clones: what causes population structure in bacteria and how can we use it? [Invited] WILLIAM HANAGE (Presenter), Epidemiology, Harvard T. H. Chan School of Public Health — In most pathogenic bacteria, the population is made up of multiple distinct lineages or ‘clones’ which are associated with properties like virulence or drug resistance. For the most part, this structure has been taken for granted and its root causes not been examined. We have recently shown, using the pneumococcus as a model organism, that we can explain which clones are present in a community with a simple model of negative frequency dependent selection operating on a subset of the genome: namely the accessory genome of loci not present in all isolates of the species. Moreover, we can use this to predict the consequences of removing some clones, for instance through vaccination. This can be achieved either through a game theory approach using the replicator equation, or through quadratic programming to determine how the equilibrium properties of the population as a whole can be restored by altering the proportions of each clone. Finally the existence of clones offers an opportunity to use emerging DNA sequencing technologies to rapidly detect them in clinical samples, which could be useful for detecting and responding to drug resistant threats.

9:12AM L68.00003: Evolutionary dynamics in large microbial communities [Invited]  BENJAMIN GOOD (Presenter), Stanford Univ — Microbial communities drive important biochemical cycles, from the ocean to the soil to the human gut. High rates of cell turnover endow these communities with an enormous potential for rapid evolutionary change – e.g., billions of new mutations are produced within a single gut microbiome every day. Despite the potential importance of these effects, we currently know very little about the evolutionary dynamics that take place in large microbial communities, and how these dynamics might deviate from our single-species intuition. In this talk, I will describe our recent efforts to address this question using data from the human gut microbiome. I will show how population genetic analysis of sequenced fecal samples can help us quantify the typical timescales of within-host evolution, and how this might constrain the ability of a community to adapt to fluctuating environmental conditions.

9:48AM L68.00004: Microbial interactions across time and space * [Invited]  BRITT KOSKELLA (Presenter), University of California, Berkeley — There is great interest in explaining microbial diversity, but a critical first step that is often downplayed is understanding the spatial and temporal scales that are relevant to the system. In this talk I discuss the relative importance of interactions among bacteria and phage viruses, between bacterial strains and species within a microbiome, and between a host and its symbionts to emphasize the role of evolution and coevolution in shaping diversity across scales. I focus primarily on the plant phyllosphere as a model system to explore these interactions both in natural, ecologically complex, and simple experimental systems.

 Phenotypic heterogeneity between genetically identical cells permits growth with lethal levels of formaldehyde stress* [Invited] JESSICA A LEE, SIAVASH RIAZI, Biological Sciences, University of Idaho, SHAHLA NEMATI, Physics, University of Idaho, JANNELL V BAZURTO, Biological Sciences, University of Idaho, ANDREAS E VASDEKIS, Physics, University of Idaho, BENJAMIN J RIDENHOUR, CHRISTOPHER H REMIEN, Mathematics, University of Idaho, CHRISTOPHER MARX (Presenter), Biological Sciences, University of Idaho — Scientists tend to appreciate microbes for their simplicity and predictability: a population of genetically identical cells inhabiting a uniform environment is expected to behave in a uniform way. However, counter-examples to this assumption are frequently being discovered, forcing a re-examination of the relationship between genotype and phenotype. In most such examples, bacterial cells are found to split into two discrete populations, for instance growing and non-growing. Here, we report the discovery of a novel example of microbial phenotypic heterogeneity in which cells are distributed along a gradient of phenotypes, ranging from low to high tolerance of a toxic chemical. Furthermore, we demonstrate that the distribution of phenotypes changes in different growth conditions, and we use mathematical modeling to show that cells may change their phenotype either randomly or in a particular direction in response to the environment. Our work expands our understanding of how a bacterial cell's genome, family history, and environment all contribute to its behavior, with implications for the diverse situations in which we care to understand the growth of any single-celled populations.

Wednesday, March 4, 2020 8:00 AM - 11:00 AM

Session L70 DPOLY DSOFT: Vitrimers and Associative Networks 208 -
Christopher Evans, University of Illinois at Urbana-Champaign - Tag(s): Focus
8:00AM L70.00001: Microscopic Theory of the Role of Strong Attractions on the Local Dynamics and Elasticity of Associating Copolymer Liquids  
ASHESH GHOSH (Presenter), KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We construct a microscopic liquid state theory for how attractions between sticky groups regularly co-polymerized in a chain backbone affect local structure and dynamics of unentangled polymer liquids. Based on the bare attractive interaction and single-chain structure as input, PRISM integral equation theory is combined with activated dynamics approaches that capture caging and physical bond formation to study emergent high frequency elasticity and local relaxation processes. The dynamic free energies and corresponding sticker and non-sticker barrier hopping timescales that define the coupled bond breakage and cage escape processes are predicted within a 2-step dynamical scenario that applies in the strong attraction regime. The first step involves non-sticker hopping (alpha process) which is perturbed due to physical bonds between sticky segments that act as pinning constraints. After the non-sticker hops, the dynamical constraints and friction experienced by the sticky groups are renormalized and activated bond-breaking defines the second step. We present representative results for structure and dynamics as a function of sticker fraction, strength and range of the attraction, density, and temperature. Connections between dynamics and equilibrium properties are identified.

8:12AM L70.00002: LINEAR VISCOELASTICITY AND FLOW OF SELF-ASSEMBLED VITRIMERS: THE CASE OF A POLYETHYLENE/DIOXABOROLANE SYSTEM  
RALM RICARTE (Presenter), Florida State Univ, FRANÇOIS TOURNILHAC, MICHEL CLOÎTRE, Molecular, Macromolecular Chemistry, and Materials, ESPCI Paris, LUDWIK LEIBLER, Gulliver, ESPCI Paris — We investigated the linear viscoelasticity of a polyethylene (PE) vitrimer that has cross-linkable dioxaborolane maleimide grafts. Strong interactions between the PE backbone and grafts cause the molten vitrimer to macro- and microphase separate into hierarchical structures. Small-amplitude oscillatory shear, stress relaxation, and creep measurements were used for characterization. Graft functionalized PE (which does not contain cross-linker, but still self-assembles) had a terminal relaxation time that was two orders of magnitude larger than neat PE. When cross-linker was added to form the vitrimer, the material exhibited a higher melt strength but did not achieve steady-state flow within 8 hr. The soluble graft-poor portion of PE vitrimer had similar flow behavior as neat PE, but its flow activation energy was twice as large. Conversely, the insoluble graft-rich fraction behaved as a viscoelastic solid that relaxed very little over 8 hr. Blend experiments suggested the interface between the graft-rich and graft-poor phases of PE vitrimer also influenced relaxation. These findings indicate that self-assembly/associative cross-linking interplay greatly impacts the rheology and, consequently, processability of vitrimers.
Effect of salt on viscoelasticity and conductivity in vitrimers and dynamic networks

8:24AM L70.00003: BRIAN JING (Presenter), CHRISTOPHER EVANS, University of Illinois at Urbana-Champaign — Polymer networks with associative dynamic bonds (vitrimers) have been investigated as recyclable and self-healing materials. We have developed vitrimers made from polyethylene glycol, dynamic boronic ester crosslinks, and added Li salt that function as Li-ion conductors. These networks were studied over a range of Li:ethylene oxide (Li:EO) ratios to understand the effect of salt concentration on conductivity and viscoelasticity. The storage modulus decreases from 10 to 0.5 MPa at room temperature with added salt, attributed to boron-anion interactions which decrease the number of elastically active boron centers (supported by $^{11}$B NMR analysis). The temperature dependent moduli also show a crossover of $G'$ and $G''$ which occurs at ~100 °C (at 1 Hz) in a neutral system and drops by 85 °C with added salt. Conductivities up to $3 \times 10^{-4}$ S/cm were measured (solvent-free) at 90 °C, and go through a maximum which is attributed to the competition of added salt and increasing Tg. The networks can also be dissolved in water back to monomer and recover conductivity after damage due to the dynamic bonds. Finally, we discuss how these vitrimers transition to dissociative networks with added salt due to anion-boron interactions which lead to non-Arrhenius stress relaxation times.

Understanding the Self-healing of Reversible Polymer Networks through Molecular Dynamic Simulation*

8:36AM L70.00004: ZHIQIANG SHEN (Presenter), HUILIN YE, YING LI, Univ of Connecticut - Storrs — Hydrogels with reversible crosslinking motifs exhibit extraordinary short healing time and high healing strength. However, the understanding about the self-healing behavior of reversible polymer network is limited. Especially, the key problem about relation between the microscopic evolution of polymer networks and the macroscopic stress-strain behaviors during the self-healing process remains largely elusive. In this work, a molecular dynamics / Monte Carlo hybrid coarse-grained model is developed to investigate the relaxation and self-healing behaviors of polymer networks with reversible crosslinking. We systematically investigate the shelf-healing process of the polymer network with a fracture. It is found that the polymer chains at the fracture interface can diffusive through the interfacial gap and form new crosslinking bonds, resulting the recovery of polymer network mechanical strength. We found that the healing time is both determined by the dwelltime of the dynamic bond and relaxation of the polymer chains. Our simulations provide a direct relation between dynamic bond and the self-healing process, which might provide an insight for the design of smart self-healing polymers.

*NSF-CMMI-#1762661
Collaborative Research: Interfacial Self-healing of Nanocomposite Hydrogels
8:48AM L70.00005: Role of Dynamic Bonds on Crystallization in Polyethylene Vitrimers
BHASKAR SOMAN (Presenter), CHRISTOPHER EVANS, University of Illinois at Urbana-Champaign —
Crystallization of linear polyethylene (PE) has been extensively investigated for decades. Here, we
study the effects of dynamic bonds on the crystallization in PE vitrimers by preparing networks
with exactly 8, 10, and 12 carbons (C₈-C₁₂) between dynamic boronic ester crosslink points. The
C₁₂ networks crystallize immediately upon cooling, while C₈ networks only show evidence of
crystallization after waiting multiple weeks at 20 °C. The C₁₀ networks show intermediate initial
crystallization. Samples were aged at room temperature for 30 days, and in all cases, monotonic
increase in melting temperature (Tₘ) is observed which is attributed to dynamic bonds allowing
local rearrangements of network strands in the amorphous regions or at the crystal-amorphous
interface. A control sample of linear PE shows instant crystallization and no substantial long term
Tₘ evolution. Initial melting temperatures are analyzed in the Hoffman-Weeks framework, and
reasonably predict the long-time Tₘ of orthorhombic crystal. Upon aging, a transition in the
morphology is observed via wide-angle x-ray scattering and the time required for the transition
tracks with dynamic bond density. Finally, we demonstrate that step annealing can result in PE
networks with Tₘ approaching 100 °C.

9:00AM L70.00006: Tuning vitrimer mechanics with prepolymer and crosslinker structure*
JULIA KALOW (Presenter), Northwestern University — Dynamic covalent polymer networks in which
the topology is reconfigured through associative exchange reactions are known as vitrimers.
These materials hold promise as repairable and recyclable thermosets and elastomers. A
hallmark of vitrimers is the Arrenhius relationship between viscosity and temperature; the
activation energy for stress relaxation is often used to describe the energetics of the
reconfiguration process. However, the mechanistic interpretation of this activation energy and its
relationship to the associative exchange event are often unclear. We combine physical organic
approaches and mechanical characterization to correlate the activation energy for stress
relaxation to molecular reactivity and macromolecular structure. This study is enabled by the use
of crosslinks that exchange via a catalyst-free conjugate addition/elimination pathway.

*This material is based upon work supported by the National Science Foundation under grants
no. CHE-1901635 and CHE-1832256.

9:12AM L70.00007: Catalyst and Architecture Effects in Polyester Dynamic Covalent
Materials [Invited] CHRISTOPHER BATES (Presenter), University of California, Santa Barbara —
Polyester networks that include dynamic covalent bonds have attracted significant attention as
materials with tunable plasticity. This talk will discuss the role of catalyst strength and building
block architecture on dynamic covalent polyester exchange kinetics and mechanical properties.
To do so, we introduce a versatile synthetic platform that provides good control over network
connectivity through formulation and precursor design. The fundamental insights described
herein expand the utility of crosslinked polyesters by broadening the range of accessible material
properties.
9:48AM L70.00008: Recycling of Poly(thiourethane) Thermosets Enabled by Thiourethane Bonds  SIJIA HUANG (Presenter), MACIEJ PODGORSKI, XUN HAN, CHRISTOPHER BOWMAN, University of Colorado, Boulder — Recycling of polyurethanes is an inviable process due to the harsh reprocessing conditions and high risk of side reactions. Constructing polymer networks incorporating covalent dynamic bonds becomes an attractive strategy in the design of recyclable materials. Here, we report findings on the dynamic nature of thiourethanes, and their application as a new class of recyclable analogs of urethane materials. A series of small molecule experiments was initially conducted to determine equilibrium constant and reverse reaction kinetic constant for the thiourethane reaction. Furthermore, incorporating those thiourethane moieties into a cross-linked network resulted in thermoset materials that can be facilely depolymerized to liquid oligomers. The resultant oligomers can be recrosslinked back to thiourethanes without any loss of performance nor properties (peak stress of 30 MPa with Young's modulus of 1 GPa). Moreover, the increase in value that thiourethane network can undergo when upcycled to the thiol oligomer enables a potential pathway to build materials with properties that exceed its pristine material. Overall, this reprocessing strategy may advance many global sustainability goals, and is applicable to other low-cost commodity materials.

10:00AM L70.00009: Rheology and Rupture of Partial Vitrimer  SHENGQIANG CAI (Presenter), University of California, San Diego — Polymer network with dynamic covalent bonds, also known as vitrimer, exhibit interesting mechanical behaviors which are very different from conventional polymers. Because of the bond exchanging reactions, vitrimers have shown great potential as excellent recyclable polymers with self-healing capability. Our recent experiments have shown that the mechanical properties of a vitrimer such as fracture toughness and stress relaxation can be greatly tuned by selectively mixing the polymer chains with dynamic covalent bonds and routine covalent bonds (referred as partial vitrimer), while the self-healing capability of the polymer can be still maintained. To quantitatively understand the stress relaxation of the partial vitrimer, we developed a simple rheological model for it with certain combinations of spring and dashpot. We have also developed a simple energy argument to explain the rupture phenomenon of vitrimer under different mechanical loading conditions.
10:12AM L70.00010: Investigation of viscoelastic behavior over wide temperature range in PDMS vitrimers  LAURA PORATH (Presenter), CHRISTOPHER EVANS, University of Illinois at Urbana-Champaign — We have prepared vitrimers of poly(dimethyl siloxane) containing dynamic boronic ester bonds to investigate the viscoelastic properties of dynamic networks with extremely low T_g. The stress relaxation times and frequency dependent behavior are probed over a > 200 °C window and show the anticipated Arrhenius behavior at temperatures ranging from 180 to 40°C. The relaxation times here are independent of network strand molecular weight, which varies from 550-11,000 g/mol. We consider this temperature range to be a reaction-limited regime far above T_g, where bond exchange kinetics dominate macroscopic relaxation. Below 40°C, non-Arrhenius behavior emerges, and the apparent activation energy decreases. Time-temperature-superposition of frequency sweeps shows that the flow regime is thermorheologically simple, while the modulus of the plateau regime increases with increasing temperature, which is consistent with a preserved network architecture. As stress relaxation times speed up by orders of magnitude, the rubbery plateau modulus increases, which leads to a strategy for decoupling dynamics from mechanics. Our studies point to the importance of measuring vitrimer properties over a broad temperature window to understand the full range of response in this class of dynamic network.

10:24AM L70.00011: Intrinsically reprocessable, self-healing elastomers  LIHENG CAI (Presenter), Univ of Virginia — Conventional elastomers formed by solely permanent, chemical crosslinks are not reprocessable, which causes environmental burden to the society. By contrast, networks crosslinked by solely reversible, physical bonds are reprocessable and self-healable. The physical bonds, however, are much weaker than chemical crosslinks, limiting the strength of the resulted polymer networks. Here, we propose a concept that exploits the self-assembly of block copolymers integrating strong physical associations and weak reversible hydrogen bonds to create an intrinsically reprocessable, self-healing elastomer. We find that the reversible bonds promote the formation of ordered nanostructures, which, in turn, result in unique macroscopic mechanical properties. Our results provide insights on the development of intrinsically reprocessable, self-healing elastomers.
10:36AM L70.00012: Melt Recyclable Shape Memory Elastomers through Main Chain Association* 

DANIEL KRAJOVIC (Presenter), MITCHELL ANTHAMATTEN, University of Rochester — Shape memory (SM) elastomers can undergo triggered actuation from metastable, deformed states to permanent shapes, offering diverse applications. Covalently crosslinked, semicrystalline SM networks are capable of storing large amounts of elastic energy (>3 MJ/m$^3$) with full recovery, however, these materials cannot be melt-processed or recycled. Here, we demonstrate that replacing covalent crosslinks with hydrogen bond interactions can enable fully melt recyclable SM elastomer with little performance loss. Two high molecular weight poly(caprolactone)s with interchain hydrogen bonding groups have been synthesized and show excellent strain fixation and shape recovery both before and after shredding, melt-pressing, and reannealing. Dynamic mechanical analysis reveals a stiffness plateau that persists to temperatures above the shape-triggering temperature. Stress relaxation studies suggest chain disentanglement is the primary relaxation mode. Disentanglement is sluggish just above the trigger temperature and is much faster at higher temperatures where plastic flow can occur. The role of the polymers’ hard segment associative strength and a first-cycle training effect are under continued investigation.

*Funding was provided by NSF under Grant ECCS-1530540.

10:48AM L70.00013: Leveraging the Stability of Ionic Liquids in Processing Polyampholytes 

DAVID DELGADO (Presenter), Northwestern University, JIAN PING GONG, Global Station for Soft Matter, Global Institution for Collaborative Research and Education, Hokkaido University, KENNETH R SHULL, Northwestern University — Double network gels composed of polyampholytes have been shown to have both tough and strong properties due to both inter and intra electrostatic bonding. Upon deformation, the weaker bonds break and dissipate energy allowing the gel to be load bearing despite retaining up to 90% water. While these gels are suited for bulk applications such as the knee or achilles heel, it remains a challenge to fabricate thin films that can coat non-planer surfaces such as the hip joint. Traditional polyelectrolyte processing has used salt to screen bonds and move across the polyelectrolyte coacervate continuum. Upon evaporation of water, however, this salt can recrystallize and disrupt film morphology. In this work, an ionic liquid composed of choline chloride and urea is used to dissolve and rapidly deposit double network gels. Moreover, in contrast to salt processing, the ionic liquid is stable at ambient conditions. Finally, rheological studies and phase diagrams are presented to understand the interplay between ionic liquid, polyampholyte, and water.

Wednesday, March 4, 2020 8:00 AM - 9:30 AM

Session L71 APS: Tutorial for Authors and Referees (8:00am - 9:30am)
8:00AM L71.00001: Tutorial for Authors and Referees (8:00am - 9:30an) — Editors from Physical Review Letters and Physical Review will provide information and tips for our less experienced referees and authors. This session is aimed at anyone looking to submit to or review for any of the APS journals, as well as anyone who would like to learn more about the authoring and refereeing processes. Topics for discussion will include advice on how to write good manuscripts, similarities and differences in writing referee reports for PRL and PR, and other ways in which authors, referees, and editors can work together productively. Following a short presentation from the editors, there will be a moderated discussion.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M01 DAMOP DCMP: Non-Equilibrium Physics with Cold Atoms and Molecules, Rydberg Gases, and Trapped Ions 103 - Vito Scarola, Virginia Tech - Tag(s): Focus

11:15AM M01.00001: Probing quench dynamics across a quantum phase transition into a 2D Ising antiferromagnet [Invited] WASEEM BAKR (Presenter), Princeton — Strongly interacting dynamics of quantum magnets is a frontier area of many body physics, and Prof Bakr's results are some of the most exciting in the area.

11:51AM M01.00002: Dynamics of a hole in a quantum antiferromagnet ANNABELLE BOHRDT (Presenter), Tech Univ Muenchen, FABIAN GRUSDT, Physics Department, Ludwig-Maximilians-Universität München, MICHAEL KNAP, Tech Univ Muenchen, JAYADEV VIJAYAN, PIMONPAN SOMPET, GUILLAUME SALOMON, JOANNIS KOEPSELL, SARAH HIRTHE, IMMANUEL FELIX BLOCH, CHRISTIAN GROSS, Max-Planck-Institut for Quantum Optics, Garching — Understanding the properties of a single mobile hole doped into an antiferromagnet allows one to reveal the interplay of spin and charge degrees of freedom. This constitutes a crucial step in the theoretical description of the Fermi-Hubbard model and by extension, strongly correlated cuprate compounds. We experimentally study the dynamical deconfinement of spin and charge excitations in real space in one dimensional Fermi-Hubbard chains of ultracold atoms. Using space- and time-resolved quantum gas microscopy, we track the evolution of the excitations through their signatures in spin and charge correlations. We numerically study the real-time dynamics of a single hole created in the ground state of the t−J model on a square lattice. Initially, the hole spreads ballistically with a velocity proportional to the hopping matrix element. At intermediate to long times, the hole propagates again ballistically but with a velocity proportional to the spin exchange coupling, showing the formation of a magnetic polaron. We provide an intuitive explanation of this dynamics in terms of a parton construction.
12:03PM M01.00003: Many-Body Dephasing after Quantum Quench with a Trapped Ion Quantum Simulator  
LINGZHEN GUO (Presenter), Max Planck Inst for Sci Light, HARVEY B KAPLAN, WEN LIN TAN, ARINJOY DE, GUIDO PAGANO, University of Maryland Department of Physics and NIST, FLORIAN MARQUARDT, Max Planck Inst for Sci Light, CHRISTOPHER ROY MONROE, University of Maryland Department of Physics and NIST — We investigate many-body dephasing in the 1D transverse-field Ising chain with long-range power-law interactions. We work in a regime where the properties of the system are closely related to the integrable Hamiltonian with global spin-spin coupling, which enables analytical predictions even for the long-time non-integrable dynamics. We study the dependence of temporal fluctuations of the average magnetization as a function of the system size. Using the eigenstate thermalization hypothesis (ETH), we are able to give an analytical expression for the temporal fluctuations. We also show the first experimental observation of persistent temporal fluctuations after a quantum quench. The measured fluctuations are exponentially suppressed with increasing system size, which is consistent with our theoretical predictions.

12:15PM M01.00004: Subdiffusion and Heat Transport in a Tilted 2D Fermi-Hubbard System*  
ELMER GUARDADO-SANCHEZ, ALAN MORNINGSTAR (Presenter), BENJAMIN M SPAR, PETER T BROWN, DAVID HUSE, WASEEM S BAKR, Princeton University — We study the late-time effective hydrodynamics of an isolated cold-atom Fermi-Hubbard system subject to an external linear potential (a “tilt”). We do this by observing the decay of prepared initial density waves as a function of wavelength \( \lambda \) and tilt strength and find that the associated decay time \( \tau \) crosses over as the tilt strength is increased from characteristically diffusive to subdiffusive with \( \tau \propto \lambda^4 \). In order to explain the underlying physics we develop a hydrodynamic model that exhibits this crossover. For strong tilts, the subdiffusive transport rate is set by a thermal diffusivity, which we are thus able to measure as a function of tilt in this regime. We further support our understanding by probing the local inverse temperature of the system at strong tilts, finding good agreement with our theoretical predictions.

**12:27PM M01.00005: Reservoir engineering and many-body decoherence in the quantum Ising model**

LINCOLN CARR (Presenter), DANIEL JASCHKE, Physics Dept., Colorado School of Mines, INES DE VEGA, Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-University Munich — We present quantitative predictions for quantum simulator experiments on Ising models from trapped ions to Rydberg chains and show how the thermalization, and thus decoherence times, can be controlled by considering common, independent, and end-cap couplings to the bath. We find (i) independent baths enable more rapid thermalization in comparison to a common one; (ii) the thermalization timescale depends strongly on the position in the Ising phase diagram; (iii) for a common bath larger system sizes show a significant slowdown in the thermalization process; and (iv) finite-size scaling indicates a subradiance effect slowing thermalization rates toward the infinite spin chain limit. We find it is necessary to treat the full multi-channel Lindblad master equation rather than the commonly used single-channel local Lindblad approximation to make accurate predictions on a classical computer. This method reduces the number of qubits one can practically classical simulate by at least a factor of 4, in turn showing a quantum advantage for such thermalization problems at a factor of 4 smaller qubit number for open quantum systems as opposed to closed ones. Thus, our results encourage open quantum system exploration in noisy intermediate-scale quantum technologies.

*Funded by NSF.

**12:39PM M01.00006: Spin squeezing dynamics and large-spin analogues in an optical lattice clock**

MICHAEL PERLIN (Presenter), ANA MARIA REY, JILA — Spin squeezing has been studied for decades as a means to overcome the so-called standard quantum limit for measurement precision. Despite numerous proof-of-principle experiments, however, spin squeezing has yet to push the state-of-the-art in any practical sensing application. We summarize a recent proposal to generate spin squeezing dynamics of two-level Sr-87 atoms in a 3D optical lattice clock, a world-class measurement system. Our proposal combines interactions and spin-orbit coupling to generate spin-squeezed states that are robust to typical sources of experimental noise. We then discuss generalizations of our protocol to the case of multilevel fermions with SU(n)-symmetric interactions, which have been experimentally realized with nuclear spin degrees of freedom. We show how the multilevel generalization of interactions, spin-orbit coupling, and external driving fields can be treated in a simple, unified form. Finally, we discuss prospects to explore the rich dynamics of interacting multilevel systems, such as multilevel spin squeezing and SYK-like models that may feature fast scrambling behavior.

12:51PM M01.00007: Dynamic instabilities and universal relaxation in quantum spin systems  JOAQUIN RODRIGUEZ NIEVA (Presenter), Stanford University, SARASWAT BHATTACHARYYA, Oxford, DRIES SELS, EUGENE DEMLER, Harvard University — The presence of symmetries and conservation laws can have striking manifestations in the dynamic behavior of interacting quantum systems. I will discuss manifestations of SU(2) symmetry on the universal dynamics of Heisenberg ferromagnets driven out of equilibrium. In particular, I will address the emergence of universal phenomena at two different timescales. Firstly, I will discuss the long-time thermalization behavior of a non-equilibrium incoherent population of magnons, and show that the distribution function can exhibit self-similar behavior in the prethermal regime[1]. Secondly, I will present a new mechanism for dynamic instabilities in a spin spiral state occurring at short timescales, and which originates from the symmetry-constrained quasiparticle interactions[2]. These two seemingly distinct phenomena provide new links between symmetries and universal phenomena occurring at different timescales.

1:03PM M01.00008: Non-local emergent hydrodynamics in a long-range quantum spin system* ALEXANDER SCHUCKERT (Presenter), IZABELLA LOVAS, MICHAEL KNAP, Technical University of Munich — Generic short-range interacting quantum systems with a conserved quantity exhibit universal diffusive transport at late times. We show [1] how this universality is extended by effective classical Lévy flights in the presence of long-range couplings that decay algebraically with distance as r^{-\alpha} for 0.5<\alpha\leq1.5. We investigate this phenomenon in a long-range interacting XY spin chain at infinite temperature by employing non-equilibrium quantum field theory and semi classical phase-space simulations. We find that the space-time dependent spin density profiles are self-similar, with scaling functions given by the stable symmetric distributions. Hence, autocorrelations show hydrodynamic tails decaying in time as t^{-1/(2\alpha-1)}. We also extract the associated generalized diffusion constant, and demonstrate that it follows the prediction of Lévy flights; quantum many-body effects manifest themselves in an overall time scale depending only weakly on \alpha. Our findings can be verified with current trapped ion experiments.

Nonequilibrium dynamics and transport in the frustrated two bath spin boson model

RON BELYANSKY (Presenter), SETH P WHITSITT, REX LUNDGREN, YIDAN WANG, ALEXEY V GORSHKOV, University of Maryland, College Park — The spin-boson model, describing a single two-level system coupled to an Ohmic bath of harmonic oscillators, is a paradigmatic model of open quantum systems. It has been used to understand the connection between quantum dissipation and classical friction and has been applied to a wide range of phenomena ranging from quantum impurity problems to quantum information, biological systems, and state of the art superconducting circuits experiments. In this work, we use numerical and analytical methods to study the dynamics of a generalized spin boson model where the spin is coupled to two independent Ohmic baths via non-commuting operators. It has already been shown that the two competing baths lead to peculiar effects, namely the absence of the phase transition and the coherent to incoherent crossover in the spin dynamics, both of which are well-known features of the single bath system. Here, we explicitly show how the frustration leads to reduced decoherence in the spin dynamics following a quantum quench. We also study the single-particle transport properties of a quasi 1D realization of the model and show asymmetrical features in the intra- and inter-bath elastic and inelastic scattering.

Unravelling open quantum systems on a NISQ Computer

FRANCESCO PETRUCCIONE (Presenter), ILYA SINAYSKIY, Univ of KwaZulu-Natal, KYUNGDEOCK PARK, JUNEOO KEVIN) RHEE, Korea Advanced Institute of Science and Technology — It is well-know that the simulation of the stochastic Schrödinger equations unravelling the typical master equations describing the dynamics of open quantum systems is a very useful computational tool. Here, we show how such unravellings can be simulated on a NISQ computer. The quantum algorithm maintains the cost of initial state preparation constant via quantum forking. Quantum forking creates an entangled state in which a single copy of a quantum state is encoded and evolves under independent quantum processes in each subspace, thereby allowing parallel unravelling from one wave function. A protocol for implementing a generic non-Hermitian evolution using quantum circuit elements is described. The algorithm is applied to the simulation of Markovian master equations describing quantum neural networks.

Linear response theory for the OTOC and entropy growth in dissipative systems

XIN CHEN (Presenter), Tsinghua University — We formulate the linear response theory to calculate the out-of-time ordered correlator (OTOC) and the entropy growth for dissipative systems, i.e. systems suddenly coupled to a thermal bath, which helps to understand the behavior of the information scrambling in the early stage. In addition, we also discuss the linear response of the OTOC to a perturbation for systems that are constantly coupled to a thermal bath and reaches the non-equilibrium static state. Particularly, we illustrated those calculations in the Dicke model.
1:51PM M01.00012: Prethermal non-equilibrium phases in classical systems  BINGTIAN YE (Presenter), FRANCISCO MACHADO, NORMAN YAO, University of California, Berkeley — High-frequency driven quantum systems exhibit long-lived prethermal regimes, where the dynamics are described by effective static Hamiltonians. The existence of such prethermal regime allows exotic non-equilibrium phases to emerge. However, generalizing these phenomena to classical many-body systems remains challenging. In our work, we elucidate the nature of the prethermal regime in classical spin systems. We first demonstrate that the chaotic nature of the classical evolution places an obstacle to define an effective prethermal Hamiltonian: for an initial state, any small error in the dynamics becomes exponentially magnified over time. While such obstacle is inevitable for a single classical trajectory, an effective description can still arise when considering the evolution of an ensemble of states. This then allows us to extend the properties of quantum prethermal dynamics to classical systems. In particular, we prove the existence of an emergent symmetry in the prethermal regime, and utilize this symmetry to generate novel non-equilibrium phases such as classical prethermal discrete time crystals (CPDTC). Finally, we will present an analytical framework as well as numerical demonstration of CPDTC.

2:03PM M01.00013: Engineering generalized Gibbs ensembles with trapped ions  FLORENTIN REITER (Presenter), Institute for Quantum Electronics, ETH Zurich, FLORIAN LANGE, Institute for Theoretical Physics, University of Cologne, SHREYANS JAIN, MATT GRAU, JONATHAN P HOME, Institute for Quantum Electronics, ETH Zurich, ZALA LENARCIC, Department of Physics, University of California, Berkeley — Generalized Gibbs ensembles (GGEs) have been introduced to describe stationary expectation values of local observables in integrable models with macroscopically many conservation laws. Recent advances showed that GGEs also describe more realistic nearly integrable systems which are weakly driven and open. In this case, integrability breaking perturbations determine the parameters of GGE. By tuning the coupling to the environment, it is thus possible to stabilize a broad range of tailored GGEs. Here we pave the way for the first experimental observation of GGEs in a nearly integrable driven-dissipative setup with trapped ions. We present an implementation scheme for a particular choice of Lindblad operators and suggest experimental observables which detect that a GGE approximately describes the stabilized steady-state. To engineer single-, as well as two-body dissipation, we use a combination of couplings which can be engineered in an array of microtraps. We assess the performance of our implementation scheme and discuss the resources required to observe a deviation from a thermal ensemble in an experiment.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M02 DAMOP: Optomechanics  105 - Srivatsan Chakram, University of Chicago
11:15AM M02.00001: Efficient bidirectional piezo-optomechanical transduction between microwave and optical frequency*  Wentao Jiang (Presenter), Christopher J Sarabalis, Yanni D Dahmani, Rishi Patel, Felix M Mayor, Timothy Mckenna, Raphael Van Laer, Amir Safavi-Naeini, Stanford Univ — Efficient interconversion of both classical and quantum information between microwave and optical frequency is an important engineering challenge. The optomechanical approach with gigahertz-frequency mechanical devices can be extremely efficient due to the large optomechanical response of common materials and wavelength-scale localization of mechanical energy. However, existing demonstrations suffer from combination of low optical quality factor, low electrical-to-mechanical transduction efficiency, and low optomechanical interaction rate. Here we demonstrate an on-chip piezo-optomechanical transducer that systematically addresses all these challenges to achieve nearly three orders of magnitude improvement in conversion efficiency. Our modulator demonstrates acousto-optic modulation with $V_\pi = 0.02$ V. We show bidirectional conversion efficiency of $10^{-5}$ with 3.3 μW red-detuned optical pump, and 5.5% with 323 μW blue-detuned pump. Further study at mK temperatures is required to understand how the efficiency and added noise are affected by reduced mechanical dissipation, thermal conductivity and capacity.

11:27AM M02.00002: Piezoelectric optomechanics in a 3D microwave cavity: A route to microwave to optical transduction*  Hugh Ramp (Presenter), Physics, University of Alberta, Krishna Balram, Kartik A Srinivasan, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, John Davis, Physics, University of Alberta — Numerous examples of microwave to optical transduction have been demonstrated for optomechanical systems. In most cases, the piezoelectric effect allows for microwave-mechanical coupling either through direct capacitive stimulation or by creating surface acoustic waves using interdigitated capacitors. Here, we inject a microwave signal into a 3D microwave cavity where a GaAs optomechanical crystal has been placed at the electric field maxima. This allows the microwave cavity to stimulate the GHz-frequency mechanical breathing mode in the optomechanical crystal through the piezoelectric effect, which is then read out using the telecom optical mode. The GaAs optomechanical crystal is a good candidate for low-noise microwave to optical transduction, as it has been previously cooled to the mechanical ground state $n = 0.7 \pm 0.4$ phonons in a dilution refrigerator [1]. Moreover, the 3D microwave cavity architecture used in this experiment can be naturally extended to couple to superconducting qubits.

Fractal-like mechanical resonators with soft-clamped fundamental mode* SERGEY FEDOROV (Presenter), ALBERTO BECCARI, NILS JOHAN ENGELSEN, MOHAMMADJAFAR BEREYHI, ROBIN GROTH, TOBIAS J. KIPPENBERG, Ecole Polytechnique Federale de Lausanne — Self-similar structures occur naturally and have been employed to engineer exotic physical properties. We show that acoustic modes of a fractal-like system of tensioned strings can display increased mechanical quality factors due to the enhancement of dissipation dilution. We describe a realistic resonator design in which the quality factor of the fundamental mode is enhanced by as much as two orders of magnitude compared to a simple string with the same size and tension. Our findings can open new avenues in force sensing, cavity quantum optomechanics and experiments with suspended test masses.

Manipulation of geometric nonlinearity to probe nonlinear damping in 2D NEMS PARMESHWAR PRASAD (Presenter), AKSHAY NAIK, Indian Institute of Science — Nonlinearity is inherent in nano mechanical (NEMS) devices. NEMS with high geometric aspect ratio are prone to these nonlinearities. Understanding the role of nonlinearities in the NEMS devices is essential to harvest the maximum benefit from them. In the current work, we probe the nonlinear damping by manipulating the effective Duffing (cubic) nonlinearity using electrical means. We take advantage of tuning of the nonlinearities with strain to minimize the effect of duffing non-linearity thus enabling the study of the effect of nonlinear damping. We use this technique to study the effect of non-linear damping in parametric oscillation regime in 2D material based NEMS resonators.
12:03PM M02.00005: Piezo-optomechanics in lithium niobate on silicon-on-insulator for microwave-to-optics conversion

RAPHAEL VAN LAER (Presenter), WENTAO JIANG, CHRISTOPHER J SARABALIS, RISHI PATEL, FELIX M MAYOR, TIMOTHY MCKENNA, AGNETTA CLELAND, EDWARD A WOLLACK, PATRICIO ARRANGOIZ-ARRIOLA, JEREMY WITMER, AMIR SAFAVI-NAEINI, Stanford Univ — Cryogenic microwave qubits are globally pursued to build a compelling quantum technology. Major efforts are underway to scale up these processors, inching closer to useful tasks beyond the reach of classical technology. However, it is currently infeasible to connect the qubits well beyond a single refrigerator, limiting their use outside the laboratory. Microwave-to-optics converters are uniquely placed to tackle this challenge. One of the leading approaches exploits electro-opto-mechanics, but even cutting-edge systems suffer from excessive dissipated energy per qubit that is converted between microwaves and optics. This dissipated energy sets an upper bound on the quantum communication rate in a severely power-constrained cryo-environment. Here, we take first steps to greatly reduce this dissipated energy by combining a strongly piezoelectric material - lithium niobate (LN) - with a leading optomechanics and photonics platform - silicon-on-insulator (SOI). This hybrid LN-on-SOI platform leverages the best properties of both materials. We observe efficient piezo- and opto-mechanical interactions involving tightly confined GHz mechanics, establishing an intriguing path towards low-energy conversion between microwaves and optics.

*Marie-Curie-665501, NSF ECCS-1808100, ARO/LPS CQTS
12:15PM M02.00006: Gallium Phosphide as a Piezoelectric Platform for Quantum Optomechanics*  
ROBERT STOCKILL (Presenter), MORITZ FORSCH, Kavli Institute of Nanoscience, Department of Quantum Nanoscience, Delft University of Technology, 2628 CJ Delft, Netherlands, GREGOIRE BEAUDOIN, Konstantinos Pantzas, Isabelle Sagnes, Rémy Braive, Centre de Nanosciences et de Nanotechnologies, CNRS, Université Paris-Sud, Université Paris-Saclay, C2N, 91767 Palaiseau, France, Simon Groeblacher, Kavli Institute of Nanoscience, Department of Quantum Nanoscience, Delft University of Technology, 2628 CJ Delft, Netherlands — Piezoelectric materials expand the capabilities of optomechanical devices to include native electromechanical interaction, enabling conversion between microwave-frequency modes and low-loss optical telecom bands. Specifically, the combination of high-cooperativity interfaces and ground-state occupation of the mechanical mode allows for transduction of a quantum state. While cryogenically cooled piezoelectric optomechanical devices have demonstrated sub-phonon occupation [1], absorption induced heating has prevented the observation of non-classical behaviour. Here, we fabricate and operate an on-chip optomechanical device made from gallium phosphide [2], realising high-cooperativity interaction with a long-lived 3-GHz mechanical mode which remains in the ground state. We observe non-classical correlations between state-projecting photons and the confined mechanical mode, establishing GaP as a piezoelectric platform for noise-free quantum-state conversion between microwave and optical carriers. [1] Ramp et al. PRL 123 93603 (2019) Forsch et al. Nat. Phys. (2019) [2] Stockill et al. PRL 123 163602 (2019)

12:27PM M02.00007: Optomechanical Quantum State Tomography*  
RISHI PATEL (Presenter), Timothy McKenna, ZhaoYou Wang, Jeremy Witmer, Wentao Jiang, Edward A Wollack, Christopher J Sarabalis, Pieter-Jan C. Stas, Raphael Van Laer, Amir Safavi-Naeini, Stanford Univ — We generate and characterize heralded quantum states of a mechanical resonator with a single added phonon. Our system consists of an optomechanical crystal cavity operated at about 10 millikelvin. We perform continuous wave sideband asymmetry measurements using single photon counters to calibrate the temperature of a 4 GHz mechanical mode. Photon and phonon pairs are generated using a continuous wave laser blue detuned from the optical cavity resonance. A detected photon at the cavity resonance frequency heralds the addition of a phonon to the mechanical mode; we characterize the generated states by continuously measuring the output cavity field, and performing tomography to determine the Husimi Q function describing the state of the mechanical oscillator.

*R.P. acknowledges support from the NSF Graduate Research Fellowship Program (grant number: DGE-1656518).
PIETIKÄINEN (Presenter), ONDREJ CERNOTIK, RADIM FILIP, Palacky Univ — In optomechanics we are often dealing with squeezing and backaction-evasion schemes that use two-tone driving. In general the time development of this kind of time-dependent Hamiltonian has to be solved from the master equation. Optomechanical system typically have large thermal noise which makes solving the master equation difficult, especially for steady state.

We introduce a method to solve the dynamics of a time-periodic system, by using the Floquet approach to write the dynamics in the form of a Lyapunov equation. With the Floquet method, we can transform a periodic linear differential equation into a time-independent linear system. After which, for the time-independent Hamiltonian that is quadratic in the canonical operators, the time development can be expressed in the form of a Lyapunov equation, which can be solved efficiently.

We demonstrate this method in an optomechanical system with dissipative generation of squeezing. We show that we can include the counter-rotating terms ignored in the rotating-wave approximation. The method is also useful with levitating particles in an amplitude modulated trapping field.

SERGEY FEDOROV, ALBERTO BECCARI, MOHAMMADJAFAR BEREYHI, NILS JOHAN ENGELSEN (Presenter), TOBIAS J. KIPPENBERG, Ecole Polytechnique Federale de Lausanne — We experimentally investigate the thermal noise properties of a room-temperature, membrane-in-the-middle optomechanical cavity in the regime of nominal quantum cooperativity approaching one. We show that with resonant laser drive, the intra-cavity amplitude noise is dominated by thermal noise up-converted by nonlinear cavity transduction of the laser-cavity detuning. This noise conversion process sets a limitation on the observability of quantum features of the optomechanical interaction, which is not specific to membrane in the middle setups.

*This work was supported by the Swiss National Science Foundation under grant no. 182103 and the Defense Advanced Research Projects Agency (DARPA), Defense Sciences Office (DSO), under contract no. D19AP00016 (QUORT). A.B. acknowledges support from the European Union’s Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant agreement no. 722923 (OMT). 1:03PM M02.00010: Phonon-Counting Experiments with Superfluid Helium Optomechanics
YOGESH PATIL (Presenter), JIAxin YU, SEAN FRAZIER, KALE G JOHNSON, Yale University, SÉBASTIEN GARCIA, KONSTANTIN OTT, JAKOB REICHEL, Laboratoire Kastler Brossel, ENS-Universite PSL, CNRS, Sorbonne Universite, JACK G E HARRIS, Yale University — Superfluid Helium is a very good platform for quantum optomechanics owing to its extremely low optical and mechanical losses. In a device consisting of a Fabry-Perot cavity filled with superfluid helium, each acoustic mode of the helium is optomechanically coupled to a single optical mode of the cavity [1]. In previous work we used such a device to measure an acoustic mode's Gaussian quantum fluctuations [2]. Here we describe new measurements in which we have incorporated single-photon detectors (and multiple cascaded optical filters) to record individual sideband photons, each of which is associated with the creation (or annihilation) of a single phonon in the acoustic mode. We will describe the prospects for using this approach to prepare and characterize non-Gaussian states of the acoustic mode.

1:15PM M02.00011: Pulsed quantum processing of two mechanical elements  SHLOMI KOTLER (Presenter), GABRIEL PETERSON, FLORENT LECOCQ, KATARINA CICAK, RAYMOND W SIMMONDS, JOSE AUMENTADO, JOHN TEUFEL, Physics Measurement Lab, National Institute of Standards and Technology — High quality mechanical elements have been shown to be a viable candidate for storage of quantum information. To become useful as processing elements, one has to be able to initialize the mechanics to a pure state, generate interactions with other mechanical elements and measure the resulting state with high efficiency. While each of these capabilities has been demonstrated separately, integrating it to a single device requires reconciling the different resulting constraints. Here we design, fabricate and measure a microwave resonator coupled to two separate mechanical resonators (drums). We use spatial addressing as well as frequency and time domain multiplexing to individually address the drums using microwave pulses. This allows us to perform ground state cooling, simultaneous readout and a two-mode coupling gate between the mechanics. Our work is a stepping stone on the path to information processing with multi-mechanical arrays.
1:27PM M02.00012: Lifetime and Coherence Measurements of an Optomechanical Quantum Memory* ANDREAS WALLUCKS (Presenter), IGOR MARINKOVIC, BAS HENSEN, ROBERT STOCKILL, SIMON GROEBLACHER, Delft University of Technology — Recent experiments have achieved quantum control of so-called nanobeam optomechanical crystals, which possess engineered mechanical resonances in the Gigahertz regime that can be addressed optically from the conventional telecom band. Here we discuss the prospects of such nanobeams with ultra-long lived mechanical modes to act as optical quantum memories. We demonstrate the heralded preparation of a single phonon Fock state which can be stored up to 2 ms while preserving the non-classicality. We further study the coherence of the memory using a superposition state of vacuum with a Fock state and find a quantum coherence time of 15 microseconds. Measurements of the mechanical frequency noise in the classical regime show a clear power dependence, allowing us to reach coherence times exceeding 100 microseconds. The protocol used in these experiments is directly applicable to existing quantum repeater architectures.

*This work is supported by the Foundation for Fundamental Research on Matter (FOM), the European Research Council, and by the Netherlands Organization for Scientific Research (NWO/OCW), as part of the Frontiers of Nanoscience program.

1:39PM M02.00013: Towards cavity quantum circuit electromechanics with millimiter-sized silicon nitride membranes* SARWAN PEITER (Presenter), ADRAIN SANZ MORA, GARY STEELE, Delft University of Technology — Many everyday use appliances consist of hybrid setups, i.e., devices that rely on a close-knit interfacing between different physical elements, each of which can carry out a given task in a complementary way. Interfaces with mechanical membranes and superconducting circuits play an active role in today's research towards a new generation of hybrid devices, the dynamics of which may be prominently ruled by quantum mechanics. Crucial to succesfully harness the quantized dynamics of such devices is their isolation from environmental noise sources. For the millimiter sized membranes we use in our circuits this even requires isolation from the acoustic noise present in the dilution refrigerators wherein they are usually hosted. Based on a systematic characterization of the noisy acoustic signals disturbing our electromechanical circuit we design different methods to suppress them, including an original mass-spring system that enables keeping our device freely suspended inside the fridge. Using these adjustments, and a phononic bandgap shield to minimize acoustic radiation loses of the membrane itself, we prove feasible ground state cooling of the membrane's fundamental mode of vibration.

*Funded by ERC
1:51PM M02.00014: Low-temperature diamond optomechanics*  
JEFF CADY (Presenter), University of California, Santa Barbara, RISHI PATEL, AMIR SAFAVI-NAEINI, Stanford University, ANIA JAYICH, University of California, Santa Barbara — Diamond mechanical devices have the potential to serve as a hybrid platform for facilitating quantum interactions between photons, phonons, and the spin and orbital degrees of freedom of embedded defect qubits, such as nitrogen-vacancy (NV) centers, which can couple to mechanical motion via crystal strain. Recent experiments [1,2] have demonstrated hybrid mechanical systems in diamond consisting of nanofabricated mechanical resonators that host coherent NV centers. However, an outstanding challenge to reaching the high-cooperativity regime in these systems, where such applications as phonon-mediated spin-spin interactions and NV-assisted mechanical cooling become realizable, is the demonstration of long-lived, high-strain mechanical modes near their ground state of motion. As a step toward this goal, we design and fabricate single-crystal diamond optomechanical crystals which host GHz-scale mechanical modes with large zero-point strain and characterize them at 6K in a closed-cycle cryostat. We observe optomechanically-driven phonon lasing, optomechanically-induced transparency, and laser cooling of the mechanical motion in these devices.

2:03PM M02.00015: Magnomechanical cross-correlation thermometry*  
CLINTON POTTS (Presenter), Univ of Alberta, VICTOR BITTENCOURT, SILVIA G VIOLA KUSMINSKY, Max Planck Institute for the Science of Light, JOHN DAVIS, Univ of Alberta — The development of hybrid quantum technologies has driven a need for low-temperature environments such as dilution refrigerators. In these cryogenic environments, accurate thermometry can be difficult to implement, expensive, and often requires calibration to an external reference. We propose a thermometric measurement of a hybrid system consisting of phonons coupled via the magnetostrictive interaction to magnons within a ferromagnetic sphere. Our approach is based on a cross-correlation measurement which is calibration-free and low temperature compatible. We demonstrate the ability to distinguish thermomechanical motion from the magnon induced back-action. Furthermore, the spectrum of back-action driven motion can be used to scale the thermomechanical motion, providing a direct measurement of the phonon temperature, independent of experimental parameters.

Session M03 GSCCM: Materials in Extremes: Equation of State and Phase Diagrams 107 - Patricia Kalita, Sandia National Laboratories - Tag(s): Focus
11:15AM M03.00001: Multiphase EOS Table for Gallium*  CARRIE PRISBREY (Presenter), CHRISTINE J WU, Lawrence Livermore Natl Lab — We developed the first LLNL multiphase equation of state (EOS) for Gallium (Ga) covering a wide range of density (10^-7-10^3 g/cc) and temperature (1-10^9K). The EOS includes three known solid phases (I, II and III) and one Ga liquid. The EOS table accurately reproduces available experimental Hugoniot, isotherms and isobar data, as well as observed phase boundaries. We demonstrate that there is a significant uncertainty in predicted phase boundaries beyond the range of existing experimental observations, since they are highly sensitive to small changes in the free energy differences between the neighboring phases. EOS model uncertainty and variations will also be explored in this study.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:27AM M03.00002: MgO at Multi-Megabar Pressures: Benchmarking the Equation of State and B1–B2 Transition Using Auxiliary-Field Quantum Monte Carlo*  SHUAI ZHANG (Presenter), Laboratory for Laser Energetics, University of Rochester, FIONN MALONE, MIGUEL A MORALES, Lawrence Livermore National Laboratory — Studying materials at up to multi-megabar pressures is important for understanding the interiors of exoplanets and testing equation-of-state (EOS) models. However, it remains challenging to both experiments (e.g., B1–B2 transition pressure, \( P_{tr} \), for MgO is uncertain by 130 GPa) and theory [two-parameter (zero-pressure bulk modulus \( K_0 \) and its pressure derivative \( K'_0 \)) EOS is subject to >10% uncertainties for compression ratio >1.5, and prevalent density-functional-theory (DFT) computations can be biased by the exchange-correlation functional]. Advances in quantum Monte Carlo (QMC) have shown remarkable successes for solids. In this work, we develop and apply auxiliary-field (AF) QMC to benchmark the EOS and \( P_{tr} \) of MgO. In contrast to DFT predictions that vary by ~3% in equilibrium volume (\( V_0 \)), ~6% in \( K_0 \) of B1 MgO, and ~30 GPa in \( P_{tr} \), AFQMC can anchor all the three quantities with significantly reduced uncertainties, thereby providing an accurate and practical approach to benchmark materials properties at such extreme conditions.

*This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003856 and by DOE Computational Materials Sciences Program and Center for Predictive Simulation of Functional Materials.
11:39AM M03.00003: The body-centered cubic Fe phase under extreme conditions: Observed yet unnoticed.* ANATOLY BELONOSHKO (Presenter), Department of Physics, KTH Royal Institute of Technology — The recently disclosed mechanism of the body-centered cubic Fe stabilization under extreme pressures and temperatures allows for a new interpretation of a number experimental observations. The high-PT bcc Fe is stabilized by a liquid-like self-diffusion. This means that Fe at high pressure and temperatures is in many respects similar to liquid. Such similarity is confusing to some experimentalists and makes them to interpret solid-solid hcp-bcc transition as melting. I will demonstrate that a number of experimental data sets get a better explanation in terms of the hcp-bcc transition rather than in terms of hcp-liquid transition. The new interpretation removes a number of controversies concerning the extreme part of Fe phase diagram. I will show that in a number of experiments the bcc Fe was observed yet remained unnoticed because of the unexpected properties of the emerging high-PT Fe bcc phase.

11:51AM M03.00004: Experimental observations on microstructure of iron and other metals at high pressures and temperatures* [Invited] ROSTISLAV HRUBIAK (Presenter), Argonne Natl Lab — Materials subjected to high pressure (P) and high/low temperature (T) treatments in the diamond anvil cell (DAC) often exhibit complexity and inhomogeneity, on length scales ranging from nanometers to tens of microns. A recently developed ability to perform detailed spatially resolved characterizations of the inhomogeneity under high P, or in the high P-T treated samples, has allowed to unlock some of the complexity and to gain an understanding of several of emerging physical phenomena in high pressure sciences.

One of the examples discussed here will be the crystal structure of iron (Fe) in the Earth’s inner core, which remains debated. Experimental evidence, based in part on spatially resolved microstructure analysis, shows a bcc-Fe appearing at P-T conditions approaching the Earth’s inner core. Recent results on the microstructure and phases of compressed zirconium metal will be discussed as well.

*This work was performed at HPCAT (Sector 16), Advanced Photon Source (APS), Argonne National Laboratory. HPCAT operations are supported by DOE-NNSA’s Office of Experimental Sciences. The APS is a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357
12:27PM M03.00005: Assessing the accuracy of first-principles DFT in describing van-der-Waals interactions in energetic molecular crystals at ambient and high pressure conditions  IVAN OLEYNIK (Presenter), KIEN NGUYEN-CONG, University of South Florida — Various density functional theory (DFT) functionals are evaluated in their ability to accurately describe vdW interactions in energetic molecular crystals, which are of critical importance to obtain an accurate isothermal equation of state as well as other basic thermodynamic properties of energetic materials. Equilibrium volumes of seven EM crystals are evaluated using several DFT functionals with or with- out semi-empirical Van der Waals corrections, as well as non-local van der Waals density functionals, and compared with available experimental data. By calculating vibrational spectra of energetic molecular crystals, zero point energy (ZPE) and thermal contributions at finite temperature to cold DFT data, pressure-dependent lattice parameters and equation of state are obtained at experimental temperatures, thus allowing direct quantitative comparison with experiment. Newly developed meta-GGA SCAN functional provides the best description of vdW interactions, and delivers an accurate EOS of EMs in a wide range of pressures and temperatures.

12:39PM M03.00006: Examination of the validity of quantum statistical potentials for carbon  HEATHER WHITLEY (Presenter), Lawrence Livermore Natl Lab, MICHAEL SEAN MURILLO, Michigan State University, LORIN BENEDICT, JOHN I CASTOR, FRANK R GRAZIANI, Lawrence Livermore Natl Lab — In recent years, high power laser facilities, such as NIF, and advanced diagnostics have enabled the determination of detailed properties of dense plasmas over unprecedented regimes. Understanding such plasmas, which may be partially degenerate and/or moderately coupled, represents a major challenge to the plasma physics community. One particular challenge for research in this area is the development of interaction potentials which appropriately incorporate the effects of high electron temperature. We examine the accuracy and applicability of approximate effective potentials in the study of structural and dynamic properties carbon in the partially and fully ionized regimes. The diffractive Coulomb potential is derived from an exact quantum solution for a pair of particles while the fermionic character of the electrons is handled via an effective Pauli potential. We compare computed pressures and internal energies for carbon to an equation of state model that was developed based on path integral Monte Carlo and density functional theory. Prepared by LLNL under Contract DE-AC52-07NA27344. LLNL-ABS-795399
12:51PM M03.00007: Wide-ranged equation of state models for elements from the atom-in-jellium approach*  LORIN BENEDICT (Presenter), DAMIAN SWIFT, THOMAS LOCKARD, PHILIP A STERNE, Lawrence Livermore Natl Lab, MANDY BETHKENHAGEN, University of Rostock, SEBASTIEN HAMEL, ALFREDO A. CORREA, RAYMOND SMITH, CHRISTINE J WU, Lawrence Livermore Natl Lab — We discuss the construction of wide-ranged equation of state models for elements using a DFT-based average-atom model. In our approach, high pressure cold, ion-thermal, and electron-thermal contributions of the free energy are all created from the atom-in-jellium paradigm. In particular, the ionic excitation piece is constructed by computing the restoring force to small displacements of the nucleus within a neutral spherical jellium cell, and the Lindemann criterion is adopted to predict the density-dependent melt curve. We show that with a minimum of fitting to low pressure experimental data (e.g., ambient density, melt temperature at ambient pressure), remarkably accurate wide-ranged equations of state can be generated using this method, as demonstrated by comparing to high pressure experimental data and more sophisticated ab initio predictions.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE- AC52-07NA27344

1:03PM M03.00008: A new multiphase wide range Equation of State for Nickel*  TRAVIS SJOSTROM (Presenter), GIULIA DELORENZI-VENNERI, SVEN PETER RUDIN, Los Alamos Natl Lab — A new equation of state for Nickel has been built and entered in the SESAME database. The EOS was built by Opensesame, based on the multiphase approach. Magnetic effects, derived from the experimental heat capacity, were included by an extra term in the electronic free energy. The solid phase was fitted to available experimental data for thermal expansion, heat capacity and bulk modulus and to data from new DFT calculations of the cold curve and phonon dispersions. The low temperature liquid was calculated, based on the V-T theory approach, from DFT data for the cold curve in the liquid. The high temperature liquid was fitted to new QMD calculations.

*ASC-PEM Program at LANL
1:15PM M03.00009: Update on multi-megabar shockless compression at Sandia’s Z machine (2020)*

JEAN-PAUL DAVIS (Presenter), JUSTIN BROWN, Sandia National Laboratories — Quasi-isentropic, shockless ramp-wave experiments promise accurate equation-of-state (EOS) data of materials in the solid phase at relatively low temperatures and multi-megabar (100’s GPa) pressures. In this range of pressure, isothermal diamond-anvil techniques have limited pressure accuracy due to reliance on theoretical EOS of calibration standards, thus accurate quasi-isentropic compression data would help immensely in constraining EOS models. Multi-megabar shockless compression experiments using the Z Machine at Sandia as a magnetic drive with stripline targets have been performed on many solid materials over the past decade. An update is given on recent results and developments, including experimental techniques, analysis methods, and uncertainty quantification.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia LLC, a wholly owned subsidiary of Honeywell International Inc. for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

1:27PM M03.00010: High-temperature, high-pressure behavior of lithium fluoride*

KANANI LEE (Presenter), Lawrence Livermore Natl Lab, SARAH M. ARVESON, Geology & Geophysics, Yale University, MINTA C AKIN, NEIL C HOLMES, BRUCE J BAER, HYUNCHAE CYNN, Lawrence Livermore Natl Lab — Lithium fluoride (LiF) is used extensively as optical windows in dynamic compression experiments and is also used as pressure media and thermal insulation in diamond-anvil cell (DAC) experiments. In order to better understand this important high-pressure standard and ubiquitous window material, we present high-temperature isothermal equations of state of LiF below its melting curve as measured in a laser-heated DAC. These measurements complement already measured low-T isotherms [Myint et al., JCP, 2019] performed with resistively-heated DACs and will be used to generate phase-aware, thermally accurate equations of state for LiF. Above its previously determined melting curve [Boehler et al., PRL, 1997], LiF exhibits strong changes in absorption, similar to other alkali halides [Arveson et al., PRB, 2018]. We explore these changes in optical properties and the significant consequences they have for temperature measurements measured spectroscopically.

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. LLNL-ABS-795563.

Wednesday, March 4, 2020 11:15 AM - 1:39 PM

Session M06 DLS: Optical Tools, Techniques, Methods, and Theory 113
11:15AM M06.00001: Ultrafast THz Probe of Phonon-Assisted Processes in Photoexcited bulk GaAs  EUGENIO CINQUANTA (Presenter), LORENZO GATTO, CNR - IFN, GABRIELE CRIPPA, Dipartimento di Fisica, Politecnico di Milano, CATERINA VOZZI, CNR - IFN, SALVATORE STAGIRA, Dipartimento di Fisica, Politecnico di Milano — Hot carrier dynamics in semiconductors governs the performances of optoelectronic devices. The out-of-equilibrium distribution of photoinjected carriers relaxes through scattering with the lattice phonons. The main relaxation path can be depicted with an initial hot LO phonon distribution that relaxes through the emission of acoustic phonon. These hot phonon population may lead to the enhancement of two-phonon absorption processes involving optical-acoustic and acoustic-acoustic transitions detectable by time-resolved FIR spectroscopy. By means of Optical Pump - THz probe experiments, we investigated the out-of-equilibrium properties of intrinsic bulk GaAs. By tuning the pump-photon energy it is possible to excite the carriers directly in the Γ and in the higher energy L and X valleys. Independently from the excitation wavelength, we observed a rich transient THz response where a broad Drude-Lorentz complex conductivity is dressed with several sharp Lorentzian features in the 0.5-2.5 THz spectral range. This response is highly fluence-dependent, suggesting a carrier density dependence of the observed behavior. Our outcomes may be related to the enhancement of two-photon absorption processes involving the optical and acoustical out-of-equilibrium phonon distribution.

11:27AM M06.00002: Observations of Group Velocity Dispersion, Raman Scattering, Stimulated Raman, and Spectral Broadening for O-waves and E-waves from a Calcite Crystal Using Femtosecond Laser Pulses  SHAH FAISAL MAZHAR (Presenter), Physics, City College of New York, HENRY MEYER, Electrical Engineering, City College of New York, ROBERT ALFANO, Physics & EE, City College of New York — Group velocity dispersion (GVD), Raman Spectra, Stimulated Raman Scattering (SRS), and Supercontinuum (SC) are investigated for ordinary (O) waves and extraordinary (E) waves from a 2.7 cm thick Calcite crystal. Using 390 fs pulses (~2 μJ pulse energy) at 517 nm, the O-wave produced a stronger sharp SRS peak at 1086 cm⁻¹ and weak SC spectrum in the visible range than E-wave. To explain the salient observation, the difference between Raman cross-section, index of refraction (walk-off), GVD, and the size of nonlinear susceptibility, χ3 for O-waves and E-waves of Calcite are presented.

Multiphoton photoemission spectroscopy of TiO$_2$ and Au/TiO$_2$ surfaces

NAMITHA JAMES (Presenter), HRVOJE PETEK, Department of Physics and Astronomy, Univ of Pittsburgh — TiO$_2$ is a widely investigated metal oxide due to its photocatalytic and photovoltaic applications. Until recently, the ability to probe the ultrafast electron dynamics of this system has been limited to transient absorption experiments. Understanding the photoexcited electron dynamics in TiO$_2$ is vital to extend its applications through a thorough understanding of its electronic structure. TiO$_2$ is known to catalyze reactions upon UV excitation. Photocatalysis in TiO$_2$ can be extended into visible by coupling it with plasmonic metal nanoparticles, which can be very efficient light absorbers in the visible through excitation of their localized plasmon resonance. Au nanoclusters coupled to TiO$_2$(110) have been shown to enhance photocatalytic properties upon visible excitation. By probing the rutile TiO$_2$(110) and Au/TiO$_2$ interface using multiphoton photoemission (mPP) with a tunable ultrashort (~20 fs) laser pulse, we investigate the dynamics of electrons excited in its conduction band. mPP spectra reveal resonances where TiO$_2$ defect state electrons absorb energy to reveal new optical energy levels and transitions between them. Decoration of the surfaces with Au overlayer introduces new resonances, but does not show a plasmonic enhancement of the optical response of Au/TiO$_2$ surfaces.

Exact Theory for Two-Color Laser-Induced Photoemission from a Biased Metal Surface*

12:03PM MO6.00005: Generation and applications of intense terahertz fields produced by multi-color laser pulses interacting with gas plasmas  LUC BERGE (Presenter), CEA, DAM, DIF - 91297 Arpajon - France — Terahertz (THz) pulses are very popular because of their numerous applications, for example in security. Located between microwaves and optical waves in the electromagnetic (EM) spectrum, their spectral domain can be exploited for molecular spectroscopy using the THz waves emitted from plasmas created by two-color femtosecond laser pulses ionizing air. Down-conversion of broadband optical spectra in the plasma produces intense EM radiation suitable for the identification of suspect materials, even remotely. The physical mechanisms involved to create terahertz radiation by laser-matter interaction, such as photocurrents, are here reviewed. The new potentialities offered by ultrafast intense lasers allow the acquisition of many spectral signatures within 20-50 THz broad bandwidths associated to high-field single-cycle THz pulses. We report new features obtained in the framework of the French project ALTESSE, the main objective of which consisted in testing the efficiency of a laser-based terahertz time-domain spectroscopy of various materials, using the air-biased coherent detection (ABCD) method. The last part of this presentation will discuss new perspectives in the production of ultra-intense terahertz pulses from laser-wakefield accelerators in relativistic plasmas.

12:15PM MO6.00006: Periodic Lensing from a One-Component Plasma Imaged by Ultrafast Transmission Electron Microscopy  OMID ZANDI (Presenter), ALLAN EUGENE SYKES, RYAN DEAN CORNELIUS, FRANCIS MARION ALCORN, Department of Chemistry, University of Illinois at Urbana-Champaign, BRYAN REED, Integrated Dynamic Electron Solutions, Inc, RENSKE M VAN DER VEEN, Department of Chemistry, University of Illinois at Urbana-Champaign — Transmission electron microscopy (TEM) has become a powerful technique to study the structure of materials at nanoscale. The temporal resolution of TEM, however, is typically limited by the maximum frame rate of the detector to the ms regime. Ultrafast TEM combines the high temporal resolution of ultrafast laser spectroscopy with the excellent spatial resolution of electron microscopy. The structural and electronic changes in the material are initiated by fs laser pulses followed by similarly short photoelectron pulses to prob the dynamics by imaging, diffraction, or electron spectroscopy. Here, we will present our ultrafast TEM at UIUC, and demonstrate its first application in observation of periodic plasma lensing. We generated a one-component electron plasma (OCEP) by two-photon photoemission from a Cu grid. We directly imaged the subsequent evolution of the OCEP under the influence of an external uniform magnetic field inside the TEM on the ps time scale. The cyclotron oscillations give rise to a periodic lensing effect which maximizes when the OCEP is refocused along the magnetic field. We analytically described the dynamics of OCEP and its time-dependent focal length to extract the number of electrons and their velocity spread. We verified the model by N-body simulations.
12:27PM M06.00007: Attosecond Pulses with Time-Varying Orbital Angular Momentum: The Self-Torque of Light  QUYNH L NGUYEN (Presenter), KEVIN DORNEY, Physics, JILA/University of Colorado Boulder, LAURA REGO, Grupo de Investigación en Aplicaciones del Láser y Fotónica, Departamento de Física Aplicada, University of Salamanca, Salamanca E-37008, Spain, NATHAN BROOKS, CHEN-TING LIAO, Physics, JILA/University of Colorado Boulder, JULIO SAN ROMAN, Grupo de Investigación en Aplicaciones del Láser y Fotónica, Departamento de Física Aplicada, University of Salamanca, Salamanca E-37008, Spain, DAVID E COUCH, ALLISON LIU, Physics, JILA/University of Colorado Boulder, EMILIO PISANTY, MACIEJ LEWENSTEIN, ICFO, Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, Av. Carl Friedrich Gauss 3, 08860, LUIS PLAJA, Grupo de Investigación en Aplicaciones del Láser y Fotónica, Departamento de Física Aplicada, University of Salamanca, Salamanca E-37008, Spain, HENRY KAPTEYN, Physics, JILA/University of Colorado Boulder, CARLOS HERNANDEZ-GARCIA, Grupo de Investigación en Aplicaciones del Láser y Fotónica, Departamento de Física Aplicada, University of Salamanca, Salamanca E-37008, Spain, MARGARET MARY MURNANE, Physics, JILA/University of Colorado Boulder — Propagating laser beams with defined orbital angular momentum (OAM) have found applications that enable new paradigms in optical metrology and communication, quantum information, photomechanical manipulation, and super-resolution imaging. To date, however, the generation and application of OAM beams has been largely based on a static interpretation of optical OAM, where OAM is time-independent. We show for the first time that propagating light waves can possess dynamic, time-varying OAM. We exploit the highly non-linear and non-perturbative process of high-harmonic generation to imprint time-dependent OAM onto extreme ultraviolet (EUV) beams. This new photonic property, self-torque (an analogy to mechanical systems that exhibit a self-induced time variation of their angular momentum), manifests as a few-to-sub femtosecond variation of optical OAM states along each pulse in the underlying attosecond pulse train. We confirm that optical self-torque endows unique properties to coherent EUV waveforms, which enable the delivery of optical torque on the natural time and length scales of charge and spin ordering in materials. Ability to sculpt the OAM wavefront of EUV beams also offers exciting potential in imaging, metrology and sensing methods for semiconductor and quantum materials.

12:39PM M06.00008: Direct in-situ single-shot measurements of the absolute carrier-envelope phases of ultrashort pulses*  DUKE DEBRAH (Presenter), GIHAN BASNAYAKE, WEN LI, Wayne State Univ — Many important physical processes such as nonlinear optics and coherent control are highly sensitive to the absolute carrier-envelope phase (CEP) of driving ultrashort laser pulses. This makes the measurement of CEP immensely important in relevant fields. Even though relative CEPs can be measured with a few existing technologies, the estimate of the absolute CEP is not straightforward and always requires theoretical inputs. Here, we demonstrate a novel in-situ technique based on angular streaking that can achieve such a goal without complicated calibration procedures. Single-shot measurements of the absolute CEP have been achieved with an estimated precision of 0.19 radians.

*Research supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), under Award # DE-SC0012628.
12:51PM M06.00009: Photoninduced quantum entanglement between remote electron-phonon systems*  KUNIO ISHIDA (Presenter), Utsunomiya Univ, HIROAKI MATSUEDA, National Institute of Technology, Sendai College —
Dynamical control of quantum entanglement by external light is an intriguing problem which is of importance in the study of light-matter interaction as well as quantum information processing. Recent experiments have shown that phonons created between remote samples are entangled by laser pulses[1], which shows that the quantum-mechanical nature of light plays a key role to understand the dynamics of quantum correlation between noninteracting systems. In this paper we discuss the dynamics of entanglement creation in remote electron-phonon systems which is mediated by irradiation of quantized light. A multimode spin-boson model is used to describe photons and phonons coupled with two-level systems[2], and we discuss the quantitative properties of quantum entanglement between photons and/or phonons revealed by numerical calculations.

*This work is partly supported by Research Funding Granted by Utsunomiya University President.

1:03PM M06.00010: Characterization of an ultrastable sapphire optical cavity operated at 10 K*  JOSE VALENCIA (Presenter), ETHAN CLEMENTS, MAY KIM, DAVID B HUME, DAVID LEIBRANDT, National Institute of Standards and Technology — The frequency stability of optical clocks is often limited by the linewidth of the probe laser, where the highest stability cavity-stabilized lasers are dominated by thermal noise in the cavity mirrors [1]. We present an optical reference cavity with a calculated thermal noise limit near Δf/f = 3x10^{-18}, which is compatible with reaching the ultimate stability limit due to quantum projection noise for clocks based on the $^1S_0^0-^3P_0$ transition in $^{27}$Al$^+$ (8 mHz natural linewidth at 267 nm) [2]. The cavity is constructed of single-crystal sapphire with GaAs/AlGaAs crystalline mirror coatings and is operated at 10 K using a closed-cycle cryocooler. We measure environmental and technical noise, including temperature fluctuations and vibrations, and characterize their impact on cavity stability. The cavity stability is found to be near 10^{-16} by comparing to room-temperature ULE cavities.

*This work is supported by the National Institute of Standards and Technology and the Office of Naval Research.
Optical manipulation system for Steady State Microbunching in storage ring. POHSUN WU (Presenter), HAO-WEN LUO, National Tsing Hua University, ALEXANDER WU CHAO, Tsinghua University, CI-LING PAN, National Tsing Hua University, CHUANXIANG TANG, Tsinghua University — Steady State Microbunching (SSMB) is one of the schemes for generation of high average power coherent synchrotron radiation (CSR) in a storage ring. As the first proof-of-principle experiment has succeeded at the MLS storage ring in Berlin, it could be a promising candidate of kW level EUV source for lithography with the advantage of narrow linewidth, high power, collimated and clean beam. To satisfy the requirement of SSMB modulation field, the turn by turn phase must be stable and the field need be as high as ~MV/m over several meters of the modulation length. We have studied the effect on microbunch formation and maintenance of turn by turn phase with arbitrary phase jitter with noise spectrum from a commercially available relatively high-power continuous wave laser with a MW level enhancement cavity. The cases of synthesized field by multicolor laser field and adiabatic modulation are also considered. Compare with single color scheme under the same power, the microbunch length of 2-color scheme can be three times smaller while 3-color scheme can be six times smaller. Thus we can generate CSR at shorter wavelength with shorter microbunch length.

This work is supported in part by MOST grant 108B0174I4.

Investigating High Harmonic Generation Beam Dynamics with Ptychographic Lensless Imaging* DAVID SCHMIDT (Presenter), LOGAN Z RAMLET, ALEX WILHELM, DAVID GOLDBERGER, DANIEL ADAMS, CHARLES G DURFEE, Colorado Sch of Mines — High Harmonic Generation (HHG) allows for tabletop EUV coherent light sources and attosecond pulses that can be used to probe material properties. While the process is relatively straightforward to implement, the beam quality of the harmonics is difficult to measure and control. A first step to realizing a tunable and fine controlled HHG setup is the ability to measure these quantities without having to change the setup drastically. Ptychography is a computational imaging technique that has already been used with HHG to reconstruct images of unique specimens. In this work, we shift the emphasis in computational imaging from reconstructing the specimen to understanding the details of the EUV light generated through HHG. Reconstructed harmonic beam profiles can then be propagated back to their generation point in the system to examine how they formed. Using this knowledge, we can optimize the factors affecting the HHG process and learn to control them.

We acknowledge funding from the United States Air Force MURI grant FA9550-16-1-0121.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M07 DQI: Superconducting Qubits: Josephson Junction-based Amplifiers and Parametric Devices II 102 - Nicolas Roch, Institut Neel
**11:15AM M07.00001: Boardband Tunable Phase Shifter for Microwaves**  JINLI ZHANG
(Presenter), MIKKO MOTTONEN, TIANYI LI, ROOPE KOKKONIEMI, KUAN YEN TAN, CHENGYU YAN, WEI LIU, Aalto University — Recently, we introduced a magnetic-flux-tunable phase shifter for propagating microwaves based on three equidistant SQUIDs operating at a single frequency. Here, we report the phase tunability with unit transmission in a frequency range from 6 to 6.28 GHz. Tunability at different frequencies suggests accurate and practical control of the phase. Our results offer a promising path to tune the phase of microwave signal in waveguides with magnetic-flux bias in quantum computation and quantum communication applications.

**11:27AM M07.00002: Phase noise of a Josephson parametric oscillator**  GOPIKA LAKSHMI Bhai (Presenter), SHOTARO SHIRAI, HIROTO MUKAI, Physics, Tokyo Univ of Science, Kagurazaka, YU ZHOU, RIKEN, VIVISHEK SUDHIR, Massachusetts Institute of Technology, JAW-SHEN TSAI, Physics, Tokyo Univ of Science, Kagurazaka — Josephson parametric amplifiers are acquiring a renewed interest in the quantum information community for implementing single-shot readout, and creating entangled photons and squeezed vacuum states. When these parametric amplifiers are driven above an instability threshold, the average number of coherent output photons increases resulting in parametric oscillation. Here we present the results on the experimental study of the phase diffusion properties of such an oscillator by measuring the phase noise spectrum.

*This research is supported by the NEDO IoT project and the JST CREST project in Japan.

**11:39AM M07.00003: A Josephson Maser Via Three-Wave Coupling**  MARIA MUCCI (Presenter), XI CAO, CHENXU LIU, RYAN KAUFMAN, DAVID PEKKER, MICHAEL JONATHAN HATRIDGE, Physics and Astronomy, University of Pittsburgh — In superconducting quantum information systems, we require coherent light to drive quantum elements such as qubits and quantum amplifiers. This is traditionally achieved by filtering hot, room temperature light sources through 60-80dB of increasingly cold attenuators. A cryogenic maser operated in the 5-10GHz range, if it could be controlled without an external microwave drive, would be ideal for such coherent drives. Instead of a three-level atom, we present a joint system of a single qubit and a three-wave mixing resonator, realized in a transmon and SNAIL (Superconducting Nonlinear Asymmetric Inductive eLement), respectively. We take advantage of the SNAIL’s parametric gain process and large engineered loss to rapidly invert the transmon’s population and drive masing in a superconducting cavity. We will present the project's preliminary experimental results, as well as plans to implement the parametric drive via a dc-biased junction for an all-dc controlled, cryogenic quantum light source.

*Work Supported by: NSF, ARO, LPS, and the Kauffman Foundation.
11:51AM M07.00004: Engineered frequency combs in a multimode Josephson network

SAEED KHAN (Presenter), HAKAN TURECI, Princeton University — We investigate the dynamics of a microwave-driven Josephson junction capacitively coupled to an arbitrary multimode linear network. Under specific symmetry conditions, we show that the classical phase diagram simplifies, and may be determined semi-analytically for an arbitrarily large network. The resulting system admits unstable regimes with emergent frequency combs akin to its single mode counterpart [1], with the latter being recently realized in superconducting circuits [2]. The multimode network enables further control over comb properties via its tunable parameters. The coherence of the combs is found to be determined by the intrinsic nonlinearity of the Josephson junction, but is also controllable via network parameters. We also clarify the connection and identify important differences between the network here which consists of a single Kerr nonlinear mode that ultimately delocalizes over the linear network due to the coupling, and standard multimode Kerr combs that have been well-studied in optical systems. The system provides a highly-engineerable platform for frequency comb generation, especially suited to realization within the superconducting circuit architecture.

12:03PM M07.00005: Theory of an on-chip Josephson quantum micromaser

DAVID PEKKER (Presenter), CHENXU LIU, MARIA MUCCI, XI CAO, MICHAEL JONATHAN HATRIDGE, Univ of Pittsburgh — Solid-state superconducting qubit systems are one of the most promising systems to achieve quantum computing. One of the shortcomings of this architecture is the lack of an on-chip coherent microwave source. To solve this problem, we explore the feasibility of building a Josephson micromaser powered by tunable superconducting transmon qubit(s) (which serve as an artificial three-level atom). Specifically, we explain how to engineer a system composed of two qubits (one a conventional transmon, the other a transmon with a SNAIL element) to construct an element that behaves like a 3-level atom coupled to a dissipative bath. We construct a master equation description of the maser and estimate its properties, like its coherence time, and their dependence on the pump power, pump noise, cavity widths, etc. Finally, we note that the possibility for highly non-linear devices in the microwave regime allow our maser to generate quantum (i.e. non-Gaussian) light.

12:15PM M07.00006: Microwave Isolation through Adiabatic Mode Conversion in Superconducting Coupled Transmission Lines  MAHDI NAGHILOO (Presenter), KAIDONG PENG, YUFENG YE, KEVIN O'BRIEN, Massachusetts Institute of Technology MIT — Non-reciprocal devices are essential for isolating superconducting quantum circuits from the noisy electromagnetic environment while allowing measurement and control. For the past decade, ferrite-based circulators and isolators have been predominantly used to protect superconducting quantum circuits, but major limitations associated with large permanent magnets motivate a non-ferrite and scalable solution. Here we discuss a new scheme that utilizes adiabatic mode conversion in coupled nonlinear Josephson junction transmission lines to realize broadband isolation without magnetic elements, allowing integration with current superconducting qubit technology. We report on progress toward implementing this device.

12:27PM M07.00007: Design of a Josephson Travelling Wave Photon Detector  YUFENG YE (Presenter), KAIDONG PENG, MAHDI NAGHILOO, KEVIN O'BRIEN, Massachusetts Institute of Technology MIT — High-fidelity and wide bandwidth single microwave photon detection remains a challenge for quantum information experiments. Here, we investigate a new design for the Josephson travelling wave photon detector[1,2], a circuit QED based detector which promises high fidelity, non-destructive, and broadband detection of microwave photons. In this design, the broadband detection relies on nonlinear interactions between signal and probe photons in coupled transmission lines. We engineer a cross-Kerr interaction using both quartons and transmons to eliminate self-Kerr and enhance the readout efficiency. By measuring a phase shift on the probe photons, we can deduce the signal photon number with high fidelity.

12:39PM M07.00008: Experimental studies of flux solitons in reversible logic gates  LIUQI YU (Presenter), WALTRAUT WUSTMANN, KEVIN OSBORN, The Laboratory for Physical Sciences, University of Maryland, USA — Reversible digital logic gates can provide a fundamental advantage in energy efficiency compared to industrial gates which are irreversible. Here we design and measure 1-bit gates implemented in superconducting circuits. The gate consists of Long Josephson junctions (LJJs) connected by a circuit interface. The gate interface includes large shunting capacitors, which is key for the resonant conservative dynamics in the gates. The dynamics of the scattering process, originally discovered in full numerical simulation, is understood using collective coordinate analysis [1,2]. Depending on the interface parameters, the gate dynamics realize different gate operations that may preserve or change the fluxon polarity, as an Identity or NOT gate. The LJ circuit layout uses niobium trilayer short junctions with connecting wiring for inductors. We plan to experimentally study how well a fluxon can travel ballistically towards the gate, and scatter to another LJ with the designed change in flux polarity (bit state).

12:51PM M07.00009: Drive-induced renormalization of Kerr nonlinearity in superconducting circuits* ALEXANDRU PETRESCU (Presenter), Université de Sherbrooke, BAPTISTE ROYER, Department of Physics, Yale University, ALEXANDRE BLAIS, Université de Sherbrooke — Josephson-junction-based amplifiers are now ubiquitously used in high-fidelity qubit readout. In a three-wave mixing parametric amplifier, a cancelation of the Kerr interaction is required. In satisfying this requirement, an important limitation is that available theory does not fully explain the dependence of the Kerr nonlinearity on drive power. We propose a perturbative expansion based on unitary transformations to calculate drive-induced corrections to Kerr interactions, with possible applications to current experiments.

*This work was undertaken thanks in part to funding from NSERC and the Canada First Research Excellence Fund.

1:03PM M07.00010: Observation of the AC Stark shift and idler-resonance in two-tone measurements of a Josephson resonator* FATEMEH FANI SANI, DANIEL BOTHNER, INES C. RODRIGUES, GARY STEELE (Presenter), Delft University of Technology — We report on the behaviour of a nonlinear Josephson cavity driven by two microwave signals. Using a single tone, the cavity exhibits the expected Duffing response of the device at high powers. For two-tone measurements, we use a strong pump at frequency $f_p$ and simultaneously measure the cavity with a weak probe. For $f_p > f_c$ (cavity frequency), a Lorentzian response of the cavity is shifted in frequency, corresponding to the AC Stark-shift of the Josephson resonator. For $f_p < f_c$, we observe an abrupt jump in the shifted cavity frequency and an additional feature in the probe spectrum with net gain, occurring at a frequency mirrored about $f_p$. We attribute this feature to resonance condition of an idler tone, generated by 4-wave mixing, with the cavity frequency, in good agreement with an analytical theory. Our results provide insight into the physics of the driven nonlinear Josephson cavity, and a starting point for exploring the strongly-driven quantum regime.

1:15PM M07.00011: Millimeter-Wave Four-Wave Mixing via Kinetic Inductance for Quantum Devices*  ALEXANDER ANFEROV (Presenter), AZIZA SULEYMANZADE, ANDREW ORIANI, JONATHAN SIMON, DAVID I SCHUSTER, University of Chicago — Millimeter-wave superconducting devices offer transformative opportunities for quantum experiments at temperatures above 1K, allowing higher device power dissipation, integration with semiconductor technologies, as well as new avenues for studying light-matter interactions in the strong coupling regime. Using the intrinsic nonlinearity associated with kinetic inductance of thin film materials, we realize four-wave mixing at millimeter-wave frequencies: a key component for superconducting quantum systems. We report on the performance of low-loss planar resonators around 100 GHz, patterned on high kinetic inductance thin films of niobium nitride grown by atomic layer deposition. With two-tone spectroscopy we explore degenerate parametric conversion at single photon powers, paving the way for a new generation of high-frequency high-temperature quantum experiments.

1:27PM M07.00012: Towards the development of a microwave to millimeter-wave quantum frequency converter*  KEVIN MULTANI (Presenter), HUBERT STOKOWSKI, JEREMY WITMER, WENTAO JIANG, RISHI PATEL, NATHAN LEE, MAREK PECHAL, Stanford Univ, EMMA SNIVELY, PAUL B. WELANDER, EMILIO NANNI, SLAC, AMIR SAFAVI-NAEINI, Stanford Univ — Quantum networks of microwave superconducting qubits may require the conversion of photons from microwave frequency to those of higher energy for transmission over thermal channels. An approach pursued across the field is to use a three-wave mixing nonlinearity to convert microwave photons to optical photons, so that optical fibers can be used as links for long-range connections. However, these systems’ conversion rate is inherently limited by optical-loss-induced heating. We pursue conversion between microwave (1-10 GHz) signals to millimeter-wave (mmWave, 50-300 GHz) signals, which has the potential to increase the conversion rate by nearly nine orders of magnitude and allow transmission with low decoherence over tens of meters. This talk will outline our experimental approach to a microwave-mmWave conversion scheme, where high bandwidth and high rate interconnects can be created at the laboratory scale. We design and implement multi-frequency antennae, with two modes in the mmWave frequency band, and one mode in the microwave frequency band. We will present recent experimental results as well as outlining possible applications in quantum sensing.

1:39PM M07.00013: Fractional harmonic instabilities in a quantum driven non-linear oscillator*  
JAYAMEENAKSHI VENKATRAMAN (Presenter), XU XIAO, YAXING ZHANG, Yale University,  
MAZYAR MIRRAHIMI, INRIA, LUIGI FRUNZIO, MICHEL H. DEVORET, Yale University — The action of  
drives on non-linear modes to engineer parametric processes is ubiquitous in circuit QED. In this  
work, we provide a map in parameter space of the instabilities that are created when the ratio of  
the drive and the mode transition frequencies coincide with rational numbers. With careful  
engineering of system parameters and knowledge of such a map, once could avoid these  
instabilities, particularly at large drive-strengths. Our findings are supported by the bifurcation  
map of the classical analogue of our system where under certain drive conditions there exist a  
manifold of degenerate steady states that would lead to the quantum heating shown in the first  
part of the talk. One could also harness this robust degeneracy and exploit it to generate cat-like  
states which could be used to store and manipulate quantum information. Preliminary  
experimental results will be shown.

1:51PM M07.00014: Dynamical Lamb effect in a superconducting circuit*  
MIRKO AMICO (Presenter), OLEG BERMAN, ROMAN KEZERASHVILI, The Graduate Center, City University of New York —  
The dynamical Lamb effect is predicted to arise in superconducting circuits when the coupling of  
a superconducting qubit with a resonator is periodically switched “on” and “off” nonadiabatically.  
We show that by using a superconducting circuit which allows one to switch between longitudinal  
and transverse coupling of a qubit to a resonator, it is possible to observe the dynamical Lamb  
effect. The switching between longitudinal and transverse coupling can be achieved by  
modulating the magnetic flux through the circuit loops. By solving the Schrödinger equation for a  
qubit coupled to a resonator, we calculate the time evolution of the number of excitations in the  
qubit and the resonator due to the dynamical Lamb effect. The number of excitations created in  
the system is maximum when the coupling is periodically switched between longitudinal and  
transverse using a square-wave or sinusoidal modulation of the magnetic flux with frequency  
equal to the sum of the average qubit and photon transition frequencies.  

*This work is partially supported by the U.S. Department of Defense under Grant No.  
W911NF1810433.
2:03PM M07.00015: Time-Domain Grating with a Periodically Driven Qutrit YINGYING HAN (Presenter), Southern University of Science and Technology, WENXIAN ZHANG, Wuhan University, FRANCO NORI, RIKEN, JIANQIANG YOU, Zhejiang University, XIAOQING LUO, Quantum Physics and Quantum Information Division, TIEFU LI, Tsinghua University — Physical systems in the time domain may exhibit analogous phenomena in real space, such as time crystals, time-domain Fresnel lenses, and modulational interference in a qubit. We report the experimental realization of time-domain grating using a superconducting qutrit in periodically modulated probe and control fields via two schemes: simultaneous modulation and complementary modulation. Both experimental and numerical results exhibit modulated Autler-Townes (AT) and modulation-induced diffraction (MID) effects. Theoretical results also confirm that the peak positions of the interference fringes of AT and MID effects are determined by the usual two-level relative phases, while the observed diffraction fringes, appearing only in the complementary modulation, are related to the three-level relative phase. Further analysis indicates that such a single-atom time-domain diffraction originates from the correlation effect between the two time-domain gratings. Moreover, we find that the widths of the diffraction fringes are independent of the control-field power. Our results shed light on the experimental exploration of quantum coherence for modulated multilevel systems and may find promising applications in fast all-microwave switches and quantum-gate operations in the strong-driving regime.

Session M08 DQI: NISQ: Noise Resilience, Mitigation, and Characterization 104 - Charles Tahan, Laboratory for Physical Sciences

11:15AM M08.00001: Error-resilient Tensor Network-based Ansatz for a Noisy Quantum Computer* UNPIL BAEK (Presenter), WILLIAM HUGGINS, BIRGITTA K WHALEY, University of California, Berkeley — Quantum computers can approximately prepare the ground states of many physical systems without using an exponential amount of resources. A hybrid quantum-classical algorithm, such as the variational quantum eigensolver (VQE), is a promising candidate for simulating electronic structures on a near-term device. Simulating complex systems with VQE, however, poses serious challenges because of limited qubit coherence times and non-negligible error rates within near-term devices. To tackle this challenge, we integrate the geometric structure of Deep Multiscale Entanglement Renormalization Ansatz (DMERA) circuits with the low-cost verification of fermionic parity symmetry to simulate ground states of the Fermi-Hubbard model. Requiring only a gate depth logarithmic in the total system size and a number of qubits independent of the system size, this protocol enables us to study larger systems than are possible for approaches with different ansatzes. Results for the Fermi-Hubbard model indicate that the protocol effectively leverages the ability of near-term devices to simulate complex lattice models.

*This work was supported by a Quantum Algorithms Focused Award from Google LLC.
(Presenter), PATRICK J COLES, Los Alamos National Laboratory — In this work, we study how machine learning can be applied to formulate noise-aware circuit compilations that can be executed on near-term quantum hardware to produce reliable results. We will demonstrate that experimentally derived noise models can be used to go beyond naive circuit compilations for several example quantum algorithms. There are two inputs to our Noise-Aware Circuit Learning (NACL) method: a task, and a noisy gate alphabet. The task is defined by either a set of classical training data or a desired output quantum state or unitary. The output of NACL is a quantum gate sequence that optimally accomplishes the inputted task in the presence of the inputted noise model. Neither an ansatz nor the circuit depth of the gate sequence is an input to NACL. This is because NACL optimizes over the circuit structure and depth, which is in the spirit of task-oriented programming. We implement NACL for several different problems, such as computing state overlap, preparing multi-body entangled states, and implementing the quantum Fourier transform. In each case, we find that our overall figure-of-merit is significantly lower for NACL than for standard methods of circuit compilation.

11:39AM M08.00003: Noise-Resilient Quantum Dynamics Using Symmetry-Preserving Ansatzes  MATTHEW OTTEN (Presenter), CRISTIAN CORTES, STEPHEN K GRAY, Argonne Natl Lab — We describe and demonstrate a method for the computation of quantum dynamics on small, noisy universal quantum computers. This method relies on the idea of ‘restarting’ the dynamics; at least one approximate time step is taken on the quantum computer and then a parameterized quantum circuit ansatz is optimized to produce a state that well approximates the time-stepped results. The simulation is then restarted from the optimized state. By encoding knowledge of the form of the solution in the ansatz, such as ensuring that the ansatz has the appropriate symmetries of the Hamiltonian, the optimized ansatz can recover from the effects of decoherence. This allows for the quantum dynamics to proceed far beyond the standard gate depth limits of the underlying hardware, albeit incurring some error from the optimization, the quality of the ansatz, and the typical time step error. We demonstrate this methods on the Aubry-André model with interactions at half-filling, which shows interesting many-body localization effects in the long time limit. Our method is capable of performing high-fidelity Hamiltonian simulation hundred of time steps longer than the standard Trotter approach. These results demonstrate a path towards using small, lossy devices to calculate quantum dynamics.
11:51AM M08.00004: Error Mitigation in Data Driven Circuit Learning*  
KATHLEEN HAMILTON (Presenter), TYLER KHARAZI, VICENTE LEYTON-ORTEGA, RAPHAEL POOSER, Oak Ridge National Lab — Mitigating state preparation and measurement (SPAM) errors has been shown to improve the performance of noisy intermediate scale quantum (NISQ) devices. This talk focuses on the incorporation of matrix-based SPAM error mitigation into data-driven circuit learning for parameterized circuits implementing generative modeling tasks. We discuss how the choice of nonlinear optimization, loss function and the structure of the target distributions can affect the computational cost associated with gradient-based training of densely parameterized quantum circuits trained on NISQ hardware accessed via cloud-based queues.

*This work was supported as part of the ASCR Testbed Pathfinder Program at Oak Ridge National Laboratory under FWP #ERKJ332

12:03PM M08.00005: Preserving Symmetries for Variational Quantum Eigensolvers in the Presence of Noise*  
GEORGE S. BARRON (Presenter), BRYAN T. GARD, ORIEN J ALTMAN, Department of Physics, Virginia Tech, NICHOLAS J. MAYHALL, Department of Chemistry, Virginia Tech, EDWIN BARNES, SOPHIA ECONOMOU, Department of Physics, Virginia Tech — One of the most promising applications of noisy intermediate scale quantum computers (NISQ) is the simulation of molecular Hamiltonians using the variational quantum eigensolver (VQE) algorithm, which has already been demonstrated on small molecules. We show that encoding symmetries of the simulated Hamiltonian at the level of the ansatz used in the VQE provides improvements to both classical and quantum resources. We further verify that these improvements persist in the presence of noise by simulating such variational forms in noisy environments and evaluating their ability to find the correct ground state. To further improve the quality of our results, we implement state of the art error mitigation techniques. Finally, we demonstrate our results in experiment by using IBMQ quantum processors.

This research used quantum computing system resources supported by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research program office. Oak Ridge National Laboratory manages access to the IBM Q System as part of the IBM Q Network.
12:15PM M08.00006: Querying quantum computers with neural networks: precise measurements and noise reduction*  ANTONIO MEZZACAPo (Presenter), ABHINAV KANDALA, IBM TJ Watson Research Center, GUGLIELMO MAZZOLA, IBM Zurich Research Lab, KENNY JING CHOO, University of Zurich, GIACOMO TORLAI, GIUSEPPE CARLEO, Flatiron Institute — In this talk I will introduce neural-network estimators for quantum observables, obtained by integrating the measurement apparatus of a quantum simulator with neural networks. Unsupervised learning of single-qubit measurement data can produce estimates of complex observables free of quantum noise. Precise estimates are achieved for quantum chemistry Hamiltonians, with a reduction of several orders of magnitude in the amount of measurements needed compared to standard estimators. Finally, I will show results on molecular systems obtained using IBM superconducting quantum processors, combining precise measurements with error mitigation strategies.

12:27PM M08.00007: Measurement Reduction in Variational Quantum Algorithms*  ANDREW ZHAO (Presenter), University of New Mexico, ANDREW TRANTER, WILLIAM KIRBY, Tufts University, SHU FAY UNG, California Institute of Technology, AKIMASA MIYAKE, University of New Mexico, PETER LOVE, Tufts University — Variational quantum algorithms are promising applications of noisy intermediate-scale quantum (NISQ) computers. These algorithms consist of a number of separate prepare-and-measure experiments that estimate terms in the Hamiltonian. The number of separate measurements required can become overwhelmingly large for problems at the scale of NISQ hardware that may soon be available. We approach this problem from the perspective of contextuality, and use unitary partitioning to define VQE procedures in which additional unitary operations are appended to the ansatz preparation circuit to reduce the number of terms one needs to measure. This approach may be tuned to hardware specifications in order to use all coherent resources available after ansatz preparation. We investigate this technique for a variety of Hamiltonian classes, in particular the electronic structure Hamiltonian from quantum chemistry. There, we prove that term reduction always scales at least linearly with respect to the number of orbitals, and we supplement this result with numerical studies.

12:39PM M08.00008: Noise Resilience of Variational Quantum Compiling  KUNAL SHARMA (Presenter), SUMEET KHATRI, Louisiana State University, Baton Rouge, MARCO CEREZO DE LA ROCA, PATRICK COLES, Los Alamos National Laboratory, New Mexico — Variational hybrid quantum-classical algorithms (VHQCAs) are near-term algorithms that leverage classical optimization to minimize a cost function, which is efficiently evaluated on a quantum computer. Recently VHQCAs have been proposed for quantum compiling, where a target unitary U is compiled into a short-depth gate sequence V. In this work, we report on a surprising form of noise resilience for these algorithms. Namely, we find one often learns the correct gate sequence V (i.e., the correct variational parameters) despite various sources of incoherent noise acting during the cost-evaluation circuit. Our main results are rigorous theorems stating that the optimal variational parameters are unaffected by a broad class of noise models, such as measurement noise, gate noise, and Pauli channel noise. Furthermore, our numerical implementations on IBM's noisy simulator demonstrate resilience when compiling the quantum Fourier transform, Toffoli gate, and W-state preparation. Hence, variational quantum compiling, due to its robustness, could be practically useful for noisy intermediate-scale quantum devices. Finally, we speculate that this noise resilience may be a general phenomenon that applies to other VHQCAs such as the variational quantum eigensolver.

12:51PM M08.00009: Quantum Dynamical Complexity and Reliability of Analog Quantum Simulation*  KARTHIK CHINNI (Presenter), PABLO POGGI, IVAN DEUTSCH, University of New Mexico — The NISQ era is characterized by the absence of fully fault-tolerant quantum simulators, which raises a question about the reliability of such devices. To address this, we seek to quantify the reliability of an analog quantum simulator, which doesn't have access to error correction, in the presence of perturbations that make the dynamics quantum chaotic. In doing so we seek to identify the relationship between the robustness of the quantities that we seek to extract from the simulator and the dynamical complexity of the analog evolution. As one measure, we quantify the complexity by the number of variables that one must track to approximately yield the output within a desired accuracy. We address these questions by studying the basic paradigms such as the ground state and the excited state quantum phase transitions in the Lipkin-Meshkov-Glick (LMG) model[1].

1:03PM M08.00010: Exploiting molecular point group symmetries for quantum simulation
KANAV SETIA (Presenter), JAMES D WHITFIELD, Dartmouth Coll, ANTONIO MEZZACAPO, JULIA RICE, MARCO PISTOIA, RICHARD CHEN, IBM — Simulating molecules is believed to be one of the early-stage applications for quantum computers. Current state-of-the-art quantum computers are limited in size and coherence, therefore optimizing resources to execute quantum algorithms is crucial. In this work, we develop a formalism to reduce the number of qubits required for simulating molecules using spatial symmetries, by finding qubit representations of irreducible symmetry sectors. We present our results for various molecules and elucidate a formal connection of this work with a previous technique that analyzed generic Z2 Pauli symmetries.

1:15PM M08.00011: Quantum-classical simulation of two-site dynamical mean-field theory on noisy quantum hardware
TREVOR KEEN (Presenter), University of Tennessee, Knoxville, THOMAS MAIER, Computational Sciences and Engineering Division, Oak Ridge National Laboratory, STEVEN JOHNSTON, University of Tennessee, Knoxville, PAVEL LOUGOVSKI, Computational Sciences and Engineering Division, Oak Ridge National Laboratory — We report on a quantum-classical simulation of a two-site dynamical mean-field theory (DMFT) calculation. We use IBM's superconducting qubit chip to compute the zero-temperature impurity Green's function in the time domain and a classical computer to fit the measured Green's function. We find that Trotter errors and noise from the quantum chip lead to inaccurate updates to impurity parameters, preventing the DMFT algorithm from converging to the correct solution. To mitigate this issue, we determine the update to the hybridization parameter by integrating the low-frequency peaks in the spectral function. This allows us to iterate the DMFT loop to self-consistency for a strongly Mott insulating system at half-filling.

1:27PM M08.00012: Nearly Optimal Measurement Scheduling for Partial Tomography of Quantum States* XAVIER BONET-MONROIG (Presenter), Institute Lorentz, Leiden University, RYAN BABBUSH, Google Inc., THOMAS O'BRIEN, Institute Lorentz, Leiden University — Many applications of quantum simulation require to prepare and then characterize quantum states by efficiently estimating k-body reduced density matrices (k-RDMs), from which observables of interest are obtained. Naive estimation of such RDMs require repeated state preparation for each matrix element. However, commuting matrix elements may be measured simultaneously, allowing for a significant cost reduction.

In this work we design schemes for such parallelization with near-optimal complexity in the system size N. We describe a scheme to sample all elements of a qubit k-RDM using only $O(3^k \log^{k-1}(N))$ unique measurements. We detail a scheme to sample all elements of the fermionic 2-RDM using only $O(N^2)$ unique measurements, with $O(N)$-depth measurement circuit. We prove a lower bound of $O(N^k)$ on the number of unique measurements required to directly sample all elements of a fermionic k-RDM, making our fermionic 2-RDM scheme asymptotically optimal. We finally construct circuits to sample the expectation value of a linear combination of $\omega$ anti-commuting 2-body fermionic operators with $O(\omega)$ gates on a linear array.

1:39PM M08.00013: Extracting state purity of a large system with limited control YARIV YANAY (Presenter), CHARLES TAHAN, Laboratory of Physical Sciences — As superconducting quantum devices with a large number of qubits become feasible, they offer an avenue for quantum simulation of equally large systems. The extraction of global information, such as a state's purity or entropy, remains a challenging prospect, generally requiring independent control of each qubit. Here, we propose a method of extracting the purity with limited control, applied through multiplexed dispersive readout. We consider the required control fidelity, and scaling of the number of measurements with system size.

1:51PM M08.00014: Evaluation of the classical sampling cost for noisy quantum circuits SHIGEO HAKKAKU (Presenter), KEISUKE FUJII, Department of Systems Innovation, Graduate School of Engineering Science, Osaka University — In order to demonstrate quantum computational supremacy, quantum computers are being developed by Google, IBM, and so on. In an actual quantum device, there is a non-negligible amount of noise, which would deteriorate the advantage of quantum computation. Therefore, it is necessary to evaluate overhead for classical simulation of quantum computation with taking the noise effect into account.

Recently, classical simulation algorithms such as stabilizer propagation and Pauli propagation. In this work, we estimate the overhead for classical simulation of noisy quantum circuits in terms of Robustness of Magic (RoM) and stabilizer norm, and compare them.

Specifically, we study simulation costs of the noisy random quantum circuits and Trotterized quantum circuits. We show that the Trotterized quantum circuits can be easily simulatable by adding small noise.
11:15AM M09.00001: Triangular color codes on trivalent graphs with flag qubits
CHRISTOPHER CHAMBERLAND (Presenter), IBM TJ Watson Research Center, ALEKSANDER KUBICA, Perimeter Institute, THEODORE YODER, GUANYU ZHU, IBM TJ Watson Research Center — The color code is a topological quantum error-correcting code with a variety of computationally-valuable and fault-tolerant logical gates. Its two-dimensional version, the triangular color code, may soon be realized with currently available superconducting hardware limited by qubit connectivity. To guide the experimental effort, we thus study the storage threshold of the triangular color code against the circuit-level depolarizing noise. First, we adapt the Restriction Decoder to the setting of the triangular color code and to phenomenological noise. Then, we propose a fault-tolerant implementation of the stabilizer measurement circuits, which incorporates flag qubits. We show how information from flag qubits can be use with the Restriction Decoder to maintain the effective distance of the code. We numerically estimate the threshold of the triangular color code to be 0.2%, which is competitive with the thresholds of other topological quantum codes. Lastly, we prove that using 1-flag stabilizer measurement circuits are enough to recover the full distance of the code.

11:27AM M09.00002: A numerical error threshold for "colorful" quantum computing*
JOSEY HANISH (Presenter), SKYLAR TURNER, University of Texas at Austin, EOIN BLANCHARD, University of Illinois at Urbana-Champaign, NOAH DAVIS, BRIAN LA COUR, University of Texas at Austin — "Colorful" quantum computing was first proposed by Héctor Bombín to realize universal, fault-tolerant quantum computing using 3D color codes, or tetrahedral codes. Unlike the well-studied surface code methods, colorful quantum computing does not require magic state distillation and instead relies on a universal set of transversal gates and measurements. Colorful quantum computing can be realized in either a 3D or a 2D system. In this paper, we numerically test 3D colorful quantum computing's resiliency to noise. In addition to the independent and identically distributed noise that affects the initial state, we must also correct errors that arise as part of the initialization process. We find a threshold for fault-tolerance on the body-centered cubic lattice. This threshold upper-bounds the more experimentally feasible 2D colorful quantum computing scheme and hopefully motivates research into color code methods of quantum computing.

11:39AM M09.00003: Reinforcement learning for toric code error correction  MATS GRANATH (Presenter), University of Gothenburg, MATTIAS ELIASSON, DAVID FITZEK, ANTON FRISK KOCKUM, Chalmers — I will present a summary of our efforts to use deep reinforcement learning (DRL) for quantum error correction of the toric code. A convolutional neural network is trained by exploration of the state space consisting of (hidden) error configurations and corresponding (visible) syndromes. No external input to the algorithm is provided apart from the current syndrome and the final success or failure of the correction episode. The trained network outputs action values of Pauli operations on the system given an input syndrome. Initial work on uncorrelated noise has shown that the DRL agent performs on par with the standard minimum weight perfect matching (MWPM) algorithm. For depolarizing noise the algorithm outperforms MWPM for all error probabilities and with a higher error threshold. The progress on extending this framework to deal with arbitrarily biased noise and syndrome measurement errors, as well as the scalability of the approach will be discussed.

11:51AM M09.00004: Qubit surface codes from rotation systems acting on Majorana fermions  [Invited] RAHUL SARKAR, Institute for Computational and Mathematical Engineering, Stanford University, THEODORE YODER (Presenter), IBM TJ Watson Research Center — A rotation system is a combinatorial description of a graph and its embedding in a 2-dimensional manifold defined by two permutations on a set of objects. We instantiate this set of objects with Majorana operators and define a Majorana code by associating stabilizers to vertices and faces of the graph embedding. We show how the resulting Majorana code corresponds to a qubit stabilizer code that generalizes the known constructions of rotated and twisted surface codes. While we obtain similar macroscopic behavior -- for instance, anyon type changing when crossing defect lines -- the microscopic details of our codes can lead to improved code parameters. For instance, we identify the [[5,1,3]] code as the smallest member of a surface code family on the torus. We find other code families (both in the plane and on higher genus surfaces) improving upon the constants in the Bravyi-Poulin-Terhal bound.

12:27PM M09.00005: Considerations for incorporating small logical qubits in digital error correction codes  DAVID RODRIGUEZ PEREZ (Presenter), ELIOT KAPIT, Colorado Sch of Mines — We introduce a hybrid error correction scheme by considering using traditional error correcting codes (e.g. Surface codes) with small logical qubit architectures, namely, the Very Small Logical Qubit (VSLQ). Previous theoretical work has shown that the VSLQ can achieve a linear scaling improvement factor, with a single qubit $T_1$ lifetime of 30 µs having a logical lifetime of up to 3 ms, all while using two high-coherence qubits and two lossy qubits or resonators, using passive error correction. In this talk, we consider using small logical qubits such as the VSLQ as part of a broader measurement-based code, and explore potential advantages and challenges from such a hybrid approach. In particular, given that digital error correction normally does not account for qubit leakage error, we explore the complexity that would be introduced in dealing with the corresponding leakage error from VSLQ logical states, as well as other concerns.

Higher-order autonomous quantum error correction

JOSE LEBREUILLY (Presenter), KYUNGJOO NOH, Department of Physics and Applied Physics, Yale University, CHIAO-HSUAN WANG, Pritzker School for Molecular Engineering, University of Chicago, STEVEN GIRVIN, Department of Physics and Applied Physics, Yale University, LIANG JIANG, Pritzker School for Molecular Engineering, University of Chicago — Autonomous quantum error correction (AutoQEC) harnesses engineered coupling to an external reservoir to protect quantum information from decoherence. First-order codes provide protection against a single fault and have simple structures. However, as a counterpart they suffer from the drawback of requiring an engineered dissipation that is typically orders of magnitude stronger than natural dissipation. In this work, we investigate the higher-order case and identify Knill-Laflamme conditions which, if satisfied up to some order $r$, lead to the existence of an AutoQEC protocol providing protection against at most $r$ consecutive errors. Furthermore, we develop a general theoretical framework for analyzing the effective dynamics in the protected code space. Within this framework we show that the effective decay rate decreases exponentially in $r$, exceeding the first-order code performance already for moderate engineered dissipation strengths. Finally, we demonstrate that the AutoQEC scheme can be combined with an error-transparent Hamiltonian so as to perform a unitary quantum computation over time scales which far exceed the physical qubits lifetime.

Characterization and critical faults of leakage errors on the surface code

NATALIE BROWN (Presenter), Georgia Inst of Tech, ANDREW CROSS, IBM T.J Watson Research Center, KENNETH BROWN, Duke University — Leakage is a particularly damaging error that occurs when a qubit leaves the defined computational subspace. Leakage errors leave qubits ill-defined and limit the effectiveness of quantum error correcting codes. The effects of leakage errors on the surface code has been studied in various contexts. However, the effects of a leaked data qubit versus a leaked ancilla qubit can be quite different. In this paper, we study the effects of data leakage and ancilla leakage separately. We show that data leakage is much less damaging. If leakage errors can be confined to data qubits, and efficiently removed with a minimum overhead leakage reducing circuit (LRC), then the surface code maintains the code distance in the presence of leakage. We also show that the distance damaging fault in the surface code comes from ancilla leakage at a particular point in the syndrome extraction circuit. Because of this critical fault location, if leakage errors are eliminated in this particular part of the circuit, the surface code can maintain its effective distance, regardless of other leakage errors that occur on either ancilla or data qubits. We simulate two physical realizations of these toy models that can be applied to both superconducting and ion trapped architectures.
1:03PM M09.00008: Fault tolerance on near-term trapped-ion logical qubits with a neural-network decoder
DAVID OBANDO VARGAS (Presenter), YEFRY LOPEZ, Physics, Universidad de Costa Rica, MAURICIO GUTIERREZ, Chemistry, Universidad de Costa Rica — A crucial step towards the construction of a fault-tolerant quantum computer is the implementation of a logical qubit with a higher fidelity than its constituent physical qubits. In this context, we perform simulations of three promising distance-3 quantum error-correcting codes: the color, surface, and Bacon-Shor codes implemented on a state-of-the-art ion trap with realistic noise sources. Our goal is to find the break-even point where the logical memory outperforms the physical one. In previous works [1], after each error correction step, a correction was performed based exclusively on the syndromes of that step. We now use the syndromes of all previous error correction steps and employ a neural-network-based decoder, which has the advantage of not discarding the syndrome history and also being flexible to different noise models. For each code, we compare the two correction approaches and find a clear improvement in the logical fidelity when the neural-network-based decoder is used. These results will serve as a useful guide to future experiments.

1:15PM M09.00009: Implementing a Logical Qubit on a Trapped Ion Quantum Information Processor*
LAIRD EGAN (Presenter), MARKO CETINA, MICHAEL L GOLDMAN, ANDREW RISINGER, CRYSTAL NOEL, DAIWEI ZHU, DEBOPRIYO BISWAS, CHRISTOPHER ROY MONROE, University of Maryland, College Park — Under the IARPA Logical Qubit (LogiQ) program, we aim to demonstrate a logical qubit using the Bacon-Shor [[9,1,3]] subsystem code. Towards this goal, we built a universal ion-trap quantum processor capable of individual qubit addressing, sympathetic cooling, and ancilla readout. The Bacon-Shor code consists of 9 data qubits, encoding 1 logical qubit, with stabilizer circuits mapped to 4 ancilla qubits capable of correcting any single qubit error. In this talk, we report on the experimental progress made towards implementation of quantum error correction, including the encoding of the logical qubit and stabilizer readout. Additionally, we will lay out the near-term path for achieving multiple rounds of error correction and the prospects for surpassing the quantum error threshold.

L. E. is also funded by NSF award DMR-1747426.
1:27PM M09.00010: Environment noise analysis and real-time decoupling feedback control for a Nitrogen-Vacancy center* ARSHAG DANAGEOZIAN (Presenter), NATHANIEL MILLER, PRATIK BARGE, NARAYAN BHUSAL, JONATHAN P DOWLING, Louisiana State University, Baton Rouge — Nitrogen-Vacancy (NV) centers in diamond have shown to be a very promising candidate for applications of quantum information processing. Given that a small percentage of the Carbon atoms in diamond are Carbon 13 isotopes, we consider how the collective nuclear spins of these atoms affect the nuclear spin state of the Nitrogen 15 atom of the NV center, which is used as our computational qubit. We accomplish this by isolating a three level lambda system out of the electronic structure of the NV center and observing the phenomenon of coherent population trapping. The information gained from this observation is used to find the optimum dynamical decoupling pulse sequence that will help us preserve the state of our computational qubit for a set duration of time.

1:39PM M09.00011: Mediator assisted cooling in quantum annealing* MANUEL PINO GARCIA (Presenter), JUAN JOSÉ GARCÍA-RIPOLL, instituto de fisica fundamental, consejo superior de investigaciones cientificas — We show a significant reduction of errors for an architecture of quantum annealing where bosonic modes mediate the interaction between qubits. These systems have a large redundancy in the subspace of solutions, as there are solutions with arbitrarily bosonic occupancies. We explain how this redundancy leads to a mitigation of errors when the bosonic modes work in the ultra-strong coupling regime. Our numerical simulations predict a large increase of qubits coherence for an specific annealing problem with mediated interactions. We provide evidences that error reduction could also occurs in other types of quantum computers with similar architectures.

Combined continuous error suppression and error correction for quantum annealing

JUAN ATALAYA, BIRGITTA K WHALEY, University of California, Berkeley,
MURPHY YUEZHEN NIU (Presenter), Google — The scheme of Jordan, Farhi and Shor for error suppression during quantum annealing [Phys. Rev. A 74, 052322 (2006)] adds energy penalty terms to an encoded Hamiltonian. The role of these penalty terms is to suppress the occurrence of errors taking the encoded quantum state out of the code space. However, errors can still occur in this scheme, albeit with lowered probability. Here we address the question of whether continuous error correction can enhance the performance of quantum annealing by further correcting the remaining unsuppressed errors. To answer this question we consider the continuous implementation of the three-qubit bit-flip quantum error correcting code, where the error syndrome operators are continuously and simultaneously measured. We show that, under certain conditions, continuous error correction combined with error suppression can lead to significantly improved final ground state fidelities. A notable feature of the combined protocol is that it requires quantum error correction operations which are different from those typically used in the operation of quantum memory under this encoding. We also discuss generalization of these results to other quantum error correcting codes.

Continuous error correction for evolution under time-dependent Hamiltonians

SONG ZHANG, Physics, University of California, Berkeley, JUAN ATALAYA, Chemistry, University of California, Berkeley, MURPHY YUEZHEN NIU, Google, ARMAN BABAKHANI (Presenter), Chemistry, University of California, Santa Barbara, JEFFREY EPSTEIN, HERMAN CHAN, Physics, University of California, Berkeley, BIRGITTA K WHALEY, Chemistry, University of California, Berkeley — We analyze the continuous operation of a three-qubit code designed to protect the coherent evolution in the code space due to an encoded Hamiltonian. Quantum error correction here requires fast detection and immediate correction of errors to avoid spurious coherent evolution in the error subspaces. To detect errors in real time, we smooth the output signals from continuous measurement of the error syndrome operators and use a double threshold protocol for error diagnosis, while correction of errors is done as in the conventional code operation. We evaluate the performance of this protocol under bit-flip errors, quantifying this in terms of fidelity and logical error rate. We show that the optimal error detection time that maximizes the final fidelity can be much shorter than that of the conventional operation, suggesting that continuous implementation is suitable for quantum error correction in the presence of encoded time-dependent Hamiltonians.

11:15AM M15.00001: Intricate instabilities in drying drops  
SRISHTI ARORA, MICHELLE R DRISCOLL (Presenter), Northwestern University — Complex fluid drops dry with a striking variety of patterns, from the ubiquitous coffee ring to a wide range and scale of cracks. Colloidal suspensions are often used in these experiments, and to date, much of this work has been focused on drops with a relatively low volume fraction of particles. The patterns are thought to be controlled by several factors such as surface wetting properties, evaporation kinetics, and particle interactions. Here, we present a study of the drying of a high-volume fraction suspension drop. We work with highly monodisperse silica and polystyrene colloids made in-house and study both the final pattern morphology, as well as the dynamics of crack growth. In this limit of high concentration, we see intriguing structures emerging: a single dimple appears near the center that then connects to growing radial fractures. The patterns we observe depend on both particle size and concentration. Furthermore, even for similarly sized particles, changing the material of the colloidal particle can qualitatively change the morphology of the crack pattern.

11:27AM M15.00002: Droplet traffic in microfluidic networks: Role of droplet collisions and occlusion  
MASOUD NOROUZI DARABAD (Presenter), SIVA A VANAPALLI, MARK W VAUGHN, Texas Tech Univ — The dynamics of droplet flows in microfluidic loop networks are governed by the frequency at which the droplets enter the loop. At low frequencies, droplets always choose the channel with lower hydrodynamic resistance, and droplets interact indirectly through their modifications to resistance of the channels. As the droplet frequency increases, direct droplet-droplet interactions in the junction also contribute to droplet decisions and may force the droplets to the channels with higher hydrodynamic resistance. Collisions are considered the main type of direct interaction between droplets. However, our study suggests that occlusion of the entrance of the channel by droplets also impacts their decisions, even when there is no collision and contact. We study droplet decision rules by use of droplet trajectories and distribution of the droplets in the junction and throughout the network. Also, application of machine learning techniques to identify decision rules and predict the droplet decisions is studied.
11:39 AM M15.00003: Joint effect of advection, diffusion, and capillary attraction on the spatial structure of particle depositions from evaporating droplets*  KONSTANTIN KOLEGOV, Astrakhan State University, LEV BARASH (Presenter), Landau Institute for Theoretical Physics — A simplified model is developed, which allows us to perform computer simulations of the particles transport in an evaporating droplet with a contact line pinned to a hydrophilic substrate. The model accounts for advection in the droplet, diffusion and particle attraction by capillary forces. The parameters chosen correspond to the experiments of Park and Moon [Langmuir 22, 3506 (2006)], where an annular deposition and snakelike chains of colloid particles have been identified. We find that the annular sediment is formed by advection and diffusion transport. The close packing of the particles in the sediment is possible if the evaporation time exceeds the characteristic time of diffusion-based ordering. The chains are formed by the end of the evaporation process due to capillary attraction of particles in the region bounded by a fixing radius, where the local droplet height is comparable to the particle size. At the beginning of the evaporation, the annular deposition is shown to expand faster than the fixing radius moves. However, by the end of the process, the fixing radius rapidly outreaches the expanding inner front of the ring. The snakelike chains are formed at this final stage.

11:51 AM M15.00004: Dynamics and stability of confined levitating droplets  STUART THOMSON (Presenter), MATTHEW DUREY, JOHN W. M. BUSH, RUBEN R. ROSALES, Mathematics, Massachusetts Institute of Technology — Millimetric droplets have been shown to bounce on the surface of a vibrating liquid bath or “walk” by means of self-propulsion through a resonant interaction with their own wave field. When confined to an annular ring, we show that single droplets are observed to exhibit a random walk like behaviour, while the collective dynamics of one-dimensional droplet lattices exhibit canonical features of driven dissipative oscillator systems, namely out-of-phase oscillations and solitary wave propagation. Our experimental results are supported by a stability analysis of an accompanying theoretical model. Some open areas of investigation of potential interest to the dynamical and non-equilibrium systems community will be discussed in conclusion.

12:03 PM M15.00005: Watching Droplets Dry in Wet and Dry Climates  PAUL LILIN (Presenter), PHILIPPE BOURRIANNE, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology MIT — The drying of sessile droplets of colloidal suspensions with particle volume fraction > 5% leads to the formation of fracture patterns. As water evaporates, a solidification front propagates from the edge of the droplet, leaving behind a thin close-packed deposit that eventually covers the entire wetted area. Evaporation-induced stresses generate radial cracks in the deposit that grow towards the droplet center, defining regular petals. These petals bend out of plane to form a blooming flower. Strikingly, while the distance between the cracks is independent of relative humidity, the bending behavior changes drastically when the relative humidity is increased; the curvature of the petals along their width becomes inverted, and the kinetics of the petal bending is modified. We discuss the relation between these changes in structure and kinetics and the deposit thickness.
12:15PM M15.00006: How air deforms the free surface just before disk impact on a liquid bath  DEVARAJ VAN DER MEER (Presenter), UTKARSH JAIN, ANAÏS GAUTHIER, DETLEF LOHSE, Univ of Twente — When a flat disk impacts onto a liquid bath, a layer of air is trapped between the disk and the free surface, a phenomenon known as air cushioning. The air layer is pushed out radially at increasing speeds, causing the water surface to be lifted up towards the approaching disk. This qualitative observation is traditionally ascribed to Bernoulli suction occurring in the low-pressure region created by the large air velocities in the gap. Here, by means of a novel high-speed imaging technique that uses the free surface as a mirror, we quantitatively measure the time evolution of the free surface profile. We show that, whereas the manner in which the surface below the center of the disk is pushed down is consistent with potential theory, this is not the case for the elevation of the free surface below the disk's edge. Instead, the surface lifting appears to be initiated by a Kelvin-Helmholtz instability occurring under the edge of the approaching disk.

12:27PM M15.00007: Dispersion of magnetic beads in flowing droplets.*  ERIC BROUZES, EVAN LAMMERTSE (Presenter), State Univ of NY - Stony Brook — Microfluidic droplets have proven useful for the manipulation and sample preparation of single-cells. However, the droplet toolkit lacks a robust and high-throughput purification module that can maintain partitions. We have demonstrated a proof-of-principle of magnetic purification from flowing droplets using an external magnetic field to partition beads within droplets before asymmetric splitting. Here, we study the interplay between the opposing effects of the magnetic and viscous forces by systematically reporting bead aggregation as a function of design parameters and droplet velocity. We used image-processing to measure aggregate count, size, and shape, allowing us to discover how the distributions of these parameters correlates with changes in experimental conditions. Data have revealed distinct aggregation regimes, in which either the magnetic attraction or the viscous dispersion forces predominate. We further explored the effect of design parameters on the transitions between these regimes both experimentally and via modeling using the dimensionless Mason number (ratio of viscous to magnetic forces). This knowledge will drive the optimization of our droplet purification module with increased throughput.

12:39PM M15.00008: Computational modeling of droplet spreading and coalescence on fiber rails*  
FANG WANG, ULF SCHILLER (Presenter), Clemson University — Flow phenomena in porous media are relevant in many technological applications including emulsion filtration, gas diffusion membranes, and biomedical implants. Fiber materials can be used as filtration membranes with tailored permeability range and controllable pore size distribution. In this talk, we will present lattice Boltzmann simulations of droplet spreading on fiber rails. The simulation results reveal the dependence of the droplet morphology on the fluid volume, fiber size, and contact angle. The transition from a barrel shaped drop to a liquid column shows hysteresis depending on the capillary pressure. We further present preliminary results on capillary trapping of droplets on fiber rails and coalescence induced detachment. We will outline how the results can be used to determine the critical capillary number between trapping and squeezing. We will discuss how these insights can be used to design functional materials for coalescence filtration and other applications.

12:51PM M15.00009: Spreading and evaporation of sessile droplets*  
CHLOE LINDEMAN (Presenter), NICHOLAS SCHADE, SIDNEY ROBERT NAGEL, University of Chicago — We measure the contact angle at which a drop of liquid sitting on a solid surface de-pins as a function of both the concentration of solute in the drop and the amount of time the drop has been allowed to sit on the surface. We do this by removing liquid from a drop via a small hole in the substrate. This procedure does not disturb the liquid surface. However, viewing the drop from the side only allows a view of two diametrically opposed points of the contact line which can create artifacts in the drop width data. Instead, we monitor the footprint of the drop from behind the substrate, using total internal reflection, to obtain simultaneous information about the entire contact line. We find that the initial spreading of the drop on the surface for both upright and inverted sessile drops can last for several minutes but is largely independent of the solute concentration. However, during evaporation we find that the de-pinning angle is highly dependent on concentration and on the waiting time.

*We are grateful for support from NSF MRSEC and NSF GRF DGE-1746045.
1:03PM M15.00010: Electric Discharge Mediated Transient Interfacial Dynamics of a Sessile Liquid Droplet: Plethora of Hydrodynamic Features* BHASKARJYOTI SARMA (Presenter), Mechanical Engineering, Indian Institute of Technology Guwahati, SUNNY KUMAR, Chemical Engineering, MaNIT Bhopal, AMARESH DALAL, DIPANKAR NARAYAN BASU, Mechanical Engineering, Indian Institute of Technology Guwahati, DIPANKAR BANDYOPADHYAY, Chemical Engineering, Indian Institute of Technology Guwahati — We experimentally demonstrate a plethora of hydrodynamic features namely jetting, crowning, and bursting, engendered from capturing electrical discharge inside a sessile liquid droplet. The intense electrical energy deposited inside the conducting droplet in a capacitor like configuration designed with a pin-type anode and thin dielectric film-coated plate type cathode. The high-speed experiments reveal the formation of thermal bubbles from the electrodes and their subsequent evolution till collapse as the dominant mechanism underlying the rich hydrodynamics of the droplet. By tuning the properties of the liquid droplet and the electric field, we can tune the intensity of the discharge and ensuing bubble dynamics, thereby enabling the transition from one regime to another. The position of the electrode can also be tuned to alter the dynamics of shape evolution. The bursting phenomena result from the high electric field and/or high conductivity of the droplet, producing numerous micron size secondary droplets. The explored regimes, specifically bursting of a liquid droplet, are highly relevant for many industrial applications involving enhanced mass transfer such as spray generation, tissue ablation to name a few.

1:15PM M15.00011: High density ratio Lattice Boltzmann simulations of immiscible drop collision* NEERU BALA (Presenter), Northumbria university, HALIM KUSUMAATMAJA, Durham university, CIRO SEMPREBON, Northumbria university — The physics and dynamics of a ternary fluid system are of special interest for a variety of practical applications, including combustion engines, ink-jet printing, and oil recovery. For example, recent experiments demonstrated that if fuel and water droplets are colliding in a combustion chamber, the water can be encapsulated by the fuel. This causes micro-explosions and enhances the burning rate of the combustion chamber. In this contribution, I will present a numerical investigation of the collision between two immiscible droplets by employing a high density ratio (~10^3) Free energy Lattice Boltzmann model, which account for the Inertial effects[1]. I mainly focus on the transition from adhesion to bouncing for a wide range of dimensionless numbers (Weber and Ohnesorge number) and Impact parameter by varying relative surface tension, Impact speed, liquid viscosity and drop size.

11:15AM M16.00001: Algorithm-specific Performance Analysis of Transmon Qubit Devices*
MICHAEL O'KEEFFE (Presenter), MIT Lincoln Laboratory, MORTEN KJAERGAARD, Research Laboratory of Electronics, Massachusetts Institute of Technology, MOLLIE SCHWARTZ, MIT Lincoln Laboratory, GABRIEL SAMACH, AMY GREENE, CHRIS MCNALLY, Research Laboratory of Electronics, Massachusetts Institute of Technology, DANNA ROSENBERG, MIT Lincoln Laboratory, WILLIAM OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology, ANDREW JAMES KERMAN, KEVIN OBENLAND, MIT Lincoln Laboratory — Many demonstrations of quantum algorithms exhibit a tradeoff between the accuracy of the algorithm and the fidelity of the circuit that implements that algorithm. In particular, for algorithms that rely on Trotter decomposition to approximate a target unitary, increasing the number of steps reduces the algorithm error. However, in current devices, uncontrolled interactions with the environment and suboptimal control limit qubit coherence and gate fidelity, which ultimately restrict circuit depth. We analyze algorithm performance on transmon qubit devices using simulated, model-based, and experimentally measured process maps for gates, and compare a number of characterization metrics. In the case of a Trotterized algorithm, we determine the optimal operating point and predict the expected performance in good agreement with experiment.

ALISTAIR MILNE (Presenter), CLAIRE EDMUNDS, CORNELIUS HEMPEL, The University of Sydney, HARRISON BALL, MICHAEL HUSH, ANDRÉ CARVALHO, Q-CTRL, MICHAEL BIERCUK, The University of Sydney — We present a technique for the characterization of noise in oscillator-mediated entangling operations applicable to a range of gate implementations in both trapped ion and superconducting circuit architectures. A major source of error in this class of entangling gates is residual coupling between the system of qubits and the intermediate oscillator modes, often caused by noise on the mode frequencies. In order to characterize this leading source of gate error, we use discrete phase modulation of the field driving the gate to construct sequences of oscillator-phase-space displacements with a band-limited sensitivity to oscillator frequency noise. By displacing the motion of a single trapped $^{171}\text{Yb}^+$ ion, we characterize the sensitivity of these sequences to engineered noise, verifying analytic predictions in the filter function formalism for the observed signal strength. We also perform sensing of intrinsic noise, leveraging tools for spectrum reconstruction based on a singular value decomposition approach developed at Q-CTRL.
**11:39AM M16.00003: Detector Tomography on IBM Quantum Computers and Mitigation of Imperfect Measurement**

YANZHU CHEN (Presenter), MAZIAR FARAHZAD, Stony Brook University, SHINJAE YOO, Brookhaven National Laboratory, TZU-CHIEH WEI, Stony Brook University — We use quantum detector tomography to characterize the qubit readout in terms of measurement POVMs on IBM Quantum Computers IBM Q 5 Tenerife and IBM Q 5 Yorktown. Our results suggest that the characterized detector model deviates noticeably from the ideal projectors. Further improvement on this characterization can be made by adopting two- or more-qubit detector models instead of independent single-qubit detectors for all the qubits in one device. We also find evidence indicating correlations in the detector behavior, i.e. the detector characterization is slightly altered when other qubits and their detectors are in operation. We also discuss how the characterized detectors' POVM can be used to estimate the ideal detection distribution.

**11:51AM M16.00004: Characterizing mid-circuit measurements with a new form of gate set tomography part 1: Theory**

KENNETH RUDINGER (Presenter), TIMOTHY PROCTOR, ERIK NIELSEN, Quantum Performance Laboratory, Sandia National Laboratories, GUILHEM RIBEILL, MATTHEW WARE, LUKE GOVIA, THOMAS A OHKI, BBN Technologies, KEVIN YOUNG, ROBIN BLUME-KOHOUT, Quantum Performance Laboratory, Sandia National Laboratories — While quantum circuits end with measurements, they can also include measurements in the middle. Such mid-circuit measurements are required for real-time feedforward control applications, such as quantum error correction. Understanding error processes in these mid-circuit measurements will be critical for building next-generation quantum processors. To that end, we extend gate set tomography (GST), a highly accurate and self-consistent protocol for diagnosing quantum gate errors, to be able to also characterize mid-circuit measurements. We will describe this extension and demonstrate its success in simulations.

12:27PM M16.00007: Efficient learning of quantum noise* [Invited] ROBIN HARPER (Presenter), STEVEN FLAMMIA, Centre for Engineered Quantum Systems, School of Physics, University of Sydney, JOEL WALLMAN, Institute for Quantum Computing and Department of Applied Mathematics, University of Waterloo — Noise is the central obstacle to building large-scale quantum computers. Quantum systems with sufficiently uncorrelated and weak noise could be used to solve computational problems that are intractable with current digital computers. There has been substantial progress towards engineering such systems. However, continued progress depends on the ability to characterize quantum noise reliably and efficiently with high precision. Here I will discuss a newly introduced protocol that completely and efficiently characterizes the qubit error rates of quantum noise. The method returns an estimate of the effective noise with relative precision and detects all correlated errors. I will show how the reconstruction allows the easy visualization of these correlated errors, enabling both the discovery of long-range correlations in the device and the construction of scalable models that describe the noise in the device to arbitrary precision. These properties of the protocol make it exceptionally well suited for high-precision noise metrology in quantum information processors. Our results are the first implementation of a provably rigorous, diagnostic protocol capable of being run on state of the art devices and beyond. These results pave the way for noise metrology in next-generation quantum devices, calibration in the presence of crosstalk, bespoke quantum error-correcting codes, and customized fault-tolerance protocols that can greatly reduce the overhead in a quantum computation.

1:03PM M16.00008: Long-Sequence Quantum Process Tomography* TAKANORI SUGIYAMA (Presenter), Univ of Tokyo — It is indispensable for development of a quantum computer to further improve accuracy of elemental quantum operations. Details of errors during the operations are useful information for achieving the accuracy improvement. Quantum tomography has a potential to provide such information, but its standard protocols suffer from low reliability due to its high sensitivity against state preparation and measurement (SPAM) errors. Self-consistent quantum tomography such as GST and RSCQT overcomes the low reliability, but it requires too large costs of experiments and data-processing. Here, we propose a new tomographic method with an error amplification, named long-sequence quantum process tomography. We theoretically prove that the error amplification can suppress effects of SPAM errors in arbitrary finite dimensional system, and numerically show that its implementation costs can be practical for one- and two-qubit systems. We also explain how to use the method for characterizing leakage and crosstalk errors, and discuss its practicality beyond two-qubit systems.

1:15PM M16.00009: Spectral Quantum Tomography*  JONAS HELEN (Presenter), KdV Institute / QuSoft, University of Amsterdam, FRANCESCO BATTISTEL, BARBARA MARIA TERHAL, Delft University of Technology — We introduce spectral quantum tomography, a simple method to extract the eigenvalues of a noisy few-qubit gate, represented by a trace-preserving superoperator, in a SPAM-resistant fashion, using low resources in terms of gate sequence length. The eigenvalues provide detailed gate information, supplementary to known gate-quality measures such as the gate fidelity, and can be used as a gatediagnostic tool. We apply our method to one- and two-qubit gates on two different superconducting systems available in the cloud, namely the QuTech Quantum Infinity and the IBM Quantum Experience. We discuss how cross-talk, leakage and non-Markovian errors affect the eigenvalue data.

1:27PM M16.00010: Independent State and Measurement Characterization on Quantum Computers*  JUNAN LIN (Presenter), JOEL WALLMAN, RAYMOND LAFLAMME, University of Waterloo — Correctly characterizing state preparation and measurement (SPAM) processes is a necessary step towards building reliable quantum processing units (QPUs). In this work, we approach this problem by assuming certain structure on SPAM and gate elements, and derive a simple experimental procedure to separately estimate the SPAM error strengths on a QPU. After discussing principles behind the experimental design, we present the protocol along with an asymptotic bound for the uncertainty in the estimated parameters in terms of quantities that can be estimated independently of SPAM processes. We test this protocol on a publicly available 5-qubit QPU and discuss the applicability of our protocol on near-term devices.

1:39PM M16.00011: Extracting Coherence Information From Random Circuits Using “Speckle Purity Benchmarking”  JULIAN KELLY (Presenter), SERGIO BOIXO, ZIJUN CHEN, JOHN M MARTINIS, HARTMUT NEVEN, Google — Budgeting the contributions of coherent and incoherent noise sources is an important component of benchmarking quantum gates. Typically, methods such as Cross Entropy Benchmarking (XEB) or Randomized Benchmarking are used to measure an error-per-gate that includes noise and control errors. These sequences can be extended to quantify the decay of a quantum state due to noise only by measuring the state purity with tomography as described in previous publications. Here, we introduce a method that allows us to extract the same information with exponentially fewer sequences from raw XEB data. We introduce “Speckle Purity Benchmarking” which quantifies the purity via the contrast (or “speckliness!”) of output bitstring probabilities. Pure quantum states generated by the XEB procedure will have high contrast, while incoherent mixtures will have low contrast. Compared to conventional XEB, this procedure can be done with zero information about the actual quantum process. Additionally, this can be scaled to a handful of qubits.
1:51PM M16.00012: Quantum noise spectroscopy for multiaxis noise models*  LEIGH NORRIS (Presenter), Dartmouth Coll, GERARDO A PAZ SILVA, Griffith University, FELIX BEAUDOIN, NanoAcademic Technologies, LORENZA VIOLA, Dartmouth Coll — Characterizing decoherence that arises from coupling to noisy environments is essential for optimized control and error correction strategies in realistic quantum information processors. Motivated by this challenge, quantum noise spectroscopy (QNS) seeks to estimate the spectral properties of noise affecting quantum systems. To date, QNS protocols have largely focused on platforms dominated by dephasing ($T_2$) processes, rendering them inapplicable to systems in which longitudinal relaxation ($T_1$) processes occur on a comparable timescale. To move beyond dephasing-dominated platforms, we extend frequency-comb based QNS to a multi-axis qubit noise model that takes into account both $T_1$ and $T_2$ processes from either classical or quantum environments. Targeted control of the qubit permits a complete spectral reconstruction, including arbitrary cross-axis correlations. Using a novel spherical representation for the noise operators, we show that three noise spectra characterize the reduced dynamics in a regime where the qubit energy splitting is large. This spherical representation enables a straightforward multi-axis extension to QNS protocols based on continuous driving, such as spin-locking.

2:03PM M16.00013: Cayley path and quantum computational supremacy: A proof of average-case #P-hardness of Random Circuit Sampling with quantified robustness*  RAMIS MOVASSAGH (Presenter), Quantum Theory and Algorithms, IBM Research — A one-parameter unitary-valued interpolation between any two unitary matrices is constructed based on the Cayley transformation, which extends our work. The entries of the interpolated unitaries are shown to be low-degree rational functions in the parameter, which we proved can be efficiently determined using an extension of the Berlekamp-Welch algorithm. We prove that this path provides scrambled unitaries with probability distributions arbitrarily close to the Haar measure. We then prove the simplest known average-case #P-hardness of random circuit sampling (RCS), which is the task of sampling from the output distribution of a quantum circuit whose local gates are random Haar unitaries, and is the lead candidate for demonstrating quantum supremacy in the NISQ era. We show that a previous work based on the truncations of the power series representation of the exponential function does not provide practical robustness. Explicit bounds on noise resilience are proved, which on a grid of $\sqrt{n} \times \sqrt{n}$ qubits with circuit depth $\sqrt{n}$ is $2^{O(-n^3)}$, and with constant-depth it is $2^{O(-n^2)}$. Improvements to $O(2^{(-n)/\text{poly}(n)})$ would prove the quantum supremacy conjecture, which may be false.

Session M17 DQI: Hybrid Systems - Spins, Quantum Dots, Microwaves

203 - Karl Petersson, Niels Bohr Inst - Tag(s): Focus
**11:15AM M17.00001: Long-distance entangling gates between quantum dot spins mediated by a superconducting resonator** [Invited] SOPHIA ECONOMOU (Presenter), Virginia Tech — A recent experimental breakthrough in gate-defined quantum dots (QDs) is the strong coupling between the spin and a superconducting resonator mode, mediated through the orbital degree of freedom. This, along with advances in the control of QD spins, indicate a path toward scalable quantum information processing devices. I will present our work on high-fidelity quantum gates, both between spin qubits in neighboring QDs and between remote QDs coupled through a resonator mode. I will also discuss possible paths to multi-qubit gates and quantum algorithms.

*This research is supported by ARO (grant number W911NF-17-0287).*

**11:51AM M17.00002: Resonant Microwave Mediated Interactions Between Distant Electron Spins** FELIX BORJANS (Presenter), XANTHE CROOT, XIAO MI, MICHAEL GULLANS, JASON PETTA, Princeton University — The ability to transfer quantum states and generate entanglement over distances much larger than qubit length scales is an important step towards maximal parallelism and the implementation of two-qubit gates on arbitrary pairs of qubits. Extending qubit interactions beyond the nearest neighbor is particularly beneficial for spin-based quantum computing architectures, which are limited by short-range exchange interactions. Experimental progress towards achieving long-range spin-spin coupling has so far been restricted to interactions between individual spins and microwave photons [1,2,3]. We demonstrate resonant microwave-mediated coupling between two electron spins that are physically separated by more than 4 mm [4]. Our results imply that microwave-frequency photons may be used as a resource to generate long-range two-qubit gates between spatially separated spins.

Interfacing epitaxial rare earth spins with superconducting circuits for high-sensitivity ESR

NOAH JOHNSON, Pritzker School of Molecular Engineering, University of Chicago, SHOBHIT GUPTA (Presenter), Physics, University of Chicago, YUXIANG PEI, Physics, University of Science and Technology of China, MANISH KUMAR SINGH, Pritzker School of Molecular Engineering, University of Chicago, SUPRATIK GUHA, Argonne National Laboratory, DAVID I SCHUSTER, Physics, University of Chicago, TIAN ZHONG, Pritzker School of Molecular Engineering, University of Chicago, JUN YANG, HAITAO ZHANG, Corning Inc. — Hybrid quantum systems interfacing superconducting circuits with solid-state spin ensembles provide a practical route to realizing long-term microwave quantum memories and high-sensitivity inductive electron spin resonance (ESR) detection [1,2]. Specifically, ensembles of erbium ions are a promising platform for quantum networks and transduction [3] due to their long coherence times and telecom band optical transition at 1.54 μm. We report on pulsed and continuous wave ESR spectroscopy measurements of erbium dopants in Y$_2$O$_3$ [4] performed at millikelvin temperature using a microwave resonator. Using a superconducting low impedance resonator on epitaxially grown thin-film Y$_2$O$_3$ will allow for further increased coupling rates between the cavity photons and electron spins on the order of kHz.

High-Speed Quantum Interface with a Quantum Dot Molecule Coupled to a Superconducting Resonator

YUTA TSUCHIMOTO (Presenter), ETH Zurich, ZHE SUN, EPFL, EMRE TOGAN, PATRICK KNÜPPEL, ETH Zurich, AYMERIC DELTEIL, CNRS, STEFAN FÄLT, MARTIN KRONER, KLAUS ENSSLIN, ANDREAS WALLRAFF, WERNER WEGSCHEIDER, ATAC IMAMOGLU, ETH Zurich — Quantum transduction between optical and microwave photons is a key element of quantum networks. An optically-active quantum dot molecule (QDM) has a large electric dipole moment which can couple to microwave (MW) photons in a superconducting (SC) resonator [1]. In our scheme, the following features with a large MW coupling strength realize fast and efficient transduction: (i) a low-Q asymmetric optical cavity encapsulating the QDM ensures high-efficient absorption of incoming optical photons; (ii) fast radiative decay of the QDM finishes the transduction in nanosecond time scales; (iii) the radiative decay channel emits heralding photons upon success of the transduction.

We fabricate an onchip hybrid device consisting of a QDM and a SC resonator and demonstrate a large MW coupling strength. With a modest device improvement, we estimate that a large conversion bandwidth of over 100 MHz with high conversion efficiency is feasible.

12:39PM M17.00006: Theory of spin-orbit mediated hole spin-photon coupling in lateral 
Ge/SiGe quantum dots* VANITA SRINIVASA (Presenter), Center for Computing Research, Sandia 
National Laboratories, RUPERT M LEWIS, LISA A TRACY, TZU-MING LU, WILL J. HARDY, Sandia National 
Laboratories, MITCHELL BRICKSON, ANDREW D. BACZEWSKI, Center for Computing Research, Sandia 
National Laboratories, DWIGHT R LUHMAN, Sandia National Laboratories — Coupling semiconductor 
spin qubits to microwave photons enables long-range quantum information transfer, and strong 
spin-photon coupling has recently been demonstrated for electron spin qubits in silicon [1, 2]. In 
this context, hole spin qubits in lateral Ge/SiGe quantum dots [3, 4] represent an attractive 
alternative platform without valley degeneracy and with strong intrinsic spin-orbit interaction. We 
present an analytical formulation of heavy hole spin-photon coupling mediated by spin-orbit 
interaction in lateral Ge/SiGe quantum dots. Using this formalism, we derive expressions for 
effective single-photon and three-photon coupling within this system and explore the strengths 
of these interactions in experimentally relevant parameter regimes.

High kinetic inductance superconducting cavity for strong coupling of Si/SiGe qubits

Achieving long range coherent interactions between qubits is a milestone of quantum information. In recent years the field of circuit quantum electrodynamics (cQED) has demonstrated long range coupling between superconducting qubits, quantum dots in various semiconductors systems, and even coupling between hybrid systems. Strong coupling between remote qubits requires that the coupling strength be larger than the decoherence rates of both the microwave cavity and the qubits. The coupling can be enhanced by increasing the impedance of the cavity. There are two possible ways to achieve such a goal: first, by using a superconductor with high kinetic inductance; second, by using an array of Josephson junctions, which constrains the application of an external magnetic field. We present a Si/SiGe quantum dot device that combines a high impedance cavity and low impedance leads to reduce the photon leakage through the DC lines. The resonator is made of NbN, a high kinetic inductance superconductor, while the leads are composed of a thin layer of NbN with a thicker layer of Nb on top to reduce the impedance of the leads. The third harmonic can be used to further enhance the coupling strength between the dots and the resonator, which is important for strong coupling.

Coupling silicon qubits via a high-impedance superconducting resonator

Spin qubits in semiconductors like silicon are widely perceived as an ideal technology platform to realize a quantum computer. Their advantages range from the high integration density and the mature manufacturing technology of classical computers, to their long lifetimes and low error rates. On the other hand, spins in semiconductors are not easy to couple over long distances. For this, optical or microwave photons are much better suited. Here, I will describe our experimental efforts to couple two spin qubits through a superconducting microwave resonator. To enlarge the coupling to the qubit charge dipole, we use a high-kinetic-inductance NbTiN nanowire resonator and achieve a large impedance of about 3 kΩ. The high impedance and kinetic inductance come with microwave engineering challenges (e.g. leakage through the gate fanout) and we discuss several approaches to overcome these. Finally, we demonstrate operation of a device with two silicon double quantum dots coupled to the same resonator. Our work opens up opportunities to adapt very powerful and well-developed techniques from circuit quantum electrodynamics and superconducting qubits to the spin qubit world. These opportunities include long-range coupling of spin qubits, and fast spin readout without charge sensors.
**1:15PM M17.00009: Sensitive spin detection using differential squids and on chip microwave waveguide**

JOSIAH COCHRAN (Presenter), GIOVANNI FRANCO-RIVERA, Department of Physics, Florida State University, LEI CHEN, ZHEN WANG, and IRINEL CHIORESCU, Department of Physics — Sensitive detection of spin resonance is essential for achieving coherent spin qubit control. Recent experiments have involved bifurcation resonators, and artificial atoms, which provide sensitivity over a wide frequency range; however, a broadband device is needed for complex materials. A novel differential squid detection method for spin systems on a microwave waveguide is being developed at NHMFL. This method utilizes a superconducting niobium coplanar strip line broadband microwave device coupled with niobium nano-squid devices. A nano-fabricated planar Dayem bridge squid is placed inside an omega loop for sensitive spin detection while a secondary squid is placed far away from the omega loop in order to measure background fields. The differential measurement of the fields measured by the two squids will result in a cancellation of background fields with the goal of having a more sensitive spin detection.

**1:27PM M17.00010: From Transistors to Circuit Realization of a 50mK Analog Amplifier in FDSOI Technology For Measuring Quantum-Dots**

LOÏCK LE GUEVEL (Presenter), GÉRARD BILLIOT, CEA-LETI, MARCO L.V. TAGLIAFERRI, CEA-IRIG, MARCos ZURITA, CEA-LETI, SILVANO DE FRANCESCHI, MARC SANQUER, CEA-IRIG, MAUD VINET, CEA-LETI, XAVIER JEHL, ALOYSIUS G.M. JANSEN, CEA-IRIG, GAËL PILLONNET, CEA-LETI — On-chip cryogenic electronics will accelerate the development of silicon-based quantum bits for quantum computing allowing for faster systematic device tests with various materials and geometries. Low-frequency analog characteristics of single FDSOI 28nm MOSFETs and available passive elements were investigated at cryogenic temperature and compared to actual model predictions. The impact on circuit specifications was studied for a transimpedance amplifier (TIA) operating down to 50mK such as the low-temperature increase of the transistor transconductance leading to a times-5 improvement of the bandwidth. This cryogenic TIA was cointegrated with a quantum dot and compared to a commonly used room-temperature measurement method. Finally, we foresee that the bandwidth of 2.6 kHz can be increased by almost two orders of magnitude while maintaining a 1 μW power consumption, compatible with available cooling power at 100 mK.
1:39PM M17.00011: 3D integrated device architecture for hybrid superconductor-semiconductor quantum dot devices*  
FELIX JULIAN SCHUPP (Presenter), XANTHE CROOT, FELIX BORJANS, XIAO MI, Physics, Princeton University, DANNA ROSENBERG, RABINDRA DAS, DAVID K KIM, ALEXANDER MELVILLE, WILLIAM OLIVER, MIT Lincoln Laboratories, JASON PETTA, Physics, Princeton University — Low internal losses in superconducting resonators require optimized fabrication that was developed in the framework of superconducting qubits. Semiconductor spin-qubit experiments in hybrid super-semi cQED involve semiconducting substrates, gate-oxides, dopants or even micromagnets, which may not be compatible with conventional resonator fabrication leading to higher internal losses. Here we present a 3D integrated super-semi architecture with the superconducting resonator chip fabricated in an environment optimized for superconducting qubits and then flip-chip bonded onto a spin-qubit chip fabricated in its own dedicated facility. Compared to previous cQED experiments with semiconductor spins, we demonstrate reduced photon losses in the few-photon regime and with Al gate-electrodes connected to the resonator. Using a perforated ground plane, we achieve Q=74k at an in-plane magnetic field of 100 mT, which is required for spin-photon coupling.

*Sponsored by ARO (W911NF-15-1-014), and the Gordon and Betty Moore Foundation's EPIQS Initiative (GBMF4535), and NSF (DMR-1409556). The devices were fabricated at MIT Lincoln Laboratories and the Princeton University Quantum Device Nanofabrication Laboratory. We acknowledge helpful discussion with Joe Kerckhoff from HRL Laboratories, LLC.

1:51PM M17.00012: Quantum physics with pulses of radiation*  
KLAUS MOLMER (Presenter), Aarhus University — The ability to control quantum systems and apply special superposition states and entangled states of light and matter is pursued with many experimental platforms and forms the basis of strategies for quantum computing, communication and metrology. I shall discuss the interaction of a quantum system with a pulse of quantized radiation. While crucial for multiple effects in quantum optics and for the entire concept of flying and stationary qubits, quantum optics textbooks do not provide a formal description of this foundational and elementary interaction process. I shall present a new (and simple) theoretical formalism [1] that accounts for the interaction of travelling pulses of quantized radiation with a local quantum system such as a qubit, a spin or a multi-level atom in a cavity. Applications of the theory are shown for recent experiments with optical, microwave and acoustic quantum pulses.

*This research was supported by the the Villum Foundation, the European Union FETFLAG program, Grant No. 820391 (SQUARE),and the U.S. ARL-CDQI program through cooperative Agreement No. W911NF-15-2-0061.
Quantum optical characterization of rare earth ion in superconductor quantum memory* OSAMA NAYFEH (Presenter), Naval Information Warfare Center Pacific — There is a need for the implementation of quantum entangled memory devices that can interface to computational qubit devices via efficient transfer of the low coherence time qubit states to the high coherence spin states of optically active ions. We present characterization in the cryogenic regime of a rare earth ion quantum memory we formed from ion implantation of Neodymium ions in superconducting Niobium Nd$^{3+}$:Nb. We examine via spectroscopy in a cryo-magneto-optical probe station, the 4F3/2 to 4I 9/2 transition in the NIR at 903.4 nm as a function of magnetic and microwave field. We quantify the spin echoes to evaluate T1 and T2 coherence times. We find an improvement when entering the superconducting regime of Niobium at 7.5 K. We study the effects of varying the laser excitation intensity and the microwave and magnetic field strengths on key parameters. The results are consistent with an increase of the spin relaxation and are discussed in accordance with theoretical models.

*We acknowledge support of the NIWC Pacific / Office of Naval Research applied research program. The views and conclusions are not to be interpreted as representing the official policies, either expressed or implied, of NIWC PAC or the U.S. Government. Approved for Public Release.

Session M18 DSOFT: Memory Formation in Matter: From Reading the Past to Designing the Future 205 - Joseph Paulsen, Syracuse University - Tag(s): Invited, Undergrad Friendly

Global Memory From Local Hysteresis and Disorder in a Jammed Solid* [Invited] NATHAN KEIM (Presenter), Physics, Pennsylvania State University, JACOB B HASS, BRIAN KROGER, DEVIN WIEKER, Physics, California Polytechnic State University, San Luis Obispio — Cyclically shearing a soft 2D jammed material can train it with a memory of strain amplitude that can be retrieved later. Using experiments with particles at an oil-water interface, we show that this memory arises from the hysteresis of particles' rearrangements within the material. A stable population of rearrangements is created by training, and disorder ensures that they collectively discriminate among different inputs. These results point to a generic way of encoding memories in hysteresis and disorder, and explain why jammed and dilute suspensions must have different kinds of memory. The behavior in jammed systems is reminiscent of the return-point memory found in ferromagnets and many other systems, but in light of jammed systems' unquenched disorder, it is unexpected.

*This work was supported by NSF DMR-1708870.
11:51AM M18.00002: Memory formation in cyclically deformed glasses* [Invited] SRIKANTH SASTRY (Presenter), MONOJ ADHIKARI, Jawaharlal Nehru Ctr Adv Sci, MUHITTIN MUNGAN, Institut fur angewandte Mathematik, Universität Bonn, IDO REGEV, Jacob Blaustein Institutes for Desert Research,, Ben-Gurion University of the Negev, KARIN ANDREA DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign —

Cyclically shear deformed glasses reach, after a transient regime, periodic orbits involving transitions between basins of energy minima that are visited repeatedly during repeated cycles of deformation, if the amplitude of deformation is not too large. These periodic orbits encode information of their deformation history, and have been shown to retain memory of training at multiple strain amplitudes. Such memory effects, in the presence of plastic rearrangements involved in transitions between basins, is surprising, but appears to be generic. Investigations of the nature of such periodic orbits reveals rich structure, whose analysis permits investigation of the presence or otherwise of features such as return point memory, and suggests protocols by which the encoded information may most efficiently be recovered.

12:27PM M18.00003: Memories in a jar [Invited] ZORANA ZERAVCIC (Presenter), ESPCI Paris — Self-assembly has emerged as a powerful technique for synthesizing structures on the nano and micro-scale. The basis of this development is the use of biopolymers, like DNA, to design specific interactions between multiple species of components, allowing the spontaneous assembly of complex structures. Inspired by biological systems, where the same set of components can assemble many different complexes, we can design mixtures of shared components that have memory of many distinct structures and are capable of assembling each at will. Moreover, these structures can transition one to another when an appropriate switch is triggered. In this talk I will discuss examples of memories modeled as structures made of DNA coated colloidal particles.

1:03PM M18.00004: Yoav Lahini Invited Talk [Invited] —
NIDHI PASHINE (Presenter), University of Chicago — Disordered materials exist in a rugged energy landscape and become trapped in metastable states that are not a global energy minimum. These far-from-equilibrium systems relax slowly as they search for lower-energy configurations. This aging often leads to material degradation and is thus thought of as undesirable. Here I show how this aging can be directed to produce a final state that has advantageous properties and unique functions not typically found naturally [1]. Aging a system subject to external constraints leaves a memory of how it was aged and creates stresses that direct its evolution [2]. Aging obeys a natural “greedy algorithm”: the material simply follows the path of most rapid and accessible relaxation. During aging, the material modifies stressed regions differently from those under less stress. Our goal is to find out what range of behaviors can be achieved by directed-aging protocols. We do this through experiments and with simulations that use simple models of the aging process in disordered networks. Our experimental networks are laser cut from EVA foam and then aged under external stress. (We can apply heat not only to accelerate the aging process but also to help the material retain a memory of how it was aged after the system has been re-cooled.) Using different applied stresses, we can achieve different functions; a memory of the stress protocol can be read out by measuring the mechanical response of the aged systems. Directed aging provides a pathway for modifying and tuning a material's elastic properties in the non-linear as well as the linear regime without having to control the material at the microscopic level.

**Wednesday, March 4, 2020 11:15 AM - 2:15 PM**

**Session M19 FIP: Physics for Development** 207 - R Peterson, University of Colorado, Boulder - Tag(s): Invited, Undergrad Friendly
11:15AM M19.00001: Actions and schemes of support towards developing countries  [Invited]
JOSEPH NIEMELA (Presenter), ICTP — This talk will highlight actions aimed at fostering advanced studies and research in the physical and mathematical sciences in developing countries. An overarching concern is the recurrent problem of scientific isolation that has remained a serious impediment to scientific career growth for those scientists who choose to remain in their home countries. The emphasis will be on programs of the Abdus Salam International Center for Theoretical Physics (ICTP), a category 1 institute of UNESCO that uniquely provides an international forum for the basic sciences for scientists from all UNESCO member states. A wide spectrum of programs has evolved, often with the collaboration of partner institutions and organizations, especially in the case of applied sciences and/or education outreach: A few examples will be drawn from collaborations with the European Physical Society (EPS), through its Physics for Development Group, the International Society of Optics and Photonics (SPIE), and Centro Fermi in Rome. The list of international partners is much longer than this, of course, and working together has proved to be very beneficial, and in some cases crucial, in achieving shared goals.

11:51AM M19.00002: The voice of physics in Africa  [Invited]  JAMES GUBERNATIS (Presenter), Los Alamos Natl Lab — In 2017, the APS's Committee on International Scientific Affairs, in co-operation with the IoP, EPS, ICTP, and SAIP conducted a survey of the state and needs of the physics community in Africa. To bridge communication gaps in and with the African physics community identified by the survey, the APS recently launched the electronically distributed quarterly, The African Physics Newsletter. The launch is timely. A lot is happening in the African physics community. In the past three years, the number of African national physical societies has increased from nine to fifteen. The Abdus Salam International Centre for Theoretical Physics (ICTP) recently opened in Rwanda its first institute in Africa, the East African Institute for Fundamental Physics. In addition, there have been numerous schools, workshops, and conferences. I will highlight several interesting articles that have appeared in the newsletter about these and other events. Subscriptions to the newsletter are free (https://go.aps.org/africanphysics). Recent issues have information about how you can contribute news articles. Whether you are from Africa or just interested in African physics, by subscribing, reading, and especially by contributing, you will be strengthening what has become the voice of physics in Africa.
12:27PM M19.00003: SESAME project in the Middle East: Synchrotron radiation for sciences
[Invited] ESEN ALP (Presenter), Argonne Natl Lab — SESAME is a modern 2.5 GeV electron synchrotron, delivering infrared, ultraviolet, soft and hard x-rays. It is governed by an International Council, and it is funded by its member states. SESAME utilizes its beamlines for general scientific purposes. It has become operational in 2018. Currently three beamlines are dedicated to x-ray absorption spectroscopy, x-ray diffraction and infrared spectroscopy studies. Three additional beamlines are in various stages of development, including a soft-x-ray photoelectron spectroscopy, hard-x-ray tomography and imaging, and a macromolecular crystallography beamlines.

There can be as many as 18 beamlines built at full operations. The beamtime allocation is based on proposal system and it is free of charge for publishable work. Recent examples of published scientific work will be presented.

1:03PM M19.00004: Fundamental physics and accelerator science in developing countries
[Invited] CHRISTINE DARVE (Presenter), European Spallation Source — Education and industrialization are essential to promote positive developments in the least developed countries. The recent evolution of technologies and ICT open the doors to innovative way to support education in developing countries. To enhance the existing African School of Fundamental Physics and Applications (ASP), Massive Open On-line Courses (MOOC) have been prepared and implemented to teach accelerator physics and technologies. The goal of those initiatives is to catalyze the development of world-class institutions through the production of high-quality scientists and engineers to stimulate economic growth and employment creation. Pursuant to this goal, the objective is to produce the next generation of African scientists and engineers by training them in the necessary technical, entrepreneurial and leadership capacities to solve African problems thus contributing to economic and social transformation.
1:39PM M19.00005: Multifunctional Materials for Emerging Technologies [Invited]  FEDERICO ROSEI (Presenter), INRS - Energie et Materiaux — As the age of fossil fuels is coming to an end, now more than ever there is the need for more efficient and sustainable renewable energy technologies. This presentation will give an overview on recent developments in solar technologies that aim to address the energy challenge. In particular, nanostructured materials synthesized via the bottom-up approach present an opportunity for future generation low cost manufacturing of devices [1]. We demonstrate various multifunctional materials, namely materials that exhibit more than one functionality, and structure/property relationships in such systems, including new strategies for the synthesis of multifunctional nanoscale materials to be used for applications in photovoltaics, solar hydrogen production, solar windows and other emerging technologies. [2-23].

Session M20 DFD GSNP: Turbulence & Nonlinear Dynamics 301 - Joel Newbolt, Harvard University
11:15AM M20.00001: Propagating oscillons in a 1Dim. Faraday experiment JOSE WESFREID (Presenter), PMMH, ESPCI PARIS, SAMANTHA KUCHER, PABLO COBELLI, DF-FCEN, University of Buenos Aires — We present the first experimental evidence of the existence of trains of propagating oscillons or localized structures in a 1D Faraday experiment in water. The fluid layer, contained within a thin annular vessel, is excited with a periodic vertical acceleration. Far beyond the threshold for Faraday instability, we have found the formation of localized structures with high nonlinear profile. In particular, we have observed cases where several structures form and propagate around the annulus at a constant velocity while keeping their relative individual position and amplitude. On the other hand, our experiments show that by phase-modulating the acceleration (driving) field it is possible to generate several individual trains of such structures distributed symmetrically over the annular region.

11:27AM M20.00002: Linearly driven flow on a rotating sphere ROHIT SUPEKAR (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology, VILI HEINONEN, KEATON BURNS, JÖRN DUNKEL, Department of Mathematics, Massachusetts Institute of Technology — We investigate a generalized Navier–Stokes (GNS) equation as an analytically tractable minimal model for fluid flows driven by active stresses. The GNS dynamics couple an advective nonlinearity with a generic linear instability and have been shown to permit exact solutions in a stationary 2D spherical geometry. Here, we extend the analysis to actively driven flows on rotating spheres, motivated in part by the complex flow patterns observed in planetary atmospheres. The resulting model generalizes the widely studied barotropic vorticity equation by accounting for internal forcing effects that depend on the flow vorticity itself. We find exact solutions of the GNS equations corresponding to time-independent zonal jets and their superposition with westward propagating Rossby waves. Simulations for large rotation rates confirm that the statistically stationary state is close to these exact solutions. The phase speed of the nonlinear Rossby waves measured in the simulations agrees well with analytical predictions.
11:39AM M20.00003: Numerical Simulations of Gravitational Waves from Early-Universe Turbulence  ALBERTO ROPER POL (Presenter), University of Colorado, Boulder — We perform direct numerical simulations of magnetohydrodynamic turbulence in the early universe and numerically compute the resulting stochastic background of gravitational waves and relic magnetic fields. We obtain kinetic and magnetic energy spectra with greater realism than earlier analytic models. The computed gravitational wave spectra have a new universal form at low frequencies, with more power than suggested by earlier analytical models. The efficiency of gravitational wave production varies significantly with the physical form of the turbulence. For the same amount of turbulent energy, we find that the gravitational wave signal is stronger for irrotational flows than for vortical ones. Our results predict that a signal produced at the electroweak scale is detectable by the planned Laser Interferometer Space Antenna if at least 1% of the total energy density is injected into magnetic fields or turbulent plasma motions.

11:51AM M20.00004: Imaging Fluorescence of He*$_2$ Excimers Created by Neutron Capture in Liquid He II—a New Approach for Turbulent Flow Research*  XIN WEN (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, SHIRAN BAO, Florida State University, LANDEN MCDONALD, University of Tennessee, Knoxville, JOSH PIERCE, Oak Ridge National Laboratory, GEOFFREY L GREENE, Department of Physics and Astronomy, University of Tennessee, Knoxville, MORRIS LOWELL CROW, Oak Ridge National Laboratory, XIN (TONY) TONG, Institute of High Energy Physics, Chinese Academy of Sciences, ANTHONY MEZZACAPPA, Department of Physics and Astronomy, University of Tennessee, Knoxville, RYAN GLASBY, University of Tennessee, Knoxville, WEI GUO, Florida State University, MICHAEL FITZSIMMONS, Oak Ridge National Laboratory — We show unequivocal evidence for formation of He*$_2$ excimers in liquid He II created by ionizing radiation produced through neutron capture. Laser beams induced fluorescence of the excimers. The fluorescence was recorded by a camera at a rate of 55.6 Hz with the ability to determine the location of an event with an uncertainty of 5 microns. The technique enables measurement of turbulence around macroscopic size (liter+) objects or vortex matter in three dimensions under conditions of extreme Reynolds number. Using thermal counterflow techniques we explored excimer flow in cryogenic He.

12:03PM M20.00005: Small-scale Energy Transfer in Turbulence*  JAMES CHEN (Presenter), MOHAMAD CHEIKH, State Univ of NY - Buffalo — The dynamics behind the multi-scale energy transfer in turbulent flows is investigated by introducing morphing continuum conservation laws on the basis of the Boltzmann-Curtiss kinetic theory. The resulting conservation laws reveal the existence of small-scale routes for the flow of energy broadening the view on energy cascade (forward or inverse). The comparison of the turbulence characteristic with the reference study indicates that the turbulence features in both frameworks are equivalent at the global and small-scales. The analysis reveals that at the small-scale both forward and inverse energy cascade exist in homogeneous isotropic turbulence while an overall negative energy flux (forward cascade) is present globally.

*This study is supported by the Air Force Office of Scientific Research under award number FA9550-17-1-0154.

12:15PM M20.00006: Optimal perturbations for transient growth in a 3D stratified channel using nonlinear direct-adjoint looping  RITABRATA THAKUR (Presenter), International Centre for Theoretical Sciences, Tata Institute of Fundamental Research, ARJUN SHARMA, Sibley School of Mechanical and Aerospace Engineering, Cornell University, RAMA GOVINDARAJAN, International Centre for Theoretical Sciences, Tata Institute of Fundamental Research — Laminar shear flows often transition to turbulence at Reynolds numbers smaller than that of their first linear instability. The underlying mechanism can be transient algebraic growth, either linear or nonlinear in nature. We obtain the maximum perturbation energy growth in a three-dimensional heated plane channel. A nonlinear technique of direct-adjoint-looping is employed to numerically achieve this. With this technique, we also obtain the initial velocity and temperature perturbation structure that leads to this growth. The energy growth associated with this optimal can be large enough to push the flow to turbulence. We study the effect of varying stratification strengths (gradient Richardson numbers), Reynolds numbers, and target times on the structure of the optimal. We show similarity or the lack thereof between the optimal perturbations for small (linear optimal) and large (non-linear optimal) initial energies.
12:27PM M20.00007: Role of elasticity and solvent viscosity on the center mode instability in pipe Poiseuille flow of Oldroyd-B fluids. INDRESH CHAUDHARY (Presenter), IIT Kanpur, GANESH SUBRAMANIAN, JNCASR Bangalore, VISWANATHAN SHANKAR, IIT Kanpur — A linear stability analysis of pipe Poiseuille flow of an Oldroyd-B fluid has been carried out to investigate the interplay among fluid inertia, elasticity and the ratio of solvent to the total viscosity. The stability has been analyzed for axisymmetric perturbations using pseudospectral and shooting methods. The system is found to be linearly unstable at the Reynolds numbers relatively lower than the values for which the transition to turbulence is typically observed for the Newtonian pipe flows. The system has been analyzed for the vast ranges of the wavelength, Reynolds number, elasticity number and the ratio of solvent to the total viscosity. In the limit of low elasticity, the fluctuations are found to be near the axis in the flow domain; hence we refer to this unstable mode as ‘centre mode’. This unstable mode stabilizes in the UCM limit (absence of solvent). Various scalings among the threshold and critical parameters have been established. Comparisons of the present results with those from the experimental studies in the existing literature have been made to establish theoretical evidence for the instability in viscoelastic flows which can potentially turn the steady laminar base flow into a turbulent one.

12:39PM M20.00008: Turbulence generation through an iterative cascade of the elliptical instability RYAN MCKEOWN (Presenter), Harvard University, RODOLFO OSTILLA MONICO, Mechanical Engineering, University of Houston, ALAIN JACK PUMIR, ENS Lyon, MICHAEL PHILLIP BRENNER, SHMUEL RUBINSTEIN, Harvard University — Turbulent flows are notoriously difficult to study due to the lack of a mechanistic framework that encapsulates how vortices interact, break down, and form new vortices, driving the cascade of energy down to the dissipative scale. We demonstrate the existence of a novel mechanism in which two counter-rotating vortices violently collide and break down, leading to the rapid development of a turbulent energy cascade mediated by iterations of the elliptical instability. We probe the full 3D dynamics of this complex breakdown by conducting both experimental flow visualizations and numerical simulations of colliding vortex rings. The onset of the elliptical instability generates an ordered array of secondary vortex filaments that are perpendicular to the original cores. Adjacent secondary filaments counter-rotate and interact with each other. In the high-Reynolds number limit, we observe another iteration of this instability, whereby even smaller tertiary filaments form in the same manner. The energy spectrum of this breakdown exhibits Kolmogorov scaling, E(k) ~ k^(-5/3), a hallmark of homogeneous isotropic turbulence. Clear evidence of this mechanism of vortex generation has also been recently observed over many length scales in recent numerical simulations of forced turbulence.
12:51PM M20.00009: 3D Visualization of Reconnections in Vortex Ring Collision  JOEL W. NEWBOLT (Presenter), RYAN MCKEOWN, SHMUEL RUBINSTEIN, Harvard University — Vortex interactions appear in many fluid systems, from the wake behind an airplane in flight to that of a ship moving through the water. This is because friction between a fluid and a solid boundary can generate vorticity in the fluid. A simple example is the vortex ring, yet even the interaction between two vortex rings can cause instabilities that break the symmetries of the flow. When two vortex rings of equal size collide head-on at moderate Reynolds number, the rings undergo an instability that brings the two vortex cores together at several points around the circumference of the rings. As the two vortex cores touch, there is an annihilation of the opposing vorticity from each ring which results in reconnection between the original two vortex rings. These reconnections have a complicated 3D structure that is difficult to measure experimentally, leading many studies to focus on numerical simulation. By scanning a laser sheet across the collision of two dyed vortex rings, we are able to reconstruct a tomographic 3D visualization of the vortex ring collision and reconnection as it occurs. This 3D visualization allows for comparison between the structure of reconnections in experiment and the predictions from numerical models.

1:03PM M20.00010: Dynamics and deformation of a vortex during pairing under the influence of external shear  PATRICK FOLZ (Presenter), University of California, San Diego — In general, a given vortex in a real flow may interact with other nearby vortices as well as large-scale background flows such as shear. To better understand the behavior of the vortices in such flows, the dynamics and interactions of a pair of two-dimensional like-signed viscous vortices having a circulation ratio $\Lambda = \Gamma_1/\Gamma_2 = (a_1^2/a_2^2)(\omega_1/\omega_2)$ under the influence of a linear background shear having vorticity $\omega_2$, of strength $\zeta = \omega_5/\omega_2$, with finite viscosity, are investigated numerically. The main flow regimes, pairing and separation, are identified and briefly discussed; this work focuses on vortex-dominated pairings, in which the shear is observed to primarily aid or hinder the onset of detrainment, which precipitates the main convective interaction that results in a single final vortex. During such pairings, the vortices revolve with varying peak-peak distance $b$, such that the strain rate each vortex induces on the other varies in time, while the orientation of this vortex-induced strain rate relative to that of the background shear also varies. This results in a periodic deformation effect. The nature of this effect is examined and discussed. The subsequent pairing outcomes are then outlined and characterized in terms of key parameters.
Two-dimensional (2d) and quasi-2d flows occur at macro- and mesoscale in a variety of physical systems. Examples include stratified layers in Earth's atmosphere and the ocean, soap films and more recently also in dense bacterial suspensions, where the collective motion of microswimmers induces patterns of mesoscale vortices. A characteristic feature of turbulence in 2d and thin fluid layers is the occurrence of an inverse energy cascade. In case of weak large-scale friction the inverse energy cascade results in the formation of large-scale coherent structures, so-called condensates, which can take the form of jets or large-scale vortices. With a view towards atmospheric physics, we study the formation of the condensate in a rotating thin layer with free-slip boundary conditions as function of the amplitude of the forcing, and we quantify the effect of large-scale friction. Direct numerical simulations show that the condensate appears in a first-order non-equilibrium phase transition, with rare transitions occurring towards and away from the condensate state. This clearly distinguishes between 2d dynamics and that of thin fluid layers, as condensate formation 2d turbulence proceeds by means of a second-order non-equilibrium phase transition.

Session M21 GERA: Energy Related Catalysis and Photo/Thermo effects 302
High throughput theoretical and experimental screening of photocatalysts for water splitting

*JULIAN FANGHANEL (Presenter), QUINN CAMPBELL, Department of Materials Science and Engineering, The Pennsylvania State University, CATHERINE BADDING, Department of Chemistry and Chemical Biology, Cornell University, HUA[I YU WANG, Department of Materials Science and Engineering, The Pennsylvania State University, JARED MONDSCHEIN, Department of Chemistry, The Pennsylvania State University, YIHUANG XIONG, NICOLE HALL, Department of Materials Science and Engineering, The Pennsylvania State University, KRITI SETH, Department of Chemistry, The Pennsylvania State University, ANDRÉS VILLARINO, Department of Chemistry and Chemical Biology, Cornell University, XAVIER QUINTANA, Department of Materials Science and Engineering, The Pennsylvania State University, T[IFFANY RIVERA, Department of Chemistry, The Pennsylvania State University, NATHAN SMITH, MEGAN PENROD, Department of Materials Science and Engineering, The Pennsylvania State University, IURII TIMROV, MATTEO COCOCCIONI, Theory and Simulation of Materials (THEOS), École Polytechnique Fédérale de Lausanne, SENORPE ASEM-HIABLIE, Institutes of Energy and Environment, The Pennsylvania State University, VENKATRAMAN GOPALAN, Department of Materials Science and Engineering, The Pennsylvania State University, HÉCTOR ABRUÑA, Department of Chemistry and Chemical Biology, Cornell University, RAYMOND EDWARD SCHAAK, Department of Chemistry, The Pennsylvania State University, ISMAILA DABO, Department of Materials Science and Engineering, The Pennsylvania State University — We apply a high-throughput computational screening process with feedback from experimental results to identify promising photocatalysts for water splitting. Using an automated linear response framework for predicting Hubbard parameters, we overcome the limitations of local and semilocal density-functional theory calculations in predicting band gaps. From our computational screening, we identify 28 promising photocatalysts, many of which have not been previously reported. We then synthesized some along with chemical derivatives from our selection, for a total of 18 synthesized materials using solid-state synthesis techniques. We report hydrogen production in a number of the materials tested for photocatalysis using gas chromatography; many of which have been previously unreported for water splitting. We further measure cyclic voltammograms, demonstrating high levels of photoactivity in several samples.

Computations for this research were performed on the Pennsylvania State University’s Institute for CyberScience Advanced CyberInfrastructure (ICS-ACI).
11:27AM M21.00002: High-Throughput DFT of Solar Thermochemical Perovskite Oxides: Comparison of Computed and Experimental Thermodynamics*  BIANCA BALDASSARRI (Presenter), JIANGANG HE, CHRISTOPHER MARK WOLVERTON, Northwestern University — Thermochemical water-splitting (TWS) offers a renewable alternative to fossil fuels by utilizing solar energy for the production of hydrogen via a two-step redox reaction sequence involving a metal oxide. Current and past efforts have been aimed at identifying the best compounds for such reactions based on thermodynamic and kinetic properties. In this context, high throughput density functional theory (HT-DFT) represents an attractive tool for a quick and efficient refinement of the pool of potential candidates. This work concentrates on ABO3 perovskite compounds, conducting a high throughput study of their reduction enthalpy, and selecting a group of 12 compounds for a critical, quantitative comparison with experimental data generated by our collaborators. Building on, and significantly extending, a previous HT-DFT study, we have confirmed the use of high throughput DFT as a reliable method for screening for potential candidates for water splitting reactions, while also demonstrating the importance of choosing the appropriate structure for the compound under investigation. Furthermore, we provided predictions for several promising compounds, highlighting the crucial role played by the B site cation and its oxidation state.

11:39AM M21.00003: Increased Hydrogen Production of Perovskite Solar Thermochemical Water Splitters by Joint Reduction on A and B Sites  ROBERT BELL (Presenter), SARAH SHULDA, DAN PLATTENBERGER, National Renewable Energy Laboratory & SLAC Linear Accelerator Laboratory, SAI GAUTAM GOPALAKRISHNAN, Princeton, NICHOLAS STRANGE, PHILIP ANTHONY PARILLA, National Renewable Energy Laboratory & SLAC Linear Accelerator Laboratory, EMILY CARTER, University of California, Los Angeles, ANTHONY MCDANIEL, Sandia National Laboratory, ELLEN B STECHEL, Arizona State University, DAVID S GINLEY, National Renewable Energy Laboratory & SLAC Linear Accelerator Laboratory — Oxide based solar-thermochemical hydrogen (STCH) production operates by cyclic creation of oxygen vacancies that then react with steam to produce hydrogen. STCH performance is strongly dependent on both the change in vacancy stoichiometry (��) during cycling (��) and the output gas ratio of H₂/H₂O. Perovskites (ABO₃) have been investigated by controlled synthesis and X-ray adsorption spectroscopy (XAS) as STCH oxides in-part due to their tunable cation-dependent oxygen vacancy enthalpies. Classically, only one site, either A or B, has been responsible for charge compensation of oxygen vacancies. However, in this work we investigate water splitting by computationally designed perovskites expected to possess dual reduction on both A and B sites, which is predicted to increase vacancy formation, and hence performance, through increased formation entropy of vacancies. In-operando X-ray absorption spectroscopy (XAS) results at Ce L-edge and Mn and V K- and L-edges will demonstrate changing oxidation states of A and B site elements. Additional in-operando diffraction and mass loss experiments will correlate and structural changes with cation reduction. This work will demonstrate the effectiveness of dual site reduction as a design criterion for STCH material design.
Photocatalytic Reaction driven by hot electrons on Plasmon-resonant Grating Nanostructures* YU WANG (Presenter), INDU ARAVIND, ZHI CAI, LANG SHEN, Univ of Southern California, GEORGE GIBSON, Physics, University of Connecticut, JIHAN CHEN, BO WANG, HAOTIAN SHI, BOXIANG SONG, Univ of Southern California, ERNEST GUIGNON, Ciencia Inc, NATHANIEL CADY, Nanoscale Science & Engineering, SUNY Polytechnic Institute, WILLIAM PAGE, ARTURO PILAR, Ciencia Inc, STEVE CRONIN, Univ of Southern California — We demonstrate hot electron injection in a Ag-based plasmon resonant grating nanostructure. By varying the incident angle of irradiation, sharp dips are observed in the photoreflectance with p-polarized light when there is wavevector matching between the incident light and the plasmon resonant modes of the grating. With 633nm light, we observe a 12-fold enhancement in the photocurrent between resonant and non-resonant polarizations at incident angles of ±7.6° from normal. At 785nm irradiation, we observe similar resonant profiles to those obtained with 633nm wavelength light but with a 44-fold enhancement factor. Using 532nm light, we observe two resonant peaks (10X enhancement) in the photocurrent at 19.4° and 28.0° incident angles. Finite difference time domain (FDTD) simulations of these grating structures confirm the resonant profiles observed in the angle-dependent spectra of these gratings and provide a detailed picture of the electric field profiles on and off resonance.

*Army Research Office (ARO) Award No. W911NF-17-1-0325 (Y.W.), National Science Foundation (NSF) Award No. CBET-1512505 (L.S.), Air Force Office of Scientific Research Grant No. FA9550-15-1-0184 (I.A), Department of Energy (DOE) Award No. DE-FG02-07ER46376 (Z.C), and ACS-PRF Grant #55993-ND5 (J.C.).

Using density functional theory to evaluate Ca-Ce-M-O (M = 3d transition metal) oxide perovskites for solar thermochemical applications SAI GAUTAM GOPALAKRISHNAN (Presenter), Mechanical and Aerospace Engineering, Princeton University, ELLEN B STECHEL, ASU Lightworks® and the School of Molecular Sciences, Arizona State University, EMILY CARTER, Office of the Chancellor, University of California Los Angeles — Solar thermochemical (STC) processes that use redox-active, off-stoichiometric, transition-metal oxide substrates to split water and/or CO₂ are an efficient way to generate reusable fuels or fuel precursors using concentrated solar flux. However, STC processes require oxides that are thermally stable, tolerate high oxygen off-stoichiometry, and be resistant to adverse phase transformations. In this work, we explore the chemical space of Ca-Ce-M-O (M=3d transition metal) oxide perovskites as potential STC candidates using density functional theory based calculations. Specifically, we use the strongly constrained and appropriately normed (SCAN) functional, with an appropriately determined Hubbard U correction to reduce the self-interaction errors of the highly-correlated 3d and 4f electrons within M and Ce, respectively. While, we consider Ca and Ce on the A site (in an ABO₃ perovskite framework) because of their similar ionic radii and the potential redox-activity of Ce, we consider all 3d transition metals except Zn on the B-site. Subsequently, we evaluate the oxygen vacancy formation energy, electronic properties, and thermodynamic stability of ternary Ca-M-O, Ce-M-O, and quaternary Ca-Ce-M-O perovskites and identify promising candidates that can improve STC efficiencies.
12:15PM M21.00006: Nanoparticle Enhancement of Plasma-driven CO\textsubscript{2} reduction to Higher-order Hydrocarbons  
SISI YANG (Presenter), BOFAN ZHAO, INDU ARAVIND, ZHI CAI, SRIRAM SUBRAMANIAN, MARTIN GUNDERSEN, STEVE CRONIN, Univ of Southern California — By discharging ns high voltage pulses across an insulating substrate containing metal nanoparticles, we observe a significant enhancement in the generation of plasma through local field enhancement on the surface of the nanoparticles. Electromagnetic simulation shows local field enhancement on the order of 10X. Since the plasma is initiated by field emission of electrons, which depends exponentially on the electric field, we believe that this 10-fold increase can result in several orders of magnitude increases in the generation of plasma. By discharging ns high voltage pulses in CO\textsubscript{2}-saturated water, we observe CO\textsubscript{2} reduction to higher-order hydrocarbons. Here, the plasma emission spectra exhibit Swan bands, which correspond to C\textsubscript{2} species, indicating that, in addition to reducing CO\textsubscript{2}, C\textsubscript{2}-species are formed, presenting the exciting possibility of converting a notorious greenhouse gas into an energy dense hydrocarbon fuel. We have also performed cryogenic NMR spectroscopy of various products in water and liquid ion chromatography(IC) ex-situ. Here, we observe clear peaks corresponding to formic acid, and acetic acid, which corresponds to a C\textsubscript{2}-hydrocarbon species. We have also observed the presence of oxalates (i.e., C\textsubscript{2}O\textsubscript{4}^{2-}), which is C\textsubscript{2} species, at approximately 150g/L using IC.

12:27PM M21.00007: Excitonic Effects in Absorption Spectra of Carbon Dioxide Reduction Photocatalysts*  
TATHAGATA BISWAS (Presenter), TARA BOLAND, ARUNIMA SINGH, Arizona State Univ — We study the quasiparticle bandstructure and excitonic properties of 52 selected materials. These materials were recently shortlisted for their potential as a photocatalyst in CO\textsubscript{2} reduction, through rigorous first-principles computation-based screening strategy. Many body perturbation theory within GW approximation has been used to explore the electronic structure of these materials. We use state-of-the-art Bethe-Salpeter formalism to inspect the excitonic effects. A high-throughput computational workflow using the “atomate” package has been used to perform the GW-BSE calculations and analyze the results. We validate our results with 10 previously studied materials found in literature and report the results for 42 promising unexplored materials. Furthermore, our study investigates the suitability of these materials in applications such as CO\textsubscript{2} photo-reduction, efficient solar cells, etc. by examining their absorption spectra and excitonic properties.

*This work used the Extreme Science and Engineering Discovery Environment (XSEDE), supported by National Science Foundation grant number ACI-1548562, through award number TG-DMR150006.
12:39PM M21.00008: Understanding the C1 Selectivity Descriptors in Electrochemical CO2 Reduction for Production of Solar Fuels* MICHAL BAJDICH (Presenter), MICHAEL T. TANG, HONGJIE PENG, PHILOMENA SCHLEXER LAMOUREUX, FRANK ABILD-PEDERSEN, SLAC - Natl Accelerator Lab — Generating solar fuels from carbon dioxide (CO2) and water offers an intriguing opportunity for a carbon-neutral, sustainable, and scalable source of energy. Electrochemical reduction of CO2 is a key reaction for the production of liquid fuels, but it follows a complex reaction network. Even for products with a single carbon atom (C1 products), two bifurcated pathways exist. In this study, we combine evidence from the experiments with a theoretical analysis of energetics to rationalize that not all steps in the reduction of CO2 are electrochemical. This insight enables us to create a selectivity map for two-electron products (carbon monoxide (CO) and formate) on elemental metal surfaces using only two energy descriptors. In the further reduction of CO*, we also find bifurcated pathway one for CHO* and one for COH*. We find Cu to be the only elemental metal capable of reducing CO2 to products beyond 2e− via the proposed COH pathway. Our analysis also rationalizes experimentally observed differences in products between the thermal and electrochemical reduction of CO2 on Cu.

*This material is based upon work performed by the Joint Center for Artificial Photosynthesis, a BES DOE Award # DE-SC0004993 and the use of the computer time allocation at NERSC DOE Award # DE- AC02-05CH11231.

12:51PM M21.00009: CO2 conversion on defect-induced single-layer h-BN* DUY LE (Presenter), TAO JIANG, Department of Physics, University of Central Florida, KATERINA L CHAGOYA, Department of Mechanical and Aerospace Engineering, University of Central Florida, DAVID J. NASH, RICHARD BLAIR, Florida Space Institute, University of Central Florida, TALAT S. RAHMAN, Department of Physics, University of Central Florida — Finding effective heterogeneous catalysts, consisting of abundant elements, for hydrogenation of waste gas carbon dioxide into value added molecules is a challenging task for global energy and sustainability solutions. In this talk, we will present results of a closely coupled computational and experimental effort that shows that reconfiguration of the frontier orbital in defect-laden hexagonal boron nitride (dh-BN) can effectively activate the CO2 molecule for hydrogenation. Our density functional theory (DFT) based calculations of reaction pathways and activation energy barriers demonstrate that activation occurs through back-donation to the π* orbitals of CO2 from frontier orbitals (defect state) of the h-BN sheet localized near a nitrogen vacancy (VN). Subsequently, CO2 is hydrogenated to formic acid (HCOOH) and methanol (CH3OH). These results were experimentally confirmed in a reactor designed to continuously produce defects in h-BN by the application of mechanical force. We find temperature-dependent switchable catalysis with formic acid formation observed at reaction temperatures above 160 °C and methanol formation at lower temperatures (as low as 20 °C).

*This work is supported in part by DOE grant DE-FG02-07ER15842
1:03PM M21.00010: Optimizing Power Output of Graphene Energy Harvesting  FERDINAND HARERIMANA (Presenter), PAUL M THIBADO, Univ of Arkansas-Fayetteville — Free standing graphene has been found to invert its curvature over time by researchers at the University of Arkansas. Recently, they have been working on building a chip for converting kinetic energy from the system to electrical energy by using a variable capacitor principle. In this study we investigate the macroscopic models of graphene energy harvesting (GEH) with the goal of finding the output power optimal conditions. We present a GEH circuit model, which contains a manually-driven variable capacitor in series with a DC voltage source, diodes components for rectification, and a storage capacitor for storing the harvested charge. The DC experiment, however, presents difficulties with measuring efficiency, controlling the frequency, and reaching high voltage limits. Therefore, we design an equivalent AC experiment, in which we replace the DC voltage with an AC source and the variable capacitor with a fixed one. Our power studies reveal that the maximum efficiency of is reached at the maximum power output point, which happens at the time of times the time constant of the circuit.

1:15PM M21.00011: Defect chemistry in La/Sr-based oxyhydrides* ANDREW ROWBERG (Presenter), Materials Department, University of California, Santa Barbara, LEIGH WESTON, Energy Technologies Area, Lawrence Berkeley National Laboratory, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — Oxyhydrides in the series La$_{2-y}$Sr$_y$LiH$_{1+y}$O$_{3-y}$ have attracted interest for solid-state hydrogen electrolytes on account of their high H$^-$ ionic conductivity. Here, we use first-principles calculations to examine the prevalence of native point defects in La$_2$LiHO$_3$ and Sr$_2$LiH$_3$O and connect our results to ionic transport properties. We find that both oxyhydrides have high concentrations of point defects. Sr$_2$LiH$_3$O, in particular, experiences a stabilizing effect from disorder caused by the presence of pairs of compensating species, such as O$_{H^-}$ and V$_{H^+}$, or O$_{H^-}$ and H$_i^{+}$. V$_{H^+}$ serves as the most important point defect for ionic conduction; its presence explains the high conductivity in Sr$_2$LiH$_3$O. We identify O-rich and moderately H-rich synthesis conditions as optimal for ensuring stability and maximizing ionic conductivity.

*This project was supported by DOE and NSF.

MASANORI KANEKO (Presenter), KOICHI YAMASHITA, Kyoto Univ — The visible light region accounts for approximately 40% of the energy of solar radiation. Therefore, tungsten oxide, which is the visible light-driven photocatalysts, has been receiving much attention. It is known that photoexcited tungsten oxide has long-lived photocarriers, which have an important role in photocatalytic reactions. In a recent study, the dynamics of photoelectrons and structural changes of tungsten oxide has been observed by femtosecond transient XAFS. They have found that the electronic state was the first to change followed by the local structure, which was affected within 200 ps of photoexcitation. However, little is known about how the structure changes and how it affects the photocarrier. Therefore, in this study, tungsten oxide was investigated by performing first-principles calculations based on density functional theory and many-body perturbation theory. We discuss the light absorption related by excitation, photoexcited carriers, and structural changes from electronic, optical, phonon, electron-phonon properties, et cetera.

*This research was supported by MEXT as "Priority Issue on Post-K computer"(Development of new fundamental technologies for high-efficiency energy creation, conversion/storage and use).

1:39PM M21.00013: Ab-initio investigation of a novel photocathode: bulk and surface properties of CuFeO₂

MATTEO FERRI (Presenter), SISSA, JOSHUA DAVID ELLIOTT, University of Manchester, MATTEO FARNESI CAMELLONE, STEFANO FABRIS, SIMONE PICCININ, CNR-IOM — Photoelectrochemical (PEC) devices offer the possibility to convert solar radiation into chemical fuels, mimicking the natural process of photosynthesis. Recent experiments have highlighted CuFeO₂ (CFO) as a promising candidate in the role of photocathode [1, 2], yet in spite of these encouraging results, improvement in the catalytic activity and charge separation is required. In this work, we present a theoretical characterization of CFO based on the DFT+U approach and refined with hybrid calculations. We characterized the stability of bulk CFO with respect to other iron and copper oxides in air and in an aqueous environment, coupling DFT with ab-initio thermodynamics. On this basis, we studied the formation energy of native defects of CFO. The low formation energy of a copper antisite defect could be detrimental for the PEC operations of CFO since states inside the energy gap could favour the electron-hole recombination. Based on our thermodynamic screening we focused our investigation on two energetically relevant surfaces. We interfaced these surfaces with water and we performed ab-initio molecular dynamics simulations to determine the alignment between the band edges and the redox potentials of water.

1:51PM M21.00014: Linking Nanoscale Grain Boundary Composition and Energetic Properties in Ceramic Oxides*  
TARA BOLAND (Presenter), ARUNIMA SINGH, PETER REZ, PETER CROZIER, Arizona State Univ — Ceramic oxides are used for a wide variety of technologically relevant applications from electrochemical devices, novel resistive switching devices and oxygen sensors. Applications such as these typically rely upon the ability of oxides to conduct ions efficiently through the lattice. Recent nanoscale compositional characterization of the GB composition has shown different nominal concentrations of solutes could result in orders of magnitude increase in GB ionic conductivity relative to the undoped samples. This study aims to predict the optimal dopants that, when present in high concentrations, increase the ionic conductivity across the GB. Computational modeling is employed using density functional theory to optimize the GB interfacial structure for various GB misorientations in CeO2. This study further develops our understanding of high solute GB composition enabling the development of methods such as selective doping to improve macroscopic ionic conductivity for both the grain and GB.

Session M22 DBIO DCP DMP DPOLY: Biomaterials IV: Nano and Bioinspired materials 303 - Pupa Gilbert, University of Wisconsin - Madison - Tag(s): Focus

DEBAPRIYA PINAKI MOHANTY (Presenter), School of Industrial Engineering, Purdue Univ, KOUSHIK VISWANATHAN, Department of Mechanical Engineering, Indian Institute of Science, India, ANIRUDH UDUPA, School of Industrial Engineering, Purdue Univ, ANIL CHANDRA, Mechanical Engineering, B M S College of Engineering, India, SRINIVASAN CHANDRASEKAR, School of Industrial Engineering, Purdue Univ — The undesirable effects of plastics on the environment are well-documented. One of the common uses of plastics is in products with short-term uses in the food industry, e.g., cutlery and plastic bags. This has focused interest in finding bio-degradable alternatives for these products that are mechanically, physically and aesthetically equal to if not superior to plastics. Areca palm sheath is a possible plant-based green alternative that can be used in the manufacture of plates and bowls. In fact, it has been in use in India for more than a century despite little knowledge about its mechanical behavior. To advance the use of these materials, it is critical to understand their formability and the nature of diffusion of water through the sheath. In this study, we report on the results of an investigation of their formability. Using measurements carried out on plates and bowls, we show that Areca sheaths are quite deformable and capable of withstanding strains as high as 0.7. The interplay between moisture content and formability is quantified. The formability and failure strains are related to the microstructure e.g., fiber, porosity of the palm sheath. The results show interesting opportunities for creating a wide range of environmentally friendly cutlery and packaging products.
11:27AM M22.00002: Polycarbonate Mold Copying Technique to Fabricate Microengineered Devices for Biophysical Studies  UTKU SONMEZ (Presenter), PHILIP R LEDUC, Carnegie Mellon Univ — Microengineered devices made out of high aspect ratio flexible polymers provide very useful experimental means to study biophysical properties of living entities at various scales ranging from single cells to multicellular small organisms by enabling application of precise forces and deformations. However, fabrication of such devices require expensive and cumbersome mold fabrication procedures which limits appreciation of this technology by experimental biophysicists. Here, we report a novel microfabrication technique that we have developed for benchtop fabrication of microengineered devices outside the cleanroom so that they can be cheaply fabricated with high throughput. The polycarbonate (PC) mold copying technique consists of reverse molding of Polydimethylsiloxane parts fabricated from master molds in order to combine different microstructures into single monolithic PC mold for subsequent flexible polymer microdevice fabrication. We have characterized dimensional fidelity of the microstructures fabricated by this technique and fabricated various microstructures with feature sizes ranging from submicron level to tens of centimeters. Lastly, we used these devices to study fibroblast alignment dynamics, Young's Modulus of Drosophila embryo and cardiomyocyte contractility.

11:39AM M22.00003: The Design and Modeling of Adsorption Based Filters and the Bioremediation of Heavy Metal Contaminated Water*  CHRIS MCCARTHY (Presenter), Mathematics, BMCC City University of New York — I will discuss kinetic models of adsorption, as well as our mathematical models of such filters. These mathematical models have been developed in support of our interdisciplinary lab group and can be used in filter design. Our group conducts research into bio-remediation of heavy metal contaminated water via filtration. The filters are constructed out of biomass, such as spent tea leaves. The spent tea leaves are available in large quantities as a result of the industrial production of tea beverages. The heavy metals bond with the surfaces of the tea leaves (adsorption). I will compare the models’ predictions to data obtained from computer simulations and experimentally by our lab group.

*CUNY Collaborative Incentive Research Grant (Round 12); CUNY Research Scholars Program; BMCC Faculty Development Grant.
11:51AM M22.00004: Reciprocal Control of Hierarchical DNA Origami-Nanoparticle Assemblies*  JOSHUA JOHNSON (Presenter), ABHILASHA DEHANKAR, JESSICA WINTER, CARLOS E CASTRO, Ohio State Univ - Columbus — A major focus in bionanotechnology is interfacing with inorganic materials, such as nanoparticles (NPs), for effective integration and control over emergent functions of composite materials. The structural precision and dynamic capabilities of DNA origami make it ideal to achieve these goals. We present an actuation scheme utilizing NPs as control elements enabling rapid and reversible thermal actuation of DNA origami and higher order assemblies. We demonstrate tunable thermal actuation between open and closed configurations on the timescale of seconds, with evidence that reconfiguration is only limited by heating or cooling rates of the bulk solution. We extend the dynamic capabilities in higher-order assemblies by polymerizing hinges which can achieve micron-scale reconfiguration. Control of NPs at the arrays scale combined with NP based control of hinges at the individual scale serves as a basis for reciprocal control of hierarchical assemblies. We also polymerize hinges side-to-side to create more compact NP arrays, or use a combination of polymerization schemes to assemble expandable 2D NP arrays. These NP-hinge composites serve as a novel basis for creating reconfigurable emergent materials.

*This work is funded by the U.S. Department of Energy under award no. DE-SC0017270.

12:03PM M22.00005: Fiber fluorescence photo thermometry during magnetic heating reveals directional alignment of suspended nanoparticles*  RAHUL MUNSHI (Presenter), Center for the Physics of Biological Function, Princeton University, MUYE HE, Physics, SUNY, Buffalo, IDOIA RUBIO-CASTELLANOS, Química Inorgánica, Facultad de Ciencia y Tecnología, UPV/EHU, KOMAL SETHI, JUNTING LIU, ARND PRALLE, Physics, SUNY, Buffalo — We developed highly sensitive camera-based fiber fluorescence photometry to measure temperature changes of magnetically heated nanoparticles. Temperature changes as small as 20 milli Kelvin were resolved with a temporal resolution of 5 ms, using common fluorophores. Suspensions of various nanoparticles, including synthesized magnetite and core-shell nanoparticles, engineered magnetoferritin and purified magnetosomes, as well as intact magnetotactic bacteria were heated in alternating magnetic fields (AMF). Using prior calibration, nanoparticle surface temperature changes were calculated from fluorescence intensity changes of the attached dyes. From nanoparticle surface temperatures, we determined the limits of concentration scaling of suspension temperature rise. We captured sudden (sub 5 ms) fluorescence changes, corresponding to AMF driven reversible nanoparticle alignment. The orientation of the AMF field lines determines the direction of the relative fluorescence changes. The rate of aggregation is modulated by changing the medium viscosity and depends on field strength and nanoparticle size. Our findings shed light on the implications of Specific Loss Power measurements and the limits of local heat confinement around freely diffusing nanoparticles.

**12:15PM M22.00006: Landscapes, nonlinearity, and optimality of ion transport in sub-nanoscale pores**  
SUBIN SAHU (Presenter), JUSTIN ELENEWSKI, CHRISTOPH ROHMANN, IREAP, University of Maryland College Park, MICHAEL ZWOLAK, Biophysics Group, National Institute of Standards and Technology — Biological ion channels evolved to have high transport rates and high selectivity, among other functional characteristics. Synthetic nanoscale pores aim to mimic these properties for applications such as desalination and osmotic power generation.\(^1\) In these systems, ion-ion and ion-channel interactions occur at sub-nanometer distances which entails large electrostatic and dehydration energies.\(^2\) The balance of these energies determines selectivity and permeation rates. Importantly, the susceptibility of transport and selectivity to minute changes in distances—changes on the order of picometers—is enormous resulting in highly-nonlinear behavior. Biological systems can exploit this susceptibility via variations in protein structure that steer the local electrostatic and structural conditions. We demonstrate how this works in a synthetic selectivity filter and discuss how to probe this system, which will help to experimentally quantify optimal transport conditions and will give the foundation for a robust understanding of more complex biological pores.

**12:27PM M22.00007: Potentiometric Detection of Single Protein Molecules in Solution by Nanoimpact Method**  
POPULAR PANDEY (Presenter), JIN HE, Physics, Florida International University — Nanoscale electrochemical methods based on nanopores and nanoelectrodes have gained enormous popularity for single-entity detection and analysis. This work integrates two aforementioned methods in one nanopipette apex to simultaneously monitor the ionic current and surface potential changes at the nanopore and the nanoelectrode when a protein translocates through the nanopore or collides with the nanoelectrode. In this presentation, I will demonstrate a facile potentiometric method of detecting protein at the single-molecule level in solution based on the nanoimpact events of proteins at the nanoelectrode, which is further supported by molecular dynamics (MD) simulation. Proteins, such as ferritin, hemoglobin, cytochrome-c, and lysozyme are tested to validate the method. When a protein molecule arrives at the vicinity of the electrically floating nanoelectrode, open-circuit potential (OCP) changes are detected at the nanoelectrode. Compared with the ionic current change, the OCP changes can be detected with better signal-to-noise ratio and higher time resolution. The nanopipette based novel potentiometric detection method provides new opportunities to study various biological entities at a single-entity level with close to physiological conditions.
12:39PM M22.00008: Drops: A bio-inspired tool to structure materials [Invited]  ESTHER AMSTAD (Presenter), EPFL — Nature uses drops to build soft materials possessing well-defined structures and locally varying compositions and therefore display exceptional mechanical properties. Inspired by nature, we use emulsion drops as building blocks of macroscopic granular hydrogels with well-defined micrometer-scale structures and locally varying compositions. I will demonstrate the influence of the micrometer-scale structure of these granular hydrogels on their mechanical properties. To render hydrogels responsive and adaptive, we employ selectively permeable capsules fabricated from water-oil-water double emulsions as building blocks. In addition, we use amorphous inorganic biominerals, such as CaCO3, as reagents that can locally change the mechanical properties of these materials.

1:15PM M22.00009: On the interaction of molecular rotors with lipid nanodroplets*  ROBERT ZIOLEK, BETHAN CORNELL, PAUL SMITH, I. EMILIE STEINMARK, KLAUS SUHLING, CHRISTIAN LORENZ (Presenter), Department of Physics, King’s College London — Lipid droplets are cytoplasmic organelles that store neutral lipids (e.g. triacylglycerols & sterol esters) that serve as reservoirs of energy. The neutral lipid core of lipid droplets are bounded by a phospholipid monolayer, which differentiates them from most other organelles that have a bilayer membrane. There are various nano-environments of different viscosities present in these complex organelles, which can be studied with fluorescent molecular rotors. In this presentation, I will present the results of several large-scale classical molecular dynamics simulations in which we investigate the molecular scale interactions of a molecular rotor, BODIPY-C12, with lipid droplets. In doing so, we investigate how the orientation and confirmation of the molecular rotors changes during their adsorption into the interface of the lipid droplets. We investigate how different compositions of the bounding lipid monolayer affect the confirmation and tilt of the molecular rotors. Finally, we will use the results of our simulations to resolve the multi-component signals observed experimentally.

*Simulations were performed with UK’s HEC MCC (EP/L000202/1, EP/R029431/1), the ARCHER UK National Supercomputing Service and the UK MMM Hub (EP/P020194/1).
1:27PM M22.00010: Design of bio-inspired surface topographies via polymer bilayer wrinkling superposition  LUCA PELLEGRINO (Presenter), SEPIDEH KHODAPARAST, JOAO CABRAL, Imperial College London — Naturally occurring patterns on surfaces have evolved to form topological micro- and nano-structures with a variety of functionalities, such as drag reduction, tuneable wetting, anti-microbial resistance and optical effects, often found in insect wings and plant leaves. Wrinkling of bi- and multi-layered materials provides a powerful, versatile, large-surface area patterning methodology to fabricate complex periodic structures with features ranging from 10s of nm to 100s of μm. Here, we investigate the formation of analogous 2D wrinkling patterns in artificial soft materials, built as a superposition of single frequency features. The pattern superposition is achieved sequentially, starting from single frequency wrinkles and generated by stretching a cross-linked elastomer slab that is simultaneously plasma oxidized. The wrinkled surface formed upon the strain release is replicated, then stretched at a specific angle to the first wrinkling step and plasma treated simultaneously to yield a prescribed wrinkling second generation. Specifically, an orthogonal superposition generates checkerboard patterns. Oblique superposition, gives rise to wavy or sand dunes-like patterns with structural characteristics that are independently tunable via changing the plasma experimental parameters.

1:39PM M22.00011: Near-IR Absorbing Quantum Dots Designed to Kill Multidrug-Resistant Pathogens  MAX LEVY (Presenter), JOHN BERTRAM, KRISTEN ELLER, YUCHEN DING, ANUSHREE CHATTERJEE, PRASHANT NAGPAL, University of Colorado, Boulder — Multidrug-resistant (MDR) pathogens infect millions of people in the US, with global predictions of 10 million annual deaths by 2050.\(^1\) New classes of antibiotics are needed to address this global public health crisis. Light-activated quantum dots (QDs) can fill this role by perturbing the bacteria’s biochemical environment using specifically designed optoelectronic properties.\(^1\) Inside bacteria, QDs can be energized by visible light, transferring electrons to \(O_2\) to generate superoxide radicals. We show that low doses of QDs can kill pathogens without harming human cells. CdTe QDs, while effective,\(^2–5\) are limited by the use of visible light for activation. As such, we recently developed two InP QDs which operate with tissue-penetrating near-IR and deep-red light.\(^6\) These heavy metal free QDs kill MDR pathogens without harming human cells. This work has the potential to treat dangerous infections of bacterial pathogens with a low-cost rational approach.

Session M24 GSNP DSOFT DFD: Granular Flows Beyond Simple Mechanical Models I 401 - Abe Clark, The Naval Postgraduate School - Tag(s): Focus
11:15AM M24.00001: Mechanics of Deformation in 3D Granular Materials Using X-ray Measurements* [Invited] RYAN HURLEY (Presenter), CHONGPU ZHAI, Johns Hopkins University, ERIC B HERBOLD, Lawrence Livermore National Lab, STEPHEN HALL, Lund University — Granular materials deform in complex ways, including through particle deformation, local particle rearrangements, inter-particle slip, and particle fracture. Discrete and continuum models have been proposed within the engineering and physics communities to capture the effects of these deformation mechanisms on mechanical and dynamical material properties. For instance, local particle rearrangements have been captured in glassy rheology models and shear transformation zone theories, while particle fractures have been captured in the continuum breakage mechanics framework. A major challenge remains the quantitative validation and calibration of these models using in-situ 3D experimental data.

In this talk, I will discuss our experiments combining in-situ X-ray computed tomography (XRCT) and 3D X-ray diffraction (3DXRD) during the deformation of granular materials. The samples we have studied to-date include tens to over 1,000 spherical and angular particles, each ranging in size from 100 to 400 μm, and each typically composed of single-crystal sapphire or quartz. We have subjected samples to a variety of loading conditions, including uniaxial compression and triaxial compression. XRCT measurements performed periodically during loading provide high-resolution 3D images of the evolving structure of granular materials during deformation. 3DXRD measurements provide the location (with several um precision), the orientation (with 0.05° precision) and the strain tensor (with $10^{-4}$ resolution) in each of thousands of particles, from which the stress tensor of each particle can be computed. I will present examples of prior work studying local particle rearrangements and inter-particle slip. I will also discuss ongoing and future work on the impact of both structure and forces on ultrasound transmission and the quantitative details of local particle rearrangements.

11:51AM M24.00002: Dimensionality and viscosity exponent in shear-driven jamming* PETER OLSSON (Presenter), Department of Physics, Umea University, Sweden — Collections of bidisperse frictionless particles at zero temperature in three dimensions are simulated with a shear-driven dynamics with the aim to compare with behavior in two dimensions. Contrary to the prevailing picture, and in contrast to results from isotropic jamming from compression or quench, we find that the critical exponents in three dimensions are different from those in two dimensions and conclude that shear-driven jamming in two and three dimensions belong to different universality classes.

*Simulations were performed on resources provided by the Swedish National Infrastructure for Computing (SNIC) at HPC2N.
**12:03PM M24.00003: Identification of a universal data collapse in the rheology of granular media**  
SEONGMIN KIM (Presenter), School of Engineering and Applied Sciences, Harvard University,  
KENNETH N KAMRIN, Department of Mechanical Engineering, Massachusetts Institute of Technology —  
We propose a reduced description of nonlocal phenomena in dense granular flows where the shear stress ratio $\mu$ is not locally determined by the inertial number (dimensionless shear rate) $I$. The nonlocal granular fluidity (NGF) model has been proposed to describe nonlocality by introducing an implicit “fluidity” field and its diffusion. A recent study found the fluidity can be roughly expressed by two physical quantities: the particle velocity fluctuations $\delta v$ and packing fraction. Here, we reduce the number of quantities from two to one revealing that only $\delta v$ is needed to explain nonlocality. We perform DEM simulations in many geometries using 3D spheres and 2D discs with various surface frictions. For each granular material, we show there exists a clear constitutive equation that works across geometries, which directly relates three local dimensionless variables: $\mu$, $I$, and the dimensionless granular temperature (dimensionless $\delta v^2$) $\Theta$. It allows us to consider the nonlocal phenomena as the result of various spatial distributions of the granular temperature, a field that is generated, diffuses, and dissipates similar to the implied behavior of the fluidity field in the NGF model. We also demonstrate how this $\mu$-$I$-$\Theta$ relation can be applied in continuum simulations of granular flows.

**12:15PM M24.00004: Nonlocal rheology of dense granular flows: the effect of particle and boundary properties**  
FARNAZ FAZELPOUR (Presenter), ZHU TANG, KAREN DANIELS, North Carolina State University — In granular rheology, one of the most promising recent advances has been the development of nonlocal rheologies, including the nonlocal rheology model proposed by Kamrin and Koval. This model extends a local Bagnold-type granular flow law to include a Laplacian term governing the diffusion of fluidity. It has been observed to successfully capture the dynamics of quasi-2D flows without the need to provide detailed particle dynamics, using a single set of experimentally-determined model parameters. For use as a modeling tool, the next step is to make predictions for particles with any particle shape/material, and to correctly model the response to various boundary conditions. We perform experiments to study particles of three different shapes and three different stiffnesses to explore their influence on the rheological parameters. We find that the nonlocal parameter varies with both particle shape and material, frictional parameter varies primarily with particle shapes, and the local parameter is approximately constant. Finally, we identify how the roughness of the boundary changes both the flow and the interparticle forces using photoelastic force measurements.

Local plastic deformation in sheared highly polydisperse foams

YONGLUN JIANG (Presenter), ERIC WEEKS, Emory University — We simulate the shear of dense two-dimensional foams using the Durian bubble model with a Lees-Edwards boundary condition. In particular, we study highly polydisperse systems with the largest bubble diameters being as much as ten times the smallest diameter. The high polydispersity requires us to rethink the conventional ideas that are applied to study the local plastic deformation of systems with comparable sizes of droplets, such as $D_{\text{min}}^2$ which highlights locally nonaffine motion (Falk & Langer, PRE 1998). We modify the conventional definition of "local" in the calculation of $D_{\text{min}}^2$ to consider the existence of big droplets and study how the "local" rearrangements differ for large and small droplets. More specifically, we find the large droplets follow the mean shear, while the small droplets have significant nonaffine motions and move more erratically. We demonstrate an optimal definition of local that best distinguishes the local nonaffine motions from the bulk shear.

Generalized Granular Resistive Force Theory for Rate-Dependent Intrusions

ANDRAS KARSAI (Presenter), Physics, Georgia Institute of Technology, SHASHANK AGARWAL, KENNETH N KAMRIN, Mechanical Engineering, Massachusetts Institute of Technology, DANIEL I GOLDMAN, Physics, Georgia Institute of Technology — The resistive forces during intrusion into granular media can be described accurately by reduced-order models like Resistive Force Theory, but rate effects may emerge as intrusion speed increase. We demonstrate with both rapid plate drag data and freely locomoting rigid wheel experiments how such rate-dependent dynamics diverge from the quasistatic limit. Additional forces from a continuum momentum balance are sufficient for describing the forces in rapid plate drag, but do not capture the effects of rapid rotational shear in the wheeled locomotion experiments. A frictional flow continuum model captures these phenomena without needing to account for micro-inertial effects such as frictional dependence on grain inertia. Based on the observed physics of the flow model simulation, we propose a modified RFT for arbitrary intruders that reconciles both cases using a geometry-dependent modification and an additional macro-inertial resistance, extending RFT beyond describing quasistatic intruding bodies.

This work was funded by the Army Research Office, Triangle Park.
Stick-slip and intermittent flow dynamics of a single-grain intruder driven through a granular medium with and without basal friction

RYAN KOZLOWSKI (Presenter), Physics Department, Duke University, C MANUEL CARLEVARO, Mechanical Engineering Department, Universidad Tecnologica Nacional, La Plata, KAREN DANIELS, Physics Department, North Carolina State University, LOU KONDIC, Mechanical Engineering Department, Universidad Tecnologica Nacional, La Plata, KAREN DANIELS, Physics Department, North Carolina State University, LUIS A PUGNALONI, Physics Department, Universidad Nacional de La Pampa, JOSHUA SOCOLAR, Physics Department, Duke University, HU ZHENG, Geotechnical Engineering Department, Tongji University, ROBERT P BEHRINGER, Physics Department, Duke University — We report on experiments in which a grain-sized intruder is pushed by a spring through a quasi-2D granular material in an annular geometry. We study intruder dynamics as a function of packing fraction for two types of supporting substrates: a frictional glass plate and a layer of water, which completely removes basal friction. In the presence of basal friction, we observe a novel crossover with increasing packing fraction from intermittent flow to stick-slip dynamics. In intermittent flow, the intruder only occasionally gets stuck by the medium; in stick-slip, the intruder advances via a sequence of distinct, rapid slip events. With lower interparticle friction, the crossover packing fraction shifts to higher values; when basal friction is removed, no crossover to stick-slip dynamics is observed. We characterize the dynamics using statistics of the intruder velocity, the force of the medium on the intruder, and the waiting times between sticking periods. Our results indicate the qualitative importance of basal friction and suggest a possible connection between intruder dynamics in a static material and clogging dynamics in granular flows.

1:03PM M24.00008: Intruder dynamics in a 2D granular system: Effects of dynamic and static basal friction

JOSHUA SOCOLAR (Presenter), Physics Department, Duke University, C MANUEL CARLEVARO, Instituto de Fisica de Liquidos y Sistemas Biologicos, CONICET, Argentina, LUIS A PUGNALONI, Departamento de Fisica, Universidad Nacional de La Pampa, CONICET, Argentina, RYAN KOZLOWSKI, Physics Department, Duke University, HU ZHENG, Tongji University, Shanghai, Department of Geotechnical Engineering, LOU KONDIC, Department of Mathematical Sciences and Center for Applied Mathematics and Statistics, New Jersey Institute of Technology — We discuss the results of simulations of an intruder pulled through a 2D granular system by a spring, using a model designed to lend insight into the experimental findings described by Kozlowski et al. [Phys. Rev. E 100, 032905 (2019)]. In that previous study, the presence of basal friction between the grains and the base was observed to change the intruder dynamics from clogging to stick–slip. Here we first show that our simulation results are in excellent agreement with the experimental data for a variety of experimentally accessible friction coefficients governing interactions of particles with each other and with boundaries. We then use simulations to explore a broader range of parameter space, focusing on the friction between the particles and the base. We consider a range of friction coefficients, which are difficult to vary smoothly in experiments. The simulations show that dynamic friction strongly affects the stick–slip behavior when the coefficient is decreased below 0.1, while static friction plays only a marginal role.

1:15PM M24.00009: Drafting of intruders in dry and fluid-saturated granular beds

BENJAMIN ALLEN (Presenter), ARSHAD KUDROLLI, Clark University — We discuss an experimental study of the drag experienced by two vertical rods as they follow each other around a circular track while being dragged across a granular bed. We systematically measure the drag experienced as a function of rod speed, separation distance, penetration depth, and the properties of the interstitial fluid. As in drafting in air and fluids, we find significant separation effects on the total drag experienced in comparison with that of a single rod [1]. The drag ratio is observed to decrease monotonically as the separation distance is decreased over a scale set by the penetration depth in a dry granular bed essentially independent of their speed. A complex rate-dependence is observed in a liquid-saturated granular bed at separation distances comparable to the penetration depth. A peak in drag is observed when the distance of separation is comparable to the penetration depth which is greater than the drag of experienced at large separation distance. We will discuss our results in light of resistive force theory, and nondimensional inertial and viscous numbers used to characterize granular mediums.

*Supported by NSF-CBET 1805398.
Reduction in Resistive Forces by Directional Air Fluidization in Dry Granular Media

MASON MURRAY-COOPER (Presenter), ANDRAS KARSAI, YASEMIN OZKAN-AYDIN, Georgia Institute of Technology, NICHOLAS NACLERIO, ELLIOT W. HAWKES, Mechanical Engineering, UC Santa Barbara, DANIEL I GOLDMAN, Georgia Institute of Technology — Directional fluidization applies the concept of granular air fluidization to vary the resistive forces locally around an intruder in a granular medium. We fabricated a cylindrical intruder (d = 30mm, length = 30 mm) capable of blowing air through a nozzle at varying flow rates (from 0 to 100 L/min) and angles relative to the direction of intruder motion in dry granular media. Varying the flow rate and angle affects the drag force parallel to the intruder's direction of motion as well as the lift force in the vertical direction. Drag experiments were performed by forcing the intruder horizontally with a robot arm at a low speed (v ~10 mm/s) in 5 cm of dry sand with grain diameters ranging from 0.4-0.8 mm. Multi-axis force data demonstrated a consistent reduction in saturated drag forces that was sensitive to air flow rate but insensitive to blowing angle (BL). Saturated lift forces showed a greater dependence on BL, with more significant reductions coinciding with steeper angles (60 - 90 degree range). These results suggest a scheme for minimizing resistive forces in lift and drag by blowing air downwards and open a door for growing robot navigation in granular media.

Properties of air-fluidized granular media*

MIGUEL ANGELO LOPEZ-CASTANO (Presenter), JUAN FRANCISCO GONZÁLEZ-SAAVEDRA, ÁLVARO RODRÍGUEZ-RIVAS, FRANCISCO VEGA REYES, Departamento de Física, Universidad de Extremadura — We study a 2D granular system of particles interacting via a short-ranged potential, and thermalized homogeneously. This achieved by means of a turbulent air flow. Particles consist of 4 cm diameter ping-pong balls. We will show that, as packing fraction and air current are increased, the system can undergo transitions from gas to liquid, glass, and hexagonal phases.

The particles, placed on a metallic mesh and are subject to an uniform air flow from. This creates vortexes past the spheres, injecting energy. Air flow is adjusted so that particles remain in contact with the mesh, so that the dynamics are purely 2D. The system can be regarded as being under a stochastic white noise.

We perform several series of measurements with varying air flow intensity and density, detecting particle positions through a CV algorithm. We then carry out an analysis on single-particle trajectories and study configurational properties: pair correlation function, and order parameters.

We compare our granular temperature results against other 2D homogeneously driven granular systems.

1:51PM M24.00012: Granular chiral separation  RUO-YU DONG (Presenter), SLAWOMIR LACH, YAROSLAV SOBOLEV, BARTOSZ GRZYBOWSKI, STEVE GRANICK, IBS Center for Soft and Living Matter — Single helical granular particle (~5 mm), when placed in a slowly rotating tube, migrates laterally to different sides dependent on the chirality. First entrained by the rotating tube up to certain height, the particle suddenly starts to slide or roll down, during which process chiral separation is made possible as the particle only rolls at certain particle orientation and thus migrates in one direction exclusively. The intricate interplay between particle shape, which determines a critical slope of rolling, and static friction, which determines a critical slope of sliding, is found responsible for the chiral separation and its efficiency. We corroborate the experimental finding with theoretical predictions and extend the single particle phenomena to multi-particles.

2:03PM M24.00013: Super-Flory scaling in compressed micro-gel packings  AHMED ELGAILANI (Presenter), CRAIG E MALONEY, Northeastern University — We perform multi-body finite element simulations of packings of hydrogel particles immersed in a large solvent bath in 2D at various particle volume fraction, φ using the Flory-Rehner constitutive law to model the mechanics of the hydrogel network. The system becomes rigid with finite osmotic pressure, Π and zero-frequency storage modulus, G, only above the random close packing point. At large enough φ regions of pure solvent are completely eliminated, and we find a qualitative change in the G vs φ curve with a weaker dependence on φ. However, in this dense limit, G exceeds the modulus of a monolithic piece of hydrogel made of the same Flory-Rehner material and continues to increase with φ. This result is surprising as we observe strong inhomogeneous non-affine relaxation which helps to reduce the modulus, however, it is in agreement with experiments which also show super-Flory behavior. Furthermore, we show that the slip at the facets between particles is proportional to the transverse gradient of the applied deformation which strongly screens the stress near facets oriented along the applied shear. Our results on the deformation kinematics during shear suggest new measurements to attempt in experiments and should open the way to quantitative theories to estimate G at high φ.

Session M25 GSNP DSOFT: Fabric, Knits and Knots I  402 - Michael Dimitriyev, Georgia Inst of Tech - Tag(s): Focus
11:15AM M25.00001: What Can Knitting Machines Make? [Invited] JAMES MCCANN (Presenter), Carnegie Mellon Univ — Industrial knitting machines are used to fabricate many complex 3D objects, including gloves, sweaters, and shaped fiber reinforcement for composites. But what are the limits of these machines? This talk will introduce two of the approaches my group has taken to answering this question.

The first -- top-down -- approach views a knitting machine as a device for shaping, splitting, and merging tubes. This leads to the observation that all manifolds with boundary whose Reeb graph under some smooth function has an upward-planar embedding are machine-knittable. This observation forms the basis of our work on knitting design tools.

The second -- bottom-up -- approach translates low-level machine instructions into a geometric description of intertwined yarns, allowing direct enumeration of structures. The important insight made in this work is that the way the yarn is routed between stitches is as important to model as the way the yarn behaves within stitches.

Taken together, these two views of knitting machine capabilities have enabled us to develop new design and simulation tools for machine knitting.

11:51AM M25.00002: Knitting Machine State Representation Using the Artin Braid Group* JENNY LIN (Presenter), JAMES MCCANN, Carnegie Mellon Univ — Industrial knitting machines are incredibly powerful, flexible machines that are capable of creating a wide variety of shapes and structures using just a few basic operations. However, effectively using these operations to take full advantage of the machine’s capabilities is nontrivial; when creating a machine knitting pattern, the designer must decide how to move loops of yarn around the machine’s hundreds of needles, all while tracking interloop connections and tangles. Furthermore, they should do so in a way that minimizes construction time and error rate.

To enable the computation of optimal machine knitting patterns, we developed an abstraction of the knitting machine state that uses the Artin braid group when describing interstitch relationships. We provide a formulation for each machine operation’s effect on this abstract representation. In addition, we leverage key properties of the braid group when considering the distance between any two machine states. These insights make searching the knitting machine state space for efficient patterns more computationally tractable, and we show several computationally planned patterns.

12:03PM M25.00003: Mechanics-Based Simulation of Multistable Knitted Fabrics  XIAOXIAO DING (Presenter), CHRISTOPHER RYCROFT, KATIA BERTOLDI, Harvard University — The pattern formation process of a one-dimensional yarn into a two-dimensional sheet of knitted fabric exhibits intricate deformation modes with complex contact description. Given this complexity, we are motivated to develop a mechanics-based predictive model that accounts for mechanical parameters in this mechanics-based process. We first characterize parameters that significantly dominate the pattern formation, such as pretension and boundary conditions on the knitted fabric. Then integrate this with development of a simulation scheme, where yarn-yarn interaction and mechanical forces are computed and cross validated against parametric study on the macroscopic mechanical response of knitted elastic fabrics. Our model is generalized to explore the rich landscape of knitted fabrics as each yarn can be parameterized with varying material properties, enabling the design space for functionality of the fabrics to be enormously enlarged. Projecting forward, we hope to extend this simulation scheme for coupled analysis on functionality and data augmentation for optimization of pattern design for multifunctional knitted fabrics.

12:15PM M25.00004: Constructing a constitutive model of knitted fabric*  MICHAEL DIMITRIYEV (Presenter), KRISHMA SINGAL, ELISABETTA MATSUMOTO, Georgia Inst of Tech — Knitting is an ancient technology wherein yarn is manipulated into an array of slipknots to form fabric. By patterning these stitches in different ways, one can create fabrics possessing a wide array of elasticities and geometries, without needing to change the type of yarn being used. Thus, knitting is a way of programming material properties via a code that describes stitch patterns. However, while there have been mechanical models of aspects of knitted fabric, there is currently no unifying description that models knitted fabric elasticity given a prescribed stitch pattern. To make progress towards this end, we seek a method of generating constitutive relations for a given stitch pattern. Using a geometric framework in which yarn degrees of freedom are modeled as elastic space curves, with stitches held together by contact interactions, we solve for energy-minimizing stitch structures numerically within the unit cell of a given pattern. We then extract the constitutive relations by monitoring the deformation of the stitch given external stresses on the unit cell. This method not only gives us predicted stress-versus-strain relations that compare favorably with experiments but it allows us to probe the role of yarn geometry in determining fabric mechanics.

*NSF: DMR 1847172
12:27PM M25.00005: Stress-Strain Studies of Knitted Swatches  KRISHMA SINGAL (Presenter), MICHAEL DIMITRIYEV, ELISABETTA MATSUMOTO, Georgia Inst of Tech — The properties of a knitted fabric are highly dependent on what stitches the fabric is made of and what patterns they are used in. Different stitches correspond to different linking topologies of the yarn that constrain the yarn configurations and therefore the overall fabric mechanics and shape. Here we examine the relationship between large scale properties of knitted swatches and the small scale yarn shape within each stitch via experiments that probe the elasticity of the swatches while imaging corresponding changes in the shape of the constituent yarn. Under stress, knitted fabric deforms not only as a bulk response, but the yarn-level deformations give rise to nonlinear elasticity. To quantify this shape change we are developing a method for tracking the 3D path of the yarn. By tracking the yarn within the fabric while we measure the stress-strain relationship, we can untangle the effects of curvature, compression, and friction on the emergent nonlinear elasticity of the textile.

12:39PM M25.00006: Emergent yarns and fabrics by twist origami*  JULIEN CHOPIN (Presenter), Physics, Universidade Federal da Bahia, ARSHAD KUDROLLI, Physics, Clark University — A first step to making functionalized fabrics is to spin yarns by twisting together a natural or synthetic soft material with a prescribed structure. We will discuss experiments that demonstrate large spontaneous shape transformations that couple with mechanical response starting with a hyperelastic rectangular sheet which is simply held under tension and twisted around its central long axis. For twists larger than half a turn, the sheet adopts an accordion shape with self-contacts and folds oriented at an angle with respect to the axis of rotation. We reconstruct the 3D shape of the folded sheet using x-ray Computed Tomography and calculate the Gaussian and mean curvature to characterize their morphology. Modeling the full soft elastic sheet undergoing such a large transformation is prohibitively difficult. Thus, we propose an origami starting with an inextensible sheet with a prescribed number of triangular folds corresponding those observed at the onset of transverse wrinkling of the elastic sheet as a starting point to analyze the emergence of the structure. Building on this insight, we then present a string model based on the origami kinematics to explain not only the emergence of the accordion folds but also its torsional response.

*Supported by NSF DMR Grant 1508186
A Study of Two-Periodic Knitted Fabrics using Tangles

SHASHANK MARKANDE (Presenter), ELISABETTA MATSUMOTO, Georgia Inst of Tech — We have previously created a framework to classify and characterize two-periodic stitch patterns of knitted fabrics that is based on knot and link theory. Using this theory, we are able to associate a unique link in three dimensional sphere $S^3$, to every two-periodic stitch pattern of a knitted fabric. In every such link, the subset of loops representing the yarn satisfy ribbonness or forms a ribbon link. A link is said to be ribbon if each of its component loops bound a 2D disk that pierces through itself making a finite number of slit like intersections lying in the interior of the collection of disks. Based on the ribbonness, and different types of yarn-needle moves catalogued in the knitting literature, we are able to describe knittable stitch patterns composed of -- knit and purl with twists, yarn overs, knit or purl two together, knit front back, slip stitch, cable etc. The description uses the notion of a tangle -- a collection of properly embedded arcs inside a euclidean three ball. This set up lets us define operator invariants for two-periodic knitted stitch patterns because tangles can be described using tensor products and composition by contraction of indices.

Untangling the mechanics of the clove hitch knot

TOMOHIKO SANO (Presenter), PAUL GRANDGEORGE, PAUL JOHANNES, Ecole Polytechnique Federale de Lausanne, CHANGYEON BAEK, Massachusetts Institute of Technology, HARMEET SINGH, JOHN MADDOCKS, PEDRO REIS, Ecole Polytechnique Federale de Lausanne — Knots can impart unique mechanical function to filamentary structures, with examples ranging across length scales, including DNA, polymer-chains, shoelaces climbing ropes, tennis racket, and surgical sutures. Still, the predictive understanding of the mechanics of this class of structures is limited. The fundamental challenge arises from the complex interplay between topology, geometry, elasticity, and friction. Here, we focus on the clove hitch knot, which typically attaches a flexible rod/filament/rope to a rigid post. The clove hitch can sustain a remarkably large tension ratio between the two ends of the rod when compared to the simpler strategy of spooling the rod around the rigid post in a helical configuration. In our study, we combine experiments (mechanical testing and X-ray tomography), finite element and a theory based on the Kirchhoff equations. We find that the twist in the rod increases with the ratio of the tensions applied to the two ends. Furthermore, in contrast to helical spooling, the clove hitch loses a significant amount of its tension at the regions of self-contact, thereby enhancing its mechanical performance.

*We acknowledge financial support in the form of Grants-in-Aid for JSPS Overseas Research Fellowship.
A stopper knot tied to the end of a climbing rope prevents it from retracting through a narrow passage in the climber’s belay device. Numerous other applications of stopper knots are found in stringing of tennis rackets, sailing and fishing. If a single-stranded stopper knot meets the requirement of preventing a rope from escaping the system, it is able to unfold its full potential by converting a high-traction force into an insignificant stress state. This sharp tension drop results from the complex interplay of the topology, the tightness of the configuration, and the nontrivial frictional interactions in regions of self-contact of the elastically deformed rod. Existing models in knot theory or Kirchhoff's theory for elastic rods are insufficient to describe this functional behavior due to the importance of finite elastic deformations of the cross-section and frictional interactions. We tackle this problem by performing a combination of mechanical testing and X-ray tomography on a variety of stopper knots. Our experimental data, combined with finite element simulations, allows us to systematically explore the different ingredients at play that conspire to dictate the mechanical performance of stopper knots.

*Supported by the Fonds National de la Recherche, Luxembourg 12439430

Knotted structures play a fundamental role in the dynamics of biological and physical systems, from DNA and polymers to liquid crystals and turbulent plasmas, as well as in climbing, weaving and sailing. Despite having been empirically studied for centuries, the subtle interplay between topology and mechanics in knotted elastic materials remains poorly understood. Here, we combine optomechanical experiments with theory and simulations to analyze the behavior of knots in flexible fibers that change their color in response to mechanical deformations. Exploiting a previously unrecognized analogy with long-range ferromagnetic spin systems, we identify simple counting rules to predict the relative mechanical stability of knots and tangles, in agreement with numerical simulations and experimental measurements for commonly used climbing and sailing knots. The underlying topological principles provide a conceptual foundation for understanding the roles of twist and writhe in untangling processes, and are expected to find broad applications in the description and control of systems with complex entanglements.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M26 DSOFT: Disordered and Glassy Systems 403 - John Crocker, University of Pennsylvania
11:15AM M26.00001: Linking Melt Dynamics with Glass Topological Phases in Ge\textsubscript{x}P\textsubscript{x}Se\textsubscript{100-2x} Ternary*  
AARON WELTON (Presenter), RALPH CHBEIR, SOUMENDU CHAKRAVARTY, PUNIT BOOLCHAND, University of Cincinnati — We have synthesized homogeneous equimolar Ge\textsubscript{x}P\textsubscript{x}Se\textsubscript{100-2x} ternary glasses over a wide range of compositions 0<x<26%. 1.5 gram sized samples in evacuated (5mm ID) quartz tube were alloyed at 960 °C for 10 days. When Raman spectra taken along the 1 inch long melt column became identical the samples were declared to be homogenous. Homogeneity means the variance of Se along the melt column decreased to ~0.1%. Modulated DSC experiments were undertaken and trends in $T_g(x)$, del $C_p(x)$ and the enthalpy of relaxation at $T_g$, del $H_{nr}(x)$, were established. We observe a reversibility window in the 9%<x<18% range fixing the three topological phases; flexible phase 0<x<9%, intermediate phase (IP) 9%<x<18%, stressed-rigid phase 18%<x<26%. The IP of this ternary is the widest of any chalcogenide multicomponent chalcogenide glass system, a feature that could be tied to the existence of the Ethylene like P\textsubscript{2}Se\textsubscript{1/2}\textsubscript{4} local structure besides the QT, Se=P(Se\textsubscript{1/2})\textsubscript{3} and PYR P(Se\textsubscript{1/2})\textsubscript{3} ones. Molar volumes reveal a volumetric window with $V_m(x)$ decreasing in the IP range from the average behavior across all x. Melt fragility index, $m(x)$, measurements show a Gaussian like minimum near $m=15$ in the center of the IP and increasing to $m(x)>20$, both in the flexible (x<9%) and stress-rigid (x>18%)

*DMR 08-53957

11:27AM M26.00002: Local and Extended range molecular structures of (Na\textsubscript{2}O)\textsubscript{x}(P\textsubscript{2}O\textsubscript{5})\textsubscript{100-x} glasses probed by Raman Scattering and Infrared reflectance*  
VAMSHI KIRAN GOGI (Presenter), AVIK MANDAL, CHANDI MOHANTY, RALPH CHBEIR, PUNIT BOOLCHAND, University of Cincinnati — Raman scattering and IR reflectance reveal striking similarities between crystalline (c-) and glassy (g-) NaPO\textsubscript{3}. The c- and g- are each composed largely of chains of $Q^2$ species, a 4-fold P having 2 bridging ($O_b$) and 2 terminal ($O_t$) Oxygen neighbors, and display three vibrational features; an asymmetric stretch (as) of P-O\textsubscript{t} (1300 cm\textsuperscript{-1}), a symmetric stretch (ss) of P-O\textsubscript{t} (1172 cm\textsuperscript{-1}) and a ss of P-O\textsubscript{b} (685 cm\textsuperscript{-1}). There are glaring differences as well, and these come from the fact that ss of P-O\textsubscript{t} and P-O\textsubscript{b} although quite narrow in the c- but are rather broad in the g-, and can be deconvoluted in terms of a triad of modes due to long chains (LC), large rings (LR) and small rings (SR) in the latter. These triad of modes are also observed in IR displaying complementary behavior, with modes of SR and LR, weakly excited in Raman but strongly in IR. These vibrational features are also observed at non-stoichiometric (x ≠ 50%) compositions ranging from 20%<x<61% and have permitted to elucidate the role of glass structure in stabilizing the three Topological phases. In the Intermediate Phase range\textsuperscript{1} (37.5%<x<46%), LC far exceed the count of LR and SR thus promoting the configurational entropy of that phase.

**M26.00003: Molecular origin of the 7-folds narrowing of the Tg transition upon aging in Se-rich multicomponent glasses**

RALPH CHBEIR (Presenter), SHREERAM J DASH, PUNIT BOOLCHAND, Univ of Cincinnati — The nature of the glass transition temperature in Se-rich (x < 4%) ternary GeₙAsₙSe₁₀₀₋₂ₓ [1] glasses is examined as a function of room temperature aging in Modulated DSC experiments. Our experiments show Tg(x) to increase by 6°C with x displaying a trapezoidal variation in the 0% < x < 4% range, with the enthalpy of relaxation, ΔHnr increasing 4-folds and the width (W) of the glass transition decreasing 7-folds upon RT aging for 8 months. The molecular origin of these changes can be connected with the polymeric Seₙ chains in the fresh glass steadily correlating with each other to become quasi-helical provided n > 8. These features are due to the undercoordinated nature of Se glass rendering compositions x < x_c to be super-flexible when the length of chains exceeds 10 atoms. Parallel results were obtained in the GeₓSe₁₀₀₋ₓ [1] binary, underscoring that these effects are strictly controlled by the topology or network connectedness.

*NSF grant DMR- 08-53957

**M26.00004: Origin of the Raman active 490 cm⁻¹ mode in binary As-S and Ge-S and ternary Ge-As-S glasses from compositional studies and Ab-initio Cluster calculations.**

SOUMENDU CHAKRAVARTY (Presenter), RALPH CHBEIR, BADRIAH ALMUTAIRI, Univ of Cincinnati, SHIBALIK CHAKRABORTY, Intel Corporation, KOBLAR JACKSON, Physics, Central Michigan University, PUNIT BOOLCHAND, Univ of Cincinnati — Raman scattering results on binary As-S and Ge-S and ternary Ge-As-S provide evidence of a mode near 490 cm⁻¹. The fractional scattering strength of the mode in question normalized to the sum of the S₈ (472cm⁻¹) and Sₙ chain (461cm⁻¹) mode reveals evidence of a local maximum near x = 25% in binary AsₓS₁₀₀₋ₓ glasses and near y = 20% in binary GeₓS₁₀₀₋ₓ glasses. These results are most suggestive that the mode in question has a frequency which is tied to the S-S stretch between a pair of AsS₃ pyramids or between a pair of GeS₄ tetrahedra. We have now carried forward NRLMOL calculations on select clusters and results of these will be compared to experiments. Preliminary results place the symmetric stretch mode frequency at 450 cm⁻¹ for a 14 atom cluster of (H-S-As)₂-S-S- (As-S-H)₂.

*NSF grant DMR-08-53957
12:03PM M26.00005: Compositional variation of the Specific Heat $C_p(x)$ in binary Ge$_x$Se$_{100-x}$ melts and glasses across the Intermediate Phase. MATTHEW BURGER (Presenter), RALPH CHBEIR, BERNARD GOODMAN, PUNIT BOOLCHAND, Univ of Cincinnati — We have examined the specific Heat $C_p$ in the glassy state and the metastable liquid state across $T_g$ in binary Ge$_x$Se$_{100-x}$ system in the 19% < x < 26% range of compositions focusing on the Intermediate Phase. The bulk glasses used in the present Modulated DSC study were the ones synthesized by Bhosle et al.\(^1\). Our results show $C_p$(glass) and $C_p$(liquid), each term to display a broad Gaussian-like maximum centered about the mid-point composition, x = 23%, of the Intermediate Phase. We are also investigating the variation of $C_p$(liquid) at higher temperature in the $T_g < T < 550°C$ range to look at any anomalies that could be related to the liquid-liquid transition recently suggested\(^2\).

12:15PM M26.00006: Universal hidden order in amorphous cellular geometries GERD SCHROEDER-TURK (Presenter), Murdoch Univ — Partitioning space into cells with certain extreme geometrical properties is a central problem in many fields of science and technology. Here we investigate the Quantizer problem, defined as the optimisation of the moment of inertia of Voronoi cells, i.e., similarly-sized ‘sphere-like’ polyhedra that tile space are preferred. We employ Lloyd’s centroidal Voronoi diagram algorithm to solve this problem and find that it converges to disordered states associated with deep local minima. These states are universal in the sense that their structure factors are characterised by a complete independence of a wide class of initial conditions they evolved from. They moreover exhibit an anomalous suppression of long-wavelength density fluctuations and quickly become effectively hyperuniform. Our findings warrant the search for novel amorphous hyperuniform phases and cellular materials with unique physical properties. This research was published in M.A. Klatt et al, Nature Communications 10, 811 (2019).
In recent years, bulk-boundary correspondence (BBC) has been one of the hot topics both in solid state physics (topological materials) and high energy theory (holography and gauge/gravity duality).

Our work is the first ever exposition of BBC yet in another domain; soft condensed matter. We for the first time hypothesize and confirm that BBC also holds in soft matter. Instead of studying the bulk nature of LC+aerosil gels–like the classical works of x-ray scattering and heat capacity measurements–we chose to study the surface of these gels using atomic-force microscopy (AFM) techniques where we managed to correlate the surface related parameters with the ones of the bulk. The essence of our study is based on the created randomness which can be systematically controlled. This is the aerosil amount in the gels. Here we study the surface effects as functions of the disorder strengths created in the 8CB+aerosil gels samples. The correspondence between the bulk (order parameter; beta) and the surface parameters (fractal dimensions) are systematically studied as functions of disorder strength (aerosil amount in the samples).

12:51PM M26.00009: The role of hydrodynamic interactions on the long-time structural fate of dense colloidal suspensions  
MONICA E. A. ZAKHARI (Presenter), JIALUN WANG, GADDEIEL OUAKNIN, ROSEANNA ZIA, Chemical Engineering, Stanford University — The colloidal glass transition presents an intriguing temporal convolution of structural, dynamical, and mechanical effects during aging. This competition simultaneously advances aging and deepens arrest. In this work, we study the mechanics of this competition by considering both the equilibrium and non-equilibrium solidification processes, i.e. crystallization and vitrification, respectively, utilizing large-scale Stokesian dynamic simulations that are massively parallelized. Jumps from liquid into the solid region are executed via controlled volume-fraction quenches, where the speed of the quench is used to modulate the particle dynamics and, consequently, permits toggling between equilibrium and arrested states. We find that the long-time structural fate of the suspension, i.e. a glass or a crystal, is determined during the quench itself and is mechanistically regulated by many-body hydrodynamic interactions.

1:03PM M26.00010: Why phonon scattering in glasses is universally small at low temperatures*  
HERVE M. CARRUZZO, CLARE YU (Presenter), Department of Physics and Astronomy, University of California, Irvine — We present a novel view of the standard model of tunneling two level systems (TLS) to explain the puzzling universal value of a quantity, $C \sim 3 \times 10^{-4}$, that characterizes phonon scattering in glasses below 1 K as reflected in thermal conductivity, ultrasonic attenuation, internal friction, and the change in sound velocity. Physical considerations lead to a broad distribution of phonon-TLS couplings that (1) exponentially renormalize tunneling matrix elements, and (2) reduce the TLS density of states through TLS-TLS interactions. We find good agreement between theory and experiment for a variety of individual glasses.

*This research was primarily supported by the National Science Foundation (NSF) through the University of Wisconsin Materials Research Science and Engineering Center (DMR-1720415).

1:15PM M26.00011: Nearest Neighbor Functions for Stealthy Hyperuniform Many-particle Ground States*  
TIMOTHY MIDDLEMAS (Presenter), SALVATORE TORQUATO, Princeton University — We present new analytical theories backed by simulation for the nearest neighbor functions of disordered stealthy hyperuniform many-particle ground states. Stealthy systems display a variety of ordered and disordered phases, and have been related to novel photonic band gaps in disordered systems. They can also be shown to have optimal transport properties, such as the fluid permeability, trapping constant, and elastic properties. The nearest neighbor functions, which include the probability to find a hole of a certain radius, are intrinsically related to the geometric properties of stealthy systems, such as their bounded hole size and quantizer error. The manner in which these functions approach the critical (bounded) hole size is a fundamental geometrical question (in particular, whether they behave like ordered lattices), and is also related to their thermodynamics. We use insights from simulation and previous analytical work to develop new analytical theories of the core and tail regions of these functions, and comment on their implications for geometric problems and material properties.

*We acknowledge support from NSF Grant No. CBET-1701843, the Taylor Fellowship, and the NSF Graduate Research Fellowship, and the use of resources from Princeton Research Computing.
1:27PM M26.00012: Analytical theory of enhanced logarithmic Rayleigh scattering in amorphous solids*

BINGYU CUI (Presenter), Univ of Cambridge, ALESSIO ZACCONE, University of Milan — The damping or attenuation coefficient of sound waves in solids due to impurities scales with the wavevector to the fourth power, also known as Rayleigh scattering. In amorphous solids, Rayleigh scattering may be enhanced by a logarithmic factor although computer simulations offer conflicting conclusions regarding this enhancement and its microscopic origin. With tensorial replica field strategy, a theoretic derivation based on heterogeneous elasticity suggests that the logarithmic enhancement to Rayleigh scattering of phonons might be ascribed to long-range (power-law) power law decay in spatial elastic disorder in amorphous solids. Further, the density of states (DOS) associated with self-consistent equations of self-energy in the model exhibit power d+1 decay in low frequency regime, supporting the evidence of numerical simulation in sound waves.

1:39PM M26.00013: Tracer Transport in Attractive and Repulsive Supercooled Liquids and Glasses*

RYAN C ROBERTS, JACINTA CONRAD, JEREMY PALMER (Presenter), Univ of Houston — The transport of small penetrants through disordered materials with glassy dynamics is encountered in drug delivery and chemical separations. Understanding the influence of matrix structure and fluctuations on penetrant motions remains a challenge. We use event-driven molecular dynamics to investigate the transport of small, hard-sphere tracers in matrices of square-well particles. Short-range attractions between matrix particles give rise to reentrant dynamics in the supercooled regime, in which the liquid's relaxation time increases dramatically upon heating or cooling. Heating results in a repulsive supercooled liquid where relaxations are frustrated by steric interactions between particles, whereas cooling produces an attractive liquid in which relaxations are hindered by long-lived interparticle bonds. Further cooling/heating, or compression, of the supercooled liquids results in the formation of distinct glasses. Our study reveals that tracer transport in these liquids and glasses is influenced by matrix structure and dynamics. The relative importance of each factor varies between matrices and is examined by analyzing mean-square displacements, caging behavior, and trajectories sampled from the isoconfigurational ensemble.

*Welch Foundation (E-1882), NSF (CBET-1705968)
1:51PM M26.00014: Glass Transition in Supercooled Liquids with Medium-Range Crystalline Order  INDRAJIT TAH (Presenter), TIFR Centre for Interdisciplinary Sciences, SHILADITYA SENGUPTA, University of Tokyo, CHANDAN DASGUPTA, Indian Institute of Science, SRIKANTH SAstry, Jawaharlal Nehru Centre for Advanced Scientific Research, SMARAJIT KARMAKAR, TIFR Centre for Interdisciplinary Sciences — The origin of the rapid dynamical slowdown in glass forming liquids in the growth of static length scales, possibly associated with identifiable structural ordering, is a much debated issue. Growth of medium range crystalline order (MRCO) has been observed in various model systems to be associated with glassy behavior. Such observations raise the question of whether molecular mechanisms for the glass transition in liquids with and without MRCO are the same. In this study we perform extensive molecular dynamics simulations of a number of glass forming liquids and show that the static and dynamic properties of glasses with MRCO are different from those of other glass forming liquids with no predominant local order. We also resolve an important issue regarding the so-called point-to-set method for determining static length scales, and demonstrate it to be a robust method for determining static correlation lengths in glass formers.

2:03PM M26.00015: Understanding how the degree of disorder affects structural colors of colloidal packings  MING XIAO (Presenter), ANNA B. STEPHENSON, VICTORIA HWANG, VINOTHAN MANOHARAN, Harvard University — Disordered structures that multiply scatter light sometimes show phenomena such as Anderson localization, structural colors, and super whiteness. We investigate the scattering from dense packings of spherical colloidal particles in a weak multiple scattering region. Using a Monte Carlo framework, we predict the wavelength-dependent reflectance (colors) of simulated packings. To quantify the degree of disorder, we calculate the structure factor. We then explore how variations in the structure factor affect both the reflectance and the angle-dependence of the colors. We find only the first peak of the structure factor determines the feature of the reflectance, which provide guidance to control colloidal packings to tune the colors.

Session M27 FIAP GIMS DMP: Optical Spectroscopic Measurements of 2D Materials 404 - Okan Koksal, Cornell University
Monolayer MoS$_2$ has become a very promising two-dimensional materials for photo-related applications. Establishing the impact of individual ambient gas components and chemical dopants on the optical properties of MoS$_2$ is a necessary step toward application development. By using in situ Raman micro-spectroscopy with an environment-controlled reaction cell, the photoluminescence (PL) intensity of CVD-grown MoS$_2$ monolayers is monitored at different intralayer locations under ambient and controlled gas environments, such as N$_2$, O$_2$, H$_2$O, and pyridine. Our study demonstrates that photoreactions with the gaseous environment on MoS$_2$ monolayer flakes should be taken into consideration even upon mild photoirradiation as they strongly impact the flakes' optical properties. The optical properties of MoS$_2$ at the edges are strongly affected by photoirradiation induced reactions with O$_2$ and H$_2$O. We have also studied the effect of the dopant phase of the same dopants – liquid and gaseous – on the optical properties of ML MoS$_2$. The gaseous n-type dopant, i.e. pyridine, completely quenches the PL intensity of ML MoS$_2$, while liquid pyridine preserved 50% of the original PL intensity attributed to its less effective charge transfer to MoS$_2$ than the gaseous counterpart.
11:27AM M27.00002: Imaging strain-localized exciton states in nanoscale bubbles in monolayer transition metal dichalcogenides at room temperature  THOMAS DARLINGTON (Presenter), University of California, Berkeley, CHRISTIAN CARMESIN, MATHIAS FLORIAN, Institute for Theoretical Physics, University of Bremen, EMANUIL YANEV, DEMI AJAYI, JENNY ARDELEAN, Mechanical Engineering, Columbia University, AUGUSTO GHIOTTO, Department of Physics, Columbia University, ANDREY KRAYEV, Horiba Scientific, JEFFREY KYSAR, Mechanical Engineering, Columbia University, ABHAY PASUPATHY, Department of Physics, Columbia University, JAMES C HONE, Mechanical Engineering, Columbia University, FRANK JAHNKE, Institute for Theoretical Physics, University of Bremen, NICHOLAS J BORYS, Department of Physics, Montana State University, P. JAMES SCHUCK, Mechanical Engineering, Columbia University — In monolayer transition metal dichalcogenides (1L-TMD's), applied strain can deterministically create quantum emitters at arbitrary sites on-demand. Despite a robust empirical correlation with strain, the nanoscopic details of these quantum emitters are poorly understood. Here we combine room-temperature nano-optical imaging of excitons in nanobubbles in 1L-WSe$_2$ with atomistic structural models to elucidate how strain induces the nanoscale confinement potentials that give rise to highly localized exciton states in 2D semiconductors. Nano-optical imaging reveals localized excitons on length scales of ~10 nm at multiple sites along the periphery of individual nanobubbles, which is in stark contrast to predictions of continuum strain models. These results agree with theoretical confinement potentials derived from measured topographies of nanobubbles. We reproduce these findings in nanobubbles of low-defect WSe$_2$ and MoSe$_2$, suggesting our results are applicable to excitons in all the semiconducting 1L-TMD's. Our results provide one-of-a-kind insight of how strain-induced confinement—without crystalline defects—can localize excitons on length scales commensurate with exciton size, providing key nanoscale structure-property information for quantum emitter phenomena in 1L-TMD's.

11:39AM M27.00003: Multi-harmonic phonon assisted upconversion in van der Waals heterostructure p-n junction photodiodes  FATEMEH BARATI (Presenter), TREVOR ARP, SHANSHAN SU, ROGER LAKE, NATHANIEL GABOR, Physics & Astronomy, UCR — In atomically thin van der Waals heterostructures, the interaction between electrons and phonons is highly restricted compared to bulk materials, suggesting that precise stacking of atomic layers could be used to manipulate vibrational coupling to photoexcited electron-hole pairs. Here, we report on phonon assisted anti-stokes absorption near the interlayer exciton edge of vdW semiconductor heterostructures composed of 2L-WSe$_2$ and MoSe$_2$. By carefully tuning the chemical potential of the heterojunction, we find highly rectifying I-V characteristics reminiscent of conventional diode behavior. Using advanced photocurrent spectroscopy measurements, we observe a strong photocurrent peak at near-infrared photon energies with several low energy echoes spaced by 30 meV below this feature. These unusual features occur only when device is precisely tuned to the charge neutrality point. We attribute this behavior to multi-harmonic phonon assisted upconversion, a process by which multiple phonons contribute kinetic energy to the electronic ground state to produce an excited state electron-hole pair. It marks the first observation of strong resonant coupling in a semiconductor system and may herald a new generation of precision optical experiments on laser cooling of vdW heterostructures.
Strong-Coupling of Hybrid Quasiparticles in Excitonic-Dielectric Gratings

BHASKAR ABHIRAMAN (Presenter), HUIQIN ZHANG, Electrical and Systems Engineering, University of Pennsylvania, QING ZHANG, Department of Electrical and Computer Engineering, National University of Singapore, JINSHUI MIAO, KIYOUNG JO, STEFANO ROCCASECCA, Electrical and Systems Engineering, University of Pennsylvania, MARK KNIGHT, Northrop Grumman Corporation, ARTUR DAVOYAN, Mechanical and Aerospace Engineering, University of California, Los Angeles, DEEP M JARIWALA, Electrical and Systems Engineering, University of Pennsylvania — Tightly bound exciton states in van der Waals semiconductors such as MX₂ (M= Mo, W; X= S, Se) are promising for optoelectronic applications. However, to-date, strong light-exciton interaction and control of excited states in them has been limited to monolayer samples with external optical cavities. Here, we demonstrate that nanostructured multilayer WS₂ provides an ideal cavity-less and exposed surface platform for exciton-photonics where the WS₂ serves the role of both the cavity and the excitonic medium. We show that by patterning sub-15 nm thick WS₂ into 300 nm wide resonators an avoided crossing of excitons and photon-polaritons with interaction potentials exceeding 410 meV can be engineered with precision. We further observe that inherently strong TMDC exciton absorption may be completely suppressed due to excitation of hybrid photon-exciton states and their interference. By modifying the system with dielectric spacers, we observe a rich platform for coupling and field confinement with bulk and monolayer TMDCs. Our work paves the way to a new class of integrated exciton optoelectronic nano-devices and their applications in light generation and manipulation.

12:03PM M27.00005: Ultrafast exciton dynamics in WSe\textsubscript{2} optical waveguides*  AARON STERNBACH (Presenter), Physics, Columbia University, SIMONE LATINI, Max Planck Institute for the Structure and Dynamics of Matter, SANGHOON CHAE, Mechanical Engineering, Columbia University, HANNES HUEBENER, UMBERTO DE GIOVANNINI, Max Planck Institute for the Structure and Dynamics of Matter, YINMING SHAO, LIN XIONG, ZHIYUAN SUN, NORMAN SHI, Physics, Columbia University, PETER KISSIN, Physics, University of California, San Diego, GUANGXIN NI, Physics, Columbia University, DANIEL A RHODES, BRIAN S Y KIM, Mechanical Engineering, Columbia University, NANNFANG YU, ANDREW MILLIS, Physics, Columbia University, MICHAEL M FOGLER, Physics, University of California, San Diego, P. JAMES SCHUCK, Mechanical Engineering, Columbia University, MICHAL LIPSON, Department of Electrical Engineering, Columbia University, XIAOYANG ZHU, Chemistry, Columbia University, JAMES C HONE, Mechanical Engineering, Columbia University, RICHARD AVERITT, Physics, University of California, San Diego, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter, DMITRI BASOV, Physics, Columbia University — We investigated dynamics of excitons in a Van der Waals Semiconducting, WSe\textsubscript{2}, waveguide. We monitored the electric-field profile of waveguided infrared radiation under intense femtosecond photo-excitation in real space and time. Drastic modifications of the complex wavevector of guided radiation were observed. The non-equilibrium energy momentum dispersion relationship implicates excitons in the photo-induced transformations. Unprecedented coherent dynamics of refraction, on the sub-ps timescale, reveal an optical stark-shift of the A-exciton resonance. Our study establishes that excitons enhance the performance of vdW optical modulators providing a tuning knob unavailable in conventional III-V semiconducting platforms. Our transient images and first-principles theoretical calculations establish fundamental limits of excitons in WSe\textsubscript{2} optical modulators.

*Support by Programmable Quantum Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), under award DE-SC0019443”, the European Research Council (ERC-2015-AdG694097), the Cluster of Excellence 'Advanced Imaging of Matter' (AIM), the Flatiron Institute, a division of the Simons Foundation, and the Alexander von Humboldt foundation are acknowledged.
**12:15PM M27.00006: Twist-angle dependent optical properties of interlayer excitons in MoSe\textsubscript{2}/WSe\textsubscript{2} heterostructures**

JUNHO CHOI (Presenter), KHA TRAN, Department of Physics, Complex Quantum Systems, and Texas Materials Institutes, University of Texas at Austin, GALAN MOODY, Department of Electrical and Computer Engineering, University of California Santa Barbara, AKSHAY K SINGH, Department of Materials Science and Engineering, Massachusetts Institute of Technology, JIAMIN QUAN, LIUYANG SUN, ROB CLAASSEN, CARTER YOUNG, Department of Physics, Complex Quantum Systems, and Texas Materials Institutes, University of Texas at Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, XIAOQIN (ELAINE) LI, Department of Physics, Complex Quantum Systems, and Texas Materials Institutes, University of Texas at Austin — We investigate the interlayer excitons in MoSe\textsubscript{2}/WSe\textsubscript{2} heterostructures, mechanically stacked with an accurately controlled twist angle and capsulated by hexagonal boron nitride. Three \textit{R}-stacking style samples with different twist angles are measured by polarization-resolved steady state and time-resolved photoluminescence at low-temperature. We observe multiple resonances of interlayer excitons which we attribute to quantized states in the moiré potential. The recombination dynamics of the interlayer excitons are found to change significantly with a small change in the twist angle.

*We gratefully acknowledge funding from NSF DMR-1720595, NSF DMR-1808042, and Welch Foundation F-1662.

**12:27PM M27.00007: Excitonic spectral features of 1L-WSe\textsubscript{2} with silicon nitride waveguide coupling**

YUEH-CHUN WU (Presenter), Physics, Univ of Mass - Amherst, SARATH SAMUDRALA, ANDREW MCCLUNG, Electrical and Computer Engineering, Univ of Mass- Amherst, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, AMIR ARBABI, Electrical and Computer Engineering, Univ of Mass- Amherst, JUN YAN, Physics, Univ of Mass - Amherst — In this study, we present excitonic spectral features of 1L-WSe\textsubscript{2} coupled to a platform with Silicon nitride (SiNx) waveguides, allowing us to excite and collect signals in different polarizations. In our high quality BN/1L-WSe\textsubscript{2}/BN/SiNx sample, bright neutral exciton, intervalley/intravalley trions, dark exciton, and bi-exciton and exciton-trion states can be clearly resolved, in agreement with previous reports. The dark exciton, which is known to have out-of-plane dipole moment and thus has been elusive in most standard optical measurements, can be selectively enhanced with out-of-plane light waveguide coupling scheme. Moreover, we study the resonance excitation with 1s bright and dark excitons with different polarizations. Interestingly, as we resonantly excite at dark exciton with out-of-plane light, we observe the up-conversion of bright exciton as well as a down conversion feature lying around 25-27meV lower which indicates dark associate states as being reported to be either dark trions or phonon replica of dark exciton in WSe\textsubscript{2}.

*This work is mainly supported by the University of Massachusetts Amherst and NSF ECCS 1509599
**12:39PM M27.00008: The Nature of Trions and Trion-Polaritons in 2D Materials: Theory and Experiments**  
OKAN KOKSAL (Presenter), MINWOO JUNG, CHRISTINA MANOLATOU, GENNADY SHVETS, FARHAN RANA, Cornell University — The traditional picture of trions as bound states of two electrons and hole has been called into question by several recent works \[1,2\]. The traditional model of trions is also inconsistent with coherent trion-polaritons \[3\]. In this work we present a many body description of trions and trion-polaritons that is valid over a wide range of electron densities. In our work, a negatively charged trion, for example, appears as a bound state of a valence band hole, two conduction band electrons, and a conduction band hole. At small electron densities, this 4-body bound state description of trions is found to be approximately correct. The binding of the conduction band hole allows coherent trion-polaritons. At much larger electron densities, bound trion states don’t exist and a many-body screened-exciton description of trions is found to be more accurate. We present experimental results for the evolution of the exciton and trion oscillator strengths and binding energies with the electron density, and also for the trion-polariton dispersion relations, in 2D-MoSe$_2$, and show very good agreements with our theoretical model. [1] Phys. Rev. B, 95, 035417 (2017), [2] Nat. Phys., 13, 255 (2016). [3] Nat. Phys., 14, 130 (2018)

*The research was funded by the NSF EFRI-1741694 and NSF DMR-1120296.

**12:51PM M27.00009: Excitonic Lifetime in CVD-Grown, Few-Layer MoTe$_2$**  
AARON SCHULZETENBERG (Presenter), JAMES JOHNS, University of Minnesota — Two-dimensional semiconductors such as transition metal dichalcogenides (TMDCs) with high binding energy excitons provide an ideal platform to study exciton physics such as exciton-exciton annihilation and chemical defect scattering. The dominant exciton decay mechanisms of chemical vapor deposition (CVD) grown, few-layer MoTe$_2$ are investigated by measuring and statistically analyzing its ultrafast, optical transient reflectivity dynamics under different pump excitation energies, fluences and temperatures. Defect interaction controls the ultrafast exciton decay pathways. Weak intralayer bonding in few-layer, CVD MoTe$_2$ causes it to have a greater defect density than in other mechanically exfoliated 2D transition metal dichalcogenides. Direct charge carrier occupation of trap states is thought to cause an additional transient feature on the A’ exciton which is not present in the absorption spectrum. Additionally, long-term ambient air exposure does not significantly affect few-layer MoTe$_2$ exciton decay time and absorption peak shape, increasing this material’s suitability for many technological applications.
Continuous Wave Sum Frequency Generation and Imaging of Monolayer and Heterobilayer 2D Semiconductors

KAIYUAN YAO (Presenter), EMANUIL YANEV, Columbia University, HSUN JEN CHUANG, MATTHEW ROSENBERGER, naval research laboratory, XINYI XU, THOMAS DARLINGTON, Columbia University, KATHLEEN M MCCREARY, AUBREY T. HANBICKI, BEREND THOMAS JONKER, naval research laboratory, XIAOYANG ZHU, DMITRI BASOV, JAMES C HONE, P. JAMES SCHUCK, Columbia University — Optical nonlinearities in two-dimensional transition metal dichalcogenides (TMDs) are greatly enhanced by excitonic resonances. Here we report continuous-wave second harmonic and sum frequency generation from two-dimensional TMD monolayers and their heterostructures, with pump irradiances several orders of magnitude lower than conventional pulsed experiments. The high nonlinear efficiency originates from above-gap excitons in the band nesting regions, as revealed by wavelength-dependent second order optical susceptibilities quantified in four common monolayer transition metal dichalcogenides. Using sum frequency excitation spectroscopy and imaging, we identify and distinguish one- and two-photon resonances in both monolayers and heterobilayers. Data for heterostructures reveal responses from constituent layers accompanied with nonlinear signal correlated with interlayer transitions. Furthermore, we demonstrate spatial mapping of heterogeneous interlayer coupling by sum frequency and second harmonic confocal microscopy on heterobilayer MoSe$_2$/WSe$_2$.

Second harmonic generation spectroscopy of MoS$_2$/WSe$_2$ heterostructure

JUNGCHEOL KIM (Presenter), HYEONSIK M CHEONG, Physics, Sogang University — Recently, heterostructures of transition metal dichalcogenides (TMDs) have attracted much interest owing to their unique physical properties. One of the most interesting characteristics is the large exciton energy of TMDs. As the electronic band structures of TMD materials are highly dependent on the number of layers, the interlayer interaction between constituent layers in the heterostructure also affects the band structure [1]. Therefore, understanding the changes of exciton states is important to revealing the band structure of the TMD heterostructure. We fabricated MoS$_2$/WSe$_2$ heterostructures by the stamping methods using exfoliated monolayer MoS$_2$ and WSe$_2$. The PL and Raman measurements were carried out to determine the quality of interface in the heterostructures. Finally, using the second harmonic generation spectroscopy, which is a useful experimental method to measure the exciton states in TMD materials [2], we observed a shift of the exciton energy in the heterostructure compare to those in individual constituent layers.

Trion valley relaxation dynamics in monolayer WSe$_2$  

Keisuke Shinokita (Presenter), Xiaofan Wang, Yuhei Miyauchi, Kyoto Univ - Uji Campus, Kenji Watanabe, Takashi Taniguchi, National Institute for Materials Science, Satoru Konabe, Department of Chemical Science and Technology, Hosei University, Kazunari Matsuda, Kyoto Univ - Uji Campus — Valley degrees of freedom of atomically thin materials have received much attention, with potential in future applications of electronics and optoelectronics as emerging valleytronics. The exploration of novel valley-dependent phenomena has been boosted by strongly Coulomb-bounded electrons and holes acting as neutral excitons and charged excitons (trions) with finite Berry curvature in monolayers of transition metal dichalcogenides. However, neutral excitons have been reported to undergo fast intervalley scattering on the order of 10 ps, which blurs observations of valley-dependent phenomena. Here we report the valley relaxation dynamics of the bright state of positively charged excitons (bright positive trions) in monolayer WSe$_2$ through polarization- and time-resolved photoluminescence and femtosecond transient reflection measurements. A long valley relaxation time, exceeding 100 ps, is observed for positive trions at low temperature, which is notably prolonged when compared with the characteristic excitonic valley relaxation time of 10 ps. With increasing temperature, the relaxation time decreases to a few ps. This finding implies that phonon-mediated intervalley scattering is important for the relaxation process of the valley-polarized bright state of positive trions.

Pressure-tunable stacking order in few-layer WS$_2$ revealed by second harmonic generation  

Chengrong Wei (Presenter), Physics, The University of Hong Kong, Huimin Su, Xuefeng Zhou, Shanmin Wang, Jun-Feng Dai, physics, Southern University of Science and Technology — In 2D material, interlayer interaction can be tuning by internal pressure. We experimentally demonstrate a controllable interlayer translation freedom in hBN-encapsulated few-layer WS$_2$ under applying hydrostatic pressure, which is characterized by Raman spectroscopy and the polarization-resolved second harmonic generation (SHG) spectroscopy. The E$_{2g}^1$ and A$_{1g}$ modes of all samples increased with pressure and there is no new peak observed in the Raman spectrum. The SHG patterns in monolayer WS$_2$ have insignificant distortion and the SHG signal in bilayer WS$_2$ is negligible. Meanwhile, SHG patterns in trilayer WS$_2$ show six asymmetric lobes. Such observations suggest that the threefold rotational symmetry is broken under pressure, which origins from a relative sliding between adjacent layers in the zigzag direction. The tunability of translation structural symmetry by using a hydrostatic pressure presented in this work provides a platform to explore novel physical properties in new class of 2D materials.

M27.00014: Donor-acceptor-pair transitions in suspended monolayer WS$_2$*  YUNKUN WANG

(Presenter), State Key Laboratory for Mesoscopic Physics and Collaborative Innovation Center of Quantum Matter, School of Physics, Peking University, HAILAN LUO, XINGJIANG ZHOU, YUAN HUANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Science, YUNAN GAO, State Key Laboratory for Mesoscopic Physics and Collaborative Innovation Center of Quantum Matter, School of Physics, Peking University — In conventional semiconductors, the donor-acceptor-pair (DAP) transitions could dominate the photoluminescence, when the sample is cooled to low temperature and the excitation is weak. Here we report observation and characterization of DAP transitions in a suspended monolayer WS$_2$ using steady-state and time-resolved photoluminescence spectroscopy. Without substrate induced doping in suspended monolayer WS$_2$, we observed an ultra-broad emission centered at 1.83 eV and with bandwidth of more than 300 meV. The bandwidth is much larger than generally observed bound excitons. These sub-band states show a sub-linear power-law dependence with an index of 0.3 at 12 K. In the DAP transitions, the recombination centers are spatially separated, and their emission energy depends on their relative distances. We observed that the board emission spectra shift to higher energy as the excitation power increased. Time-resolved photoluminescence spectra show the broad emission shifts from higher energy to lower one along the intensity decay. This work provides further deep understanding of trap states and decay channels in transition metal dichalcogenides.

Session M28 FIAP: Imaging in Industry 405-407 - Matthew Thompson, BAE Systems - Tag(s): Careers, Industry, Invited, Undergrad Friendly
11:15AM M28.00001: Subterranean Visualization Through Multi-Sensor Fusion* [Invited] JOE MORRIS (Presenter), Lawrence Livermore National Laboratory — We depend upon the subsurface for much of the energy and raw material that enables civilization. Groundwater sources often supply water for agricultural, drinking, and industrial use. However, we remain relatively blind in the subsurface environment. Geological formations can be strongly heterogeneous at all length scales, making it difficult to locate resources. Furthermore, the performance of subsurface engineering is difficult to monitor due to our blindness.

I will describe challenges associated with engineered geothermal systems (EGS) and hydraulic fracturing in shale formations. In both instances, our optimization of an engineered system is impeded by gaps in understanding of the fundamental processes and our inability to monitor and visualize system performance.

I will present sensors that help us image the subsurface. Of note is the recent growth of fiber optic measurements. Leveraging interferometry applied to light pulses sent down a fiber, we infer the state of the fiber along its entire length. However, each sensor technology has strengths and weaknesses. By combining multiple sensors, we can best avoid blind spots. I will discuss examples of multi-sensor fusion in petroleum and EGS field projects where concurrent measurements of velocity, acoustic, chemical, thermal, and resistive properties enable determination of system performance. Today, such projects rely on large teams of scientists and engineers to collect and interpret data and make engineering decisions. Increasing automation through machine learning is showing promise for decreasing the lag between measurement and decision making. I will close by describing a new initiative that seeks to develop a comprehensive platform for integrating data and providing a virtual environment for exploring the subsurface.

*This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:51AM M28.00002: How Self-Driving Cars Find Their Way [Invited] COLIN MCCORMICK (Presenter), Georgetown University — Autonomous vehicles such as self-driving cars (SDCs) use sophisticated sensors and complex perception and planning algorithms to navigate in a variety of environments. The sensor systems include lidar, radar and RGB video cameras, while the algorithms include localization, object detection and tracking, and path planning. SDCs have the potential to save thousands of lives when widely deployed, but they face technical, economic and regulatory barriers. Industry is currently investing billions of dollars to develop SDC technology, and it is eager to identify technical talent. Physicists are extremely well suited to work on these technical issues, and have many opportunities to do so. I will describe the basics of SDC technology, give a brief summary of the economic and policy landscape, and highlight ways that physicists can enter this important and interesting field.

12:27PM M28.00003: Augmented Reality in Aerospace [Invited] SHELLY PETERSON (Presenter), Lockheed Martin — TBD
The Role of Physics in Overhead Imaging

Jonathan Edwards, BAE Systems — Basic physics has profound implications for overhead imaging. This presentation will examine illustrative surveillance concepts for defense applications using unmanned and space-based platforms. We focus on two topics where physics plays a crucial role: 1) wide-area drone surveillance, and 2) low-earth orbit (LEO) imaging.

To accommodate drone limitations, sensor concepts minimizing size and weight while maximizing scene coverage and resolution are preferred. One intriguing concept uses composite focal plane arrays (CFPA). CPFAs apply multiple discrete FPAs on a flat surface behind a single optical path. For this technology, we discuss trade-offs for field-of-view and resolution and describe a number of engineering challenges addressed for a realizable system.

Given CFPA ‘big-data’ acquisition, physical principles are invoked to facilitate a key capability – automated object tracking. Here, traditional kinematics permits the tracking of moving entities from a moving platform over a large area.

Cheaper and frequent rocket launches have resulted in a burgeoning ‘small satellite’ market. This has motivated desire for small earth-observing payloads. We discuss critical trade-space drivers including LEO’s high velocity and stringent platform volume bounds. The space environment also presents challenges for analysis using traditional electronics. We discuss the trade-off of cost and reliability that defines LEO operation by examining the impact of the physical radiation environment.
The need for persistent microwave imaging spectrometry of the Earth within 100-200 GHz and with sub-hourly temporal resolution for severe weather monitoring had been identified in 1978 by Staelin et al. in a NASA-sponsored study [1]. The clear need presented in this study has driven the laboratory-level development of large geostationary filled-and synthetic-aperture microwave sounders throughout the past period of more than four decades. However, the recent demonstration of small CubeSat-based imaging microwave spectrometers in this frequency range suggests a new pathway to achieving these goals. The successful launch in April 2019 and subsequent demonstration of the Global Earth Monitoring System (GEMS) GEMS-1 In-orbit Demonstration (IOD) mission using a 118-GHz imaging microwave spectrometer supports this goal. Importantly, however, it enables a scalable constellation framework with the capability to provide temporal Nyquist-sampled microwave imagery of the Earth’s troposphere and lower stratosphere.

GEMS-1 IOD was developed by Orbital Micro Systems in partnership with the University of Colorado’s Center for Environmental Technology and the UK Space Applications Catapult. The GEMS-1 IOD sensor is currently the highest spatial resolution microwave temperature sounding sensor on orbit. The GEMS-1 sensor design, its on-orbit performance, and the pathway to an evolved GEMS constellation capable of meeting and exceeding the severe weather observation requirements set forth over 40 years ago will be discussed.

*OMS is grateful for support in the development of the GEMS constellation by the US Air Force under the Commercial Weather Data Pilot program and Innovate UK / Space Applications Catapult through the In-Orbit Demonstrator (IOD-1) program.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M29 DSOFT DPOLY: Liquid Crystals II: Phases and Transitions
501 - Vianney Gimenez-Pinto, Lincoln University, Missouri
**11:15AM M29.00001: Theory of the splay nematic phase**  
MICHELY ROSSETTO, Universidade Estadual de Maringá, JONATHAN SELINGER (Presenter), Kent State Univ - Kent — Recent experiments have reported a novel splay nematic phase, which has alternating domains of positive and negative splay [1]. To model this phase, researchers have considered a 1D splay modulation of the director field, accompanied by a 1D modulation of polar order. When the flexoelectric coupling between splay and polar order becomes sufficiently strong, the uniform nematic state becomes unstable to the formation of a modulated phase [1,2]. Here, we re-examine this theory in terms of a new approach to liquid crystal elasticity [3], which shows that pure splay deformation is double-splay rather than planar single-splay. Following that reasoning, we propose a structure with a 2D splay modulation of the director field, accompanied by a 2D modulation of polar order, and show that the 2D structure generally has a lower free energy than the 1D structure. We also investigate a generalized flexoelectric coupling between director deformations and tetrahedral order, but still find a lower free energy for the 2D modulation.

*This work was supported by NSF Grant No. DMR-1409658 and by CAPES Finance Code 001.

**11:27AM M29.00002: Twisted topological defect lines in achiral nematic liquid crystal confined in glass capillaries**  
ZHAOFEI ZHENG (Presenter), JOSE X VELEZ, Johns Hopkins University, DANIEL BELLER, Physics, School of Natural Sciences, University of California, Merced, FRANCESCA SERRA, Johns Hopkins University — Chirality occupies a remarkable space in biology and soft matter. In liquid crystals, chirality at the molecular scale propagates to the macroscale in non-trivial ways and can emerge even from achiral components. Here we report that common nonchiral thermotropic liquid crystals confined in square capillary tubes with homeotropic anchoring can show a spontaneous twist during the phase transition from smectic-A to nematic. The chiral structure is transient, but it can be stabilized for a few hours by accurate control of the temperature. We hypothesize that this chiral structure is related to the different rate of change of the twist and bend elastic constants at the phase transition. However, also the shape of the confining capillary plays a key role. In fact, this effect is clearly seen in capillaries, with square cross-section: the edges of the capillary, on the one hand, stabilize disclination lines in the nematic phase, and on the other hand they induce the formation of many defects in the smectic phase.
11:39 AM M29.00003: Phase Transition Triggering in a Liquid Crystal Droplet*  
JAKE SHECHTER (Presenter), Physics, University of Massachusetts - Amherst, NOE ATZIN CANAS, RUI ZHANG, ALI MOZAFFARI, Molecular Engineering, University of Chicago, BENJAMIN A STRAIN, LINDA M OSTER, Physics, University of Massachusetts - Amherst, MANISHA CHAHAR, Chemistry, University of Massachusetts - Amherst, JUAN DE PABLO, Molecular Engineering, University of Chicago, S. THAI THAYUMANAVAN, Chemistry, University of Massachusetts - Amherst, JENNIFER L ROSS, Physics, Syracuse University — Liquid crystals (LCs) are a class of molecules that form a variety of phases easily influenced by external interactions. Of particular interest are rod-like LC molecules confined to a spherical geometry, which have a competition between interfacial tension and elastic deformations. The phase of the liquid crystal inside a droplet can be controlled using surfactants, influencing the boundary conditions, in an oil-in-water emulsion. Here, we test the effects of the surfactant sodium dodecyl sulfate (SDS) on the phase of polydisperse LC droplets in an aqueous background examining different diameter sizes and SDS concentrations. We trigger phase transitions by the increase or decrease of SDS concentration while observing an individual LC droplets held in place using an optical tweezer. The dynamic phase transitions are compared to previous molecular dynamic simulations that predicted the intermediate states of the LC inside the droplets. We observe a hysteresis in the SDS concentration that induces the phase transition from radial to bipolar and back as well as a fluctuation in state when the phase transition starts.

11:51 AM M29.00004: Nanoparticle Network embedded polymer films formed using liquid crystal transition templating.*  
ALAUNA WHEELER (Presenter), LINDA S. HIRST, University of California, Merced — Our lab recently demonstrated that nanoparticles, well-dispersed in the isotropic liquid crystal (LC) phase, will self-assemble into hollow structures when the LC solvent undergoes cooling through the isotropic-to-nematic (I-N) phase transition. The form and size of the nanoparticle structures can be controlled by varying the nanoparticle concentration and the cooling rate (1). Thus far this process has only been accomplished using 5CB (4’-pentyl-4-Biphenylcarbonitrile) as the LC solvent. In this study we demonstrate that hollow networks of self-assembled nanoparticles can be formed in different nematic LC mixtures, compatible with polymerization. The cooling rate across the I-N phase transition can be used to control the size and density of the network structures. We embed these nanoparticle structures in a thin film by using a polymerizable LC mixture in the formation process and characterize the properties of the film.

*National Science Foundation grant numbers CBET 1507551, DMR 1625733
12:03PM M29.00005: One pot synthesis of hollow colloidal gel* DEVIKA GIREESAN SUDHA (Presenter), JOCELYN OCHOA HERNANDEZ, LINDA S. HIRST, University of California, Merced — Liquid crystal (LC) phase transitions can drive the assembly of dispersed nanoparticles. Hollow microstructures of various morphologies can be created, on cooling through the nematic-isotropic transition temperature (T_{NI}) at different temperature quenches. At high quench rates single compartment hollow capsules are observed. These colloidal capsules frustrate orientational order in the liquid crystal leading to topological defects. These defects stabilize the capsules into a mechanically robust gel. The capsule sizes can be controlled by varying the quench depth. Here we present structural analysis using confocal and fluorescence imaging of these gels for a range of capsule sizes. We also observed continuous tubular network morphologies at lower quench rates. These networks under birefringence show the presence of defect lines and loops. Such one pot synthesis technique leads to the rapid self-assembly of liquid crystal nanocomposites, that may find applications in controlled release, sensing and catalysis.

*The authors would like to acknowledge generous funding from the NSF grant number CBET 1507551. The data in this work was collected, in part, with a confocal microscope acquired through the NSF MRI Award Number DMR-1625733.

12:15PM M29.00006: Intertwined spontaneous helix formation in achiral bent-core liquid crystals* VIKINA MARTINEZ (Presenter), ADAM GREEN, CHEOL PARK, Physics and Soft Materials Research Center, University of Colorado Boulder, MATTHEW GLASER, University of Colorado, Boulder, JOSEPH E MACLENNAN, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado Boulder — Inspired by several reports of spontaneous helix formation in bent-core smectics, we have investigated the smectic phases of a series of bent-core mesogens with 4-cyanoresorcinol bisbenzoate cores. In PAL30, the homolog with n=14 alkyl tails, we observed an incommensurate, bent-core phase with a single helix incommensurate with the smectic layering [1], a structure broadly analogous to the phase of rod-shaped molecules. In the PAL29, the n=16 homolog, we have confirmed, using both resonant and non-resonant x-ray diffraction, as well as electro-optical methods, the existence of a phase with intertwined helices, similar to the structure recently reported by Salamonczyk and co-workers [2]. Establishing the existence of the intertwined double-helical phase and the single-helical phase in such closely related homologs is an important step in understanding the competing interactions that lead to such exotic phase structures.

12:27PM M29.00007: Transformations Between Different Self-Organized Defect Arrays at the Nematic-Smectic A Phase Transition*  DANIEL BELLER (Presenter), University of California, Merced, AHRAM SUH, MIN-JUN GIM, DONG KI YOON, Graduate School of Nanoscience and Technology, Korea Advanced Institute of Science and Technology (KAIST) — We model transformations in self-organized liquid crystal defect arrays in hybrid-aligned thin films at the nematic-smectic A phase transition. The smectic A phase forms a packing of focal conic domains, while the nematic phase features a square lattice of boojum surface-defects at larger spacing. Heating from smectic A to nematic transforms the focal conic domain packing into a dense array of boojums, which we study through Landau-de Gennes numerical modeling and a connection to graph theory. The reverse transformation upon cooling proceeds through a very different morphological sequence, beginning with a stripe instability which we examine analytically and numerically. The focal conic domain packings that emerge retain a geometric memory of the nematic boojum configuration.

12:39PM M29.00008: Investigation of Thermal Properties of Itraconazole at Ultra-Fast Rates*  JOHN ZAPATA-HINCAPIE (Presenter), MADHUSUDHAN REDDY PALLAKA, SINDEE L SIMON, Texas Tech Univ — The thermal behavior of itraconazole (ITZ) was studied using a conventional differential scanning calorimeter (DSC) and a flash differential scanning calorimetry (Flash DSC) over five decades of cooling rates. Itraconazole forms a smectic glass and shows two endothermic liquid crystal transitions located at 74 and 90 °C at all cooling rates in DSC. On the other hand, in the Flash DSC, the glass that is formed can have smectic order for the lowest cooling rates, nematic order at intermediate cooling rates, and no ordering (i.e., an isotropic glass is formed) at the highest cooling rates of 1000 K/s. The T_g values obtained in conventional and Flash DSC are similar at comparable cooling rates and can be described by the WLF equation over five decades of cooling rate. No discernible change in the T_g versus cooling rate relationship is evident as different glasses are formed, suggesting that differences in T_g for the three glasses is solely attributable to the different cooling rates and not due to the difference in structures. Additionally, the kinetics of the liquid crystal transformations and the kinetics of structural recovery are followed by annealing at different temperatures ranging from -30 to 92 C.

*The authors are grateful to NSF under the grant CMMI-1662046
12:51PM M29.00009: Coalescence Dynamics of Fluids in Two Dimensions: Merging of Islands in Freely-Suspended Smectic Films*  DUONG NGUYEN, Physics and Soft Materials Research Center, University of Colorado Boulder, KIRSTEN HARTH, Institute of Solid State Physics, Otto-von-Guericke Universitat, AARON GOLDFAIN, CHEOL PARK, JOSEPH E MACLENNAN (Presenter), MATTHEW GLASER, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado Boulder — Smectic liquid crystal films a few molecular layers thick that are freely suspended in air are used as a model system to study the coalescence of fluids in two dimensions. High-speed video microscopy is used to study the coalescence of islands, thicker, disk-shaped regions of the film bounded by edge dislocations. The early time growth of the bridge connecting the merging islands is essentially linear, while at long times the relaxation dynamics are exponential. The observations are compared with Hopper's classical hydrodynamic model of the coalescence of two infinitely long, fluid cylinders [Journal of the American Ceramic Society 76, 2947 (1993)] and with models appropriate to quasi-two dimensional fluids developed by Mann [Phys. Rev. E 51, 5708 (1995)] and Camley [Biophysical Journal 99, L44 (2010)] to explain their observations of domain relaxation in Langmuir films.

1:03PM M29.00010: Phase behavior and elastic response of liquid crystal mixtures in atomistic models  JIALE SHI (Presenter), HYTHEM SIDKY, JONATHAN K. WHITMER, University of Notre Dame — In practical applications, liquid crystal devices tend to utilize mixtures of liquid crystal molecules. Liquid crystals mixtures can be formulated to have a broad nematic phase range, elastic responses and dielectric anisotropies which are distinct compared to the components. Elasticity, in particular, is important in determining equilibrium morphologies and material responses. Despite this importance, limited knowledge exists about the connections between microscopic composition and macroscopic elastic response in liquid crystal blends. Here, we apply advanced sampling methods in atomistic models to study both the phase behavior and elastic response of liquid crystal mixture. Our simulation work can help understand the elasticity of liquid crystals mixtures and help to rationally design new liquid crystal mixtures.
Macroscopic sheets of negative order parameter Liquid Crystal Elastomer with high dissipation and auxetic properties*  
DEVESH MISTRY (Presenter), ROSS VOLPE, NICHOLAS TRAUGUTT, CHRISTOPHER YAKACKI, University of Colorado, Denver — Negative Order Parameter (NOP) Liquid Crystal Elastomers (LCEs) offer a route to new LCE actuation modes and the study of previously impossible LC systems.[1-3]

Mistry et. al. reported an acrylate LCE with a strain-induced NOP, coinciding with a negative Poisson's ratio (auxeticity).[1,2] Jampani et. al. reported microfluidic thiol-acrylate NOP LCE shells. [3] Due to the microfluidic synthetic process, there are 2 mechanisms for the development of the NOP state in the LCE shells – the shell wall either anisotropically deswelling or being biaxially strained through osmotic pressure. [4] Results Urayama et. al. suggest the latter method does not lead to NOP states.[5]

However, here we create NOP LCEs via the biaxial straining of polydomain LCEs. Using 2 methods we prepare >2x2 cm sheets of NOP LCEs – large enough for the first characterisation of a NOP LC system. Our NOP LCEs have higher levels of energy dissipation and display auxeticity at significantly lower threshold strain compared to LCEs of conventional ordering.[2]

1:27PM M29.00012: Oligomeric odd–even effect in liquid crystals.*  RONY SAHA (Presenter), GRETA BABAKHANOVA, ZEINAB PARSOUZI A.SH, MOJTABA RAJABI, PRABESH GYAWALI, Kent State Univ - Kent, CHRIS WELCH, GEORG H. MEHL, University of Hull, JAMES GLEESON, OLEG D LAVRENTOVICH, SAMUEL N SPRUNT, ANTAL ISTVAN JAKLI, Kent State Univ - Kent — In organic materials, they are usually associated with the number of methylene groups in aliphatic chains. In this work, we unveil multiple signatures of a new odd–even effect in liquid crystals that occurs at the larger scale of molecular moieties that by themselves express liquid crystalline behavior. We demonstrate that oligomeric liquid crystals, with \( n = 1–4 \) number of rigid mesogenic segments connected by flexible aliphatic chains with an odd number of methylene groups, produce an odd–even effect in optical anisotropy and the bend elastic constant of the liquid crystal oligomer. This effect is different from the usual odd–even effects with respect to the parity of carbon atoms in an aliphatic chain and can be understood in term of the average molecular shape and the associations between \( n \)-mers based on the packing of these shapes. We also show that, in spite of the fact that there is no long-range electron density modulation, careful analysis of synchrotron SAXS results can provide important information about the molecular associations in the N and NTB phases that other techniques cannot access.

1:39PM M29.00013: Relative orientation of defects in smectic-C films*  XINGZHOU TANG (Presenter), JONATHAN SELINGER, Kent State Univ - Kent — In a 2D liquid crystal, each topological defect has a topological charge and a characteristic orientation, and hence can be regarded as an oriented particle. Theories predict that the trajectories of annihilating defects depend on their relative orientation [1,2]. Recently, these predictions have been tested in experiments on smectic-C films [3]. Those experiments find curved trajectories that are similar to the predictions, but the detailed relationship between the defect orientations and the far-field director field is different. To understand this difference, we improve the previous theories by adding the effects of elastic anisotropy and nonequilibrium dynamics. We find that the theory with elastic anisotropy gives good agreement with the experiment, and hence can describe the effects of defect orientation.

*This work was supported by NSF Grant No. DMR-1409658.
Tying knots in liquid crystals. The topological nature of knots in fields has fascinated physicists and mathematicians. Experimentally they had been found only as transient features or required complex boundary conditions to exist until recently [1]. Here we present energetically stable, micrometer-sized knots in the chiral background of liquid crystals. These knots are spatially localized and diffusing in all directions. They self-assemble into crystalline lattices with open and closed structures, resembling colloidal particles and atomic nuclei. These knots are robust and topologically distinct from the host medium and can be morphed and reconfigured by weak stimuli under conditions such as those in displays. We use a combination of energy-minimizing numerical modeling and optical imaging to uncover the internal structure and topology of individual knots and the various hierarchical crystalline organizations they form. We further explore the effects of elastic anisotropy and external fields on the stability of these knots.

Computational model of a Maier-Saupe field theory for nematic liquid crystals. We develop a computational model based on a field theory extension of the Maier-Saupe molecular model of a uniaxial, nematic liquid crystal. A tensor order parameter is defined as the second moment of an orientational probability distribution, leading to a free energy that is not convex within the isotropic-nematic coexistence region, and that goes to infinity if the eigenvalues of order parameter become non-physical. An elastic free energy is added which is an expansion in spatial gradients of the order parameter up to third order, allowing for parametric control over the anisotropy and elasticity of the liquid crystal. Computations of the spatial profile of the order parameter are presented for an isotropic-nematic interface in one dimension, a nematic defect in two dimensions, and a tactoid in two dimensions. We compare the simulation results to those given by the Landau de-Gennes free energy.

Session M30 DSOFT DPOLY: Soft Mechanics via Geometry II

Rochester Institute of Technology - Tag(s): Focus
11:15AM M30.00001: The topography of tuning [Invited]  ELENI KATIFORI (Presenter), University of Pennsylvania — Allosteric proteins globally adjust their conformation upon binding a ligand in order to control the activity of a distant active site. Inspired by such a system, we explore how mechanical systems achieve a specified complex function such as strain propagation in mechanical networks. We investigate computationally the maximum complexity of a tuned function that can be achieved as a function of network size. Further, we identify the structural features responsible for function in these tuned networks. We show how we can use topographical information to improve the tuning process and how the complexity of the tuned function scales with network size. Using persistent homology, we show that networks tuned to perform such functions develop characteristic features that are similar for different networks that perform the same function, regardless of differences in the local link connectivity.

11:51AM M30.00002: Mechanics of soft fibrous mats with inter-fiber adhesion and friction* CATALIN PICU (Presenter), VINEET NEGI, Rensselaer Polytechnic Institute — Many soft materials of biological and industrial interest are composed from nanofibers and take the form of quasi-two-dimensional mats with stochastic structure. Examples include membranes in the human and animal bodies, geotextiles, non-wovens used in consumer products and tissue scaffolds. We investigate the mechanical behavior of such structures, which is largely controlled by geometry and adhesive and frictional interactions of constituent fibers. We consider two cases: one in which the fibrous mat is stabilized by adhesion, and the other in which fibers interact only frictionally. Both systems exhibit rich non-linear mechanics. We determine the scaling of material properties with the intensity of adhesion, and describe the interplay between frictional interactions and geometry in defining the mechanics of the mat. Stress in these systems is primarily associated with dissipation and exhibits interesting dependence on the network architecture.

12:03PM M30.00003: Nonlinear Poisson effect in critical mechanical networks* JORDAN SHIVERS (Presenter), SADJAD ARZASH, FRED C MACKINTOSH, Department of Chemical and Biomolecular Engineering, Rice University — Fibrous networks of stiff athermal biopolymers such as collagen, a major structural component of the extracellular matrix, have been shown to exhibit anomalously large apparent Poisson ratios, i.e. significant transverse contraction under small applied longitudinal extension. Here we show that this effect can be understood in the context of a macroscopic mechanical phase transition from a bending-dominated regime to a stretching-dominated regime at a critical applied extension controlled by the network connectivity. We measure this effect using a variety of 2D and 3D model network structures and propose a phase diagram governing the transition as a function of connectivity and strain.

12:15PM M30.00004: Shear modulus discontinuity in fiber networks*   SADJAD ARZASH (Presenter), JORDAN SHIVERS, FRED C MACKINTOSH, Department of Chemical & Biomolecular Engineering, Rice University — Fibrous networks such as collagen are common in physiological systems. One important function of these networks is to provide mechanical stability for cells and tissues. It has been shown that athermal coarse-grained models of fibers with bending and stretching interactions can explain the experimental observations. By applying an extensional or shear deformation, subisostatic fiber networks with only central force interactions undergo a phase transition from a floppy to a rigid state. By simulating various network models, we confirm that although the network's stiffness exhibits a discontinuity, the transition is critical in nature. We study the finite-size scaling behavior of this discontinuity in order to identify the corresponding non-mean-field critical exponent in the thermodynamic limit.

12:27PM M30.00005: Shaping curved surfaces using origami.   THÉO JULES (Presenter), Laboratoire de Physique, Ecole Normale Superieure de Lyon, FREDERIC LECHENAULT, Laboratoire de Physique, Ecole Normale Superieure, MOKHTAR ADDA-BEDIA, Laboratoire de Physique, Ecole Normale Superieure de Lyon — In order to understand the full range of equilibrium shapes and mechanical response of origami-based metamaterials, one is led to take into account both the geometrical constraints induced by the crease network and the elasticity of the material. A model example for this is a shell formed by an accordion-like origami, made from a single elastic sheet decorated by a series of parallel creases, crossed by a central longitudinal crease. Surprisingly, while the imprinted crease network does not have a geodesic curvature, the emergent three-dimensional structure is characterized by an effective curvature along the central line. We craft these patterns and scan them using a structured-light 3D-scanner. Our study captures the exotic zoology of face deformations that appear due to kinematic constraints imposed by the crease network, ranging from simple bending to ribbon-like behavior, as confirmed by FEM simulations.
**Non-Hookean Elastic Moduli of 2D Tissue Model**

ARTHUR HERNANDEZ (Presenter), University of California, Santa Barbara, MICHAEL MOSHE, The Racah Institute of Physics, Hebrew University, M CRISTINA MARCHETTI, MARK J BOWICK, University of California, Santa Barbara —

We study the peculiar mechanical response of a discrete vertex model (VM) of 2D epithelia. In the absence of T1 rearrangements, the VM exhibits a transition between a soft and a stiff solid tuned by the target shape index of the cells and associated with the onset of geometric incompatibility. By examining the response to a variety of deformations, we show that the stiff solid phase exhibits nonlinear elastic response that cannot be recast in the framework of conventional Hookean elasticity even in the limit of infinitesimal strain. The soft solid is characterized by floppy modes that can absorb strain. As a result, the linear mechanical response is not fully characterized by two independent Lamé coefficients, as in linear elasticity of a 2D isotropic solid, but depends on the specific imposed deformation. We show that this unconventional mechanical behavior is in agreement with a continuum version of the model developed recently by some of us.

**Geometry and kinetics determine the packing structure on evolving surfaces**

ZHAOYU XIE (Presenter), CHRISTOPHER BURKE, BADEL L MBANGA, Tufts Univ, PATRICK T SPICER, School of Chemical Engineering, University of New South Wales Sydney, TIM ATHERTON, Tufts Univ — We consider the evolution, arrest and jamming of particulate media on an evolving surface. As the shape changes, local regions of compression and rarefaction induce local solidification or melting and, consequently, rich kinetic effects. Here we resolve the relative influence of kinetics and geometry in determining the structure of a model system: the coalescence of Pickering emulsion droplets that can be arrested by the solid particles coated on the surface. By Monte Carlo simulations, we demonstrate that in the quasi-static regime, the geometry still governs the microstructure of these particles, resembling the spherical crystallography regime explored in previous literature. Conversely if the evolution of surface is fast, the kinetics can change the structure at the arrest point depending on the local surface deformation, with jamming fronts that develop from the compressed area. Other surfaces and particles are explored and we propose a new class "metric jamming" to describe the transition to rigidity under shape deformation.

1:03PM M30.00008: Crumple-Origami Transition for Twisting Cylindrical Shells*  
LI-MIN WANG (Presenter), Department of Physics, Natl Tsing Hua Univ, SUN-TING TSAI, Department of Physics and Institute for Physical Science and Technology, University of Maryland, CHIH-YU LEE, Hsinchu Senior High School, PAI-YI HSIAO, JIA-WEI DENG, HUNG-CHIEH FAN CHIANG, Department of Physics, Natl Tsing Hua Univ, YICHENG FEI, Department of Physics and Astronomy, Rice University, TZAY-MING HONG, Department of Physics, Natl Tsing Hua Univ — Origami and crumpling are two extreme tools to shrink a 3-D shell. In the shrink/expand process, the former is reversible due to its topological mechanism, while the latter is irreversible because of its random-generated creases. We observe a morphological transition between origami and crumple states in a twisted cylindrical shell. By studying the regularity of crease pattern, acoustic emission and energetics from experiments and simulations, we develop a model to explain this transition from frustration of geometry that causes breaking of rotational symmetry. In contrast to solving von Karman-Donnell equations numerically, our model allows derivations of analytic formula that successfully describe the origami state. When generalized to truncated cones and polygonal cylinders, we explain why multiple and/or reversed crumple-origami transitions can occur.

1:15PM M30.00009: Statistical mechanics of nanotubes*  
SIDDHARTHA SARKAR (Presenter), ANDREJ KOSMRLJ, Princeton University — We investigate how thermal fluctuations affect mechanical properties of nanotubes by employing renormalization group procedure. For 2D sheets it was previously shown that thermal fluctuations effectively renormalize elastic constants beyond a characteristic thermal length scale (a few nanometers for graphene at room temperature), where the bending rigidity increases, while the in-plane elastic constants reduce with universal power law exponents. However, the curvature of nanotubes produces new phenomena. Specifically, we find that in the axial direction the in-plane elastic constants stop renormalizing at the elastic length scale (proportional to geometric mean of the radius and the effective thickness of the shell), while in the circumferential direction they continue to renormalize albeit with different universal exponents. On the other hand, the bending rigidity stops renormalizing in the circumferential direction at the elastic length scale. These results were verified with molecular dynamics simulations by measuring the mechanical response to axial loads and external pressure. We also comment on how these temperature dependent properties affect the critical buckling loads for nanotubes.

*Work was supported by the NSF Career award DMR-1752100.
1:27PM M30.00010: Braided biopolymer filament bundles produce topologically protected kinks  VALENTIN SLEPUKHIN (Presenter), University of California, Los Angeles, MAXIMILIAN GRILL, Technical University of Munich, QINGDA HU, ELLIOT BOTVINICK, University of California, Irvine, WOLFGANG WALL, Technical University of Munich, ALEX LEVINE, University of California, Los Angeles — Bundles of stiff filaments are ubiquitous in the living world, found both in the cytoskeleton and in the extracellular medium. These bundles are typically held together by smaller cross-linking molecules. We demonstrate analytically, numerically and experimentally that such bundles can be kinked, i.e., have localized regions of high curvature that appear to be at least long-lived metastable states. We find analytically three possible mechanisms of kink stabilization: the different trapped length of the filaments between two cross-links; the endpoint of the filament in the middle of the bundle; the braiding of the filaments in the bundle. For a high concentration of cross-links, last two effects lead to the topologically protected kinked state. Finally, we explore the transition of the metastable kinked state to the stable straight bundle state both numerically and analytically.

1:39PM M30.00011: Fabrication of supported lipid bilayers of designed shape with micro-printing and replica-molding  MELISSA RINALDIN (Presenter), LUCA GIOMI, DANIELA JUTTA KRAFT, Leiden University — Membrane curvature is a fundamental part of the cellular machinery. In cells, membrane curvature can be generated by different mechanisms, including cytoskeletal scaffolding and lipid and protein sorting. In protein-free systems in vitro, membrane curvature can be artificially obtained by, for example, membrane micro-manipulation, phase separation, and supported lipid bilayers fabrication. However, until now, these methods allowed for studying a restricted range of shapes only. Here, we present a general and facile method to obtain membranes of designed curvature with high precision. By combining 3D micro-printing and replica-molding lithography, we fabricate scaffolds of designed shape and size suitable for lipid coating. We show that the resulting supported lipid bilayers are homogeneous and fluid. We demonstrate their potential by using them for fluorescence after photobleaching and phase separation experiments on curved surfaces. We anticipate that our method will open new possibilities to investigate curvature sensing proteins and, more generally, the role of membrane curvature in biology.
1:51PM M30.00012: Curvature-driven propulsion of floating films: Part 1*  MONICA RIPP
(Presenter), ZACHARIAH SCHRECENGOST, ELIZABETH LAWSON-KEISTER, JOSEPH PAULSEN, Syracuse University — Water striders can propel themselves up a curved liquid meniscus by repositioning their feet to match the curvature of their destination, providing one example of propulsion along an interface due to a mismatch in geometry [1]. How does a highly-flexible elastic solid respond when it is placed on a liquid surface with a curvature different than its own? We find that flat films spontaneously flee highly-curved menisci towards flatter regions, whereas curved shells are attracted to regions with finite curvature. These findings are borne out of experiments where polymer films are released from different initial positions in overfilled petri dishes. Focusing on flat films that are ~1 cm wide and ~100 nm thick, we examine the effects of film thickness, liquid viscosity, and meniscus curvature on the velocity of this motion. Our data across a wide range of parameters are in agreement with a theoretical picture in which the sheet is propelled by its ability to cover progressively more liquid surface area in the regions where it is attracted [2]. We develop this model and its consequences in the next talk. (This is part 1 of a 2-talk series.)

*Support from NSF-DMR-CAREER-1654102 is gratefully acknowledged

2:03PM M30.00013: Curvature-driven propulsion of floating films: Part 2*  ZACHARIAH SCHRECENGOST (Presenter), MONICA RIPP, JORDAN V BARRETT, Syracuse University, VINCENT DÉMERY, Physics, Université de Lyon, JOSEPH PAULSEN, Syracuse University — The remaining pieces of breakfast cereal spontaneously clump together in a cereal bowl due to the interactions of the menisci around each particle. A highly-bendable elastic sheet participates in a very different interaction with the liquid around it. In the previous talk, experimental results were given where a polymer film spontaneously propels itself to a region that more closely matches its intrinsic curvature. These results were interpreted as falling within a geometric framework, where the sheet bends and wrinkles in such a way as to minimize the exposed liquid surface area [1]. Implementing this model is a nontrivial optimization problem, due to the wide variety of configurations available to the sheet and interface. We use Surface Evolver simulations and analytic calculations to study the energetic cost of placing an ultrathin elastic disc on a local topography of arbitrary curvature. We establish scaling laws that relate the total energy to the principal radii of curvature. By estimating the fluid drag forces, we develop theoretical predictions for sheet velocity, which we compare with our experiments. (This is part 2 of a 2-talk series).

*Support from NSF-DMR-CAREER-1654102 is gratefully acknowledged.

Session M31 DSOFT: Directed Assembly 2: Field Driven 503 - Alex Travesset, Ames Lab
**11:15AM M31.00001: Hyperuniform structures formed by shearing colloidal suspensions**

SAM WILKEN (Presenter), RODRIGO EMIGDIO GUERRA, DAVID J PINE, PAUL M CHAIKIN, New York Univ NYU — Time-reversibility is an essential feature of viscous, creeping flow that is lost when rigid particles suspended in the liquid are forced to collide with each other. In periodically sheared suspensions this loss manifests as a dynamical phase transition between reversible and chaotic particle trajectories characterized by a critical strain amplitude. Repulsive, non-hydrodynamic interactions between colliding particle surfaces have been proposed as the likely source of this broken symmetry, and a toy model that emphasizes particle collisions, called Random Organization\(^1\), qualitatively reproduces the dynamical features of this transition. This model also displays a concomitant structural reorganization characterized by vanishingly small density fluctuations on long length-scales, called hyperuniformity, at criticality\(^2\). Here we show that the particles in periodically sheared suspensions organize into structures with anisotropic short-range order but isotropic, long-range hyperuniform order when oscillatory shear amplitudes approach the critical strain amplitude.

\*This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-1420073.

**11:27AM M31.00002: Optimized Large Hyperuniform Binary Dipolar Colloidal Suspensions in Two Dimensions**

ZHENG MA (Presenter), Princeton University, ENRIQUE LOMBA, Instituto de Química Física Rocasolano, SALVATORE TORQUATO, Princeton University — We have developed a protocol to guide experimentalists to fabricate large disordered hyperuniform two-phase system in two dimensions by binary colloidal particles. In our model, colloidal particles are doped such that it induces dipole-dipole interactions when a magnetic field is applied. We show that despite each component is not hyperuniform, there exists an optimal composition that makes the resulting two-phase system effectively hyperuniform. By changing magnetic fields or the doping level/size of particles, the system can self-organize into tunable structures. Our approach provides a general solution for making large hyperuniform materials in labs in an efficient manner.
**Assembly of gold nanoparticles directed by light polarization**

PANUPON SAMAIMONGKOL, ERICH M SEE, Physics, Virginia Tech, CHERYL L PECK, WEBSTER L SANTOS, Chemistry, Virginia Tech, HANS ROBINSON (Presenter), Physics, Virginia Tech — When polarized light is incident on a small metal nanoparticle, the light intensity at the particle surface is enhanced in two opposite polar regions defined by the polarization direction. By functionalizing the nanoparticles with photosensitive ligands, this intensity distribution can be transferred into permanent surface properties, forming two opposite patches on the particle. Using a ligand that photocleaves to reveal a positively charged amine group, we assemble smaller (15 nm diameter) gold nanoparticles onto the larger (80 nm diameter) functionalized patchy particle. Since all areas of the 80 nm particle are exposed to light, binding can take place in any orientation, but is strongly preferential to the direction set by the polarization of the exposing light, resulting in arrays of oriented nanoparticle assemblies. Interestingly, we also see increased particle binding around the equator of the particle, where light exposure was at a minimum. Possibly, this is due to electrostatic bias in the random walk toward the polar regions being absent around the equator, leading to a relative accumulation of the 15 nm particles in this region.

**Acoustokinetics: Organizing Soft Matter with Acoustic Holograms**

MOHammed ABDELAZiZ (Presenter), DAVID G GRIER, New York Univ NYU — Factoring the pressure field of a harmonic sound wave into its amplitude and phase profiles provides the foundation for an analytical framework for studying acoustic forces that not only provides novel insights into the forces exerted by specified sound waves, but also addresses the inverse problem of designing sound waves to implement desired force landscapes. These force landscapes could be used to transport and organize matter on scales from microns to millimeters. We illustrate the benefits of this acoustokinetic framework through case studies of purely nonconservative force fields, standing waves, pseudo-standing waves, and tractor beams.

**12:03PM M31.00005: Landau theory of complex spherical packing phases**

SARAH DAWSON (Presenter), DUNCAN MCCLENAGAN, ANCHANG SHI, McMaster Univ — The complex spherical packing phases, including the Frank-Kasper $\sigma$ and A15 phases, appear in a diverse array of soft-condensed matter systems. The universality of these novel ordered structures points to some common underlying physics that can be probed by a suitable Landau theory. The stability of several complex phases was investigated in two theories that are often used to study pattern formation: The Landau-Brazovskii and Ohta-Kawasaki models. Unexpectedly, these phases were found to be stable in the former theory and not the latter. Appropriately scaled, these two free-energy functionals favour periodic modulation of the order parameter at a particular wave number, and differ only in the shape of the free-energy about this value. Motivated by this result, we studied how the shape of the free-energy about its optimal wave number can influence the relative stability of the complex phases over the BCC and FCC spherical phases. This talk is concerned with how these results can inform us of the general mechanisms guiding the formation of the complex spherical phases.

*This research is supported by the Natural Science and Research Council (NSERC) of Canada*

**12:15PM M31.00006: Templated assembly of self-propelled particles in targeted micromachines**

ANTOINE AUBRET (Presenter), JEREMIE PALACCI, University of California, San Diego — In this talk, I will show how we can carve non-equilibrium pathways for the controlled self-assembly of active microparticles using light as a tool. We previously demonstrated the light-triggered self-assembly of self-propelled particles in robust geared micromachines [Aubret et al., Nature Physics 2018]. The gears constitute the fundamental components of synchronized micro-machineries, whose dynamics is tuned by the spins of their internal components. Here, we demonstrate a new approach -tempered assembly- which exploits optical forces and the activity of the colloids to create larger ensembles of self-spinning microgears. Thanks to our approach, the chirality of the gears can be selected and changed over time. It allows us to finely examine the interaction between multiple gears depending on their precise arrangement, and to explore the non-equilibrium interaction potential of the gears, which is due to both hydrodynamics and phoretic phenomena. Our study demonstrate the potential of light to manipulate and image the non-equilibrium interactions between dynamical colloidal architectures.

*This material is based on work supported by the National Science Foundation under Grant No. DMR-1554724. J.P. thanks the Sloan Foundation for support through grant FG-2017-9392.*
12:27PM M31.00007: Synchronization of colloidal oscillators  JINZI HUANG, YAOCHENG DESMOND LI (Presenter), ANTOINE AUBRET, JEREMIE PALACCI, University of California, San Diego — Christiaan Huygens invented pendulum clocks and observed ‘an odd sympathy’ that pendulum clocks hanging on the same wall autonomously synchronize with one another. However, the phenomenon was a mysterious until coupling by the wall was shown to be the driving force for the synchronization. Indeed, interactions between dynamical systems promote synchronization, and we aim to study such phenomena on a micro scale by designing colloidal oscillators. Using self-assembly of microswimmers with passive structures, we develop colloidal clocks that oscillate. We show that pairs of microclocks are able to synchronize with each other, in spite of thermal noise, and compare well with a stochastic model. Further, assemblage of clocks are achieved to study how the clocks can achieve synchronicity in situations of spatial frustration.

12:39PM M31.00008: Development of surface composition and ordering during reverse-emulsion assembly of binary colloidal particle mixtures  CHRISTIAN HEIL (Presenter), THOMAS E GARTNER, ARTHI JAYARAMAN, Chemical and Biomolecular Engineering, University of Delaware — Nanoparticle assembly at a fluid-fluid interface is a proven route to precisely engineer materials with controlled optical properties. In this talk, we will present our recent work using coarse-grained Langevin dynamics simulation that mimics reverse-emulsion directed assembly of binary nanoparticle mixtures into supraballs. We model a binary mixture of silica and synthetic melanin particles in implicit solvent within a shrinking spherical confinement to replicate the shrinking reverse-emulsion droplet. The simulation protocol captures the physics of this process by reproducing the experimental observation of melanin and/or smaller nanoparticles enriching the water-octanol interface. For all mixtures, we observe enrichment of the melanin particles at the supraball surface compared to the supraball interior. This enrichment decreases with increasing melanin/silica size ratio. We observe appreciable crystalline ordering only for systems with similarly sized particles. Particle size dispersity, finite assembly timescale, and curvature of the supraball surface all serve to suppress particle ordering. These findings serve as design rules for tailoring the supraballs for structural color applications and improve our fundamental understanding of particle assembly near curved interfaces.
12:51PM M31.00009: Enhanced Diffusion and Magnetophoresis of Paramagnetic Colloidal Particles in Rotating Magnetic Fields  ZACHARY SHERMAN (Presenter), University of Texas at Austin, JULIA L PALLONE, Massachusetts Institute of Technology, RANDALL M ERB, Northeastern University, JAMES SWAN, Massachusetts Institute of Technology — Dispersions of paramagnetic colloids can be manipulated with external magnetic fields to assemble structures and control transport. For fields held steady in time, the structure and dynamics are coupled, which becomes problematic for processes where aggregation competes against particle transport. Rotating the field direction in time drives dispersions out of equilibrium, allowing the structure and dynamics to be tuned independently to enhance transport. Fundamental transport properties, like the diffusivity and magnetophoretic mobility, dictate a suspension's nonequilibrium response and are crucial to understand to design processes utilizing rotating fields. Here, we investigate the transport properties of paramagnetic colloids in rotating magnetic fields using dynamic simulations. We find that self-diffusion is enhanced in rotating fields compared to steady fields, and that the self-diffusivity in the plane of rotation reaches a maximum value at intermediate rotation frequencies that is larger than the Stokes-Einstein diffusivity of an isolated particle. While the magnetophoretic velocity through bulk fluid decreases with increasing rotation frequency, enhanced in-plane diffusion allows for faster magnetophoretic transport through porous materials in rotating fields.

1:03PM M31.00010: Mesoscale simulation approach for dynamics and assembly of deformable objects  TOLUWANIMI BELLO (Presenter), TEJUS SHAISTRY, SANGWOO LEE, PATRICK UNDERHILL, Rensselaer Polytechnic Institute — In concentrated suspensions, surfactant micelles, emulsion droplets, and microgels often form contacts among the objects leading to nonspherical shapes. In this limit, the dynamics and assembly of the suspension depend more on the interfaces between objects than the bulk objects themselves. This type of deformation of domains also occurs in microphase separation of block copolymer systems. We have adapted a mesoscale approach (called vertex models) in order to apply it to the dynamics and assembly of small deformable objects. In this way, we are developing a unifying framework to understand micelles, emulsions, microgels, and block copolymers. In this talk, we will describe the application of vertex models to small deformable objects. In particular, we have quantified the phase diagram of assembly in thin films of particles (2D simulations) and bulk assembly of particles (3D simulations). A balance of thermal fluctuations and deformability leads to an order-disorder transition in both cases. A unique feature of 3D materials is that multiple ordered states are possible. We have quantified their meta-stability and transitions between ordered states. These transformations are well-known in metallic systems, but have only recently been found in experiments with soft materials.
1:15PM M31.00011: Ordering and Interactions of Gold Nanoparticles (AuNPs) with Fractional Surface Coverage of Ligands*  MORGAN E REIK, CHRIS LIEPOLD, SEAN D GRIESEMER, WEI BU, ALEX SMITH, STUART A RICE, JUAN DE PABLO, Binhua Lin (Presenter), University of Chicago — We studied the properties of self-assembled AuNPs monolayers. These monolayers are formed from solutions with varying thiol concentrations. We show that equilibrium between adsorbed thiols on Au cores and thiols in the bulk solution imply fractional coverage of the Au cores. The equilibrium coverage of AuNPs is adequately described by Langmuir adsorption kinetics, and, therefore, we interpret the way in which varying thiol concentration affects the nanoparticle-nanoparticle interactions as a function of surface coverage of the Au core [1]. We also examine the structure and general shape of the ligand envelope as a function of the surface coverage using molecular dynamics simulation and demonstrate that the equilibrium structure of the envelope and the deformation of that envelope generated by interaction between the AuNPs are coverage-dependent, so that the shape, depth, and position of the minimum of the potential of mean force display a systematic dependence on the ligand coverage [2].

1:27PM M31.00012: Divine Proportions and the Fractal Dimension of DLCA Aggregates*  Chris Sorenson (Presenter), Kansas State Univ — Aggregation is a non-equilibrium process of fundamental importance for all dispersed particulate systems. Here I present a restricted hierarchical model of diffusion limited cluster-cluster aggregation (DLCA). The model yields an analytical calculation of the fractal dimensions and self-preserving cluster shapes in two and three spatial dimensions in excellent agreement with those found in nature and simulations. Remarkably the shape is described by the Fibonacci series and the divine proportion in two dimensions and d-dimensional generalization of the Fibonacci series and the divine proportion in three and higher dimensions.

*The author is supported by NSF grant AGS 1649783
1:39PM M31.00013: Polydisperse Gold Nanocrystals and Hard Sphere Diameters* XUN ZHA (Presenter), ALEX TRAVESSET, Iowa State University — A fundamental property of nanocrystals is its hard sphere diameter. In this talk, I will provide a critical discussion on how to compute the diameter, why it is important and in what situations determines the nearest neighbor distance through packing considerations. I will then classify polydisperse nanocrystals of the truncated octahedral family and show that it consists of 351 different types within the size range 1-5nm. I will compute the hard sphere diameter and show how it changes with system size for all these cases. Connections with experiments with 16% polydispersity in alkylthiolated gold nanocrystals, which show crystal fractionalization, will also be discussed.

1:51PM M31.00014: Effect of Water Vapor on the Pair Potential Between Ligated Nanoparticles* MICHAEL MARTINEZ (Presenter), MIAOCHEN JIN, ALEX SMITH, KEVIN SLATER, LINSEY NOWACK, BINHUA LIN, STUART A RICE, University of Chicago — We have carried out all-atom molecular dynamics simulations to illuminate the physical basis for the change in Young’s modulus of a monolayer of dodecane thiol ligated Au nanoparticles discovered by Wang et al.[1] For a water vapor concentration that would generate 80% monolayer coverage of the nanoparticle surface we find that water molecules form large fluctuating “hemispherical” clusters on the nanoparticle surface with the correct macroscopic contact angle. We have constructed AuNP-AuNP potential curves for both wet and dry systems; the difference in the shapes of these curves near their minima is consistent with the change in Young’s Modulus found by Wang et al. [1] The in vacuum all-atom NP ligand conformations and NP-NP potential agrees well with those previously obtained from united-atom simulations.[2] Additionally, both the wet and dry potential energy curves differ significantly between sampled frozen orientations, implying the possibility of variation in the local NP energy in a self-assembled ordered AuNP array.

2:03PM M31.00015: Ligand Structure and Free Energy of Nanoparticles on Substrates*
MATTHEW PHAM (Presenter), ALEX TRAVESSET, Iowa State University — 2D nanoparticle superlattices are commonly assembled on or transferred to solid substrate supports such as silicon wafers, silica, or graphene. In order to better understand nanoparticles in this context, molecular dynamics simulations were carried out to study the nanoparticle-substrate interactions. Simulations were run using HOODLT/HOOMD-blue to analyze the capping ligand vortices and adhesion free energies of substrate supported gold nanoparticles of various sizes grafted with hydrocarbons of various lengths. The relation of this work to nanoparticle superlattices is also discussed.

Session M32 DSOFT DPOLY: Physics of Complex Liquid Interfaces 504 -
Gordon Christopher, Texas Tech Univ - Tag(s): Focus
The dependence of the Laplace pressure, $\Delta P = 2\gamma/R$, on alveolar radius, $R$, means that interconnected alveoli are metastable if $\gamma$ is constant. However, while not generally appreciated in the medical literature, but well known in the foam and emulsion stability literature, the dynamic resistance of an interfacial film to compression can reverse the Laplace instability. The dilatational modulus, $\varepsilon = A \partial \gamma / \partial A$, relates the change in surface tension, $\gamma$, to the change in molecular area, $A$, as the interface is compressed at frequency, $\omega$ (ranging from 1-20 radians/second for normal breathing). If the dilatational modulus is large enough, the resistance to interfacial compression can overcome the Laplace pressure so that the gas pressure in the alveolus no longer increases with decreasing radius. For $(2\varepsilon - \gamma) > 0$, the Laplace pressure decreases with decreasing radius and increases with increasing radius, which reverses the Laplace instability, thereby stabilizing the alveoli against collapse. Under normal conditions, lung surfactant generates conditions such that $(2\varepsilon - \gamma) > 0$, and the lung remains stable. However, during Acute Respiratory Distress Syndrome, trauma or disease leads to a dramatic increase in the concentration of albumin and lysophosphatidylcholine, soluble surface-active molecules that compete for the interface with lung surfactant. Using a newly designed capillary microtensiometer, we have found that increasing concentrations of lysophosphatidylcholines, a product of the inflammation induced degradation of phospholipids, causes the dilatational modulus to decrease as $\omega$ decreases, resulting in $(2\varepsilon - \gamma) < 0$, creating conditions that induce the Laplace instability. This suggests a mechanism underlying ARDS which kills 50,000 people each year with no known cure. Increasing the breathing frequency or decreasing the lysophosphatidylcholine concentration can increase the dilatational modulus and may restore proper lung function in ARDS.

**11:51AM M32.00002: Solutal Marangoni spreading in the presence of pre-deposited insoluble surfactant monolayers** MADELINE SAULEDA (Presenter), STEPHEN GAROFF, ROBERT TILTON, Carnegie Mellon Univ — Marangoni spreading can be used for pulmonary drug delivery. However, endogenous surfactant in the lung may inhibit that spreading. Here we investigate how the density of pre-existing phospholipid monolayers impacts Marangoni flows induced by exogenous surfactants on a thin fluid subphase. A dipalmitoylphosphatidylcholine (DPPC) monolayer is pre-deposited at a predetermined lateral density on an aqueous subphase before depositing a drop of oleic acid, an insoluble surfactant. Talc tracer particles monitor the extent of spreading, and a trans-illumination method is used to measure the temporal evolution of the subphase surface deformation. This reveals the outwardly moving “Marangoni ridge”. As long as the surface pressure of the DPPC monolayer is less than that of an oleic acid monolayer, spreading proceeds until the surface pressures of the monolayers are equal. The final area per molecule of DPPC in the compressed monolayer is thus the same in each case. The trajectory and degree of interface deformation caused by Marangoni flow are altered by increasing initial DPPC concentration. Unlike Marangoni flow on bare subphases, there is surface flow ahead of the Marangoni ridge as the DPPC monolayer is compressed.
12:03PM M32.00003: Exploring the free energy landscape to predict surfactant adsorption isotherm at nanoparticle-water interface  PAOLO DE ANGELIS (Presenter), ANNALISA CARDELLINI, PIETRO ASINARI, Politecnico di Torino — The long-lasting stability of nanoparticle (NP) suspensions in aqueous solutions is commonly reached by the addition of surfactants. However, a tailored prediction of surfactant concentration enabling a well dispersion of NPs is still an ambitious objective (Cardellini et al., 2019). Here, by coupling Steered Molecular Dynamics (SMD) with the Langmuir theory, we predict the adsorption isotherm of Sodium-Dodecyl-Sulphate (SDS) on α-alumina NP. Beyond the design, our results unveil the role of NP curvature and morphology in the adsorption phenomena at solid-liquid interface. First, the Free Energy Landscapes (FELs) obtained via SMD show the dominance of the entropic contribution by increasing the SDS molecules on target bare NP. Second, a thorough analysis on the FELs, clarifies how the enhanced adsorption deviates from a Markovian dynamics in a curved interface. In fact, both NP curvature and morphology promote modification of the thermodynamics state of adsorption with consequent free energy profiles splitting and the identification of specific sites of adsorption. The proposed modelling framework provides physical insights in the surfactant adsorption onto spherical NPs and suggests guidelines to design NP suspensions in aqueous solutions. (De Angelis et. al, accepted on ACScs).

12:15PM M32.00004: Finite-size line tension effects for nanoparticles at the air-liquid surface*  BRUCE LAW (Presenter), Kansas State Univ, HIROKI MATSUBARA, JO OTSUKA, Chemistry, Kyushu University — The line tension of nanoparticles, at the air-liquid surface, can be deduced by examining the variation in surface tension with nanoparticle bulk concentration. The line tension of dodecane thiol ligated Au nanoparticles at the octadecane-air surface (at 30°C) is found to vary with nanoparticle size. This finite-size line tension effect is qualitatively explained by integrating over the van der Waals contributions to the line tension at the three-phase solid-liquid-air contact line [1].

12:27PM M32.00005: Adsorption of nanosheet particles to surfactant-laden interfaces*  NISHAT ANJUM (Presenter), YA-WEN CHANG, Texas Tech Univ — It is known that particles with appropriate wettability spontaneously adsorb to neat water-oil interfaces. The combined effect of particles and surfactants at interfaces, however, is still poorly understood. In this work, we show that selected oil-soluble surfactants promote the adsorption of hydrophilic nanosheet particles and enhance bulk oil-in-water emulsion stability. Using microfluidics, we evaluate interface stability against coalescence and the competitive adsorption dynamics of particles versus surfactant for nanosheets of varying degrees of surface activity.

*Texas tech university and ACS PRF
12:39PM M32.00006: What are the effects of processing conditions on the interfacial viscoelasticity of asphaltene interfaces?  GARRETT COLE, GORDON CHRISTOPHER (Presenter), Texas Tech Univ — Stable crude/water emulsions that form during processing result in the formation of the rag layer, which is a major detriment to petroleum processing. The stability of the rag layer is determined by drop resistance to coalescence. Interfacial asphaltenes and other surface active components create viscoelastic interfaces that inhibit coalescence, resulting in stable rag layers. Although, there have been efforts into studying asphaltene interfaces, there are still many open questions regarding their behavior. In particular, the formation pathway of the asphaltene interface on final interfacial elasticity.

We have examined how large amplitude dilatational strains change the interfacial shear viscoelasticity of asphaltene interfaces. We see changes in viscoelastic moduli that depends on how the interface was formed: adsorption, larger single compression, or multistep small compressions. Interfaces that adsorb show larger viscoelastic moduli than single step compression interfaces, but smaller values than multistep compression. Small interfacial expansions result in minimal changes of the interface, but large expansions significantly disrupt surface structure creating weak interfaces. These results shed important light on how processing of these interfaces may affect rag layers.

12:51PM M32.00007: Pore scale, multi phase flow assessment for industrial applications
MATHIAS STEINER (Presenter), RODRIGO NEUMANN, RONALDO GIRO, MICHAEL ENGEL, IBM Research - Brazil — We report progress of our research of flow analysis at nanometer to micrometer scales for industrial applications. For an investigation of oil recovery at pore scale, digital representations of capillary networks in reservoir rocks are derived from data obtained by applying microscopic computer tomography to representative rock samples. The capillary network representations derived from digital rock are used as geometric boundaries for numerical flow simulations of complex fluids containing water, oil, and additives such as polymers or surfactants. The hierarchical, multiphase flow models deployed in the numerical simulations are calibrated at nanometer scale through molecular dynamics simulations. Importantly, the flow simulations are experimentally verifiable by means of a nanofluidic rock-on-chip measurement platform integrated with semiconductor technology. The laboratory method allows extracting physical parameters that determine surface wetting and capillary flow properties at microscopic scales. The methods developed in our research are more generally applicable to problems of fluid flow in porous media. Their combined application will increase accuracy and enable cost and time reduction in permeability assessment for exploration and production of natural resources.
1:03PM M32.00008: 2D to 3D transition of nanoparticles assembled at the liquid interface

YU CHAI (Presenter), ALYSIA LUKITO, Lawrence Berkeley National Laboratory, JAFFAR HASNAI, ANJU TOOR, University of California, Berkeley, WENQIAN FENG, Lawrence Berkeley National Laboratory, YUFENG JIANG, University of California, Berkeley, JOE FORTH, YUNHUI TANG, HONGHAO HOU, TERESA WILLIAMS, RAVI CHANDRA, DONG LI, Lawrence Berkeley National Laboratory, PHILLIP GEISSLER, University of California, Berkeley, BRETT HELMS, THOMAS RUSSELL, PAUL ASHBY, Lawrence Berkeley National Laboratory — With in situ atomic force microscopy (AFM) imaging, the structure of nanoparticles assembled at the water-oil interface is clearly resolved with the nanometer in 3D. The increase in the surfactant concentration in the oil phase leads to the increase in the contact angle of the nanoparticles at the water-oil interface. Unlike the prediction by equilibrium theory, a 2D monolayer to a 3D multilayer transition of nanoparticles is observed at high surfactant concentrations, which is attributed to the co-existence of completed wetted and partially wetted nanoparticles at the water-oil interface. The contact angle change and structural transition of nanoparticles induced by the increase of surfactant concentration is further confirmed macroscopically by the phase-inversion of Pickering emulsions and anomalous compliance of liquid interface. Our study sheds light on the importance of both thermodynamics and kinetics on the assembly of nanomaterials at the liquid interface and also demonstrate the advantage of using in situ AFM to characterize the assembly of nanomaterials at the liquid interface.

1:15PM M32.00009: Co-surfactant based interfacial strategies for the formation and stabilization of multiple nanoemulsions

TANVI SHETH (Presenter), MATTHEW E. HELGESON, University of California, Santa Barbara — There has been significant recent interest in the production of multiple emulsions – i.e., droplets in droplets – of increasingly small size, especially at the nanoscale. However, the energetic cost of stabilizing many highly curved interfaces makes it challenging to produce and stabilize such multiple nanoemulsions. Here, we propose a general method for promoting and stabilizing complex nanodroplet structures by manipulating their interfacial mechanics through co-surfactants of opposing spontaneous curvature. Using asymmetric pairs of ethoxylated co-surfactants, we experimentally show that this strategy induces the preferential formation of droplets with multiple highly curved interfaces and develop a theoretical framework to predict the observed droplet structures. Using neutron spin echo experiments, we measure the equilibrium dynamics of these ultra-low surface tension systems to determine the effective elastic constants of the mixed surfactant membranes. Using the measured elastic constants, we develop equilibrium interfacial free energy models to quantify conditions under which multiple nanoemulsion structures are stabilized, providing a rational means for engineering co-surfactant systems to promote the formation and stability of multiphase nanodroplets.
1:27PM M32.00010: High-speed X-ray Photon Correlation Spectroscopy studies of dynamics in liquid-liquid extraction systems  DINA SHEYFER (Presenter), QINGTENG ZHANG, TROY DAVID LOEFFLER, JYOTSANA LAL, ERIC DUFRESNE, SURESH NARAYANAN, LYNGA SODERHOLM, SUBRAMANIAN SANKARANARAYANAN, ALEC RUSSELL SANDY, MARK ANTONIO, GREGORY BRIAN STEPHENSON, Argonne Natl Lab — X-ray Photon Correlation Spectroscopy (XPCS) and newly available high-speed X-ray detector systems provide a golden opportunity for shedding new light on a problem of both practical and fundamental importance – the dynamics of fluctuations near critical points in complex fluids. Here, we present a high-speed XPCS study of critical fluctuation dynamics in an important class of complex organic fluids designed for chemical separations. In these liquid-liquid extraction systems, an amphiphilic extractant molecule is used to selectively transfer targeted species from an aqueous phase into an organic phase through the formation of nanoscale molecular complexes. The most efficient extraction typically occurs near a critical point where the correlation length of the complexes becomes large. Our XPCS studies reveal the microsecond dynamics of the molecular assemblies both away from and at the critical temperature $T_c$. The observed fluctuation dynamics can be characterized as a function of $Q$ and $T$ using predictions from the theory of critical phenomena. In particular, we see that the dynamic critical exponent $z$ describing the $Q$ dependence of $\tau \sim Q^{-z}$ changes from 2 to 3 as the critical temperature $T_c$ is approached.

1:39PM M32.00011: Tubulation and dispersion of oil by growth of marine bacteria on oil droplets  VINCENT HICKL (Presenter), GABRIEL JUAREZ, University of Illinois at Urbana-Champaign — The activity of bacteria on surfaces exhibits collective behaviors such as active turbulence and active stresses, which result from motility or growth and interactions with the local surroundings. Here, we describe experimental observations on the emergence of tubular structures resulting from the growth and division of rod-shaped bacteria on the liquid interface of oil droplets. Using microfluidics and time-lapse microscopy, we quantify the dimensions and growth rates of individual tubular structures as well as the bulk biofilm formation on hundreds of droplets over 72 hours. We find that the length of tubular structures is comparable to the initial droplet radius and that they are composed of an outer shell of bacteria that stabilize an inner filament of oil. The oil filament undergoes breakup into smaller microdroplets dispersed within the bacterial shell, where the average radius of the dispersion is described by the most unstable Plateau-Rayleigh wavelength. This work provides insight into active stresses at deformable interfaces and improves our understanding of microbial oil biodegradation and its potential influence on the transport of oil droplets in the ocean water column.
1:51PM M32.00012: Effect of polymer topology on the structure and dynamics of block copolymers at Liquid/Liquid Interfaces*  KUN QIAN (Presenter), MESFIN TSIGE, Univ of Akron — The behavior of molecules such as polymers at liquid/liquid interfaces is both scientifically and technologically important and has been the focus of much attention in recent years given the various types of materials that have been successfully assembled at liquid/liquid interfaces. Polymers do assemble in various ordered aggregates at liquid/liquid interfaces and understanding the effect of polymer topology on the overall behavior of a given polymer at surfaces and interfaces and especially at liquid/liquid interfaces is very important. Molecular dynamics simulations using a bead-spring model on representative block copolymer architectures at immiscible liquid/liquid interfaces have been carried out. The results of our detailed investigation on the structure and dynamics of the block copolymers at the interface will be presented and discussed.

*This work has been funded by NSF DMR-1912329.

2:03PM M32.00013: A novel method for interfacial rheology using an indirect interfacial rheometer  IAIN MUNTZ (Presenter), JOB H. J. THIJSSEN, Univ of Edinburgh — We have developed a system for performing interfacial rheology without attaching a probe directly to the interface itself. This indirect rheology is motivated by the applications of Pickering type systems, where rather than shear being applied directly to an interface, one of the continuous phases is sheared. The behaviour of the system as a whole is then governed, in part, by the rheology of that interface.

We use this setup to measure flow curves in a system of poly(methyl methacrylate) particles at a water/dodecane interface. The lack of a direct probe ensures two things: 1) we avoid substantial pre-shearing and 2) the response measured is due to the interface itself and not the probe [1]. In this indirect setup a shear is applied to the upper oil phase using a standard stress controlled rheometer. The response of the interface is then measured by confocal microscopy. A range of rheological behaviour is observed dependent on surface coverage, shear rate and surface structure. The direct visualisation of the interface allows all of these input parameters to be measured and various flow curves can be produced to observe their effect on the rheology of the interface.

Session M33 DSOFT GSNP: Kinetic Theory and Its Applications in the Physical, Biological and Social Sciences 505 - Tag(s): Focus
11:15AM M33.00001: Kinetic theory of defect dynamics in active nematics* [Invited] M CRISTINA MARCHETTI (Presenter), University of California, Santa Barbara — Active nematics are fluids of elongated active agents that exhibit self-sustained flows and liquid crystalline order. Realizations include suspensions of cytoskeletal filaments and motor proteins, epithelial tissue, and vibrated layers of granular rods. At high activity, active nematics exhibit spatio-temporal chaotic, turbulent-like flows with proliferation of topological defects. In this talk I will show that, focusing on the defects as the relevant quasiparticles driving the non-equilibrium dynamics, we can formulate a kinetic theory of the active defect gas and describe the onset of active turbulence as activity-driven defect unbinding. By coarse-graining the kinetic theory, we obtain a hydrodynamic description of the active defect gas.

*This work was supported by NSF award DMR-1609208.

11:51AM M33.00002: Kinetic theory for financial Brownian motion: a microscopic model based on forex data analysis and its mean-field theory* [Invited] KIYOSHI KANAZAWA (Presenter), Univ of Tsukuba — Kinetic theory is a powerful mathematical framework in statistical physics and has been applied to understand physical Brownian motions from their microscopic setups. In light of this success, it is an interesting attempt to extend kinetic theory for various social phenomena beyond physics. In particular, we have focused on its application to financial markets since they exhibit random motions quite similar to physical Brownian motion. In this presentation, we will show our recent kinetic approach (K. Kanazawa et al., PRL 2018; PRE 2018) to financial Brownian motion in the context of high-frequency data analyses. First, we have analyzed trading log data of individual traders, to identify the microscopic dynamics in a forex market. The proposed microscopic model of the financial market is then solved systematically via the kinetic theory: we derive the Liouville equation, the Bogoliubov-Born-Green-Kirkwood-Yvon hierarchy, the Boltzmann equation, and the Langevin equation for the financial market as a parallel mathematical program to conventional kinetic theory. Our work highlights the potential power of kinetic theory to understand social phenomena from their microscopic dynamics.

12:27PM M33.00003: A generalization of the Glansdorff-Prigogine criterion for stability based on information geometry and thermodynamic uncertainty relationships*  
SOSUKE ITO (Presenter), Universal biology institute, The University of Tokyo — To consider the relationship between the excess entropy production and the Fisher information of time, we have generalized the Glansdorff-Prigogine criterion for stability. In information geometry, the Fisher information of time is the speed of a statistical manifold, and then our generalized criterion can be interpreted as a criterion by acceleration (deceleration) of this speed. If this speed is accelerated (decelerated), dynamics is unstable (stable).

Our generalization does work even for chemical kinetics driven by the non-linear master equation (e.g., the autocatalytic reaction), where the Glansdorff-Prigogine criterion does not work well. Moreover, our generalization is connected to the recent progress of thermodynamic uncertainty relationships (TURs), and we can quantitatively discuss the stability of dynamics based on TURs.

12:39PM M33.00004: Pattern Selection of Shallow Suspensions of Shrimp  
ANDREA WELSH (Presenter), KRISHMA SINGAL, DIVYA VELIVELA, ELLIE FINCH, MICHAEL BARNHILL, FLAVIO H FENTON, Georgia Inst of Tech — Swarming, a self-organization phenomenon which occurs in many biological systems, can emerge spontaneously, arising without any sort of centralized control or leadership. Many crustaceans, such as brine shrimp, produce swarms, in which individuals cluster together rather than spreading out uniformly in their environment. The motion of these crustaceans is also affected by light due to their phototactic nature. The size and distribution of these swarms are governed by local interactions between individuals but are also affected by the boundaries of the container. We discuss the three-dimensional patterns that can be observed in brine shrimp swarms, specifically of the Great Salt Lake strain of *Artemia franciscana*, at high concentration. We experimentally test the effects of average concentration, temperature, and container size on the basic length and times scales of the patterns, the type patterns selected, and the stability of those patterns. We then discuss the physical mechanism behind the formation and selection of these patterns.
**12:51PM M33.00005: Hydrodynamics of Active Lévy Matter**
ANDREA CAIROLI (Presenter), CHIU FAN LEE, Imperial College London — Collective ordered motion is often modeled within the framework of active fluids, where hydrodynamic descriptions typically rely on microscopic models of active self-propelled particles subjected to alignment interactions and reorientational dynamics. However, single-particle superdiffusion is also widespread in biology as it can represent an optimal search strategy for living organisms. Nevertheless, the collective properties of interacting systems exhibiting such anomalous diffusive dynamics -- denoted here as active Lévy matter -- cannot be captured by current active fluid theories. Here, we formulate the hydrodynamic description of active Lévy matter by coarse-graining a microscopic model of alignment interacting active particles performing superdiffusion manifest as Lévy flights. This theory predicts characteristic disordered and ordered phases. Linear stability analysis suggests that the phase transition can be critical. This analysis highlights the need for more realistic models of active matter integrating both anomalous diffusive motility and inter-particle interactions and suggests that these models can shed new light on the universal properties of active systems.

*Dr. Andrea Cairoli acknolewdges funding of the Royal Commission for the Exhibition of 1851.

**1:03PM M33.00006: Towards a statistical mechanics of chiral active gases**
MING HAN (Presenter), MICHEL FRUCHART, COLIN SCHEIBNER, SURYANARAYANAN VAIKUNTANATHAN, WILLIAM THOMAS MARK IRVINE, JUAN DE PABLO, VINCENZO VITELLI, University of Chicago — Statistical mechanics allows to describe materials near equilibrium using just a few thermodynamic variables. Extending this approach far-from-equilibrium is tempting but often unfeasible. In this talk, we present the footprints of a statistical mechanical treatment of chiral active fluids composed of self-spinning particles. The nature of self-spinning breaks time-reversal symmetry and detailed balance. Nevertheless, such active fluids converge to a non-equilibrium steady state exhibiting Boltzmann statistics with a universal effective temperature determined by the active torques. Beyond exhibiting analogues of common thermodynamic properties, the chiral active gas also displays a dissipation-less odd viscosity in addition to the shear viscosity. Both transport coefficients satisfy a Kubo relation in terms of our effective temperature. We show that the stochastic dynamics of this many body system can be represented as a chiral Brownian motion in shear-stress space. Using this assumption, we derive analytically the full frequency dependence of the viscosities in agreement with simulations.
1:15PM M33.00007: Hydrodynamic memory and driven microparticle transport: hedging against fluctuating sources of energy* SEAN SEYLER (Presenter), STEVE PRESSÉ, Physics, Arizona State University — In a viscous fluid, the motion of an accelerating particle is retained as an imprint on the vorticity field, giving rise to the famous $t^{-3/2}$ decay of the velocity autocorrelation. For nonuniform particle motion at low Reynolds number, this hydrodynamic memory effect is captured by the Basset-Boussinesq-Oseen (BBO) equation, which can be derived from various physical perspectives, including (fluctuating) hydrodynamics and kinetic theory. Moreover, finite-temperature dynamics can be modeled by using fluctuation-dissipation to reincorporate (correlated) thermal noise, turning BBO into a generalized Langevin equation. In this work, we numerically solve the BBO equation to simulate driven microparticles and show that hydrodynamic memory generally reduces transport friction, particularly when driving forces do not vary smoothly. Remarkably, this enables coasting over uneven potentials that otherwise trap particles modeled by pure Stokes drag. Our results are germane to questions surrounding intracellular transport efficiency and, more generally, provide direct physical insight into the role of particle-fluid coupling in microparticle transport.

*Supported by ARO Grant No. W911NF-17-1-0162.

1:27PM M33.00008: Cargo transport by dissipative solitons-director bullets in nematics* BINGXIANG LI (Presenter), RUI-LIN XIAO, SERGIJ V SHIYANOVSII, OLEG D LAVRENTOVICH, Chemical Physics Interdisciplinary Program; Advanced Materials and Liquid Crystal Institute, Kent State Univ - Kent — An alternating current (AC) electric field applied to a uniformly aligned nematic liquid crystal is capable to excite and drive particle-like three-dimensional dissipative solitons, the so-called director bullets [1, 2]. The bullets represent regions of a distorted molecular orientation of broken left-right or head-tail symmetry that propagate perpendicularly to the driving field. Here, we demonstrate that the bullets can be generated around colloidal spheres with both tangential and radial anchoring, dispersed in the nematic. The effect represents a soliton-mediated liquid crystal-enabled electrophoresis, in which the electric field first breaks the quadrupolar symmetry of the director field around the sphere and then drives oscillations of this asymmetric director field to power a directional motion of the sphere dressed in the soliton. The effect can be used to transport microscopic cargo when modes of liquid crystal-enabled electrotokinetics based on static asymmetry are ineffective, which is the case of tangentially anchored inclusions.

*The work was supported by NSF grant DMR-1905053.
1:39PM M33.00009: Brownian motion in confinement  MAXIME LAVAUD (Presenter), Laboratoire Ondes et Matière d'Aquitaine, CNRS, PIERRE SOULARD, PSL Research University : UMR7083, ESPCI, Gulliver, VINCENT BERTIN, DAVID DEAN, Laboratoire Ondes et Matière d'Aquitaine, CNRS, RAPHAEL SARFATI, Department of Chemical and Biological Engineering, Boulder, ELIE RAPHAEL, PSL Research University : UMR7083, ESPCI, Gulliver, YANN LOUYER, THOMAS SALEZ, YACINE AMAROUCHENE, Laboratoire Ondes et Matière d'Aquitaine, CNRS — Brownian motion in confinement is a paradigm for numerous biological situations. Here, we study the diffusion of micrometer-sized beads in water confined between two walls that are separated by a micrometric distance. Using holographic microscopy, we track the particles in three dimensions with a precision approaching the nanometric range. From statistical analysis performed on the individual trajectories, we extract the local diffusion coefficient as a function of the position of the bead in the microcavity. The experimental results are in good agreement with the numerical and analytical predictions — which paves the way towards the study of other situations of confinement, such as soft boundaries.

1:51PM M33.00010: Superdiffusion and diffusion in active matter using a stochastic field theory*  PATRICK UNDERHILL (Presenter), PETER R KRAMER, Rensselaer Polytechnic Institute — One important impact of the out-of-equilibrium nature of active matter is the enhanced fluctuations in the system and the mixing of passive tracers. Interesting properties arise in both small and large concentrations of the active objects. Agent based models can incorporate fluctuations and interactions, but are limited to smaller systems. It can also more difficult to extract physical insight from the results. One of the most successful alternative approaches has been a mean field theory. However, in some situations the mean field theory makes predictions that differ significantly from experiments and direct (agent or particle based) simulations. There are also some quantities that cannot be calculated by the mean field theory. In this talk, we will describe our new approach which uses a stochastic field to overcome the limitations of the mean field assumption. The characteristic superdiffusion observed for passive tracers can be computed along with the longtime diffusivity. We will describe how this enhanced diffusion depends on the characteristics of the active particles and their hydrodynamic interactions.

M33.00011: Disordered hyperuniform state of circularly swimming algae* MINGJI HUANG (Presenter), Shanghai Jiao Tong Univ, WENSI HU, East China Normal University, SIYUAN YANG, Shanghai Jiao Tong Univ, QUAN-XING LIU, East China Normal University, HEPENG ZHANG, Shanghai Jiao Tong Univ — Active matter comprises of individual units that convert locally stored energy into mechanical motion. Interactions between active units can lead to a wide range of collective phenomena, which do not exist in equilibrium systems. Here we show that density fluctuations in active system can be greatly suppressed. Our experiments are carried out with marine algae (*Symbiodinium voratum*). Cells swim in circles at interface and long-ranged nature of hydrodynamic interactions suppresses density fluctuations; disordered hyperuniform state is observed over a wide range of conditions. Emergence of hyperuniformity can be quantitatively reproduced in a numerical model whose main ingredients are hydrodynamic interactions and uncorrelated random cell motion. Our results demonstrate a new form of collective state in active matter and suggest the possibility to use hydrodynamic flow to assemble active matter into hyperuniform states.

Session M34 DSOFT GSNP DCOMP: Machine Learning in Nonlinear Physics and Mechanics 506 - Shmuel Rubinstein, Harvard University - Tag(s): Focus

11:15AM M34.00001: Learning the onset of frictional motion [Invited] YOHAI BAR-SINAI (Presenter), Google Research — The onset of frictional motion is a central process in modeling mechanical phenomena, from squeaking hinges to catastrophic earthquakes. The processes involved in it are complex and to a large extent not understood. Specifically, the simple notion of "static friction coefficient" is most probably not a well-defined material parameter, as experiments show that it is variable, even for a single interface under carefully controlled experimental conditions. I will show that, in a well-controlled laboratory setup with detailed interfacial measurements, relatively simple linear models can explain much of the observed variance, indicating that a significant portion of the uncertainty is non-stochastic and is encoded in the frictional interface. In addition, I will discuss recent data-driven efforts in predicting the onset of frictional motion in geophysical faults, i.e. earthquake forecasting, which is a long-standing and very challenging problem. However, the confluence of new kinds of measurements and advances in machine learning offers new and promising directions.
11:51AM M34.00002: Detecting Depinning and Nonequilibrium Transitions with Unsupervised Machine Learning*  DANIELLE MCDERMOTT (Presenter), Pacific Univ, CYNTHIA REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — Using numerical simulations of a model disk system, we demonstrate that a machine learning generated order parameter can detect depinning transitions and different dynamic flow phases in systems driven far from equilibrium. We specifically consider monodisperse passive disks with short range interactions undergoing a depinning phase transition when driven over quenched disorder. The machine learning derived order parameter identifies the depinning transition as well as different dynamical regimes, such as the transition from a flowing liquid to a phase separated liquid-solid state that is not readily distinguished with traditional measures such as velocity-force curves or Voronoi tessellation. The order parameter also shows markedly distinct behavior in the limit of high density where jamming effects occur. Our results should be general to the broad class of particle-based systems that exhibit depinning transitions and nonequilibrium phase transitions.

12:03PM M34.00003: Machine Learning and Benchtop Experiments  SHMUEL RUBINSTEIN (Presenter), Harvard University — Machine learning has generated much recent excitement within the physics community and provides a powerful new tool to analyze and understand many physical systems. However, in the experimental study of complex physical systems, the usage of machine learning is still in its infancy. Specifically, it is not obvious which scientific questions are susceptible to machine learning disruption and, even more interesting, which questions are not? In this talk, I will address our approach to these questions, sharing our attempts to leverage lab models of complex systems for this study. I will discuss our tactics to holistically amalgamate experiments with simulations.

12:15PM M34.00004: Supervised Autoencoder for Inverse Kirigami Design  PAUL HANAKATA, Harvard University, EKIN DOGUS CUBUK (Presenter), Google Inc., DAVID K CAMPBELL, HAROLD S. PARK, Boston University — Recently, machine learning (ML) methods have shown successes in predicting mechanical properties of composite materials as a forward solver. While ML approach is much faster than the conventional physics-based solvers (e.g. molecular dynamics), most current ML techniques need to screen the entire library in order to perform inverse design. Thus, this approach might no longer be practical for a system with a very large design space. Here, we use a supervised-autoencoder (sAE) to perform inverse design in graphene kirigami where predicting ultimate stress or fracture point is known to be difficult due to nonlinear effects arise from the out-of-plane buckling. Unlike the standard autoencoder, our sAE is not only able to reconstruct cut configurations but also to predict mechanical properties of graphene kirigami and classify graphene kirigami with either parallel or orthogonal cuts. Furthermore, we find that by interpolating different configurations the sAE is able to generate new designs consisting of mixed parallel and orthogonal cuts while only being trained with kirigami structures with parallel and orthogonal cuts. This allows us to design and optimize materials in the latent space, which is more efficient than to perform optimization in the original representation.
12:27PM M34.00005: Softness Correlations in Low-Temperature Supercooled Liquids*
RAHUL CHACKO (Presenter), James Franck Institute, University of Chicago, FRANÇOIS P LANDES, AO Team, Laboratoire de Recherche en Informatique, GIULIO BIROLI, Laboratoire de Physique, École normale supérieure, OLIVIER DAUCHOT, Laboratoire Gulliver, École supérieure de physique et de chimie industrielles de la Ville de Paris, ANDREA JO-WEI LIU, Department of Physics and Astronomy, University of Pennsylvania, DAVID REICHMAN, Department of Chemistry, Columbia University — Local structure is known to play a dominant role in determining where structural relaxation occurs [1,2]. This can be quantified using a machine learning approach, yielding a linear model mapping local structure to "softness", a quantity that predicts the propensity of a particle to rearrange [3]. We find that this machine-learned weighted integral of the pair correlation function, when trained on an athermal system relaxing under gradient descent, performs surprisingly well when predicting the dynamics of a supercooled liquid. We use swap Monte Carlo [4] to study the evolution of the spatial correlation of the so defined softness, down to deeply supercooled temperatures. We then compare this length scale to other length scales that have been identified in the literature.

*This work was funded by the Simons Collaboration “Cracking the glass problem” via 454935 (GB), 327939 and 454945 (AJL), 454951 (DR) and 348126 (SRN).

12:39PM M34.00006: Data-driven inference of thermodynamic properties from non-equilibrium stochastic fluctuations YOON JUNG (Presenter), JUNANG LI, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Living systems are driven out of equilibrium via an input of cellular chemical energy, part of which is dissipated into the environment. For systems that exhibit non-equilibrium steady states, thermodynamic fluctuations encode signatures that can be used to infer properties of the system. For example, model-based approaches can be used to quantify how far the system is from equilibrium by measuring the dissipation rate. Here, we present a data-driven approach for inferring system properties based on scattering transforms. The method utilizes symmetries arising from the stationary nature of stochastic fluctuations which allows solving inverse problems with fewer measurements. The results from simulations and experimental data demonstrate that the proposed approach serves as an effective method to infer system properties from thermodynamic fluctuations in living systems.
12:51PM M34.00007: Inverse learning of material physics through in-situ image data and continuum modeling  HONGBO ZHAO (Presenter), Massachusetts Institute of Technology MIT, BRIAN D STOREY, Toyota Research Institute, RICHARD BRAATZ, MARTIN BAZANT, Massachusetts Institute of Technology MIT — With the availability of microscopic spatio-temporal image data of materials, there is a tremendous amount of hidden information about the material properties. Using a framework of PDE-constrained optimization, we demonstrate that multiple constitutive relations can be extracted simultaneously from a small set of images of pattern formation. Examples include state-dependent properties such as the diffusivity, kinetic prefactor, free energy, and direct correlation function in the Cahn-Hilliard equation, Allen-Cahn equation, or dynamical density functional theory (Phase-Field Crystal Model). Compared to the data-driven modeling approach and the recent work on PDE discovery, our approach provides clear physical interpretability by prescribing a general governing equation while achieving a high expressive power through nonlinear and/or nonlocal (integro-differential) constitutive relations. We demonstrate that the inversion technique can be applied to experimental images of lithium-iron phosphate (LFP) particles. By mapping the evolution of lithium concentration in the particles during charge and discharge, we are able to extract its free energy and reaction kinetics, which are difficult to obtain through traditional electrochemical measurements alone due to phase separation.

1:03PM M34.00008: Using Machine Learning to analyze Defect Annihilation Dynamics in Smectic C films*  MATTHEW GLASER (Presenter), ERIC MINOR, STIAN HOWARD, ADAM GREEN, CHEOL PARK, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado Boulder — We demonstrate a method for training a convolutional neural network with simulated images for usage in the study of topological defect annihilation in freely-suspended SmC liquid crystal films. Modern machine learning methods require large, robust training data sets to generate accurate predictions. Generating these training sets requires a significant up-front time investment that is often impractical for small-scale applications. Here we demonstrate a ‘full-stack’ computational solution, where the training data set is generated on-the-fly using a noise injection process to produce simulated data characteristic of the experimental system. The experiment requires accurate observations of both the spatial distribution of the defects and the total number of defects at every time step, making it an ideal system for testing the robustness of the trained network. The fully trained network was found to be comparable in accuracy to identifying the defects by hand, with a four-orders of magnitude improvement in time efficiency.

1:15PM M34.00009: Experimental Realization of Reservoir Computing with Wave Chaotic Systems*  SHUKAI MA (Presenter), THOMAS M ANTONSEN, EDWARD OTT, SARTHAK CHANDRA, STEVEN ANLAGE, University of Maryland, College Park — The execution of machine learning (ML) software largely depends on the computing `substrate', which is often not optimized for running ML tasks. The invention of ML-tailored hardware may greatly improve the computing speed and power efficiency. Photonic devices are well-suited for ML due to the parallelism of light. Reservoir computing (RC) is essentially a one-layer neural network (NN) with nonlinear connections, but radically simpler than NN since only the coupling between the reservoir nodes and outputs is trained. Thus RC is well-suited for physical realizations. Here we utilize the complicated wave dynamics inside a chaotic-shaped overmoded electromagnetic cavity containing nonlinear elements to emulate the complex dynamics of an RC. We propose unique techniques to create virtual RC nodes by both frequency stirring and spatial perturbation. The computational power of the wave chaotic RC is experimentally demonstrated with the so-called observer task, where we predict the future evolution of chaotic Rossler y(t) and z(t) time series using the x(t) series as the input. Different tasks are executed with a single RC physical device by simply switching output couplers.

1:27PM M34.00010: Chaotic source separation solved by a tank of water through invertible generalized synchronization*  ZHIXIN LU (Presenter), JASON KIM, DANIELLE BASSETT, University of Pennsylvania — Statistical methods such as independent component analysis and principal component analysis were proposed to separate a set of source signals from a mixed signal by assuming the statistical independence of sources. Here, we focus on chaotic source separation where the sources are chaotic systems. We assume that one has no knowledge about the governing equations of the source signals, and that the mixed signal is simply the sum of the sources. From the perspective of dynamical systems, we propose a supervised learning framework that can solve this problem through an intermediate dynamical system. To demonstrate the power of this framework, we employ a simulated tank of water as the intermediate system, and train it to regenerate chaotic signals from a mixed signal that is the sum of any 2 chaotic trajectories from 6 chaotic systems. We elucidate the underlying mechanism as constructing a nonlinear state-observer utilizing the concept of invertible generalized synchronization. We predict that it is impossible to perfectly separate the chaotic sources if the two sources systems are governed by the same dynamical equations.

1:39PM M34.00011: The Dependence of Reservoir Computing on System Parameters*
LOUIS PECORA (Presenter), THOMAS L CARROLL, United States Naval Research Laboratory — Reservoir computing (RC) has become an interesting topic for the nonlinear Dynamics field. More so because despite many demonstrations of RC abilities the actual dynamical reasons RCs work is still not well understood. We examined several aspects of RC using fitting and prediction of signals as a benchmark. Among the parameters we explored [1] were network heterogeneity of link weights, existence of symmetries in the networks, variations of node parameters and vector fields, and spectral radius of the network. One important result is that the number of independent signals that can be used from a driven RC is limited and independent of the number of nodes above a certain vertex number.

1:51PM M34.00012: Reduced network extremal ensemble learning (RenEEL) scheme for community detection in complex networks*
KEVIN E. BASSLER (Presenter), JIAHAO GUO, PRAMESH SINGH, Department of Physics and TcSUH, Univ of Houston — We introduce an ensemble learning scheme for community detection in complex networks. The scheme uses a Machine Learning algorithmic paradigm we call Extremal Ensemble Learning. It uses iterative extremal updating of an ensemble of network partitions, which can be found by a conventional base algorithm, to find a node partition that maximizes modularity. At each iteration, core groups of nodes that are in the same community in every ensemble partition are identified and used to form a reduced network. Partitions of the reduced network are then found and used to update the ensemble. The smaller size of the reduced network makes the scheme efficient. We use the scheme to analyze the community structure in a set of commonly studied benchmark networks and find that it outperforms all other known methods for finding the partition with maximum modularity.

2:03PM M34.00013: Visualizing statistical models in Minkowski space: an analytical coordinate embedding*  HAN KHENG TEOH (Presenter), Cornell University, KATHERINE QUINN, Princeton University, COLIN B CLEMENT, JARON KENT-DOBIAS, QINGYANG XU, JAMES PATARASP SETHNA, Cornell University — Dimensionality reduction techniques are often used to provide a lower dimensional description of high dimensional data. Quinn et. al [1] proposed an intensive isometric embedding, InPCA in visualizing probabilistic models manifold with the Bhattacharyya distance. It was observed that the InPCA manifolds form a hierarchy of cross-sectional spans that shrinks geometrically in Minkowski space, allowing the use of only a few principal components to capture most of the variation. Here, we show that for a large class of multiparameter models that takes the form of exponential families, a different intensive embedding- the isKL embedding, built on symmetrized Kullback Liebler divergence generates an explicitly and analytically tractable embedding in a Minkowski space of dimension equal to twice the number of parameters. In principle, this technique not only offers a great dimensionality reduction, it also allows one to uncover a hidden exponential family that describes an experiment or a simulation if the isKL embedding gives a cutoff after N+N dimensions. We will discuss the optimization of isKL embedding in producing a good visualization with several statistical models.

Session M35 GMAG: Novel Functional Magnetic Materials and Structures 507 - Shinji Miwa, Univ of Tokyo
11:15AM M35.00001: Interplay of local moment and itinerant magnetism in cobalt-based Heusler ferromagnets: Co$_2$TiSi, Co$_2$MnSi and Co$_2$FeSi* GUANHUA QIN (Presenter), University of Missouri, WEI REN, Shanghai University, DAVID SINGH, University of Missouri — Heusler ferromagnets based on Co are important materials for spintronics due to the exceptional combinations of high Curie temperature and strong spin polarization. We investigate the electronic structure, magnetism and spin excitations in the cobalt-based full Heusler compounds, Co$_2$TiSi, Co$_2$MnSi and Co$_2$FeSi using first principles calculations. Co$_2$TiSi and Co$_2$MnSi are half-metals, while Co$_2$FeSi is not. The trends in the Curie temperature of Co$_2$MnSi and Co$_2$FeSi are well reproduced by the calculated spin wave dispersions. Remarkably, Co$_2$TiSi is a very itinerant magnet, while both Co$_2$FeSi and Co$_2$MnSi show local moment behavior regarding the Fe and Mn, while retaining the itinerancy of the Co magnetism. Although our results do not support the half-metallic character proposed for Co$_2$FeSi, consistent with the reported high Curie temperature, we find a very strong positive transport spin polarization, which combined with the large moment, cubic structure and high Curie temperature supports the further investigation of Co$_2$FeSi as a material for spintronic applications.

*Work at the University of Missouri is supported by the Department of Energy, Award Number DE-SC0019114.

11:27AM M35.00002: Effect of V substitution on structural, magnetic, transport and mechanical properties of the half-metal-type Heusler alloy Co$_2$FeGe* RABIN MAHAT (Presenter), SHAMBHU K KC, Physics and Astronomy, University of Alabama, DANIEL WINES, Physics, University of Maryland Baltimore County, SUDHIR REGMI, UPAMA KARKI, Physics and Astronomy, University of Alabama, FATTIH ERSAN, CAN ATACA, Physics, University of Maryland Baltimore County, ARUNAVA GUPTA, Chemistry and Biochemistry, University of Alabama, PATRICK LECLAIR, Physics and Astronomy, University of Alabama — Half-metallic ferromagnets are ideal candidates for spintronic applications due to their ∼100% spin polarization. High Curie temperature $T_c$ is one of the important prerequisite from the application point of view. Co$_2$Fe- based Heusler alloys in L$_{21}$ structure have attracted great interest for this reason. We present a combined experimental and theoretical study of quaternary Heusler alloys Co$_{2-x}$V$_x$FeGe and Co$_2$Fe$_{1-x}$V$_x$Ge (0 ≤ x ≤ 1) as promising candidates for spintronic applications. Single phase microstructures for arc-melted alloys are observed for V substitution for Co from x = 0.25 to x = 0.625, but when V substitutes for Fe only x = 0.25 and 0.375 yield single phase microstructures. All single phase samples show fcc structures with L$_{21}$ ordering, corroborated by X-ray diffraction. Low-temperature saturation magnetic moments agree well with our theoretical results and obey the Slater-Pauling rule, a prerequisite for half metallicity. All alloys are soft ferromagnets with high $T_c$'s, allowing for applications at room temperature and above. Transport measurements are performed to elucidate the electronic structure of the alloys. Relatively high mechanical hardness values are also observed.

*NSF DMREF Grant number 1235396, NSF DMR Grant number 1508680 and NSF DMR Grant number 1726213.
11:39 AM M35.00003: Half-metallicity in CrAl-terminated \( \text{Co}_2\text{CrAl} \) thin film  
JULIANA C. HERRAN, Université de Franche-Comté, RYAN CARLILE, University of Northern Iowa, PARASHU R. KHAREL, South Dakota State University, PAVEL LUKASHEV (Presenter), University of Northern Iowa — Half-metals with high Curie temperature are ideal candidates for applications in spintronics. Many half-metallic materials have been predicted theoretically, and some have been confirmed experimentally. At the same time, in thin-film geometry the electronic structure of these materials may change due to the potential presence of surface/interface states, which could limit practical applications of these materials in nano-size devices. Here, from first principles we study a full Heusler compound, \( \text{Co}_2\text{CrAl} \) in thin film geometry. This material has been studied extensively, and it has been reported that it exhibits half-metallic properties in the bulk. We show that this material retains 100% spin polarization in CrAl-terminated thin film geometry (Co-termination results in destroyed half-metallicity) as well. Moreover, we confirm that under biaxial strain \( \text{Co}_2\text{CrAl} \) retains half-metallicity for a practically feasible range of considered pressure. The magnetic alignment of \( \text{Co}_2\text{CrAl} \) is confirmed to be ferromagnetic, with the non-integer total magnetic moment of Co-terminated cell, and the integer total magnetic moment of CrAl-terminated cell. If confirmed experimentally, these results may have an important impact in spin-based electronics.

11:51 AM M35.00004: Anomalous Hall effect in a two sub-lattice ferrimagnet.  
NISHCHAL THAPA MAGAR (Presenter), DINA MICHEL, NIRMAL GHIMIRE, Department of Physics and Astronomy, George Mason University — The anomalous Hall effect (AHE) is a characteristic of ferromagnets where a finite Hall effect proportional to the magnetization appears in zero external magnetic field. It is now known that the AHE can also arise in non-collinear and non-coplanar antiferromagnets due to spin chirality and in materials consisting of topologically non-trivial electronic structure such as Weyl semimetals. Here we will present the observation of an anomalous Hall effect in a hexagonal ferrimagnet TbMn\(_6\)Sn\(_6\) consisting of two spin sub-lattices due to Mn and Tb ordering. Both spin sublattices order simultaneously above room temperature and show a spin reorientation below 310 K from the basal plane towards c-axis. The AHE that is observed at temperatures well below the spin reorientation temperature does not follow the underlying net magnetization, indicating the formation of a non-coplanar or complex chiral spins textures.
12:03PM M35.00005: Itinerant ferromagnetism and intrinsic anomalous Hall effect in amorphous iron-germanium*  DINAH SIMONE BOUMA, NEAL REYNOLDS (Presenter), University of California, Berkeley, and Lawrence Berkeley National Laboratory, ZHANGHUI CHEN, Lawrence Berkeley National Laboratory, FRANK BRUNI, University of California, Berkeley, BINHUA ZHANG, Fudan University, MICHAEL FLATTÉ, University of Iowa, University of Chicago, and Eindhoven University of Technology, ROBERT STREUBEL, LIN-WANG WANG, Lawrence Berkeley National Laboratory, RUQIAN WU, University of California, Irvine, FRANCES HELLMAN, University of California, Berkeley, and Lawrence Berkeley National Laboratory — The amorphous iron-germanium system (a-Fe$_x$Ge$_{1-x}$) lacks long-range structural order and hence lacks a meaningful Brillouin zone. The magnetization of a-Fe$_x$Ge$_{1-x}$ is well explained by the Stoner model for $x \geq 0.4$, indicating that the local order of the amorphous structure preserves the spin-split density of states of the Fe-3$d$ states sufficiently to polarize the electronic structure despite $k$ being a bad quantum number. Measurements show an enhanced anomalous Hall resistivity relative to crystalline FeGe; comparison to density functional theory calculations of the anomalous Hall conductivity (AHC) resolves its underlying mechanisms. The intrinsic mechanism, typically understood as the Berry curvature integrated over occupied $k$-states but equivalent to the density of curvature (DOC) integrated over occupied energies, dominates the AHC of a-Fe$_x$Ge$_{1-x}$ (0.38 $\leq x \leq$ 0.61). The DOC is the sum of spin-orbit correlations of local orbital states and can hence be calculated with no reference to $k$. This result and the accompanying Stoner-like model for the intrinsic AHC establish a unified understanding of the physics of the anomalous Hall effect in both crystalline and disordered systems.

12:15PM M35.00006: Unusual Friedel and RKKY responses in 3D quadratic band-touching Luttinger semimetals  LOUIS J. GODBOUT (Presenter), SERGUEÏ TCHOUMAKOV, WILLIAM WITCZAK-KREMPA, Universite de Montreal — We study the response of Luttinger semimetals, such as alpha-Sn, HgSe, HgTe, YPtBi and Pr$_2$Ir$_2$O$_7$, to charge and magnetic impurities. In these materials the strong spin-orbit coupling and quadratic band-touching lead to unusual Friedel and Ruderman-Kittel-Kasuya-Yoshida (RKKY) oscillations, as well as an asymmetry in the response upon electron or hole doping. We also examine the magnetic Pauli and Landau susceptibilities, which differ from those of regular metals. These results motivate the study of Kondo physics in Luttinger semimetals, where novel quantum phases can arise due to spin-orbit coupling.
Search for new permanent magnet materials: methodology and applications. OLGA VEKILOVA (Presenter), Physics and Astronomy, Uppsala University — Permanent magnets (PMs) are of vital importance for sustainable industry and in particular, are parts of most of the sources of “green” energy. The theory-assisted search for new PMs, especially those that are free from expensive rare-earth elements, has now become an active field of research. We could recently suggest a number of promising PMs using the ab initio-based analyses and high-throughput approach [1,2]. One of key target properties is the proper ferromagnetic state with high Curie temperature. To be able to effectively describe that, especially in the course of high-throughput calculations, we have introduced a novel theoretical method, combining molecular dynamics with the magnetic state search [3]. The implementation and examples showing the power of the method will be considered.

The Voltage-Controlled Magnetic Anisotropy Effect Under High Electric Field* BOWEI ZHOU (Presenter), MENG XU, PRAVIN KHANAL, YU ZHANG, WEIGANG WANG, Univ of Arizona — The discovery of voltage-controlled magnetic anisotropy (VCMA) effect in perpendicular magnetic tunneling junction (pMTJ) has attracted considerable interests for low-power and high-speed memory application. In a recent DFT study1, the VCMA effect is expected to diverge from commonly observed linear PMA vs E-field relation and exhibit nonlinearity under high E-field. However, limitations of established methods make high E-field unattainable.

Modified TMR method is performed in this work. By using pulsed voltage, on-time can be reduced by at least 2 orders of magnitude, which increases the MTJ breakdown voltage and allows for higher E-field (>800mV/nm). Unexpected magnetoresistance independent of relative FM spin alignment was discovered and attributed to impurity-assisted tunneling. Efforts were made to exclude it from conventional TMR and a nonlinear E-field dependence of PMA can be observed under high bias. Electron doping with different metals as buffer and insertion is carried out and their influence is reported and compared with DFT study.

12:51PM M35.00009: Energy-efficient stochastic computing with superparamagnetic tunnel junctions* MATTHEW W DANIELS (Presenter), National Institute of Standards and Technology, ADVAIT MADHAVAN, PHILIPPE TALATCHIAN, ALICE MIZRAHI, IREP, University of Maryland, MARK STILES, National Institute of Standards and Technology — We design an efficient stochastic bitstream generator based on superparamagnetic tunnel junctions, which can produce low energy, truly random bits, in turn drastically reducing cross-correlation. This bitstream generator allows us to address an outstanding issue in stochastic computing: that it has been limited by the inaccuracies introduced by correlations between the pseudorandom bitstreams used in the calculations. This bitstream generator gives us the freedom of not having to design around correlations and allows us to propose a low-energy approach to stochastic computing. To demonstrate the effectiveness of this approach, we incorporate it into an efficient CMOS neural network design. Our simulations of this network reach error rates comparable to recent work in stochastic-computing-based neural networks at nearly an order of magnitude lower energy expenditure.

*AM, AM, PT, and MD acknowledge support from the Cooperative Research Agreement between the University of Maryland and the National Institute of Standards and Technology Center for Nanoscale Science and Technology, Award 70NANB14H209, through the University of Maryland.

1:03PM M35.00010: Atomic scale magnetic and structural imaging by achromatic electron microscopy ZECHAO WANG (Presenter), JING ZHU, Tsinghua University — The atomic-level knowledge of local spin configuration of the magnetic materials is of great importance to predict and control their physical properties, in order to meet the challenges of ever-increasing demands on performance of functional materials. However, it is highly challenging to experimentally characterize magnetic properties of such materials with atomic scale spatial resolution. Here, we show that a combination of electron energy-loss magnetic chiral dichroism (EMCD) and chromatic-aberration-corrected transmission electron microscopy, which can provide element-selective orbital and spin magnetic moments atomic plane by atomic plane. This unique capability, which we demonstrate for Sr\textsubscript{2}FeMoO\textsubscript{6}, opens the door to local atomic level studies of spin configurations in a multitude of materials that exhibit different types of magnetic coupling, thereby contributing to a detailed understanding of physical origins of magnetic properties of materials at the highest spatial resolution. 

1:15PM M35.00011: Electrical transport in FIB-microstructures of single-crystalline Mn$_{1.4}$PtSn

MORITZ WINTER, SANDRA HAMANN, MARC UHLARZ, Dresden High Magnetic Field Laboratory, Helmholtz Zentrum Dresden Rossendorf, JACOB GAYLES, PRAVEEN VIR, MARKUS KOENIG, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, JOACHIM WOSNITZA, TONI HELM (Presenter), Dresden High Magnetic Field Laboratory, Helmholtz Zentrum Dresden Rossendorf — Mn$_{1.4}$PtSn is a half-Heusler compound with tetragonal crystal structure that hosts a D2d symmetry and strong Dzyaloshinskii-Moriya interactions. These are key-ingredients for the possible presence of Antiskyrmion phases. Recently, Antiskyrmions were observed well above room temperature by Lorentz transmission microscopy (LTEM) in polycrystalline nanoscaled ingots of the material [1]. Such a magnetic texture may cause a topological Hall effect (THE) leading to a significant deviation from the expected anomalous Hall effect. Indeed, a topological component of high magnitude was revealed by Hall measurements, conducted on bulk single crystals [2]. It however, only was observed below the spinreorientation transition at T$_{SR} = 160$ K associated with the formation of a non-coplanar spin structure. We investigate transport devices fabricated by the application of focused ion beams (FIB) from high-quality single crystals. Assisted by FIB we are able to conduct experiments on devices with sub-micron feature sizes. Our study of the temperature, field, and thickness dependent transport reveals clear signatures of THE originating from both, the non-coplanar spin structure as well as Antikyrmions, with apparent differences.

1:27PM M35.00012: Valence instability across magnetostructural transition in USb$_2^*$

ZACHARY BRUBAKER (Presenter), Oak Ridge National Laboratory, YUMING XIAO, PAUL CHOW, CURTIS KENNEY-BENSON, JESSE SMITH, Argonne National Laboratory, HYUNCHAE CYNN, CHRISTOPHER REYNOLDS, Lawrence Livermore National Laboratory, NICHOLAS BUTCH, National Institute of Standards and Technology, RENA ZIEVE, University of California, Davis, JASON R JEFFRIES, Lawrence Livermore National Laboratory — Pressure dependent transport measurements on USb$_2$ indicate an abrupt antiferromagnetic–ferromagnetic (AFM–FM) transition near P = 8 GPa, accompanied by a reduction in ordering temperature by more than 100 K. The AFM–FM transition has been the subject of several recent theoretical calculations, though only few experimental probes have been reported. To elucidate the behavior near this magnetic transition, we performed pressure dependent X-ray diffraction and resonant X-ray emission spectroscopy experiments on USb$_2$. The magnetic transition coincides with a tetragonal to orthorhombic structural transition resulting in a 17% volume collapse as well as a transient f-occupation enhancement. The AFM–FM transition width determined from structural and spectroscopic measurements agrees well with previously published transport measurements and suggests a sluggish transition from about 8 to 11 GPa. Except for the enhancement across the transition region, the f-occupation decreases steadily with pressure, demonstrating the multiconfigurational nature of actinide materials.

Effect of Co, Ni, and Co-Ni doping on magnetic and electronic properties of MnBi by first-principles calculations

CHANDANI NANDADASA (Presenter), BIPIN LAMICHHANE, DINESH THAPA, Department of Physics and Astronomy, Mississippi State University, MINYEONG CHOI, YANG-KI HONG, Department of Electrical and Computer Engineering and MINT Center, The University of Alabama, SEONG-GON KIM, Department of Physics and Astronomy, Mississippi State University — While Manganese Bismuth (MnBi) is a well-studied rare-earth free permanent magnetic material, its magnetic and electronic properties in the presence of dopants have not been discovered extensively. We studied the magnetic and electronic properties of MnBi doped with Co, Ni, and Co-Ni using the Generalized Gradient Approximation (GGA) method within Density Functional Theory (DFT). GGA+U method is used to get electronic correlation in 3d electrons in transition metal alloys. We considered both interstitial and substitutional sites in the MnBi lattice when adding Co, Ni, and Co-Ni. The addition of Co, Ni, and Co-Ni into interstitial sites has yielded a significant increase in the magnetization with dopant concentration. However, substitutional doping into Mn site decreased its magnetization with dopant concentration. Our results show that individual Co and Ni doping prefers parallel spin configurations with Mn site while Co-Ni doping prefers both parallel and antiparallel configurations. We further calculated magnetic anisotropy energy (MAE) and magnetic anisotropy constant ($K_u$) of pure MnBi and doped-MnBi. Electronic properties were examined to describe exchange interactions between the dopants and the MnBi lattice.

Kardar-Parisi-Zhang Universality in the Infinite Temperature spin-half Heisenberg Chain

NICHOLAS SHERMAN (Presenter), JOEL MOORE, University of California, Berkeley — There are two simple paradigms of how conserved quantities transport through a system: thermalizing systems with effectively random collisions in the system leading to diffusion, and particles moving freely in a material giving rise to ballistic transport. In the spin-half XXZ model in one dimension, both of these behaviors have been shown rigorously. Recent studies have suggested at the isotropic point of the model, the spin-half Heisenberg model, there is a third behavior at infinite temperature given by the stochastic classical Kardar-Parisi-Zhang (KPZ) universality class. In this work, I computed the dynamical structure factor at infinite temperature using matrix product states for the spin-half Heisenberg, and show that it exhibits the scaling function from the KPZ universality class, strengthening the claim that KPZ dynamics are present in quantum spin systems.
Mechanically Induced Thermal Breakdown in Magnetic Shuttle Structures

OLYA A. ILINSKAYA, SERGEIJ I. KULINICH, ILYA V. KRIVE, B. Verkin Institute for Low Temperature Physics and Engineering of the National Academy of Sciences of Ukraine, ROBERT SHEKHTER, Gothenburg University, HEE CHUL PARK (Presenter), Institute for Basic Science, MATS JONSON, Gothenburg University — A theory of a thermally induced single-electron “shuttling” instability in a magnetic nanomechanical device subject to an external magnetic field is presented in the Coulomb blockade regime of electron transport. The model magnetic shuttle device considered comprises a movable metallic grain suspended between two magnetic leads, which are kept at different temperatures and assumed to be fully spin polarized with antiparallel magnetizations. For a given temperature difference shuttling is found to occur for a region of external magnetic fields between a lower and an upper critical field strength, which separate the shuttling regime from normal small-amplitude “vibronic” regimes. We find that (i) the upper critical magnetic field saturates to a constant value in the high temperature limit and that the shuttle instability domain expands with a decrease of the temperature; (ii) the lower critical magnetic field depends not only on the temperature independent phenomenological friction coefficient used in the model but also on intrinsic friction caused by magnetic exchange forces and electron tunneling between the quantum dot and the leads. The feasibility of using thermally driven magnetic shuttle systems to harvest thermal breakdown phenomena is discussed.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M36 GDS FED: Data Science in the Physics Curriculum

11:15AM M36.00001: Designing curricula for data science based on fundamental skills and competencies informed by expert interviews* [Invited]  DEVIN SILVIA (Presenter), NATHANIEL HAWKINS, BRIAN W O'SHEA, MARCOS DANIEL CABALLERO, Computational Mathematics, Science, and Engineering, Michigan State Univ — With computational modeling and data analysis skills becoming an increasingly integral part of modern scientific work and research, understanding the specific competencies and skills required for individuals to participate in this work is growing more important. Previous efforts have defined these competencies and skills to varying degrees, with recommendations ranging from writing scientific software to designing entire degree programs in data science; however, the existing computational science education literature is incomplete in some ways. Primarily, much of the existing literature lacks a research-based foundation. We conducted a series of semi-structured interviews with experts in academic and industry settings to broadly describe the skills that students need to have in order to participate in work and research in computational science. In this talk, I will present the results of our research and highlight some of the design choices we have made for our introductory computational science course and how those choices connect to our research findings.

*We acknowledge the MSU Department of Computational Mathematics, Science, and Engineering and the MSU College of Natural Science for their generous support of this research.
A university-wide approach to integrative data science education and career paths

Sarah Stone (Presenter), University of Washington — All areas of science, particularly the physical sciences, are experiencing a data revolution that is changing our approaches to discovery. This “data science” transformation is being driven by factors such as advancements in high-throughput instrumentation, new modes of scalable computing, and perhaps most importantly, new breakthroughs in algorithms such as deep learning. Harnessing these advances with a coherent and intentional approach is essential to enabling new discoveries. As such, researchers need access to state-of-the-art data science methods and tools. Moreover, these methods and tools must evolve rapidly, driven by the requirements of discovery. This rate of advancement is currently limited by the “intellectual infrastructure” of trained data science practitioners. At the University of Washington’s eScience Institute, we have developed a university-wide approach to addressing this challenge by developing an integrative education program through formal data science options, now offered by 18 academic units at UW, and informal education programs. We have also supported transformational individuals, in both traditional and non-traditional academic roles, who bridge data science methods development and applied research. As a hub for data science on the UW campus, the eScience Institute has grown and fostered an interdisciplinary community focused on advancing data-intensive research and education across all fields.

In collaboration with: David Beck, University of Washington

A beginner’s guide to using data science for physicists

Trevor David Rhone (Presenter), Physics, Rensselaer Polytechnic Institute — The data revolution is changing the way we live. Exploiting data using data science tools has sparked innovation, spanning areas as diverse as spam filters, driverless cars and image recognition. Data science is rapidly becoming the latest addition to the physicist's toolkit. But, what is data science? Why is it useful? How does it work? This talk provides a beginner’s guide to data science for the inquisitive physicist. We will explore the major aspects of data science and discuss useful applications. In addition, I will provide a step by step guide on how to get started learning data science and share the secret to mastery of this exciting new field.
1:03PM M36.00004: Deep Learning Data Science Competencies to Promote Workplace Readiness [Invited] AMIR SHAHMORADI (Presenter), University of Texas at Arlington — Data science is a rapidly growing field with a 663% increase in the number of job postings for a data scientist between 2013 and 2018. The demand for college graduates who are trained in data science skills spans every field of science. Therefore, undergraduate and graduate programs must be responsive to align their curricula with these dynamic needs. However, the data scientist title is relatively new and formal data science competencies are yet to be defined. In this talk, I will describe our efforts at the University of Texas to 1. determine what these data science technical and soft skill competencies are by analyzing data from national job postings, and 2. systematically investigate how the pattern of required skills varies by co-occurrence, domain of science knowledge, and characteristics of the jobs and employers. Such knowledge can help identify gaps between academic preparation and the skills employers seek by identifying data science competencies employers are requesting within and between domains of science, and then evaluating how well these skills align with science curriculum and finally, predicting the future of job market’s supply versus demand for data science skills.

1:39PM M36.00005: Data Science Tools in the Classroom [Invited] MOHAMMAD SOLTANIEH-HA (Presenter), Boston Univ — Teaching methods for programming and data science-related topics have been evolving faster than ever before. This has been heavily influenced by the fast-growing popularity of cloud-based tools. In this talk, I will provide an overview of tools and techniques that can improve both the learning experience of the students and the instructor’s ability to manage the class and materials. I will discuss the best practices to manage and distribute code and data, as well as the platforms used in a data science project. Among a vast space of competitive solutions, I have decided to use Google products as the primary platform. Google Colaboratory (Colab) will be introduced as a solution to run and share the code. Beyond Colab, I will present an end-to-end data science project on a cloud-based ecosystem, using Google Cloud Platform (GCP). In addition to the essential elements of GCP, I will cover ways to tackle big data problems using Hadoop and Spark, as well as utilizing containerized applications for large scale parallel processing. I will illustrate how I have used GCP in my classes at Boston University and share feedback from the students. Additionally, I will touch on open-source auto-grading tools.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M37 FPS FOEP: Communicating Science to the Public 605 - Richard Wiener, Research Corporation - Tag(s): Invited, Outreach, Undergrad Friendly
11:15AM M37.00001: Joseph A. Burton Forum Award talk: Physics, Truth and the Crisis of Science Denial [Invited] ADAM FRANK (Presenter), Department of Physics and Astronomy, University of Rochester — In this talk I will discuss the current state of relations between Physics (and Science in general) and the non-scientific public. After many years as both a practicing astrophysicist and a science writer/communicator, I have watched as the public perception of science has changed dramatically. Because of critical issues such as climate change, a remarkably large section of the public views science as tainted by "elite" interests rather than as a means of achieving some degree of truth about the physical world. In this talk I will review how this state of affairs came to be, using my own experiences in writing for venues like NPR, The New York Times and elsewhere. The current situation presents great challenges to our community and to the US scientific effort as a whole. I will attempt to articulate both its causes and possible mechanisms with which we can ensure that science maintains its vital role in ensuring the health, welfare and security of the US and global communities.

11:40AM M37.00002: Andrei Sakharov Award talk: Scientific espionage, open exchange, and American competitiveness [Invited] XIAOXING XI (Presenter), Temple Univ — As the federal government warns universities and colleges about the risk of China to academia in the United States, professors, scientists, and students of Chinese ethnic origin are under heightened scrutiny. In 2015, I became a casualty of this campaign despite being innocent. This experience gave me insights into the challenges Chinese scientists face and the immediate threat to the open environment in fundamental research on university campuses. Based on my personal experience and the recent events involving Chinese scientists in the US, I urge the audience to join an increasing number of scientists, university administrators, and professional societies in speaking up to defend liberty, support reaffirmation of NSDD-189 on open fundamental research, and safeguard America’s research enterprise.

12:05PM M37.00003: The role of news journalism [Invited] DENNIS OVERBYE (Presenter), New York Times — tbd
12:30PM M37.00004: The National Academy of Sciences Goes to Hollywood: Employing Creative Engagement Strategies to Connect with Broad Audiences* [Invited]  ANN MERCHANT (Presenter), Office of the Chief Communications Officer, National Academy of Sciences — Entertainment media saturates our lives. According to the Motion Picture Association of America, an average of 600 new movies are created in the United States every year. With the exception of 2009, when the global economic crisis slowed production in Hollywood, the number of movies released in North America has steadily increased since the year 2000. In 2018, a record 878 movies graced U.S. screens.

In 2008 the National Academy of Sciences (NAS) launched The Science & Entertainment Exchange (The Exchange) to connect entertainment industry professionals with top scientists and engineers to create a synergy between accurate science and engaging storylines in both film and television programming. The goal of The Exchange is to use the vehicle of popular entertainment media to deliver sometimes subtle, but nevertheless powerful, messages about science that catalyze more storytelling grounded in authentic science, encourage the depiction of richer, more diverse STEM characters in order to challenge traditional stereotypes, and inspire new media projects driven by science and engineering themes.

Learn more about the ways in which The Exchange has worked closely with the Hollywood community to foster and incubate a collaborative community of scientists, engineers, and entertainment industry professionals to generate science-inspired film, television, and video game projects that have the potential to impact the next generation of scientists and engineers.

*The Science & Entertainment Exchange is grateful to the Alfred P. Sloan Foundation, Howard Hughes Medical Institute, Google, the Simons Foundation, The Walt Disney Company, the Lyda Hill Philanthropies, the Cabot Wellington Family Foundation, and the many individual donors who make our work possible.

12:55PM M37.00005: The art of interviewing scientists [Invited]  IRA FLATOW (Presenter), Science Friday — tbd

1:10PM M37.00006: Panel Discussion [Invited] —

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M38 CSWP: Proactive Ways to Recruit and Retain Women in Physics 607 - Kristen Burson, Hamilton College - Tag(s): Diversity, Education, Invited, Undergrad Friendly
Despite increasing numbers of students graduating with physics and other STEM degrees, the percentage of women earning bachelor’s degrees in physics has stagnated at approximately 20% for the past decade. The drop in representation of women in physics occurs at the high school/college transition. Nearly half of high school physics students are young women, but only one-fifth of physics majors at college entrance are women. Thus, efforts to increase the representation of women in physics need to focus on high school, which is many students’ first and last exposure to physics. STEP UP is a nationwide community with the goal of inspiring young women to pursue physics bachelor’s degrees. We have developed two lessons for use by high school physics teachers: Careers in Physics and Women in Physics. The lessons are grounded in research on physics identity, goal orientation, career intentions, and gender. In this talk, I will give an overview of the project and present results of the pilot study conducted in Fall 2017 and the experimental study conducted in Fall 2018. Learn more about STEP UP and join the movement at http://www.STEPUPphysics.org

*STEP UP* (Supporting Teachers to Encourage the Pursuit of Undergraduate Physics) is funded by the National Science Foundation under Grant Nos. 1720810, 1720869, 1720917, and 1721021.
12:27PM M38.00003: Outcome of the Conferences for Undergraduate Women in Physics
[Invited] PEARL SANDICK (Presenter), University of Utah — The APS Conferences for Undergraduate Women in Physics (CUWiPs) are simultaneous regional conferences designed to help undergraduate students continue in physics by providing them the opportunity to network with other physicists, learn about career options and graduate school, discuss issues associated with underrepresentation in science, and participate in professional development activities. CUWiP attendance has been steadily increasing since the first conference in 2006. In 2019, approximately 2000 undergraduate students attended a CUWiP at one of twelve host sites throughout the US and Canada. The number of attendees has roughly doubled since 2014. In this talk, I'll give an overview of the APS CUWiPs, typical programming, and impact. I'll also discuss the role of the National Organizing Committee and individual host sites, as well as how to apply to host a CUWiP.

1:03PM M38.00004: Julianne Pollard-Larkin Invited Talk [Invited] —

1:39PM M38.00005: Physics – We Have a Problem [Invited] PATRICIA RANKIN (Presenter), University of Colorado, Boulder — Thirty years ago when people asked me why more women did not study physics I did not have a good answer. Now I do. Attempts to increase the percentage of women in Physics go in phases. Early on, the belief was that more female role models would help (they do, but not enough, and intersectionality matters when giving people role models they can see themselves as). Later we went through the “Fix the Women” / “Lean in” stage and the focus was on teaching women the skills (such as negotiation) it was felt they needed to be successful in Physics. I will explain why this approach was not as effective as hoped and why the emphasis has now shifted to looking at processes and policies to make organizations more inclusive not just more diverse. We are now in the “Lean Out” era. This presentation will emphasize research based practice and include some specific suggestions on how to make recruitment less subject to bias.

Wednesday, March 4, 2020 11:15 AM - 2:03 PM

Session M39 DCOMP GDS DMP: Machine Learning for Quantum Matter
II 703 - Estelle Inack, Perimeter Inst for Theo Phys - Tag(s): Focus

11:15AM M39.00001: Materials discovery through artificial intelligence [Invited] MURATAHAN AYKOL (Presenter), Toyota Research Institute — New, suitable materials are almost always at the core of new technologies. This endeavor now is spurred by exciting developments at the intersection of artificial intelligence (AI) and materials science. In this talk, I will present new AI tools developed at TRI for end-to-end material discovery systems. Using these tools, codified agents of research can incorporate machine-learning, physics, chemistry, logic or heuristics to make decisions to meet their goals, for example, on which structures to simulate using high-fidelity quantum mechanics. New agent designs can also be simulated a priori, projecting their performance in real-world discovery campaigns. Examples of simulations and executions of stable material discovery campaigns will be shown.
11:51AM M39.00002: Working without data: overcoming gaps in deep learning and physics-based extrapolation [Invited] ISAAC TAMBLYN (Presenter), National Research Council of Canada — Despite its many recent successes, several fundamental issues remain with the application of deep learning to experimental data and first-principles based simulation.

These problems include the ability to extrapolate to unseen experimental conditions, transfer knowledge across length-scales, and the challenge of interpreting results within a physically motivated framework. Other challenges include the lack of a standardized methodology for reporting and understanding model errors as well as the frequent requirement for large quantities of data.

I will outline some of our ongoing efforts to address some of these challenges, with special attention paid to the concept of extrapolation (including the physical conditions of study and across length scales). To explore these ideas, we explore model spin-systems, 2d materials, and optical lattices.

12:27PM M39.00003: Machine learning models of properties of hybrid 2D materials as potential super lubricants* MARCO FRONZI (Presenter), IRCRE, Xi'an Jiaotong University, MUTAZ ABU GHAZALEH, University of Technology Sydney, OLEXANDR ISAYEV, University of North Carolina, DAVID WINKLER, La Trobe University, JOE SHAPTER, Flinders University, MICHAEL J FORD, University of Technology Sydney — The screening of novel materials is an important topic in the field of materials science. Although traditional computational modeling, especially first-principles approaches, is a very useful and accurate tool to predict the properties of novel materials, it still demands extensive and expensive state-of-the-art computational resources. Additionally, they can be often extremely time-consuming. We describe a time and resource-efficient machine learning approach to create a large dataset of structural properties of van der Waals layered structures. In particular, we focus on the interlayer energy and the elastic constant of layered materials composed of two different 2-dimensional (2D) structures, that are important for novel solid lubricant and super-lubricant materials. We show that machine learning models can recapitulate results of computationally expansive approaches (i.e. density functional theory) with high accuracy.

*National Natural Science Foundation of China (No. 51323011), the Australian Government through the Australian Research Council (ARC DP16010130), National Computational Infrastructure (NCI), which is supported by the Australian Government.
12:39PM M39.00004: Charge Density Prediction through 3D-CNN for Fast Convergence of Self-Consistent DFT calculation*  IORI KURATA (Presenter), Univ of Tokyo, CHIKASHI SHINAGAWA, RYOHTO SAWADA, Preferred Networks, Inc. — The electronic charge density plays an important role in understanding the physical properties of quantum materials. Although the charge density can be obtained by solving the Kohn-Sham equation of density functional theory (DFT), one needs to solve a self-consistent equation which takes time until convergence. Recent studies have tried to directly predict the charge density using machine-learning methods, but the target materials are limited to slabs or organic molecules because they only considered local electronic features [1,2,3]. In this study, we propose a machine-learning algorithm to predict the charge densities of crystals using a three-dimensional convolutional neural network (3DCNN). To deal with the periodicity of crystals, we use FFT grid-based representation and a periodic convolution filter. We demonstrate that our model can predict the charge densities of ABO$_3$-type crystalline compounds without solving the self-consistent equation. It will accelerate the high-throughput DFT calculations for materials discovery.

*This work was supported by Preferred Networks, Inc.

12:51PM M39.00005: Data-driven studies of the magnetic anisotropy of two-dimensional magnetic materials*  YIQI XIE (Presenter), TREVOR DAVID RHONE, GEORGIOS TRITSARIS, Harvard University, OSCAR GRÅNÅS, Uppsala University, EFTHIMIOS KAXIRAS, Harvard University — Two-dimensional materials with intrinsic ferromagnetic order are at the forefront of condensed matter research. How many of these materials exist in nature? What is the relationship between their crystal structure and magnetic properties? Remarkably, atomically-thin magnetic structures can exhibit novel spin properties which do not exist in the corresponding bulk materials. We use first-principles calculations, based on density functional theory, and machine learning to study the magnetocrystalline anisotropy of monolayer transition metal trichalcogenides of the form A$_2$B$_2$X$_6$. That is, we created permutations of the chemical composition of the ferromagnetic semiconductor Cr$_2$Ge$_2$Te$_6$. Specifically, we identify trends in their magnetocrystalline anisotropy data. We find that the X site dominates the machine learning prediction of the magnetocrystalline anisotropy of an A$_2$B$_2$X$_6$ monolayer. Our data-driven study aims to uncover physical insights into the microscopic origins of magnetism in reduced dimensions and to demonstrate the success of a high-throughput computational approach for the targeted design of quantum materials with potential applications from sensing to data storage.

1:03PM M39.00006: Robust cluster expansion of multicomponent systems using machine learning with structured sparsity*  ZHIDONG LEONG (Presenter), TECK LEONG TAN, Institute of High Performance Computing — Identifying a suitable set of descriptors for modeling physical systems often utilizes either deep physical insights or statistical methods. In machine learning, a class of methods known as structured sparsity regularization combines both physics- and statistics-based approaches. We present group lasso as an efficient method for obtaining robust cluster expansions (CE) of multicomponent systems, a popular computational technique for modeling the thermodynamic properties of such systems. Via convex optimization, group lasso selects the most predictive set of atomic clusters as descriptors in accordance with the physical insight that if a cluster is selected, so should its subclusters. These selection rules avoid spuriously large fitting parameters by redistributing them among lower order terms, resulting in more physical, accurate, and robust CEs. We showcase these features of group lasso using the CE of bcc ternary alloy Mo-V-Nb. These results are timely given the growing interests in applying CE to increasingly complex systems, which demand a more reliable machine learning method to handle the larger parameter space.

1:15PM M39.00007: Generalizing an Energy Predictor based on Wavelet Scattering for 3D Atomic Systems  PAUL SINZ, MICHAEL SWIFT (Presenter), XAVIER BRUMWELL, KWANG JIN KIM, YUE QI, MATTHEW J HIRN, Michigan State Univ — The dream of machine learning in quantum matter is for a neural network to learn the underlying physics of an atomic system, allowing it to move beyond interpolation of the training set to the prediction of properties that were not present in the original training data. Achieving this ambitious goal will require a method to convert a 3D atomic system into neural-network-friendly features that preserve rotational and translational symmetry, smoothness under small perturbations, and invariance under reordering. The atomic orbital wavelet scattering transform preserves these symmetries by construction, and has achieved great success as a featurization method for machine learning energy prediction. Both in small molecules and in the amorphous Li$_x$Si system, neural networks using wavelet scattering coefficients as features have demonstrated a comparable accuracy to Density Functional Theory at a small fraction of the computational cost. In this work, we test the generalizability of our Li$_x$Si energy predictor to properties that were not included in the training set, such as elastic constants and migration barriers. We also discuss the potential for future improvements in generalizability through automatic training-set expansion based on active learning.
1:27PM M39.00008: Using Machine Learning Models to Predict Higher-Level Quantities from Energy Models*

OLIVIER MALENFANT-THUOT (Presenter), MICHEL COTE, Universite de Montreal — Machine learning methods are now used more and more as a substitute for Density Functional Theory calculations due to their low computational costs. However, in some cases, relevant datasets are not available, and the effort that would be necessary to generate this data suppresses the advantages of using machine learning to speed up the calculations. Furthermore, the process of training a reliable model is not trivial and can also be expensive. For those reasons, we are developing a python package named ML_Calc_Driver\(^1\), which goal is to allow to use portable trained models to make predictions easily. Energy datasets are numerous and, through the use of implemented finite difference workflows, can be used to predict higher-level quantities such as forces, phonon energies, and infrared intensities. As of now, the package is interfaced to use SchNetPack\(^2\) trained models, and more model types can easily be added as our workflows are independent of the actual calculators.

1:39PM M39.00009: AI-guided engineering of nanoscale topological materials*

SRILOK SRINIVASAN (Presenter), MATHEW J CHERUKARA, DAVID JASON ECKSTEIN, ANTHONY AVARCA, SUBRAMANIAN SANKARANARAYANAN, PIERRE DARANCET, Argonne Natl Lab — Nanoscale organic materials have long been known to host topologically protected excitations. Inspired by recent progress in classifying topological phases in armchair, cove-edged and chevron graphene nanoribbons, we develop a high-throughput framework based on the computation of the Zak phase and the Z2 invariants using tight-binding and density functional theory to explore the topology of low-symmetry 1D and 2D periodic organic compounds. As of today, we have identified 224,071 new topological nanoribbons using our framework. Training deep neural networks on the graphs of these Hamiltonians, we analyze the graphical features conducive to topological excitations in these systems. We show how this workflow can help the atomic assembly of topologically non-trivial artificial lattices.

1:51PM M39.00010: Motif-based machine learning for crystalline materials  HUTA BANJADE (Presenter), Physics, Temple University, SHANSHAN ZHANG, SANDRO HAURI, SLOBODAN VUCETIC, Computer and information Sciences, Temple University, QIMIN YAN, Physics, Temple University — With the development of advanced algorithms and improvements in computational power, machine learning (ML) has been widely successful in predicting various physical and chemical properties of materials. The success of any ML model mainly depends on the good representation of the input data, and there have been surging interests in identifying effective representations for crystalline materials. In this talk, we propose a novel representation of crystalline solid-state materials (such as complex metal oxides) as graphs composed of structure motifs. This motif-based representation serves as input to a graph convolutional network for the learning and prediction of material properties, such as bandgaps and formation energies. Our test results indicate that, when combined with atomic information and related networks, the inclusion of motif information in the network architecture improves the prediction performance, especially for complex oxide materials.

M39.00011: Machine learning powered kinetic energy functional finding in solid state physics  HONGBIN REN (Presenter), Chinese Academy of Sciences, Institute of Physics, XI DAI, Physics, Hong Kong University of Science and Technology, LEI WANG, Chinese Academy of Sciences, Institute of Physics — Kinetic energy functional is crucial to speed up the density functional theory calculation. However, deriving it directly from first principle is challenging, and existing approximations all have significant flaw. In this work, we use machine learning method to build a kinetic energy functional for 1D extended system, our solution combines the dimensionality reduction method with the Gauss process regression, and use a simple scaling trick to generalize the functional to 1D lattice with arbitrary lattice constant. Besides reaching chemical accuracy in kinetic energy calculation, our solution also performs well in functional derivative prediction, and integrating it into the current orbital free density functional theory scheme provide us with expected ground state electron density.

Session M40 DCOMP DMP: Matter in Extreme Environments IV: Superconductivity  705 - Antonio dos Santos, Oak Ridge National Lab - Tag(s): Focus
11:15AM M40.00001: Room-Temperature Superconductivity in High-Pressure Hydrides: An electronic structure perspective* [Invited] LILIA BOERI (Presenter), Univ of Rome La Sapienza — Conventional Superconductivity near Room Temperature was observed for the first time almost fifty years after its theoretical prediction, when a superconducting critical temperature ($T_c$) of 203 K was reported in sulfur hydride, $\text{SH}_3$.\[1\] $T_c$’s exceeding 200 K have later been reported also in lanthanum and yttrium hydrides.\[2\]

In this talk, I will show how electronic structure methods can be used to understand the material-specific aspects that underlie high-$T_c$ superconductivity in different classes of hydrides,\[3\] and identify strategies to reduce the pressure for high-$T_c$ conventional superconductivity.\[4\]

*I acknowledge funding from the FWF Grant P-30269-N36 Superhydra and Progetto Ateneo Sapienza 2017 and 2018.

11:51AM M40.00002: Design of Ternary Ca-S-H System that are Superconducting Under Pressure YAN YAN (Presenter), TIANGE BI, NISHA GENG, XIAOYU WANG, EVA ZUREK, State Univ of NY - Buffalo — Hydrogen-rich compounds are promising candidates as high pressure superconductors under high compression. Among the most promising hydrides for high temperature superconductivity are those of sulphur and calcium. The high pressure phase transition of S-H system has resulted in the second highest $T_c$ to date, 203 K at 160 GPa, while a $T_c$ of 220-235K has been predicted for $\text{CaH}_6$ at 150 GPa. Here, we present a systematic investigation of Ca-S-H phases with various stoichiometries. We find that $\text{CaSH}_2$, $\text{CaSH}_6$ and $\text{CaSH}_{20}$ are thermodynamically stable at pressures accessible in diamond anvil cells. In these structures hydrogen still exists in its molecular form, and all of these phases are semiconductors with small band gaps. However, an interesting phase with the composition $\text{CaSH}_3$ has been found, which is metastable and metallic, and does not contain any H-H bonds. This unique structure has a $T_c$ up to 46 K at 250 GPa. Analysis of its electronic structure, including the sulphur and hydrogen contributions, reveals a van Hove singularity in the density of states near the Fermi Energy. This feature may be important for the superconductivity. Our approach may pave the way for finding high-$T_c$ superconductors in various ternary hydrides.
Quantum Crystal Structure in the 250 K Superconducting Lanthanum Hydride

ION ERREA (Presenter), University of the Basque Country UPV/EHU, FRANCESCO BELL, Centro de Física de Materiales, LORENZO MONACELLI, La Sapienza, ANTONIO SANNA, Max-Planck Institute of Microstructure Physics, TAKASHI KORETSUME, Tohoku University, TERUMASA TADANO, Research Center for Magnetic and Spintronic Materials, RAFFAELLO BIANCO, Centro de Física de Materiales, MATTEO CALANDRA, Institut des Nanosciences de Paris, RYOTARO ARITA, University of Tokyo, FRANCESCO MAURI, JOSE A. FLORES LIVAS, La Sapienza — Hydrogen-rich materials at high pressures are at the verge of reaching room-temperature superconductivity. Electrical and x-ray diffraction measurements determined a weakly pressure-dependent Tc for LaH10 between 137 and 218 gigapascals in a structure with a fcc arrangement of La atoms. Here we show that quantum atomic fluctuations stabilize in this pressure range a high-symmetry Fm-3m crystal structure consistent with experiments. Even if ab initio classical calculations predict this structure to distort below 230 GPa, the inclusion of quantum effects evidences the Fm-3m as the true ground state. The agreement between the calculated and experimental Tc values further supports this phase as responsible for the 250 K superconductivity. The relevance of quantum fluctuations questions many of the crystal structure predictions made for hydrides within a classical approach that at the moment guide experiments. Furthermore, quantum effects are revealed to be crucial to stabilize solids with extraordinary electron-phonon coupling, reducing the pressures needed for their synthesis.

High field phase diagram of LaH$_{10}$

DAN SUN (Presenter), Los Alamos National Laboratory, VASILY S MINKOV, PANPAN KONG, ALEXANDER DROZDOV, Max-Planck-Institut fuer Chemie, SHIRIN MOZAFFARI, LUIS BALICAS, National High Magnetic Field Laboratory, MIKHAIL EREMETS, Max-Planck-Institut fuer Chemie, FEDOR BALAKIREV, Los Alamos National Laboratory — Recent research on the hydrogen-rich hydrides pushes the superconducting transition temperature ($T_c$) near the limit of room temperature. In the hydrides family, LaH$_{10}$ keeps the current record of $T_c$ of 250 K. Using a pulsed magnet, we mapped out the phase diagram of LaH$_{10}$ under pressure of 140 GPa. The normal state has a linear temperature dependence and high resistance. $H_{c2}$ has been measured above 60 T. The information on the vortex liquid region, coherence length and density of states are obtained by our measurement, providing valuable information for theoretical and experimental hydride development.

This work was performed at the National High Magnetic Field laboratory, which is supported by National Science Foundation Cooperative Agreement No. DMR-1644779, and the State of Florida.
Effect of pressure on the noncentrosymmetric antiferromagnet CeNiC2

JUN GOUCHI, Institute for Solid State Physics, University of Tokyo, TORU SHIGEOKA, Grad. Sch. of Sci. Eng., Yamaguchi University, YOSHIYA UWATOKO (Presenter), Institute for Solid State Physics, University of Tokyo — Recently, the pressure-induced superconductivity in the CeNiC2 polycrystal has been discovered at 3.5 K around 11 GPa, the highest superconducting transition temperature in a Ce-based heavy-Fermion compound [1]. The intermetallic CeNiC2 crystalizes in orthorhombic structure (space group Amm2) where the lattice lacks the inversion symmetry along c-axis. With decreasing temperature CeNiC2 displays multiple magnetic transitions, an incommensurate antiferromagnetic (iAFM) order at TN1 = 20 K followed by a commensurate AFM order at TN2 = 10 K and a ferromagnetic order at TC = 2 K [2]. In this talk, I will present the pressure phase diagram of CeNiC2 single crystal based on our recent pressure dependence of transport and magnetic data. We observed superconductivity in a narrow pressure range in the vicinity of the vanishing point of TN1. The remarkable coincidence of non-Fermi liquid behavior and the optimal , coupled with moreover, the non-centrosymmetric crystal structure suggest that superconductivity in CeNiC2 is unconventional and exotic in nature.

AB3Si3 (A= Na, K, Rb, Cs), the alkali metal borosilicide in sodalite structure with superconductivity under high pressure

MIAO ZHANG (Presenter), EVA ZUREK, Department of Chemistry, State University of New York at Buffalo — Prediction of high-temperature superconductivity in clathrate-like hydrogen cage under high pressure has generated an irresistible interest of searches for clathrate-like superconductors. However, when the pressure is released, atomic hydrogens will decompose into H2, accompanying the disappearance of superconductivity. We herein report the structural and physical properties of AB3Si3 (A= Na, K, Rb and Cs) in clathrate-based sodalite structure, whose frameworks consist of covalent B-Si bonds, by first-principles calculations. Our results show that KB3Si3 and RbB3Si3 are thermally stable within pressure ranges of 6.9-37.0 GPa and 7.3-34.2 GPa, respectively. Phonon calculations confirm that RbB3Si3 is dynamically stable at both ambient and high pressures, while KB3Si3 is not at ambient pressure. Electron-phonon calculations predict that RbB3Si3 possess a Tc of 14.5 K at ambient pressure. Moreover, RbB3Si3 is mechanically stable, and its estimated Vickers hardness values are between 11.8 – 15.2 GPa, which are in good agreement with the ideal strength results.
1:15PM M40.00007: Charge Transfer Induced Band Gap Closure: Trend in Rare Earth Tetrahydrides Discovered under Pressure*  TIANGE BI (Presenter), EVA ZUREK, Chemistry, University at Buffalo — The recent success of the high-pressure synthesis of CaH$_4$ inspired this analysis of a plethora of previously predicted high-pressure rare-earth metal tetrahydrdes: MH$_4$ (M = Ca, Sr, Sc, Y, La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu). This type of structure, assuming the space group of $I4/mmm$ and resembling the ThCr$_2$Si$_2$ structure type, contains layers of edge-sharing tetrahedra in the xy plane comprised by the negatively charged atomistic hydrogen layers and molecular H$_2$ layers. When this set of structures are optimized to 0 GPa, while the pressure-induced band broadening is eliminated, the H-H distances within the H$_2$ units are inversely associated with the charges transferred to it, which leads to bandgap closure. The existence of quasi-molecular H$_2$ is stabilized by the electron donation from H$_2$ $\sigma$ bonding state to the vacant metal $d$ states and the back donation from occupied metal $d$ states to the H$_2$ $\sigma^*$ anti-bonding states. The analysis of the electronic properties and stabilization mechanisms of these high-pressure rare earth metal tetrahydrides would potentially benefit the understanding of their exotic physical properties: i.e. superconductivity novel, magnetic behavior.

1:27PM M40.00008: Fermiology Study of YBCO* [Invited]  AUDREY GROCKOWIAK (Presenter), WILLIAM A CONIGLIO, STANLEY W TOZER, Florida State Univ — We report on high pressure SdH studies of YBCO6.5 (p=0.1) at He-3 temperatures in pulsed fields to 85 T and 7 GPa at HLD and dc fields of 45 T and pressures of 25 GPa at NHMFL using plastic and metal diamond anvil cells (DACs), respectively, that are coupled with an LC tank circuit based on a tunnel diode oscillator. Our high pressure studies show an enhancement of the superconducting critical field from 24 to 42T between ambient pressure and 6 GPa, which limits the observation of QO to 5 GPa in the 45T Hybrid. Our Fermiology studies clearly show a strongly diverging effective mass at 4.5 GPa along with a local maximum in frequency and superconducting critical temperature, attributed to the effect of various charge orders present in this material. For pressures greater than 15 GPa we are able to measure a critical field of the order of 30T and to measure again QOs. We find that the orbital frequency has increased from 550 T at ambient pressure to 690 T at 15 GP and above. Assuming that the samples are driven by pressure to the overdoped state, those results do not match the reported frequency of 18kT observed for the overdoped analog TI-2201. This indicates that pressure and doping are not playing an equivalent role on the CDWs and the superconducting state as also pointed in other studies, and shows that pressure is a new axis in the YBCO phase diagram which can help understand the interplay between CDWs and superconductivity in this material.

M40.00009: Superconductivity in Li$_6$P electride* GUOCHUN YANG (Presenter), Department of Physics, Northeast Normal University — Electrides are unique compounds where most of the electrons reside at interstitial regions of the crystal behaving as anions, which strongly determines its physical properties. Interestingly, the magnitude and distribution of interstitial electrons can be effectively modified either by modulating its chemical composition or external conditions (e.g. pressure). Most of the electrides under high pressure are non-metallic, and superconducting electrides are very rare. Here, we report that a pressure-induced stable Li$_6$P electride, identified by first-principles swarm structure calculations, becomes a superconductor with a predicted superconducting transition temperature $T_c$ of 39.3 K, which is the highest among already known electrides. The interstitial electrons in Li$_6$P, with dumbbell-like connected electride states, play a dominant role in the superconducting transition. Our work opens up the interest to explore high-temperature superconductivity in similar binary compounds.

Session M41 GMAG DMP FIAP DCOMP: Spin Phenomena in Nonmagnetic 2D Materials II 707 - Wei Yuan, University of California, Riverside

11:15AM M41.00001: The Electronic Properties of Quasi-One-Dimensional TiS$_3$ and ZrS$_3$
SIMEON GILBERT (Presenter), University of Nebraska - Lincoln, ANDREW J. YOST, Oklahoma State University, MINGXING LI, Brookhaven National Lab, HEMIAN YI, SOLEIL, ALEXEY LIPATOV, TAKASHI KOMESU, University of Nebraska - Lincoln, JOSÉ AVILA, SOLEIL, ALEXANDER SINITSKII, University of Nebraska - Lincoln, JIAN WANG, Canadian Light Source, MARIA ASENSIO, Madrid Institute of Materials Science, PETER A DOWBEN, University of Nebraska - Lincoln — The transition metal trichalcogenides (TMTs) are an emerging class of 2D materials in which 2D sheets are formed by the van der Waals-like bonding of quasi-1D chains. Here we present our work on the electronic properties of two TMTs, TiS$_3$ and ZrS$_3$, including the experimental band structure from nanospot angle resolved photoemission spectroscopy (nanoARPES). The band structures of both TMTs exhibit strong in-plane anisotropy due to their quasi-1D structure. The extracted effective hole mass for both materials is doubled along the chain direction, giving rise to a preferential charge transport direction. Additionally, high resolution nanoARPES measurements show a spin-orbit coupling splitting at the top of the valence band in TiS$_3$. This spin-orbit coupling splitting is expected to increase for heavier TMTs such as ZrS$_3$ and could be utilized to produce a spin polarized surface current.
11:27AM M41.00002: Origin of Magnetism in undoped and Ta doped anatase TiO$_2$ free-standing films  
SONU DEVI (Presenter), THIRUMALAI VENKATESAN, Natl Univ of Singapore — Thin films of anatase titanium dioxide (TiO$_2$) are semiconducting and exhibit signs of room temperature ferromagnetism. However, the role of the surface, substrate and interface in the observed magnetism are controversial. Here, the magnetic properties of two systems, Ta-doped anatase and undoped-anatase have been studied in detail. To avoid the effects from the substrate as well as interface we have fabricated free-standing films using an epitaxial, water-soluble Sr$_3$Al$_2$O$_6$ sacrificial buffer layer. We have found a strong linear correlation between the observed magnetism and Ta-doping, in addition to an intrinsic contribution. The magnetization exhibits a minimum as a function of the oxygen pressure present during film deposition and the result are consistent with a model where Ti interstitials and oxygen vacancies may be responsible for the magnetism at low oxygen pressure while at the high oxygen pressures, Ti vacancies dominate. This study proves that magnetism in anatase TiO$_2$ system is intrinsic and cannot be arising from either the interface or the substrate.

11:39AM M41.00003: Efficient intrinsic spin-to-charge current conversion in an all-epitaxial single-crystal perovskite-oxide heterostructure of La$_{0.67}$Sr$_{0.33}$MnO$_3$/LaAlO$_3$/SrTiO$_3$* 
SHINOBU OHYA (Presenter), DAISEI ARAKI, LE DUC ANH, SHINGO KANETA, MUNETOSHI SEKI, HITOSHI TABATA, MASAAKI TANAKA, Department of Electrical Engineering and Information Systems, The University of Tokyo — The two-dimensional electron gas formed at the interface between insulating perovskite oxides LaAlO$_3$ (LAO) and SrTiO$_3$ (STO) is promising for efficient spin-charge conversion, so-called the (inverse) Edelstein effect (EE). A giant (inverse) EE has been observed in multilayer structures composed of a polycrystalline ferromagnetic layer and LAO/STO; however, the reported temperature dependences of the (inverse) EE are significantly different from each other, and unified understanding of its real mechanism is still lacking. Here, we demonstrate efficient intrinsic spin-to-charge current conversion in an all-epitaxial single-crystal heterostructure of La$_{0.67}$Sr$_{0.33}$MnO$_3$/LAO/STO, which can suppress spin scattering and give us an ideal environment to investigate intrinsic spin-charge conversion. With decreasing temperature to 20 K, the spin-to-charge current conversion efficiency is drastically enhanced to +6.7 nm, which is the largest value among those reported for LAO/STO. Our band-structure calculation well reproduces this behavior and predicts further enhancement by controlling the Fermi level position [1]. [1] S. Ohya et al., arXiv:1906.06016.

Magnetic proximity effects in vdW heterostructures of layered materials  

JACOB GOBBO (Presenter), RYAN MUZZIO, IGOR PINCHUK, JYOTI KATOCH, SIMRANJEET SINGH, Carnegie Mellon Univ — The van der Waals (vdW) based heterostructures of different layered materials have emerged as a modular solid-state platform to engineer tunable properties in novel quantum systems. The vdW superlattices offer unprecedented flexibility to tune the interfacial interactions at the atomic scale to engineer spin related phenomena in two-dimensional (2D) materials. In this talk, we will present our preliminary results in the direction of probing magnetic proximity effects in vdW based heterostructures of 2D-magnetic systems and transition metal dichalcogenides (TMDs). We will discuss the preparation of high-quality vdW interfaces of 2D-magnets and TMDs in controlled environment. The proximity induced magnetic correlations in otherwise non-magnetic TMDs are probed through variable temperature magneto-transport measurements and will be discussed in this talk.

Magnetic proximity in a van der Waals heterostructure of magnetic insulator and graphene.

BOGDAN KARPIAK (Presenter), Chalmers Univ of Tech, ARON CUMMINGS, Catalan Institute of Nanoscience and Nanotechnology, KLAUS ZOLLNER, University of Regensburg, MARC VILA, Catalan Institute of Nanoscience and Nanotechnology, DMITRII KHOKHRIAKOV, MD ANAMUL HOQUE, ANDRÉ DANKERT, Chalmers Univ of Tech, PETER SVEDLINDH, Uppsala University, JAROSLAV FABIAN, University of Regensburg, STEPHAN ROCHE, Catalan Institute of Nanoscience and Nanotechnology, SAROJ DASH, Chalmers Univ of Tech — By investigating the the van der Waals heterostructures of the ferromagnetic insulator Cr$_2$Ge$_2$Te$_6$ and graphene, we observe an out-of-plane proximity-induced ferromagnetic exchange interaction in graphene$^1$. The perpendicular magnetic anisotropy of Cr$_2$Ge$_2$Te$_6$ results in significant modification of the spin transport and precession in graphene, which can be ascribed to the proximity-induced exchange interaction. Furthermore, the observation of a larger lifetime for perpendicular spins in comparison to the in-plane counterpart suggests the creation of a proximity-induced anisotropic spin texture in graphene. Our experimental results and density functional theory calculations open up opportunities for the realization of proximity-induced magnetic interactions and spin filters in 2D material heterostructures and can form the basic building blocks for future spintronic and topological quantum devices.

12:15PM M41.00006: Novel Exciton Condensation and Lorenz Number in Graphene  SANG-BOO NAM (Presenter), Retired — We present a novel condensation of boson (exciton = electron + hole) in 2 dimension at the temperature $T_c = (6/\pi^2)^{1/2} T_F$ (fermi temperature). At $T_c$, the condensed bosons are to become fermions, electrons to holes, and vice versa. We found the Lorenz number peak value (LNPV) in the case of the elastic scatterings, \[ \frac{L(b)}{L(0)} - 1 = \frac{2bg}{3}, \] \[ L(0) = \frac{(9/4) \zeta(3)}{\ln 2} = 3.895 = 1.183 \left(\frac{\pi^2}{3}\right) \] in the unit of $(k_B/e)^2$, where $b = \text{boson/fermion} = \frac{2gp}{n}$, $g$ and $n$ are the fermion degeneracy and density, respectively, $p$ the optimum density for the condensation, with the temperature full width (the intrinsic nature) for the half LNPV, $Tw = 2(1 - w) T_c$, $w = \left[\frac{1 + b}{2 + b}\right]^{1/2}$. Calculated LNPV and $Tw$ for $g = 4$, account very well, without any parameter, for the data in graphene by Crossno et al, Science 351, 1058 (2016). We found the optimum $2bg/3 = 64/3$, $p = 4 \times 10^9 /\text{cm}^2$, $v_F = 1.03 \times 10^8 \text{ cm/s}$, $T_c = 45 \text{ K}$, and $Tw = 4.5 \text{ K}$ for graphene. We predict the Hall resistance (Rh) peak value and the plasmon frequency square (Ws) dip value, \[ \frac{Rh(b)}{Rh(0)} - 1 = b = \frac{W_s(0)}{W_s(b)} - 1 , \] respectively, with the same $Tw$ as before.

12:27PM M41.00007: Giant spin-layer locking in novel two-dimensional $X_2Bi_2$ (X=Si, Ge, or Sn)  SEUNGJUN LEE (Presenter), YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee Univ - Seoul — In contrast to the general view in spin-orbit interaction, it was reported that even in materials with centro-symmetry may have Rashba spin-orbit coupling (the R-2 effect) resulting in spatial spin splitting. However, not only its underlying fundamental physics been still unclear, but the search for materials emerging the R-2 interaction has also been very limited. Here, we propose novel two-dimensional materials $X_2Bi_2$ (X=Si, Ge, or Sn), which exhibit spin-layer locking with giant Rashba parameter value ($\alpha_R \leq 12.3 \text{ eV nm}$). Our first principles calculations show the top and bottom atomic sublayers in $X_2Bi_2$ produce opposite out-of-plane dipole moments leading to the spin-layer locking phenomenon for in-plane spin moment. We also find that the local orbital angular momentum (OAM) plays a crucial role in determining the R-2 spin splitting. We further suggest possible manipulation strategies for securing the R-2 spin splitting: 1) Strain reinforces the R-2 effect via changing OAM distribution, and 2) layer stacking ensures further spatial spin splitting.
**12:39PM M41.00008: Edgetronic and spintronic applications of carbon phosphide nanoribbon**

LIEMAO CAO (Presenter), YEE SIN ANG, QINGYUN WU, LAY KEE ANG, Singapore University of Technology and Design — Carbon phosphide (CP) monolayer, a hybrid of graphene and phosphorene that simultaneously preserves their high electrical mobility, finite band gap and air stability, has been successfully synthesized in recent experiment. In this work, we study the electronic and transport properties of CP nanoribbons in α-phase with different edge configurations using first-principle density functional theory simulation. We found that Zα-CPNRs can mimic the behaviors of graphene and phosphorene nanoribbon depending on the edge configurations Intriguingly, when the external electric field exceeds a critical value, the charge transport channel becomes strongly localized to only one edge, and the edge localization can be tuned by an external electric field, thus opening up a new device concept of edgetronics. Our findings reveal the potential of CP nanoribbon as a spintronic materials that fuses the strengths of both graphene and phosphorene.

**12:51PM M41.00009: Rashba spin splitting and perpendicular magnetic anisotropy of Gd-adsorbed zigzag graphene nanoribbon modulated by edge states under external electric fields**

ZHENZHEN QIN (Presenter), Zhengzhou Univ, GUANGZHAO QIN, University of South Carolina, BIN SHAO, XU ZUO, Nankai University — The one-dimensional (1D) Rashba effect has become much important due to its key role in basic science to realize exotic electronic phenomena, such as Majorana bound states. Similar to the 2D or 3D systems, the modulation of Rashba effect in 1D matrix is the kernel of spintronics for manipulating electron spin. Herein, by investigating the effects of transverse and vertical external electric field (EEF) on the Rashba spin splitting and magnetic anisotropy energy (MAE) of Gd-adsorbed zigzag graphene nanoribbons from first principles, we found that the Rashba spin splitting in such 1D system can be effectively regulated by the transverse EEF. Moreover, perpendicular magnetic anisotropy holds with either transverse or vertical EEF applied, despite obvious modulation of the MAE contributions in k-space as well as the Rashba spin splitting. It is found the modulation of Gd-5dx^2-y^2, dxy by C-p_z orbitals of edge states is the key to manipulating the magnetic anisotropy, which even plays a decisive role on modifying the Rashba spin splitting in such 1D nanoribbon system. Our study introduces a new strategy to manipulate Rashba spin splitting by edge states and provides new insight into the magnetic anisotropy in 1D Rashba system.
1:03PM M41.00010: Observation of Giant Optical Linear Dichroism and Pseudo Critical Slowing Down in van der Waals Zigzag Antiferromagnets  KYLE HWANGBO (Presenter), QI ZHANG, QIANNI JIANG, University of Washington, DI XIAO, Carnegie Mellon University, JIUN-HAW CHU, XIAODONG XU, University of Washington — Two-dimensional antiferromagnetism (AFM) has been a topic of great interest due to its intertwined relationship with various correlated phenomena like unconventional superconductivity and its potential applicability in novel spintronic devices. In contrast to its ferromagnetic counterpart, direct optical probing and study of AFM order is challenging due to the absence of net magnetization and the resulting weak magneto-optical coupling. Here, we report an optical study of an atomically thin zigzag antiferromagnet, FePS$_3$. We observed a large optical linear dichroism associated with the zigzag AFM order. By performing time-resolved polarimetry measurements, we further examined the critical fluctuations of the AFM order parameter, which exhibit a prominent pseudo-critical slowing down behavior near the Néel temperature. Our findings point to a new optical approach to identify zigzag AFM order and study its non-equilibrium dynamics in strongly correlated systems.

1:15PM M41.00011: Ferromagnetism in multilayered graphite nanostructures doped with nitrogen*  ARAM MANUKYAN, CAL State University, Los Angeles, HARUTYUN GYULASARYAN, Physics, Russian-Armenian (Slavonic) University, Yerevan, Armenia, EDUARD SHAROYAN, Laboratory of Solid State Physics, Armenia, Institute for Physical Research, NAS of Armenia, PAUL OYALA, Division of Chemistry and Chemical Engineering,, California Institute of Technology, Pasadena, OSCAR BERNAL, ARMEN KOCHARIAN (Presenter), CAL State University, Los Angeles — Carbon microspheres consisting of multilayered nanographite structures are prepared using solid-phase pyrolysis of metal-free phthalocyanine H$_2$(C$_{32}$N$_8$H$_{16}$). The mean diameter $d=3\pm0.2\mu$m of carbon microspheres have been obtained at pyrolysis $T_{\text{pyr}}=670^\circ\text{C}$, and $t_{\text{pyr}}=30\text{min}$. Morphology and structure of prepared samples at two temperatures $T_{\text{pyr}}$ were investigated by HRTEM, X-ray diffractometry, Raman and XPS spectroscopy. Magnetic properties of samples were investigated using vibrational magnetometer and magnetic fields up to 80 kOe, as well as X-band ESR spectrometer in range of temperature, $T=5$-300K. We found that the temperature dependences of saturation magnetization closely follow the behavior of integrated magnetic resonance intensity. Parameters of ESR spectrum are following g-factor 2.0031, intensity $\sim5\times10^{19}$ spin/g and narrow linewidth of 0.8Oe due to strong exchange. Maximum values of saturation magnetization $M_s\approx0.03\text{emu/g}$ and coercive force $H_c=400\text{Oe}$ have been obtained at 25K. The results suggest that observed ferromagnetism in multilayer graphene can be attributed to nitrogen atoms and zigzag edges.

Modulating electronic and magnetic properties of ferromagnetic Hf2MnC2O2 MXenes*  
EDIRISURIYA SIRIWARDANE (Presenter), Univ of North Dakota, PRAGALV KARKI, University of Oregon, YEN LEE LOH, DENIZ CAKIR, Univ of North Dakota — In this work, density functional theory calculations were carried out to evaluate the electronic and magnetic properties of the uniaxial and biaxial strains applied, and surface defects introduced Hf2MnC2O2 ferromagnetic MXene. The bare Hf2MnC2O2 monolayer is an indirect bandgap semiconductor with a 0.282 eV bandgap. Our calculations show that the semiconductor-to-half-metal phase transition occurs at 7%, and 9% under uniaxial tensile strain in zig-zag and armchair directions, respectively. The same phase transition can be seen at 8% biaxial tensile strain. This ferromagnetic semiconductor can become a metal under small uniaxial and biaxial compressive strains. We are also able to show that the bare Hf2MnC2O2 monolayer contains an easy-plane anisotropy. The anisotropy of the monolayer transforms into an enhanced, easy-axis anisotropy when the O vacancies and the H adatoms are introduced.

1:39PM M41.00013: Raman signatures on a van der Waals antiferromagnet  
YUJIN CHO (Presenter), University of California, Los Angeles, SUBHAJIT GHOSH, University of California, Riverside, ZHANGJI ZHAO, CHAOWEI HU, JIN HO KANG, University of California, Los Angeles, FARIBORZ KARGAR, University of California, Riverside, NI NI, University of California, Los Angeles, ALEXANDER BALANDIN, University of California, Riverside, CHEE WEI WONG, University of California, Los Angeles — Mixing other exotic properties, such as magnetism or superconductivity, into a topological material has been drawing a lot of researchers’ attention due to its potential as quantum computation and realizing topological phenomena. MnBi2Te4 has been demonstrated to be the first intrinsic antiferromagnetic (AFM) topological insulator (TI) [1]. It consists of Bi2Te3 and Mn-Te bilayer. So far, most studies focused on magnetic properties or electronic structure of the bulk material via magnetic susceptibility, angle-resolved photo-emission spectroscopy, and magnetotransport [2]. When the material comes down to 2D limits, optical Raman spectroscopy becomes advantageous due to its sensitivity and strong layer-dependent characteristic in 2D materials. Raman peaks can also reflect spin interactions that are related to magnetic ordering [3], as well as in-plane magnetic anisotropy. In this project, we will correlate the optical Raman spectrum on MnBi2Te4 with its magnetic transition temperature (~25K) and the in-plane magnetic anisotropy.

Detection of Spin Canting Using Magnetic Field Modulated Microwave Spectroscopy.  

ALEX HOJEM (Presenter), JAMES WAMPLER, IVAN K. SCHULLER, Physics, University of California, San Diego — Magnetic field modulated microwave spectroscopy (MFMMS) is the most sensitive technique for detecting superconducting transitions[1]. While superconducting transitions exhibit a reproducible peak behavior, magnetic transitions can have a range of responses including: slopes, steps and local minima in the temperature dependent MFMMS measurements. Other work has shown that a magnetic response in a similar microwave spectroscopy technique can be caused by spin canting[2]. One system of materials that provides an interesting test case for this is the Ruthenocuprates[3]. These compounds have a ferromagnetic response due to spin canting, above the onset of superconductivity. Here, we show that the temperature and field dependence of spin canting of the Ru-1212 system (RuSr$_2$GdCu$_2$O$_8$) can be determined by comparing the MFMMS to magnetometry and resistance measurements.

Session M42 GMAG: Spin Transport and Magnetization Dynamics in Ferrimagnets and Antiferromagnets 709/711 - Himanshu Fulara - Tag(s): Focus
11:15AM M42.00001: Decoherence of transverse spin currents in ferrimagnetic CoGd*  
YOUNGMIN LIM (Presenter), BEHROUZ KHODADADI, Physics, Virginia Tech, JIE-FANG LI, DWIGHT D VIEHLAND, Materials Science and Engineering, Virginia Tech, SATORU EMORI, Physics, Virginia Tech — It has been predicted that the coherence length $\lambda_c$ of transverse spin current in antiferromagnetic and ferrimagnetic metals can be much longer than $\lambda_c \approx 1$ nm in ferromagnets. A recent experiment reports $\lambda_c > 10$ nm in ferrimagnetic CoTb alloys [1], although this is rather surprising given the strong spin-orbit coupling in CoTb. Here, we determine $\lambda_c$ in ferrimagnetic Co$_{1-x}$Gd$_x$ alloys with much weaker spin-orbit coupling than CoTb. We perform spin pumping measurements on NiFe/Cu/CoGd trilayers, where a coherent spin current pumped from NiFe decoheres in the CoGd spin sink. The spin sink thickness dependence of Gilbert damping enhancement of the NiFe layer allows us to quantify $\lambda_c$. We demonstrate a maximum of $\lambda_c \approx 4$ nm for the composition of CoGd close to magnetic compensation, indicating partial enhancement of spin coherence due to compensated antiferromagnetic order. We also observe a monotonically decreasing effective spin-mixing conductance with increasing Gd content, suggesting the dominance of Co 3d bands in spin current transport across the interface of the ferrimagnet.

11:27AM M42.00002: Thermal Hall effect, spin Nernst effect, and spin density induced by thermal gradient in collinear ferrimagnets from magnon-phonon interaction*  
SUNGJOON PARK (Presenter), Department of Physics and Astronomy, Seoul National University, NAOTO NAGAOSA, Department of Applied Physics, The University of Tokyo, BOHM-JUNG YANG, Department of Physics and Astronomy, Seoul National University — We study the thermal Hall and spin Nernst effect in collinear ferrimagnets on a honeycomb lattice with broken inversion symmetry between the nearest neighbors. The broken inversion symmetry allows nearest-neighbor inplane Dzyaloshinskii-Moriya interaction, which has no effect in the linear spin wave theory. However, it induces large Berry curvature in the magnetoelastic excitation spectrum through the magnon-phonon interaction (MPI) to produce spin-polarized thermal Hall current, so that both spin Nernst and thermal Hall currents are produced. Because the MPI does not conserve the spin, we also compute the boundary spin accumulation. Surprisingly, we do not find any asymmetric boundary spin accumulation, which we attribute to spin nonconservation. However, the MPI induces non-vanishing total spin expectation value in the system with armchair edges.

11:39AM M42.00003: Electric-Field Control of Strain-Driven Tuning of FMR in the Low-Loss Ferrimagnetic Coordination Compound V[TCNE]_x

SETH KURFMAN (Presenter), ANDREW FRANSON, Ohio State Univ - Columbus, PIYUSH SHAH, GOPALAN SRINIVASAN, MICHAEL PAGE, Materials and Manufacturing Directorate, Air Force National Laboratory, EZEKIEL JOHNSTON-HALPERIN, Ohio State Univ - Columbus — Electric-field control of magnetic resonance has application potential in the design of low-power, compact, high-frequency magnetoelectronic devices, such as microwave filters and circulators. To date, this work has exploited low-loss ferrite materials mechanically coupled to piezoelectric substrates. However, traditional ferrites typically require lattice-matched substrates and extreme growth conditions to produce high-quality material, making on-chip integration while maintaining low damping a significant challenge. Here, we demonstrate electric-field control of the FMR properties of the low-loss ($\alpha = (3.98 \pm 0.22) \times 10^{-5}$), organic-based, room-temperature ferrimagnet vanadium tetracyanoethylene ($\text{V[TCNE]}_{x \approx 2}$) in $\text{V[TCNE]}_x$/piezoelectric composite heterostructures. These structures show shifts in the resonant frequency position by $\sim 50$ MHz, or more than six times the resonant linewidth. These results demonstrate the potential of $\text{V[TCNE]}_x$ to complement traditional ferrites in electrically-controlled magnetoelectronic devices. For example, since $\text{V[TCNE]}_x$ can be deposited on a variety of inorganic substrates, it has the potential to be directly integrated into magnetoelectric devices without the need for flip-chip fabrication techniques.

11:51AM M42.00004: Non-local spin transport measurement in TbIG thin films grown by pulsed laser deposition

WEI YUAN (Presenter), JUNXUE LI, VICTOR ORTIZ, YAWEN LIU, JING SHI, University of California, Riverside — Ferrimagnetic insulators (FMIs) attract a lot of attention in spintronics recently. As a medium, FMIs support pure spin current carried by magnon transport over a relatively long distance. In this work, we use nonlocal method to probe spin transport in terbium iron garnet (Tb$_3$Fe$_5$O$_{12}$ or TbIG). We obtain high-quality epitaxial TbIG thin films on the substrates of GGG(111) using a PLD system. After 750 degree Celsius post-growth rapid thermal annealing, clear RHEED patterns demonstrate the single crystal quality of TbIG films, which is further confirmed by X-ray diffraction and atomic force microscopy results. The non-local signal has a sign reversal at 270 K, which corresponds to the compensation temperature of TbIG. Below the compensation temperature, the non-local signal stays approximately constant until a dramatic increase sets in at 50 K, which persists to the lowest temperature of 2 K. We attribute this rapid increase to the spin current transport associated with paramagnetic Tb-spins. We also discuss the temperature dependence of the nonlocal signal in garnets with and without rare-earth moments.

**12:03PM M42.00005: Anomalous spin Hall angle of a metallic ferromagnet determined by a multiterminal spin injection/detection device**

TOBIAS WIMMER (Presenter), Bayerische Akademie der Wissenschaften, Walther-Meißner-Institut, BIRTE COESTER, Spintronics Device Research Group, Nanyang Technological University, STEPHAN GEPRÄGS, RUDOLF O GROSS, Bayerische Akademie der Wissenschaften, Walther-Meißner-Institut, SEBASTIAN T. B. GOENNENWEIN, Technische Universität Dresden, HANS HUEBL, MATTHIAS K ALTHAMMER, Bayerische Akademie der Wissenschaften, Walther-Meißner-Institut — We report on the determination of the anomalous spin Hall angle in the ferromagnetic metal alloy cobalt-iron (Co$_{25}$Fe$_{75}$, CoFe). This is accomplished by measuring the spin injection/detection efficiency in a multiterminal device with nanowires of platinum (Pt) and CoFe deposited onto the magnetic insulator yttrium iron garnet (Y$_3$Fe$_5$O$_{12}$, YIG). Applying a spin-resistor model to our multiterminal spin transport data, we determine the magnon conductivity in YIG, the spin conductance at the YIG/CoFe interface and finally the anomalous spin Hall angle of CoFe as a function of its spin diffusion length in a single device. Our experiments clearly reveal a negative anomalous spin Hall angle of the ferromagnetic metal CoFe, but a vanishing ordinary spin Hall angle. This work therefore adds new observations to the results reported in Refs. [1,2], where the authors found finite contributions of the ordinary spin Hall angle in the ferromagnetic metals Co and permalloy.

*This work is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany’s Excellence Strategy -- EXC-2111 -- 390814868 and project AL2110/2-1.*
12:15PM M42.00006: Investigation of nonequilibrium processes of magnetoelastic waves and evidence of their BEC formation in an antiferromagnetic system* VLADIMIR L SAFONOV, DEREK BAS, Air Force Research Laboratory, YURI V ROSTOVTSEV, JAMES A ROBERTS, Department of Physics, University of North Texas, DIANA BERMAN, Department of Materials Science and Engineering, University of North Texas, MICHAEL E MCCONNEY, MICHAEL PAGE (Presenter), Air Force Research Laboratory — The canted antiferromagnet FeBO$_3$ exhibits strong nonlinear interactions between magnetoelastic waves that can manifest as a variety of interesting phenomena. We show that excited magnetoelastic waves and their quanta, which we refer to as mexons, exhibit a wide range of nonequilibrium nonlinear wave phenomena including mode competition under noisy pumping, full submission to external coherent fields, and evidence of quasi-equilibrium Bose-Einstein condensation (BEC) at room temperature. The mode we suggest as the mexon BEC exhibits extremely high efficiency with a quality factor of $Q \sim 8 \times 10^5$. Remarkably, this behavior occurs in a system that is very near its transition temperature due to the heat generated by microwave pumping. Our results suggest that such systems can be of technological importance due to the uniqueness of the mode quality and ability to modulate external signals, as well as from the standpoint of studying a whole class of nonlinear wave phenomena usually taking place in a wide range of environments and conditions.

*The work was partially supported by the Air Force Office of Scientific Research (AFOSR) Award No. FA9550-15RXCOR198.

12:27PM M42.00007: Elimination of two-magnon scattering for evaluation of intrinsic spin decay length in antiferromagnetic insulator* HIROTO SAKIMURA (Presenter), TAKASHI HARUMOTO, YOSHIO NAKAMURA, JI SHI, School of Materials and Chemical Technology, Tokyo Institute of Technology, KAZUYA ANDO, Applied Physics and Physico-Informatics, Keio University — We present an experimental evaluation of the intrinsic spin decay length in an antiferromagnetic insulator (AFI). A frequently-used sample configuration to study the spin-current propagation in AFIs is a ferromagnet/AFI/heavy-metal trilayer structures, where the ferromagnet and heavy-metal act as spin-current injectors and detectors, respectively. We found that at the ferromagnet/AFI interface, a spin current generated by spin pumping is strongly suppressed by two-magnon scattering enhanced by position-dependent fluctuation of microscopic exchange bias, which is inevitable at ferromagnet/antiferromagnet junctions. By eliminating the two-magnon contribution from the spin transmission signal, we discovered that the characteristic length of spin decay in polycrystalline NiO, a prototypical AFI, was around 100 nm, which is an order of magnitude longer than what was previously believed. Our results provide a new perspective in the emerging field of antiferromagnetic spintronics, especially for the fundamental understanding of spin transport physics in insulators.

*JSPS Grant-in-Aid for Research Fellowship for Young Scientists (DC1) No. JP17J03624
12:39PM M42.00008: Nuclear spin Seebeck effect in antiferromagnets  DEREK REITZ
(Presenter), YAROSLAV TSERKOVNYAK, University of California, Los Angeles — The spin Seebeck effect (SSE) involves transfer of spin angular momentum between a magnet and a metal from internal thermal fluctuations. SSE is usually dominated by electronic, rather than nuclear, spins, since interfacial exchange is much stronger than interfacial hyperfine coupling. At low temperatures, however, electronic magnon thermal occupation numbers are exponentially suppressed, while nuclear spins remain active. The nuclear spins are paramagnetic, weakly polarized in the large hyperfine field of the Neel order. One source for nuclear SSE is interfacial nuclear, metal spin flip-flops, known as Korringa relaxation. Nuclear SSE is then determined by competing rates: thermalization with phonons via hyperfine coupling to electrons in the magnet, and Korringa relaxation into the metal.

12:51PM M42.00009: Topological Hall effect in canted antiferromagnets  JOTARO NAKANE
(Presenter), Physics, Nagoya University, KAZUKI NAKAZAWA, Earth and Space Science, Osaka University, HIROSHI KOHNO, Physics, Nagoya University — The topological Hall effect (THE) is a Hall effect caused by a noncoplanar spin texture, or its spin chirality, in ferromagnetic conductors. This effect is absent in antiferromagnets (AF) due to the cancellation of the two sublattice chiralities. However, if the AF spins are canted, the overall spin chirality, hence the THE, can be finite.

Motivated by a recent experiment [1], we study the THE in a canted AF with textured Neel and uniform moments. Treating the two textures by a spin gauge field, we derive an analytical expression for the topological Hall conductivity (THC). The emergent magnetic field is written as $\nabla \times A$, where A is an emergent vector potential in canted AF. With the obtained THC, we discuss various regimes such as the strong and weak coupling regimes, and large and small canting regimes. In particular, in the strong-coupling large-canting limit, the THC is given by the Berry phase formula ("Bruno formula") multiplied by a reduction factor because of the presence of the Neel moment.

Magnetization dynamics and spin transport in compensated ferrimagnets [invited]  KYUNG-JIN LEE (Presenter), Korea Univ — Spintronics is a multidisciplinary field whose central theme is the active manipulation of electron spins in solid-state systems. The core magnetic system for spintronics research has been ferromagnets since they serve as spin-polarizers/detectors and offer non-volatile memory and logic technologies. Recently, much effort has been expended in employing antiferromagnetic coupled systems as core elements because of their fast dynamics and efficient spin-torque generation. We will discuss the underlying mechanism of fast dynamics of compensated and uncompensated staggered spin moments, driven by magnetic fields or spin torques [1-3]. We will also discuss the increased efficiency of spin torques due the weakened spin dephasing in compensated ferrimagnets [4,5].

Thermal spin-Edelstein effect in an antiferromagnetic insulator/normal metal heterostructure*  HANTAO ZHANG (Presenter), RAN CHENG, University of California, Riverside — In an antiferromagnetic insulator with biaxial anisotropy and the Dzyaloshinskii-Moriya interaction (DMI), symmetry ensures a spin-momentum locking similar to that of gapped Rashba electrons. A temperature gradient can generate an interfacial magnon accumulation with a preferred spin polarization, realizing the magnonic counterpart of the spin Edelstein effect. This thermally-driven magnonic spin accumulation can be injected into an adjacent heavy metal and converted into a measurable voltage, which depends monotonically on both temperature and DMI but non-monotonically on the surface-induced magnetic anisotropy. It is found that the overall response coefficient has to be solved under a nontrivial boundary condition regarding spin transmission across the interface.

Strain-Tunable Magnetic Anisotropy in Sputtered Thulium Iron Garnet (TIG) Thin Films and TIG/Au/TIG Trilayers*

GILVANIA DA SILVA VILELA (Presenter), Plasma Science and Fusion Center, and Francis Bitter Magnet Laboratory, MIT and Universidade de Pernambuco, HANG CHI, Plasma Science and Fusion Center, and Francis Bitter Magnet Laboratory, and U.S. Army CCDC, MIT and Army Research Laboratory, GREGORY STEPHEN, Department of Physics, Northeastern University, CHARLES SETTENS, Materials Research Laboratory, MIT, PRESTON ZHOU, Department of Electrical Engineering, California Institute of Technology, YUNBO OU, DHAVALA SURI, Plasma Science and Fusion Center, and Francis Bitter Magnet Laboratory, MIT, DON HEIMAN, Department of Physics, Northeastern University, JAGADEESH MOODERA, Plasma Science and Fusion Center, and Francis Bitter Magnet Laboratory, and Department of Physics, MIT — Ferromagnetic insulator thin films have been explored for developing spintronic devices. When combined with quantum materials, the strongly correlated interaction from the proximitized interface results in intense local magnetic fields which modulates them to displaying new interface physical phenomena. We investigate ways to tune the magnetic anisotropy in TIG films by selecting their thickness, substrate, and annealing conditions. When deposited over (111) GGG, they present a negative magnetostriction constant which favors a perpendicular magnetic anisotropy (PMA). While PMA allows high magnetic storage density in hard disk drives, it is required for breaking the time-reversal symmetry in topological insulators (TIs) to aim towards quantized anomalous Hall state in TIs. Controlling the film preparation parameters we observed that TIG films under compressive strain display an in-plane magnetic anisotropy, whereas films under tensile strain demonstrated PMA. These results led to the successful fabrication of TIG/Au/TIG magnon valve structures with independent magnetic switching of each TIG layer.

Quantum Dynamics of Matrix Product States on Transformed bases*

AMIR MOHAMMADAGHAEI (Presenter), KIRILL SHTENGEL, University of California, Riverside — Numerical simulation of the quantum states under the unitary evolution with generic non-integrable Hamiltonians still remains a challenge. The exact diagonalization (ED) method only works for very small system sizes and methods based on matrix product states (MPS), such as time dependent variational principle (TDVP) fail to capture long time behavior of the systems, such as the diffusion constant, with controlled precision. The main culprit is believed to be the rapid entanglement growth to volume-law in real space cuts. The entanglement blow-up makes the long-times inaccessible for variational ansatz that are designed to represent states with area-law entanglement entropy. In this work, we explore a MPS time evolution but on a set of transformed bases that are local both in real and fourier space. We benchmark this method on the anti-ferromagnetic Heisenberg chain with longer range exchange terms to bring the system out of integrability. We demonstrate the possibility of achieving longer time simulations by comparing the results to exact ED as well as TDVP on real space.

*BSF grant 2016255
11:15AM M43.00001: Computationally driven discovery of new borides in the ternary Li-Ni-B system* [Invited] JULIA ZAIKINA (Presenter), Department of Chemistry, Iowa State University — The crystal structure prediction of multinary inorganic materials is a challenging task given the diversity of potential structures. Experimental validation of the computational predictions is a vital step for accelerated materials discovery, however solid state chemistry synthetic routes lack the predictability of the synthesis outcome. Yet, theoretical predictions of structure and thermodynamic stability of the new ternary phases can yield the desired roadmap for the targeted synthesis. On the other hand, efficient synthesis allows for the fast screening of compositional space, providing timely feedback for the iterative improvement of theoretical predictions. 

Here we report on two novel lithium nickel boride polymorphs RT-LiNiB and HT-LiNiB with layered crystal structures.¹ This family of compounds was theoretically predicted by using the adaptive genetic algorithm (AGA)² and subsequently synthesized by a hydride route with LiH as the lithium source. Unique among the known ternary transition-metal borides, the LiNiB structures feature Li layers alternating with almost planar [NiB] layers. A comprehensive study using a combination of single-crystal/synchrotron powder X-ray diffraction, solid-state NMR spectroscopy, scanning transmission electron microscopy, quantum-chemical calculations, and magnetism revealed on the intrinsic features of these polymorphic compounds. The unique layered structures of LiNiB compounds make them ultimate precursors for preparation of two-dimensional transition-metal borides, MBenes.

*Financial support from the Iowa State University is gratefully acknowledged.
11:51AM M43.00002: Corrosion-resistant magnesium alloy design based on the first-principles calculation  
YAOWEI WANG (Presenter), TIAN XIE, ZHE LUO, HONG ZHU, XIAOQIN ZENG, Shanghai Jiao Tong Univ — Second phase strengthening has been widely used in alloys designs, many of which however have been reported to enhance the galvanic corrosion of magnesium alloys. In this study, a semi-empirical model was proposed based on the first principles calculation to analyze the galvanic corrosion behaviour. Our model is validated in the case of Mg-Ge alloys, which is composed of anode Mg matrix and cathode Mg$_2$Ge second phase. First principles calculations on the hydrogen evolution reaction upon Mg$_2$Ge reveal that the rate-determining step is the hydrogen adsorption, which is extremely energetically unfavored but an inevitable intermediate state. The estimated exchange current of the hydrogen evolution upon Mg$_2$Ge is about 3 orders of magnitude smaller than that on pure Mg, indicating the depressed galvanic corrosion of the Mg-Ge alloys is the result of the low hydrogen exchange current upon Mg$_2$Ge. Moreover, some typical intermetallics, such as MgZn$_2$ and MgSc, were selected to compare the corrosion properties of different Mg alloys, which is in close agreement with the experimental observations. Our model provides a promising perspective for designing better corrosion-resistant magnesium alloys.

12:03PM M43.00003: Automation of the first-principles calculation to search functional materials in high entropy alloys*  
HIORI KINO (Presenter), Natl Inst for Materials Sci, TETSUYA FUKUSHIMA, ISSP, University of Tokyo, TOYOHIRO CHIYO, Natl Inst for Materials Sci — The high entropy alloys attract much attention originally because of strength/hardness. They are potentially also useful as functional materials, such as high Curie temperature and high magnetic moment, and large spin-orbit coupling. However, the difficulty of the research of the high entropy alloys is that there exist too huge number of possibilities for humans to handle. Therefore, it is wise and inevitable to screen materials that have high functionality in the first-principles before executing experiments. We will introduce a newly developed scientific workflow to converge the electric structure self-consistently and to estimate physical properties of random alloys automatically in the first-principles calculation, KKR-CPA. We will also introduce some of the first-principles results, and explain key features for high Curie temperatures and high magnetic moment.

*This work is partially supported by MI^2I.
YING SUN (Presenter), JIAN LV, YU XIE, HANYU LIU, YANMING MA, State Key Laboratory for Superhard Materials, College of Physics, Jilin University — The recent theory-orientated discovery of record high-temperature superconductivity ($T_c \sim 250$ K) in sodalitelike clathrate LaH$_{10}$ [1-4] is an important advance toward room-temperature superconductors. Here, we identify an alternative clathrate structure in ternary Li$_2$MgH$_{16}$ with a remarkably high estimated $T_c$ of $\sim 473$ K at 250 GPa, which may allow us to obtain room-temperature or even higher-temperature superconductivity. The ternary compound mimics a Li- or electron-doped binary hydride of MgH$_{16}$. The parent hydride contains H$_2$ molecules and is not a good superconductor. The extra electrons introduced break up the H$_2$ molecules, increasing the amount of atomic hydrogen compared with the parent hydride, which is necessary for stabilizing the clathrate structure or other high-$T_c$ structures. Our results provide a viable strategy for tuning the superconductivity of hydrogen-rich hydrides by donating electrons to hydrides via metal doping. Our approach may pave the way for finding high-$T_c$ superconductors in a variety of ternary or quaternary hydrides.

CHANG-JONG KANG (Presenter), GABRIEL KOTLIAR, Rutgers University, New Brunswick — We apply material design methodology and find a new indium iodine compound, CsInI$_3$, which is thermodynamically stable but is not reported in Inorganic Crystal Structure Database (ICSD) yet. By using the ab initio evolutionary algorithm, we find several meta-stable structures of CsInI$_3$ and investigate their physical properties. The ideal cubic perovskite structure, which is one of the meta-stable phases, shows the structural instability of the iodine breathing mode at zero temperature. However, the cubic perovskite is eventually stabilized at finite temperature due to the contribution of the phonon entropy. The cubic perovskite shows band inversion above the Fermi level, indicating that it is a topological material. Other meta-stable structures are derived from the cubic perovskite and have two different sizes of indium octahedrons, thereby presenting bond and charge disproportionation. The new compound of CsInI$_3$ presents diverse physics including bond and charge disproportionation, topological nature, and a possible application for photovoltaics, thereby providing an ideal playground for these research fields.
A MoON Race: Computational Design of a Heteroanionic Metal-Insulator Transition Compound Molybdenum Oxynitride.* LAUREN WALTERS (Presenter), NATHAN J SZYMANSKI, DANilo PUGGIONI, JAMES RONDINELLI, Northwestern University — Using symmetry principles and electronic structure calculations we designed a novel metal-insulator transition (MIT) compound MoON. The alpha and beta phase of this material were identified from a set of prototype AB\textsubscript{2} structures based upon energetics, band gap, and the c/a ratio. We show that the \textit{fac} ordering of the polyhedra are important for charge localization, singlet formation, and opening of the band gap. Our density functional calculations show how changes in the electronic band gap are driven by structural distortions, including 1D chain canting and dimer formation. Last we draw parallels between MoON and the well-studied VO\textsubscript{2}, demonstrating that properties such as the c/a lattice parameter ratio could be used for further design and identification of other rutile MIT materials.

From materials discovery to solar cells: LaYS\textsubscript{3} as a product of the computation/experiment loop ANDREA CROVETTO (Presenter), RASMUS NIELSEN, MOHNISH PANDEY, KARSTEN WEDEL-JACOBSEN, OLE HANSEN, BRIAN SEGER, IB CHORKENDORFF, PETER VESBORG, DTU Physics, Technical University of Denmark — One of the current key challenges in solar photovoltaics and solar-driven water splitting is to identify an efficient, stable, and inexpensive material to be used as a high-band gap (1.6-2.0 eV) absorber in tandem devices. With this purpose in mind, we have computationally screened 705 sulfide perovskites (ABS\textsubscript{3}). Only 15 compounds pass all the screening rounds, which include criteria such as phase stability, suitable band gap, low effective mass, and defect tolerance. The list of 15 compounds includes a number of materials that have not yet been reported experimentally. We have therefore attempted to synthesize some of those novel ABS\textsubscript{3} compounds. Among them, LaYS\textsubscript{3} was experimentally confirmed as a stable and especially attractive high-band gap photoabsorber [1], and it was possible to fabricate some prototype LaYS\textsubscript{3} solar cells [2].

In this contribution, we will use our work on LaYS\textsubscript{3} to reflect upon challenges and opportunities in the much-cherished computation/experiment loop for the discovery new materials. In particular, we will discuss the gaps between measured and calculated properties, and the feedback received from the computational and experimental teams.

Ab initio prediction of Metal Organic Frameworks* JAMES DARBY

(Presenter), Department of Physics, University of Cambridge, MIHAELS ARHANGELSKIS, Faculty of Chemistry, University of Warsaw, ATHANASSIOS KATSENIS, JOSEPH MARRETT, TOMISLAV FRIŠČIĆ, Department of Chemistry, McGill University, ANDREW J MORRIS, Univ of Birmingham — First-principles crystal structure prediction is a well established technique which is routinely used across a diverse range of systems such as periodic solids, interfaces, and encapsulated nanowires. Here we present the first example of ab initio prediction of a Metal-Organic Framework (MOF).

We use the Ab Inito Random Structure Searching\(^1\) method and introduce a new approach for generating trial crystal structures from molecular fragments\(^2\). Our method makes use of molecular symmetries to directly generate structures with molecules on special Wyckoff sites. To test our approach we searched for a selection of Zinc based MOFs with differing ligands and metal coordination. These results are presented alongside a more detailed discussion of the method and its application beyond MOFs.

Predicting the phase stability of high entropy oxides

*KRISHNA CHAITANYA PITUKE (Presenter), Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN, CRAIG A. BRIDGES, Chemical Sciences Division, Oak Ridge National Lab, Oak Ridge, TN, JIANG BO, Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN, KATHARINE L. PAGE, Neutron Scattering Division & Materials Science and Engineering Department, Oak Ridge National Laboratory, Oak Ridge, TN & University of Tennessee, Knoxville, TN, VALENTINO COOPER, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN — High entropy, multicomponent systems are interesting due to the role that cation disorder may play in defining their mechanical, magnetic, reversible energy storage properties, etc. Within the class of high entropy oxides; rocksalt, fluorite, spinel and perovskite phases have all been recently synthesized. Complementing these endeavors, the current work explores a method for calculating the stability of high entropy oxides – compounds in which one cation-site is randomly and equally occupied by five chemical species – through a collaborative computational and experimental efforts. We construct a nearest neighbor (NN) model from enthalpies of mixing of end member oxides and binary oxide mixtures – in their respective potential stable phases – estimated through DFT calculations. The candidates for the high entropy oxides are predicted from the configurational landscapes of the five component oxides, estimated through Monte Carlo simulations using the NN model. Our approach allows us to evaluate potential impurity phases thereby making realistic predictions of novel multicomponent oxides that can be synthesized.

Theoretical and computational methods for accelerated materials discovery

*NIKOLAI A ZARKEVICH (Presenter), DUANE D JOHNSON, Ames Laboratory, Iowa State University — Predicting properties of materials and phase transformation using theoretical and computational multi-scale methods involving artificial intelligence and machine learning is important and highly rewarding. We investigate reliability of the relevant methods, apply them to caloric materials and high-entropy alloys, and demonstrate how theoretical guidance for experiment accelerates materials discovery.

*We acknowledge support by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. Consideration of phase transitions in caloric materials is partially supported by the U.S. DOE, Advanced Manufacturing Office of the Office of Energy Efficiency and Renewable Energy, through CaloriCool(TM). Ames Laboratory is operated for DOE by Iowa State University under Contract No. DE-AC02-07CH11358.
1:39PM M43.00011: Stabilities and electronic structures of XYZ$_2$ thermoelectric materials

LIU KE, CAI XIAOMENG (Presenter), HONG ZHU, Shanghai Jiao Tong Univ — A new class of high-performance thermoelectric materials XYZ$_2$ has been revealed based on high-throughput simulations. But they could also have multiple phase transformations similar to many other high-performance thermoelectric materials like PbTe. Thus, it's important to study the stability and electronic structure of different phases, and how these are related to the chemistry of the compound. The phase stabilities have been assessed by support vector machine methodology. We find compounds with larger X ionic radius have P3m1 space group with X ion in octahedral interstices, while smaller X ionic radius favors a tetrahedral site occupation with a space group of the compound of I-42d. Based on the gradient boosting algorithm, density of states effective mass $m^*_S$ and fermi surface complexity factor $N^*_V*K*$ are identified as important descriptors to enhance $zT$ values. Compounds with larger $m^*_S$ have a flat band to enhance Seebeck coefficient if the X-$s$ (Y-$d$) orbitals have similar energy with Z-$p$ orbital near the VBM. Cu and Ag based compounds with P3m1 space group are benefited from the Y-$d$ orbital contribution to the high $N^*_V*K*$. These results demonstrate altering ionic size and molecular orbitals may be used in strategies to improve the thermoelectric performance of XYZ$_2$ compounds.

1:51PM M43.00012: The analytic metric for geometric series diffraction from icosahedral quasicrystals

ANTONY BOURDILLON (Presenter), emeritus, UHRL — Sharp diffraction patterns show long range order [1] in i-Al$_6$Mn; translational symmetry is seen—by phase-contrast, optimum-defocus imaging—to be hierarchic. The icosahedral diffraction pattern was novel in two ways: that it included five-fold symmetric axes; having moreover diffraction orders in geometric series, imprecisely called Fibonacci. The orders differ from Bragg diffraction which is linear. How does a plane wave X-ray, or electron beam, scatter off the hierarchic structure? The diffraction angles due to scattering from the quasiperiodic solid diverge from Bragg conditions: quasi-Bragg angles are derived from quasi-structure factors with a metric that is derived numerically and analytically. The metric is a conversion factor, $1/(\tau-0.5)$, where $\tau$ is the golden section: the metric harmonizes the incident sine wave with hierarchic scattering (all atoms scatter) while the response occurs in geometric series. The hierarchic structure is represented by triads of golden rectangles, each having principal planes, separated by spaces in geometric series, like the diffraction pattern [2]. [1] Shechtman, D, et al. (1984) Phys. Rev. Lett. 53, 1951, http://dx.doi.org/10.1103/PhysRevLett.53.1951 [2] A.J.Bourdillon, A.J., J. Mod. Phys. 10 [6] 624 (2019), DOI: 10.4263/jmp.2019.106044
2:03PM M43.00013: Elucidating the role of anharmonic effects in understanding oxidation of methane  PREETI BHUMLA (Presenter), SASWATA BHATTACHARYA, Dept of Physics, Indian Institute of Technology Delhi, New Delhi —
In heterogeneous catalysis, materials property changes under operational environment (temperature ($T$), pressure ($p$)). Here we study $T$, $p$ dependence of the composition, structure, and stability of metal oxide clusters using a relevant model system for practical applications: free transition metal (Ni) clusters in a combined oxygen and methane atmosphere. We have employed a robust methodological approach that integrates various levels of theory combined into one multi-scale simulation. To obtain the global minimum structures of the Ni$_4$O$_x$(CH$_4$)$_y$ clusters, an extensive data set is generated using a massively parallel cascade genetic algorithm at the hybrid density functional level. The low energy clusters obtained from GA are further analysed to estimate their free energy of formation at realistic $T$, $p_{O_2}$ and $p_{CH_4}$. By analyzing this large dataset, we show that the conventional harmonic approximation miserably fails to predict thermodynamic stability and capturing the anharmonic effects to the vibration free energy contribution is indispensable. To include the anharmonic vibrational free energy to the configurational entropy, we evaluate the excess free energy of the clusters numerically by thermodynamic integration with ab initio molecular dynamics simulation inputs.

Session M44 DCOMP: Heat Transport in Condensed Systems II 704 - Elif Ertekin, University of Illinois at Urbana-Champaign - Tag(s): Focus

11:15AM M44.00001: Coherent phonon manipulation in van der Waals Graphene-MoS$_2$ Hetero-structure  SHIQIAN HU (Presenter), JUNICHIRO SHIOMI, Univ of Tokyo — Generally, the difference in the intrinsic lattice structures of the constituent materials inevitably generates interface disorder during the fabrication process, greatly limiting direct experimental observation of the coherent phonon transport. The flexible integration and atomistic interlayer smoothness of van der Waals hetero-structure provide an ideal platform for the coherent phonon transport manipulation. Thus, in this work, using the non-equilibrium molecular dynamics simulations, we investigate the coherent phonon transport in van der Waals graphene-MoS$_2$ hetero-structure with different stacking order at room temperature. The histogram of the phonon transmissions in different disordered structure exhibits a log-normal distribution, which reveals the localization of the coherent phonons. Furthermore, the optimal stacking order of the graphene and MoS$_2$ is efficiently identified from tens of thousands of candidates by machine learning. The significantly suppressed of the phonon transmission in the low frequency (<5THz) phonons of the optimized structure lead to a significant reduction (~95%) of the thermal conductance compared with the graphite. Finally, the effects of the temperature and strain effect on the graphite and optimized structures are also discussed.
Amorphous-like Thermal Conductivity in Crystalline Solids

Thermoelectric materials (TEs) could play an important role in future energy management through environmentally sound cooling and power generation, e.g., converting waste heat into electricity. Efficient TEs inhibit the propagation of heat (low thermal conductivity, $\kappa$) but conduct electricity well (high power factor). Although $\kappa$ in a given material can be reduced via alloying and nanostructuring, identifying materials with intrinsically low $\kappa$ is still needed. Previously, it has been shown that soft phonon modes due to weakly bonded atoms and $s^2$ lone-pair electrons are common to materials with low-$\kappa$. Here, we predict a series of new materials which are weakly bonded systems with same constituent elements but different stoichiometry either with $s^2$ lone-pair electrons or high mass density. Due to resulting giant phonon anharmonicity and low phonon group velocities, they offer extremely low $\kappa$ (0.3-0.6 W/mK) at 300K approaching those found in the amorphous/disordered regime. In addition to low-$\kappa$, high Seebeck coefficients and high electrical conductivities in these materials may provide a new opportunities for high-efficiency thermoelectrics at room temperature.

Characterization of Phonon Dynamics and Thermal Environments in FinFET Architectures

Physical device scaling for traditional chip architectures is expected to end by 2021. As a result, alternatives are being aggressively pursued that can meet the increasing computing demands imposed by data-centric computing and sensor networks. Three-dimensional IC architectures are particularly promising due to high levels of integration and enhanced performance. However, increased integration leads to thermal bottlenecks that greatly reduce device performance. To understand the bottlenecks, we use atomistic modeling techniques to characterize the nanoscale phonon dynamics and map the thermal landscape of modern fin field-effect transistors (FinFET). We identify phonon modes of FinFET subcomponents that contribute strongly to thermal transport using a lattice dynamics (LD) framework based on a quasi-harmonic Green-Kubo approximation. In parallel, we generate subcomponent temperature profiles using molecular dynamics (MD) simulations. We establish a relationship between the MD temperature profiles and the corresponding populations of the LD-identified phonon modes using a machine learning algorithm. This relationship is used to predict the full phonon dynamics of the entire FinFET device.

*This project is funded by the National Science Foundation [Award No.: HDR-DIRSE-1940153].
Advances in material science and fabrication techniques enabled the fabrication of samples with nanometric dimensions where it is possible to control the propagation of photons (NIR range) and acoustic-phonons (GHz-THz frequencies) in a single device. In this presentation, I will describe the behavior of a plethora of devices able to control acoustic phonons and the interactions with light and charge at the nanoscale [1-3]. I will introduce some strategies to generate, manipulate and detect ultra-high frequency acoustic phonons both in the time and spectral domains [4-5].

The presented results open a new playground in the control of acoustic vibrations in solids and constitute a new platform to study topological effects, quantum phenomena, and thermal transport properties.

12:27PM M44.00005: Complex bond distortion behaviors of anharmonic thermal carriers in van der Waals bonded molecular crystal α-RDX* GAURAV KUMAR (Presenter), PETER W. CHUNG, University of Maryland, College Park — Understanding of phonon properties in molecular crystals is critical due to their influence over, for instance, sensitivity of explosives, and charge separation in organic semiconductors. In particular, hot-spot formation in shocked energetic materials, are known to follow from bond scission events. However, the phonon-mediated mechanisms that promote bond breaking are still unclear. In this work, we examine how distortion of bonds carry heat in van der Waals bonded molecular crystal α-RDX. We rank order the phonons and their distortions to the lattice by their importance as carriers of heat. The motions of the atoms that constitute the bond distortions are determined using the phonon mode energy and mode shapes under the harmonic approximation. We also estimate the thermal conductivity of α-RDX using the Allen-Feldman (AF) harmonic theory. The AF model takes into account the contribution of highly anharmonic diffusive carriers which dominate thermal transport in many molecular crystals. Our preliminary results indicate that the the low frequency modes (< 4 THz) contribute ~90% to the total thermal conductivity as well as ~90% to the total bond strain, among which N-N and N-O bonds were found to exhibit the largest strains and rotations.

12:39PM M44.00006: Ab initio-based scanning Seebeck microscopy simulation of epitaxial graphene on 6H-SiC EUICHEOL SHIN (Presenter), YONG-HYUN KIM, Department of Physics, KAIST — Heat, diffusive and incoherent phenomena, has not been considered as surface scanning means. In spite of those characteristics of heat, the local variation of charge carrier was shown by using coherent electron transport via the temperature difference between tip and sample which is so-called scanning thermoelectric microscopy (SThm). It successfully measured atomic-scale local majority carriers variation at room temperature.

We conducted first-principle scanning Seebeck microscopy (SSM) simulation in order to explain heat-based SThM images. The SSM simulation of freestanding monolayer graphene could successively reproduce the experimental thermoelectric contrast between carbon and void sites at the atomic scale. More importantly, SThM for the supported graphene showed the unique oblique slope of the thermoelectric voltage between A and B sites in graphene unit cell stem from the difference of local charge carrier environment.

Here, SSM simulations for free-standing bilayer graphene and supported monolayer graphene on 6H-SiC are numerically demonstrated. The Seebeck profile of both cases was able to show the opposite results of A and B sites depending on the Fermi energy, and the oblique slope of the previous study could not be explained.
12:51PM M44.00007: First-principles study of enhanced thermal conductivity in ordered AlGaO₃ alloys*  
SAI MU (Presenter), Materials Department, University of California, Santa Barbara,  
HARTWIN PEELAERS, Department of Physics and Astronomy, University of Kansas, CHRIS VAN DE WALLÉ, Materials Department, University of California, Santa Barbara — Monoclinic gallium oxide (Ga₂O₃) has promising applications in high-power and high-frequency electronics due to its wide band gap. However, practical device applications are hampered by its low thermal conductivity. To improve the thermal properties of Ga₂O₃ devices, we propose to alloy Ga₂O₃ with Al₂O₃, forming a low-energy ordered structure at the 50% concentration [1]. We investigate the lattice thermal conductivity of monoclinic Ga₂O₃ and of the ordered AlGaO₃ alloy using the phonon Boltzmann transport equation, with the harmonic and third-order anharmonic force constants calculated from density functional theory. We find that the thermal conductivity of AlGaO₃ is raised by more than 70% compared to Ga₂O₃. The enhancement is ascribed to (1) increased group velocities and (2) reduced anharmonic scattering rates due to the reduced weighted phase space. The findings offer an avenue towards improved heat dissipation from Ga₂O₃ devices.

1:03PM M44.00008: Disentangling mass effects from crystal chemistry in the thermal properties of III-V insulators*  
SABRINA J LI (Presenter), ETHAN RITZ, NICOLE A BENEDEK, Cornell University — B₃As, a III-V insulator, has a thermal conductivity comparable to diamond and a higher thermal conductivity than other cubic III-V boron compounds. The origin of this high thermal conductivity has been attributed to the mass ratio and unique chemical bonding character of B₃As, both of which give rise to specific features in the phonon dispersion curve. We use first-principles density functional theory in combination with the Boltzmann transport equation to systematically explore and disentangle the effects of mass ratio and bonding and chemistry on the thermal conductivity of the entire column of cubic III-V boron compounds, from c-BN to BSb. Our preliminary results and previous work [J. Appl. Phys. 116 073503 (2014)] suggest that although the mass ratio of B₃As may optimally maximize thermal conductivity, there may be a pathway to further increasing thermal conductivity through modifying bonding and chemistry. Our work provides hints regarding the chemical characteristics of high thermal conductivity materials.

1:15PM M44.00009: Precise yet Fast High-Throughput Search for Thermal Insulators
FLORIAN KNOOP, THOMAS A PURCELL (Presenter), MATTHIAS SCHEFFLER, CHRISTIAN CARBOGNO,
Fritz Haber Institute of the Max Planck Society, Berlin — We present a systematic and numerically precise computational search for thermal insulators in material space performed with the FHI-vibes high-throughput framework [1]. FHI-vibes employs a robust metric that quantifies the degree of anharmonicity in the nuclear dynamics via the statistical comparison of first-principles forces with those forces that would act in the harmonic approximation. This enables us to efficiently scan over thousands of materials, including complex oxides and chalcogenides as well as ternary structures like perovskites, and single out strongly anharmonic ones. For these systems, we perform ab initio Green-Kubo simulations to model their thermal-transport properties, thereby naturally including all anharmonic effects [2]. Our strategy allows to avoid redundant calculations and achieve a much higher quality of information than achieved in traditional high-thoughput studies. Besides validating the performed search and analyzing its results, we discuss how big-data analytics techniques can be utilized to further accelerate and guide this search.

1:27PM M44.00010: Optimization of thermal conductivity at interfaces using learning algorithms
*ANNE CHAKA (Presenter), ZEXI LU, MALACHI SCHRAMP, Pacific Northwest National Laboratory — In material science, we are frequently interested in understanding the properties and design implication of material at interfaces. These interfaces can be manipulated to improve the desired characteristics of the bulk material. In this study, we are interested in understanding and optimize the impact of interfacial atomic defects on the thermal transport across a Cu/Si junction. To that end, we developed a reinforcement learning based framework to optimize over a potentially large parameter search. Using this technique allows us to accumulate knowledge of the system of a given type of atoms and store this information into a neural network. In this study, we present our results on optimizing the thermal transport by varying the fraction and length of the interfacial atomic defects using molecular dynamics (MD) simulations with normal mode analysis (NMA) to investigate thermal transport.

1:39PM M44.00011: Valley filtering effect of phonons in graphene with a grain boundary*

XIAOBIN CHEN (Presenter), School of Science, Harbin Institute of Technology, Shenzhen, YONG XU, Collaborative Innovation Center of Quantum Matter and State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, China, JIAN WANG, Department of Physics and the Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China, HONG GUO, Department of Physics, 3600 University, McGill University, Montreal, Quebec H3A 2T8, Canada — Due to their possibility to encode information and realize low-energy-consumption quantum devices, control and manipulation of the valley degree of freedom have been widely studied in electronic systems. In contrast, the phononic counterpart--valley phononics--has been largely unexplored, despite the importance in both fundamental science and practical applications. In this work, we demonstrate that the control of "valleys" is also applicable for phonons in graphene by using a grain boundary. In particular, perfect valley filtering effect is observed at certain energy windows for flexural modes and found to be closely related to the anisotropy of phonon valley pockets. Moreover, valley filtering may be further improved using Fano-like resonance. Our findings reveal the possibility of valley phononics, paving the road towards purposeful phonon engineering and future valley phononics.

Session M45 DCOMP GDS DSOFT DPOLY: Emerging Trends in Molecular Dynamics Simulations and Machine Learning III 706 - Dvora Perihia, Clemson University - Tag(s): Focus
The Self Learning Kinetic Monte Carlo (SLKMC) method augmented with data analytics for adatom-island diffusion on surfaces* [Invited]

TALAT RAHMAN (Presenter), Department of Physics, University of Central Florida — The Self-Learning Kinetic Monte Carlo (SLKMC) method with its usage of a pattern recognition enabled the collection of a large database of diffusion pathways and their energetics for two-dimensional adatom islands containing 2-50 atoms on fcc(111) metal surfaces [1]. A variety of diffusion mechanisms involving single and multiple island atoms were uncovered in long time (comparable to experiments) KMC simulations. In this talk, I will present results for the diffusion kinetics of two dimensional adatoms islands in homoepitaxial and heteroepitaxial systems. With examples of diffusion of Ag and Pd adatom islands on Ag(111) and Pd(111), and that of Cu and Ni adatoms islands on Ni(111) and Cu(111) [2], I will draw attention to the relative role of lateral interactions and binding energy in the size dependence of island diffusion characteristics. These and a few other descriptors have been the key for application of data driven techniques for the training of predictive models, which we find to yield activation energy barriers that are accurate and obtained with little computational cost. Efforts are also underway to obtain reliable neural network derived interatomic potentials that have accuracy similar to those obtained from density functional theory based calculations. These results are promising for the development of tools for multiscale modeling of morphological evolution of nanostructured systems.

**11:51AM M45.00002: Accelerated Discovery of Dielectric Polymer Materials Using Graph Convolutional Neural Networks**

ANKIT MISHRA (Presenter), Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, PANKAJ RAJAK, Argonne National Lab, EKIN DOGUS CUBUK, Google Inc, KEN-ICHI NOMURA, RAJIV KALIA, AIICHIRO NAKANO, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, AJINKYA DESHMUKH, Department of Chemistry, University of Connecticut, Storrs, LIHUA CHEN, Department of Material Science and Technology, Georgia Tech, GREG SOTZING, Department of Chemistry, University of Connecticut, Storrs, YANG CAO, Department of Electrical Engineering, University of Connecticut, Storrs, RAMAMURTHY RAMPRASAD, Department of Material Science and Technology, Georgia Tech, PRIYA VASHISHTA, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California — Polynorbornene (PNB) is an important amorphous polymer system, which has potential applications as a high energy density polymer due to its high breakdown strength with low dielectric loss and high thermal stability. Moreover, electrical properties of PNB can be significantly enhanced by incorporation of defects or synthesis with controlled crystallinity by hydrogenation reaction. However, this process is challenging since it involves experimental synthesis and characterization of combinatorial large number of polymer systems to identify potential candidates. Here, we propose a deep learning-based graph convolutional neural network (GNN) model that can identify polymer systems capable of exhibiting increased energy and power density. The GNN model is trained to predict dielectric constant for a polymer, where the training data for the high frequency dielectric constant of the PNB polymers are computed via ab-initio molecular dynamics simulation. Our model can significantly aid experimental synthesis of potentially new dielectric polymer materials which is otherwise difficult using simplistic statistical procedures.

**12:03PM M45.00003: Deep Learning embedding layers for better prediction of atomic forces in solids**

SIVAN NIV (Presenter), Department of Physical Electronics, Tel Aviv University, GOREN GORDON, Industrial Engineering, Tel-Aviv University, AMIR NATAN, Department of Physical Electronics, Tel Aviv University — The evaluation of atomic forces and total energy is a key challenge for large-scale atomistic simulations of materials. In recent years, machine learning techniques are successfully used to predict potential energies and to derive the atomic forces through the energy gradient. The training data is usually produced by quantum calculations, typically Density Functional Theory (DFT). The direct prediction of atomic forces by deep learning (DL) models was recently demonstrated by us and other groups, it has the advantage of being local and slightly faster while still maintaining state of the art mean absolute error (MAE). A disadvantage is that the predicted forces might be non-conserving. Like models which predict the energy, direct force models should behave well under symmetry operations and permutation of atoms. Here, we show how the use of self-learned embedding layers help to achieve better models for direct prediction of atomic forces. We also examine some sophisticated loss models to assure that the forces are smooth and close to conserving. We demonstrate this by the calculation of phonons in several solids and by the analysis of force derivatives in systems where we move single atoms and compare the DL predicted force derivatives to the DFT results.
12:15 PM M45.00004: A molecular dynamics study of water crystallization using deep neural network potentials of ab-initio quality*  PABLO PIAGGI (Presenter), ROBERTO CAR, Princeton University — We study the crystallization of water into hexagonal ice (Ih) using molecular dynamics simulations. We describe the complex interactions between water molecules using deep neural network potentials[1] and employ state of the art enhanced sampling methods[2] to convert reversibly liquid water into ice Ih. From the simulations we calculate the difference in free energy between these two phases. The ice Ih configurations that emerge contain proton disorder as observed in experiments[3]. The proton disorder has an important contribution to the entropy of the solid[4] that most free energy methods are unable to capture. We assess whether our technique is able to capture it and we study the effect of the interaction potential in the proton disorder.

*P.M.P was supported by an Early Postdoc.Mobility fellowship from the Swiss National Science Foundation. This work was conducted within the center: Chemistry in Solution and at Interfaces funded by the DoE under Award DE-SC0019394.

12:27 PM M45.00005: Machine learning force field using decomposed atomic energies from ab initio calculations*  LIN-WANG WANG (Presenter), Lawrence Berkeley National Laboratory — The development of machine learning (ML) force field from ab initio calculation is currently an intensely studied topic. In this talk, we will present our results using both neural network model and Gaussian process regression to represent such force fields. Examples of one element systems (e.g., Si) and two element systems (e.g., Fe-H) will be represented. We show that the ML force field can reproduce well the density functional theory (DFT) ab initio results. Large scale crystal growth can be simulated using the ML force field. In our ML force field development, we have used not only the atomic forces, but also a special decomposed DFT energy on each atom to carry out the training. We deployed a systematic feature function set to describe the atomic environment of a central atom. We will also present the comparison between the neural network model and the Gaussian process regression model.

*This work is supported by the Director, Office of Science (SC), Basic Energy Science (BES)/Materials Science and Engineering Division (MSED) of the U.S. Department of Energy (DOE) under the Contract No. DE-AC02-05CH11231 through the Theory of Material project.
Machine learning to derive quantum-informed and chemically-aware force fields to simulate interfaces and defects in hybrid halide perovskites  ROSS E LARSEN (Presenter), MATTHEW JANKOUSKY, DEREK VIGIL-FOWLER, AARON M HOLDER, National Renewable Energy Laboratory, K. GRACE JOHNSON, Department of Chemistry, Stanford University — The paradigm for creating materials for energy applications is no longer simply discovering a single material but instead involves combining multiple materials to achieve a desired functionality. Simulating interfaces between disparate materials or entire devices requires large systems, often approximated by classical simulations based on force fields (FFs). The accuracy of such simulations can be questionable because standard FFs may not accurately respond to changing chemical environments near an interface. We demonstrate a machine learning (ML) approach to predict quantum-derived atomic properties (e.g., charge, dipole moment, etc.) from descriptors of the local environment. The properties are used to compute chemically-aware, many-body inter-atomic forces, because the local environment descriptors encode more than just pairwise information. We apply these ML-derived FFs to several all-inorganic halide perovskite systems, CsBX$_3$ (B = Sn, Pb, X = Br, I) with local and extended defects, and to the interfaces between these materials, to correctly capture the anomalous charge and electrostatic multipole dynamics observed in these systems. We report on the MLFFs methods developed, and the resulting materials implications of charge dynamics on halide perovskite functionality.

Active Learning of Coarse Grained Force Fields with Gaussian Process Regression  BLAKE DUSCHATKO (Presenter), JONATHAN VANDERMAUSE, NICOLA MOLINARI, BORIS KOZINSKY, Harvard University — Many physically relevant spatial and temporal scales remain inaccessible with leading MD techniques, especially in soft matter and composite materials. Consequently, it is common practice to replace the all-atom representation with effective beads using coarse graining approaches. However, development of coarse grained force fields is a laborious procedure, and available force fields tend to lose orientation information, making all-atom reconstruction, or fine-graining, difficult. We propose a novel machine learning method for automatically constructing coarse grained force fields by active learning. In addition these force fields contain predictive uncertainty and allow for fine-grain reconstruction. We demonstrate that Gaussian Process Regression can alleviate the need for large initial all-atom trajectories that are generally required for achieving thermodynamically consistent results in the latent space. Moreover, we will discuss the performance of such models in the context of a variety of molecular systems possessing different amounts of rotational symmetry.
1:03PM M45.00008: **External Potential Ensembles to Improve the Learning of Transferable Coarse-Grained Potentials**

KEVIN SHEN (Presenter), KRIS T DELANEY, M. SCOTT SHELL, GLENN H FREDRICKSON, University of California, Santa Barbara — Simulation of complex, heterogeneous molecular systems requires models that are transferable across environmental conditions. However, current bottom-up strategies for parametrizing accurate coarse-grained (CG) models often rely on explicitly targeting the selected thermodynamic quantities (measured from experiments or atomistic simulations), which can be difficult to obtain. We argue that this information limitation can be overcome by coarse graining using thermodynamically informative ensembles, where variables conjugate to the thermodynamic variables of interest are allowed to fluctuate. We demonstrate this approach by using external potential ensembles with the relative entropy optimization to parametrize highly coarse grained models of solvent mixtures from atomistic force fields. The CG models can reproduce the activity coefficient of the atomistic model to within 0.1kT accuracy across the entire composition range, without explicitly measuring and matching chemical potentials during the parameterization process. This approach allows for the efficient transfer of exciting improvements of atomistically detailed models to fast, coarse-grained simulations of macro-scale systems.

*Funded by the BASF California Research Alliance*

1:15PM M45.00009: **Data-driven parameterization of coarse-grained models of soft materials using machine learning tools**

LILIAN JOHNSON (Presenter), FREDERICK PHELAN, National Institute of Standards and Technology — Many advances have been made in coarse-grained (CG) models of polymers to reduce computational effort yet capture the relaxation behavior imparted by hierarchical structure, resulting in two primary classes: “bottom-up” methods which preserve chemical-specificity and “top-down” methods which reproduce physical properties. Here, we combine a bottom-up coarse-grained model with a dissipative potential to obtain a chemically specific, thermodynamically consistent, and dynamically correct model. We parametrize the conservative forces using the iterative Boltzmann inversion (IBI) method to develop a CG force field from short all-atom (AA) simulations to recover AA structure, and thus, thermodynamics. We employ machine learning and filtering techniques to produce smooth distributions that enable automation and rapid convergence to smooth force profiles. We develop a similar approach for parameterization of the dissipative potential to correct the dynamics of the IBI-generated force field. In this method, we match AA diffusivity as a proxy for tuning monomeric friction. We demonstrate this method for oligomers in the melt state. Efforts to develop these methods into complementary automated packages will be discussed.

*LCJ acknowledges support from a NIST NRC Postdoctoral Associateship.*
1:27PM M45.00010: JAX, M.D. End-to-End Differentiable, Hardware Accelerated, Molecular Dynamics in Pure Python  
SAM SCHOENHOLZ (Presenter), EKIN DOGUS CUBUK, Google Inc. — A large fraction of computational science involves simulating the dynamics of particles that interact via pairwise or many-body interactions. These simulations, called Molecular Dynamics (MD), span a vast range of subjects from physics to drug discovery. Most MD software involves significant use of handwritten derivatives and code reuse across C++, FORTRAN, and CUDA. This is reminiscent of the state of machine learning (ML) before automatic differentiation became popular. Here, we bring the substantial advances in software that have taken place in ML to MD. JAX, M.D. is an end-to-end differentiable MD package written entirely in Python that can be just-in-time compiled to CPU/GPU/TPU. JAX MD allows researchers to iterate extremely quickly and lets researchers easily incorporate ML into their workflows. Finally, since all of the simulation code is in Python, researchers can have unprecedented flexibility in setting up experiments. JAX MD also allows researchers to take derivatives through whole-simulations as well as seamlessly incorporate neural networks into simulations. In this presentation we explore the architecture of JAX MD and its capabilities through several vignettes. Code is at github.com/google/jax-md along with a Colab notebook with experiments from the presentation.

1:39PM M45.00011: A neural network interatomic potential for molten NaCl*  
QINGJIE LI (Presenter), Massachusetts Institute of Technology MIT, EMINE KUCUKBENLI, Harvard University, STEPHEN LAM, BORIS KHAYKOVICH, Massachusetts Institute of Technology MIT, EFTHIMIOS KAXIRAS, Harvard University, JU LI, Massachusetts Institute of Technology MIT — Molten salts have been widely exploited for clean energy applications such as molten salt reactor (MSR) and concentrated solar power (CSP) technologies. These applications impose stringent requirements on the choice of molten salts such as excellent thermophysical properties, stability under extreme conditions, tolerance to impurities as well as compatibility with major structural materials. Optimizing/searching appropriate molten salt systems thus calls for a deep understanding of the underlying molecular structures, chemistry and dynamics in a vast salts space. In this talk, we present the application of artificial neural-network (NN) in training accurate interatomic potentials that enable fast evaluations of salt properties on desired time-and length-scales. In particular, we highlight the feasibility of neural-network interatomic potential to accurately predict the short to medium range structures and thermophysical properties of ionic liquids. We also propose a generic strategy to address the short-range interactions that are generally difficult to be learned by artificial NN.

1:51PM M45.00012: Simulating Aluminum Corrosion Using DFT Trained Deep Neural Network Potentials  
WISSAM A SAIDI (Presenter), Mechanical Engineering & Materials Science, University of Pittsburg, SHYAM DWARAKNATH, Lawrence Berkeley National Laboratory — Current materials challenges necessitate simulations at length and time scales that often exceed the capabilities of the state of the art in density functional theory (DFT). Many effective Hamiltonian methods that can scale beyond these limits, such as cluster expansion, tight-binding, and interatomic potentials, often require a significant amount of expertise to train and employ. Machine learning methods such as deep neural networks exchange expertise for data-volume in what are typically expert-driven processes. Here we demonstrate the power of a deep neural network potential (DNP) to model the stability of various phases and terminations of Al2O3 on Al. This model builds off previous work using DFT to demonstrate that the relative stability of alpha-, gamma-, and amorphous Al2O3 changes with the film thickness, but was limited to one coherency constraint. With our DNP, we are able to find lower strain but less coherent interfaces for all three phases altering the layer thickness at which relative stability shifts. More importantly, we see strong correlations with interface chemistry suggesting that the environment chemical state can play a strong role in the nucleation and early stages of Al2O3 film growth.

2:03PM M45.00013: Tensor-Field Molecular Dynamics: A Deep Learning model for highly accurate, symmetry-preserving force-fields from small data sets*  
SIMON BATZNER (Presenter), LIXIN SUN, Harvard University, TESS E SMIDT, Computational Research Division, Lawrence Berkeley National Laboratory, BORIS KOZINSKY, Harvard University — Simulating the dynamic behavior of molecules and extended materials over large time-scales and with high fidelity has been a long-standing goal in computational physics. Recently, Deep Neural Networks have shown great promise in learning energies and atomic forces from atomistic data, thereby providing access to efficient and accurate interatomic force-fields. However, most existing methods still require the construction of very large reference training sets, consisting of tens of thousands of structures, often computed with expensive first-principles approaches. This provides a challenging bottleneck in the construction of interatomic force-fields, limiting Deep Learning-based approaches to systems for which such large training sets are feasible to generate. We present a framework to learn highly accurate Machine-Learning Force-Fields from small training sets. We show that our proposed method is able to obtain high-accuracy force predictions on a variety of different atomic systems, including organic molecules, bulk solids as well as complex interfaces and discuss the resulting Molecular Dynamics simulations.

Session M46 GMAG: Quasi-2D Frustration: Honeycomb Lattice and Other Geometries  
708 - Kate Ross, Colorado State University
11:15AM M46.00001: Topological Quantum Many-Body Scars in Quantum Dimer Models
ALEXANDER SEIDEL (Presenter), Department of Physics, Washington University in St. Louis, JULIA WILDEBOER, Department of Physics, Arizona State University, ANNE E. B. NIELSEN, Max Planck Institute for the Physics of Complex Systems, ONUR ERTEN, Department of Physics, Arizona State University — We construct two-dimensional lattice models with quantum dimer degrees of freedom that violate the eigenstate thermalization hypothesis (ETH) by featuring quantum many-body scars in their excitation spectrum. These scars consist of single exactly known excited eigenstates with atypical (area law) entanglement entropy. We explicitly construct such models for the kagome and checkerboard lattices. We compute entanglement entropy numerically for the surrounding states, and analytically for the scar states themselves. Furthermore, we corroborate the non-integrable nature of these quantum dimer models by studying the statistics of the spacings between consecutive energy levels.

11:27AM M46.00002: Novel Quantum Phase Transition of the Shastry-Sutherland Model
TORU SAKAI (Presenter), HIROKI NAKANO, Graduate School of Material Science, Univ of Hyogo — The Shastry-Sutherland model - the $S = 1/2$ Heisenberg antiferromagnet on the square lattice accompanied by orthogonal dimerized interactions - is studied by the numerical-diagonalization method. Large-scale calculations provide results for larger clusters that have not been reported yet. The present study successfully captures the phase boundary between the dimer and plaquette-singlet phases and clarifies that the spin gap increases once when the interaction forming the square lattice is increased from the boundary. Our calculations strongly suggest that in addition to the edge of the dimer phase given by $J_2/J_1 \sim 0.675$ and the edge of the Neel-ordered phase given by $J_2/J_1 \sim 0.76$, there exists a third boundary ratio $J_2/J_1 \sim 0.70$ that divides the intermediate region into two parts, where $J_1$ and $J_2$ denote dimer and square-lattice interactions, respectively. We report the result from the investigation about this possible novel quantum phase transition in the plaquette singlet phase[1].

11:39AM M46.00003: Antiferromagnetic-to-ferrimagnetic phase transition in frustrated polar magnet CaBaCo$_4$O$_7$  TSUYOSHI OMI (Presenter), YOSHITO WATANABE, NOBUYUKI ABE, YUSUKE TOKUNAGA, Univ of Tokyo-Kashiwanoha, AKIKO NAKAO, KOJI MUNAKATA, CROSS, HAJIME SAGAYAMA, KEK IMSS, TAKA-HISA ARIMA, Univ of Tokyo-Kashiwanoha — Magnetic frustration often plays important roles in multiferroic properties as is exemplified by the electric polarization induced by the spiral magnetic order. CaBaCo$_4$O$_7$ belongs to the orthorhombic space group $Pbn_2_1$. Magnetic Co ions form Kagomé- and triangular- lattice layers, which alternately stack along the $c$-axis. CaBaCo$_4$O$_7$ shows a ferrimagnetic transition at $T_c \sim 60$ K at zero magnetic field. CaBaCo$_4$O$_7$ is a multiferroic material hosting magnetic frustration[1]. It exhibits an electric polarization change of about 17 mC/m$^2$ at the ferrimagnetic transition which is the largest among all the multiferroic materials so far[2]. The specific heat and the electric permittivity of single crystal CaBaCo$_4$O$_7$ exhibits another anomaly at $T_N$~69 K slightly higher than $T_c$ in zero magnetic field, while the origin of the anomaly was not clarified[2].

We investigate the phase transition of CaBaCo$_4$O$_7$. An antiferromagnetic phase is formed between $T_c \sim 60$ K and $T_N \sim 69$ K in our magnetization measurement and single-crystal neutron diffraction measurement. The large electric polarization change in CaBaCo$_4$O$_7$ should be attributed to the antiferromagnetic-to-ferrimagnetic transition.

11:51AM M46.00004: Sign-switching of dimer correlations in SrCu$_2$(BO$_3$)$_2$ under hydrostatic pressure*  SIMON BETTLER (Presenter), LENA STOPPEL, ZEWU YAN, SEVERIAN GVASALIYA, ANDREY ZHELUDEV, ETH Zurich — Magnetic and vibrational excitations in SrCu$_2$(BO$_3$)$_2$ are studied using Raman spectroscopy at hydrostatic pressures up to 34 kbar and temperatures down to 2.6 K. The frequency of a particular optical phonon, the so-called pantograph mode, shows a very strong anomalous temperature dependence below about 40 K. We link the magnitude of the effect to the magnetic exchange energy on the dimer bonds in the Sutherland-Shastry spin lattice in this material. The corresponding dimer spin correlations are quantitatively estimated and found to be strongly pressure dependent. At around $P_2 \sim 22$ kbar they switch from antiferromagnetic to being predominantly ferromagnetic.

*This work was partially supported by the Swiss National Science Foundation, Division 2.
12:03PM M46.00005: Large spin fluctuation in the magnetization process of S=1/2 frustrated square lattice model  TSUYOSHI OKUBO (Presenter), Department of Physics, University of Tokyo — In the frustrated spin systems, a lot of interesting phenomena including non-collinear magnetic orders, magnetization plateaus and spin liquids occur. Such frustrated interactions often appear in geometrically frustrated lattices, such as triangular, kagome or pyrochlore lattices. In addition to these lattice, when we consider further neighbor interactions or combination of ferromagnetic and antiferromagnetic interactions, frustrations can happen even in the square lattice. Motivated by several compounds, we discuss the nature of S=1/2 square lattice Heisenberg magnets with ferromagnetic and antiferromagnetic nearest-neighbor interactions. By means of the infinite tensor product states (iTPS) ansatz, we investigated magnetization process of the models numerically. We show that in the model corresponding to the compound [1], a part of spins reveals very strong spin fluctuation around the half of saturation magnetization. This is because spins connected by strong antiferromagnetic interaction form spin singlet. By varying the interaction strength, we show that such spin fluctuation is related to the 1/2 magnetization plateau stabilized in the vicinity of the model.

12:15PM M46.00006: Quantum Phases Diagram of the Plaquette State of the Shastry-Sutherland Compound SrCu₂(BO₃)₂  SARA HARAVIFARD (Presenter), ZHENZHONG SHI, SACHITH DISSANAYAKE, Duke University, DAVID E GRAF, National High Magnetic Field Laboratory, PHILIPPE R. CORBOZ, Universiteit van Amsterdam, FREDERIC MILA, Ecole polytechnique federale de Lausanne, DANIEL SILEVITCH, THOMAS F ROSENBAUM, Caltech, HANNA DABKOWSKA, McMaster University, CASEY MARJERRISON, Duke University — The Shastry-Sutherland compound SrCu₂(BO₃)₂ features 2D layers of Cu²⁺ S=1/2 spin dimers which are orthogonal to each other. The ground state of the system is determined by the relative strength of the nearest neighbor and next-nearest neighbor interactions, J and J′ respectively. The ratio of J/J′ can be tuned continuously by application of hydrostatic pressure. The ground state changes from a spin dimer singlet state at ambient pressure to an antiferromagnet state at high pressure. At intermediate pressure a novel 4-spin plaquette singlet state has recently been reported. However, the nature of this plaquette state and how it evolves into other phases remains unclear. Here, we report a comprehensive study of the quantum phase diagram of the plaquette state by tuning temperature, pressure, magnetic field, and chemical doping. We mapped out the evolution of the ground states using complementary techniques such as magnetic susceptibility, magnetization and neutron scattering measurements. The results provide insights into the nature of the plaquette state, and also has implications in areas such as studies of deconfined quantum criticality.
We study a fractionally frustrated XY model on the square lattice. This type of frustration is induced by regularly placing a gauge $A_{ij}$ on each link of the lattice, with the requirement that the circulation $\sum_{ij \in \square} A_{ij} = 2\pi f$ where $f$ is a fraction. The model is represented by the Hamiltonian

$$H = -J \sum_{ij} \cos(\theta_i - \theta_j - A_{ij})$$

where $\theta_i$ is the orientation of spin on $i$-th lattice site.

We study (via replica exchange Monte Carlo) how the Berezinskii-Kosterlitz-Thouless(BKT) phase of the conventional ($f = 0$) XY model changes for general fractional $f$.

Ref:

For decades, constrained models with dimer degrees of freedom have been a powerhouse of statistical physics and various branches of theoretical and mathematical physics, in particular aspects of quantum magnetism. For analytic purposes, their utility is usually limited to models defined on planar lattice graphs, where, thanks to a powerful theorem by Kasteleyn, many questions can be answered exactly. Here we present analytic results on a special dimer model on a \{it nonplanar\} checkerboard lattice of interacting dimers, which does not permit for parallel dimers to surround diagonal links. We report exact results on the enumeration of closed packed dimer coverings on finite checkerboard lattices under periodic boundary conditions. Furthermore, we comment on the behavior of the dimer-dimer correlations and find that the correlations between any two dimers vanish identically if their distance is larger than two unit cells. Connections with $\mathbb{Z}_2$ gauge theory, known from planar models, are extended to the present case.
Magnetic structure of the stuffed honeycomb antiferromagnet $\text{GdInO}_3$ 

ERXI FENG (Presenter), Oak Ridge National Lab, XIANGHAN XU, Department of Physics and Astronomy, Rutgers University, EVE EMMANOUILIDOU, Department of Physics and Astronomy, University of California Los Angeles, JAE WOOK KIM, Department of Physics and Astronomy, Rutgers University, YAN WU, LEI DING, ALEXANDER KOLESNIKOV, Oak Ridge National Lab, NI NI, Department of Physics and Astronomy, University of California Los Angeles, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, HUIBO CAO, Oak Ridge National Lab — Rare-earth indium oxides $\text{RInO}_3$ ($\text{R} = \text{rare earth}$), in which $\text{R}^{3+}$ ions occupy two nonequivalent sites forming a honeycomb lattice with a superimposed triangular lattice (so-called stuffed honeycomb lattice), present an excellent platform to study the combination of two different frustrated lattices. Since the total angular moment $L$ of $\text{Gd}^{3+}$ ion is zero, $\text{GdInO}_3$ is expected as pure spin magnetism and may be considered as a classical Heisenberg spin system in the stuffed honeycomb lattice. A high quality isotope single crystal $^{160}\text{GdInO}_3$ was synthesized for neutron scattering studies to avoid the high neutron absorption of natural Gd. The specific heat measurement shows that the compound exhibits two step magnetic phase transitions at 2.2 K and 1.08 K corresponding to two different antiferromagnetic phases that were characterized by single crystal neutron diffraction. These phases transition may be explained via the order-by-disorder mechanism.

Frustrated magnetic interactions in an $S=3/2$ bilayer honeycomb lattice compound $\text{Bi}_3\text{Mn}_4\text{O}_{12}(\text{NO}_3)$ 

MASAAKI MATSUDA (Presenter), SACHITH DISSANAYAKE, DOUGLAS L ABERNATHY, Oak Ridge National Lab, YIMING QIU, JOHN COLEY, NIST, NOBUHIRO KUMADA, Univ. of Yamanashi, MASAKI AZUMA, Tokyo Inst. of Tech. — Inelastic neutron scattering study has been performed in an $S=3/2$ bilayer honeycomb lattice compound $\text{Bi}_3\text{Mn}_4\text{O}_{12}(\text{NO}_3)$ at ambient and high magnetic fields [1]. Relatively broad and monotonically dispersive magnetic excitations were observed at ambient field, where no long range magnetic order exists. In the magnetic field-induced long-range ordered state at 10 T, the magnetic dispersions become slightly more intense, albeit still broad as in the disordered state, and two excitation gaps, probably originating from an easy-plane magnetic anisotropy and intrabilayer interactions, develop. Analyzing the magnetic dispersions using the linear spin-wave theory, we estimated the intraplane and intrabilayer magnetic interactions, which are almost consistent with those determined by $\textit{ab initio}$ density functional theory calculations [2], except the third and fourth neighbor intrabilayer interactions. Most importantly, as predicted by the theory, there is no significant frustration in the honeycomb plane but frustrating intrabilayer interactions probably give rise to the disordered ground state.

Observations of antiferromagnetic, antiferroelectric and ferroelastic orderings in honeycomb-lattice Mn$_2$V$_2$O$_7$*  

HUNG-CHENG WU (Presenter), DONG-JIE HSIEH, TSUNG-WEN YEN, PO-JUNG SUN, D. CHANDRASEKHAR KAKARLA, Department of Physics, National Sun Yat-sen University, JIM-LONG HER, Division of Natural Science, Center for General Education, Chang Gung University, Y. H. MATSUDA, Institute for Solid State Physics, University of Tokyo, CHUNG-KAI CHANG, YU-CHUN CHUANG, YEN-CHUNG LAI, National Synchrotron Radiation Research Center, MELISSA GOOCH, LIANGZI DENG, Texas Center for Superconductivity and Department of Physics, University of Houston, KYLE GRANT WEBBER, Department of Materials Science and Engineering, Friedrich-Alexander Universität Erlangen-Nürnberg, CHING (PAUL) W CHU, Texas Center for Superconductivity and Department of Physics, University of Houston — The dielectric and magnetic anomalies were observed in Mn$_2$V$_2$O$_7$ between 275 K and 300 K. Isothermal capacitance-stress hysteresis loop measurements along with crystallographic Aizu notation supported a martensitic phase transition ($T_M$) driven ferroelastic behavior near room temperature. Another dielectric anomaly was also observed near the long-range antiferromagnetic (AFM) ordering temperature ($T_N \sim 16.4$ K) along with noticeable magnetodielectric (MD) coupling below $T_N$, signifying the multiferroic nature of Mn$_2$V$_2$O$_7$. With increasing pressure, the antiferromagnetic ordering ($T_N$) greatly increased, while the ($T_M$) was suppressed. Taking all of these comprehensive research findings into account, we suggest that Mn$_2$V$_2$O$_7$ is a unique multifunctional material with the coexistence of antiferromagnetic, antiferroelectric and ferroelastic orderings.

NMR study on the honeycomb-lattice antiferromagnet Na$_2$Co$_2$TeO$_6$  

WEIQIANG YU (Presenter), ZE HU, Renmin Univ of China, YUAN LI, WEILIANG YAO, Peking University — The honeycomb-lattice magnetic materials have caused a lot of research interests recently, because of possible realization of Kitaev or proximate Kitaev quantum spin liquid in these systems. Na$_2$Co$_2$TeO$_6$, as a new honeycomb-lattice antiferromagnet, has a zigzag magnetic order which can be suppressed by magnetic field. Here we report our NMR studies on Na$_2$Co$_2$TeO$_6$ single crystals, and show rich properties revealed in this system both at zero field and at finite fields.
1:39PM M46.00013: Cooperative liquid-like paramagnetic state in nanoengineered honeycomb lattice*  GEORGE YUMNAM (Presenter), YIYAO CHEN, JIASEN GUO, Univ of Missouri - Columbia, HAILE ARENA AMBAYE, VALERIA LAUTER, Oak Ridge National Laboratory, DEEPAK K SINGH, Univ of Missouri - Columbia — Geometrically frustrated honeycomb structured artificial magnetic lattice has emerged as a testbed to explore the competing physics of energy vs. entropy in a thermally tuned magnetic phase transition. A magnetic honeycomb lattice with competing exchange interactions between Ising moments is theoretically predicted to exhibit disordered magnetic state with macroscopic degeneracy. We demonstrate the realization of a liquid-like magnetic state, comprised of low integer and energetically forbidden high integer magnetic charges, in nanostructured magnetic honeycomb lattice of ultra-small, sub-12 nm, connecting elements. Magnetic charges, related to magnetic moment and interacting via magnetic Coulomb's interaction, act as quantum mechanical entities. Detailed polarized neutron reflectometry measurements on magnetic honeycomb reveal a robust degenerate ground state at low temperature, which remains minimally affected by magnetic field application. Our finding provides a new vista to investigate quantum mechanical phenomena from the perspective of dynamic magnetic charges, instead of magnetic moments, in a classical system.

*The research at MU is supported by the U.S. Department of Energy, Office of Basic Energy Sciences under Grant No. DE-SC0014461.

1:51PM M46.00014: Field induced phase transition in the classical honeycomb Gamma model  ZHONGZHENG TIAN (Presenter), ZHIJIE FAN, PREETHA SAHA, GIA-WEI CHERN, Physics, University of Virginia — Recent studies have indicated the importance of the symmetric anisotropic exchange interaction, also called the Γ term, in the so-called Kitaev materials. Moreover, a new type of classical spin liquid was shown to be the ground state of the classical Γ model on the honeycomb lattice [1]. In our previous paper [2], we further demonstrated that thermal order-by-disorder drives the system toward a novel plaquette ordering that spontaneously breaks the lattice translation symmetry. In this work, we study the effects of magnetic field on the plaquette-ordered state. Our extensive Monte Carlo simulations uncover a field-induced phase transition above which the $\sqrt{3}\times\sqrt{3}$ flux order is replaced by a new spin order. We will present our characterization of this intermediate phase and discuss the nature of the phase transitions. [1] I. Rousochatzakis and N. B. Perkins, Phys. Rev. Lett. 118, 147204 (2017). [2] P. Saha, Z. Fan, D. Zhang, and G.-W. Chern, Phys. Rev. Lett. 122, 257204 (2019).

Session M47 GMAG DMP: Dynamics of Skyrmions and Chiral Magnetic Textures 710/712 - Sonny H. Rhim, Univ of Ulsan - Tag(s): Focus
In ferromagnet systems, engineered interfaces can give rise to the chiral Dzyaloshinskii-Moriya interaction (DMI) in otherwise symmetric systems. Research has primarily focused on the study of chiral solitons in metallic systems, where heavy metal underlayers provide a large spin-orbit torque and an interfacial DMI. This resulted in extensive research of chiral solitons in ferromagnetic systems. However, damping in metals is generally high, which limits soliton mobility. The low damping and ferrimagnetic dynamics of insulating garnets make them ripe candidates for ultrafast spin textures. Moreover, spin-orbit effects and spin-transport phenomenon from adjacent heavy metal layers have been used to manipulate the magnetisation in these materials. Here, we use a pure spin current from an adjacent Pt overlayer to characterise chiral domain wall motion and DMI in epitaxial iron garnet films with perpendicular magnetic anisotropy. We use the significant interfacial DMI and a large spin-orbit torque to drive chiral domain walls to record velocities of a few thousand meters per second.

11:27AM M47.00002: Universal high-speed dynamics of distorted bubble skyrmions in an uncompensated amorphous ferrimagnet*  
KAI LITZIUS (Presenter), FELIX BUETTNER, ANGELA WITTMANN, Massachusetts Institute of Technology MIT, WEI ZHOU, CHUNG T MA, Department of Physics, University of Virginia, JOACHIM GRAEFE, NICK-ANDRÉ TRAEGER, Max Planck Institute for Intelligent Systems, SIMONE FINIZIO, Swiss Light Source, Paul Scherrer Institut, DANIEL SUZUKI, SIYING HUANG, LUCAS CARETTA, MANTAU HUANG, Massachusetts Institute of Technology MIT, YASSINE QUESSAB, Department of Physics, New York University, HANS NEMBACH, GRANT A RILEY, JUSTIN SHAW, Quantum Electromagnetics Division, National Institute of Standards and Technology, ANDREW KENT, Department of Physics, New York University, GISELA SCHUETZ, Max Planck Institute for Intelligent Systems, JOSEPH POON, Department of Physics, University of Virginia, GEOFFREY BEACH, Massachusetts Institute of Technology MIT — Magnetic skyrmions are topologically stabilized spin configurations that, like domain walls (DWs), can react to external stimuli by collective displacement, which is both physically intriguing and bears promises to realize next generation non-volatile data storage technologies.

Analytical equations of motion describe straight 180° DWs in the one-dimensional (1D) model while rigid, circular bubble domains and skyrmions move according to the Thiele equation. However, DWs and skyrmions are often not perfectly straight or circular.

Here, we study how strongly deformed DWs and bubble skyrmions move in uncompensated ferrimagnetic Pt/CoGd/W in response to current pulses. We find that all 1D spin textures exhibit velocity saturation at ~300 m/s in agreement with the 1D model, while all fully enclosed spin textures, even if significantly distorted, reach >500 m/s. We attribute this significant difference in the dynamics to the topology and the canting of spins in the skyrmion's encircling DWs.

*DARPA TEE program. Devices were fabricated using equipment in the MIT Microsystems Technology Laboratory and the MIT Nanostructures Laboratory.

11:39AM M47.00003: Chiral Edge Currents for ac Driven Skyrmions in Confined Pinning Geometries  
CHARLES REICHHARDT (Presenter), CYNTHIA REICHHARDT, Los Alamos Natl Lab — We show that ac driven skyrmion lattices in a weak pinning channel confined by regions of strong pinning exhibit edge transport carried by skipping orbits while skyrmions in the bulk of the channel undergo localized orbits with no net transport. The magnitude of the edge currents can be controlled by varying the amplitude and frequency of the ac drive or by changing the ratio of the Magnus force to the damping term. We identify a localized phase in which the orbits are small and edge transport is absent, an edge transport regime, and a fluctuating regime that appears when the ac drive is strong enough to dynamically disorder the skyrmion lattice. In some cases, multiple rows of skyrmions participate in the transport due to a drag effect from the skyrmion-skyrmion interactions. The edge currents are robust for finite disorder and should be a general feature of skyrmions interacting with confined geometries or inhomogeneous disorder under an ac drive. Similar effects can occur for skyrmion lattices at interfaces or along domain boundaries for multiple coexisting skyrmion species. The edge current effect provides a new method to control skyrmion motion that has similarities to the emergence of edge currents in chiral active matter systems and gyroscopic metamaterials.
11:51AM M47.00004: Antiferromagnet-based Neuromorphics using dynamics of topological charges*

SHU ZHANG (Presenter), YAROSLAV TSERKOVNYAK, Physics, University of California, Los Angeles — Compared with conventional computers, the human brain is extremely energy efficient and can perform complicated cognitive tasks. Spintronics-based hardware implementations of neuromorphic computing has several advantages, such as low energy dissipation, consistent material platform, and nonvolatile memory. In this work, we propose a new candidate for neuromorphic hardware based on the dynamics of topological charges in an antiferromagnet. The two basic elements—neuron and synapse—are realized and we demonstrate their functionalities that are crucial to form a spiking neural network. A single magnetic domain exhibits binary switch and performs leaky integrate-and-fire as a neuron. A synapse with spike-timing-dependent plasticity is realized by a one-dimensional interacting gas of domain walls, where the synaptic weight is simply the degree of saturation of domain walls. Due to the full compatibility of our artificial neurons and synapses, Hebbian learning can be achieved by simple action rules in the connected system.

*This work is supported by NSF under Grant No. DMR-1742928.

12:03PM M47.00005: Three-dimensional current-induced magnetic hopfion dynamics*

JIADONG ZANG (Presenter), Univ of New Hampshire, YIZHOU LIU, Institute of Physics, CAS — Magnetic hopfions are three-dimensional (3D) topological spin textures characterized by the Hopf invariant. As manifesting by their 3D real-space topologies, magnetic hopfions may exhibit interesting dynamics. Here, we study the current-induced dynamics of a magnetic hopfion in 3D space. The current mainly drives a translational hopfion motion. Depending on the applied current direction, hopfion also shows different moving patterns. We then analyze the equation of motion and find these current-induced dynamics further reflect the 3D nature of hopfion. Such 3D hopfion dynamics may shed light on the study of novel 3D topological spin textures and provides a new pathway to the development of 3D spintronics.

*U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award No.DE-SC0020221
Skyrmions have been suggested for a variety of applications including memory but in particular also non-conventional computing such as probabilistic computing [1]. A key problem for probabilistic computing is that cascading gates propagate undesired correlations. Therefore one needs to reshuffle the signals to keep them uncorrelated. While for many non-conventional computing approaches non-magnetic implementations are most promising, for building a “reshuffler”, skyrmions might be ideally suited due to the low footprint and low power compared to e.g. CMOS implementations [1]. We have studied low skyrmion pinning materials where we can stabilize skyrmions and controllably nucleate and displace them by current pulses due to spin-orbit torques [2]. We find topologically non-trivial N=1 skyrmions that move in the direction of the current pulses. At zero applied current, we find thermally activated skyrmion motion. We track the trajectories of skyrmions and from the dependence of their mean-square-displacement (MSD) on time, we can identify motion by diffusion and obtain the diffusion constant [2]. There is a strong dependence of the skyrmion diffusion parameter on temperature and the skyrmion size. Finally we patterning the reshuffler geometry and ascertain its performance.

Beyond ferromagnetic skyrmions, we are evaluating the efficiency of skyrmion spin structures in antiferromagnets, which have major advantages. In addition to the absence of a skyrmion Hall effect [3], also antiskyrmions can be stabilized for which first indications have been found.

*We thank in particular the ERC, the German Research Foundation and the IEEE Magnetics Society Distinguished Lecturer Program.
NICOLAS VIZARIM (Presenter), CHARLES REICHHARDT, T4, Los Alamos National Laboratory, CYNTHIA REICHHARDT, T1, Los Alamos National Laboratory, PABLO A. VENEGAS, Departamento de Física, UNESP — In this work we simulate the dynamic behavior of skyrmions under the influence of a square lattice of obstacles [1,2]. First, we consider a single skyrmion while varying the size and strength of the obstacles. We find that as the obstacle size is changed, several dynamic phases may appear or vanish. For smaller obstacles, the system exhibits fewer dynamic phases because as the obstacle size is reduced. On the other hand, if the obstacle size is too large, the system may also exhibit fewer dynamic phases due to the reduction in the size of the gaps between the obstacles, which confines the skyrmion motion. Thus, the highest number of dynamic phases appears for intermediate obstacle sizes. Motivated by these results, we consider the behavior of skyrmions of different species [3] under the influence of the square obstacle array. Our preliminary results indicate that is possible to separate the species according to their different skyrmion Hall angles when a driving current is applied.

*This work was supported by the São Paulo Research Foundation (FAPESP), grant: 2018/13198-7

CHRISTINA PSAROUDAKI (Presenter), Physics, California Institute of Technology, DANIEL LOSS, Physics, University of Basel — We investigate the quantum depinning of a weakly driven skyrmion out of an impurity potential in a mesoscopic magnetic insulator. For small barrier height, the Magnus force dynamics dominates over the inertial one, and the problem is reduced to a massless charged particle in a strong magnetic field. The universal form of the WKB exponent, the rate of tunneling, and the crossover temperature between thermal and quantum tunneling is provided, independently of the detailed form of the pinning potential. The results are discussed in terms of macroscopic parameters of the insulator Cu2OSeO3 and various skyrmion radii. We demonstrate that small enough magnetic skyrmions, with a radius of ~10 lattice sites, consisting of some thousands of spins, can behave as quantum objects at low temperatures in the mK regime [1].

1:15PM M47.00009: Thermal Decay of a Single Néel Skyrmion via Helicity Slip in a Nanodisk  
NAVEEN SISODIA, PRANABA MUDULI (Presenter), Department of Physics, Indian Institute of Technology, Delhi — Dynamics of the decay of a single skyrmion confined in a ferromagnetic nanodisk in the presence of stochastic thermal noise are studied using micromagnetic simulations. By analyzing the time-varying oscillations of the in-plane and out-of-plane magnetization under the influence of the thermal field, we identified the presence of two skyrmion eigenmodes with frequencies differing by an order of magnitude— a low-frequency mode associated with gyration of skyrmion core, and a high-frequency breathing mode associated with the oscillations of the skyrmion radius. We show that the thermal fluctuations not only affects the topological charge but also the helicity of the skyrmion, changing the helicity to oscillate around ±π/4—a value which is in between that of the Néel skyrmion and a vortex. We also reveal a phenomenon of helicity slip between +π/4 and -π/4 due to the thermal fluctuations. We explain the helicity slip based on an energy barrier that arises due to a combination of thermally induced deformation of skyrmion and the finite size of the disk.

1:27PM M47.00010: Electron Induced Massive Dynamics of Magnetic Domain Walls*  
HILARY HURST (Presenter), Joint Quantum Institute, National Institute of Standards and Technology, VICTOR GALITSKI, Joint Quantum Institute and Department of Physics, University of Maryland, TERO T HEIKKILÄ, Department of Physics and Nanoscience Center, University of Jyväskylä — We study the effect of conduction electrons on domain walls (DWs) in metallic, ferromagnetic nanowires. Using the Keldysh collective coordinate technique, we show how electrons act as an external bath and derive the Langevin equations of motion for a DW. The DW dynamics is described by two collective degrees of freedom: position and tilt-angle. The coupled Langevin equations therefore involve two correlated noise sources, leading to a generalized fluctuation-dissipation theorem (FDT). The DW response kernel due to electrons contains two parts: one related to dissipation via FDT, and another ‘inertial' part. We prove that the latter term leads to a mass for both DW degrees of freedom, even though the intrinsic bare mass is zero. The resulting equations of motion contain rich dynamical solutions and point toward a new way to control domain wall motion in metals via the electronic system properties. We discuss experimental consequences including two observable signatures of the mass: hysteresis in the DW dynamics and resonant response to ac current.

1:39PM M47.00011: Fast, low-power defect-induced polarity switching of a magnetic vortex core* MAHDI MEHRNIA (Presenter), JEREMY N TRIMBLE, Physics, Case Western Reserve University, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, JESSE BEREZOVSKY, Physics, Case Western Reserve University — The core polarity of a topologically-protected magnetic vortex state is predicted to be extremely stable, and as such is considered as a candidate for non-volatile memory storage. However, here we show that the vortex core (VC) polarity is susceptible to rapid, repeatable switching even under low-amplitude motion. We excite vortices in thin permalloy disks with a magnetic field pulse, and observe the dynamic response using 3D time-resolved Kerr microscopy. In as-fabricated samples, we observe typical gyrations of the VC as it relaxes back to equilibrium. However, we observe a radically altered VC trajectory as prolonged pulsed laser exposure begins to change the VC pinning behavior near the disk center. In this region, the sense of gyration switches multiple times over tens of nanoseconds, indicating highly deterministic switches of the VC polarity that remain clear over >10^6 averaged repetitions. By translating the VC equilibrium position, we can tune the number of switches to zero, or obtain single deterministic switches using field pulses of less than 0.5 mT amplitude and 3 ns duration. Finally, we show simulation results of VC-defect interaction that shed light on this phenomenon.

1:51PM M47.00012: Energy Storage in Spin System via Vortices DALTON JONES (Presenter), JI ZOU, YAROSLAV TSERKOVNYAK, University of California, Los Angeles — We formulate an energy-storage concept based on the topological spin textures in magnetic insulators. These textures, such as vortices, are metastable states associated with free energy. Here we propose to store energy in the topological texture of an XY ferromagnetic or antiferromagnetic annulus with easy plane anisotropy. Injecting vortices into the system will establish a net winding texture (energy density) within the bulk as vortices pass through the magnetic system. Once we complete the charging process, we can turn off the vortex conductivity and thus the energy associated with the winding texture is stored.
M47.00013: Current-driving skyrmion motion in inhomogeneous films* XIANG RONG WANG (Presenter), Physics, Hong Kong University of Science and Technology, HUAIYANG YUAN, Physics, Southern University of Science and Technology, XIN GONG, Physics, Hong Kong University of Science and Technology — In this talk, I will discuss current-driven skyrmion motion in disordered films. There are three phases: pinning phase, disorder-boosted transverse motion, and disordered-suppressed transverse motion. I will focus on the origin of the transverse motion boosting. Random potential landscape generate a force on a skyrmion. The force is perpendicular to the current direction when the skyrmion is pinned. The disorder-induced force is opposite to the skyrmion velocity when it is moving. Under a sufficient high current, disorders below a critical strength can boost the transverse skyrmion motion and hinder the longitudinal motion. The boosting comes mainly from the pinning force that is opposite to the driving force of the current. Skyrmions are pinned under a low current and above the critical disorder strength. Both transverse and longitudinal skyrmion motions are hindered at an intermediate current. The phase diagram will also be discussed.

Wednesday, March 4, 2020 11:15 AM - 2:03 PM

Session M48 DCMP: Superconductivity: Materials, Growth, Structure
Mile High Ballroom 1A - Ulrich Welp, Argonne Natl Lab

11:15AM M48.00001: An Investigation into the Characteristics of the Superconductive Phase in Heavily P-doped Germanium KASRA SARDASHTI (Presenter), TRI D NGUYEN, MEHDI HATEFIPOUR, JOSEPH YUAN, WILLIAM MAYER, JAVAD SHABANI, New York Univ NYU — Realization of superconductivity in group IV semiconductors is anticipated to be the key in the scalability of the qubit devices. Such materials are promising candidates for fault-tolerant hybrid semiconductor-superconductor quantum systems due to their high purity and ease of processing. In this study, superconducting Ge is realized via ion implantation of Ga, followed by activation annealing. For all annealing temperatures, transport measurements showed an abrupt normal-superconductor transitions at 2.5–3.5 K, with residual resistances < 50 mΩ at 20 mK. Typical values for critical magnetic fields were about 0.6 to 0.8 T, corresponding to coherence lengths of 20 to 25 nm. Microscopy measurements revealed presence of a 20nm thick polycrystalline Ga-rich Ge layer near the top surface. To localize the superconducting region, implantation energy was reduced. The resulting superconducting layer showed no grain structure in micrometer scale, but Raman measurements confirmed its nanocrystalline nature. By reducing the implantation energy and the annealing temperatures, coherence length only decreased to ~18 nm. To further characterize the superconducting Ge films, strategies for their integration into all-Ge Josephson junctions and transistors will be discussed.
**11:27AM M48.00002: Physical properties of Li-based LiPd$_2$M Heusler compounds (M = Si, Ge, Sn)**

KAROLINA GÓRNICKA, Faculty of Applied Physics and Mathematics, Gdansk University of Technology, GABRIEL KUDEROWICZ, BARTOMIEJ WIENDLOCHA, Faculty of Physics and Applied Computer Science, AGH University of Science and Technology, ELIZABETH M. CARNICOM, ROBERT J. CAVA, Department of Chemistry, Princeton University, TOMASZ KLIMCZUK (Presenter), Faculty of Applied Physics and Mathematics, Gdansk University of Technology — We synthesized and studied LiPd$_2$M, M = Si, Ge and Sn, Heusler-type compounds. All three compounds crystallize in the cubic Fm-3m crystal structure with estimated lattice parameters $a = 5.9016$ Å (LiPd$_2$Si), 6.0105 Å (LiPd$_2$Ge) and 6.2642 Å (LiPd$_2$Sn). The compounds were characterized by means of magnetic susceptibility, heat capacity and resistivity. For LiPd$_2$Ge bulk transition was confirmed by a large HC anomaly at $T_c = 1.96$ K. Fitting the HC data yields $\gamma = 5.8$ mJ mol$^{-1}$ K$^{-2}$ and $\Theta_D = 244$ K. The electron-phonon coupling $\lambda_{e-p} = 0.53$ implies weak-coupling superconductivity. Electronic structure, phonons and electron-phonon interaction functions were computed using the density functional theory. LiPd$_2$Ge exhibits the strongest electron-phonon coupling within the studied series, in agreement with the observation of superconductivity. In all the compounds a phonon soft mode is found in the $\Gamma$-K direction, and it is most pronounced in the case of the superconducting LiPd$_2$Ge, which suggests its correlation with the electron-phonon interaction.

*The work at GUT and AGH-UST was supported by the National Science Center (Poland), project 2017/27/B/ST5/03044 and 2017/26/E/ST3/00119, respectively. At Princeton it was supported by the DOE, Division of Basic Energy Sciences, grant DE-FG02-98ER45706.

**11:39AM M48.00003: Layered tin pnictides as a new class of layered superconductors**

YOSUKE GOTO (Presenter), YOSHIKAZU MIZUGUCHI, Tokyo Metropolitan Univ — We report SnPn-based (Pn: pnictogen) materials as a new class of layered superconductors. The crystal structure of these compounds is characterized by two layers of a buckled honeycomb network of SnPn, bound by the van der Waals (vdW) forces and separated by Na ions. Measurements of electrical resistivity and specific heat indicate the bulk nature of superconductivity with transition temperature ($T_c$) of 1.3 K for NaSn$_2$As$_2$ and 2.0 K for Na$_{1-x}$Sn$_2$P$_2$ [1,2]. Recent studies on temperature-dependent magnetic penetration depth and thermal conductivity show that superconductivity of NaSn$_2$As$_2$ is fully gapped s-wave state in the dirty limit. Because there are various structural analogues containing SnPn conducting layers, our results indicate that SnPn-based layered compounds can be categorized into a novel family of layered superconductors. Furthermore, these compounds have also been gaining interest for application as thermoelectric materials and topological materials. In the conference, we will also report our recent progress for the studies on functionalities of SnPn-based layered materials.

11:51AM M48.00004: Interface superconductivity in complex metal-oxide heterostructures

PRIYANKA BROJABASI (Presenter), GUILLAUME HARDY, PATRICK FOURNIER, Universite de Sherbrooke — Interface superconductivity in oxide superstructures (SS) proposes new paths to explore further the mechanism for high-\(T_c\) superconductors allowing the manipulation of their electronic properties, but also discovering novel *artificial* materials [1], e.g., electron transfer from \(\text{LaFeO}_3\) (LFO) to electron-doped \(\text{Sm}_2\text{CuO}_4\) was explored in SS grown by RF sputtering [2]. In the present study, we have grown SS of infinite-layer \(\text{SrCuO}_2\) (SCO) and LFO as well as SS of electron-doped (Sr,Nd)\(\text{CuO}_2\) (SNCO) and LFO by pulsed-laser deposition with various thicknesses and annealing conditions. The coherent growth of SCO/LFO and SNCO/LFO SS has been confirmed by X-ray diffraction. Resistivity and Hall effect measurements confirm superconductivity in selected samples of SNCO/LFO SS, but no superconductivity and little doping by charge transfer has been observed in SCO/LFO SS. However, we observe a strong correlation between the critical temperature and the thickness of the SS subcomponents for SNCO/LFO SS. Our findings indicate that charge transfer may not be playing a significant role behind the superconductivity in these structures.

*We acknowledge the financial support from NSERC, FRQ-NT, CFREF and CFI.

12:03PM M48.00005: Electron-Hole Competition and Structural Response in the Two-Band Superconductor \(\text{Nb}_2\text{Pd}_x\text{Se}_5\) *

JENNIFER NEU (Presenter), DAVID E GRAF, KAYA WEI, Natl High Magnetic Field Lab, ALYSSA GAISER, Chemistry and Biochemistry, Florida State Univ., YAN XIN, Natl High Magnetic Field Lab, THOMAS ALBRECHT-SCHMITT, Chemistry and Biochemistry, Florida State Univ., RYAN BAUMBACH, Natl High Magnetic Field Lab, DAVID J SINGH, Physics, Univ. of Missouri, THEO SIEGRIST, Natl High Magnetic Field Lab — The superconducting properties of \(\text{Nb}_2\text{Pd}_x\text{Se}_5\) are highly dependent on the Pd stoichiometry. We have synthesized single crystals of \(\text{Nb}_2\text{Pd}_x\text{Se}_5\) with \(x\) in the range of 0.68 to 0.96 and have carried out detailed single crystal x-ray structural studies. We observe a pivotal shift in the atomic positions that depend on palladium occupancy at the threshold for superconductivity. We will discuss the crystal growth process, our recent findings of the subtle but profound structural changes, and present the rich spectrum of electronic behavior observed for different Pd occupancy regions. At the threshold Pd stoichiometry for superconductivity, a miscibility gap is apparent, with commensurate change in the electronic transport properties. Electron-hole competition in this two-band system is thought to be responsible for this behavior.

Characterizing the penetration depth and coherence length of superconductor-normal superlattices

PATRICK QUARTERMAN (Presenter), National Institute of Standards and Technology, NATHAN SATCHELL, Michigan State University, BRIAN JAMES KIRBY, National Institute of Standards and Technology, REZA LOLOEE, Michigan State University, GAVIN BURNELL, University of Leeds, NORMAN BIRGE, Michigan State University, JULIE ANN BORCHERS, National Institute of Standards and Technology — Ferromagnetic Josephson junctions are a viable candidate for a low power cryogenic memory alternative compared to traditional CMOS technologies. There have been many reports concerning the supercurrent passing through the Josephson junction, including the discovery of spin triplet Cooper pairs in these systems [1]. Previously, we have found that by replacing the bottom Nb layer with a Nb/Al or Nb/Au superlattice, where the Al and Au layers are quite thin, the surface roughness is reduced compared to Nb. This decrease in surface roughness yields improved areal dependence of the critical current [2]. Previously, the effects on the penetration depth and coherence length from the insertion of a thin normal metal between Nb layers have not been fully explored, given that the use of such superlattices in Josephson junctions yielded behavior that was consistent with Nb. In this work, we report on our observation of an increased penetration depth and decreased coherence length in Nb/Al and Nb/Au superlattices utilizing polarized neutron reflectometry and electrical transport, respectively.

Study of electronic properties and mechanical dissipation in epitaxially grown La$_{2-x}$Sr$_x$CuO$_4$ thin films using scanning probe microscopy*

LARISSA LITTLE (Presenter), Harvard University, XUGUANG WANG, Institute of Physics, Chinese Academy of Sciences, WENJIE GONG, DILEK YILDIZ, JASON HOFFMAN, JENNIFER E. HOFFMAN, Harvard University — Understanding interplay between the superconducting dome and adjacent phases is important to better design and manipulate superconductors with high critical temperatures. Here we use the techniques of non-contact atomic force microscopy (nc-AFM) and scanning tunneling spectroscopy (STS) in ultrahigh vacuum to characterize thin films of La$_{2-x}$Sr$_x$CuO$_4$ (LSCO). We grow the LSCO with molecular beam epitaxy and an oxygen plasma source. We produce high quality LSCO (001) samples with precise control over Sr doping level and choose the level of epitaxial strain our films experience by using different substrates (e.g., SrTiO$_3$ or LaSrAlO$_4$). We use nc-AFM to measure excitation and frequency shift as a function of tip distance from the surface and applied voltage bias. These measurements give us insight into the electronic nature of our films, as well as information about how energy dissipates into the sample.

*Work supported by the STC Center for Integrated Quantum Materials, NSF Grant No. DMR-1231319, Gordon and Betty Moore Foundation’s EPIQS Initiative through Grant No. GBMF4536, Office of Naval Research, Grants N00014-18-1-2691 and N00014-19-1-2622. LL supported by the Department of Defense (DoD) through the National Defense Science & Engineering Graduate Fellowship (NDSEG) Program.
12:39PM M48.00008: Acoustic Phonon Dynamics and Optical Properties of Bi-2212 Crystals
BRAD MCNIVEN (Presenter), G. TODD ANDREWS, JAMES P. F. LEBLANC, Memo Univ of Newfoundland — Acoustic phonon behaviour and optical properties of bulk Bi-2212 crystals at room temperature were probed using Brillouin light scattering spectroscopy and refined optical contrast methods. Values for the complex refractive index at a wavelength of 532 nm are presented and, along with Brillouin peak frequency shift data, used to determine transverse and longitudinal acoustic phonon mode velocities in these crystals.

12:51PM M48.00009: Electron counting and chemical complexity in the Ta-Nb-Hf-Zr-Ti HEA superconductors
FABIAN VON ROHR (Presenter), Department of Chemistry, University of Zurich, ROBERT J. CAVA, Department of Chemistry, Princeton University — High-entropy alloys (HEAs) are a new class of materials that consist of several principal elements arranged on simple lattices. These structures are stabilized by the high configurational entropy of the random mixing of the elements. The recently discovered Ta-Nb-Hf-Zr-Ti HEA superconductor appears to display properties of both crystalline intermetallics and amorphous materials; e.g., it has a well-defined superconducting transition along with an exceptional robustness against disorder. In this presentation, we will show that the properties of these superconducting HEAs are strongly related to the electron count and that the $T_c$s of these alloys fall between those of analogous crystalline and amorphous materials [1-3]. We find that despite the large degree of randomness and disorder in HEAs, the superconducting properties are nevertheless strongly dependent on the chemical composition and complexity. We argue that HEAs are excellent model systems for understanding how superconductivity evolves from crystals to amorphous solids.

1:03PM M48.00010: Enhancement of Superconductivity in Monolayer NbSe$_2^*$

HEMIAN YI (Presenter), TIMOTHY PILLSBURY, RUN XIAO, FEI WANG, CHENGYE DONG, YIFAN ZHAO, GUANG WANG, LINGJIE ZHOU, LING ZHANG, JOSHUA ROBINSON, MOSES HUNG-WAI CHAN, NITIN SAMARTH, CUI-ZU CHANG, Pennsylvania State University — The superconducting transition temperature of single unit cell FeSe on SrTiO$_3$ (STO) heterostructure is known to be significantly enhanced over that of bulk FeSe, presumably due to a combination of the electron charge transfer from the STO substrate to FeSe and an enhanced electron-phonon interaction across the heterointerface. Here, we explored the possibility of similar physics in monolayer NbSe$_2$ on $n$-type and $p$-type graphene substrates and found that the transition temperature is much higher in the latter heterostructures than in the former ones. The enhancement of superconductivity in monolayer NbSe$_2$ on $p$-type graphene is likely a result of the charge transfer effect. We also studied the temperature dependence of the resistance of NbSe$_2$ under an in-plane magnetic field. The extracted in-plane upper critical field of monolayer NbSe$_2$ overcomes the Pauli paramagnetic limit, suggesting Ising pairing property. We will talk about the properties of monolayer NbSe$_2$ films grown on other oxide substrates.

*This work is supported by the NSF-CAREER awards (DMR-1847811 and DMR-1453924), DOE (#DE-SC0019064), the Alfred P. Sloan Research Fellowship, and NSF 2DCC-MIP (DMR-1539916).

1:15PM M48.00011: MBE synthesis, ARPES and STM characterization of DyBa$_2$Cu$_3$O$_{7-\delta}$ thin films*

ZEBIN WU (Presenter), Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, DANIEL PUTZKY, Max Plank Institute for Solid State Research, ASISH KUNDU, HUI LI, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, GENNADY LOGVENOV, BERNHARD KEIMER, Max Plank Institute for Solid State Research, KAZUHIRO FUJITA, TONICA VALLA, ILYA DROZDOV, Condensed Matter Physics and Materials Science, Brookhaven National Laboratory — Growth and characterization of HTSC cuprate DyBa$_2$Cu$_3$O$_{7-\delta}$ has been achieved in an OASIS system[1], combining together ozone-assisted oxide molecular beam epitaxy (OMBE), angle-resolved photoemission spectroscopy (ARPES), and spectroscopic-imaging scanning tunneling microscopy (SI-STM). Superconducting transition temperature (Tc) of over 80K measured in mutual inductance can be routinely achieved by shuttering via a real-time feedback from RHEED in OMBE. Leveraging on the synergistic capabilities of the instrument, the in-situ grown DyBa$_2$Cu$_3$O$_{7-\delta}$ are transferred in-vacuo into ARPES and SI-STM modules for characterization of their electronic properties. Dispersing quasi-particles are observed in photoemission and superconductivity is confirmed in tunneling spectroscopy.

*This work was supported by the US Department of Energy, Office of Basic Energy Sciences, contract no. DE-SC0012704.
1:27PM M48.00012: Growth and electrical transport properties of (110) YBa$_2$Cu$_3$O$_7$ / (110) PrBa$_2$(Cu$_{0.8}$Ga$_{0.2}$)$_3$O$_7$ heterostructure*  
HOM KANDEL (Presenter), NATHAN D ARNDT, Physics, University of Wisconsin-Parkside, JUNGWOO LI, CHANG-BEOM EOM, Materials Science & Engineering, University of Wisconsin-Madison — We performed pulsed laser-based thin film deposition and study of electrical transport properties on (110)-oriented YBa$_2$Cu$_3$O$_7$ (YBCO)/ (110)-oriented PrBa$_2$(Cu$_{0.8}$Ga$_{0.2}$)$_3$O$_7$ heterostructure for the nanofabrication of Superconductor (S) / Insulator (I) / Superconductor (S) tunneling Josephson junction device which may have many advantages over the conventional low-temperature superconductor-based Josephson junction devices including low cost, cryogenic system simplicity, and high $I_cR_n$ product (with $I_c$ being the junction critical current and $R_n$ the normal resistance). X-ray diffraction pattern (XRD) analysis, atomic force microscopy (AFM), and electrical transport studies were carried out to check the orientation, thickness, roughness, surface morphology, critical temperature ($T_C$), and electrical resistivities of the heterostructures. Here, we report the optimization process for the layer by layer growth, multi-layer epitaxy, thickness control of the superconductor and insulator layers, and the electrical transport properties of the (110) YBa$_2$Cu$_3$O$_7$ / (110) PrBa$_2$(Cu$_{0.8}$Ga$_{0.2}$)$_3$O$_7$ heterostructure.

*This research was supported by WiSys and UW System Applied Research Grant (ARG 2019-2020).
1:39PM M48.00013: Magnetic and superconducting properties of the Ir - rich compounds

MIr₃ (M=Ce, Th and Nd)*

KAROLINA GÓRNICKA (Presenter), Faculty of Applied Physics and Mathematics, Gdansk University of Technology, ELIZABETH M. CARNICOM, Department of Chemistry, Princeton University, DEBARCHAN DAS, Institute of Low Temperature and Structure Research, Polish Acad. of Sci., SYLWIA GUTOWSKA, BARTOMIEJ WIENDLOCHA, Faculty of Physics and Applied Computer Science, AGH University of Science and Technology, WEIWEI XIE, Louisiana State University, ROBERT J. CAVA, Department of Chemistry, Princeton University, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Acad. of Sci., TOMASZ KLIMCZUK, Faculty of Applied Physics and Mathematics, Gdansk University of Technology — Recently we have synthesized and studied CeIr₃, NdIr₃ and ThIr₃ compounds that are members of the RE₂m+nT₄m+5n family (m, n > 0). The bulk nature of the superconducting transitions for CeIr₃ and ThIr₃ are evident from the visible anomalies at Tc = 2.5 K and 4.4 K, respectively. The heat capacity experiment revealed that CeIr₃ is a weak-coupling BCS superconductor and ThIr₃ is a moderately coupled type-II superconductor. Theoretical calculations indicate a multi-band character for the Fermi surfaces, with the dominating contribution to the density of states at the Fermi level coming from the 5d states of Ir.

In the case of NdIr₃, our measurements indicate a ferromagnetic ground state with the Curie temperature TC = 10.6 K. The heat-capacity anomaly confirms the bulk nature of the transition, though Cp = 11.7 J mol⁻¹K⁻¹ is lower than expected for J = 9/2 and instead close to that of a J = 1/2 system. This suggests that the Nd ions are subject to a crystalline electrical field that removes spin degeneracy and leaves the Nd ions in a doublet ground state.

*This work was supported by Ministry of Science and Higher Education (Poland) under project DI2016 020546. The work at Princeton was supported by the Department of Energy, Division of Basic Energy Sciences, Grant DE-FG02-98ER45706.
1:51PM M48.00014: Effects of heteroepitaxy on the crystal structure in superconducting DyBa$_2$Cu$_3$O$_{7-x}$ thin films*  DANIEL PUTZKY (Presenter), PADMA RADHAKRISHNAN, GEORG CHRISTIANI, PETER WOCHNER, YI WANG, PETER VAN AKEN, Gennady LOGVENOV, EVA BENCISER, BERNHARD KEIMER, Max Planck Institute for Solid State Research — High-quality DyBa$_2$Cu$_3$O$_{7-x}$ thin films were grown by molecular beam epitaxy (MBE). In contrast to the previous growth by MBE using co-deposition technique, we have employed an atomic-layer-by-layer shuttering sequence with in-situ RHEED feedback. Epitaxial films grown on various oxide substrates have a sharp superconducting transition above 80 K. Scanning-transition electron microscopy (STEM) shows atomically sharp substrate-film interfaces and the absence of stacking faults, unlike films previously grown by pulsed-laser deposition (PLD). We employed synchrotron-based X-ray diffraction (XRD) to determine structural differences imposed by the heteroepitaxy with substrates with varying lattice parameters and crystal symmetry. A particular focus was put on the investigation of twinning which usually occurs in bulk orthorhombic crystal structure. However, in thin films the orthorhombic twinning can be hindered while the films still remain superconducting.

*We thank the Deutsche Forschungsgemeinschaft (DFG) for financial support under Grant No. TRR 80, Project No. G1.

M48.00015: Properties of Superconducting R$_2$O$_2$Bi (R = Y, Er) with Anti-ThCr$_2$Si$_2$-type Structure*  ZHUAN XU (Presenter), Zhejiang University — A new family of bismuth compounds, R$_2$O$_2$Bi (R = Y, Ce and Er etc.) crystallized in the anti-ThCr$_2$Si$_2$-type structure where Bi ions form a square net, has attracted much attention because this family exhibits various interesting ground states including antiferromagnetic (AFM) order, heavy fermion behavior and superconductivity (SC). We have investigated two compounds Ce$_2$O$_2$Bi and Er$_2$O$_2$Bi by measuring transport and magnetic properties, as well as specific heat. While Ce$_2$O$_2$Bi behaves as a Kondo lattice and experiences an antiferromagnetic (AFM) transition at $T_N$ of about 6.7 K, Er$_2$O$_2$Bi is a superconductor with $T_c$ of 1 K. A coexistence of AFM and SC is found. There is a correlation between the oxygen content and $T_c$. This work offers a new candidate material for studying the interplay between SC and 4f electron magnetism.

*The work was supported by the National Key Projects for Research & Development of China (Contract No. 2016YFA0300402) and NSFC.

Wednesday, March 4, 2020 11:15 AM - 1:51 PM

Session M49 DCMP: Superconductivity: Devices and Applications  Mile High Ballroom 1B - Lei Wang, Yale University
11:15AM M49.00001: Development of NbTiN constriction junctions and superconducting quantum interference devices*  ANDREW J MILLER (Presenter), Sandia National Laboratories, CHARLES HARRIS, Sandia National Laboratories, Center for Integrated Nanotechnologies, RUPERT M LEWIS, Sandia National Laboratories, TZU-MING LU, Sandia National Laboratories, Center for Integrated Nanotechnologies — Superconducting Quantum Interference Devices (SQUIDs) have become a leading tool for magnetometry with a wide range of applications. In this work, we investigate the properties of NbTiN SQUIDs created with a patterned constriction junction. The NbTiN film was grown through reactive sputtering, and then patterned using e-beam lithography and ion milling. SQUIDs were fabricated with constrictions as narrow as 50nm across, and loop areas of approximately 1μm². At 250mK, field dependent voltage oscillations were observed up to .3T, with an effective area consistent with the physical dimensions of the device.

*This work was supported by the Laboratory Directed Research and Development Program at Sandia National Laboratories and was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government.

11:27AM M49.00002: Reducing 1/f flux noise in superconducting devices in situ with UV light.* SEAN O’KELLEY (Presenter), Lawrence Livermore Natl Lab, MATTHEW S MARTENS, STEVEN M ANTON, Physics, UC Berkeley, J S BIRENBAUM, DAVID K KIM, JONILYN YODER, MIT-Lincoln Lab, GENE C. HILTON, NIST Bouder, WILLIAM OLIVER, MIT-Lincoln Lab, JOHN CLARKE, Physics, UC Berkeley — Magnetic flux noise with a 1/f power spectrum is pervasive in superconducting devices, and presents a fundamental limit to both the low-frequency energy resolution of dc SQUIDs and the high-frequency coherence of flux-sensitive superconducting qubits. Studies of the scaling of the magnitude of the flux noise with SQUID geometry are consistent with generation of the noise by fluctuating magnetic dipoles on the superconducting surface. Kumar et al. showed that the magnetic dipoles are adsorbed molecular oxygen, and reduced the noise with processes in a room-temperature hermetic sample enclosure. We demonstrate a factor of about three reduction of the 1/f flux noise power spectrum in Nb SQUIDs by applying 240-nm UV light from a Light Emitting Diode at cryogenic temperatures. Subsequent exposure of the SQUIDs to oxygen at atmospheric temperature and pressure restored the flux noise to its original value. Re-exposure to UV at cryogenic temperatures again reduced the flux noise. These results are consistent with molecular oxygen being the source of the noise. Our work demonstrates a practical technique to reduce the flux noise of superconducting devices in situ.

11:39AM M49.00003: Integration of two-dimensional transition-metal dichalcogenide superconductors into superconducting circuits operated at DC and GHz frequencies*

MICHAEL SINKO (Presenter), Carnegie Mellon Univ, OLIVIA LANES, Physics and Astronomy, University of Pittsburgh, SERGIO DE LA BARRERA, Physics, Massachusetts Institute of Technology, DAVID PEKKER, MICHAEL JONATHAN HATRIDGE, Physics and Astronomy, University of Pittsburgh, BENJAMIN HUNT, Carnegie Mellon Univ — Two-dimensional (2D) transition-metal dichalcogenide (TMD) superconductors have unique and desirable properties for integration with conventional superconducting circuits, including the ability to form atomically-flat and clean interfaces with stable tunnel barriers, increased kinetic inductance due to the atomically-thin geometry, and resilience to large in-plane magnetic fields. We created 2D-3D Josephson junction contacts with R=0 and critical currents between 0.15uA-128uA. We study the flux response and observe a Fraunhofer pattern with a frequency proportional to a large fraction of the area of the 2D superconductor. This experimental result is confirmed by our numerical modeling, using the Ginzburg-Landau equation to describe screening currents induced in the flake by the magnetic field. We attribute the large effective area and small distortions of the Fraunhofer pattern to the almost uniform penetration of the TMD by the magnetic field and the distribution of screening currents. We have also embedded these 2D-3D contacts in an RF tank circuit (Q>4000) to measure the kinetic inductance. Our work lays the foundation for the analysis of TMD nano-devices in superconducting circuits.

11:51AM M49.00004: A quantum heat switch based on a single driven qubit*  CYRIL ELOUARD (Presenter), University of Rochester, GEORGE THOMAS, JUKKA P PEKOLA, Department of Applied Physics, Aalto University, ANDREW N JORDAN, University of Rochester — With the growing interest to nano and quantum technologies, a lot of attention has been paid to the challenge of controlling the heat currents at the nanoscale. Here we study the photonic heat transfer through a coherently driven qubit coupled to a hot and cold baths and show that such setup behaves as a quantum heat switch. More precisely, the heat flow from the hot bath can be activated or completely suppressed varying the parameters of the drive, its intensity or its frequency. We show the complete suppression of the heat flow is a quantum effect occuring for specific drive parameters and analyze the role of the coherences in the free qubit energy eigenbasis. Such scheme can be tested in state-of-the-art circuit QED setups, e.g. involving a transmon qubit coupled to thermal resistances.

12:03PM M49.00005: Tunable photonic thermal rectification via superconducting qubit

AZAT GUBAYDULLIN (Presenter), BAYAN KARIMI, JORDEN L SENIOR, YU-CHENG CHANG, ALBERTO RONZANI, JOONAS PELTONEN, CHIIDONG CHEN, Aalto University, JOACHIM ANKERHOLD, Institute for Complex Quantum Systems and IQST, University of Ulm, JUKKA P PEKOLA, Aalto University — The intense studies into superconducting circuit quantum electrodynamics (QED) together with the progress in ultrasensitive nanoscale bolometry provide a unique platform for studying heat transport in the quantum limit. On chip integration of superconducting qubits coupled with superconducting resonators together with the tools of ultra-sensitive microwave bolometry have been considered as promising systems to realize such quantum devices as the recently demonstrated heat valve [1] and rectifier [2]. We will present our recent results of the flux-tunable photonic heat transport between thermal reservoirs coupled via a superconducting artificial atom. To study the possibility of manipulating heat currents and the directionality of photonic heat transport, we couple the Xmon qubit to two asymmetric resonators, and implement a flux-tunable wireless quantum thermal rectifier. We will present spectroscopy results of the resonator-qubit-resonator assembly [3].

12:15PM M49.00006: Multi-terminal superconducting quantum interference device

HANHO LEE (Presenter), NATALIA PANKRATOVA, ROMAN KUZMIN, KAUSHINI S WICKRAMASINGHE, University of Maryland, College Park, MAXIM G VAVILOV, University of Wisconsin-Madison, JAVAD SHABANI, New York University, VLADIMIR MANUCHARYAN, University of Maryland, College Park — External flux control of the superconducting phase difference is predicted to be a powerful tool to generate and manipulate Majorana bound states in a topological multi-terminal Josephson Junction (JJ). We study multi-terminal superconducting quantum interference devices (SQUID) fabricated from a semiconductor/superconductor (InAs/Al) heterostructure. Such a device consists of superconducting loops connecting some of terminals of a multi-terminal JJ. Due to non-local superconducting coherence, we observe for the first time an effect of “dragging” of the phase difference between one pair of terminals produced by the flux applied through the loop connecting two other terminals. Our ground state measurement implies the existence of novel multi-terminal Andreev bound states (ABS) which depend on more than two superconducting phase differences. Progress in tunneling spectroscopy of such states will also be discussed.
Synthesis of Quantum-Voltage Waveforms with Pulse-Driven High-$T_c$ Josephson Junctions

Josephson Junctions

ADAM WEIS (Presenter), NATHAN E FLOWERS-JACOBS, National Institute of Standards and Technology, STUART BERKOWITZ, Out of the Fog Research, LLC, HORST ROGALLA, SAMUEL P BENZ, National Institute of Standards and Technology — Josephson junctions (JJs) driven by a single-frequency microwave source have been established as quantum-accurate dc voltage standards [1]. Similar JJ devices are biased by patterns of fast pulses to create precise time-varying voltages [2], used for ac voltage standards and pseudo-random voltage noise references integrated into noise thermometry systems. Voltage standards typically use niobium-based JJs, but superconductors with higher-transition temperature, $T_c$, can be an attractive alternative. These high-$T_c$ JJ circuits can have critical currents near 1 milliamp at temperatures between 60 K and 80 K and thus can use compact low-power cryocoolers.

Investigation of high-temperature JJs in quantum voltage devices at NIST has focused primarily on grain-boundary junctions in YBa$_2$Cu$_3$O$_{7-x}$. By driving these high-$T_c$ junctions with pulse codes clocked at microwave frequencies we have demonstrated synthesis of programmable quantum-based voltage waveforms in a miniaturized cryocooler system. We'll also discuss relevant uncertainties, sensitivity of the output to bias currents, and applicability of this waveform-synthesis system to Johnson-noise thermometry.

Demonstration of a circuit-QED maser based on a nanowire Josephson junction*  

WILLEMIJN UILHOORN (Presenter), QuTech and Kavli Institute of Nanoscience, Delft University of Technology, MAJA C CASSIDY, Microsoft Quantum Lab Sydney, University of Sydney, JAMES KROLL, DAMAZ DE JONG, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, DAVID J. VAN WOERKOM, Microsoft Quantum Lab Delft, Delft University of Technology, PETER KROGSTRUP, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen and Microsoft Quantum Materials Lab Copenhagen, LEO P KOUWENHOVEN, Microsoft Quantum Lab Delft, Delft University of Technology — On-chip coherent microwave generation can be achieved by strongly coupling a dc biased Josephson junction to a high quality factor superconducting cavity [1]. The incorporation of a gate-tunable semiconducting nanowire Josephson junction in such a device enables fast control of the junction-cavity coupling and laser emission, paving the way for efficient scalable on-chip microwave control of superconducting qubits.

In these devices, the efficient down-conversion at higher order harmonics stimulates the creation of multiple coherent photons with a single Cooper pair tunneling event, increasing the phase coherence. However, performance is currently limited by incoherent dissipative processes such as quasiparticle poisoning (QPP) that suppress the laser coherence.

Here we report on the quenching of the coherence above the 4th order harmonic. We track the emission dynamics of the 5th order harmonic in time and observe emission blinking due to QPP events with characteristic timescales $T_{\text{poisoning}} = 200 \pm 10 \mu s$ and $T_{\text{unpoisoning}} = 17 \pm 2 \mu s$.

12:51PM M49.00009: Epitaxial Josephson junctions for superconducting qubits made by wafer-bonding* ANTHONY MCFADDEN (Presenter), University of California, Santa Barbara, COREY RAE MCRAE, RUICHEN ZHAO, DAVID PAPPAS, NIST, CHRIS J PALMSTROM, University of California, Santa Barbara — State-of-the-art transmons most often utilize Al/AIO_x/Al Josephson junctions (JJs) even though the amorphous AIO_x is known to be defective and lossy. A scalable process to realize epitaxial JJs with low loss barrier dielectrics could improve qubit performance beyond state-of-the-art; however, challenges in materials integration have not yet been overcome. In this work, a wafer-bonding technique is used to realize epitaxial JJ structures utilizing conventional semiconductors for the JJ dielectric. Semiconductors and epitaxial superconductors are grown by molecular beam epitaxy on III-V semiconductor substrates and bonded to low-loss substrates. Selective etching is used to remove the III-V substrate followed by surface cleaning and superconductor regrowth, resulting in epitaxial Al/Semiconductor/Al tri-layers on low loss substrates.

1:03PM M49.00010: Confluence of complex surface impedance and critical current studies of model defects in niobium films near critical temperature* COUGAR GARCIA (Presenter), Northrop Grumman & University of Maryland College Park, ALEX SIROTA, Northrop Grumman, BAKHROM ORIPOV, University of Maryland, College Park, NICHOLAS D RIZZO, ANNA HERR, VLADIMIR TALANOV, Northrop Grumman, STEVEN ANLAGE, University of Maryland, College Park — Studying and manipulation of vortex matter is key to understanding fundamental physics of superconducting materials, improving the properties of superconducting devices, and developing new concepts for superconductor applications. Two major approaches to experimentally characterize vortex dynamics are to measure (i) the critical current density or (ii) surface impedance as a function of applied field. In this work we combine both approaches to characterize thin 200 nm Nb films used in superconducting electronic circuits. We measured the vortex pinning constant (2 kN/m^2), viscous drag (~1e-8 N-s/m^2), and depinning frequency (~ 10 GHz) near the critical temperature (~0.85Tc) using a Parallel Plate Resonator technique. In addition, we measured the depairing critical currents (~ 0.75 MA/cm^2 at 0.9Tc) and the pinning force density (~1 MN/m^3 at 0.989Tc) as a function of temperature near Tc. The test results agree well with vortex wiggling experiments using a Scanning SQUID Microscope, and our numerical simulations of vortex potentials and vortex attempt frequencies based on the Ginzburg-Landau model and Kramers theory of escape rate of a Brownian particle from a potential well, respectively.

1:15PM M49.00011: 1/B resistance oscillations within the superconducting regime of heterostructure with disordered superconductor*  ASBJORN DRACHMANN (Presenter), ABHISHEK BANERJEE, ANTONIO FORNIERI, ALEXANDER WHITICAR, Center for Quantum Devices and Microsoft Quantum Lab - Copenhagen, University of Copenhagen, CANDICE THOMAS, Department of Physics and Astronomy and Birck Nanotechnology Center, Purdue University, SERGEI GRONIN, Birck Nanotechnology Center and Microsoft Quantum Purdue, Purdue University, TIANTIAN WANG, Department of Physics and Astronomy and Birck Nanotechnology Center, Purdue University, GEOFF C GARDNER, Birck Nanotechnology Center and Microsoft Quantum Purdue, Purdue University, MICHAEL MANFRA, Department of Physics and Astronomy, Birck Nanotechnology Center, Microsoft Quantum Purdue, School of Materials Engineering & School of Electrical and Computer Engineering, P, CHARLES MARCUS, Center for Quantum Devices and Microsoft Quantum Lab - Copenhagen, University of Copenhagen — In-situ growth of Al on top of shallow InAs 2DEG heterostructures gives close to perfect superconducting proximity effect [1]. In recent work, we used anodic oxidation to thin down the Al by oxidizing from the top down, allowing us to create an ultra-thin and disordered Al film with a large perpendicular critical field $B_c > 3$ T on a mesoscopic structure. [2]

For $B > B_c$, the sample resistance rises to >1 kΩ whereas for $B < B_c$, we observe reproducible resistance oscillations of <30 Ω. The oscillations have a 1/B periodicity from which standard SdH analysis yields a density matching closely with the carrier density of the underlying 2DEG. This indicates strong electronic contact between the disordered Al layer and the high mobility InAs 2DEG, creating a novel material system to study disordered 2D superconductivity.

Furthermore, fully oxidizing the Al layer gives rise to quantum Hall effect ($\rho_{xx}=0$) emerging at $B \sim 2.5$ T [2] making this material system a candidate for studying proximitized quantum Hall edge states with close to unity transparency to the superconducting Al, contacting the 2DEG from the top.

1:27PM M49.00012: Spectroscopy of barrier defects coupled to superconductors in Van der Waals tunneling devices* DEVIDAS T R (Presenter), The Racah Institute of Physics, The Hebrew University of Jerusalem, TOM DVIR, QuTech, Delft University of Technology, ITAI KEREN, HADAR STEINBERG, The Racah Institute of Physics, The Hebrew University of Jerusalem — Superconductor-Quantum Dot (SC-QD) coupling is a subject of an intense research effort. We report on SC-QD devices realized in Van der Waals tunneling heterostructures consisting of transition metal dichalcogenide (TMD) semiconducting barrier and the 2-band superconductor NbSe$_2$. The QDs in our study are naturally occurring defects in the TMD barrier. As reported earlier by Dvir et. al. [1], Andreev Bound states may form due to proximitized defects in an NbSe$_2$-WSe$_2$ system. Here we focus on two device structures. In the first, tunneling through an MoS$_2$ barrier into a graphene-NbSe$_2$ stack reveals zero-energy Kondo features which arise due to the presence of carriers associated with the NbSe$_2$ low-energy band turning normal. In the 2$^{nd}$ device, defect-dot energies are tunable by use of a graphene tunneling electrode which permits the penetration of electric field from an electrostatic gate. This allows the QD to be used as spectroscopic probe to study resonant tunnelling into the superconductor, allowing low-energy spectroscopy of the inner band of NbSe$_2$.

1:39PM M49.00013: Local measurement of temperature dependent London Penetration Depth in Superconductors using Nitrogen Vacancy Centers in Diamond* KAMAL JOSHI (Presenter), Ames laboratory, Ames, IA, WILLIAM S. SETTERBERG, Macalester College, Saint Paul, MN, NAUFER M NUSRAN, SUNIL GHIMIRE, KYUIL CHO, MAKARIY TANATAR, SERGEY L. BUD'KO, PAUL C CANFIELD, RUSLAN PROZOROV, Ames laboratory, Ames, IA — Local optical magneto-sensing based on nitrogen-vacancy (NV) centers in diamond [1] was used to measure temperature-dependent London penetration depth, $\lambda$ (T), in two different unconventional superconductors, Ba(Fe$_1-x$Co$_x$)$_2$As$_2$ (BaCo122) and YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO). The results are compared with the sensitive bulk measurements of the same samples using tunnel-diode resonator (TDR). Each sample was measured in two orientation to separate the effects of platelet geometry and surface morphology, imaged using SEM. Not only this study compares the absolute numbers from two different techniques, it also allows us to discuss a more realistic picture of the magnetic field penetration into superconducting samples.

We computed the force exerted on a solenoid in a magnetic field, and compared with the experimental results to verify the effect of magnetic moment gradient on exerted force. Based on the concept, a superconducting solenoid thruster driven by geomagnetic field is devised, which has advantages of low energy consumption and propellant-free. To further enhance the force exerted on the solenoid, we replaced an aluminum core with an iron core. Moreover, we placed the solenoid in the geomagnetic field and measured the forces corresponding to different gradients due to variation of cross-sectional area and electric current magnitude. The results demonstrated a proportionality between the force and these two factors, as predicted by the theory. By measuring and calculating the force exerted on a superconducting solenoid at low temperature, we can simulate the condition when such a thruster is used in space. The results showed that the force exerted on a superconducting solenoid at low temperature matched the predicted force relation versus the gradient of varying cross-sectional area and electric current magnitude at room temperature. Therefore, the relation can provide a reference for design of an alternative thruster for space exploration.

Session M50 DCMP: Non-Equilibrium Dynamics

11:15AM M50.00001: Ultrafast magnetic dynamics in insulating YBa$_2$Cu$_3$O$_{6+x}$ revealed by time resolved two-magnon Raman Scattering.*  

DMITRY REZNIK (Presenter), JHIH-AN YANG, NICK PELLATZ, Physics, University of Colorado, Boulder, THOMAS WOLF, Karlsruhe Institute of Technology — Measurement and control of magnetic order and correlations in real time is a rapidly developing scientific area relevant for magnetic memory and spintronics. In these experiments an ultrashort laser pulse (pump) is first absorbed by excitations carrying electric dipole moment. These then give their energy to the magnetic subsystem monitored by a time-resolved probe. A lot of progress has been made in investigations of ferromagnets but antiferromagnets are more challenging. Here we introduce time-resolved two-magnon Raman scattering as a novel real time probe of magnetic correlations especially well-suited for antiferromagnets. Its application to antiferromagnetic charge transfer insulator YBa$_2$Cu$_3$O$_{6+x}$ revealed rapid demagnetization within 90fs of photoexcitation. The relaxation back to thermal equilibrium is characterized by much slower timescales. One of these, which is extremely slow, indicates a novel metastable state hosting trapped charge carriers.

*Work at the University of Colorado was supported by the NSF under Grant No. DMR-1410111
11:27AM M50.00002: Ultrafast charge dynamics in bulk alpha-Fe$_2$O$_3^*$  NASEEM UD DIN (Presenter), VOLODYMYR TURKOWSKI, Physics, Univ of Central Florida, HUNG-TZU CHANG, ALEXANDER GUGGENMOS, MICHAEL ZUERCH, STEPHEN R. LEONE, Chemistry, UC Berkeley, TALAT S. RAHMAN, Physics, Univ of Central Florida — Details of the ultrafast charge dynamics in oxides is crucial for interpretation of recent experimental data and for potential application of such materials in modern technologies. In this talk, we present results for ultrafast charge dynamics in laser pulse-excited antiferromagnet alpha-Fe$_2$O$_3$ obtained with the combined time-dependent density-functional theory and dynamical mean-field theory approach. In particular, we have calculated the time-resolved occupancies of the involved O(p) valence and Fe(d) conduction orbitals and demonstrated that due to strong electron-electron correlations there is delay of a few femtosecond in the charge accumulation in the electron and hole Fe(d) orbitals as compared to the O(p) hole orbitals. The obtained results for the ultrafast dynamics helps explain the attosecond transient absorption spectroscopy data for alpha-Fe$_2$O$_3$ which demonstrate ultrafast modification of the absorption spectra due to ligand-to-metal charge transfer. Our approach can be further extended to treat the femtosecond- and sub-femtosecond resolved dynamics of photoexcitation in strongly correlated materials, specifically, photo-induced insulator-to-metal transitions.

11:39AM M50.00003: Non-equilibrium dynamics of vibrationally coupled electrons excited by coherent radiation*  JOHN SOUS (Presenter), BENEDIKT KLOSS, Columbia University, DANTE KENNES, RWTH Aachen University, DAVID REICHMAN, ANDREW MILLIS, Columbia University — The non-equilibrium dynamics of matter induced by coupling to light fields have made it possible to induce electronic phases of matter that may not exist at equilibrium, and which can be probed by optical and time-resolved spectroscopy. Transient superconductivity induced in atomic solids as a result of enhancement of atomic vibrations excited by light presents one exciting avenue. Here we employ tensor network methods to simulate the dynamics of a metal driven to a highly excited state at initial time by a pump that excites specific vibrational modes. We study the evolution with time of electronic and vibrational observables and observe non-trivial dynamics of density wave and superconducting correlations.

High Harmonic Generation and Nonequilibrium Quasiparticle Dynamics in an Unconventional Superconductor with Competing Order* JIAN-XIN ZHU (Presenter), BENEDIKT FAUSEWEH, Los Alamos Natl Lab, WEI ZHU, Westlake Institute for Advanced Study, CHEN-YEN LAI, Los Alamos Natl Lab — A common feature of unconventional superconductors, ranging from high-temperature cuprate, heavy fermion, and recently discovered iron-based compounds, is the close proximity of unconventional superconductivity to an antiferromagnetic phase. The interplay of the unconventional superconductivity with the competing order remains an interesting scientific question. Recently, the ultrafast laser pulse pump-probe technique has become a powerful approach to uncover novel phases and associated quasiparticles dynamics in strongly correlated electron systems. Here we study an effective $t'$-$U$-$V$ Hubbard model which captures the competition between antiferromagnetic spin-density wave (SDW) and d-wave superconducting (DSC) orderings. We show that an ultrafast electromagnetic field can drive the two competing order parameters uniquely depending on different regimes of hole doping. We further elucidate the consequence of the photoinduced electronic states by calculating the high harmonic generation and nonequilibrium momentum-dependent single-particle spectral function.

*This work was carried out under the auspices of the U.S. DOE NNSA (Contract No. 89233218CNA000001) and was supported by the LANL LDRD Program.

Characterization of photoexcited states in the half-filled one-dimensional extended Hubbard model assisted by machine learning KAZUYA SHINJO (Presenter), Tokyo Univ of Science, Katsushika, SHIGETOSHI SOTA, SEIJI YUNOKI, RIKEN, TAKAMI TOHYAMA, Tokyo Univ of Science, Katsushika — Photoinduced nonequilibrium states can provide new insight into dynamical properties of strongly correlated electron systems. One of the typical and extensively studied systems is the half-filled one-dimensional extended Hubbard model (1DEHM). Here, we propose that the supervised machine learning (ML) can provide useful information for characterizing photoexcited states in 1DEHM [1]. Using entanglement spectra as a training dataset, we construct a neural network. Judging from the trained network, we find that bond-spin-density wave (BSDW) order can be enhanced in photoexcited states if the frequency of a driving pulse nearly resonates with a gap. We separately calculate the time evolution of local and non-local order parameters and confirm that the correlation functions of BSDW are enhanced by photoexcitation as predicted by ML. Predicting BSDW demonstrates the advantage of ML to assist characterizing photoexcited quantum states.

12:15PM M50.00006: Negative absolute conductivity in photoexcited metals* GIULIANO CHIRIACO (Presenter), Columbia Univ, ANDREW MILLIS, Center for Computational Quantum Physics, The Flatiron Institute, IGOR L ALEINER, Columbia Univ — We show that in a model of a metal photoexcited by a pump pulse resonant with a phonon mode, the absolute dc conductivity may become transiently negative, depending on the interplay between the electronic structure, the phonon frequency and the pump intensity. The analysis includes the effects of inelastic scattering and thermal relaxation. Results for the time evolution of the negative conductivity state are presented, showing that the associated non-equilibrium physics may persist for long times after the pulse. Our findings provide a theoretical justification for previously proposed phenomenology and indicate new routes to the generation and exploration of intrinsically non-equilibrium states.

12:27PM M50.00007: Matrix product state investigations of time-dependent spectral functions after a photoexcitation* CONSTANTIN MEYER (Presenter), SALVATORE MANMANA, University of Gottingen — We study the time-dependent dynamical structure factor after a photoexcitation of a variant of the 1d Hubbard model with a background staggered magnetic field using matrix product state (MPS) techniques. In particular, we use the time-dependent variational principle (TDVP) to investigate the time evolution of the band population, which is a quantity accessible to time-resolved ARPES experiments. Different scenarios for the photoexcitations are discussed, e.g., Peierls-substitution or direct excitation in k-space. Using MPS, we can study in detail the effect of the electron-electron interaction on the redistribution of the band populations in the various photoexcitation setups. An outlook to the relevance of electron-electron interactions on light-harvesting mechanisms in correlated materials is given.

*We acknowledge financial support by SFB/CRC 1073 "Atomic Scale Control of Energy Conversion" (project B03) of the Deutsche Forschungsgemeinschaft (DFG).
12:39PM M50.00008: Field-Driven Correlated Quantum Systems, Bridging the Gap Between the Transient and the Steady State  ERIC DOHNER (Presenter), HERBERT FOTSO, University at Albany, ALEXANDER F KEMPER, North Carolina State University, JAMES FREERICKS, Georgetown University — Correlated quantum systems away from equilibrium have rightfully generated a lot of interest. Computational methods play an important role in understanding these systems but they are constrained by difficulties inherent to correlated systems that are exacerbated away from equilibrium. This prevents a full characterization of the dynamics. Previously, a set of relaxation scenarios were identified when systems initially in equilibrium are suddenly driven by a DC electric field. In particular, for certain parameters both the Hubbard and the Falicov-Kimball models evolve monotonically towards infinite temperature steady states that can be fully characterized by formulating solutions directly in the steady state. In the process these systems evolve through successive quasi-thermal states obeying the fluctuation dissipation theorem. We demonstrate an extrapolation scheme that can be leveraged to extend the characterization of the system from equilibrium to steady state at minimal computational cost. Namely, we extrapolate the monotonic temperature of the system and use the fluctuation dissipation theorem to construct the self-energy beyond the transient. All momentum dependent quantities can then be obtained within the DMFT formalism.

12:51PM M50.00009: Photon echo in the Coloumb glass phase as observed with 2D non-linear THz spectroscopy*  FAHAD MAHMOOD (Presenter), University of Illinois at Urbana-Champaign, DIPANJAN CHAUDHURI, DAVID BARBALAS, Johns Hopkins University, RAHUL NANDKISHORE, University of Colorado Boulder, PETER ARMITAGE, Johns Hopkins University — Phosphorous doped Silicon (P:Si) near the metal insulator transition (MIT) hosts a Coulomb glass phase where charge carriers are localized and have strong long-range Coulomb interactions. Here we perform 2D non-linear THz spectroscopy to study the low energy non-linear electrodynamics of charge carriers in the Coulomb phase. Two time-delayed THz pulses with field strengths on the order of 100 kV/cm are applied sequentially on the sample to extract a 2D spectrum of the non-linear susceptibility of the sample as a function of emission and absorption frequencies. Distinct third-order nonlinear signals are identified in the 2D spectra including a photon echo, the anti-diagonal linewidth of which is used to determine the decoherence time ($T_2$) of excited carriers. This is compared with the energy relaxation time ($T_1$) to understand the interplay between site disorder and long-range interactions as the MIT is approached.

1:03PM M50.00010: The quadratically driven nonlinear photonic lattice and its dissipative phase transition: from quantum to classical*  
WOUTER VERSTRAELEN (Presenter), UAntwerpen, RICCARDO ROTA, VINCENZO SAVONA, EPFL, MICHEIL WOUTERS, UAntwerpen — Phase transitions (PT) appear in many flavors. In a Classical PT it results from a competition between energy and entropy, whereas in a quantum PT at zero temperature it results from the competition between non-commuting terms in the Hamiltonian. A quantum PT at finite temperature either vanishes or exhibits a continuous crossover to a classical PT [1]. The fate of a quantum PT at finite dissipation is much less understood.

A paradigmic example of a driven-dissipative system are lattices consisting of nonlinear optical cavities. By driving this system with a two-photon laser, the system retains a $Z_2$-symmetry, that can be spontaneously broken [2].

Here, I show how, using quantum trajectories with a Gaussian ansatz [3], we are able to explore a much larger parameter regime than before. In lattices up to 12x12 cavities we observe a transition from quantum to classical critical behavior, consistent with the interpretation of losses acting as temperature.

This work has been performed in collaboration with Riccardo Rota, Vincenzo Savona and Michiel Wouters.

*I acknowledge FWO travel grant V413119N.

1:15PM M50.00011: Accessing quantum phases in Hubbard honeycomb lattice using an electromagnetic drive*  
UMESH KUMAR (Presenter), SHIZENG LIN, Theoretical Division, T-4, Los Alamos National Laboratory — In the recent past, there has been a great interest in creating novel states of matter under driven conditions, in the condensed matter physics. The Hubbard honeycomb lattice is known to host rich phases [1]. The presence of a periodic drive such as an electromagnetic field in the lattice can be used to tune parameters and to generate new interactions, which can stabilize novel quantum states that is absent in equilibrium. Using Schrieffer-Wolff transformation for the periodically driven system [2] and high-frequency approximation on the drive, we evaluate an effective low-energy Hamiltonian for the Hubbard honeycomb lattice in the presence of drive. We estimate the conditions on the electromagnetic drive that can allow one to tune to different quantum phases, such as transient superconductivity in our model.

*This work was carried out under the auspices of the U.S. DOE NNSA under contract No. 89233218CNA000001 through the LDRD Program.
1:27PM M50.00012: Long-lived coherent states in photo-excited NiO

DENIS GOLEZ (Presenter), Simons Foundation, KONRAD GILMEISTER, Department of physics, Institute of Physics Martin-Luther-Universitat Halle-Wittenberg, NIKOLAJ BITTNER, Department of Physics, University of Fribourg, YAROSLAV PAVLYUKH, Technische Universität Kaiserslautern, Department of Physics, CHENG-TIEN CHIANG, Department of physics, Institute of Physics Martin-Luther-Universitat Halle-Wittenberg, PHILIPP WERNER, Department of Physics, University of Fribourg, WOLF WIDDRA, Department of physics, Institute of Physics Martin-Luther-Universitat Halle-Wittenberg — Charge excitations across electronic band gaps are a key ingredient for transport in optoelectronics and light harvesting applications. In contrast to conventional semiconductors, studies of above-band-gap photoexcitations in strongly correlated materials are still in their infancy.

We will present a combined experimental and theoretical study of the ultrafast dynamics in strongly correlated photo-excited NiO [1]. By combining time-resolved two-photon photoemission experiments and the non-equilibrium extension of dynamical mean-field theory we revealed an ultrafast electronic relaxation (<10 fs) and related photo-induced in-gap states connected with the Hund excitations. Remarkably, the weight of these in-gap states displays long-lived coherent THz oscillations up to 2 ps. The frequency of these oscillations corresponds to the strength of the antiferromagnetic superexchange interaction in NiO and their lifetime vanishes as the Neel temperature is approached. Numerical simulations of a two-band t-J model reveal that the THz oscillations originate from the interplay between local many-body excitations and long-range antiferromagnetic order.

1:39PM M50.00013: Creation of Nonthermal Excited State Populations in a Large U Mott Insulator*

DANIEL NEVOLA (Presenter), Brookhaven National Laboratory, ALEXANDER W BATALLER, ANKIT KUMAR, SAMANVITHA SRIDHAR, JORDAN FRICK, SHAUN O’DONNELL, HARALD W ADE, PAUL MAGGARD, ALEXANDER F KEMPER, KENAN GUNDOGDU, DANIEL DOUGHERTY, North Carolina State University — The ability to tune between thermal and nonthermal populations lies at the heart of quantum control on ultrafast timescales. In this work, we perform time- and angle-resolved spectroscopy on the spin-orbit assisted Mott insulator α-RuCl₃. We demonstrate the ability to tune between thermalized and nonthermalized populations in the upper Hubbard band by tuning the pump energy. These populations are also shown to thermalize and decay on timescales much faster than those predicted by theory.

*Surface characterization (ARPES, 2PPE, and LEED) was funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under award No. DE-SC0010324. 2PPE instrumentation was funded by a UNC-GA ROI award. Theoretical modeling was supported by the National Science Foundation under Grant No. DMR-1752713.
1:51PM M50.00014: Laser pulse driven nonequilibrium dynamics in the Kondo lattice model*  BENEDIKT FAUSEWEH (Presenter), JIAN-XIN ZHU, Los Alamos National Laboratory — Experimental advances in nonlinear optics and ultrafast spectroscopy allow for unprecedented access to nonequilibrium physics of strongly correlated materials. By using this approach, many new and exciting phenomena have been discovered in recent years. They include light-induced superconductivity, the generation of Higgs oscillations, and the dynamical coupling of ferroelectric and ferromagnetic order. Heavy fermion systems are one prototypical class of strongly correlated materials. The interplay between localized magnetic moments and conduction electrons are the driver behind unconventional superconductivity and quantum criticality. The Kondo lattice model is used to describe the emergent phenomena of such systems. By using the powerful time-dependent variational Monte Carlo method, we investigate the nonequilibrium dynamics of the model after strong laser excitation. We demonstrate that the spin and charge fluctuations can be manipulated by varying shape and intensity of the laser pulse in different regimes of electron filling factor. In addition, experimentally measurable quantities are calculated to manifest the dynamics.

*This work was carried out under the auspices of the U.S. DOE NNSA under Contract No. 89233218CNA000001, and was supported by the LANL LDRD Program.

2:03PM M50.00015: Out-of-equilibrium dynamics in a 2D electron system with screened Coulomb interactions*  LILY STANLEY (Presenter), DRAGANA POPOVIC, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ — Considerable experimental evidence suggests that Coulomb interactions are responsible for a variety of phenomena observed in the metallic regime of 2D systems, as well as for glassy behavior near the 2D metal-insulator transition (MIT) and in the insulating regime. To address the fundamental question whether glassy behavior of electrons exists in the absence of long-range Coulomb interactions, we report a study of conductivity relaxations after excitation out of equilibrium, in particular after applying a large change of carrier density $n_s$, over a wide range of temperatures and $n_s$, spanning the 2D MIT. Experiments were performed on strongly disordered thin-oxide Si MOSFETs in which the Coulomb interaction is screened by the nearby metallic gate. The results show differences in the dynamics compared to the case of long-range interactions, and suggest the key role of long-range Coulomb interactions in the existence of glassy behavior of electrons near the 2D MIT in strongly disordered samples.

Session M51 DCMP: Optical Studies of 2D Materials and Their Twisted Heterostructures  Mile High Ballroom 1D - Archana Raja, Lawrence Berkeley National Laboratory
11:15AM M51.00001: Fabrication of Single-Photon Emitters in 2D Hexagonal Boron Nitride via Carbon Annealing  YAOZHENG ZHU (Presenter), CHAO LYU, YU YE, Peking Univ — As the most recent addition to the single-photon emitter library, defects in hexagonal boron nitride (hBN) have attracted much attention due to their high brightness at room temperature and stability. These emitters also have the potential to integrate with cavities and photonic waveguides thanks to their 2D hosting system. Here, we developed a new method to activate single-photon emitters in 2D hBN, which is highly desired for their further application. We annealed mechanically exfoliated hBN under mixed atmosphere with methane as carbon source, and our simple one-step annealing process yields a tremendous increase in the concentration of emitters in hBN. With several related experiments, the single defects fabricated by our method are confirmed to be quantum emitters. Some other photophysical properties indicate that the emitters show higher brightness and become more stable after carbon annealing. Our approach to the design of single photon emitters in 2D hBN opens up new avenues for the generation of single photon emitters and their integration in quantum nanophotonic devices.

11:27AM M51.00002: Density functional theory of strain engineering on single photon emitter in hexagonal boron nitride  MEHDI ABDI, Department of Physics, Isfahan University of Technology, SONG LI (Presenter), JYH-PIN CHOU, City Univ of Hong Kong, GERGO THIERING, PÉTER UDVARHELYI, Wigner Research Centre for Physics, Hungarian Academy of Sciences, ALICE HU, City Univ of Hong Kong, MARTIN PLENIO, Institute of Theoretical Physics and IQST, Ulm University, ADAM GALI, Wigner Research Centre for Physics, Hungarian Academy of Sciences — Hexagonal boron nitride has been found as excellent host for color centers as single photon emitters. The complex defect which is a nitrogen vacancy next to a nitrogen antisite (VN\textsubscript{N}B) is regarded as promising candidate due to the nontrivial electronic structure.\textsuperscript{1,2} Here, using density functional theory, we provide detailed investigation of the geometric and electronic evolution of VN\textsubscript{N}B under external strain. The VN\textsubscript{N}B prefers the C\textsubscript{1h} symmetry making the defect as a dynamic Jahn-Teller system.\textsuperscript{3} By lowering the symmetry, the first transition which considered to be a dark state can be activated, inducing the compete between two possible excitation pathways.\textsuperscript{4} The zero phonon line shows non-linear evolution as a function of in plane strain indicating the important role of the out of plane strain between defect atom and its ambient structure. It is predicted that a significantly stronger redshift than blueshift of emission can be realized by applying armchair strain. Our analysis provides insightful understanding of the color centers as single photon emitters.

EMMA REGAN (Presenter), DANQING WANG, CHENHAO JIN, IQBAL UTAMA, University of California, Berkeley, BEINI GAO, Huazhong University of Science and Technology, XIN WEI, University of Chinese Academy of Sciences, SIHAN ZHAO, WENYU ZHAO, University of California, Berkeley, KENTARO YUMIGETA, MARK BLEI, Arizona State University, JOHAN CARLSTROEM, University of California, Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SEFAATTIN TONGAY, Arizona State University, MICHAEL F CROMMIE, ALEX ZETTL, FENG WANG, University of California, Berkeley — Moiré superlattices can be used to engineer strongly correlated phenomena in van der Waals heterostructures, as recently demonstrated in graphene-based systems. Aligned transition metal dichalcogenide (TMDC) heterostructures may also support correlated electronic states, with additional opportunities arising from the strong-light matter interaction and large spin-orbital coupling. Using a novel optical detection technique, we observe correlated electronic phases in semiconducting WSe\textsubscript{2}/WS\textsubscript{2} moiré superlattices. Further, we demonstrate that the spin-valley optical selection rules in TMDCs can be used to optically create and study low-energy spin excitations in the correlated states.

HUAN ZHAO (Presenter), YOUNGHEE KIM, ANDREW JONES, Center for Integrated Nanotechnologies, Materials Physics and Applications Divison, Los Alamos National Laboratory, ANDREI PIRYATINSKI, Theoretical Division, Los Alamos National Laboratory, HAN HTOON, Center for Integrated Nanotechnologies, Materials Physics and Applications Division, Los Alamos National Laboratory — Recently, 2D twisted bilayers with interlayer lattice mismatch and/or rotational misalignment have emerged as a powerful platform for studying unconventional properties such as the interlayer exciton (IX), where electrons and holes located in different monolayers couple to form a bound state. The IXs can further be spatially concentrated into periodic potential minima modulated via the moiré landscape, forming uniform periodic quantum-dot-like emitter array. In this talk, I will introduce optical characterization of 2D heterobilayer transition metal dichalcogenides (TMDCs) interlayer excitons under different configurations of interlayer twisting angles and material selections. 2D heterobilayers with deterministic interlayer twist angle were prepared using a custom-built layer stacking system. Here, we studied the light emission properties with time-resolved photoluminescence (PL), temperature-dependent PL, and magneto-PL. Through the PL studies, we were able to extract key parameters of interlayer excitons such as lifetime, binding energy, valley polarization, etc. These results represent an advance in the understanding of the physics of 2D interlayer excitations and the future implementation of these TMDC materials within tunable light-emitting devices.
12:03PM M51.00005: Anomalous bright narrow interlayer exciton photoluminescence in MoSe$_2$-WSe$_2$ heterostructures*  FATEME MAHDIKHANYSARVEJAHANY (Presenter), Univ of Arizona, MICHAEL KOEHLER, Department of Materials Science and Engineering, University of Tennessee, DAVID MANDRUS, Department of Physics and Astronomy, University of Tennessee, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, OLIVER MONTI, BRIAN J LEROY, JOHN SCHAIBLEY, Univ of Arizona — Van der Waals heterostructures provide a new platform for studying spatially indirect interlayer excitons, where the constituent electrons and holes are located in different layers. These heterostructures are made by stacking two or more two-dimensional materials via a polymer stamping technique. Stacking layers with a lattice mismatch and/or twist angle between layers will form a moiré pattern in real space. This moiré lattice can modulate the exciton energy, resulting in so-called moiré excitons where excitons are trapped at the moiré potential minima. Recent studies on - heterostructures have shown narrow lines in low power photoluminescence(PL), which were attributed to moiré excitons. Optical measurements of our high-quality - heterostructures encapsulated by hBN shows an anomalous bright narrow interlayer exciton PL localized to a small area of the sample. The PL of this structure shows interlayer PL emission whose linewidth is comparable to delocalized interalayer excitons in high quality samples. We will discuss the density and temperature dependence of this bright interlayer exciton PL and how it relates to other recent reports of interlayer moiré excitons in transition metal dichalcogenide heterostructures.

*We thank NSF-DMR 1838378 for the funding.

12:15PM M51.00006: Emergent magnetic field from the moiré of homobilayer 2D semiconductors*  DAWEI Zhai (Presenter), The University of Hong Kong, HONGYI YU, Sun Yat-Sen University (Zhuhai Campus), MINGXING CHEN, Hunan Normal University, WANG YAO, The University of Hong Kong — The spatial texture of internal degree of freedom of electrons has profound effects on material properties. Such texture in real space can manifest as an emergent magnetic field, which is expected to induce interesting transport phenomena. Moiré pattern as a spatial variation at the interface of 2D atomic crystals provides a natural platform for investigating such real space Berry phase effect [1]. Here we study Moiré structures formed in homobilayer TMD due to twisting, uniform strains, and their combinations [2], where electrons can reside in either layer with the layer index serving as an internal degree of freedom. The layer pseudospin exhibits vortex/antivortex textures in the Moiré supercell, which leads to a giant magnetic field. We will show that strain and interlayer bias can be used to engineer the in-plane and out-of-plane layer pseudospin texture, respectively. Therefore, the profile, intensity, and flux of the magnetic field are highly tunable, rendering TMD Moiré structures promising for transport and topological material applications.

*The work is supported by RGC of HKSAR (17306819).
12:27PM M51.00007: Induced spin-orbit coupling in twisted graphene-TMDC heterobilayers: Twistorics meets spintronics

ALESSANDRO DAVID (Presenter), Department of Physics, University of Konstanz, PÉTER RAKYTA, ANDOR KORMANYOS, Department of Physics of Complex Systems, Eötvös Loránd University, GUIDO BURKARD, Department of Physics, University of Konstanz — Transport experiments in graphene deposited on monolayer transition metal dichalcogenide (TMDC) have demonstrated weak antilocalization, Shubnikov-de Haas oscillations, spin lifetime anisotropy, spin Hall effect and Rashba-Edelstein effect [1]. This suggests that spin-orbit coupling (SOC) in graphene is enhanced by the strong intrinsic SOC of the nearby TMDC layer. Setting up a theoretical model of the graphene-TMDC heterobilayer we are able to explain the origin and predict the interlayer twist angle dependence of the induced SOC [2]. We derive the induced valley Zeeman and Rashba type SOC in terms of the TMDC band structure parameters and interlayer tunneling matrix elements. We find that the strength of the induced SOC can be strongly tuned by the twist angle. Provided that the energy of the Dirac point is close to the TMDC conduction band, up to a tenfold increase of the valley Zeeman (at 18 degrees twist angle) and a fourfold increase of the Rashba type induced SOC can be achieved. Moreover, we have extended our model to the case of graphene encapsulated in two TMDC layers, where the induced SOC is also modulated by the additional twist angle.

12:39PM M51.00008: The optical evidence of atomic reconstruction in twisted bilayer MoS$_2$*

JIAMIN QUAN (Presenter), University of Texas at Austin, LUKAS LINHART, Vienna University of Technology, MIAO-LING LIN, Chinese Academy of Sciences, CHUN YUAN WANG, WEI-TING HSU, JUNHO CHOI, CARTER YOUNG, University of Texas at Austin, TAKASHI TANIGUCHI, National Institute of Material Science in Tsukuba, CHIH-KANG SHIH, ALLAN MACDONALD, University of Texas at Austin, PING-HENG TAN, Chinese Academy of Sciences, FLORIAN M LIBLESCH, Vienna University of Technology, XIAOQIN (ELAINE) LI, University of Texas at Austin — In two-dimensional materials, Moiré superlattices formed by stacking two monolayers with lattice constant mismatch or rotational misalignment have been widely used to manipulate their electronic and optical properties. Here, we employ low-frequency Raman measurements and DFT calculations to demonstrate atomic reconstruction in the MoS$_2$ homobilayer with a small twist angle ($\theta$). For $0^\circ < \theta \leq 3.5^\circ$, only interlayer Raman mode of 3R stacking with stable peak position is presented, indicating the overwhelming expansion of stable stacking in small twist angle due to structural relaxation. For $3.5^\circ < \theta \leq 6^\circ$, the small Moiré supercell with weak relaxation results in mixed in-plane and out-of-plane vibrations. The shear mode quickly disappears with an increasing twist angle, while mixed breathing modes are observed. Our work provides a novel strategy to understand and monitor the evolution of structural relaxation in moiré superlattices in two-dimensional van der Waals materials.

*Funding from DOE and a catalyst grant provided by the College of Natural Science at the University of Texas-Austin are gratefully acknowledged.
12:51PM M51.00009: Interlayer Excitons in van der Waals Heterostructures in a Magnetic Field
JINLYU CAO (Presenter), HERBERT FERTIG, Indiana Univ - Bloomington, LUIS BREY, Instituto de Ciencia de Materiales de Madrid-CSIC, Cantoblanco — We investigate particle-hole excitations in bilayer 2D van der Waals heterostructures in a magnetic field. Such systems are interesting because the two constituents of the excitons can reside in band environments of very different Berry’s curvatures. This allows the neutral excitations to carry signatures of the fermionic electronic structures of the individual materials. Moreover, the heterostructures can give rise to a large moiré unit cell. The effective periodicity relaxes momentum conservation so that the exciton dispersion at finite momentum could be detected by light absorption. As an example, we study an MoS$_2$-graphene heterostructure, for which both valleys host Berry’s curvature in only one layer. We consider variational single particle-hole pair wavefunctions, both in terms of the Landau levels and eigenstates of magnetic translation operators. The formalism allows one to identify how wavefunction overlaps determine the exciton state and energy. We show for this heterostructure that the energy disperses remarkably slowly. The impacts of many-body effects and the quasi-periodic tunneling between the layers associated with the moiré pattern on exciton dispersions and light absorption are also considered.

1:03PM M51.00010: Near field study of twisted transition metal dichalcogenide bilayers
SHUAI ZHANG (Presenter), AARON STERNBACH, Department of Physics, Columbia University, BAICHANG LI, Department of Mechanical Engineering, Columbia University, LIN ZHOU, WENJING WU, Department of Chemistry, Columbia University, LIN XIONG, Department of Physics, Columbia University, ESSANCE RAY, NATHAN P WILSON, XIAODONG XIU, Department of Physics, University of Washington, XIAOYANG ZHU, Department of Chemistry, Columbia University, JAMES C HONE, Department of Mechanical Engineering, Columbia University, DMITRI BASOV, Department of Physics, Columbia University — Twistronics has recently emerged as a novel tuning knob to engineer the properties of electrons and excitons in two dimensional van der Waals heterostructures. However, directly probing the properties of vdW heterostructures within a single moiré unit cell remains elusive. In this talk, we utilize near-field optical microscopy to explore twisted transition metal dichalcogenides (TMD) bilayers. The atomically thin vertical p-n junction of WSe$_2$/MoSe$_2$ bilayer is fabricated by mechanical exfoliation and stacking. The type-II band alignment of the WSe$_2$/MoSe$_2$ facilitates electron-hole separation permitting photocurrent measurements at the nanoscale. Features with ~100 nm periodicity are observed and show systematic evolution under electrostatic gating. More experiments are carrying out to conclusively assign these features to the moiré. Our study demonstrates a viable pathway towards probing and manipulating moiré patterned TMD heterostructures at the nanoscale.
1:15PM M51.00011: Floquet-Engineered Topological Flat Bands in Irradiated Twisted Bilayer Graphene* YAN TAO LI (Presenter), HERBERT FERTIG, BABAK H SERADJEH, Indiana Univ - Bloomington — We propose a tunable optical setup to engineer topologically nontrivial flat bands in twisted bilayer graphene under circularly polarized light. Using both analytical and numerical calculations, we demonstrate that nearly flat bands can be engineered at small twist angles near the magic angles of the static system. The flatness and the gaps between these bands can be tuned optically by varying laser frequency and amplitude. We study the effects of interlayer hopping variations on Floquet flat bands and find that lattice relaxation favors their formation. Furthermore, we find that, once formed, the flat bands carry nonzero Chern numbers. We show that at currently known values of parameters, such topological flat bands can be realized using circularly polarized UV laser light. Thus, our work opens the way to creating optically tunable, strongly correlated topological phases of electrons in moire superlattices.

*This work is supported in part by the NSF awards DMR-1350663, DMR-1506263, DMR-1914451, ECCS-1936406, US-Israel BSF grant No. 2016130, the Research Corporation Cottrell SEED Award, the Max-Planck Institute for the Physics of Complex Systems in Dresden, the Aspen Center for Physics via NSF grant PHY-1607611, and the College of Arts and Sciences at Indiana University.

1:27PM M51.00012: Doping-dependence of exciton energies and MCD in TMD moiré superlattices* IGOR BLINOV (Presenter), ALLAN MACDONALD, Physics department, University of Texas at Austin — The long-period pattern formed by two-dimensional crystals that are slightly misaligned or have slightly different lattice constants is known as a moire superlattice. It was recently discovered that the moiré superlattices have a pronounced effect on the electronic properties of many two-dimensional materials. I will discuss the influence of a moiré superlattice on excitons in transition metal dichalcogenide heterostructures. Existing effective boson theories of the moiré excitons do not allow the effect of electron or hole doping to be predicted. I will present a microscopic calculation of the optical response at finite doping, as well as a simple phenomenological model, which captures the main results. When the carriers are valley polarized the optical response exhibits circular dichroism. I will discuss the use of the circular dichroism of the exciton spectrum as a probe of ground state valley polarization.

*Work supported by the Army Research Office (ARO) Grant # W911NF-17-1-0312 (MURI).
1:39PM M51.00013: Excitonic insulator and spin-valley superfluid in twisted bilayer transition metal dichalcogenide* ZHEN BI (Presenter), LIANG FU, Massachusetts Institute of Technology MIT — Recently striking correlated phenomena emerge in twisted bilayer WSe$_2$ -- including a correlated moiré insulating dome at half-filling -- over a range of small twist angles. In this work, we show the half-filling state is an intervalley excitonic insulator, where the electron-hole pairing is strongly enhanced for a certain range of displacement field due to the proximity of a van Hove singularity to the Fermi level. The mean field phase diagram as a function of displacement field, temperature and magnetic field shows a good agreement with the experiment. Furthermore, the excitonic insulator hosts a spin-valley density wave order which can be viewed as a spin superfluid. We propose an all-optical setup to study the superflow of spins in the twisted bilayer transition metal dichalcogenide systems.

1:51PM M51.00014: Dielectric engineering in monolayer WSe$_2$/graphene heterostructures YANG XU (Presenter), CONNOR HORN, Cornell University, NY, USA, DANIEL A RHODES, Columbia University, NY, USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, Japan, JAMES C HONE, Columbia University, NY, USA, JIE SHAN, KIN FAI MAK, Cornell University, NY, USA — The strong Coulomb interaction between charge carriers in atomically thin transition metal dichalcogenides (e.g. MoS$_2$, WSe$_2$) is sensitive to the nearby dielectric environment. Here, we investigate the optical response of monolayer WSe$_2$, which is in contact with gate-tunable graphene in van der Waals heterostructures, by optical reflection spectroscopy. We find that both the exciton binding energy and quasiparticle bandgap of WSe$_2$ can be renormalized by the dielectric screening effect. The effect can also be modulated upon the formation of Landau levels in graphene under perpendicular magnetic fields. Furthermore, we directly observe inter-band Landau level transitions of WSe$_2$, which helps to accurately determine the quasiparticle bandgap and effective cyclotron mass in WSe$_2$ as a function of dielectric screening.
HECTOR OCHOA, ANA ASENJO-GARCIA (Presenter), Columbia University — We present a minimal continuum model describing the electronic reconstruction in twisted bilayers of hexagonal boron nitride. The relative twist creates regions of unnatural stacking within the moiré cell, where ions of the same polarity lie on top of each other. The gap is strongly modulated, giving rise to very narrow quasi-bands at relative large twist angles. The absence of a magic angle condition emphasizes the different nature of these flat bands as compared to the case of twisted graphene systems. In particular, changing the parameters of our model we can describe both situations, which are separated by a topological phase transition controlled by inter-band coherences of the envelope wave functions around the moiré zone center. Transitions between these flat bands are manifested as sharp resonances in the optical absorption spectrum. We also evaluate the Hall counter-flow ascribed to the chiral symmetry of the system, which gives rise to different absorption cross sections for right-handed and left-handed circularly-polarized light (circular dichroism).

Session M52 DCMP: Surface Studies of Transition Metal Dichalcogenides Mile High Ballroom 1E - Daniel Dougherty, North Carolina State University

SOYEONG KWON (Presenter), YUGYEONG JE, JUNGEUN SONG, EUNAH KIM, BORA KIM, SANG WOOK LEE, DONGWOOK KIM, EWHA Woman's Univ — Understanding the physical properties of metal-semiconductor contacts is crucial for both electrical characterizations and device applications. In this work, MoS$_2$ monolayers were transferred on Au nanostripe arrays. The surface potential distributions of the samples in dark and under light illumination were investigated using Kelvin probe force microscopy, which has a few tens of nm spatial resolution. To explain the surface potential contrast change in dark and light, we proposed the energy band diagrams considering the strain and electronic interaction. Optical micro-reflectivity spectra was also obtained and compared with numerical simulation results. The relationship between the surface potential maps and the optical characteristics of the samples will be discussed in this presentation.
11:27AM M52.00002: Studies of Band Alignment in WS2/MoS2/Al2O3 Heterostructures using Kelvin Probe Force Microscopy  BORA KIM (Presenter), EWHA Woman's Univ, PO-CHENG TSAI, Research Center for Applied Sciences, Academia Sinica, JAYEONG KIM, EUNAH KIM, SOYEONG KWON, SEOKHYUN YOON, EWHA Woman's Univ, SHIH-YEN LIN, Research Center for Applied Sciences, Academia Sinica, DONGWOOK KIM, EWHA Woman's Univ — Two-dimensional (2D) crystals can be assembled into van der Waals (vdW) heterostructures by mechanical exfoliation or chemical vapor deposition. Charge transport and recombination processes are determined by the band alignment in the heterostructures. Therefore, investigation of the band alignment is a crucial step toward the applications of the 2D vdW heterostructures. In this work, we fabricated WS2/MoS2 heterostructures on single crystal Al2O3 wafers, using sulfurization of pre-deposited transition metal layers. The surface potential of the sample in dark and light was measured using Kelvin probe force microscopy, which allowed us to suggest the band diagrams of the vdW heterostructures. The measured Raman spectra of the heterostructures supported the proposed band alignment, considering the electronic interaction at the interface and the interlayer screening effects.

11:39AM M52.00003: Mottness versus unit-cell doubling as the driver of the insulating state in 1T-TaS2  CHRISTOPHER BUTLER (Presenter), MASARO YOSHIDA, TETSUO HANAGURI, CEMS, RIKEN, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — Recent debate about the nature of the insulating ground state in 1T-TaS2 has largely hinged around the stacking pattern of its quasi-2D charge ordered layers. The stacking determines whether the 3D unit-cell contains one or two ‘Star-of-David’ (SD) clusters, each of which hosts 13 unpaired Ta orbitals. For simple stacking with one SD per cell, the insulating state must be explained by Mott physics, but for stacking with a dimerized pair of SDs per cell, ab initio calculations predict a band insulator [1,2]. We will describe scanning tunneling microscopy measurements [3] showing two distinct terminations of the 3D charge order - the sign of a stacking pattern with two SDs per cell - and determine the inter-layer stacking vectors. We argue that the persistence of a spectral gap even at the surface which breaks the SD dimers is a manifestation of Mottness. We also identify a stacking vector, extrinsic to the natural pattern, which renders the surface metallic. These results help to understand this material's mysterious insulating state, and its potentially useful metal-insulator transitions.

11:51AM M52.00004: Confinement Heteroepitaxy: A Novel Route for Realizing Exotic 2D Materials*  ALEXANDER VERA (Presenter), WILSON YANEZ, NATALIE BRIGGS, TIMOTHY BOWEN, SIAVASH RAJABPOUR, NITIN SAMARTH, JOSHUA ROBINSON, Pennsylvania State University — Advancement of nascent electronic quantum frontiers (spintronics, photonics, and sensing) has been mediated through development of materials platforms with non-trivial band topologies, allowing distinct access to quantum information otherwise lost through decoherence. However, access to the more exotic quantum phenomena within these frontiers still pose a materials challenge due to synthesis difficulties or small windows of performance, which render these routes limited in scalability. We have demonstrated facile synthesis of air-stable, atomically thin, single crystal two-dimensional (2D) metals (gallium, indium, tin, lead, and silver) within a silicon carbide and epitaxial graphene interface through high-pressure intercalation (i.e. confinement heteroepitaxy, or CHet). The non-centrosymmetric nature, coupled with potentially strong spin orbit coupling and superconductivity, in these 2D metals, suggest this novel synthesis route as an avenue for manifesting exotic effects (such as topological superconductivity) due to non-trivial band topology.

12:03PM M52.00005: Surface Engineering of Monolayer MoS₂ for Atomic Layer Deposition of TiO₂*  JARON KROP (Presenter), CAN ATACA, THEODOSIA GOUGOUSI, Univ of Maryland-Baltimore County — We investigate methods to improve the growth of high-quality TiO₂ films on MoS₂ via atomic layer deposition (ALD). Untreated MoS₂ surfaces are hydrophobic, and as a result, ALD results in discontinuous films that nucleate only on defect sites. Since pristine MoS₂ monolayers have low defect density, argon ion bombardment is used to create sulfur vacancies. The vacancy concentration is monitored in-situ with x-ray photoelectron spectroscopy. We use thiols to passivate the vacancies and act as a seed layer for ALD. However, spontaneous oxidation of the defective MoS₂ layer can occur, and ALD on argon sputtered MoS₂ results in uniform TiO₂ films with and without the thiol treatment. Without thiol treatment, dissociative adsorption of oxygen molecules on the sulfur vacancies may seed the ALD by leaving behind adsorbed atomic oxygen. With density functional theory, we investigate the electronic properties of defective, thiol- and oxygen-passivated sulfur vacancies in MoS₂. Thiol- or oxygen-passivated MoS₂ retains desirable electronic properties. Careful control of the sulfur vacancy concentration followed by functionalization can provide a means of tuning the electronic properties of MoS₂ and providing seed sites for high quality ALD film growth.

NSF ECCS-1407677
Monolayers on Periodic Au Nanostructures  JUNGEUN SONG (Presenter), SOYEONG KWON, EUNAH KIM, BORA KIM, DONGWOOK KIM, EWHA Woman's Univ, SEONGYEON LEE, KIJU YEE, Chungnam National Univ — MoS\(_2\) monolayers were prepared on hexagonal arrays of Au nanotriangles (NTs) and nanoholes (NHs), fabricated by nanosphere lithography. Photoluminescence (PL) and optical reflectivity spectra of the samples on the Au NT and NH arrays were investigated. The surface plasmon excitation and Wood anomaly affected the reflectivity data, which could be clearly explained by numerical simulations. Also, light-induced surface potential change, determined by spatial distribution of the photo-generated charge carriers, was studied using Kelvin probe force microscopy. The comparison of the two kinds of samples on the NT and NH arrays could show us how the periodic metal nanostructures influenced the physical characteristics of the MoS\(_2\) layers.

Scanning tunneling microscopy study of monolayer NbSe\(_2\)*  MENGKE LIU (Presenter), JIA YU, CHIH-KANG SHIH, University of Texas at Austin — Two-dimensional transition metal dichalcogenides (TMD) have received significant interest due to their unique structural and electrical properties. Within the family of TMD materials, NbSe\(_2\) has a 2H phase which is metallic in nature and interestingly exhibits a charge density wave and superconducting phase transition. Naturally occurring bulk NbSe\(_2\) is a 2H phase, however, recently a 1T phase of NbSe\(_2\) was grown by MBE. Intriguingly, this 1T phase exhibits an energy gap and insulating behavior at low temperatures. In this work, we study MBE grown monolayer NbSe\(_2\) using scanning tunneling microscopy and spectroscopy (STM/S). We report both 2H and 1T phases are present in the growth, and whose relative abundance suggests a growth temperature dependence. We further report comparative studies of the electronic properties of both 2H and 1T phases using STM/S.

**12:39PM M52.00008: Thickness Dependent Electronic Structures of Pd Dichalcogenides: A First Principles Study**  
LIANG-YING FENG (Presenter), ROVI ANGELO B. VILLAOS, ZHI-QUAN HUANG, CHIA-HSIU HSU, FENG-CHUAN CHUANG, Natl Sun Yat Sen Univ — Among the family of transition metal dichalcogenides (TMDs), Pd-based TMDs have been one of the less explored materials. In this study, using first-principles calculations, we investigate the electronic properties of PdX$_2$ (X=S, Se, or Te) with respect to film thickness. With regards to the structural stability, the bulk and thin film structures of PdS$_2$ and PdSe$_2$ exhibit pyrite phase, while PdTe$_2$ exhibits 1T phase as their most stable configurations. For the electronic properties, the most stable bulk configurations demonstrate semi-metallic features, while their corresponding monolayer structures for pyrite PdS$_2$ and PdSe$_2$ are insulating with band gaps of 1.399 eV and 1.548 eV, respectively, while 1T PdTe$_2$ remained to be semi-metallic. For the band properties, we observe that all these materials manifest decreasing/closing of indirect band gap with increasing thickness. Moreover, all the stable monolayer band structures exhibit flat bands and diverging density of states near the Fermi level, indicating the presence of van Hove singularity.

**12:51PM M52.00009: Electronic Growth Modes in Metal Dichalcogenide Interfaces**  
TIM KIDD (Presenter), EVAN O'LEARY, ANDREW STOLLENWERK, Univ of Northern Iowa — The transition metal dichalcogenides (TMDCs) are a family of materials of great interest for chemical tunability and novel electronic properties. The TMDC surface terminates at a van der Waals gap, making a stable, highly non-interacting growth surface. We have found that this lack of interaction can induce a variety of metals to spontaneously organize into films or nanostructures with strongly preferred heights upon the TMDC surface. The terraces of these features are atomically flat and highly oriented. Their structure can be predicted using only the electronic structure of the metal. This electronic growth differs from previously reported magic height systems in that high temperature annealing enhances growth properties, implying true equilibrium conditions. This process could be extended to a great number of highly 2D materials and open new avenues of research for self-assembled nanostructures with various electronic or spin-based confinement.

*The initial stages of work on Au/MoS$_2$ were supported by funding from National Science Foundation Grant No. DMR-1410496 for the initial stages of research on the Au/MoS$_2$ system. The work performed to refine the Au/MoS$_2$ system and with metals was supported by the grant DE-SC0020334 funded by the U.S. Department of Energy, Office of Science.*
1:03PM M52.00010: Doping WS$_2$ armchair nanoribbons with transition metals* YAN-HONG CHEN, Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan, ROC., CHI-HSUAN LEE, Graduate Institute of Applied Physics, National Chengchi University, Taipei, Taiwan, ROC., SHUN-JEN CHENG, Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan, ROC., CHIH-KAI YANG (Presenter), Graduate Institute of Applied Physics, National Chengchi University, Taipei, Taiwan, ROC — Armchair WS$_2$ nanoribbons are semiconductors with band gaps close to 0.5 eV. When a W atom is replaced by a transition metal, impurity states can have tremendous effect on the overall electronic structures. By using first-principles calculations based on density functional theory, we investigated substitutional of Ti, V, Cr, Mn, Fe, Co for WS$_2$ ribbons of different widths. We found that Fe-doped ribbons have two-channel conduction separately in the middle part of the ribbon and at the edges. Co-doped ribbons are turned in to spin filters, having 100% spin-polarized conductions. These results should be useful for nano-electronic circuit design.

1:15PM M52.00011: Induction of Phase Transition in Transition Metal Dichalcogenides on Metal Substrates* CHI SIN TANG (Presenter), XINMAO YIN, Natl Univ of Singapore, DI WU, Shenzhen University, WEILONG KONG, QIXING WANG, Natl Univ of Singapore, MING YANG, Agency for Science, Technology and Research, MARK B. H. BREESE, Natl Univ of Singapore, WENJING ZHANG, Shenzhen University, ANDRIVO RUSYDI, ANDREW THYE SHEN WEE, Natl Univ of Singapore — Two-dimensional transition metal dichalcogenides (2D-TMDs) possess unique structural phases including the semiconducting 1H and quasi-metallic 1T' phases. They show intriguing optical and electronic properties. 1H to 1T' phase transition processes are important to be utilized for novel device applications. We present a high-yield 1H to 1T' phase transition of monolayer-MoS$_2$ on Cu and monolayer-WSe$_2$ on Au via an annealing-based process. Both experimental and first-principles studies are conducted to study the phase transition mechanism. The 1T' phase yield is increased via interfacial hybridizations enhancement through interfacial binding energy, charge transfer, shorter interfacial spacing, and weaker bond strength.

1:27PM M52.00012: Tuning the Electronic Band Structure of Copper Selenide Cu$_2$Se Thin Films Grown via Molecular Beam Epitaxy* RYAN TREY VAN HAREN (Presenter), TOYANATH JOSHI, DAVID LEDERMAN, Department of Physics, University of California, Santa Cruz — Cu$_2$Se has long been known to be an excellent thermoelectric material whose electronic band structure that is tunable by introducing copper vacancies into the crystal structure. More recently, this compound has been predicted to host topologically-protected surface states. In this work, we will present our successful epitaxial growths of Cu$_{2-x}$Se thin films via molecular beam epitaxy (MBE). Using reflection high energy electron diffraction (RHEED) and x-ray diffraction (XRD) measurements, we will show how we are able to quantify the copper concentration by analyzing the subtle shifts in our observed XRD spectra corresponding to small changes in the lattice spacing due to these copper vacancies and how these vacancies influence electronic transport in the film. In this manner we will demonstrate how we are able to tune the copper vacancies and electronic band structure by precise control of the crystal's growth parameters.

*Funding was provided by the University of California Multicampus Research Programs and Initiatives (grant MRP-17-454963).

1:39PM M52.00013: Fabrication of Copper Selenate Thin Films by Pulsed Laser Deposition* DAVID KING (Presenter), JINKE TANG, UPPALAIHA ERUGU, Physics and Astronomy, University of Wyoming, JOHN ACKERMAN, Chemical Engineering, University of Wyoming — Cu$_2$OSeO$_3$ is a rare material with properties that are highly desirable for spintronic devices: it is an insulating ferrimagnet that also hosts magnetic skyrmions. Previous investigations of Cu$_2$OSeO$_3$ have emphasized single crystals. However, skyrmions are typically more stable in thin films than in bulk materials. Also, thin films are more suitable for device applications than single crystals. In this research, we present results of using pulsed laser deposition (PLD) to fabricate thin films of Cu$_2$OSeO$_3$, specifically accounting for the high disparity in vapor pressure between the reactants CuO and SeO$_2$. Data showing the film's magnetic properties, crystallography, and electrical properties are presented.

*This work was supported by the National Science Foundation (DMR-1710512).
1:51PM M52.00014: Dimensionality-Mediated Semimetal-Semiconductor Transition in Ultrathin PtTe$_2$ Films

MENG-KAI LIN (Presenter), University of Illinois at Urbana-Champaign, ROVIN ANGELO B. VILLAOS, Physics, National Sun Yat-Sen University, JOSEPH HLEVYACK, PENG CHEN, RO-YA LIU, University of Illinois at Urbana-Champaign, CHIA-HSIU HSU, Physics, National Sun Yat-Sen University, JOSÉ AVILA, SynchrotronSOLEIL and Université Paris-Saclay, SUNG-KWAN MO, Advanced Light Source, Lawrence Berkeley National Laboratory, FENG-CHUAN CHUANG, Physics, National Sun Yat-Sen University, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign — Platinum ditelluride (PtTe$_2$), a type-II Dirac semimetal in the bulk form, is made of Te-Pt-Te tri-atomic layers (TLs) loosely bonded together by van der Waals interactions. It remains semimetallic in ultrathin films down to just two TLs, but a further reduction of the film thickness to just a single TL induces a Lifshitz electronic transition to a semiconductor with a sizable gap. This transition is evidenced by experimental mapping of the band structure by angle-resolved photoemission spectroscopy for films of various thicknesses prepared by molecular beam epitaxy on a bilayer-graphene-terminated SiC substrate. Layer-by-layer evolution of the band structure is well resolved, which facilitates absolute layer counting. The measured semiconducting band structure for the single TL is in excellent agreement with theoretical calculations. Our results demonstrate a novel electronic transition at the single-layer, or two-dimensional limit through film thickness control.

2:03PM M52.00015: Structural response of a slit-shaped graphene nanopore to adsorption: Observation by in situ neutron diffraction*

JOSEPH SCHAEPERKOETTER (Presenter), MURR, Univ of Missouri - Columbia, HASKELL TAUB, Physics, Univ of Missouri-Columbia, HELMUT KAISER, MURR, Univ of Missouri - Columbia, ZACHARY BUCK, Physics, Univ of Missouri-Columbia, MATTHEW CONNOLLY, National Institute of Standards and Technology Boulder, CARLOS WEXLER, Physics, Univ of Missouri-Columbia — We have investigated adsorption-induced deformation in graphene oxide framework materials (GOFs) using neutron diffraction at sample pressures up to 140 bar. GOFs, made by solvothermal reaction of graphite oxide (GO) and benzene-1,4-diaboronic acid (DBA), are a suitable candidate for deformation studies due to their narrow (∼1 nm), monodispersed, slit-shaped pores whose width can be measured by diffraction techniques. We have observed, in situ, a monotonic expansion of the slit width with increasing pressure upon adsorption of xenon, methane, and hydrogen under supercritical conditions [1]. We find that the expansion of the three gases can be mapped onto a common curve based solely on their Lennard-Jones parameters, in a manner similar to a law of corresponding states. All scattering measurements were performed on the 2-axis powder diffractometer at the Missouri University Research Reactor (MURR).

Session M53 DMP: Two-Dimensional Magnetism Mile High Ballroom 1F - Tag(s): Focus
Of magnetic van der Waals materials, TMPS3 with TM=transition metal elements have attracted significant attentions as it can exhibit the three fundamental magnetic model of Ising (FePS3), XY (NiPS3) and Heisenberg (MnPS3) Hamiltonian depending on the TM elements. Using these materials, we have studied some of the fundamental theorems of modern magnetism. In addition, we have also investigated how correlation physics plays a role in the optical spectroscopy data. In this talk, I will demonstrate how we can use this unique magnetic property of these materials to learn of the old physics.

A van der Waals metal thiophosphate ferromagnetic semiconductor AgVP$_2$Se$_6$  

YUXUAN PENG (Presenter), XING CHENG, PINGFAN GU, FANGGUI WANG, JIE YANG, WENYUN YANG, YU YE, JINBO YANG, School of Physics, Peking University — The recent realization of two-dimensional (2D) magnetism in van der Waals (vdWs) magnets holds the promise for the low-power spintronic applications. The 2D semiconducting ferromagnets, which remain rare, are special important in developing 2D magnetic devices with new functionalities. Metal thiophosphate (MTP), a multifunctional 2D material system that combines the sought-after properties of complex oxides, is a promising 2D magnet system. Here, we successfully synthesize single crystals of a novel 2D ferromagnetic semiconductor MTP AgVP$_2$Se$_6$ with a bandgap of 2.14 eV at room temperature. Due to the nature of vdWs bonding along the c axis, the magnetic properties of the few-layer AgVP$_2$Se$_6$ with different thicknesses are characterized on the exfoliated samples. The AgVP$_2$Se$_6$ flakes exhibit significant thickness-dependent magnetic properties, and a rectangular hysteresis loop with a large coercive field of 750 Oe at 2 K and an undiminished Curie temperature of 19 K are observed in the 6.7 nm AgVP$_2$Se$_6$ flake. The discovered 2D hard ferromagnet AgVP$_2$Se$_6$ with semiconducting behavior will provide alternative platforms for exploring 2D magnetism and potential applications in spintronic devices.

Tunable defect-induced magnetism in Pt-based dichalcogenides*

PRIYANKA MANCHANDA (Presenter), PRATIBHA DEV, Howard University — The much-sought-after magnetism in two-dimensional (2D) materials is not only important for its potential applications in spintronic and magneto-optical devices, but also due to its impact on our understanding of fundamental principles in solid state physics. In addition, 2D magnetic solids offer a unique opportunity for heterogeneous assembly with potentially new emergent phenomena. Amongst recent reports of magnetic 2D materials, magnetism was experimentally observed in PtSe$_2$ thin films and was attributed to the naturally-occuring Pt vacancies. In this theoretical work, we show that the defect-induced magnetism in the PtSe$_2$ thin films is highly sensitive to: (i) the PtSe$_2$ layer-thickness (ii) defect density, (iii) the strain in the layer, and (iv) substrate choice. These different factors dramatically modify magnetic properties such as, the magnitude of the local moments, strength of coupling, and even the nature of coupling between the moments. The tunability of the magnetic properties in the Pt-based dichalcogenides can be used to design novel devices for magnetoelectric and magneto-optics applications.

12:51PM M53.00005: Atomic-Scale Visualization of Reversible Phase Transformation in 2D Ferroelectric In$_2$Se$_3$  
FAN ZHANG (Presenter), Beijing Academy of Quantum Information Science, Beijing 100193, China;  
Department of physics, Virginia Tech, ZHE WANG, International Center for Quantum Design of Functional Materials, University of Science and Technology of China, LIXUAN LIU, ZHONGYUAN LIU, State Key Laboratory of Metastable Materials Science and Technology, Yanshan University, WENQUANG ZHU, International Center for Quantum Design of Functional Materials, University of Science and Technology of China, CHENGGGANG TAO, Department of Physics, Virginia Tech — Phase transformation in emerging two dimensional (2D) materials is crucial for understanding and controlling the interplay between structure and electronic properties. In 2D In$_2$Se$_3$ synthesized via CVD, we observe that In$_2$Se$_3$ layers with thickness ranging from single layer to ~20 layers stabilize at the $\beta$ phase with a superstructure at room temperature. At around 180 K the $\beta$ phase converts to a more stable $\beta'$ phase that is distinct from previously reported phases in 2D In$_2$Se$_3$. The kinetics of the reversible thermally driven $\beta$-to-$\beta'$ phase transformation is investigated by temperature dependent TEM and Raman spectroscopy, corroborated with the expected minimum-energy pathways obtained from our first-principles calculations. DFT calculations further reveal in-plane ferroelectricity in the $\beta'$ phase. We will also discuss domain boundaries between $\beta'$ phase domains with different orientations. The domain boundary structures are visualized by atomically resolved STM imaging and the localized boundary states are revealed by STS.

1:03PM M53.00006: Anisotropic magnetic properties of novel correlated van der-Waals materials*  
SAICHARAN ASWARTHAM (Presenter), SEBASTIAN SELTER, YULIIA SHERMERLIUK, ANJA WOLTER, BERND BUECHNER, Inst for Festkorper Werkstoffforschung — Layered van der Waals crystals with Weak couplings between individual layers has generated enormous interest in scientific community, because of the presence of long range magnetic order down to monolayer limit. The family of transition metal trichalcogenides (TMTC) belongs to the class of layered van der Waals materials. These TMTCs exhibits many interesting physical properties such as the metal/insulator transition, magnetism, and superconductivity under pressure. Also, when thinned down to the monolayer limit, significant changes in the physical properties have been observed. Most of these properties steam from the strong 2D character associated with the layered crystal structure. Cr$_2$Ge$_2$Te$_6$ is a ferromagnetic insulator whereas Ni$_2$P$_2$S$_6$ & Fe$_2$P$_2$S$_6$ are aniferromagnetic insulators. In this talk, I will discuss about synthesis, physical properties and the tunability of their anisotropic magnetic properties of these novel TMTCs.

Intrinsic ferromagnetism in quasi two-dimensional chromium telluride nanoplates*  
AMANDA COUGHLIN (Presenter), Department of Physics, Indiana University - Bloomington, YUE YAO, Department of Physics and Astronomy, University of Utah, ZHIPENG YE, Department of Electrical and Computer Engineering, Texas Tech University, HUA GUO, Department of Materials Science and NanoEngineering, Rice University, YAROSLAV LOSOVYJ, Department of Chemistry, Indiana University - Bloomington, HERBERT FERTIG, Department of Physics, Indiana University - Bloomington, JUN LOU, Department of Materials Science and NanoEngineering, Rice University, RUI HE, Department of Electrical and Computer Engineering, Texas Tech University, YAN LI, Department of Physics and Astronomy, University of Utah, SHIXIONG ZHANG, Department of Physics, Indiana University - Bloomington — The recent demonstration of ferromagnetic order in atomically thin crystals has opened many new opportunities to study two-dimensional (2D) magnetism for novel spintronic applications. Most of the 2D magnets realized so far are van der Waals materials. In this talk, we report on the chemical vapor deposition and magnetic studies of thin nanoplates of chromium telluride, a layered magnetic material with a non-van der Waals structure. Bulk magnetization and magneto-optic Kerr effect (MOKE) measurements demonstrate a ferromagnetic order below a $T_c$ of ~ 180 K and a strong magnetic anisotropy with an easy axis along the c-axis. We will discuss how the magnetic properties are influenced by the nanoplate thickness based on MOKE measurement of individual nanoplates. We will also discuss in detail the aging effect at ambient conditions, one of the major challenges of 2D magnets with regards to practical applications.

*This work is supported in part by NSF DMR-1506460, DMR-1760668 and ECCS-1936406

Ferromagnetism in nitrogen-doped graphene*  
MUKUL KABIR (Presenter), ROHIT BABAR, IISER Pune — Metal-free magnetism in graphene has remained a subject of intense research, and many research groups have invested in understanding the roles of doping, structural defects and edge structure in finite-sized nano-flakes. However, a robust long-range magnetic order has remained elusive. In this context, nitrogen-doped graphene is experimentally proposed to be a promising candidate, though the corresponding exchange mechanism endures unclear and is essential to tune further and manipulate magnetism. In this talk, we will systematically discuss the local moment formation and the concurrent interaction between various defect complexes. The importance of adatom diffusion on the differential defect abundance will be elaborated. We will establish that the direct exchange mechanism between the delocalized magnetic moment originating from the $\pi$-electron at the prevalent triazine complex to be responsible for the observed ferromagnetism. We will also discuss the role of B co-doping that further improves ferromagnetism. The present results not only provide the microscopic understanding but also direct to a synthesis strategy towards robust magnetism.

*We acknowledge the Indian Department of Science and Technology through Nano Mission project SR/NM/TP-13/2016.
1:39PM M53.00009: Unraveling the Relationship Between Layer Stacking and Magnetic Order in Nb₃X₈ Systems* ELISABETH BIANCO (Presenter), ISMAIL EL BAGGARI, Cornell University, CHRISTOPHER PASCO, Johns Hopkins University, BERIT GOODGE, Cornell University, TYREL MCQUEEN, Johns Hopkins University, LENA KOURKOUTIS, Cornell University — Niobium halides of form Nb₃X₈ (X=Cl or Br) are cluster-based, 2D materials that exhibit an antiferromagnetic to non-magnetic transition. In Nb₃Cl₈, the loss of magnetic order occurs below 90 K and has been coupled to a layer re-stacking from a 2-layer (α-phase) to 6-layer (β-phase) unit cell. The transition temperature, however, depends strongly on composition with Nb₃Br₈ transitioning at 293 K. While tuning magnetic ordering temperature through composition is appealing, the layer re-stacking mechanism is not understood. Here, we used controlled-temperature cryogenic scanning transmission electron microscopy (cryo-STEM) to study the re-stacking in Nb₃Br₈ with atomic-resolution. Our results reveal a reversible transformation from the α-phase to β-phase at ~250 K upon cooling and the reverse at ~425 K upon heating through a series of intermediate phases. Tracking the emergence of intermediates with electron diffraction and Multislice image simulations provides a clearer picture of favorable stacking configurations for van der Waals Nb₃X₈. Understanding these stacking changes and their effect on magnetic ordering will afford handles for materials with tailored transition temperatures.

1:51PM M53.00010: High mobility in a layered antiferromagnet* SHIMING LEI, JINGJING LIN, YANYU JIA, Princeton University, MASON GRAY, Boston College, TONG GAO, Princeton University, ANDREAS TOPP, MPI for solid state research, FANNY RODOLAKIS, JESSICA L MCCHESENY, Advanced Photon Source, CHRISTIAN R AST, MPI for solid state research, KEN BURCH, Boston College, SANFENG WU, N. PHUAN ONG, LESLIE SCHOO (Presenter), Princeton University — 2D, or ultrathin, magnetic materials are being studied as a new paradigm for device design. Intrinsic magnetic order in atomically thin layered materials has been confirmed only recently. Thus far magnetic 2D materials are mostly insulating or semiconducting; none possesses high electronic mobility. A material that exhibits simultaneously magnetic order and high mobility would enhance development of high-speed spintronic devices. In this talk, I will show how we can use chemical rules to design a material that can combine high mobility and magnetism and also crystallizes in a structure with a van der Waals gap. I will introduce the LnTe₃ family as such highly conducting antiferromagnetic layered materials. In bulk GdTe₃, the mobility reaches more than 60,000 cm²/Vs, [3] which is the highest mobility yet recorded for layered magnetic (ferro or antiferro) materials, and is comparable to non-magnetic, high-mobility materials such as black phosphorous. I will also show GdTe₃ can be mechanically exfoliated to the monolayer limit, which will allow future investigation of the properties in the 2D limit as well as open avenues for future device design.

*DMR-1420541. Arnold and Mabel Beckman foundation.
11:15AM M54.00001: Moving Majoranas across a quantum point contact in 2D topological insulators*  ALESSIO CALZONA (Presenter), BJORN TRAUZETTEL, University of Wurzburg —
Majorana fermions are zero-energy excitations of topological superconductors which obey non-Abelian exchange statistics and are basic building blocks for topological quantum computation. In order to observe and exploit their extraordinary properties, we need to be able to properly manipulate them, for instance, by braiding a couple of them in real space. We propose a setup based on the helical edges of two-dimensional topological insulators (2DTI) which allows for a high degree of tunability by only controlling a handful of superconducting phases. In particular, our setup allows to move the Majoranas along a single edge as well as to move them across two different edges coupled by a quantum point contact. The versatility of the system represents an essential step forward towards probing the non-Abelian exchange statistics of Majoranas.

*We acknowledge support by the Wurzburg-Dresden Cluster of Excellence on Complexity and Topology in Quantum Matter (EXC 2147, project-id 39085490).

11:27AM M54.00002: Transport properties of Majorana bound state networks in the Coulomb blockade regime*  JOHAN EKSTRÖM (Presenter), University of Luxembourg Limpertsberg, PATRIK RECHER, Braunschweig University of Technology, THOMAS SCHMIDT, University of Luxembourg Limpertsberg — Topologically protected qubits based on nanostructures hosting Majorana bound states (MBSs) hold great promise for fault-tolerant quantum computing. We study the transport properties of nanowire networks hosting MBSs with a focus on the effects of the charging energy and the overlap between neighboring MBSs in short mesoscopic samples. In particular, we investigate structures hosting four MBSs such as Tjunctions and Majorana boxes. Using a Markovian master equation, we discuss the leading transport processes mediated by the MBSs. Single-electron tunneling and processes involving creation and annihilation of Cooper pairs dominate in the sequential tunneling limit. In the cotunneling regime, Andreev processes are suppressed due to the charging energy and transport is dominated by transitions via virtual intermediate states. Our results show that four-terminal measurements in the T-junction and Majorana box geometries can be useful tools for the characterization of the properties of MBSs with finite overlaps and charging energy.

11:39AM M54.00003: Josephson radiation from nonlinear dynamics of Majorana modes in topological Josephson junctions*  JIA-JIN FENG, Sun Yat-sen University, ZHAO HUANG, Los Alamos National Laboratory, ZHI WANG (Presenter), Sun Yat-sen University, QIAN NIU, The University of Texas at Austin — Recently, in topological Josephson junctions, the electromagnetic emission with the quantized frequency of eV/h has been experimentally observed as a consequence of the 4π-periodic Josephson effect, showing a phase-sensitive signature of Majorana zero modes. However, experiments show that this nontrivial radiation vanishes above a critical voltage, sharply contradicting previous theoretical results of the standard resistively shunted junction model. We extend this model to include the Majorana dynamics and show a quantitative agreement with the experimental results. Furthermore, we predict a fragment emission line and a chaos regime which can be observed experimentally by altering the junction parameters. We reveal that all these unique features come from the nonlinear dynamics of Majorana zero modes. The fragmental emission line and its vanishment are well explained with a fixed-point portrait, while the chaotic behavior is understood as the result of the bifurcation of fixed points. Our work will inspire more works to examine the structure of the radiation spectrum of topological Josephson junctions, which is wildly presented in experimental devices.

*This work was partially supported by U.S. DOE Office of Basic Energy Sciences E3B5.

11:51AM M54.00004: Signatures of topological ground state degeneracy in Majorana islands  JUKKA VAYRYNEN (Presenter), University of California, Santa Barbara, ADRIAN FEIGUIN, Northeastern University, ROMAN LUTCHYN, University of California, Santa Barbara — We consider a mesoscopic superconducting island hosting multiple pairs of Majorana zero-energy modes. The Majorana island consists of multiple p-wave wires connected together by a trivial (s-wave) superconducting backbone and is characterized by an overall charging energy $E_c$; the wires are coupled to normal-metal leads via tunnel junctions. Using a combination of analytical and numerical techniques we calculate the average charge on the island as well as non-local conductance matrix as a function of a p-wave pairing gap $\Delta_p$, charging energy $E_c$ and dimensionless junction conductances $g_i$. We find that the presence of a topological ground-state degeneracy in the island dramatically enhances charge fluctuations and leads to the suppression of Coulomb blockade effects. Specifically, in contrast with conventional (s-wave) mesoscopic superconducting islands, we find that Coulomb blockade effects are suppressed in Majorana islands regardless of the ratio $E_c/\Delta_p$ or the magnitude of the conductances $g_i$. We also discuss our findings in relation to the so-called topological Kondo effect.
**12:03PM M54.00005: Majorana Bound States at the Superconducting Vortex from Magnetic Skyrmions**

CANON SUN (Presenter), SHU-PING LEE, YI LI, Johns Hopkins University — We show topological superconductivity can arise at the interface of ferromagnetic skyrmion material in proximity to an s-wave superconductor in the presence of strong spin-orbit coupling. We study the Majorana zero modes localized at the interface of the heterostructure and propose a pathway towards a useful platform for the manipulation of Majorana fermions via controlling skyrmions.

*This work is supported by the Institute for Quantum Matter under DOE EFRC grant DE-SC0019331 and in part by the Alfred P. Sloan Research Fellowships.

**12:15PM M54.00006: Topological superconductivity and Majorana fermions in the heterostructure of EuS island and planar gold surface**

YINGMING XIE (Presenter), KAM TUEN LAW, PATRICK A LEE, Hong Kong University of Science and Technology — In a recent work [1], possible signatures of a pair of Majorana zero-energy modes were found within the platform forming by EuS island and gold wire. In this work, we show the gold wire can be replaced by a large gold surface in this platform. Furthermore, we found the chemical potential step between the EuS island covering region and bare gold surface region are essential for keeping a sizable topological region in the large gold surface case. Our results suggest the feasibility of depositing EuS wires on a large area of gold and simplify the fabrication process further.

---

**12:27PM M54.00007: Transmission Amplitude through a Coulomb blockaded Majorana Wire**

MATTHIAS THAMM (Presenter), BERND ROSENOW, Univ Leipzig — We study electronic transport through a Coulomb blockaded superconducting Rashba wire in the co-tunneling regime between conductance resonances. Embedding such a wire into one arm of an electron interferometer allows to study the amplitude for coherent transmission. Varying an external Zeeman field allows to tune the wire into a topological regime, where localized Majorana zero modes are formed at both ends of the wire. In this topological phase, the nonlocal transport through Majorana zero modes is the dominant mechanism and gives rise to a maximum in the transmission amplitude as a function of Zeeman field, whose height is proportional to the wire length. On the other hand, for tunneling through a generic extended state or through a pair of Andreev bound states, the transmission amplitude is independent of wire length. Hence, the Zeeman field and length dependence of the transmission amplitude are unique signatures for the presence of Majorana zero modes.
Parafermion braiding in fractional quantum Hall edge states with finite chemical potential

SOLOFO GROENENDIJK, ALESSIO CALZONA, HUGO TSCHIRHART, EDVIN IDRISOV, THOMAS SCHMIDT (Presenter), University of Luxembourg — Parafermions are non-Abelian anyons which generalize Majorana fermions and hold great promise for topological quantum computation. We study the braiding of $Z_{2n}$ parafermions which have been predicted to emerge as bound states in fractional quantum Hall systems at filling factor $\nu=1/n$ (n odd). Using a combination of bosonization and refermionization, we calculate the energy splitting as a function of distance and chemical potential for a pair of parafermions separated by a gapped region. Braiding of parafermions in quantum Hall edge states can be implemented by repeated fusion and nucleation of parafermion pairs. We simulate the conventional braiding protocol of parafermions numerically, taking into account the finite separation and finite chemical potential. We show that a nonzero chemical potential poses challenges for the adiabaticity of the braiding process because it leads to accidental crossings in the spectrum. To remedy this, we propose an improved braiding protocol which avoids those degeneracies.

*The authors acknowledge support by the National Research Fund, Luxembourg under grants ATTRACT 7556175, INTER 11223315, AFR 11224060 and PRIDE/15/10935404, as well as by Würzburg-Dresden Cluster of Excellence in Complexity and Topology in Quantum Matter.

Entanglement in topological spin Josephson junctions

PEI-XIN SHEN (Presenter), Tsinghua University, SILAS HOFFMAN, University of Basel, MIRCEA T TRIF, Tsinghua University — We study the spin transport through 1D quantum Ising-XY-Ising junctions that emulates topological Superconducting-Normal-Superconducting junctions via Jordan-Wigner transformation. We calculate, both numerically and analytically, the spectrum of Andreev bound states and the resulting $Z_2$ fractional spin Josephson effect from Majorana Fermions. Deep in the topological regime, we identify an effective time-reversal symmetry that leads to $Z_4$ fractional spin Josephson effect in the presence of interactions within junctions. Interestingly, in the lattice model, a hidden lattice time-reversal symmetry is revealed to protect $Z_4$ fractional spin Josephson effect in odd chain sites that persists in the absence of interactions. We also evaluate the resulting spin texture in the presence of the spin currents and highlight the effects of Majorana bound states on the entanglement of neighboring spin within junctions quantified by the concurrence. We propose to use a microwave cavity setup (cQED) for detecting the aforementioned Josephson effects by dispersive readout methods. Our results are relevant for a plethora of spin systems, such as trapped ions, coupled quantum dots, or magnetic impurities on surfaces.

1:03PM M54.00010: Effect of Magnetic Field on Multi-terminal Josephson Junctions  A. BARIS OZGULER (Presenter), University of Wisconsin - Madison, HANHO LEE, VLADIMIR MANUCHARYAN, University of Maryland, College Park, MAXIM G VAVILOV, University of Wisconsin - Madison — Junctions with three or more superconducting terminals gained broad interest as they provide means to study physics and topology in higher dimensions and to braid Majorana fermions for fault-tolerant quantum computation. We study effect of perpendicular magnetic field on Andreev energy levels and critical currents in a 3-terminal Josephson junction with conventional s-wave superconducting leads and a normal 2DEG scattering region. In a 3-terminal junction, currents through two terminals determine the DC Josephson effect which occurs when the two currents are limited by the Critical Current Contour (CCC). We study the Fraunhofer diffraction patterns that manifest itself as oscillations in the diameter and area of the CCC. We show that the oscillations remain in 3-terminal devices but the additional terminal reduces the amplitude of the oscillations. We also show that magnetic field mixes with the superconducting phases in the leads and deforms the ground state energy landscape. We argue that a peculiar modulation of CCC with magnetic flux is the signature of coherent Josephson effect in multi-terminal Josephson junctions.

1:15PM M54.00011: Generic quantized zero-bias conductance peaks in superconductor-semiconductor hybrid structures*  HAINING PAN (Presenter), WILLIAM S COLE, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland — We show theoretically that quantized zero-bias conductance peaks should be ubiquitous in superconductor-semiconductor hybrids by employing a random matrix model with continuous tuning parameters. We demonstrate that NS junction conductance spectra can be generically obtained in this model replicating all features seen in recent experimental results. The theoretical quantized conductance peaks, which explicitly do not arise from spatially isolated Majorana zero modes, are easily found by preparing a contour plot of conductance over several independent tuning parameters, mimicking the effect of Zeeman splitting and voltages on gates near the junction. This suggests that even stable, apparently quantized, conductance peaks need not correspond to isolated Majorana modes; rather the a priori expectation should be that such quantized peaks generically occupy a significant fraction of the high-dimensional tuning parameter space that characterizes the NS tunneling experiments.

1:27PM M54.00012: Repulsive interactions enhance the coupling of superconductors to fractional quantum Hall edges  BARAK KATZIR (Presenter), NETANEL LINDNER, Technion - Israel Institute of Technology, ADY STERN, EREZ BERG, Weizmann Institute of Science — We study helical gapless modes arising on the edges of Abelian fractional quantum Hall liquids proximity coupled to a superconductor. This setup can be utilized to create non-Abelian parafermion zero modes if the coupling to the superconductor opens a gap in the helical modes. However, when the coupling to the superconductor is weak it is ineffective and does not open a gap due to the competition with the repulsive interactions stabilizing the fractional quantum Hall liquid. We therefore investigate the possibility for obtaining a gapped phase at strong coupling to the superconductor. To this end, we use an effective wire construction model for the quantum Hall liquid and employ renormalization group methods to obtain the phase diagram of the system. Surprisingly, at strong coupling we find a gapped phase which is stabilized by strong repulsive interactions in the bulk of the quantum Hall fluids. To investigate the possibility for obtaining a gap in the intermediate coupling regime, we identify a duality transformation that maps between the weak coupling and strong coupling regimes. We find conditions on the existence of a gap in the intermediate coupling regime by investigating self-dual points of the model.

1:39PM M54.00013: Survival of the fractional Josephson effect in time reversal invariant topological superconductors  CHRISTINA KNAPP (Presenter), AARON CHEW, JASON F. ALICEA, Caltech — A one-dimensional time reversal invariant topological superconductor (TRITOPS) hosts a Kramers pair of Majorana zero modes at each end. Previous work has established that TRITOPS phases do not enable rigid non-Abelian braiding, even when time-reversal symmetry is preserved throughout: local operators can mix the Majorana Kramers pair, yielding non-universal contributions to the non-Abelian Berry phase. Nonetheless, TRITOPS phases have been predicted to display other topological signatures, including a $4\pi$ periodic fractional Josephson effect. This talk will revisit the fractional Josephson effect and explore to what extent the anomalous periodicity remains robust in the presence of local mixing terms that destroy rigidity of non-Abelian braiding.
1:51PM M54.00014: Presence versus absence of end-to-end nonlocal conductance correlations in Majorana nanowires: Majorana bound states versus Andreev bound states

YI-HUA LAI (Presenter), JAY SAU, Physics, University of Maryland, College Park — By calculating the differential tunneling conductance spectra from the two ends of a Majorana nanowire with a quantum dot embedded at one end, we establish that a careful examination of the nonlocal correlations of the zero bias conductance peaks, as measured separately from the two ends of the wire, can distinguish between topological Majorana bound states and trivial Andreev bound states. In particular, there will (not) be identical correlated zero bias peaks from both ends for Majorana bound states (Andreev bound states), and thus the presence (absence) of correlated zero bias conductance from the two wire ends could imply the presence (absence) of topological Majorana zero modes in the system. We present detailed results for the calculated conductance, energy spectra, and wavefunctions for different chemical potentials at the same magnetic field values to motivate end-to-end conductance correlation measurements in Majorana nanowires.

2:03PM M54.00015: Dissipative response of a topological Josephson junction at the critical point

VLADISLAV KURILOVICH (Presenter), Yale University, CHAITANYA MURTHY, UCSB, PAVEL KURILOVICH, Yale University, BERNARD VAN HECK, Microsoft, LEONID GLAZMAN, Yale University, CHETAN NAYAK, Microsoft — A semiconducting nanowire proximitized by a superconductor is emerging as a building block of a topological qubit. Magnetic field applied to a proximitized nanowire drives it through the critical point into a topological state. We investigate signatures of this quantum phase transition in the dissipative response of a nanowire Josephson junction. The gap between the ground and excited states vanishes at the transition point. We find, that the low-frequency dissipation may remain weak despite the gap closing; this is markedly different from the conventional transition between the superconducting and normal states. In the absence of phase bias across the junction, the dissipative component of the admittance scales as \( \sigma(\omega) \sim \omega^2 \). At a finite phase bias \( \varphi \) across the junction, \( \sigma(\omega) \sim \varphi^2 \) is frequency-independent in the interval \( \omega \leq \Delta \) (here \( \Delta \) is the value of the proximity-induced gap at zero field). We establish the complete scaling functions for the admittance in the vicinity of the transition. In the presence of a finite gap (i.e., upon detuning from the critical point) the scaling function for \( \sigma(\omega) \) at a finite \( \varphi \) agrees with conventional Mattis-Bardeen formula. However, it is modified substantially and characterized by a much stronger frequency dependence if \( \varphi = 0 \).

Wednesday, March 4, 2020 11:15 AM - 2:03 PM

11:15AM M55.00001: Bulk insulation and surface electrons’ properties of Pb(Bi,Sb)2Te4 Topological Insulator  YUYA HATTORI (Presenter), YUKI TOKUMOTO, KEIICHI EDAGAWA, Univ of Tokyo — In the field of Topological Insulators (TIs), almost all the transport studies are limited to (Bi,Sb)2(Te,Se,S)3 (BSTS)Ts. For now, BSTS-TIs has the largest bulk resistivity and transport properties of surface states have been revealed in detail. However, the utilization of surface states for device application is still a bit difficult for now.
In such context, many theoretical researchers are motivated to find new TIs, and PbBi2Te4 series TIs were discovered. The topological index of Pb-TI is (1;111), which is completely different from BSTS’s (1;000). Also, PbBi2Se4 is considered to have considerably large bulk band gap of 600meV, which is higher than Bi2Se3’s 300meV. However, the single phase and single crystal of PbBi2Te4 series TIs are difficult to grow, which hampers clarification of surface electrons’ nature.
In our study, we fabricated a series of Pb(Bi,Sb)2Te4 TI single crystal from off-stoichiometry mixture. By changing Bi, Sb ratio, we systematically studied the transport properties in order to enhance bulk resistivity. Precise control of Sb concentration made it possible to fabricate bulk insulating samples for the first time in this system. The results of nano-flake transport measurements and STM study to clarify surface electrons’ nature will be presented.

11:27AM M55.00002: Robustness of Helical Edge States Under Proximate Band Reconstruction*  NIELS JOHN (Presenter), BERND ROSENOW, Universität Leipzig, ADRIAN DEL MAESTRO, University of Vermont — We analyze the edge structure of two-dimensional topological insulators described by the Bernevig-Hughes-Zhang model with the help of a self-consistent electrostatic modeling of sample edges, combined with a time-dependent perturbation theory approach. We find that for sufficiently smooth confinement, strongly interacting additional edge states arise under fairly general conditions. While their ground state is spin unpolarized, a spin-exchange coupling between helical and reconstructed edge states can lead to a dynamical spin polarization of the latter. However, we show that spatially random spin-orbit coupling inhibits such dynamical spin polarization and protects the helical edge states against backscattering. Further, we argue that at low electron density, the reconstructed edge states are well described by a Luttinger liquid.

*We acknowledge financial support to DFG grant RO 2247/10-1.

11:39AM M55.00003: Transport properties of a topological system in non-integer dimensions  SONJA FISCHER (Presenter), LARS FRITZ, MIKAEL FREMLING, Univ of Utrecht — In recent years, the subject of topological materials has inspired a very active field of research. A considerable amount of effort was put into investigating the stability of topological edge modes under various kinds of disturbances, such as disorder.
Another less explored avenue is the stability of edge modes under variation of the dimensionality. By putting a topological system on a lattice with fractal geometry and considering and investigating the transport properties we are able to detect the influence of non-integer dimensionality on the topological properites and stability of the system.
11:51AM M55.00004: Probing spin-orbit interactions in monolayer WTe$_2$ edge states
ELLIOTT RUNBURG (Presenter), WENJIN ZHAO, ZAIYAO FEI, JOSHUA MUTCH, PAUL MALINOWSKI, BOSONG SUN, University of Washington, XIONG HUANG, YONGTAO CUI, University of California, Riverside, XIAODONG XU, JIUN-HAW CHU, DAVID COBDEN, University of Washington — Monolayer WTe$_2$ displays edge conduction that is consistent with the material being a two-dimensional topological insulator. The expected helical nature of the edge conduction should limit the conductance between adjacent contacts on an edge to $e^2/h$, and this is consistent with experiments to date. However, the helical nature has not been supported by experiments that probe the form of the Hamiltonian of the edge states. To address this, we investigate the angular dependence of the magnetic field on the conduction of edges and cracks in monolayer WTe$_2$ flakes as a function of gate voltage, temperature, and edge orientation relative to the crystal axes as determined by scanning microwave impedance microscopy.

12:03PM M55.00005: Coulomb Drag in 2D bilayer Topological Insulator systems* KAI-JIE YANG (Presenter), CHAOXING LIU, Pennsylvania State University — InAs/GaSb quantum wells are 2D bilayer topological insulator systems possessing the inverted band structure with the conduction band bottom of the InAs layer below the valence band top of GaSb layer. Recent transport experiment in InAs/GaSb quantum wells has revealed an anomalous high frequency quantum oscillation coexisting with a large resistance when the chemical potential is tuned into the charge neutrality point. The high oscillation frequency (large carrier density) and large resistance (insulating behaviors) are in contradiction with each other and this fact cannot be explained in a single-particle picture, thus motivating us to study the interaction effect of this system. Based on the linear response theory and diagrammatic methods, we carefully investigated the Coulomb drag effect in this 2D topological insulator systems based on the simplified models. Our results shed the light in understanding the anomalous quantum oscillation in 2D bilayer topological insulator systems.

12:15PM M55.00006: Electrical study of Bi$_2$Te$_3$, Sb$_2$Te$_3$ and (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$ films*  SOORYA SURESH BABU (Presenter), YANG BAI, JAMES ECKSTEIN, University of Illinois at Urbana-Champaign — Bi$_2$Te$_3$ and Sb$_2$Te$_3$ are semiconductors that also behave as topological insulators when they are thin films. The topological properties mean that the surface conducting states have carriers that have spins locked normal to their momentum states. We have studied the growth of thin films grown by molecular beam epitaxy containing Bi$_2$Te$_3$, Sb$_2$Te$_3$ and alloys of (Bi$_{1-x}$Sb$_x$)$_2$Te$_3$. As was discovered earlier$^1$, this allows the chemical potential to be tuned from p-type to n-type by varying the relative composition. We have also grown short period superlattices and thin bilayers of the tellurides to study how this occurs when the binary phases are kept in separate layers. The growth on c-plane sapphire crystallizes into a flatter film when Bi$_2$Te$_3$ is the interfacial layer. Like in the case of alloys, the carrier type in the bilayers can be tuned by modifying layer thickness. In bilayers with different thicknesses we have studied how the conductivity depends on layer thickness.

12:27PM M55.00007: Wide band gap topological insulator via band engineering*  IDO LEVY (Presenter), CODY YOUMANS, THOR A GARCIA, HAIMING DENG, STEVEN ALSHEIMER, The City College of New York, CHRISTOPHE TESTELIN, CNRS, Institut des NanoSciences de Paris, Sorbonne Université, LIA KRUSIN-ELBAUM, POUYAN GHAEMI, MARIA C TAMARGO, The City College of New York — Molecular beam epitaxy (MBE) growth of Bi$_2$Se$_3$ and Sb$_2$Te$_3$ is hindered by a high bulk background doping due to selenium vacancies (n-type) and tellurium anti-sites defects (p-type). In order to explore the unique properties of these topological insulators (TIs), the bulk carriers must be suppressed. We previously presented the growth of TI/TI superlattices (SLs). By growing SLs of Bi$_2$Se$_3$ and Sb$_2$Te$_3$, which have a type III band alignment, a reduction of bulk background doping by more than one order of magnitude, from 1.2x10$^{20}$ cm$^{-3}$ to 8.5x10$^{18}$ cm$^{-3}$ was observed as the period was decreased from 12 nm to 5 nm. We attributed this to the formation of SL bands that create an enhancement of the bulk bandgap. Here we present tight binding calculations, which predict a SL gap of up to 400% larger than the bandgaps of the constituent layers when the SL is grown with the appropriate thicknesses. The calculations also predict the preservation of the Dirac cone, along with these large bandgaps. Measurements of magnetoconductance confirm preservation of the surface states for a SL with period thickness of 5nm. Direct measurement of the bandgaps by FTIR spectroscopy will also be reported.

12:39PM M55.00008: Pb-doped p-type Bi$_2$Se$_3$ thin films via interfacial engineering

JISOO MOON (Presenter), ZENGLE HUANG, WEIDA WU, SEONGSHIK OH, Department of Physics and Astronomy, Rutgers, The State University of New Jersey — Due to high density of native defects, the prototypical topological insulator, Bi$_2$Se$_3$, is naturally n-type. Although Bi$_2$Se$_3$ can be converted into p-type by substituting 2+ ions for Bi, only light elements such as Ca have been so far effective as the compensation dopant. Considering that strong spin-orbit coupling (SOC) is essential for the topological surface states, a light element is undesirable as a dopant, because it weakens the strength of SOC. In this sense, Pb, which is the heaviest 2+ ion, located right next to Bi in the periodic table, is the most ideal p-type dopant for Bi$_2$Se$_3$. However, Pb-doping has so far failed to achieve p-type Bi$_2$Se$_3$ not only in thin films but also in bulk crystals. Here, by utilizing an interface engineering scheme, we have achieved the first Pb-doped p-type Bi$_2$Se$_3$ thin films. Furthermore, at heavy Pb-doping, the mobility turns out to be substantially higher than that of Ca-doped samples, indicating that Pb is a less disruptive dopant than Ca.

12:51PM M55.00009: Thermoelectric transport in helical edge states via chiral hydrodynamics

XINGHAI ZHANG (Presenter), MATTHEW FOSTER, Rice Univ — We study thermoelectric transport in a 1D helical liquid, as appears at the edge of a 2D topological insulator. We employ semiclassical “chiral hydrodynamics”, which directly incorporates the axial anomaly, and we consider the combination of Rashba-mediated umklapp backscattering and quenched disorder. The conductivity is computed from the balance between umklapp scattering and the anomaly; the results agree with previous bosonization calculations. We also compute the thermoelectric power (TEP) and thermal conductivity. In the clean limit, chiral hydrodynamics gives a TEP equal to the thermodynamic entropy per charge, while the Wiedemann-Franz law is violated for the thermal conductivity by umklapp scattering. In the dirty limit, the electric and thermal conductivities scale the same way with temperature, while the TEP vanishes. We will also discuss results in the nonlinear response regime.

*We acknowledge funding from Welch Foundation under Grant No. C-1809 and NSF CAREER Grant No. DMR-1552327.
1:03PM M55.00010: Proximity-induced quantum anomalous Hall effect in
(Zn,Cr)Te/(Bi,Sb)$_2$Te$_3$/(Zn,Cr)Te heterostructure

RYUTARO YOSHIMI (Presenter), RIKEN, RYOTA WATANABE, University of Tokyo, MINORU KAWAMURA, RIKEN, MASATAKA MOGI, University of Tokyo, ATSUSHI TSUKAZAKI, Tohoku University, XIUZHEN YU, KIYOMI NAKAJIMA, KEI TAKAHASHI, RIKEN, MASASHI KAWASAKI, University of Tokyo, YOSHINORI TOKURA, RIKEN — The quantum anomalous Hall effect (QAHE) is an exotic quantum phenomenon originating from dissipation-less chiral channels at the sample edge. While the QAHE has been observed in magnetically doped topological insulators (TIs), exploiting magnetic proximity effect on the TI surface from adjacent ferromagnet layers may provide an alternative approach to the QAHE by opening an exchange gap with less disorder than that in the doped system. Nevertheless, the engineering of a favorable heterointerface that realizes the QAHE based on the magnetic proximity effect remains to be achieved. Here, we report on the observation of the QAHE in a proximity coupled system of non-magnetic TI and ferromagnetic insulator (FMI). We have designed sandwich heterostructures of (Zn,Cr)Te/(Bi,Sb)$_2$Te$_3$/(Zn,Cr)Te that fulfills two prerequisites for the emergence of the QAHE; the formation of a sizable exchange gap at the TI surface state and the tuning of the Fermi energy into the exchange gap. The efficient proximity coupling in the all-telluride based heterostructure as demonstrated here will enable a realistic design of versatile tailor-made topological materials coupled with ferromagnetism, ferroelectricity, superconductivity, and so on.

1:15PM M55.00011: Franckeite: A new naturally occurring topological insulator*

JUAN PALACIOS (Presenter), Univ Autonoma de Madrid, WENDEL SILVA PAZ, Instituto de Física, Universidade Federal do Espírito Santo, MARCOS MENEZES, RODRIGO CAPAZ, Instituto de Física, Universidade Federal do Rio de Janeiro — Franckeite is a layered material formed by alternating tin disulfide-based Sn(Sb)S$_2$ - pseudohexagonal (H) - and lead sulfide-based Pb(Sb)S - pseudotetragonal (Q) - layers. These layers exhibit different symmetry and periodicity, leading to an incommensurate crystal structure bound by not-so-weak van der Waals interactions between interleaved layers. The electronic properties at large concentration of Sb on the H layer are those of an indirect gap heterostructure (holes and electrons belonging to different layers) [1]. Here we present DFT results on the opposite limit of concentration. For 100% Sn on the H layer, franckeite becomes a topological insulator. This is corroborated by Wilson loop and Z2 number evaluations (the latter when forced into a centro-symmetric structure). We have also evaluated the structural composition of the energetically favorable thinnest possible layer, corresponding this to 0.5Q/H/0.5Q. This layer behaves as a 2D topological insulator, very much like InAs/GaSb quantum wells. [1] Molina-Mendoza et al., Nature Communications 8, 14409 (2017).

*Spanish MICINN through Grant No. FIS2016-80434-P, the María de Maeztu Program for Units of Excellence (MDM-2014-0377), and the European Union Graphene Flagship under Grant Agreement No. 604391 Graphene Flagship.
1:27PM M55.00012: Possible topological protection and superconducting proximity effects in surface states of HfNiSn single crystals* LUCIA STEINKE (Presenter), University of Florida, WILLIAM BAKER, MICHAEL BABB, MASON KLEMM, HARLAN R HARRIS, Texas A&M University, MEIGAN ARONSON, University of British Columbia — Surface states of HfNiSn single crystals were shown to exhibit unconventional properties like nonlocal transport, time-reversal symmetry breaking in the absence of external fields or magnetism, and nonlinear I(V) characteristics indicating electronic correlations [1], possible characteristics of a correlated topological state similar to a quantum Hall system. Oscillations in the magnetoresistance suggest quantum interference with coherence lengths up to 1 μm. The combination of quantum Hall edges or similar chiral one-dimensional states and superconductors is particularly attractive, as such junctions are expected to host the elusive Majorana fermions that could provide a possible platform for topological quantum computing, where the chiral nature of quantum Hall edge states could enable braiding operations. Our first tests of metal deposition on HfNiSn single crystals show promising results, where proximity to superconducting tin or niobium leads to conductance steps of approximately 0.5 e²/h. We further observe a clear disruption of quantum interference patterns at the superconducting transition, and magnetoresistance features associated with the critical field that can be traced up to 80 K.

*This work was supported by the Army Research Office.

1:39PM M55.00013: Influence of electronic band topology on sound waves SANGHITA SENGUPTA (Presenter), MOHAMED NABIL YACINE LHACHEMI, ION GARATE, Physics, Institut quantique de l'Université de Sherbrooke — We present a semiclassical theory of acoustic waves in topologically nontrivial materials. Combining the Boltzmann equation with the dynamical theory of elasticity, we calculate the influence of the electronic Berry curvature on sound velocity and attenuation. We predict signatures of nontrivial electronic band topology in the magnetic-field-dependence of sound propagation and discuss their possible experimental observation.
**1:51PM M55.00014: Thermoelectric Transport Coefficients of a Dirac Electron Gas in High Magnetic Fields**  
VIKTOR KÖNYE (Presenter), MASAO OGATA, Univ of Tokyo  
We study the massive Dirac Hamiltonian in high magnetic fields focusing on the effects of the mass term and we show the main differences that arise compared to massless Dirac fermions. We calculate the thermoelectric transport coefficients based on the formalism developed by Luttinger, and study the transverse components of the electric conductivity, Seebeck, and heat conductivity tensors in high magnetic fields. We prove that the Mott formula and the Wiedemann-Franz law are valid at low temperatures. The magnetic field dependence of measurable quantities strongly depend on the magnetic field dependence of the scattering rate, thus our result relies on the proper treatment of the impurities. We include impurities through the first Born approximation using screened charged impurities as impurity potential. We recovered analytically the experimentally measured linear magnetoresistance in the massless case. The effect of the mass term becomes relevant at high magnetic fields in the quantum limit. We show that in the high field limit the electric conductivity does not change qualitatively in the case of finite mass term. On the other hand we find that the mass term causes significantly different behavior in the Seebeck tensor.

**M55.00015: Epitaxial growth and electronic properties of few-layer stanene on InSb (111)**  
JIANFENG ZHANG (Presenter), XIAOHU ZHENG, RUI-RUI DU, International Center for Quantum Materials, Peking University  
Stanene has been predicted to be a 2D topological insulator with a large band gap, potentially hosting a room-temperature quantum spin Hall effect [1]. Here, stanene with controllable layers has been epitaxially grown on InSb (111) and its electronic properties have been investigated by scanning tunneling microscopy/spectroscopy (STM/STS) and low-temperature magnetotransport experiments [2]. STS results reveal a large band gap on both the wetting layer (~ 0.35 eV) and the subsequently grown single-layer (~ 0.2 eV) stanene. Spectroscopy evidences of edge state with energy inside the band gap, are also observed on the step of stanene film. Furthermore, the magnetotransport results show clear Shubnikov–de Haas oscillations in the bulk state of single-layer stanene. A brief discussion along with the data will be presented.

**Session M56 DCMP: Fractional Quantum Hall and Non-Fermi Liquids**

Mile High Ballroom 2C - Andres Felipe Schlief Raether, Max Planck Institute for the Physics of Complex Systems
11:15AM M56.00001: Fractional Quantum Hall Effect from Hilbert Space Algebra and New Approaches for Experimental Realisation  
BO YANG, Nanyang Tech Univ, YING-HAI WU (Presenter), Physics Department, Huazhong University of Science and Technology, ZLATKO PAPIC, Physics Department, University of Leeds — We show that model states of fractional quantum Hall (FQH) fluids for many topological phases can be uniquely determined by the Hilbert space algebra manifested as the classical reduced density matrix constraints, or the local exclusion constraint (LEC). The scheme allows us to identify filling factors, topological shifts and clustering of topological quantum fluids universally without resorting to microscopic Hamiltonians. Elementary excitations of the FQH phases can also be characterised by the LECs. More interestingly, the LEC formalism leads to a new perspective for the FQH model Hamiltonians, which can now be understood as a the von Neumann lattice of local potentials. This suggests a completely new way of experimentally realising the FQH states, including the coveted non-Abelian states (e.g the Moore-Read and Fibonacci states). We show that by tuning the local one-body potential profile, one can effectively tune the individual pseudopotentials (not just two-body, but few-body pseudopotentials) independently, and this can be done in experiments in principle. (related arXiv papers: Bo Yang, arXiv: 1901.00047, Bo Yang, Ajit Balram, arXiv:1907.09493, Bo Yang, Ying-Hai Wu, Zlatko Papic, arXiv:1907.12572)

11:27AM M56.00002: Parton construction of particle-hole-conjugate Read-Rezayi parafermion fractional quantum Hall states*  
AJIT COIMBATORE BALRAM (Presenter), Institute of Mathematical Sciences, MAISSAM BARKESHLI, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, College Park, MARK RUDNER, Niels Bohr International Academy and the Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — The fractional quantum Hall (FQH) effect encompasses a wide range of quantum many-body phases which are characterized by exotic topological orders. Among these, the Read-Rezayi (RR) states harbor parafermionic excitations, whose non-Abelian braiding properties could potentially be used to carry out fault-tolerant quantum computation. Recent intriguing numerical results indicate that the 12/5 FQH state realized in GaAs could be described by the particle-hole conjugate of an RR state. However, numerically constructing the RR states for large systems, which is necessary for their characterization and for the demonstration of the exotic properties of their excitations, is computationally prohibitive. In this work, we use the parton framework to construct states that lie in the same phases as the particle-hole conjugates of the RR states. A nice feature of our parton states is that their wave functions can be evaluated for very large system sizes, thus, paving the way for the numerical investigation of parafermions.

*ERC Grant Agreement No. 678862, Villum Foundation, NSF CAREER (DMR-1753240), JQI-PFC-UMD and Sloan Research Fellowship. Some numerical calculations were performed using the DiagHam package, for which we are grateful to its authors.
11:39AM M56.00003: Bosonic Integer and Fractional Quantum Hall effect in an interacting lattice model  GAURAV KUMAR GUPTA (Presenter), Technion - Israel Institute of Technology, KRISHNAMURTHY H. R., Physics, Indian Institute of Science, SUBHRO BHATTACHARJEE, International Centre for Theoretical Sciences, Bengaluru — We explore the presence of bosonic integer, as well as the fractional quantum Hall effect in an interacting lattice model. Our model is defined over the bipartite honeycomb lattice with $\pi$ magnetic flux per unit cell and is populated by bosons with hardcore constraint. The bosons can hop to the nearest neighbor (simple hopping) and to the next nearest neighbor (correlated hopping). We use the Lanczos algorithm (Exact Diagonalization (ED)) to find the ground state as well as a few excited states of the system with an aim to characterize the different phases of the system. We have performed calculations for two different fillings and provide evidence for the presence of the bosonic integer quantum Hall effect (BIQHE) and the bosonic fractional quantum Hall effect (BFQHE). We also show the phase transition from the bosonic quantum Hall state to the superfluid (SF) state. We have also performed the adiabatic flux threading to confirm the presence of quantum Hall states.

11:51AM M56.00004: Parafermions in Hierarchical Fractional Quantum Hall States  LUIZ SANTOS (Presenter), Physics, Emory University — Non-Abelian quasiparticles are sought-after building blocks of fault-tolerant quantum computation. These quasiparticles can occur as extrinsic defects on interfaces and edges of two-dimensional Abelian topological phases, of which the Fractional quantum Hall (FQH) effect provides the most abundant realization. In this talk, we will discuss the properties of parafermion zero modes that arise as extrinsic non-Abelian defects in domain walls formed on interfaces of hierarchical FQH Jain states with filling fraction $p/(2mp+1)$ of the lowest Landau level, where $m$ and $p$ are positive integers. Exploring the condensation of bulk Abelian anyons, we use Abelian bosonization to construct local interactions that gap modes with opposite chirality at the interface of two Jain states with the same filling fraction. We identify a class of such local interactions that breaks charge conservation and gives rise to an interface anyon condensate supporting parafermion zero modes whose quantum dimension reflects the topological order and the hierarchy of the bulk FQH Jain state. Our results shed light on the hierarchy of non-Abelian defects in two-dimensional Abelian topological phases.
**12:03PM M56.00005: Josephson frequency of fractional charges from Shot Noise measurements**  
MAËLLE KAPFER (Presenter), Department of Physics, Columbia University, PREDEN ROULLEAU, MATTIEU SANTIN, Service de Physique de l'Etat Condense, CEA Saclay, IAN FARRER, Department of Electronic and Electrical Engineering, University of Sheffield, DAVID A RITCHIE, Cavendish Laboratory, University of Cambridge, CHRISTIAN GLATTLI, Service de Physique de l'Etat Condense, CEA Saclay — The determination of the quasiparticles charge $e^*$ is crucial to understand the Fractional Quantum Hall Effect (FQHE) phases occurring at fractional filling factors $\nu$. Among various attempts to measure $e^*$, the most reliable were based on the tiny shot noise produces by their granularity\(^1,2\). However, for complex FQHE states such as $\nu=2/5$ or $2/3$, noise measurements may give unexpected charges depending on experimental conditions\(^3,4\). Here, we present a novel fractional charge measurement based on the Josephson frequency $f_j = e^* V / h$ which manifests as singularities in the Photo-Assisted Shot Noise (PASN) when $f_j$ matches the microwave irradiation frequency $f$. Measurements are done on a QPC realized on high mobility GaAs/AlGaAs heterojunctions. Cross-correlated and auto-correlated current fluctuations are recorded to provide the shot noise. The Josephson frequency gives $e^* = e/5$ for $\nu=2/5$, while for $\nu=1/3$ $f_j$ gives $e^* = e/3$ even at low temperature.

**12:15PM M56.00006: Absence of diffusion on the edge**  
LUCA DELACRETAZ (Presenter), PAOLO GLORIOSO, University of Chicago — The edge of a FQH droplet supports gapless excitations that are protected by a U(1) anomaly. At small but finite temperature, diffusive spreading is expected to occur around the chiral ballistic front. We show that this chiral diffusive fixed point is never stable. Hydrodynamic long-time tails give large corrections to dissipative transport on the edge, leading to a breakdown of diffusion. We comment on the connection to a possible lack of thermalization in the $\nu u=5/2$ state.
Consequences of Chern bands in twisted bilayer graphene

SHUBHAYU CHATTERJEE (Presenter), NICK BULTINCK, MICHAEL ZALETEL, University of California, Berkeley — In magic angle twisted bilayer graphene (TBG), alignment of hexagonal Boron Nitride (h-BN) substrate with one or both graphene monolayers can lead to nearly flat Chern bands labeled by valley and spin indices. At odd-fillings, we discuss how interaction effects in topologically non-trivial bands lead to a ferromagnetic Chern insulator with an anomalous Hall conductance that has been recently observed [1,2]. At the even filling of 2 of 4 conduction bands, we argue that charged skyrmions (allowed by Chern bands) offer a natural explanation of the magnetoresistance [1]. Finally, we discuss how the Chern character of the bands also places strong constraints on superconductivity in TBG.

Microscopic theory for the nematic fractional quantum Hall effect

BO YANG (Presenter), Nanyang Tech Univ — We analyse various properties of the nematic fractional quantum Hall effect (FQHE) in the thermodynamic limit, and present necessary conditions required of the microscopic Hamiltonians for the nematic FQHE to be robust. Analytical expressions of the degenerate ground state manifold, ground state energies, and gapless Goldstone modes are given in compact forms with the input interaction and the corresponding ground state structure factors. We relate the long wavelength limit of the neutral excitations (serving as the nematic FQHE ground state from spontaneous symmetry breaking) to the guiding center metric deformation, and show explicitly the family of trial wavefunctions for the Goldstone modes with spatially varying nematic order. We show for short range interactions, the dynamics of the nematic FQH is completely determined by the long wavelength part of the ground state structure factor. This is the only part that requires numerical studies in the future work, which is potentially more tractable than the conventional numerical approaches.
Quantum-confined electrons in one dimension (1D) constitute a Luttinger liquid, which features charge spin separation and other intriguing properties distinctly different from the Fermi liquid. Single walled carbon nanotubes (SWNTs) provide the ideal platform to explore such Luttinger liquid physics due to strong lateral quantum confinement and the presence of nanotubes of different species. But in many 1D materials including semiconducting SWNTs, the deviation from linear dispersion can greatly alter the electron behaviors. In order to describe the high-energy electron behaviors in 1D materials with nonlinear band structures, novel theoretical approaches have been employed to replace the linear dispersion with a generic one, which is known as the nonlinear Luttinger liquid theory. Here we probe the nonlinear Luttinger liquid physics in semiconducting SWNTs by combining electronic transport and infrared nano-imaging methods. The electron behaviors in semiconducting SWNTs are well captured by the nonlinear Luttinger liquid theory and are in strong contrast to the linear Luttinger liquid as in metallic SWNTs. Our findings provide novel insight into 1D systems beyond the conventional linear Luttinger liquid paradigm.
It is notoriously hard to study theoretically interacting quantum systems outside the Luttinger-liquid regime, particularly when considering higher-energy excitations in finite 1D systems. Recent theoretical work has focused on extending this theory to include such regimes [1,2], where it is predicted that, for higher-order excitations, length-dependent 'replica' parabolic dispersions with higher momenta or negative effective mass should be observed. Our work focuses on the experimental detection and quantification of these higher-order modes. We measure momentum-resolved tunnelling of electrons to and from an array of 1D wires to a 2D electron system formed within a GaAs heterostructure, and map their dispersion both in the equilibrium and nonequilibrium regimes [3,4]. We present recent experimental data obtained for a variety of wire lengths where both first- and second-order replica modes can be observed. We also observe these features even when multiple subbands are occupied, beyond the regime of the models.

1:15PM M56.00011: Competing phases and critical phenomena in three coupled spinless Luttinger liquids*

SARBAJAYA KUNDU (Presenter), Physics, University of Sherbrooke, Sherbrooke, Quebec, VIKRAM TRIPATHI, Theoretical Physics, Tata Institute of Fundamental Research, Mumbai, India — Coupled one-dimensional systems of interacting fermions appear in diverse contexts, and bosonization, along with a scaling treatment, is the usual method for studying low-energy properties of such systems. If three or more fermionic species are present, the scaling procedure generically introduces off-diagonal corrections to the stiffness matrix in the quadratic part of the bosonized Hamiltonian, requiring both rescaling as well as large rotations of the fields. In this talk, I will discuss phase competition in a system of three coupled spinless Luttinger liquids, using bosonization, along with a renormalization group analysis which takes into account these rotations, generating a coupling between different interaction channels even at the tree-level order in the coupling constants. I will further discuss the different instabilities in the particle-particle and particle-hole channels, the nature of the phase transitions, and the conditions under which valley symmetry breaking and intervalley orders may appear. These results may be directly relevant for systems with multiple small Fermi pockets (like graphite intercalates and bismuth) subject to quantizing magnetic fields, and cylindrical nanotubes at high fields.

1:27PM M56.00012: Confinement Tuning of Non Magnetic Fractional Quantized Conductance*

SANJEEV KUMAR (Presenter), MICHAEL PEPPER, University College London, DAVID A RITCHIE, Cambridge University, IAN FARRER, University of Sheffield — There has been considerable interest in the possibility of fractional quantization of conductance in the absence of a magnetic field [1]. In the absence of spin-orbit coupling, appropriate systems have been modelled as 2D lattice site with a flat potential. In this work, we have investigated electron transport of a weakly confined quasi-1D quantum wire formed in a GaAs/AlGaAs heterostructure. The conductance measured almost on the verge of the 2D transition, resulted in conductance plateaux (in units of $e^2/h$) dependent on confinement conditions. Thus flat plateau can be observed with both even and odd denominators such as 1/6, 1/2 and 2/5. On the application of a fixed in-plane magnetic field of 10T, additional plateaux at 2/5 and 2/7 appeared as a function of increasing asymmetry in confinement potential. We suggest that the Coulomb interactions between electrons create correlated motion and formation of a zigzag array of electrons with a consequent emergence of fractional behavior [2,3].

1:39PM M56.00013: Super van Hove singularities in graphene-like materials*  
BAOKAI WANG (Presenter), Northeastern University, BAHADUR SINGH, SZU-NUS Collaborative Center, ShenZhen University, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University — We discuss the crossover from weak to strong correlations in Dirac materials by analyzing the excitonic insulator (EI) transition in a paradigmatic family of ‘slow’ graphenes. We consider the exciton modes at Q = (0, 0) and (π, 0), and show that pristine graphene is free of an excitonic instability. When the band structure is compressed, a gap opens first in a Q = (π, 0) EI phase before a Q = (0, 0) EI phase is triggered when the bands are further compressed. The gap in the Q = (π, 0) phase dominates over that in the the Q = (0, 0) phase throughout the band compression process. Interestingly, we find the presence of high order van Hove singularities in both the EI phases driven by the interaction-induced changes in the band structure. Our study suggests that two-dimensional slow graphenes could provide a novel platform for exploring the physics of EI phases and high order van Hove singularities.

1:51PM M56.00014: Topological Orders and Phase Transitions in Hofstadter-Chern Bands  
JIAN WANG (Presenter), LUIZ SANTOS, Emory University — The quantum Hall effect provides a realization of topological phases of matter in the presence of an external magnetic field. In conventional semiconductors, the achieved magnetic flux per unit cell is orders of magnitude smaller than the magnetic flux quantum h/e, giving rise to degenerate Landau levels enabling strong electronic correlations. Motivated by the realization of two-dimensional moiré superlattices with unit cell of few to hundreds of nanometers in linear size, we discuss a lattice composite fermion theory that accounts for topological states in the opposite regime where the magnetic flux per unit cell is of the order of the magnetic flux quantum, which gives rise to Hofstadter-Chern bands that can be partially filled by electrons. Through analytical and numerical methods, we uncover classes of candidate topological states beyond the Landau level regime, which are characterized by strong coupling of electronic states with the lattice. We explore this setting to establish the existence of topological phase transitions mediated by modulations of the lattice potential. Our study, therefore, identifies new topological orders and how to manipulate them in two-dimensional Hofstadter-Chern lattices.

Mile High Ballroom 3A - Matthew Yankowitz, Columbia University - Tag(s): Focus
Tunneling Spectroscopy of Superconducting States in Magic-Angle Twisted Bilayer Graphene

JEONG MIN PARK (Presenter), YUAN CAO, DANIEL RODAN-LEGRAIN, Massachusetts Institute of Technology MIT, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — The discovery of correlated insulating states and unconventional superconductivity in the twisted bilayer graphene (TBG) systems has instigated numerous follow-up experiments and theories in the past year. However, the origin of the superconducting states, including the nature of the correlated insulating states, parent metallic states, pairing mechanism, size of the superconducting gap, etc. still remain greatly unknown. Recent scanning tunneling spectroscopy experiments have analyzed the local density of states in the insulating states, revealing the splitting of the van Hove singularities near half-filling and the breaking of rotational symmetry. Here, we develop highly tunable magic-angle TBG systems with various gate geometries that allow several different tunneling transport regimes within each device. The results of our tunneling spectroscopy experiments on the superconducting states are presented.

Nature of superconductivity in highly-homogeneous twisted bilayer graphene

YU SAITO (Presenter), JINGYUAN GE, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ANDREA YOUNG, University of California, Santa Barbara — Twisted bilayer graphene with a twist angle of around 1.1 degree hosts superconducting, ferromagnetic and insulating states at partial band filling, all of which are associated with the formation of a nearly-flat electronic band. The experimental difficulty of this system is to fabricate highly angle-homogeneous samples, a necessary prerequisite for exploring the intrinsic properties. In this talk, I will report the results of transport measurements in several homogeneous twisted bilayer graphene at or near the flat band condition. We find that superconductivity near negative half-filling robustly appears regardless of the existence of a resistive state while the optimal critical temperature is very sensitive to the twist angle and is maximized around 1.1 degree.
11:39AM M57.00003: Proximity induced Josephson effect in twisted bilayer graphene near the magic angle

YIRAN ZHANG (Presenter), Department of Physics, California Institute of Technology, ROBERT POLSKI, HARPREEET SINGH ARORA, Watson Laboratory of Applied Physics, California Institute of Technology, YOUNGJOON CHOI, Department of Physics, California Institute of Technology, HECHEN REN, Watson Laboratory of Applied Physics, California Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, STEVAN NADJ-PERGE, Watson Laboratory of Applied Physics, California Institute of Technology — Twisted bilayer graphene (TBG) near the magic angle (~1.1°) has been established to be a highly tunable platform that hosts superconducting, ferromagnetic and correlated insulating states associated with the formation of flat bands. Though numerous models have been proposed to explain basic physics of flat bands and correlations in this system, many questions related the precise origin of insulating and superconducting states are still elusive. Here we report on the observation of the Josephson effect in correlated states of TBG near the magic angle. The detailed measurements of critical current as a function of gate voltage, temperature and magnetic field provide novel insights into the interplay between superconductivity and insulating states in this correlated system.

*This work has been partly supported by NSF CAREER program (DMR-1753306), DOE BES DE-SC0019166 and Gist-Caltech memorandum of understanding. S. N-P also acknowledges support from the IQIM (NSF funded physics frontiers center).

11:51AM M57.00004: On the electronic phases of magically twisted bilayer graphene

CHUAN CHEN (Presenter), ANTONIO HELIO CASTRO NETO, VITOR MANUEL PEREIRA, Natl Univ of Singapore — We explore in detail the electronic phases of a system consisting of three non-collinear arrays of coupled quantum wires, each rotated 120 degrees with respect to the next. A perturbative renormalization-group analysis reveals that multiple correlated states can be stabilized: a smectic or d \( \pm \) id superconductor, a charge density wave insulator, a two-dimensional Fermi liquid, and a 2D Luttinger liquid (also known as smectic metal or sliding Luttinger liquid). The model provides an effective description of electronic interactions in small-angle twisted bilayer graphene and we discuss its implications in relation to the recent observation of correlated and superconducting ground states near commensurate densities, as well as the “strange metal” behaviour at finite temperatures as a natural outcome of the 2D Luttinger liquid phase.

*This work was supported by the National Research Foundation of Singapore under its Medium-Sized Centre Programme.
12:03PM M57.00005: Interacting domain-wall network model in twisted bilayer graphene

YANG-ZHI CHOU (Presenter), Physics, University of Maryland College Park — The interacting domain-wall network systems, which are naturally realized in the twisted bilayer graphene (TBLG) at sub-degree twist angles, are discussed in this talk. Motivated by the superconductor-insulator transition in the TBLG at the magic angle, a simplified model that is composed of a collection of crossed one-dimensional quantum wires whose intersections form a superlattice. At each superlattice point, we place a locally superconducting puddle which can exchange Cooper pairs with the quantum wires. We show that for a range of repulsive intrawire interactions, the system is superconducting at `generic' incommensurate fillings, with the superconductivity being `interrupted' by an insulating phase at commensurate fillings. We further show that the gapped insulating states at commensurate fillings give way to gapless states upon application of Zeeman fields. These features are consistent with experimental observations in magic-angle TBLG despite the distinct microscopic details. We also discuss novel phases driven by the interplay of small velocity and network structure.

12:15PM M57.00006: Prominent Cooper Pairing Away From the Fermi Level and its Spectroscopic Signature in Twisted Bilayer Graphene

ALEX APERIS (Presenter), FABIAN SCHRODI, PETER OPPENEER, Uppsala University — We investigate phonon-mediated Cooper pairing in flat electronic band systems by solving the full-bandwidth multiband Eliashberg equations for superconductivity in magic angle twisted bilayer graphene using a realistic tight-binding model [1]. We find that Cooper pairing away from the Fermi level [2] contributes decisively to superconductivity by enhancing the critical temperature and ensures a robust finite superfluid density. We show that this pairing yields particle-hole asymmetric superconducting domes in the temperature--gating phase diagram and gives rise to distinct spectroscopic signatures in the superconducting state. We predict several such features in tunneling and angle resolved photoemission spectra for future experiments.

12:27PM M57.00007: Quantum simulation of the Hubbard model in a moiré superlattice
[Invited] KIN FAI MAK (Presenter), Cornell University — The Hubbard model, first formulated by physicist John Hubbard in the 1960s, is a simple theoretical model of interacting quantum particles in a lattice. The model is thought to capture the essential physics of high-temperature superconductors, magnetic insulators, and other complex emergent quantum many-body ground states. Although the Hubbard model is greatly simplified as a representation of most real materials, it has nevertheless proved difficult to solve accurately except in the one-dimensional case. Physical realizations of the Hubbard model in two or three dimensions, which can act as quantum simulators, therefore have a vital role to play in solving the strong-correlation puzzle. In this talk, I will discuss a recent experimental realization of the two-dimensional triangular lattice Hubbard model in angle-aligned WSe$_2$/WS$_2$ bilayers, which form moiré superlattices because of the difference in lattice constant between the two 2D materials. We obtain a quantum phase diagram of the two-dimensional triangular lattice Hubbard model near the half filling by probing both the charge and magnetic order of the system. Implications for future studies will also be discussed.

1:03PM M57.00008: Imaging Viscous Flow of the Dirac Fluid in Graphene Using a Quantum Spin Magnetometer* MARK JEN-HAO KU, TONY ZHOU (Presenter), Harvard University, QING LI, MIT, YOUNG J. SHIN, JING SHI, CLAIRE BURCH, HUILIANG ZHANG, FRANCESCO CASOLA, YONGLONG XIE, ANDREW PIERCE, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, PHILIP KIM, AMIR YACOBY, RONALD L WALSWORTH, Harvard University — The electron-hole plasma in charge-neutral graphene, known as the Dirac fluid, is predicted to realize a quantum critical system whose transport features a universal hydrodynamic description, even at room temperature. In this work$^{[1]}$, we directly image viscous Dirac fluid flow at room temperature via measurement of the associated stray magnetic field. Nanoscale magnetic imaging$^{[2,3]}$ is performed using quantum spin magnetometers realized with NV centers in diamond. Our measurement reveals a parabolic Poiseuille profile for electron flow in a graphene channel near the charge neutrality point, establishing the viscous transport of the Dirac fluid. Measurement of viscosity indicates that a nearly-ideal electron fluid presides in graphene at room temperature. Our results pave the way to study hydrodynamic transport in quantum critical fluids relevant to strongly-correlated electrons in superconductors.

1:15PM M57.00009: Mott insulation and superconductivity in the cluster Hubbard model for magic-angle twisted bilayer graphene* SHIN-MING HUANG (Presenter), Natl Sun Yat Sen Univ, YI-PING HUANG, Condensed Matter Theory Group, Paul Scherrer Institute, TING-KUO LEE, Natl Sun Yat Sen Univ — We investigate the strongly correlated electronic system in magic-angle twisted bilayer graphene. Owing to the extended figure of Wannier orbitals, we study the two-orbital cluster Hubbard model with spin-valley fourfold degeneracy, focusing around half filling of valence bands below the neutrality point. The theory shows relatively impotent long-ranged hoppings after renormalization and predicts multiple Mott insulator phases at fractional filling, not only for integer charges per moire site. From second-order perturbation, spin-valley fluctuations give rise to the pairing attraction, exhibiting superconducting domes adjacent to Mott insulator phases. The cluster interaction generates high entanglement among clusters, implying plenty possibilities of nontrivial states.

1:27PM M57.00010: Chiral symmetry breaking induced gap and flat band in a correlated graphene CHANGHUA BAO (Presenter), HONGYUN ZHANG, LAIPENG LUO, SHAOHUA ZHOU, QIAN LI, WEI YAO, SHUYUN ZHOU, Tsinghua University — The low-energy excitations of graphene are relativistic massless Dirac fermions with opposite chiralities at K and K' valleys. Breaking the chiral symmetry could lead to gap opening (in analogy to mass generation in quantum electrodynamics) and other intriguing phenomena. Despite many theoretical predictions, so far experimental realization of chiral symmetry breaking (CSB) in a real honeycomb lattice has been missing. Here I will present our recent experimental work on graphene with large CSB induced gap. In addition, a flat band is observed near the Fermi energy, opening up new opportunity for investigating correlated physics and interaction driven superconductivity.
1:39PM M57.00011: Phonon-mediated superconductivity in graphene and hexagonal boron nitride*  
EVEN THINGSTAD (Presenter), AKASHDEEP KAMRA, JUSTIN WELLS, ASLE SUDBO, Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology (NTNU) — Insight into why superconductivity in pristine and doped monolayer graphene seems strongly suppressed has been central for the recent years' various creative approaches to realize superconductivity in graphene and graphene-like systems. We provide further insight by studying superconductivity in doped monolayer graphene based on intrinsic phonon modes and solving the gap equation using a detailed model for the effective attraction based on electron tight binding and phonon force constant models. The various system parameters can be tuned at will, and our results show that the Coulomb interaction induces non-uniform gap textures along the Fermi surface and plays a main role in suppressing superconductivity at realistic dopings. We also perform similar calculations in the gapped hexagonal boron nitride (h-BN), which has direct onset of a large density of states. Somewhat counter-intuitively, however, the dimensionless electron-phonon coupling strength cannot capitalize on this for small charge dopings.

1:51PM M57.00012: Ultrafast dynamics of electron-phonon coupling in correlated graphene revealed by time- and angle-resolved photoemission spectroscopy*  
HONGYUN ZHANG (Presenter), CHANGHUA BAO, SHAOHUA ZHOU, LAIPENG LUO, QIAN LI, SHUYUN ZHOU, Tsinghua University — Electron-phonon coupling plays important roles in many intriguing physics, including superconductivity, charge and spin density waves. Graphene is a model material with novel electronic properties and provide an ideal platform to study electron-phonon interactions. Despite many researches on non-equilibrium graphene electron system, the direct observation of momentum-resolved electron-phonon coupling dynamics is still missing. Here, by using time- and angle-resolved photoemission spectroscopy, we directly observe multiple electron-phonon coupling and ultrafast dynamics in correlated graphene. In addition, we observe significant suppression of decay rate induced by self-energy effects, which provide important information for controlling and understanding many-body interactions in graphene.

M57.00013: Gate tunable exciton superfluid and topological phases in van der Waals heterobilayer* QIZHONG ZHU (Presenter), South China Normal University, WEI-YUAN TU, The University of Hong Kong, QINGJUN TONG, Hunan University, HUAZHENG SUN, YONG WANG, Nankai University, WANG YAO, The University of Hong Kong — Van der Waals heterostructures of 2D materials provide a powerful approach toward engineering various quantum phases of matter. In one work, we show that heterobilayers of 2D valley semiconductors can be tuned through interlayer bias between an exciton superfluid, a quantum anomalous Hall insulator, and a QSH insulator. The tunability between these distinct phases results from the competition of Coulomb interaction with the interlayer quantum tunneling that has a chiral form in valley semiconductors. In another work, we realize electrically tunable QSH insulator with large gap in van der Waals heterobilayer of monolayer transition metal dichalcogenide and hexagonal boron arsenide (BAs), in particular the WSe$_2$/BAs heterobilayer. Our findings point to exciting opportunities for harnessing both protected topological edge channels and bulk superfluidity in an electrically configurable platform.

Session M58 DCP: Plyler Prize, Jankunas Award Mile High Ballroom 3B

11:15AM M58.00001: Understanding Electron Correlation via Computational Quantum Chemistry JOONHO LEE (Presenter), MARTIN P HEAD-GORDON, University of California, Berkeley — Computational quantum chemistry has become a valuable tool to understand complicated physics arising from the correlated motion of electrons in molecules and materials. In quantum chemistry, we categorize electron correlation mainly into two classes: weak and strong correlation. Weakly correlated electrons can be efficiently handled by perturbation theory (PT). On the other hand, such PT methods completely break down for systems with strong correlation, which then usually requires far more computationally demanding approaches. My thesis addresses multiple aspects of the challenges posed by these two classes of correlation. In this talk, I will present three representative examples from my thesis. First, I will discuss the development of a PT method that can distinguish weak and strong correlation [1]. Secondly, I will present a Kohn-Sham density functional theory approach that can handle some strongly correlated systems by breaking time-reversal symmetry [2]. Lastly, I will discuss the development of a method that can efficiently treat strong spin correlation between electrons and its application to a single molecular magnet [3].

JOHN SOUS (Presenter), Columbia University — Striking emergent phenomena crucial to understanding the dynamical behavior of complex many-body molecular systems manifest thanks to coupling to vibrational excitations, including vibrationally stabilized Rydberg molecules and vibration-mediated binding of electron pairs in superconductors. Here, I show that the Peierls coupling, describing the modulation of electron motion due to vibrations, stabilizes light yet strongly bound bipolarons that survive strong Coulomb repulsion. I show that these properties result from the specific form of the vibration-mediated interaction, which is of 'pair-hopping' instead of regular density-density type. Furthermore, I provide evidence suggestive of a regime of bipolaronic phases stable against phase separation. These light bipolarons could well undergo Bose-Einstein condensation at high temperatures, opening a door to a new mechanism for high-temperature superconductivity. This may help resolve open questions regarding superconductivity in vibrationally coupled systems.

12:03PM M58.00003: Quantum control of cold molecular collisions using Stark-induced adiabatic Raman passage*  

WILLIAM PERREAULT (Presenter), Stanford Univ — One of the most fundamental goals in chemical physics is to understand the interaction forces that bind matter together at the quantum level. Molecular scattering experiments are the foremost tool with which to interrogate these forces, but the amount of detailed information that can be extracted from these experiments is limited by how precisely the input and output quantum states are defined. This talk will present the progress made by our group towards completely quantum state controlled scattering experiments. We first developed the Stark-induced adiabatic Raman passage technique to prepare specific internal molecular quantum states in simple molecules, and then used this technique to study the rotationally inelastic scattering of state-prepared molecules at very low collision energies. Under these conditions, nearly complete control over the quantum states was achieved, allowing us to experimentally derive insight into the dynamics of molecular scattering. This work shows the power of complete control over the input quantum states and complete measurement of the output quantum states to understand the molecular-scale world experimentally.

*This work has been supported by the U.S. Army Research Office.
Quantum Chemistry in the Continuum [Invited] ANNA KRYLOV (Presenter), Univ of Southern California — Owing to the progress in many-body theories and computer hardware, quantum chemistry tools are now routinely used in chemistry and physics, providing both high-quality quantitative data (often rivaling experimental measurements) and invaluable qualitative insights (crucial for interpretation of experimental observations). Despite its success in treating a broad range of electronic structures, ranging from ground-state closed-shell molecules to excited states and strongly correlated systems, quantum chemistry is still lagging behind when electronically metastable states (i.e, resonances embedded in the ionization continuum) are concerned. This lecture will provide an overview of the progress in extending quantum chemistry into the continuum. The main emphasis will be on exploring the ideas of non-Hermitian quantum mechanics within the framework of coupled-cluster and equation-of-motion coupled-cluster theory.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M59 DMP: Antiferromagnetic Kagome metals Mile High Ballroom 3C -

11:15AM M59.00001: Tuning magnetic properties of a Weyl semimetal with low current density QIUYUAN WANG (Presenter), YI ZENG, KAI YUAN, XING CHENG, YU YE, Peking Univ — Recently, Co$_3$Sn$_2$S$_2$ was proved to be a magnetic Weyl semimetal, which may serve as an ideal platform to realize chiral magnetic effects and quantum anomalous Hall effect. In a perfect quantum anomalous Hall state, theoretical works have predicted that Co$_3$Sn$_2$S$_2$ has a larger domain-wall moving velocity and a smaller field threshold to drive domain-wall motion than conventional metals. This feature is highly attractive for energy-efficient and high-performance spintronic devices, such as magnetic domain-wall racetrack memories. Here we report experimental results of current modulation of the magnetic properties of Co$_3$Sn$_2$S$_2$, and observed a lower current density threshold than conventional metals.
11:27AM M59.00002: Multipole control of large electric and magnetic responses in Weyl antiferromagnets* [Invited] SATORU NAKATSUJI (Presenter), Department of Physics, University of Tokyo — Antiferromagnets have attracted recent interest for designing next generation high-density and ultrafast spintronics devices because they produce no stray fields and have much faster dynamics. Here we present novel functionality found in chiral antiferromagnets with vanishingly small magnetization, namely, topological Weyl magnets that can be easily controlled by magnetic field, produce large responses, and thus could be useful for applications. In particular, we discuss frustrated antiferromagnets, Mn3X (X =Sn and Ge) as the examples of a magnetic Weyl semimetal or Weyl magnet [1,2,3]. We show that the cluster multipole order on the kagome lattice of Mn moments can be easily controlled and allows the system to exhibit a variety of new functions at room temperature that have never been seen in antiferromagnetic metals. These include the large anomalous Hall and Nernst effects [1,2,4], large magnetic optical Kerr effect [5] and a novel type of spin Hall effect (magnetic spin Hall effect) [6]. Finally, we show that they should be significantly useful for designing antiferromagnetic spintronics [7], and energy harvesting technology for magnets [8]. This presentation is based on the collaboration with T Tomita, T Higo, M Ikhlas, Y Otani, M Kimata, K Kondo, K Kuroda, T Kondo, S Shin, P Goswami, H Chen, A MacDonald, R Arita, M Suzuki, T Koretsune.

**12:03PM M59.00003: Magnetic structure of Weyl semi-metal candidate Mn$_3$Sn**

YOUZHE CHEN (Presenter), JONATHAN GAUDET, GUY G MARCUS, SAYAK DASGUPTA, Johns Hopkins University, MUHAMMAD IKHLAS, TAISHI CHEN, TAKAIRO TOMITA, Univ of Tokyo-Kashiwanoa, JIAO LIN, Spallation Neutron Source, Oak Ridge National Laboratory, WANGCHUN CHEN, YANG ZHAO, NIST Center of Neutron Research, National Institute of Standards and Technology, MATTHEW STONE, Spallation Neutron Source, Oak Ridge National Laboratory, SATORU NAKATSUJI, Univ of Tokyo-Kashiwana, OLEG TCHERNYSHYOV, COLLIN LESLIE BROHOLM, Johns Hopkins University — The interplay between frustrated magnetism and itinerant electrons can give rise to topological non-trivial properties such as anomalous Hall and Nernest effects in Mn$_3$Sn. Density functional thoery shows Weyl points close to Fermi energy are responsible for anomalous transport properties and can be controled by magnetism via spin-orbit coupling.

In this talk, I will present our neutron diffraction results at various temperatures and magnetic fields to understand the magnetic structure of Mn$_3$Sn in different magnetic phases. With vertical magnet and polarized neutron beam, we are able to clear the ambiguity in previous works and establish the exact k=0 anti-chiral spin structure at room temperature. For the incommensurate phase, the relation between ordering vectors and temperature was investigated and a refined mangetic structure at 250K will be presentated. At the end of this talk, the orgin of the incommensurabilities will be discussed with a proposed Hamiltonian.

**12:15PM M59.00004: Magnetic Phase Diagram of Non-Collinear Antiferromagnetic Weyl Metal Mn$_{3-x}$Sn$_{1-x}$**

MUHAMMAD IKHLAS (Presenter), TAKAIRO TOMITA, ISSP, The University of Tokyo, SATORU NAKATSUJI, Department of Physics, The University of Tokyo — The non-collinear antiferromagnet Mn$_3$Sn shows large spontaneous time-reversal odd responses [1-4] in the inverse triangular spin structure state, which are considered to be signatures of Weyl nodes near the Fermi energy [5]. Mn$_3$Sn single crystals are known to be stable in the presence of excess manganese atoms. Depending on the composition, three distinct magnetic phases can be realized as a function of temperature, namely the high temperature triangular spin structure phase ($\mathbf{q} = 0$), the intermediate-temperature helical phase ($\mathbf{q} \neq 0$), and the low-temperature cluster spin glass phase [7]. Here we present our study on the compositional dependence of Mn$_{3-x}$Sn$_{1-x}$ and discuss the systematic evolution of the three magnetic phases in Mn$_3$Sn based on transport and magnetic properties.

12:27PM M59.00005: Observation of zero bias anomaly in noncolinear antiferromagnet/heavy metal heterostructures  
JOYNARAYAN MUKHERJEE (Presenter), KARTHIK RAMAN, TIFR Centre for Interdisciplinary Sciences — Noncolinear antiferromagnets (NC-AFMs) show exotic transport phenomena such as anomalous and topological Hall effect due to their non-vanishing Berry curvature\(^1\). Although many reports have focused on the transport properties of NC-AFMs, we have explored the differential conductance spectroscopy to probe the electronic structure of heterostructured device comprising of NC-AFM, Mn\(_3\)Pt, in proximity to heavy metal(Ta). Mn\(_3\)Pt/Ta and Ta/Mn\(_3\)Pt/Ta heterostructures were grown by co-sputtering on STO (100) substrate. We observe a strong zero bias conductance peak (ZBCP), only in the Mn\(_3\)Pt/Ta structure, below 10 K with the peak amplitude increasing with cool down and saturating at 4 K, with a magnitude of 4 times the conductance in the flat regime at high bias. Additionally, we observe sister peaks on both sides of the ZBCP twice in magnitude of conductance in the flat regime. Similar phenomena are reported in Dirac semimetal/superconductor heterostructure\(^2\) attributed to the superconducting nature of the device. Our study therefore, highlights that such ZBCP may be observed even in non-superconducting devices and may be driven by interface effects in these topologically nontrivial materials.

12:39PM M59.00006: A new stress dilatometer, and measurement of the thermal expansion under uniaxial stress of Mn\(_3\)Sn  
KENT SHIRER (Presenter), Max Planck Institute for Chemical Physics of Solids, MUHAMMAD IKHLAS, Institute for Solid State Physics, the University of Tokyo, PO-YA YANG, ANDREW MACKENZIE, CLIFFORD W. HICKS, Max Planck Institute for Chemical Physics of Solids, SATORU NAKATSUJI, Institute for Solid State Physics, the University of Tokyo — We present new a new device for measuring the thermal expansion of materials under tunable uniaxial stress. We have performed first measurements on Mn\(_3\)Sn - a room temperature antiferromagnet (AFM) that exhibits a spontaneous Hall effect\([1]\). Measurement of thermal expansion provides thermodynamic data about the nature of phase transitions, and uniaxial stress provides a powerful tuning method that does not introduce disorder. Mn\(_3\)Sn exhibits an anomaly in its thermal expansion near \(\sim270\) K, associated with a first order change in the magnetic structure. We show that this transition temperature is suppressed under uniaxial compression along the c-axis. These results show the efficacy of our stress-dilatometer as well as provide new, thermodynamic insight into the response to applied stress of Mn\(_3\)Sn.

Magnetic and topological properties of Kagome metal YMn$_6$Sn$_6$

NIRMAL GHIMIRE (Presenter), Department of Physics and Astronomy, George Mason University, LEKhanath POudel, REbecca DALLy, NIST Center for Neutron Research, National Institute of Standards and Technology, NISHChal THAPA MAGAR, NICHOLAS BISHOP, Department of Physics and Astronomy, George Mason University, MICHAEL MCguire, Materials Science and Technology Division, Oak Ridge National Laboratory, J SAMUEL JIANG, Materials Science Division, Argonne National Laboratory, IGoR MAZIN, Department of Physics and Astronomy, George Mason University, JOhn MITCHELL, Materials Science Division, Argonne National Laboratory, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology — The Kagome lattice has historically been known for frustration-driven novel phenomena, such as spin-liquid phases. Recent experiments have indicated that 3D kagome magnets provide a natural platform to study the effect of the interplay between magnetism and electronic topology. For example, Weyl fermions and a non-collinear spin texture are observed in Mn$_3$Sn, heavy Dirac bands are reported in frustrated ferromagnet Fe$_3$Sn$_2$, and flat bands and Dirac cones are realized in antiferromagnetic FeSn. Here we present our recent findings of the complex nature of the magnetism and topological features in the electronic structure of a ternary kagome magnet, YMn$_6$Sn$_6$. This compound orders with a commensurate antiferromagnetic helical structure below 340 K, which on cooling shows an incommensurate double helical structure. Both wave vectors are temperature dependent with the difference in $q$ between the two helices gradually decreasing with decreasing temperature but remaining in the ground state. Electronic band structure calculations show the presence of a Dirac point near the Fermi energy, and a linear magnetoresistance is observed at low temperature when a magnetic field is applied along c-axis.
1:03PM M59.00008: Neutron diffraction results on the in-field magnetic structure of Y\text{Mn}_6\text{Sn}_6  
REBECCA DALLY (Presenter), LEKHANATH POUDEL, NIST Center for Neutron Research, National Institute of Standards and Technology, NISHCHAL THAPA MAGAR, Department of Physics and Astronomy, George Mason University, MARKUS BLEUEL, NIST Center for Neutron Research, National Institute of Standards and Technology, J SAMUEL JIANG, Materials Science Division, Argonne National Laboratory, MICHAEL MCGUIRE, Materials Science Division, Oak Ridge National Laboratory, JOHN MITCHELL, Materials Science Division, Argonne National Laboratory, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, NIRMAL GHIMIRE, Department of Physics and Astronomy, George Mason University — A current focus of condensed matter physics is to find materials where magnetism can tune topological properties or vice versa. Research has focused on the study of non-centrosymmetric compounds with Dzyaloshinskii-Moriya interactions, but recent studies suggest that magnetic frustration is another route to search for topological properties. Our measurements indicate that Y\text{Mn}_6\text{Sn}_6 is a promising candidate to explore the interplay of magnetic and topological properties. It is a centrosymmetric, antiferromagnetic (AF) metal with layered kagome networks of magnetic Mn atoms. The ground state magnetic structure is helical and competing ferromagnetic and AF interlayer exchange is the source of frustration in the system. The structure is far from standard though, as two, long-range, incommensurate wavevectors persist throughout a large region of the $B$-$T$ phase space. We will focus on neutron diffraction data that track the evolution of these two wavevectors as a function of magnetic field, which clearly elucidates the nature of the multiple field-induced transitions seen in AC susceptibility. Additionally, the topological Hall resistivity undergoes changes as a function of field that can be connected to those in the magnetic structure, signifying a strong interplay between the two.

1:15PM M59.00009: Transport evidence of Chern gapped Dirac fermions in the kagome magnet TbMn6Sn6  
XITONG XU (Presenter), WENLONG MA, HUIBIN ZOU, SHUANG JIA, Peking Univ — The kagome magnet TbMn6Sn6 is a new member of correlated topological metals, featuring Chern gapped Dirac fermions from the spinless Haldane model. Here we report combined electric and thermal transport study of TbMn6Sn6. Quantum oscillations are observed both in magnetoresistance and magneto-thermopower. The derived Fermi length, the cyclotron mass and their angle-dependence confirm the picture of 2D Dirac dispersion in this hard magnet. Besides, we observe complex Fermi surfaces arising from interlayer interactions, which probably consist of 2D networks and 3D sheets. We also found a phase reversal in the thermal conductivity oscillations, which may be related to competition between electronic contribution and electron-phonon interaction in thermal conductivity. Our observations provide crucial information for theoretical modelling this quantum material.
HISASHI INOUE (Presenter), Tohoku University, MINYONG HAN, LINDA YE, TAKEHITO SUZUKI, JOSEPH G CHECKELSKY, Massachusetts Institute of Technology — Kagome metals are metals with the crystal structures of the kagome lattice, the two-dimensional structure with atoms arranged in corner-sharing triangles, and other two-dimensional layers. The hexagonal arrangement and the lattice symmetry produce Dirac fermions in its band structure [1]. FeSn is an antiferromagnetic version of kagome metal where magnetic element Fe populates the kagome lattice. Taking advantage of magnetic interactions, FeSn is a promising platform to control the properties of Dirac fermions by the magnetic degree of freedom in electronic devices. Here we report the first realization of high quality epitaxial FeSn thin films [2]. Using optimized growth schemes, and electrical and magnetic torque measurements, we observed that the thin films show residual resistivity ratio between 300 K and 2 K up to 24, and support an antiferromagnetic ordering temperature 353 K comparable to the bulk one. This opens a route toward electronic and spintronics device applications of magnetic Dirac fermions.

Magnetic Imaging of Antiferromagnetic Domain Walls in Magnetic Topological Materials*

PAUL SASS (Presenter), WENBO GE, WEIDA WU, Department of Physics and Astronomy, Rutgers University, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, DIMUTHU OBEYSEKERA, JUNJIE YANG, Department of Physics, New Jersey Institute of Technology — The study and control of domains and domain walls (DW) in topological materials is crucial to understanding and utilizing their exotic phenomena, such as axion insulator and quantum anomalous Hall states\textsuperscript{1-3}. Domains of alternating sign in these materials cancel out these states and thus it is imperative to understand how these antiferromagnetic (AFM) domains form and can be controlled. Despite many efforts, it has been challenging to directly visualize AFM domains or DWs with nanoscale resolution in general, especially in magnetic field. Here, we report the magnetic imaging of domains and DWs in several uniaxial AFMs, the topological insulator MnBi\textsubscript{2}Te\textsubscript{4} family\textsuperscript{4} and the topological semimetal EuMnBi\textsubscript{2}\textsuperscript{5}, using cryogenic magnetic force microscopy (MFM)\textsuperscript{6}. Our MFM results reveal higher magnetic susceptibility or net moments inside the DWs than in domains. DWs in these AFMs form randomly with strong thermal and magnetic field dependences.

1:51PM M59.00012: Topological surfaces states of MnBi$_2$Te$_4$ at finite temperatures and at domain walls KEVIN GARRITY (Presenter), SUGATA CHOWDHURY, FRANCESCA TAVAZZA, National Institute of Standards and Technology — MnBi$_2$Te$_4$ has recently been the subject of intensive study, due to the prediction of axion insulator, Weyl semimetal, and quantum anomalous Hall insulator phases, depending on the structure and magnetic ordering. Experimental results have confirmed some aspects of this picture, but several experiments have seen zero-gap topological surfaces states at low temperature, in conflict with expectations. In this work, we develop a first-principles-based tight-binding model that allows for arbitrary control of the local spin direction and spin-orbit coupling, enabling us to accurately treat large unit-cells. Using this model, we examine the behavior of the topological surface state as a function of temperature, finding a gap closure only above the Neel temperature. In addition, we examine the effect of magnetic domains on the electronic structure, finding that the domain wall zero-gap states extend over many unit-cells and can mimic the high temperature topological surface state when many domains are averaged over, potentially reconciling theoretical results with experiments.

2:03PM M59.00013: Mobius Insulator and Higher-Order Topology in MnBi$_{2n}$Te$_{3n+1}$* RUIXING ZHANG (Presenter), FENGCHENG WU, University of Maryland, College Park — We propose MnBi$_{2n}$Te$_{3n+1}$ as a magnetically tunable platform for realizing various symmetry-protected higher-order topology. Its canted antiferromagnetic phase can host exotic topological surface states with a Mobius twist that are protected by nonsymmorphic symmetry. Moreover, opposite surfaces hosting Mobius fermions are connected by one-dimensional chiral hinge modes, which offers the first material candidate of a higher-order topological Mobius insulator. We uncover a general mechanism to feasibly induce this exotic physics by applying a small in-plane magnetic field to the antiferromagnetic topological insulating phase of MnBi$_{2n}$Te$_{3n+1}$, as well as other proposed axion insulators. For other magnetic configurations, two classes of inversion-protected higher-order topological phases are ubiquitous in this system, which both manifest gapped surfaces and gapless chiral hinge modes. We systematically discuss their classification, microscopic mechanisms, and experimental signatures. Remarkably, the magnetic-field-induced transition between distinct chiral hinge mode configurations provides an effective “topological magnetic switch”.

11:15AM M60.00001: Majorana multipole response of topological superconductors [Invited]
MASATOSHI SATO (Presenter), Kyoto Univ — Crystalline symmetry enriches topological phases of matter. For instance, Dirac semimetals with crystalline symmetry are one of the promising ways to realize a variety of topological superconductivity. In contrast to elementary Majorana particles, emergent Majorana fermions (MFs) in topological crystalline superconductors may have electromagnetic multipoles. We developed a general theory of magnetic multipoles for surface helical MFs on time-reversal-invariant superconductors. The results show that the multipole response is governed by crystal symmetry, and that a one-to-one correspondence exists between the symmetry of Cooper pairs and the representation of magnetic multipoles under crystal symmetry. The latter property provides a way to identify nonconventional pairing symmetry via the magnetic response of surface MFs. We also find that most helical MFs exhibit a magnetic-dipole response, but those on superconductors with spin-3/2 electrons may display a magnetic-octupole response in leading order, which uniquely characterizes high-spin superconductors. Detection of such an octupole response provides direct evidence of high-spin superconductivity, such as in half-Heusler superconductors.

11:51AM M60.00002: Anomalous normal fluid response in helical spin-triplet superconductor UTe2*
SEOKJIN BAE (Presenter), HYUNSOO KIM, University of Maryland, College Park, SHENG RAN, National Institute of Standards and Technology, YUN SUK EO, I-LIN LIU, WESLEY T FUHRMAN, JOHNPIERRE PAGLIONE, University of Maryland, College Park, NICHOLAS BUTCH, National Institute of Standards and Technology, STEVEN ANLAGE, University of Maryland, College Park — We report evidence for a helical spin-triplet pairing state of UTe2 with significant surface normal fluid response. The microwave surface impedance of UTe2 crystals was measured and converted to complex conductivity. The anomalous residual normal fluid conductivity (real part) in the zero temperature limit supports the presence of a significant normal fluid response in the ground state. The superfluid conductivity (imaginary part) follows the low temperature behavior predicted for the helical spin-triplet state. The temperature dependence of the superfluid conductivity also reveals a low impurity scattering rate and low frequency-to-energy-gap ratio, implying that the observed normal fluid response is not due to an extrinsic origin. Candidate mechanisms such as a surface Majorana normal fluid, which are predicted for the helical spin-triplet superconductor, are discussed.

Microscopic evidence for chiral superconductivity in a heavy fermion superconductor UTe$_2$*  

LIN JIAO (Presenter), SEAN HOWARD, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois Urbana-Champaign, SHENG RAN, NIST Center for Neutron Research, National Institute of Standards and Technology, ZHENYU WANG, JORGE OLIVARES RODRIGUEZ, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois Urbana-Champaign, MANFRED W SIGRIST, Institute for Theoretical Physics, ETH Zurich, ZIQIANG WANG, Department of Physics, Boston College, NICHOLAS BUTCH, NIST Center for Neutron Research, National Institute of Standards and Technology, VIDYA MADHAVAN, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois Urbana-Champaign — Spin-triplet superconductivity is a condensate of electron pairs with spin-1 and an odd parity pair wavefunction. A particularly interesting manifestation of triplet pairing is a chiral p-wave state which is topologically non-trivial and a natural platform for realizing Majorana edge modes. Triplet pairing is however rare in solid state systems and so far, no unambiguous identification has been made in any bulk compound. Since pairing is most naturally mediated by ferromagnetic spin fluctuations, uranium based heavy fermion systems containing f-electron elements that can harbor both strong correlations and magnetism are considered ideal candidate spin-triplet superconductors. In this talk I will present scanning tunneling microscopy (STM) studies of the newly discovered heavy fermion superconductor, UTe$_2$ with a $T_{SC}$ of 1.6 K. We find signatures of coexisting Kondo effect and superconductivity which show competing spatial modulations within one unit-cell. Most strikingly, STM spectroscopy at step edges show signatures of chiral edge states, indicating UTe$_2$ is a 3D chiral superconductor.

*We gratefully acknowledge support from U.S. Department of Energy under Award Number DE-SC0014335.

Effects of uniaxial pressure in Uranium-based superconductors*  

SEAN THOMAS (Presenter), FREDERICO BENEDETTO SANTOS, TOMOYA ASABA, ERIC BAUER, JOE D THOMPSON, PRISCILA ROSA, FILIP RONNING, Los Alamos National Laboratory — Uranium-based superconductors have been proposed to host a number of exotic superconducting states. In some p- and d-wave superconductors, uniaxial stress is expected to split the superconducting transition temperature between the two components of the order parameter. The anisotropic dependence of this splitting can provide hints about the underlying nature of the superconductivity in these materials. Here, we probe several Uranium-based superconductors using in-situ tuning of uniaxial stress and discuss the implications of the results on the allowed pairing mechanisms.

*Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering.
12:27PM M60.00005: Majorana fermions in narrow zigzag honeycomb nanoribbons*  
RENA BENTO RIBEIRO CAMPOS, Physics Department, Federal Fluminense University, JORGE HUAMANI CORREA, Physics Department, Brasilia Federal University, ANTONIO CARLOS SERIDONIO, Physics Department, Paulista State University (Unesp), MARCOS FIGUEIRA (Presenter), Physics Department, Federal Fluminense University — In this work, we study the generation of Majorana fermions in narrow zigzag honeycomb nanoribbons (ZHNR) deposited over an 's' superconductor. We study the system using an effective minimal model that consists of the first nearest neighbor hopping, Rashba spin-orbit interaction, triplet superconducting pairing between the magnetic moments of the ZHNR edges and an external exchange magnetic field [1].

We present results of the band structure, density of states and conductance for the infinite case as well as the energy spectrum as a function of the chemical potential for the finite one. In the infinite case, the band structure exhibits several topological phase transitions associated with spin-up or spin-down Majorana fermions. The results for the finite ZHNR show an energy spectrum with zero-energy modes at the chemical potential, which are the signature of Majorana fermions. A striking result of the work is that the nanoribbon spins polarize the Majorana fermions, generating regions of chemical potential where there are only spin-up or spin-down zero-energy modes. The results show that the system could develop Majorana half-metallic behavior.

*We thank Brazilian agencies CAPES and CNPq to support this work.

12:39PM M60.00006: Atomic limit and inversion-symmetry indicators for topological superconductors  
ANASTASIIA SKURATIVSKA (Presenter), TITUS NEUPERT, MARK H FISCHER, University of Zurich — Symmetry indicators have proven to be extremely helpful in identifying topologically non-trivial crystalline insulators using symmetry-group representations of their Bloch states. An extension of this approach to superconducting systems requires defining an appropriate atomic limit for Bogoliubov-de-Gennes Hamiltonians. Here, we introduce such a notion of atomic limit and derive a \( \mathbb{Z}_2^d \)-valued symmetry indicator for inversion-symmetric superconductors of \( d \) dimensions. This indicator allows for a refined topological classification including higher-order phases for systems in the superconducting symmetry classes D and DIII. We further elucidate the bulk-boundary correspondence of these phases using Dirac surface theories. Requiring only the normal-state band structure and the superconducting order-parameter symmetry as an input, this indicator is well suited for a search of topological superconductors using first-principles calculations.
12:51PM M60.00007: Unconventional Superconductivity in spin-3/2 fermions  JULIA LINK  (Presenter), Physics, Simon Fraser University, IGOR BOETTCHER, Joint Quantum Institute, University of Maryland, IGOR HERBUT, Physics, Simon Fraser University — We study unconventional superconductivity in spin-orbit-coupled three-dimensional electronic systems without inversion symmetry, featuring gapless fermions with the Hamiltonian given by $H = p \cdot J$, where $J$ are the generators of total angular momentum of 3/2. These systems have a Fermi points with a fixed ratio of the Fermi velocities. A favorable short-range interaction can lead to a d-wave superconductivity which is described by a complex tensor order parameter. We investigate the structure of the corresponding Ginzburg-Landau free energy and demonstrate that already at the quartic level the superconducting state of the system is uniquely determined. For a chemical potential right at the Fermi point, the ground state of the system is given by an uniaxial nematic state. In the case of a finite chemical potential, we find that the cyclic state is favored as a ground state. The cyclic state breaks time-reversal symmetry maximally, has no average magnetization, and exhibits robust small Bogoliubov Fermi surfaces in the excitation spectrum of the quasiparticles.

1:03PM M60.00008: Chemical doping effect on a topological superconductor candidate*  KAYA KOBAYASHI (Presenter), TAKESHI TAKAHASHI, HARALD JESCHKE, JUN AKIMITSU, Okayama Univ — Au$_2$Pb crystallizing in a cubic Laves phase exhibits a bulk Dirac cone in the vicinity of the Gamma point. The material also shows superconductivity, but not in the cubic phase because the material goes through several structural transitions at low temperatures. On the other hand, one of the oldest alloy superconductors Au$_2$Bi possesses the same crystal structure as the cubic Laves phase. There is no detailed report for the latter compound apart from the superconducting transition temperature (Tc) at 1.8 K. We will report the enhancement of Tc by Bi substitution in Au$_2$Pb associated with the suppression of structural transitions.

*This work is supported by Grants-in-Aid for Scientific Research (Grant No. 18K03540, 19H01852).
Observation of half-quantum flux in topological superconductor β-Bi$_2$Pd

YUFAN LI (Presenter), XIAOYING XU, Johns Hopkins University, M.-H. LEE, M.-W CHU, Center for Condensed Matter Sciences and Center of Atomic Initiative for New Materials, National Taiwan University, CHIA-LING CHIEN, Johns Hopkins University — Magnetic flux quantization is one of the defining characteristics of a superconductor. We report the observation of half-integer magnetic flux quantization in mesoscopic rings of superconducting β-Bi$_2$Pd thin films [1]. The half-quantum fluxoid manifests itself as a π-phase shift in the quantum oscillations of the superconducting critical temperature. The superconducting ring energetically prefers half flux quanta with fractional quantum numbers of 1/2, 3/2, 5/2, etc., instead of usual integer numbers of 0, 1, 2, etc. This result is consistent with β-Bi$_2$Pd having a spin-triplet pairing symmetry, which may be expected from β-Bi$_2$Pd as a topological superconductor [2,3]. Our findings usher in new venues for studying topological superconductivity, and new designs of flux qubit for quantum computing, which may operate without external magnetic fields.

Spin-triplet Superconductivity Evidenced by Half-Integer Quantum Flux in a Non-centrosymmetric Superconductor

XIAOYING XU (Presenter), YUFAN LI, CHIA-LING CHIEN, Johns Hopkins University — Spin-triplet superconductors, rare and challenging to identify, play central roles in Majorana fermions and quantum computing. It has been proposed that superconductors with broken inversion symmetry may host spin-triplet Cooper pairs. Unique features of half-quantum fluxoid in flux quantization is one of the few methods that can identify spin-triplet superconductors [1]. We fabricated thin films of non-centrosymmetric a-BiPd by sputtering and patterned them into sub-µm-sized rings. Measurements of the Little-Parks oscillations in magnetoresistance show half-quantum fluxoid ($n + ½)\Phi_0$, a key signature of spin-triplet pairing, where flux quantum $\Phi_0 = hc/2e$ and $n$ is an integer. Our extensive measurements support mixing pairing states of spin-singlet and spin-triplet Cooper pairs in α-BiPd.

The co-existence of spatial and non-spatial symmetries together with appropriate commutation/anticommutation relations between them can give rise to static higher-order topological phases, which host gapless boundary modes of co-dimension higher than one. Alternatively, space-time symmetries in a Floquet system can also lead to anomalous Floquet boundary modes of higher co-dimensions, with different commutation/anticommutation relations with respect to non-spatial symmetries. In my talk I will review how these dynamical analogs of the static HOTI's emerge, and also show how a coherently excited phonon mode can be used to support non-trivial Floquet higher-order topological phases.

Ultrafast dynamics in single-layer FeSe/SrTiO$_3$, (Li$_{0.84}$Fe$_{0.16}$)OHFe$_{0.98}$Se, and Sr$_3$Ir$_2$O$_7$: revealing coupling between different degrees of freedom

JIMIN ZHAO (Presenter), Chinese Academy of Sciences — We have demonstrated ultrafast dynamics evidence of high-$T_c$ superconductivity in single-layer FeSe/SrTiO$_3$, with clear identification of the SC $T_c$, SC gap, and electron-phonon coupling (EPC) constant $\lambda$. In addition, we also observe the quasiparticle dynamics and coherent phonons in the intercalated novel superconductor of (Li$_{0.84}$Fe$_{0.16}$)OHFe$_{0.98}$Se. Furthermore, the EPC strength is compared among the single-layer FeSe/SrTiO$_3$, bulk FeSe, KFe$_2$Se$_2$, (Li$_{0.84}$Fe$_{0.16}$)OHFe$_{0.98}$Se, Fe$_{1.01}$Se$_{0.2}$Te$_{0.8}$, Fe$_{1.05}$Se$_{0.2}$Te$_{0.8}$, and many other reported iron-based superconductors, we find that the EPC strength has a positive correlation with SC $T_c$ among almost all types of iron-based superconductors, thus bridging the bulk and monolayer system, as well as FeAs- and FeSe-based superconductors. We also investigated the $A_{1g}$ coherent phonon in strong correlated iridate Sr$_3$Ir$_2$O$_7$, finding the strongest pseudospin-lattice coupling (PLC) known so far. We discover that PLC is the dominating interaction in low temperature, which leads to phonon anomaly and negative thermal expansion.

Our results demonstrate promising venues for ultrafast optical investigation of the quantum properties of oxide interfaces, bulk high $T_c$ superconductors, and transition metal oxides. It is non-contact, single-layer sensitive, and gap-perceptive, being capable of detecting ultrafast lifetime, EPC strength, and coherent bosons. Hence it provides important clues to understanding the SC mechanism and couplings between different degrees of freedom.

[2] Q. Wu, Jimin Zhao* et al., Ultrafast Quasiparticle Dynamics and Electron-Phonon Coupling in (Li$_{0.84}$Fe$_{0.16}$)OHFe$_{0.98}$Se, arXiv:1910.09859 (2019).

**11:51AM M61.00002: Frustrated spin order in FeSe**  
ANDREAS BAUM (Presenter), Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, HARRISON N RUIZ, Stanford University, NENAD LAZAREVIĆ, Institute of Physics Belgrade, YAO WANG, Harvard University, THOMAS U BOEHM, RAMEZ HOSSEINIAN AHANGHARNEJHAD, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, THOMAS WOLF, Karlsruhe Institute of Technology, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University, RUDOLF HACKL, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities — Magnetism in the structurally simplest iron based superconductor, FeSe, poses a challenge. Unlike in the related iron pnictide compounds, no magnetic order was found down to lowest temperatures in FeSe. However, recent theoretical and experimental studies point towards frustration quenching long range order. Here we demonstrate that inelastic light scattering can distinguish between itinerant and localized magnetism. We find the Raman response from FeSe to be more similar to localized systems such as cuprates. Together with simulations of a spin-1 Heisenberg model this furnishes evidence that FeSe hosts an almost fully frustrated system of essentially localized moments.

**12:03PM M61.00003: Angle Resolved Photoemission Measurements of Metastable Single Crystals of Tetragonal CoSe**  
CHRISTOPHER PARZYCK (Presenter), Cornell University, XIUQUAN ZHOU, Argonne National Laboratory, BRANDON WILFONG, EFRAIN RODRIGUEZ, University of Maryland, KYLE M SHEN, Cornell University — Using topochemical deintercalation methods, single crystals of the tetragonal phase of Cobalt Selenide, isostructural to the iron based superconductor FeSe, have recently been synthesized$^{1,2}$. Here, we present synchrotron angle resolved photoemission (ARPES) measurements of these metastable crystals and compare to recent ARPES measurements of MBE synthesized thin films$^{3}$ as well as density functional theory calculations$^{4}$. We discuss similarities and differences between bulk tetragonal CoSe and FeSe in terms of correlation and renormalization effects on the band structure and the effects of dimensionality.

There are profound connections between dynamical magnetism and unconventional superconductivity in Fe-based superconductors. Recently, new aspects associated with their multi-band, multi-orbital nature and the resulting orbital physics came to prominence in iron the chalcogenide family. While early neutron scattering experiments already presented indication of an orbital-selective electron localization and ferro-orbital order in the FeTe parent material [1,2], an orbital-selective Cooper pairing was recently discovered in the FeSe end member by STM [3]. Here, we present polarized neutron scattering studies of magnetic dynamics in FeTe parent material and FeTe$_{0.45}$Se$_{0.55}$ optimally doped superconductor, where we analyze the wave vector dependence of the magnetic form factor in order to understand the orbital state of magnetic electrons. Our results indicate an unusual, energy- and temperature-dependent orbital composition of dynamical magnetism revealed by polarized neutron spectroscopy.

Quantum Monte Carlo calculations of dynamic spin excitations in FeSe

SEHER KARAKUZU (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6164, USA, JONATHAN PELLICIARI, NSLS-II, Brookhaven National Laboratory, Upton, NY, 11973, USA and Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, RICCARDO COMIN, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, STEVEN JOHNSTON, Department of Physics and Astronomy, The University of Tennessee, Knoxville, Tennessee 37996, USA and Joint Institute of Advanced Materials at The University of Tennessee, Ktn, THOMAS MAIER, Center for Nanophase Materials Sciences,Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831-6164, USA and Computational Sciences and Engineering Division, Oak Ridge Nat — The rich physics of bulk and monolayer FeSe has been widely studied in the condensed matter physics community. The pairing mechanism giving rise to the enhanced superconductivity of the monolayer is mainly attributed to spin fluctuations. Here we discuss unbiased dynamical cluster approximation (DCA) quantum Monte Carlo calculations to understand the physics of these compounds. Specifically, we calculate the dynamic spin susceptibility of a two-orbital Hubbard model with parameters tuned to describe both bulk and monolayer FeSe and use the maximum entropy method to perform the analytic continuation to real frequencies. We compare the DCA results with neutron scattering data for bulk FeSe as well as resonant inelastic x-ray spectroscopy (RIXS) data for the monolayer compound.

Resistivity, magnetotransport and superconductivity across the nematic quantum critical point in the iron chalcogenides

NIGEL HUSSEY (Presenter), High Field Magnet Laboratory and Radboud Univ., Nijmegen, The Netherlands — Selected by Focus Topic Organizer Leonardo Civale

Effects of Strong Correlations in the Lattice Dynamics of Iron-based Superconductors

GHANASHYAM KHANAL (Presenter), KRISTJAN HAULE, Rutgers University, New Brunswick — Strong electron-electron interaction leads to a plethora of complex physical mechanisms in many materials which includes, magnetism, spin fluctuation and high $T_c$ superconductivity. A Combination of Density Functional Theory (DFT) and Embedded Dynamical Mean-Field Theory (EDMFT) has been extremely successful for electronic structure calculations of these strongly correlated systems. We use this method on 11-type and 111-type family of iron-based superconductors (FeSC) to show that correlations play an important role to determine the vibrational properties of real systems. In this work, we present an very good agreement with the experiment to calculated values of internal parameters, phonon density of states and the phonon frequencies at high symmetry points.

*The authors acknowledge the funding from NSF DMR-1709229.
**1:27PM M61.00008: Thickness dependence of band structure of FeSe**  
JIA SHI (Presenter), Department of Physics, University of Science and Technology Beijing, DUY LE, TALAT S. RAHMAN, Department of Physics, University of Central Florida, QIANG GU, Department of Physics, University of Science and Technology Beijing — Thin film FeSe attracts a great deal of attention thanks to its unusually high-temperature ($T_c$) superconducting properties. We report results of our density functional theory based calculations of the electronic structures of FeSe consisting of 1 to 5 layers. For the case of monolayer, there is a gap of about 0.5 eV at Γ, the Brillouin zone center. We did not find significant difference between the band structures of higher layered FeSe, rather the characteristics slowly converge to that of bulk FeSe, in which the occupied bands cross the Fermi level overlapping with the conducting bands. We discuss the details of the electronic structure and comparison of the Fermi surfaces and phonon spectra of the thin films to shed light on the high $T_c$ behavior of monolayer FeSe.

**1:39PM M61.00009: Chemical pressure effect of electron-doped FeSe films**  
NAOKI SHIKAMA (Presenter), YUKI SAKISHITA, FUYUKI NABESHIMA, ATSUTAKA MAEDA, Dept. of Basic Science, Univ. of Tokyo — The superconducting transition temperature ($T_c$) of FeSe increases from 9 K in bulk to 40-45 K with electron doping. To search for higher $T_c$, it is interesting to study the chemical pressure effect for the electron-doped FeSe. We fabricated the electric double layer transistor configuration of FeSe$_{1-x}$S$_x$ and FeSe$_{1-y}$Te$_y$ films for wide range of $x$ and $y$, and measured transport properties under finite gate voltage. Increasing S and Te content decreases $T_c$ of electron-doped FeSe$_{1-x}$S$_x$ and FeSe$_{1-y}$Te$_y$ in a similar manner. This $T_c$ behavior of electron-doped samples is very different from that of non-doped samples [1]. On the other hand, this behavior agrees well with that of the intercalated FeSe$_{1-x}$S$_x$ and FeSe$_{1-y}$Te$_y$, whose $T_c$ is also around 40 K. Our results suggest that the mechanism of superconductivity is different between 25 K class non-doped case and 40 K class doped case.

MBE preparation and in-situ characterization of FeTe thin films

VANDA MOTA PEREIRA (Presenter), CHI-NAN WU, CHENG-EN LIU, SHENG-CHIEH LIAO, CHUN-FU CHANG, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, CHANG-YANG KUO, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, CEVRIYE KOZ, ULRICH SCHWARZ, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, HONG-JI LIN, CHIEN-TE CHEN, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, LIU TJENG, SIMONE G ALTENDORF, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — Within the family of Fe based superconductors, Fe chalcogenides have received particular attention due to their simple crystal structure. Fe\textsubscript{1+y}Te, which is not superconducting, has been studied extensively in bulk form and, more recently, some efforts have been made regarding the synthesis of thin films, resorting to pulsed laser deposition and molecular beam epitaxy (MBE). Here we report the results of Fe\textsubscript{1+y}Te thin films grown by means of MBE under Te-limited growth conditions. We found that epitaxial layer-by-layer growth is possible for a wide range of excess Fe values, wider than expected from what is known from studies on the bulk material. Using x-ray magnetic circular dichroism spectroscopy at the Fe $L\textsubscript{2,3}$ and Te $M\textsubscript{4,5}$ edges, we observed that films with high excess Fe contain ferromagnetic clusters while films with lower excess Fe remain nonmagnetic. Moreover, x-ray absorption spectroscopy showed that it is possible to obtain films with very similar electronic structure as that of a high-quality bulk single crystal Fe\textsubscript{1.14}Te. Our results suggest that MBE with Te-limited growth may provide an opportunity to synthesize FeTe films with smaller amounts of excess Fe as to come closer to a possible superconducting phase.

Influence of iron vacancies on the transport properties of (Fe-Ni)Te\textsubscript{0.65}Se\textsubscript{0.35} crystals

MARTA CIEPLAK (Presenter), IRYNA ZAYTSEVA, KATARZYNA KOSYL, WOJCIECH PASZKOWICZ, DARIUSZ J GAWRYLUK, Institute of Physics, Polish Academy of Sciences — The role of iron vacancies in the improvement of superconductivity is studied in Fe\textsubscript{1−y}Ni\textsubscript{y}Te\textsubscript{0.65}Se\textsubscript{0.35} single crystals, with $y$ in the range from 0 to 0.08, grown by Bridgman’s method using different crystallization rates. As shown previously [1], slow crystallization leads to crystals with single tetragonal phase, but with superconducting properties inferior to crystals obtained by fast crystallization, which contain nanometer size iron deficient regions. Using matrix formalism for multicarrier systems we extract carrier concentrations and their mobilities from the low-temperature Hall effect data for crystals with $y>$0.03, in which superconductivity is suppressed. The evolution of the majority carriers with increasing $y$ is similar for all crystals, from holes for $y<$0.06 to electrons for $y>$0.06, indicating electron doping by Ni substitution. However, at low T the T-dependence of the majority and minority carrier concentrations and their mobilities differ significantly in crystals with and without iron vacancies. These differences lead to the conclusion that inhomogeneity induced by iron vacancies enhances electron doping, what most likely contributes to the enhancement of superconducting fluctuations. Ref.: [1] D. J. Gawryluk, et al., Supercond. Sci. Technol. 24, 065011 (2011).
The Observation of Majorana Zero Mode and Conductance Plateau in an Iron-based Superconductor

HONGJUN GAO (Presenter), Institute of Physics and University of Chinese Academy of Sciences Chinese Academy of Science — Majorana zero-modes (MZMs) are spatially-localized zero-energy fractional quasiparticles with non-Abelian braiding statistics that hold great promise for topological quantum computing. Recently, by using scanning tunneling microscopy/spectroscopy (STM/STS), a new breakthrough of Majorana zero mode (MZM) was achieved in a single material platform of high-$T_c$ iron-based superconductors, FeTe$_{0.55}$Se$_{0.45}$, which combined advantages of simple material, high-$T_c$, and large ratio of $\Delta / E_F$ [1]. A detail STM/STS study of a FeTe$_{0.55}$Se$_{0.45}$ single crystal, also revealed the mechanism of two distinct classes of vortices present in this system, which directly tied with the presence or absence of zero-bias peak [2]. To further investigated the MZM, it is still needed to find a “smoking-gun” type of evidence for the existence of MZM, and a quantized conductance plateau is widely believed to be one of them.

Here we report an observation of the Majorana conductance plateau in vortices on the iron superconductor FeTe$_{0.55}$Se$_{0.45}$ surface by using STM/STS [3]. We found that both extrinsic instrumental convoluted broadening and intrinsic quasiparticle poisoning can reduce the conductance plateau value. When extrinsic instrumental broadening is removed by deconvolution, the plateau is found to nearly reach a $2e^2/h$ quantized value. The direct observation of a conductance plateau on a single zero-mode in a vortex strongly supports the existence and protection of MZMs in this iron-based superconductor, which can serve as a single-material platform for Majorana braiding at relatively high temperature.
In an effort to spatially resolve excited state properties of nanomaterials with sub-nm resolution, our group has developed an excited state imaging technique known as single-molecule absorption scanning tunneling microscopy (SMA-STM). This technique allows us to probe changes in tunneling associated with laser excitation, creating an image that maps the excited state electronic structure of nanomaterials. We have applied this technique widely to study excited state properties of quantum dots (QDs) and carbon nanotubes (CNTs) and will discuss results surrounding the interaction of optically excited QDs with CNTs. Our results show a distant-dependent transverse polarization of CNTs in the presence of an excited QD, while semiquantitative tight-binding calculations performed on an analogous system allow us to model the observed interaction. We will also discuss our preliminary work with traditional STM on carbon nanothreads and their variants, which aims to characterize the ground state electronic properties of these carbon materials. Initial results show highly variable band gaps of aggregate structures likely due to varied ordering and defects, while techniques allowing for investigation of individual threads will ultimately position us for excited state characterization.

Controlling transport in single molecules remains a major challenge, in part due to the difficulties of predicting the electronic structure of a molecule when supported in a metallic nanostructure. Here we discuss the possibility of using molecular dipole moments as built-in electric fields in single molecules to shift the energy level alignment and therefore tailor quantum transport. On the basis of advanced statistical analysis of experimental data from a set of model molecules, we are able to differentiate even rather small differences in the conductance, which enables us to investigate whether built-in electric fields are a useful approach to tailor the interfacial electronic structure in single molecule junctions.
**12:15PM M62.00004: Giant Thermopower in Quasi-One-Dimensional LaAlO$_3$/SrTiO$_3$ Quantum Wires**

PUQING JIANG (Presenter), YUHE TANG, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — SrTiO$_3$-based heterointerfaces possess new effects ranging from superconductivity to magnetism. In particular, the two-dimensional (2D) LaAlO$_3$/SrTiO$_3$ interface was previously shown to have highly enhanced and oscillating thermopower when back-gated close to the insulating state [1]. Here we investigated the electrical and thermoelectric transport properties of quasi-one-dimensional (1D) LaAlO$_3$/SrTiO$_3$ quantum wires [2] at a low temperature of 80 mK. We find significantly enhanced and oscillating thermopower for the quantum wires, with values that are comparable to reports for 2D LaAlO$_3$/SrTiO$_3$ [1]. The Mott relation, which governs the diffusive thermopower of non-interacting electrons, works surprisingly well despite the highly ballistic nature of electron transport and evidence of electron-electron interaction in these quantum wires. Our results suggest that the highly enhanced thermopower in 2D SrTiO$_3$-based systems may originate from naturally formed quasi-1D channels at the heterointerfaces.

---

**12:27PM M62.00005: Effects of writing parameters on electron transport in sketched single-electron transistors**

PHILIP SHENK (Presenter), Univ of Pittsburgh, JOHN MAIER, Department of Physics, University of Notre Dame, YANG HU, Univ of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — Fabrication of single-electron transistors (SETs) and other mesoscopic devices typically requires elaborate nanofabrication techniques. We approach this challenge using a reversible conductive-AFM lithography technique that can locally control the conductivity of the LaAlO$_3$/SrTiO$_3$ interface. We characterize the properties of “sketched” nanostructures as a function of experimentally controllable variables such as writing parameters, back-gate voltage, temperature and magnetic field. Here we focus on the SketchSET geometry [1] which shows discrete addition energies that we can track as a function of source-drain bias and magnetic field. Our findings yield insights into intrinsic interactions between electrons confined within the SET islands.

12:39PM M62.00006: Controlling Nonlinear Thermoelectricity of a Quantum Dot by Quantum Interference* NOBUHIKO TANIGUCHI (Presenter), Physics Div., Univ of Tsukuba — We theoretically study how one can control and enhance nanoscale nonlinear thermoelectricity by regulating quantum interference. We take the configuration of a quantum-dot interferometer (a quantum dot embedded in the ring geometry), which can also represent a model of a single-molecule junction. One can adjust quantum coherence by modifying direct conducting channels between the leads (Fano's effect). Within the linear response theory, such Fano resonances have been suggested to enhance drastically the thermoelectric figure of merit, which reaches an order-of-unity value even for a non-thermoelectric material. We revisit the idea by examining the efficiency and the output power in the nonlinear response regime. Based on the microscopic model and nonequilibrium Green function techniques, we can incorporate the strong correlation on the dot and charge-blocking effect. We show how the presence of direct conducting channels can greatly enhance nonlinear thermoelectric performance, even when the resonance width is much larger than temperature.

*The author gratefully acknowledges financial support from JSPS KAKENHI Grant No.~19K03682.

12:51PM M62.00007: Bell-state correlation in electric currents through lead electrodes connected to a quantum dot* RUI SAKANO (Presenter), Institute for solid state physics, University of Tokyo, AKIRA OGURI, Physics, Osaka city university, MIKIO ETO, Physics, Keio university — We study quantum entanglement that is excited in currents through lead electrodes connected to a quantum dot. To assess the emerging entanglement among the lead electrode, we use Bell's inequality with cross-correlations of current fluctuations [1]. The correlations of the current fluctuations are calculated by using the Anderson impurity model and Green's function in the Keldysh formalism. Electron-hole pairs are induced between two electric leads. We show that quantum entanglement can be formed in the current even if there is no effective Coulomb interactions in the quantum dot. Namely, we investigate current that is induced by sequential tunneling or free quasiparticles scattering in the Kondo regime. Specifically, we find that application of bias-voltages among the lead electrode generate electron-hole, electron-electron, and hole-hole pairs are excited among the lead electrodes. These pairs can violate Bell's inequality

1:03PM M62.00008: Coherent Refraction Across Atomically-Precise Molecular Graphene Junctions  MORGAN BRUBAKER (Presenter), YI-TING CHEN, BEATRIZ SARAH YANKELEVICH, ALISON DAY, HARI C. MANOHARAN, Stanford Univ — The construction of functional nanoscopic devices requires an in-depth understanding of electronic transport across interfaces. Electrons in graphene exhibit lightlike behavior due to their massless dispersion relation near the Dirac points; this suggests the ability to construct nanostructures that control electrons analogously to how optical devices such as lenses control light, provided that transport at the interface is understood. Molecular graphene, assembled with atomic manipulation of individual molecules in a low-temperature, ultra-high-vacuum scanning tunneling microscope so as to confine itinerant two-dimensional electrons to a honeycomb lattice, serves as a new tunable form of graphene that features atomically-precise edges and is thus ideal for probing interface transport. We report experiments that use quasiparticle interference measurements to probe the behavior of Dirac electrons incident upon junctions between molecular graphene and a nearly-free two-dimensional electron gas, and between differently-doped regions of molecular graphene. Our results indicate that Dirac electrons are refracted coherently across the junction, analogous to light bending across an interface between two media with mismatched indices of refraction.

1:15PM M62.00009: Persistent Coulomb Blockade Across the Metal-Insulator Transition in Nanoparticle Solids  DAVIS UNRUH (Presenter), CHASE HANSEN, University of California, Davis, ALBERTO CAMJAYI, JOEL BOBADILLA, University of Buenos Aires, MARCELO J ROZENBERG, CNRS, GERGELY T ZIMANYI, University of California, Davis — Nanoparticle (NP) solids in opto-electronic and photovoltaic applications have disadvantageously low carrier mobilities. The mobility is suppressed by the disorder driving the NP solids insulators. A Filling-Controlled (FC) Coulomb blockade further suppresses transport at integer fillings. Transport at non-integer fillings can be improved by driving NP solids across a Disorder-Controlled Metal-Insulator Transition (DC-MIT) into their Metallic Phase by enhancing the kinetic energy to overcome the disorder and thus delocalizing the electron wavefunctions. However, the evolution of the FC-Coulomb blockade at integer fillings across the DC-MIT has not been analyzed yet, leaving the question open whether the FC-Coulomb blockade dissolves or persists in some form as the electron wavefunctions delocalize when the DC-MIT is crossed. The work reported here explores this question of how the FC-Coulomb blockade evolves across the DC-MIT by analyzing transport in the Insulating Phase by our Hierarchical Nanoparticle Transport Simulator, and in the Metallic Phase by Dynamical Mean-Field Theory. Remarkably, the FC-Coulomb blockade is found to persist across the DC-MIT.
1:27PM M62.00010: Theoretical Design of Topological Heteronanotubes*  CHEN HU  (Presenter), VINCENT MICHAUD-RIOUX, McGill Univ, WANG YAO, University of Hong Kong, HONG GUO, McGill Univ — We propose and investigate the idea of topological heteronanotubes (THTs) for realizing a one-dimensional (1D) topological material platform that can pave the way to low-power carbon nanoelectronics at room temperature. We predict that the coaxial double-wall heteronanotube, a carbon nanotube (CNT) inside a boron nitride nanotube (BNNT), can act as a THT. Dissipationless topological conducting pathways on the THT are protected by a valley-dependent topological invariance that originates from local topological phase transitions of the CNT modulated by the CNT-BNNT interaction. Spiral THTs, where topological current flows spirally around the tube, function as nanoscale solenoids to induce remarkable magnetic fields due to the dense moire nanopatterning.

*This work is financially supported by Natural Science and Engineering Research Council (NSERC) of Canada, and the Fonds de recherche du Québec - Nature et technologies (FRQNT) of the Province of Quebec (H.G.). We thank Compute Canada and the High Performance Computing Center of McGill University for substantial computational support.

1:39PM M62.00011: Towards quantum criticality in Al/InAs Kondo systems*  PRAVEEN SRIRAM  (Presenter), CONNIE HSUEH, Department of Applied Physics, Stanford University, ASBJORN DRACHMANN, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, CANDICE THOMAS, GEOFFREY C. GARDNER, Microsoft Quantum at Station Q Purdue, TIANTIAN WANG, Department of Physics and Astronomy and Station Q Purdue, Purdue University, SERGEI GRONIN, MICHAEL MANFRA, Microsoft Quantum at Station Q Purdue, CHARLES MARCUS, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, DAVID GOLDHABER-GORDON, Department of Physics, Stanford University — Hybrid metal-semiconductor two-dimensional systems are an attractive platform for exploring correlated electron-electron interactions. Flexible nanopatterning allows design of structures to emulate particular Hamiltonians with electrostatically tunable parameters. Pierre et al. recently demonstrated a quantum phase transition based on a charge Kondo effect[1]. Based in a GaAs heterostructure, the metal was an annealed ohmic contact, requiring much effort to obtain a highly-transparent interface even for a few-micron metal island. InAs may offer significant advantages: pinning of the surface Fermi level in the conduction band allows for direct electrical contact to metals. For example, in-situ epitaxy of aluminum on InAs has resulted in pristine interfaces, leveraged to probe topological superconductivity[2]. Small metallic islands with large charging energies may allow building on earlier charge Kondo work without requiring as low electron temperatures. I will present our initial efforts towards realizing charge Kondo devices on InAs 2DEGs tuned into the quantum Hall regime, with edge states controlled by lithographically defined QPCs.

*Supported by US DoE, contract DE-AC02-76SF00515
M62.00012: Kondo resonance assistant thermoelectric transport through strongly correlated quantum dot* YONGXI CHENG (Presenter), Beijing Computational Science Res Ctr, JIANHUA WEI, Renmin University of China, HONG-GANG LUO, Lanzhou University, HAI-QING LIN, Beijing Computational Science Res Ctr — We theoretically study the thermoelectric transport properties of a strongly correlated quantum dot system in the presence of Kondo effect, on the basis of accurate numerical evaluations. The thermocurrent versus gate voltage shows a distinct sawtooth line-shape at high temperature. In particular, the sign of current changes from positive (hole charge) to negative (particle charge) in the electron number N = 1 region due to Coulomb blockade effect. However, at low temperature, where Kondo effect takes place, the thermocurrent charge polarity reverses, together with also a significantly enhanced magnitude. As anticipated, the current sign can be analyzed by the occupation difference between particle and hole. Moreover, one could further define the characteristic turnover temperature, at which the influences of Coulomb blockade and Kondo resonance are in effective balance. When magnetic field is applied, a spin-polarized thermocurrent could be obtained, which could be tested in future experiments.

M62.00013: Ballistic p–n junctions in three-dimensional Dirac semimetal Cd₃As₂ nanowires

MINKYUNG JUNG (Presenter), DGIST Research Institute, DGIST, JANICE BAYOGAN, SUNG JIN AN, JUNGPIL SEO, Department of Emerging Materials, DGIST — We demonstrate a ballistic p–n junction in a three-dimensional Dirac semimetal (DSM) Cd₃As₂ nanowire with two recessed bottom gates. The device exhibits four different conductance regimes with gate voltages, confirming that device forms p–n junction. The conductance in the p–n junction regime decreases drastically when a magnetic field is applied perpendicular to the nanowire, which is due to the suppression of Klein tunneling. In this regime, the device shows quantum dot behavior. On the other hand, clear conductance plateaus are observed in the n–n regime likely owing to 1-D subbands of carriers at high magnetic fields. In other devices, we also observe Fabry-Perot interference in the p–n junctions, indicating that our devices are in the ballistic regime. Our experiment shows that the ambipolar tunability of DSM nanowires can enable the realization of quantum devices based on electron optics.

Session M63 DMP DCMP FIAP: Defects in Oxides and Chalcogenides Mile
High Ballroom 4D - Cyrus Dreyer, State Univ of NY - Stony Brook - Tag(s): Focus
Chalcogenide phase change materials can exist in multiple structural states at room temperature. There is a large difference in the electrical and optical properties between the structural states of these materials. Importantly the phase transition time can be just picoseconds [1], and this makes these materials ideal for both optical and electrical data storage[2]. Indeed, they have recently been commercialised in Intel’s Optane memory[3].

The most common data storage materials exist along a pseudo-binary compositional line between Sb$_2$Te$_3$ and GeTe. These materials tend to have a small electronic band gap and consequently strongly absorb visible light. This means that it is challenging to use these common PCMs for many visible photonics applications.

We will discuss how phase change materials can be used in visible photonics. We will discuss the plasmonic property of the common phase change materials and also introduce a new phase change material with an electronic band gap of 2 eV[4]. We will discuss the prospect of using electrical fields to control phase changes in these materials. We believe these results will open new opportunities to design programmable photonics devices that operate at visible wavelengths.

*We are grateful for funding from A* Star (Project: NSLM, Grant #: A18A7B0058) and the Singapore Ministry of Education (Project: Electric-field induced transitions in chalcogenide monolayers and superlattices, Grant #: MOE2017-T2-1-161).
11:51AM M63.00002: Electron mobility in crystalline and amorphous metal-oxide semiconductors

IGOR EVANGELISTA (Presenter), ANDERSON JANOTTI, Department of Materials Science and Engineering, University of Delaware — Charge carrier mobility in amorphous semiconductors is significantly reduced when compared to the crystalline phase. For instance, room-temperature electron mobility in crystalline silicon is 1400 cm$^2$/V.s, while that for amorphous silicon is only ~0.1 cm$^2$/V.s. Amorphous metal-oxide semiconductors are unique in this respect, as they display relatively high electron mobilities when compared to their crystalline counterpart. Here we investigate the microscopic origin of this intriguing effect. Using first-principles molecular dynamics to generate amorphous configurations and electronic structure calculations of prototype metal oxides, we investigate why metal-oxide semiconductors display relatively high electron mobilities even in an amorphous phase. We analyze their band structure, the effects of volume, the change in the absolute band edge positions, and provide a detailed comparison between amorphous silicon and Ga$_2$O$_3$, paying special attention to the presence of band tail states and the change in band gaps.

12:03PM M63.00003: Amorphous Oxide Semiconductors: role of disorder and composition in defect formation, carrier generation, and transport properties

JULIA MEDVEDEVA (Presenter), Missouri Univ of Sci & Tech — Unlike Si-based semiconductors, amorphous oxide semiconductors (AOSs) exhibit optical, electrical, thermal, and mechanical properties that are comparable or even superior to those possessed by their crystalline counterparts. Although amorphous materials lack grain boundaries and periodicity, the electron transport is more complex than in the crystalline phases: strong local distortions in the metal-oxygen polyhedra and intricate structural morphology in AOSs affect carrier mobility via composition, defects, thermal vibrations, nano-crystallinity, and lattice strain. Moreover, given many degrees of freedom in amorphous materials, defects in AOSs have the structural, thermal, and electronic characteristics that differ fundamentally from those in the crystalline transparent conducting oxides.

In this talk, complex deposition-structure-property relationships in several prototype AOSs are discussed. The results of systematic computationally-intensive ab-initio Molecular Dynamics followed by comprehensive structural analysis and accurate density-functional calculations, are integrated with experimental measurements to understand the origins of complex behavior in the disordered materials and to derive versatile design principles for next-generation transparent amorphous semiconductors.
Amorphous oxide semiconductors (AOS) possess many unique properties, including high carrier mobility (>>a-Si:H) and optical transparency, making them attractive materials for a wide range of optoelectronic applications. Unlike Si-based semiconductors or silica glasses, AOS exhibit strong distortions in local polyhedral structure due to weaker Metal-Oxygen bonds that are ionic in nature. These distortions have been shown to cause strong electron localization near the valence and conduction band edges and deep inside the band gap when oxygen content, known to dope the oxide materials n-type, is varied. Moreover, due to the large number of degrees of freedom in AOS, thermal or photo activation may switch bond configurations out of shallow states into deep bound states or vice versa, making a static characterization inadequate for AOS. In this work, ab-initio molecular dynamics simulations are combined with accurate density-functional calculations to study time- and temperature-dependent characteristics of defects with different formation energies and degree of localization in amorphous InOx. The microscopic understanding of the structural dynamics highlights the complex nature of AOS and helps explain the observed non-equilibrium conductivity in the materials under illumination.

Recent discoveries of amorphous and quasi-amorphous phases in SrTiO₃ (a-STO) open up a wide range of possible applications in electronic devices that prohibit utilization of crystalline STO (c-STO) due to fundamental or technological barriers. While oxygen vacancies are known to play key role in the electronic properties of c-STO, the results may not be applicable to a-STO. Upon amorphization, changes in the local structure and morphology may affect the formation energy of oxygen defects and their diffusion. In addition, a reduction of the material's density may lead to voids and other structural defects, important for material's behavior. All the above calls for a comprehensive study of the microscopic origins of the observed electronic and optical properties in a-STO.

Here we employ ab-initio molecular dynamics liquid-quench simulations and accurate density-functional calculations to understand how the local and medium-range structural characteristics change upon amorphization in STO. Specifically, we analyze the Ti-O and Sr-O coordination, polyhedra sharing, and morphology as a function of density, quench rates, and oxygen deficiency in a-STO and determine the role of the structural changes in the resulting electronic and optical properties of this disordered material.
12:39PM M63.00006: Hydrogen doping of crystalline/amorphous In$_2$O$_3$ interface: the structure and electronic properties. KAPIL SHARMA (Presenter), JULIA MEDVEDEVA, Missouri Univ of Sci & Tech — Hydrogen doped In$_2$O$_3$ has grabbed attention of scientific community due to its high carrier mobility, high carrier concentration, and transparency in near-IR region, with values exceeding those in commercial ITO. While H-doped crystalline In$_2$O$_3$ has been studied, the results may not be applicable to amorphous In-based oxides, employed in state-of-the-art display technologies. The lack of periodicity, the strong local and medium-range distortions in the Metal-Oxygen (M-O) polyhedra, and the increased number of degrees of freedom in amorphous materials are likely to affect the formation of M-OH and M-H bonds as well as their thermal stability. Hence, the resulting properties of hydrogenated amorphous oxide semiconductors may differ from those in the crystalline counterpart.

In this work, amorphous/crystalline In$_2$O$_3$ Interface with >100 initial locations of H radical is investigated using ab-initio molecular dynamics and density functional calculations. The relaxed structures and their electronic properties are analyzed based on the calculated total energy, interatomic distances, effective coordination numbers, local distortions, and charge density distribution before and after H-doping. In addition, the effect of H on the interface morphology and crystallization are investigated.

12:51PM M63.00007: Thermoelectric properties of Pb$_{2-x}$Y$_x$Ru$_2$O$_{7-z}$ pyrochlore SEPIDEH AKHBARIFAR (Presenter), WERNER LUTZE, IAN L PEGG, Catholic Univ of America — Thermoelectric materials convert heat to electrical energy and are considered for various applications such as refrigeration or in power generations. Thermoelectric properties are characterized by a figure of merit ($ZT$), $ZT=\frac{S^2\sigma T}{k}-1$. $ZT$ is a function of the Seebeck coefficient or Thermopower ($S$), electrical conductivity ($\sigma$), temperature ($T$) and thermal conductivity ($k$). This work aims to study the respective properties of lead ruthenate (Pb$_2$Ru$_2$O$_{6.5}$) doped with yttrium oxide in the temperature range of 25 to 300°C. Lead ruthenate has a defect pyrochlore crystal structure and has metal-like electrical conductivity. Y$_2$Ru$_2$O$_7$ is an insulator. Molar fractions of Pb have been substituted by yttrium, i.e., Pb$_{2-x}$Y$_x$Ru$_2$O$_{7-z}$ with $x$ varied between 0 and 1. The compounds were prepared by solid-state synthesis and characterized by XRF, X-ray diffraction, and SEM/EDX for composition, structure, phase content, morphology and crystal size. Micron-sized powders were pressed into pellets to measure the thermoelectric properties. The results will be discussed, particularly the transition from conductive to insulating and its effect of $ZT$. 
1:03PM M63.00008: Role of defects in photocatalytic water splitting: Monodoped vs codoped SrTiO\textsubscript{3} * MANISH KUMAR (Presenter), SASWATA BHATTACHARYA, Indian Inst of Tech-New Delhi — SrTiO\textsubscript{3} can be utilized as a photocatalyst for water splitting owing to its suitable band edge positions, thermal stability and low cost. However, it could not harness the visible light due to its wide band gap (3.25 eV). Doping is one of the prominent solutions to tailor the band gap and inducing the visible light response and thus, enhancing the photocatalytic activity. We address the role of monodoping of a metal (Mn) and a non-metal (N), as well as their codoping in SrTiO\textsubscript{3} for photocatalytic water splitting using state of the art density functional theory and \textit{ab initio} atomistic thermodynamics. N\textsubscript{O} reduces the band gap, but introduces the deep trap states that degrade the photocatalytic efficiency. Mn\textsubscript{Sr} could not reduce the band gap of SrTiO\textsubscript{3}. Mn\textsubscript{Ti} could reduce the band gap, but it lowers down the conduction band edge and hence, lowers the reduction power. Our results reveal that the Mn\textsubscript{Sr}N\textsubscript{O} (codoping of Mn at Sr and N at O in SrTiO\textsubscript{3}) is the promising candidate as a photocatalyst for water splitting as it induces the visible light response as well as passivates the deep level states and its band edge positions straddle the redox potential of water.

1:15PM M63.00009: Rutile GeO\textsubscript{2}: an ultra-wide-band-gap semiconductor with ambipolar doping SIEUN CHAE (Presenter), KELSEY A. MENGLE, Univ of Michigan - Ann Arbor, HANJONG PAIK, Platform for the Accelerated Realization, Analysis, and Discovery of Interface Materials (PARADIM), Cornell University, JIHING LEE, JOHN HERON, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — Ultra-wide-band-gap (UWBG) semiconductors have tremendous potential to advance electronic devices as device performance improves superlinearly with increasing gap. Ambipolar doping, however, has been a major challenge for UWBG materials as dopant ionization energy and charge compensation generally increase with increasing gap. Using hybrid density functional theory, we demonstrate rutile germanium oxide (r-GeO\textsubscript{2}) to be an alternative UWBG (4.68 eV) material that can be ambipolarly doped. We identify Sb\textsubscript{Ge}, As\textsubscript{Ge}, and F\textsubscript{O} as possible donors with low ionization energies and propose growth conditions to avoid charge compensation by native acceptor-type defects. Acceptors such as Al\textsubscript{Ge} have relatively large ionization energies (0.45 eV) due to the formation of localized hole polarons. Yet, we find that the co-incorporation of Al\textsubscript{Ge} with H\textsubscript{i} can increase the solubility limit of Al and enable hole conduction in the impurity band. We also calculate electron (153.6 cm\textsuperscript{2}V\textsuperscript{-1}s\textsuperscript{-1}) and hole mobilities (4.7 cm\textsuperscript{2}V\textsuperscript{-1}s\textsuperscript{-1}) of r-GeO\textsubscript{2} at 300 K, suggesting r-GeO\textsubscript{2} has outstanding electronic properties that can compete with the state-of-the-art UWBG semiconductors such as β-Ga\textsubscript{2}O\textsubscript{3}. We will also discuss on our recent experimental progress on thin-film growth and electrical characterization of r-GeO\textsubscript{2}.
**1:27PM M63.00010: Quasiparticle Properties of Sulfur Doped SrTiO3**

GABE LOPEZ-CANDALES (Presenter), PEIHONG ZHANG, Physics, University at Buffalo — Strontium Titinate (SrTiO3) is a potential candidate for photocatalytic water-splitting application due to a favorable conduction band edge position with respect to the hydrogen reduction potential level [1]. Despite having an ideal conduction band placement, the large band gap (3.25 eV (indirect) and 3.75 eV (direct)) [1] limits its photocatalytic and photovoltaic applicability. The distorted chalcogenide-perovskite counterpart (SrTiS3), on the other hand, is predicted to have a significantly lower band gap (0.9 eV) [2]. In this work, we report GW quasiparticle calculations of the electronic properties of sulfur doped of SrTiO3 using a recently developed accelerated GW approach [4] that allows efficient GW calculations for large system. Our results elucidate a complex relationship between atomic and electronic structure, predicting a notable trade-off between band gap and structural stability.

*This work is supported in part by the NSF (Grant Nos. DMR-1506669 and DMR-1626967).

**1:39PM M63.00011: Defect physics in rare-earth doped wide band-gap materials**

KHANG HOANG (Presenter), North Dakota State Univ — Rare-earth (RE) doped wide band-gap materials are of great interest for optoelectronic and spintronic applications. The determination of defect energy levels associated with RE-related defect centers has been challenging, however, both in experimental and theoretical/computational studies. Yet such knowledge is crucial to understanding luminescence or persistent luminescence in the materials. In this talk, we present a hybrid density-functional study of the interaction between RE dopants (Er, Eu, Dy, etc.) and host materials (GaN and SrAl2O4), including intrinsic point defects and other impurities that may be present in the host materials. In light of our results, we identify possible luminescent RE-related centers and elucidate luminescence (or persistent luminescence) mechanisms in the RE-doped materials and develop guidelines for defect engineering to design materials with improved performance.
Tuning the Transport Properties of Artificial Synapses: A DFT-Supported Experimental Approach*  DIP DAS (Presenter), ARABINDA BARMAN, Department of Physics, Shiv Nadar University, India., PRANAB KUMAR SARKAR, Dept of Applied Science and Humanities, Assam University, India., RENE HUBNER, Electron Microscopy Laboratory, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Bautzner Landstrasse, Dresden, Germany, DINAKAR KANJILAL, Ion beam facilites, Inter-University Accelerator Centre, New Delhi, India, PRIYA JOHARI, ALOKE KANJILAL, Department of Physics, Shiv Nadar University, India. — Defect engineering is an essential aspect of resistive switching (RS) memories. This work illustrates cationic dopant (Ni) controlled RS characteristics in the thin film of anatase titanium dioxide (A-TiO₂). A significant increase in ON/OFF ratio to 10^3 with a gradual change in resistance state is accomplished and such RS characteristics are highly expedient for neuromorphic computing applications. Detailed investigations by transmission electron microscopy (TEM) and X-ray photoelectron spectroscopy (XPS) as well as density functional theory (DFT)-based first-principles calculations establish the role of Ni in memristive operation. In particular, TEM results show an evolution of two different Ni-concentration regions within the films that help to reduce the host Ti-site from its +4 valence state, as obtained from Ti-2p XPS analysis. This claim is further verified by DFT calculations, showing a change in the charge density near the Ni-site form the Bader charge analysis and electron localisation function (ELF) plots. Moreover, the role of those two Ni-concentration regions in regulating transport properties of the Au/ Ni:A-TiO₂ /Pt devices similar to the biological synapse is discussed.

Hot-electron mediated ion diffusion in semiconductors for ion-beam nanostructuring*  CHENG-WEI LEE (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Ion-beam-based techniques are widely utilized to synthesize, modify, and characterize semiconductors at the nanoscale. Interactions of the beam with the target are fundamentally interesting, as they trigger multi-length- and time-scale processes that need to be quantitatively understood to achieve nanoscale precision. Here we demonstrate for magnesium oxide¹ that, in a beam energy regime in which electronic effects are usually neglected, a proton beam efficiently excites oxygen-vacancy-related electrons and changes the charge state of the F-center. We quantify the beam-energy-dependent electronic excitation and the emerging ion dynamics using first-principles techniques. We further bridge time scales from ultrafast electron dynamics directly after impact to ion diffusion over migration barriers in semiconductors and discover a diffusion mechanism that is mediated by hot electrons. Our quantitative simulations predict that this mechanism strongly depends on the projectile-ion velocity, suggesting the possibility of using it for precise sample manipulation via nanoscale diffusion enhancement in semiconductors with a deep, neutral, intrinsic defect.

11:15AM M64.00001: Neutron diffraction and inelastic neutron scattering in the magnetodielectric regime of Ce$_2$O$_3$*  ALEXANDRA COTE (Presenter), ASTHA SETHI, University of Illinois at Urbana-Champaign, TARAS KOLODIAZHNYI, National Institute of Materials Science, JEFFREY LYNN, National Institute of Standards and Technology, S. LANCE COOPER, GREG MACDOUGALL, University of Illinois at Urbana-Champaign — The metastable material Ce$_2$O$_3$ has drawn recent attention due to reports of a giant magnetodielectric response of unknown origin, below a putative antiferromagnetic transition at $T_N=6.2K$. In the same temperature region, Raman spectroscopy has revealed the emergence of vibronic modes, which represent a relatively uncommon mixing of phonon and crystal field excitations.

Following up on these observations, we have performed a series of both neutron diffraction and inelastic scattering measurements on powders of Ce$_2$O$_3$. Our diffraction data allow us to comment on both the nature of the magnetically ordered state at low temperatures, and the variation in atomic structure as the material is varied through $T_N$. Our inelastic measurements focus on the temperature dependence of crystal field and phonon excitations at the energies of reported vibronic modes. I will present these data in the context of existing literature, and give our conclusions about the nature of the AF ground state and spin-lattice coupling in this material.

11:27AM M64.00002: Local polarization in oxygen-deficient LaMnO$_3$ induced by charge localization in the Jahn-Teller distorted structure  
CHIARA RICCA, ULRICH ASCHAUER  
(Presenter), University of Bern — The functional properties of transition metal oxides result from a complex interplay between magnetism, polarization, strain, and stoichiometry. Here, we show that for materials with a cooperative Jahn-Teller distortion, such as LaMnO$_3$ (LMO), the orbital order can also couple to the defect chemistry and induce novel material properties. At low temperatures, LMO is an A-type antiferromagnet with a distorted orthorhombic perovskite structure. It is insulating due to the Jahn-Teller distortion that splits the $e_g$ orbitals of the high-spin Mn$^{3+}$ ions, leading to alternating long, short, and intermediate Mn-O bond lengths. Our DFT+$U$ calculations show that, as a result of these peculiarities, the charge localization in LMO upon oxygen vacancy ($V_O$) formation is different compared to other manganites, like SrMnO$_3$, where the two extra electrons reduce the Mn sites adjacent to the vacancy. In LMO, relaxations around the $V_O$ depend on which type of Mn-O bond is broken, affecting the $d$-orbital energies and leading to an asymmetric and hence polar localization of the excess electrons with respect to the vacancy. Furthermore, we show how isostatic and epitaxial strain can be used to affect the Mn-O bond lengths and orbital order and consequently the charge localization and polarity.

11:39AM M64.00003: Geometrical frustration and piezoelectric response in oxide ferroics*  
VALERI PETKOV (Presenter), Physics, Central Michigan Univ — Despite years of investigation, the exact structural origin of the increased piezoelectric response of oxide ferroics is still unclear. We will present results from resonant high-energy x-ray diffraction experiments on exemplary sodium-potassium niobate ferroics. In particular, we will show that their increased piezoelectric response is due to a geometrical frustration in the underlying perovskite lattice induced by local fluctuations in the tilt pattern of the constituent niobium-oxygen octahedra, and not to a crystal-crystal phase transition or distinct nanodomains. The fluctuations peak when the sodium to potassium ratio approaches one, leading to softening of the perovskite lattice and easing of polarization rotation under electric field. Based on the experimental findings and model calculations, we will also show that the fluctuations are driven by the mismatch between the radii of sodium and potassium atoms, and the increased piezoelectric response of sodium-potassium niobates indeed scales with the variance in the distribution of these radii about their average value. The relevance of our work to the ongoing search for oxide ferroics with improved functionality will be briefly discussed.

11:51AM M64.00004: Magnetic Field Dependent Local Structure of Charge-Ordered AMnO₃ Perovskites* SIZHAN LIU, New Jersey Inst of Tech, MILINDA ABEYKOON, Brookhaven National Laboratory, TREVOR TYSON (Presenter), New Jersey Inst of Tech — Complex oxide perovskites exhibit closely lying structural phases at low temperatures. External parameters including pressure and magnetic field can be used to stabilize distinctly different structural phases. In this project, we utilize pair distribution function measurements to determine the changes in the local structure in AMnO₃ perovskites when going from the charge-ordered insulating phased to the metallic phase at fixed temperature when applying an external magnetic field. The structure on a range of length scales will be explored. The results will be compared to the corresponding temperature dependence of the structure.

*This work is supported by NSF Grant No. DMR-1809931.

12:03PM M64.00005: Infrared nano-spectroscopy of ferroelastic domain walls in hybrid improper ferroelectric Ca₃Ti₂O₇ KEVIN SMITH (Presenter), Chemistry, University of Tennessee, Knoxville, ELIZABETH NOWADNICK, Material Science and Engineering, University of California, Merced, SHIYU FAN, Physics, University of Tennessee, Knoxville, OMAR KHATIB, Physics and Chemistry, University of Colorado, Boulder, SEONG JOON LIM, BIN GAO, Physics and Astronomy, Rutgers University, NATHAN HARMS, SABINE NEAL, JUSTIN KIRKLAND, Chemistry, University of Tennessee, Knoxville, MICHAEL MARTIN, Advanced Light Source Division, Lawrence Berkeley National Lab, CHOONG-JAE WON, Laboratory for Pohang Emergent Materials, Pohang Accelerator Laboratory and Max Planck POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, MARKUS B. RASCHKE, Physics and Chemistry, University of Colorado, Boulder, SANG-WOOK CHEONG, Physics and Astronomy, Rutgers University, CRAIG FENNIE, School of Applied and Engineering Physics, Cornell University, G CARR, National Synchrotron Light Source II, Brookhaven National Lab, HANS BECHTEL, Advanced Light Source Division, Lawrence Berkeley National Lab, JANICE L MUSFELDT, Chemistry, University of Tennessee, Knoxville — Ferroic materials are well known to exhibit heterogeneity in the form of domain walls. Understanding the properties of these boundaries is crucial for controlling functionality with external stimuli and for realizing their potential for ultra-low power memory and logic devices as well as novel computing architectures. In this work, we employ synchrotron-based near-field infrared nano-spectroscopy to reveal the vibrational properties of ferroelastic (90° ferroelectric) domain walls in the hybrid improper ferroelectric Ca₃Ti₂O₇. By locally mapping the Ti-O stretching and Ti-O-Ti bending modes, we reveal how structural order parameters rotate across a wall. Thus, we link observed near-field amplitude changes to underlying structural modulations and test ferroelectric switching models against real space measurements of local structure. This initiative opens the door to broadband infrared nano-imaging of heterogeneity in ferroics.
Coupled structural distortions, domains, and control of phase competition in polar SmBaMn$_2$O$_6$ ELIZABETH NOWADNICK (Presenter), University of California, Merced, JIANGANG HE, Northwestern University, CRAIG J FENNIE, Cornell University — Complex oxides display highly tunable ground states, where small perturbations to the crystal structure can stabilize distinct electronic and magnetic phases. We use group theoretic methods and density functional theory calculations to analyze the polar crystal structure of A-site ordered SmBaMn$_2$O$_6$, which hosts a charge- and orbitally-ordered antiferromagnetic ground state. We show that a set of couplings between structural distortions are key for establishing the structural, electronic, and magnetic ground states and also establishes a hybrid improper ferroelectric mechanism in this material. We analyze the domain structure and show how the coupled degrees of freedom in SmBaMn$_2$O$_6$ leads to a network of coupled domains and domain wall vortices. Finally, we explore how competing electronic and magnetic phases may stabilize, for example at structural domain walls and in epitaxially strained thin films. This work provides new understanding of the complex physics realized across multiple length scales in SmBaMn$_2$O$_6$ and demonstrates a framework for the systematic exploration of correlated and structurally complex materials.
The search for new quantum materials with novel properties is often focused on materials containing transition-metal or rare-earth elements. The presence of the atomic-like $d$ or $f$ orbitals provides a fruitful playground to generate novel phenomena and understanding the behavior of those $d$ and $f$ electrons is essential for designing and tuning new materials. Therefore, identifying the $d$ or $f$ orbitals that actively participate in the formation of the ground state is crucial. So far, these orbitals have mostly been deduced from optical, X-ray and neutron spectroscopies in which spectra must be analyzed using theory or modelling. This, however, is also a challenge in itself, since ab-initio calculations hit their limits due to the many-body nature of the problem.

Here we developed a new experimental method that circumvents the need for involved analysis and instead provides the information as measured. With this technique, we can make a direct image of the active orbital and determine what the atomic-like object looks like in a real solid. The method, s-core-level non-resonant inelastic X-ray scattering (s-NIXS), relies on high momentum transfer in the inelastic scattering process, which is necessary for dipole-forbidden terms to gain spectral weight. To demonstrate the strength of the technique, we imaged the text-book example, $x^2-y^2/3x^2-r^2$ hole orbital of the Ni$^{2+}$ ion in NiO single crystal [1]. We will present the basic principles of s-NIXS and its experimental implementation. We will also show how we can apply this technique to unveil the active orbitals in complex oxides as well as to determine the orbital character in highly metallic systems such as elemental Cr, Fe, and Ni.

1:03PM M64.00008: Interplay of orbital selectivity and local environment in correlated materials: the case of metal-insulator transition in CaFeO$_3$  
GHEORGHE PASCUT (Presenter), MANSiD Research Center, Stefan Cel Mare University (USV), JENNIFER COULTER, 1 John A. Paulson School of Engineering and Applied Sciences, Harvard University, PREMALA CHANDRA, KARIN M RABE, KRISTJAN HAULE, Dept. of Physics and Astronomy, Rutgers University, New Brunswick — Density Functional Theory (DFT) with Embedded Dynamical Mean Field Theory (eDMFT) is a very successful method in describing novel electronic states of matter where (I) Mott and metallic orbitals coexist (orbital-selective Mott state) (II) Mott, metallic and semi-metallic orbitals coexist (site-orbital-selective Mott state) and (III) Mott and band orbitals coexist (band-Mott state). Recently, forces for structural relaxations within the DFT+eDMFT have been developed, and the predictive power of the method for electronic-structural interplay at finite temperatures was demonstrated on correlated materials that have novel states with orbital and site selectivity, such as NdNiO$_3$, LaMnO$_3$, BiMnO$_3$, TM$_2$Mo$_3$O$_8$ (TM=Mn, Fe). Through the use of this method, we apply DFT+eDMFT to study the electronic-structural interplay at finite temperature, in order to describe the interplay between Mott, band and metallic-like orbitals and the local environment (characterized by the bond length and bond angle) in CaFeO$_3$, as it goes through the metal to insulator transition.

1:15PM M64.00009: Atomic-scale insight into lattice and electronic modulation induced by the substitution of bismuth in iron garnet with enhanced magneto-optical effect*  
KUN XU (Presenter), Tsinghua University, LUO ZHANG, Beijing Normal University, H. W. ZHANG, University of Electronic Science and Technology of China, JING ZHU, Tsinghua University — In this study, Bismuth substituted lutetium iron garnet prepared by liquid epitaxial method shows large Faraday rotation up to 1.64 degree/µm at 633nm at room temperature, whose structure variation and element distribution in atomic scale have been directly interpreted by using analytical scanning transmission microscopy (STEM). The substituted Bismuth located in dodecahedral site of lutetium iron garnet can induced the change of lattice and furtherly will lead to the distortion of octahedral Fe sites, but magnetic order is not modified, which is all verified by using energy loss spectrum (EELS). Combined with density function theory (DFT) calculation, distorted octahedral magnetic sublattice contributes to the reduced crystal field splitting energy and orbital degeneracy.

*This work was financially supported by Chinese National Natural Science Foundation (51390471, 51527803, 51761135131), National 973 Project of China (2015CB654902), and National key research and development program (2016YFB0700402).
JOHN SLIMAK (Presenter), ASTHA SETHI, University of Illinois at Urbana-Champaign, TARAS KOLODIAZHNYI, National Institute for Materials Science, Japan, S. LANCE COOPER, University of Illinois at Urbana-Champaign — The energetic overlap of phonons and low-lying crystal electric field (CEF) excitations in rare-earth sesquioxides is conducive to strong electron-phonon coupling and dramatic magnetostructural phenomena. For example, our previous temperature and magnetic field dependent Raman scattering studies on a member of this series, A-type Pr2O3, revealed significant phonon softening and a level repulsion between electronic and phononic levels. To explore these results further, we present a pressure-dependent Raman scattering study of Pr2O3 aimed at tuning the coupling between electron and phonon levels to modify the low temperature phase behavior. We observe that the degeneracy of the lowest lying CEF doublet is lifted under the application of pressure below 60 K and that the energy splitting increases linearly with increasing pressure or magnetic field. These results are indicative of a pressure-induced Structural Distortion that appears to be instigated by pressure-dependent electron phonon coupling. We discuss the possible effects of pressure on the magnetostructural properties of Pr2O3.

STEVEN HARTMAN (Presenter), Institute of Materials Science and Engineering, Washington University, St. Louis, AYANA GHOSH, Materials Science and Engineering, University of Connecticut, ROHAN MISHRA, Institute of Materials Science and Engineering, Washington University, St. Louis, CHRISTOPHER STANEK, BLAS PEDRO UBERUAGA, GHANSHYAM PILANIA, Materials Science and Technology Division, Los Alamos National Lab — Perovskite compounds—with a generic formula of ABX3— represent a versatile class of materials exhibiting tremendous synthetic flexibility and technological applications. Going beyond “single” perovskites, two or more species can occupy each sublattice. While origins and design rules of cation ordering in perovskites are well known, anion ordering in heteroanionic perovskites remains a largely uncharted territory. This talk will share insights from a first principles analysis of anion-ordered AB(O0.5S0.5)3 oxysulfide chemistries, studied in all possible anion configurations, with A=Ca,Sr,Ba and B=Ti,Zr,Hf. We find that the stable local ordering is always an all-cis arrangement (i.e., a fac-type ordering) in each BO3S3 octahedron, stabilized by a combination of electronic, strain and electrostatic interactions. We further study the relative stability of this ordering as a function of A and B site chemistries and probe its effect on the electronic structure. Most remarkably, we show that the ground state anion ordering breaks inversion symmetry to create a family of polar oxysulfides with polarization >30 µC/cm², exhibiting a significant promise for electronic applications.

*We acknowledge support from Laboratory Directed Research and Development (LDRD) program (Project# 20190043DR).
1:51PM M64.00012: Symmetry analysis of anion order, cation-vacancy order, and octahedral tilting in oxyfluoride double perovskites*  RICHARD SABALLOS (Presenter), JAMES RONDINELLI, Northwestern University — In simple homoanionic double perovskites, the possible phase space based on octahedral tilting and cation ordering has been established and is useful in resolving known structures as well as performing computational studies to determine viable phase transitions [1][2]. However, a similar study incorporating octahedral tilting and ordering in heteroanionic materials has yet to be carried out. Initial work in oxynitrides has determined that by coupling octahedral tilting and anion ordering, it is possible to further lower the phase symmetries of materials [3]. This coupling can also be used to break inversion symmetry, leading to improvement in dielectric responses and ferroelectricity. Here we use the P4/nmm phase of [J]KNaNbOF₅ as a prototype structure to explore how independently and in combination anion ordering, A-site vacancy ordering, and octahedral tilting lead to variations in symmetries [4]. We apply materials physics principles to understand commonalities among the structure space and perform electronic structure calculation to ascertain the microscopic origins.

*NSF's MRSEC program (DMR-1720139) at NU.

2:03PM M64.00013: Understanding the Appearance of Local and Long-Range Anion Order in Heteroanionic Layered Perovskites*  JAYE HARADA (Presenter), JAMES RONDINELLI, Northwestern University — The prediction of the appearance, or lack thereof, of anion ordering in mixed-anion and heteroanionic materials is an important, yet unsolved problem. This issue has a significant impact on the prediction of properties in these materials, especially properties whose appearance is reliant on long-range noncentrosymmetry, such as ferroelectricity, piezoelectricity and nonlinear optical phenomena such as second harmonic generation. We examine this issue in Ruddlesden-Popper oxyfluorides where both anion ordered and disordered structures exist, such as Sr₂FeO₃F and Sr₂ScO₃F, and fluoride preferentially occupies the apical anion site of the 2D perovskite layers. We use density functional theory calculations to understand and attempt to quantify the contributions of the B-site cation size, covalency, and magnetism to the configurational entropy or the appearance of local and long-range ordered anions.

**11:15AM M65.00001: Observation of flat bands and singularity collapse in back-gated semiconductor artificial graphene**  
LINGJIE DU, Physics, Nanjing University, ZIYU LIU (Presenter), Columbia University, LOREN PFEIFFER, Princeton University, MICHAEL MANFRA, Purdue University, ARON PINCZUK, Columbia University — Electronic flat bands are key predicted features in tunable artificial graphene (AG) near M points in the Brillouin zone. Such dispersionless electron flat bands could support unconventional superconducting states. Here, we report the first direct observation of flat bands in semiconductor AG transistors where the electron density is tuned by applied voltage. Doublets observed in low temperature photoluminescence (PL) display a density dependence that is linked to the van-Hove singularity doublet near M points. We find that the doublets in PL persist for a large range of electron densities, suggesting a pinning of the Fermi energy in a flat band. Interestingly, as the temperature is lowered to below 10K, the lineshape of the doublet in PL spectra shows a dramatic temperature dependence in which the higher energy peak quickly collapses. This unexpected temperature dependence suggests possible formation of electron liquid states near the flat band at low temperature.

*Supported by NSF grant DMR-1306976 and DOE grant DE-SC0010695.

YEONGROK JIN (Presenter), JAEKWANG LEE, Pusan Natl Univ — The flexoelectricity, electrical polarization induced by a strain gradient, is one of the very exotic physical phenomena because it can induce the huge piezoelectricity even in centrosymmetric materials. Here, combining density functional theory calculation and mathematical analysis, we find that the corrugation generates the great out-of-plane polarization mediated by the flexoelectric effect even in centrosymmetric two-dimensional materials. The flexoelectricity in 2D materials is highly sensitive to the corrugation strength and tunable by adjusting the curvature at the nm scale. The correlation between curvature, flexoelectricity and resulting out of plane polarization will be discussed and associated underlying mechanisms will be introduced in detail.
11:39AM M65.00003: Electronically Engineered Nanoporous Graphene*  PETER JACOBSE (Presenter), RYAN MCCURDY, DANIEL RIZZO, JINGWEI JIANG, PAUL L BUTLER, GREGORY VEBER, STEVEN LOUIE, FELIX FISCHER, MICHAEL F CROMMIE, University of California, Berkeley — Recent advances in the synthesis of graphene nanoribbons using on-surface bottom-up techniques have enabled fabrication of not only atomically well-defined one-dimensional structures, but also two-dimensional structures such as nanoporous graphenes. These are particularly interesting for applications due to their sieve-like topology. Here we present a new methodology for creating covalently connected, fully conjugated two-dimensional graphene structures through the utilization of cyclopentadiene (CP) moieties. CP elements exhibit a propensity to initiate fusion between nanoribbons and result in a two-dimensional structure with well-defined interface topology. The resulting new material is analyzed using scanning tunneling microscopy (STM), scanning tunneling spectroscopy (STS), and bond-resolved scanning tunneling microscopy (BRSTM). We observe emergent interface-localized electronic states that hybridize to yield a dispersive two-dimensional band of states at an energy inside the bandgap of an isolated GNR.

11:51AM M65.00004: Band structure engineering of 2D materials using 1D superlattice*  YUTAO LI (Presenter), SCOTT A DIETRICH, CARLOS FORSYTHE, SHAOWEN CHEN, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, JAMES C HONE, CORY DEAN, Columbia University — Atomically thin 2D materials such as graphene provide promising new platforms to realize synthetic band structures by superlattice (SL) patterning. We exploit our recently developed technique of dielectric superlattices to pattern graphene with a 1D superlattice potential with periodicity as low as 47nm. We observe strong anisotropy in electrical transport features along directions parallel versus perpendicular to the SL basis vector. The main and mini Dirac points, induced by the SL potential, may be “flattened” at certain strengths of SL modulation, leading to an alternating sequence of resistance maxima and minima in the direction parallel to the SL basis vector. Our results establish a multitude of possibilities of band structure engineering on a 2D material under a 1D superlattice potential with possible applications in ballistic electron optics, van der Waal FETs, and plasmonics.

**12:03PM M65.00005: Periodic strain-induced magnetization in graphene over NbSe₂**

ANTONIO MANESCO (Presenter), Kavli Institute of Nanoscience, Delft University of Technology, JOSE L. LADO, Department of Applied Physics, Aalto University, EDUARDO RIBEIRO, GABRIELLE WEBER, DURVAL RODRIGUES JR., University of Sao Paulo — Electronic correlations are known to dramatically impact the electronic properties of graphene in the presence of real or artificial gauge fields, as a consequence of the strongly enhanced density of states. Paradigmatic examples of this include the magnetically-ordered quantum Hall state in monolayer graphene, and the correlated and superconducting phases in twisted graphene multilayers. Motivated by recent experiments, here we explore the emergence of a periodic-modulated magnetization caused by epitaxial-induced strain in graphene stemming from a NbSe₂ substrate. In particular, we show the emergence of a magnetic state induced by the elastic substrate-induced pseudo gauge field, its interplay with the superconducting state of NbSe₂, and the potential tunability of the correlated state by means of external electric and magnetic fields. Our results put forward a hybrid graphene/NbSe₂ heterostructure with tunable correlations, providing a powerful platform to explore correlated physics in hybrid van der Waals materials.

*The work of ALRM was supported by São Paulo Research Foundation Grants No. 2016/10167-8 and 2019/07082-9. DRJ is a CNPq researcher.

**12:15PM M65.00006: Strain tunable magnetotransport study of ABC trilayer graphene/h-BN moiré superlattices**

CHUANKUN LIU (Presenter), RYUICHI TSUCHIKAWA, JAMESON G BERG, VIKRAM V DESHPANDE, University of Utah — The number of atomic layers changes the electronic band structure of graphene dramatically. While monolayer graphene hosts linear bands with massless fermions, trilayer ABC-stacked graphene exhibits a very flat quartic band at the K point and is a particularly suitable platform for strongly correlated physics. When ABC trilayer graphene is aligned with the h-BN layer, the addition of the moiré superlattice can create narrow minibands, and low energy bands can become flat and isolated near charge neutrality. Mott insulating states and unconventional superconductivity have been observed in ABC-TLG/h-BN heterostructures. Perpendicular electric field and strain are important ways to tune these bands. In our work, we have fabricated ABC-TLG/h-BN aligned heterostructures with dual graphite gates, on flexible substrates to apply both perpendicular electric field and intralayer strain onto the device. We study the responses of low energy bands by performing magnetotransport measurements at low temperatures.
12:27PM M65.00007: Interaction-driven broken symmetry states in moiré vdWs heterostructure*  ZHIREN ZHENG (Presenter), THAO H DINH, Massachusetts Institute of Technology MIT, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SUYANG XU, Harvard university, NUH GEDIK, QIONG MA, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology MIT — The freedom of stacking different layers of 2D van der Waals (vdW) materials with an arbitrary twist angle opens up tremendous opportunities in studying emergent properties that are not accessible in the natural crystal form. In particular, the recently discovered magic-angle twisted bilayer graphene shows that the twist angle and moiré potential can substantially enhance electron correlations for spontaneously broken symmetry states and turn semi-metallic graphene into insulator, superconductor, and quantum anomalous Hall insulator at will. With the right system and careful design, interaction-driven broken symmetry states can have many other manifestations that are not only fundamentally intriguing but also invaluable to new device applications. Here, we report on our design and experimental exploration of a multiferroic system based on moiré vdW heterostructures. Our study will open the door to a new class of 2D multiferroics, which has a potential implementation in many important applications, such as memristive devices for neuromorphic computing.

*The work was partially supported as part of the Center for the Advancement of Topological Materials, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

12:39PM M65.00008: Optical study of electric field tunable 2D semiconductor moiré superlattices  LIZHONG LI (Presenter), YANHAO TANG, KIN FAI MAK, JIE SHAN, Cornell University — Moiré superlattices based on graphene or transition metal dichalcogenide (TMD) heterostructures provide an interesting platform to explore emerging quantum phases in the strong correlation regime. The large electron mass in monolayer TMDs and the lack of magic angle requirement make TMD moiré heterostructures a particularly robust platform for studying problems in strong electron correlation physics[1]. For instance, it has been recently shown that WSe2/WS2 moiré superlattices can simulate the physics of the triangular lattice Hubbard model [2]. Whereas electrostatic doping can continuously tune the filling factor of the system, a vertical displacement field could also effectively tune the relative band alignment of the heterostructure and other important parameters of this strongly correlated system. In this talk, I will discuss our recent optical study on electric field tunable TMD moiré superlattices and the search for novel quantum phases of matter.

12:51PM M65.00009: Charge transfer in transition metal dichalcogenide superlattices and moiré quantum chemistry  YANG ZHANG (Presenter), NOAH YUAN, LIANG FU, Massachusetts Institute of Technology MIT — We theoretically investigate the band structure and interaction effects in moiré superlattices of transition metal dichalcogenides and find the Mott and charge-transfer insulating phases around half filling. The charge transfer length of a charge-transfer insulator can be several nanometers, and the magnetic susceptibility of the Mott insulator is also worked out as a probe for the antiferromagnetic ground state. This highly tunable system provides an ideal platform to simulate diatomic solids under strong interactions.

1:03PM M65.00010: Stokes spectroscopy applied to monolayer MoS$_2$ photoluminescence at room temperature; different helicities observed for A-exciton and A-trion  EHSAN ZOLGHADR (Presenter), SOURAV GARG, PATRICK KUNG, Univ of Alabama - Tuscaloosa, NEWTON MARTINS BARBOSA NETO, Universidade Federal do Para, PAULO T ARAUJO, Univ of Alabama - Tuscaloosa — Strong electron-electron and/or electron-hole Coulomb interactions play important roles in optical transitions in monolayer semiconducting transition metal dichalcogenides (TMDCs). These optical transitions reflect the behaviors of excitons and/or trions. Here, we present our investigation of room temperature Stokes spectroscopy applied to the photoluminescence emitted by a large-area MoS$_2$ monolayer grown by CVD technique standing on a SiO$_2$ substrate. Stokes spectroscopy allows for simultaneous measurement of any helicity, which is advantageous compared to the traditional helicity-resolved photoluminescence measurement. Our results show that the PL emission presents significant amount of circularly polarized light when non-resonantly excited with linearly polarized light at 532 nm. Analyzing the Stokes spectra leads to a deconvolution in which the A-exciton and A-trion peaks have opposite helicities. While the exact valley polarization dynamics and selection rule mechanisms that leads to the optical properties still need to be clarified, this study opens the door for a better understanding of the room temperature exciton and trion physics on monolayer MoS$_2$, an ideal candidate for industrial atomically thin opto-electronic devices such as solar cells and photodetectors.
1:15PM M65.00011: Studying Transition Metal Dichalcogenide Superlattices with nano-ARPES  
CONRAD STANSBURY (Presenter), IQBAL UTAMA, University of California, Berkeley, CLAUDIA FATUZZO, Materials Science Department, Lawrence Berkeley National Lab, CHRIS JOZWIAK, AARON BOSTWICK, Advanced Light Source, Lawrence Berkeley National Lab, JOSÉ AVILA, Synchrotron SOLEIL, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Lab, FENG WANG, ALESSANDRA LANZARA, University of California, Berkeley — Two-dimensional layered materials, especially monolayer transition metal dichalcogenides, have demonstrated lasting impact as a platform for combining and tuning electronic and optical behaviors on the nanoscale. The realization that moiré superlattices in these systems provide tunable control over correlations has sparked renewed interest through analogy to the family of high-temperature superconductors and in light of new phenomena such as moiré excitons. As a complement to modeling, a bottom-up understanding of these phenomena and interlayer hybridization motivates direct measurements of the electronic structures of the host materials. Nano-ARPES enables these experiments on clean, mechanically-exfoliated heterostructures where the impact of substrate and superlattice interaction on the electrons can be fully explored. In this talk, I show how this technique can address basic questions of electronic and structural order in a few model systems: heterobilayer interfaces, and in the interface of TMD monolayers with a substrate. Among the rich phenomena present at the interface, we will focus especially on the presence or absence of hybridization effects in short and long wavelength superlattices.

1:27PM M65.00012: Tip-enhanced nano-imaging of 2D alloy with gradual concentration profile  
HANA HRIM (Presenter), SHARAD AMBARDAR, DMITRI V VORONINE, Univ of South Florida — Systematic optical studies of 2D MoₓW₁₋ₓS₂ alloys, with 0.05≤x≤0.45 grown by chemical vapor deposition (CVD) on Si/SiO₂ were carried out using Raman and photoluminescence (PL) spectroscopy using 532 nm laser. Atomic force microscopy (AFM) imaging showed the correlation with the optical images. We demonstrate nano-optical imaging using tip-enhanced photoluminescence (TEPL) as a function of the composition x for obtaining the higher spatial resolution beyond the diffraction limit. Quantum plasmonic quenching of the TEPL signals was observed for larger x revealing the tunneling electron injection. In order to overcome the problem of excitation efficiency we used a 405 nm laser for TEPL which showed efficient excitation of different x components. Tip-enhanced Raman spectroscopy (TERS) confirms the alloy composition at the nanoscale.
1:39PM M65.00013: Clean 2D superconductivity in a bulk van der Waals superlattice

ARAVIND DEVARAKONDA (Presenter), Department of Physics, Massachusetts Institute of Technology MIT, HISASHI INOUE, Frontier Research Institute of Interdisciplinary Sciences, Tohoku University, SHIANG FANG, Department of Physics and Astronomy, Rutgers University, CIGDEM OZSOY KESKINBORA, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, TAKEHITO SUZUKI, Department of Physics, Massachusetts Institute of Technology MIT, MARKUS KRIENER, Center for Emergent Matter Science (CEMS), RIKEN, LIANG FU, Department of Physics, Massachusetts Institute of Technology MIT, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University, DAVID CHARLES BELL, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, JOSEPH G CHECKELSKY, Department of Physics, Massachusetts Institute of Technology MIT — Recent interest in bulk van der Waals systems has been driven by the search for exotic physics in thin flakes exfoliated from bulk crystals and, more broadly, the desire to add novel functionalities to those available in the van der Waals heterostructure toolkit. This top down approach has proved successful in unveiling novel phenomena, the $MX_2$ transition metal dichalcogenides being one such case where both flakes and heterostructures have been used to uncover and design exotic ground states, respectively. However, such devices have intrinsic limitations that can impede powerful experimental probes or prevent the realization of exotic physics in the first place due to disorder introduced through the fabrication process. Here, we report experimental evidence for a possible solution in the form of a bulk single crystal, van der Waals superlattice that simultaneously exhibits high cleanliness and two-dimensional superconductivity.

M65.00014: Algorithm on the absolute formation energy of edges in transition metal dichalcogenides

CHUEN KEUNG SIN (Presenter), JUNYI ZHU, Physics, The Chinese University of Hong Kong — Equilibrium shapes are the keys to fully understand the growth dynamics of quasi 2D structures, such as transition metal dichalcogenides. However, the intrinsic complexity of the quasi 2D nature near the edge makes it challenging to formulate successful algorithm with good accuracies. As a result, the theoretical investigations on the growth thermodynamics and kinetics are limited. To solve the fundamental problem, we proposed a new calculation scheme to calculate the formation energy of edges in monolayer MoS$_2$. With the help of electron counting model, we found the proper passivation scheme of pseudo hydrogen on the edge of ribbons and wedges and obtained semiconducting nature with excellent accuracies.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M66 DCMP: Fractons: from symmetry and fractionalisation to dynamics and realisations

Four Seasons 1 - Rahul Nandkishore, University of Colorado, Boulder -
11:15AM M66.00001: Fracton topological order via quantum elasticity duality* [Invited] LEO RADZIHOVSKY (Presenter), MICHAEL PRETKO, MICHAEL A HERMELE, Department of Physics, University of Colorado, Boulder — I will discuss a recent discovery that elasticity theory of a two-dimensional quantum crystal is dual to a fracton tensor and to a coupled-vector gauge theories, thereby providing a concrete realization of the “fracton order” phenomenon. The disclinations and dislocations respectively map onto charges and dipoles of these gauge theories. The fractionalized mobility of fractons matches the constrained dynamics of lattice topological defects. These dualities lead to predictions fractonic phases, and phase transitions to their descendants, that are duals of the commensurate crystal, supersolid, smectic, and hexatic liquid crystals. Extensions of this duality to generalized elasticity theories provide a route to discovery of new fractonic models and their potential experimental realizations.

*Simons Investigator Award from the Simons Foundation

11:51AM M66.00002: Foliated Fracton Order [Invited] XIE CHEN (Presenter), Caltech — The quantum information study of quantum codes and quantum memory has led to the discovery of a new class of exactly solvable fracton models. The fracton models are similar to the better understood topological models in that they also support fractional excitations and have stable ground state degeneracy. But it is also clear that the fracton models exist beyond the realm of conventional topological order due to their extensive ground state degeneracy and the restricted motion of their fractional excitations. In this talk, I will present a new framework, which we call the “foliated fracton order”, to capture the nontrivial nature of the order in a large class of fracton models. Such a framework not only clarifies the connection between various different models, but also points to the direction of search for interesting new features.

12:27PM M66.00003: Fractons: The Road to Reality [Invited] MICHAEL PRETKO (Presenter), University of Colorado, Boulder — In this talk, I will give an overview of progress towards connecting the field of fractons with experiments. I will begin with a brief introduction to fractons, describing some of the models and phenomenology encountered in the field. I will then describe some advances in proposed spin models realizing fracton behavior, along with some experimental diagnostics which are useful for detecting fractons. Finally, I will discuss several new platforms for realizing fracton physics, such as hole-doped antiferromagnets and electric circuits.
Coulomb spin liquids are well studied spin liquid states exhibiting emergent electromagnetism, having a coarse-grained description corresponding to Maxwell’s laws. It has recently been appreciated that even more exotic scenarios are possible, realizing generalizations of electromagnetism with rank-2 electric and magnetic fields. These are of particular interest since the emergent charges of the rank-2 electromagnetism can be fractons, with fundamentally constrained mobility.

In this talk I will describe an approach to finding simple, bilinear models, for classical spins which realize rank-2 Coulomb phases at low temperature [1,2]. Such models provide access to rank-2 Coulomb phase physics in a setting amenable to efficient numerical study and also suggest directions to look for rank-2 Coulomb phases in experiment.

Remarkably, we find that a traceless, vector-charged, rank-2 Coulomb phase can be generated by perturbing a simple Heisenberg model on the pyrochlore lattice with breathing anisotropy and weak Dzyalozhinskii-Moriya interactions [2]. This enables us to identify Yb-based breathing pyrochlores as potential candidate systems and to make explicit predictions for how the rank-2 Coulomb phase would manifest itself in experiment.

Ergodicity-breaking arising from Hilbert space fragmentation in dipole-conserving Hamiltonians* [Invited] FRANK POLLMANN (Presenter), PABLO SALA DE TORRES-SOLANOT, TIBOR RAKOVSZKY, RUBEN VERRESEN, MICHAEL KNAP, Department of Physics, Technical University of Munich — We show that the combination of charge and dipole conservation---characteristic of fracton systems---leads to an extensive fragmentation of the Hilbert space, which in turn can lead to a breakdown of thermalization. As a concrete example, we investigate the out-of-equilibrium dynamics of one-dimensional spin-1 models that conserve charge (total Sz) and its associated dipole moment. First, we consider a minimal model including only three-site terms and find that the infinite temperature auto-correlation saturates to a finite value. The absence of thermalization is identified as a consequence of the strong fragmentation of the Hilbert space into exponentially many invariant subspaces in the local Sz basis, arising from the interplay of dipole conservation and local interactions. Second, we extend the model by including four-site terms and find that this perturbation leads to a weak fragmentation: the system still has exponentially many invariant subspaces, but they are no longer sufficient to avoid thermalization for typical initial states. More generally, for any finite range of interactions, the system still exhibits non-thermal eigenstates appearing throughout the entire spectrum.

Wednesday, March 4, 2020 11:15 AM - 2:15 PM

Session M67 DCMP: DCMP Prize Session Four Seasons 2-3 - Andrei Rutgers

Oliver E. Buckley Condensed Matter Physics Prize talk [Invited] PABLO JARILLO-HERRERO (Presenter), Massachusetts Institute of Technology MIT — In this talk I will review the discovery of correlated insulator states and superconductivity in magic-angle twisted bilayer graphene, as well as some of the recent developments in the field.
**11:51AM M67.00002: What have we learned from Dynamical Mean Field Theory and what lies ahead?**  
[Invited]  
ANTOINE GEORGES (Presenter), Collège de France, Paris and Flatiron Institute, New York  
— Dynamical Mean-Field Theory (DMFT) provides both an original perspective on the physics of strongly correlated electron materials and an efficient computational framework to understand and predict their properties. In this talk, I will review the main ideas at the heart of the DMFT construction and physical perspective. Through select examples, I will outline how the efforts of a whole community over almost three decades have managed to develop the theory to such a point that it can successfully be applied to a real material, taking into account its structure and chemical composition. I will also outline how the theory is being extended and generalized in many fruitful directions.

*I acknowledge the support of the European Research Council (ERC-319286-QMAC) and the Simons Foundation.

**12:27PM M67.00003: Towards a Theory of Strongly Correlated Materials the Dynamical Mean Field Theory Road**  
[Invited]  
GABRIEL KOTLIAR (Presenter), Condensed Matter Physics, Brookhaven National Laboratory  
— Strongly correlated electron materials pose great conceptual and computational challenges. Dynamical Mean Field Theory (DMFT) has enabled a community of scientists to achieve great progress in this area. We will review some basic ideas underlying this approach, such as the reduction of the full many body problem into a quantum impurity model satisfying a self consistency condition. We will then provide some examples from materials containing elements from different regions of the periodic table, ranging from 3d's(*) to 5f's(**) of how DMFT ideas and implementations in combination with electronic structure methods have enabled predictions in materials which were not tractable by other methods, work under way to overcome its limitations(*) and point towards great challenges ahead.

(*)This work was supported by the Computational Materials Sciences Program funded by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
There has been great interest in the development of composite optical materials and metamaterials for applications in modern optical technology. Materials with a strongly nonlinear response are required for many applications, and especially in photonics for processes such as all-optical switching. It is of particular interest to design composite structures that enhance the value of the third-order optical susceptibility $\chi^{(3)}$. Under ideal conditions, this composite $\chi^{(3)}$ can exceed the $\chi^{(3)}$ values of the constituents of the composite [1]. This enhancement of the nonlinear response can be understood as a consequence of the judicious use of local field effects [2]. Enhanced nonlinear response of composite materials and structures has been demonstrated for a variety of materials [3-7]. Recent work has shown an additional means of enhancing the nonlinear optical response by making use of a material that possesses a vanishingly small electric permittivity at the wavelength of interest. Such materials are known as epsilon-near-zero (ENZ) materials [8], and they have been observed to display extremely large values of the $\chi^{(3)}$ response [9]. These materials, on their own or when incorporated into metasurfaces [10], hold great promise for high-speed, all-optical switching applications and operate with minimal power requirements.

We first review the recent developments and novel applications for space-time-frequency metasurfaces. Then we outline hybrid, plasmonic-photonic meta-structures for quantum information systems and discuss a new approach for high-speed quantum photonics operating at THz rates. The use of plasmonics to optimize light-matter coupling and speed-up quantum processes so that they outpace quantum decoherence and losses will be also discussed.
11:15AM M68.00001: Three-dimensional imaging of force-generating molecular networks inside of cells using cryo-electron tomography [invited] MATTHEW SWULIUS (Presenter), Pennsylvania State University — Dynamic networks of cytoskeletal polymers commonly take part in generating fundamental cellular forces. In order to understand the mechanical role of these cytoskeletal networks in development and disease, multimodal information across multiple dimensions and scales need to be integrated. In this presentation, I will briefly overview the protein components that make and regulate these cytoskeletal networks, and talk about how my lab is using live-cell imaging and cryo-electron tomography to study these molecules in the context of neuronal outgrowth.

11:51AM M68.00002: Opening a new window into the cell with super-resolution imaging and in situ cryo-electron tomography* [invited] STEPHEN CARTER, California Institute of Technology, CHERI HAMPTON, ROBERT LANGLOIS, Columbia University, ROBERTO MELERO, Centro Nacional de Biotecnología, ZACHARY FARINO, MICHAEL CALDERON, Univ of Pittsburgh, WEN LI, Columbia University, CALLEN WALLACE, Univ of Pittsburgh, ROBERT GRASSUCCI, Columbia University, WILLIAM RICE, New York Structural Biology Center, MEIR ARIDOR, KENNETH FISH, Univ of Pittsburgh, DEBORAH FASS, SHARON WOLF, Weizmann Institute, SIMON WATKINS, Univ of Pittsburgh, JOSE MARIA CARAZO, Centro Nacional de Biotecnología, GRANT JENSEN, California Institute of Technology, JOACHIM FRANK, Columbia University, ZACHARY FREYBERG (Presenter), Univ of Pittsburgh — Super-resolution light and electron microscopy have revolutionized our ability to visualize cell machinery. We use live-cell super-resolution imaging including stimulated emission depletion (STED) microscopy together with highly inclined thin illumination (HiLo) and high-speed three-dimensional widefield imaging to visualize organelle dynamics in real time. We have integrated these approaches with in situ cryo-electron tomography (cryo-ET), and cryo-correlative light and electron microscopy (cryo-CLEM) to visualize the endoplasmic reticulum (ER) and its relationships with other intracellular organelles in near-native states. The combination of these methods has revealed a novel ER-derived compartment that is mobile, vesicular, and associated with mammalian 80S cytoplasmic ribosomes. Moreover, with cryo-focused-ion-beam (FIB) milling and cryo-ET, we show that these vesicles exist as discrete structures separate from the intact reticular ER architecture. We call these organelles Ribosome-Associated Vesicles (RAVs). Detailed characterization of the RAVs revealed that these structures are conserved across multiple cell types and species using both conventional transmission electron microscopy (TEM) and cryo-ET.

12:27PM M68.00003: Automatic analysis of cryo-electron tomography using computer vision and machine learning* [Invited] XIANGRUI ZENG, XU MIN (Presenter), Carnegie Mellon Univ — Cryo-electron tomography (cryo-ET) is an emerging technology for the 3D visualization of structural organizations and interactions of subcellular components at near-native state and submolecular resolution. Tomograms captured by cryo-ET contain heterogeneous structures representing the complex and dynamic subcellular environment. Since the structures are not purified or fluorescently labeled, the spatial organization and interaction between both the known and unknown structures can be studied in their native environment. The rapid advances of cryo-electron tomography (cryo-ET) have generated abundant 3D cellular imaging data. However, the systematic localization, identification, segmentation, and structural recovery of the subcellular components require efficient and accurate large-scale image analysis methods. We developed and adapted a suite of computer vision and machine learning methods for such analysis.

1:03PM M68.00004: Visualizing mitochondrial division machinery in situ [Invited] DANIELLE GROTJAHN (Presenter), Department of Integrative Structural and Computational Biology, The Scripps Research Institute — Mitochondria are dynamic organelles that serve a variety of metabolic roles for eukaryotic cells, including ATP generation and cell signaling. Unlike other organelles, mitochondria cannot be produced “de novo”, and instead rely on a tightly regulated division process called “fission”, which functions as a quality control mechanism to maintain a healthy population of mitochondria. However, several cellular stress pathways promote hyperactivation of the mitochondrial fission pathway that fragment the mitochondrial network and induce cell death (apoptosis). Despite increasing evidence that mitochondrial fragmentation is a hallmark feature of many neurodegenerative diseases, the molecular mechanisms that contribute to the mitochondrial fission process remain poorly defined. We recently developed a three-dimensional imaging approach using a combination of cryo-focused ion beam milling and cryo-electron tomography to visualize snapshots of mitochondrial constriction events in mammalian cells. Our three-dimensional reconstructions represent the highest resolution structures of the ultrastructural interactions between mitochondria and other subcellular components to date, enabling unprecedented analysis of these associations. Further analyses reveal that the endoplasmic reticulum and the cytoskeleton preferentially associate with mitochondrial membrane constrictions. Interestingly, we also observe the presence of a previously unidentified filamentous structure in association with dividing mitochondria, which we propose is a member of the septin family of intermediate cytoskeletal filaments. By mapping out the precise interactions of these components relative to mitochondrial membranes, our work describes the complete ultrastructural architecture of the mitochondrial fission machinery required for membrane constriction, and establishes cellular tomography as a valuable approach for studying snapshots of mitochondrial dynamics in situ.

1:39PM M68.00005: Anthony Fitzpatrick Invited Talk [Invited] —
Wednesday, March 4, 2020 11:15 AM - 12:03 PM

Session M70 DCMP FED DCOMP: Physics Outreach, Education and Society 208 - Jessica Thomas, American Physical Society - Tag(s): Education, Outreach, Undergrad Friendly

11:15AM M70.00001: Design and implementation of professional development workshops that support women in STEM in Tanzania*  JILL WENDEROTT (Presenter), Materials Science and Engineering, Northwestern University, JOYCE ELISADIKI, Physics, University of Dodoma — Women, particularly at the graduate and professional levels, are underrepresented worldwide in STEM fields. Empowering younger women at the secondary- and undergraduate-level to pursue STEM as a career path, as well as providing organizational tools for women in STEM once at the university level, can help to improve their retention and long-term representation in STEM fields. To meet the aim of encouraging women in STEM globally, the women supporting women in the sciences (WS2) program was developed as between Northwestern University graduate Society of Women Engineers (NU GradSWE) and graduate women in STEM from several Tanzanian universities. The first objective of the WS2 program was to build professional development workshops for women in STEM in Tanzania focused on (1) career development and (2) organizing as women in STEM. To this end, two workshops were created collaboratively via virtual meetings between NU GradSWE and Tanzanian volunteers. The workshop content was then taught online to prospective facilitators from Tanzania, with the hope to pilot the workshops in Tanzania in early 2020. This talk will discuss the stages of professional development workshop creation, as well as anticipated outcomes and long-term goals of the program.

11:27AM M70.00002: A Free Renewable Energy-based Physics Day Camp for Middle School Girls*  ROBERTO RAMOS (Presenter), University of the Sciences — On its seventh year, the Physics Wonder Girls Program¹ provided a free, novel renewable energy physics-based immersion experience to two cohorts of middle school girls selected from a pool of high-performing students in the Philadelphia-New Jersey area. The girls came from diverse communities, including underserved school districts. Girls were introduced to the theme of renewable energy, took a crash course on circuits using solar cell kits, and then built and raced solar cars, and solar boats on a portable pool. They compared the efficiencies of silicon cells versus organic solar cells, built solar cells based on dyes from raspberry and blackberry fruit, and used a thermal imager to audit heat leaks. They explored wind power using model turbines, digital anemometers, and a commercial turbine. They met women physicists engineers from the local food industry, toured a local food company and presented demonstrations to a community of friends and teachers.

Scientists in Public Service: Running for office as a STEM candidate

SHAUGHNESSY NAUGHTON (Presenter), 314 Action — The Washington Post declared 2018 the “Year of the Scientist Running for Office.” But despite scientifically and technologically complex challenges facing elected officials, public service is still a rare path for scientists. This session seeks to demystify the ways that scientists at all levels can engage in the democratic process, from casting a ballot to being on the ballot themselves. Participants will learn what it is like to run for office and to better understand the unique barriers to entering into politics as scientists. They will engage with scientists who have first-hand experience running for office, and leave with concrete ideas about getting involved in the 2020 elections.

314 Action is the scientific community’s premier organization in electoral politics—recruiting and training scientists to run for office, uniting the community in support of STEM based candidates and working to challenge and hold accountable politicians who base policy on ideology rather than evidence.

Through its nonpartisan trainings, 314 Action has trained 1,500 scientists to run for office since 2017.

In 2018 a record number of scientists were elected to office: nine new and seven incumbent STEM Members of the 116th Congress and 35 STEM members to state legislatures across the country.

Making a basic mathematics course compulsory for everyone studying science at pre-college and college level

PRITAM MANDAL (Presenter), Durgapur Women's College — From a study based on personal teaching experiences and one-to-one and in-group interaction with a large number of students (9th to 12th Grade and UG levels) and teachers across India, we found that science students not having mathematics in their subject combination, suffer from physics-phobia.

In pre-college programs (at 11th and 12th grades) when students are first exposed to “real” science curriculum (with Physics, Chemistry, Mathematics, Biology and Computer Science), many students in India do not take up mathematics, having the option to rule out mathematics as they aspire to be medical doctors or biologists. Students are moulded into the mindset that to study biology or medical science in future, mathematics is useless. These students take admission into 11th grade with a pre-installed idea that mathematics would be an extra burden on their pathways to become biologists or doctors.

As a consequence these non-maths students severely suffer in physics classes and start viewing physics as a dry, calculation-based abstract subject, missing out the true beauty and essence of physics.

We suggest a compulsory basic mathematics course for everyone studying science at the 11th-12th grade as well in UG level in India to build better citizens of science.

Wednesday, March 4, 2020 11:15 AM - 11:15 AM
M71.00002: A Novel Focused Electrohydrodynamic Printing Method

MATTHEW STROHMAYER (Presenter), ATUL DHALL, PUJHITHA RAMESH, NATALYA TOKRONOVA, CARL VENTRICE, SUNY Polytechnic Institute — The main advantages of additive manufacturing include limited waste and the ability to build complicated structures. Recently, a cost-effective, versatile method of high-resolution printing called electrohydrodynamic (EHD) printing has been introduced. This method allows for spatial resolution in the hundreds of nanometers. This process works similarly to a typical ink jetting system, except instead of the ink/polymer being pushed out of a tip, it is pulled out by an applied electric field allowing for the resultant droplet to be much smaller than the needle diameter. EHD systems are typically used in a drop-on-demand mode. Although operating in a continuous spray mode will increase throughput, its resolution is limited because of electrostatic repulsion between the drops. To overcome this limitation, we have incorporated an Einzel lens into the system to focus the droplets. To validate this approach, simulations were performed to test for different parameters, including droplet size changes and lens optimization. These parameters were then used to build a real system. This printhead system was then characterized for how well it performed. This includes comparisons of line widths of different focusing voltages.

M71.00003: 3D printed Liquid Crystal Elastomer mechanical devices*

DEVESH MISTRY (Presenter), NICHOLAS TRAUGUTT, ROSS VOLPE, SABINA ULA, CHRISTOPHER YAKACKI, University of Colorado, Denver — 3D printing allows the creation of macro-sized Liquid Crystal Elastomer (LCE) devices.[1,2] Here we show 3 cm-scale 3D printed mechanical LCE devices. The 1st project is a dynamically crystallizing LCE spinal fusion cage designed to treat degenerative disc disease (DDD). Compared to existing devices, our device conforms to the vertebral endplates and provides a large surface area and minimizes stress concentrations – thus minimizing the chance of conditions such as subsidence and adjacent level disease.

The 2nd project explores the structure property relationships of anisotropic dissipative LCE devices. Using these materials and techniques we demonstrate a prototype total disc replacement device that offers same functionality as the natural intervertebral disc.

The third project demonstrates highly dissipative and rate dependent LCE lattice structures created via digital light processing (DLP) printing. Compared to DIW, DLP printing allows us to create complex overhanging geometries with micron-resolution. The high rate dependency of our LCE resin means our devices provide effective shock absorbance over range of impact speeds.

M71.00004: Effect of Post-Processing on Thermo-Mechanical Properties of a 3D-Printed UV-Curable Polymer  
KATHERYN HUSMANN (Presenter), BRANDON MCREYNOLDS, STEPHAN COMEAU, JOHN MCCOY, New Mexico Tech, ALEXANDRIA N. MARCHI, Los Alamos National Laboratories — The effect of UV and thermal processing on the properties of a UV-curable polymer fabricated with 3D printing was studied. The polymers studied were proprietary methacrylate based resins (Formlabs) and samples were printed directly in test geometries. Uniaxial compression tests at room temperature were performed for Young's modulus, Poisson's ratio, and yield stress. Thermal tests using a Differential Scanning Calorimeter (DSC) described the glass transition temperature range, physical aging and (additional) high-temperature reactions of the samples. Post-processing consisted of either additional UV exposure time or high temperature "soak" time (or both). These indicated that post-processing has a pronounced effect on the mechanical and thermal properties. Both aspects of post-processing (UV and high-T soaks) increase the yield stress, the modulus and the glass transition. Combining high-T soaks with additional UV exposure is particularly effective.

M71.00005: Competition between Phase Separating and UV Curing Kinetics during Photopolymerization-Induced Phase Separation in Confined Resin Films  
ANNA SMALLWOOD (Presenter), OLIVIA T. SHERMAN, CHANG RYU, Chemistry and Chemical Biology, Rensselaer Polytechnic Institute — Polymerization-induced phase separation is the segregation of agents in a multicomponent mixture triggered by polymerization to convert low molecular weight (MW) monomers into high MW polymers or networks. Several factors control the nature and structure of polymerization-induced phase separation, including blend composition, molecular weight of the phase separation agent, and polymerization kinetics of the monomers. When properly controlled, these factors can dictate a specific morphology of the resulting structure, allowing for tuning of characteristics of the resulting network. This study seeks to investigate these factors during photopolymerization-induced phase separation. Real-time turbidity to measure UV light transmittance through a blend sample of predetermined thickness will be employed as the main tool to monitor the phase separation process during UV irradiation. UV LED intensity and wavelength, resin reactivity, and end functionality of polymer additives will be studied to investigate the effect of each on the phase separation process and resulting network morphology within the confined space of UV-curable resin films. Scanning electron microscopy and other microscopy tools will be used for the study of morphology for the photopolymerization-induced phase separation.
**M71.00006: Triplet Triplet Annihilation Polymerization for High Resolution 3D Printing**

DAVID LIMBERG (Presenter), JI-HWAN KANG, RYAN HAYWARD, Univ of Mass - Amherst — Two-photon polymerization (TPP) offers by far the highest spatial resolution (< 1 μm) of current 3D printing methods, but suffers from limited volumetric write speeds compared to conventional stereolithography and requires the use of pulsed laser sources. Here, we demonstrate a new method of high-resolution 3D printing using triplet-triplet-annihilation (TTA) that achieves sub-micron resolution while maintaining high throughput and requiring only a light emitting diode (LED) source with an intensity six orders of magnitude lower than typically required for TPP. We demonstrate a robust 3D printing mechanism capable of printing a diverse array of materials with high resolution, low surface roughness, and high write speeds, without requiring high-intensity pulsed laser illumination.

**M71.00007: Digital Printers and Image Quality**

SURESH AHUJA (Presenter), xerox corporation — Photoreceptor is a central device in digital printers. The outer layer, Charge Transport Layer made up of polycarbonate and Charge Transport Molecule is prone to abrasion by stresses of developing system or cleaning system when it is repeatedly used in printing process. The abrasion of the photoreceptor causes deterioration of electrical properties such as lowering sensitivity or lower charging and results in irregular image such as lower image density and image stain. Single and multiple coating were made with filled and unfilled binder polymers and their modulus and hardness were measured by nano-indenter. The effect of the nanoparticles on composite modulus is dependent on many variables particularly on the morphology of the polymer matrix as well as the interaction between the filler and matrix. The state of dispersion depends on balance of repulsive and attractive forces. on the particles.. Charge Transport Molecule reduced modulus and hardness thus increasing photoreceptor wear rate. Nano-filler silica in the polymer either polycarbonate or polyester increased modulus and hardness with higher photoreceptor life.

**M71.00008: Immersion Precipitation 3D Printing (ip3DP)**

RAHUL KARYAPPA (Presenter), MICHINAO HASHIMOTO, Singapore University of Technology and Design — We present a novel method of 3D printing to fabricate micro-to-nanoporous 3D models in one-step, which we termed immersion precipitation 3D printing (ip3DP). Methods to impart porosity to 3D printed objects have been limited to date. Addition of sacrificial materials to printing materials, followed by their removal, are the established approaches, but such approaches require post-processing to impart porosity. Solvent-cast 3D printing (SC3DP), which is direct 3D printing of polymer inks with in situ evaporation of solvents, has allowed fabricating 3D porous structures with stringent requirements of rheological properties of the printing ink (e.g., high viscosity and high vapor pressure). We developed an alternative approach to print polymeric inks directly in a bath of a nonsolvent and solidified them in situ via immersion precipitation. The porosity of the 3D printed objects was readily controlled by the concentrations of polymers and additives, and the types of solvents. This work is the first demonstration of three-dimensionally controlled immersion precipitation based on digitally controlled depositions of polymer solutions. Wide selection of printable materials, and the ability to tailor their morphologies and properties, make ip3DP a versatile method of 3D printing.
M71.00009: 3D Printing with Waste High-Density Polyethylene  
ANIKET GUDADHE, NIRMALYA BACHHAR, Polym Sci Engg, Natl Chem Lab, ANIL KUMAR, PREM ANDRADE, Ansys, GURUSWAMY KUMARASWAMY (Presenter), Indian Inst of Tech-Bombay — HDPE has widely been considered to be impossible to 3D print using fused filament fabrication (FFF). When HDPE is FFF printed, the printed object warps significantly and debonds off the print substrate. Therefore, it is difficult to preserve registry as the polymer filament is laid down layer by layer during FFF. We demonstrate a strategy for FFF of waste-derived HDPE. There are two aspects to our approach. (i) We formulate the HDPE by blending with dimethyl dibenzylidene sorbitol (DMDBS), that forms a nanofibrillar network in the HDPE melt as it cools and (≈ 10%) linear low density polyethylene (LLDPE). (ii) We use a thin “brim” around the printed object that helps it adhere to the print substrate using common paper glue. This dramatically reduces warpage, allowing FFF of HDPE objects with complex geometries. FEM simulations indicate that our approach decreases the stresses that develop due to crystallization induced shrinkage during cooling. Given the volume of HDPE that finds its way to the waste stream, our results have important implications for extending the use life of HDPE.

M71.00010: Printing Resolution and Depth-Of-Cure Study For Stereolithography 3D Printing Resins  
KEITH DAVID DENIVO (Presenter), ANNA SMALLWOOD, CHANG RYU, Rensselaer Polytechnic Institute — Stereolithography (SLA) is a method of 3D printing of polymer resins using photoinitiated polymerization. Polymer thermosets with crosslinked networks are being formed in SLA. We have studied how the characteristics of SLA photocurable resins affect the 3D printing resolution and mechanical properties. Characteristics include the viscosity and the depth dependent UV polymerization kinetics. Real time FTIR with attenuated total reflectance sample stage was used to thoroughly study the UV penetration depth effects on the photopolymerization kinetics in terms of the rate of polymerization, on-set time for photopolymerization and monomer conversion. Three types of commercially available SLA resins are compared for the printing resolution and depth-of-cure characteristics. Additional tuning of depth-of-cure characteristics has been performed by mixing additional photoinitiator or inhibitor for the investigation of 3d printing resolution studies. Controlled post UV-curing is also performed to further manipulate their mechanical properties with an aim to elucidate how the network structure in SLA samples affect the stress-strain behavior of thermosets under tensile elongation. The layer curing process and morphology has been also investigated by DSC and microscopy techniques.
M71.00011: Geometrical and Mechanical Characterization of Interlayer Bonding Quality in Fused Filament Fabrication* LICHEN FANG, YISHU YAN, OJASWI AGARWAL, Johns Hopkins University, JONATHAN SEPPALA, National Institute of Standards and Technology, KEVIN J. HEMKER, SUNG KANG (Presenter), Johns Hopkins University — To obtain a fundamental understanding of the large variation of mechanical properties and geometry of printed parts prepared by fused filament fabrication (FFF), we focused on the interlayer bonding region of polycarbonate samples prepared by FFF and performed 3D geometrical characterizations using micro-CT followed by uniaxial tensile tests. The results showed significant property variations depending on printing conditions. Specifically, the layer height impacted bonding area. In addition, there was an almost linear relation between bonding zone area and fracture strength. However, when nozzle temperature increased, the strength showed a rising trend first then reached plateau. Interestingly, we also found a trend of Young's modulus reduction with higher layer height, which could be explained by finite element simulations based on scanned sample geometries, indicating the bonding zone geometry change is the main reason of modulus variation. We envision that our findings can guide the selection of printing parameter as well as provide benchmark data for future simulation models.

M71.00012: Study of the end-to-end probability distributions of low-molecular weight, aqueous polyethylene oxide solutions using experimental DEER measurements and molecular dynamics simulations* NICK SHERCK, THOMAS WEBBER (Presenter), DENNIS ROBINSON BROWN, Chemical Engineering, University of California, Santa Barbara, TIMOTHY KELLER, Chemistry and Biochemistry, University of California, Santa Barbara, JACOB MONROE, Chemical Engineering, University of California, Santa Barbara, MIKAYLA BARRY, Materials, University of California, Santa Barbara, RACHEL A SEGALMAN, GLENN H FREDRICKSON, SCOTT SHELL, Chemical Engineering, University of California, Santa Barbara, SONGI HAN, Chemistry and Biochemistry, University of California, Santa Barbara — Low molecular weight, dilute, aqueous polyethylene oxide (PEO) chain end-to-end distance ($R_{ee}$) probability distributions, $P(r)$, were measured experimentally and calculated from simulation, filling a fundamental gap in the existing literature for one of the most widely used water soluble polymers. The distributions were measured by Double Electron Electron Resonance (DEER) spectroscopy, resolving the full $P(r)$ distribution within the technique's range of validity (~2-9 nm). The DEER technique uses small spin probes conjugated to the polymer ends. The probes in simulation are observed to hydrophobically aggregate below the range accessible to DEER (<1.5 nm), with the perturbation to the distributions dropping off rapidly with molecular weight. The distributions and their average $R_{ee}$ indicate aqueous PEO is a semi-flexible polymer in good solvent. The average $R_{ee}$ exhibits excluded volume scaling with molecular weight above the Kuhn length (~0.96 nm), which is quantitatively consistent with scattering data from high molecular weight (>10kDa) PEO.

*This work was supported as part of the Center for Materials for Water and Energy Systems (M-WET), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #DE-SC0019272
M71.00013: PEO-Sn Nanofibers* MATAZ ALCOUTLABI (Presenter), MAXIMILIANO AGUILAR ALONSO, MOHAMMED UDDIN, BRYAN HOKE, FRANCISCO DESANTIAGO, ELAMIN IBRAHIM, JUAN HUITRON, MIRCEA CHIPARA, University of Texas Rio Grande Valley — Polyethylene oxide (PEO) nanofibers loaded by various concentrations of Sn have been obtained by force spinning. Homogeneous solutions of PEO in deionized water, with concentrations ranging between 8 and 12 % wt. PEO have been prepared. Various amounts on Sn nanoparticles have been added to these solutions. The as-obtained mixtures were homogenized by stirring 4 h, at room temperature and 1,000 rotations per minute and then subjected to the force spinning, at room temperature, and various spinning rates ranging between 1,000 and 9,000 rotations per minute. The structure and morphology of mates of PEO based nanofibers loaded by various amounts of Sn nanoparticles and of the corresponding thick films were investigated by Raman, FTIR, X-Ray, and UV-Vis spectroscopy. The effect of the concentration of the nanofiller on the position of Raman and FTIR lines was analyzed in detail and related to the elastic features of these nanocomposites. The differences between mats and macroscopic samples (thick films) are discussed in detail. Additional X-Ray data focused on the crystal structure including crystallites sizes and orientations are reported.

M71.00014: Unraveling the Morphological Evolutions during Solvent Vapor Annealing for Organic Solar Cells Using in situ Resonant Soft X-Ray Scattering WENKAI ZHONG (Presenter), ISVAR CORDOVA, YUFENG JIANG, CHENG WANG, Lawrence Berkeley National Laboratory, FENG LIU, Shanghai jiaotong University, THOMAS RUSSELL, Lawrence Berkeley National Laboratory — Solvent vapor annealing (SVA) is one of the most effective pre-electrode deposition techniques, which has been applied in many efficient organic solar cells. In current research, we used a customized in situ multimodal system to reveal the dynamics of phase separation inside the bulk-heterojunction thin films during SVA via resonant soft x-ray scattering (RSoXS). Solvent-vapor-induced molecular crystallization is of importance to provide the driving force of the domain generation and evolution processes. However, with the introduction of solvent vapor for a long time, coarsening of the film appeared at the film surface, which led to the deteriorating of the device performances. These results indicated that in situ RSoXS is a quite useful technique to bridge the gap to understand the relationship of film growth mechanisms and device efficiency.
M71.00015: The Effect of Electrostatic Interactions on the Interfacial Adsorption and Covalent Reaction of Coiled Coil Bundles  
MATTHEW LANGENSTEIN (Presenter), DARRIN JOHN POCHAN, Univ of Delaware, JEFFERY G SAVEN, Chemistry, University of Pennsylvania, CHRISTOPHER J. KLOXIN, Univ of Delaware — Coiled coil bundles (CCBs), known as bundlemers, are a series of computationally designed peptides that self-assemble in water into monodisperse nanoparticles with tunable surface chemistry. We have shown CCB viability as molecular building blocks by producing predesigned 2D lattices, nanocages, and nanotubes through tailoring their surface chemistry and solution assembly conditions. Recently, we have used CCBs as macromonomers to create stiff extremely high aspect ratio supramolecular polymers through covalent chemistry between CCB ends. As the CCB library continues to grow, it’s important to develop processing methods to grow new nanostructures out of these versatile building blocks. By first templating a surface through the directed self-assembly of CCBs onto a flat planar substrate, it should be possible to grow CCB nanoforests of highly aligned nanorods with tunable surface chemistry and packing structure. Ongoing work on the formation of the template layer has shown a dependence between deposition kinetics and electrostatic interactions between CCBs. This presentation will overview the impact of pH, ionic strength, and CCB surface charge on deposition kinetics as well as show the stages of CCB deposition through a combination of AFM, QCM-D, and reflectivity measurements.

M71.00016: Development and use of a new model for the Worm Like Chain  
ANGELO SETARO (Presenter), PATRICK UNDERHILL, Rensselaer Polytechnic Institute — The behavior of polymers is determined in large part by their flexibility. Nestled between the rigid and flexible limits are semiflexible polymers, whose behavior is distinct from either of the aforementioned regimes. Whereas the rigid limit is defined by bending energetics and the flexible limit is defined by conformational entropy, the behavior of semiflexible polymers is typified by the interplay of both phenomena. This makes their behavior incredibly rich, but also incredibly difficult to model. At present, models exist to study polymers at very fine (e.g. Kratky-Porod) and very coarse (e.g. Marko-Siggia) length scales. Though efforts have been made to decrease the gap between these two modeling approaches, these still exists a length scale over which no good model currently exists. To address this modeling limitation, we utilize a different approach to develop a model for the Worm Like Chain that reproduces some of the essential behavior of the Kratky-Porod model, while being coarse grained enough to allow for study of semiflexible polymers on longer timescales and under non-equilibrium conditions.
M71.00017: Enrichment and Distribution of Pb\(^{2+}\) Ions in Zwitterionic Poly(cysteine methacrylate) Brushes at the Solid-Liquid Interface  QIMING HE (Presenter), University of Chicago, YINJUN QIAO, Tsinghua University, WEI CHEN, Argonne National Laboratory, MATTHEW TIRRELL, University of Chicago — We prepared cysteine-based (PCysMA) polyzwitterionic brushes, and surface zeta potential investigations on pH-responsiveness of these PCysMA brushes confirm their zwitterionic character at intermediate pH range, while at pH values either below pH 3.50 or above pH 8.59, they exhibit polyelectrolyte character. Under acid (pH < 3.50) or base (pH > 8.59) conditions, they possess either cationic or anionic character, respectively. In the zwitterionic region, these PCysMA brushes show positive surface zeta potential in the presence of Pb(CH\(_3\)COO)\(_2\) solutions of various concentrations. The results are in line with microscopic investigations using anomalous X-ray reflectivity (AXRR) carried out along the absorption edge of Pb\(^{2+}\) ions. By varying the photon energies around the absorption L\(_3\) edge of lead (13037 eV), the Pb\(^{2+}\) concentration normal to the silicon substrates, as a function of depth inside PCysMA brushes, could be revealed at the nanoscale. Both zeta potential and AXRR measurements confirm the enrichment of Pb\(^{2+}\) ions inside PCysMA brushes, indicating the potential of PCysMA to be used as a water purification material.

M71.00018: Oligomeric Cellulose Based Block Copolymer  XIN ZHANG (Presenter), FENG JIANG, ROBERT BRIBER, HOWARD WANG, University of Maryland, College Park — Novel water soluble block copolymer based on oligomeric cellulose and PEG was produced by coupling reaction. The oligomeric cellulose was produced by phosphoric acid assisted hydrolysis with PDI of 1.04 and a degree of polymerization of 7 (DP7). The DP7-b-PEG-b-DP7 triblock copolymer showed tunable PEG crystallization behavior by changing the molecular weight ratio between PEG and cellulose. At Mw ratio of 1:2:1, the PEG crystallization is fully suppressed. The morphologies of DP7-b-PEG-b-DP7 triblock copolymer solutions and film are also presented. The synthesis route can be extended to non-PEG based polymers.
M71.00019: Resistive Pulse Sensing of Phytoglycogen Nanoparticle Translocation: Examining Structure and Brownian motion* WILLIAM R LENART (Presenter), MICHAEL HORE, Macromolecular Science and Engineering, Case Western Reserve University — Dendrimers are an important platform for a variety of applications such as cosmetics, lubricants, and drug delivery. Understanding the relationship between structure, mobility, and mechanical properties is crucial for designing new systems for these applications. In particular, examining the transport of nanoparticles (NPs) through nanopores and nanochannels by translocation may enable high-throughput analysis of these properties. These measurements track ionic current through the nanochannel, which is blocked when a particle occludes the channel. Here, we studied experimentally the translocation of phytoglycogen NPs through single solid-state SiNx nanochannels with diameters between 40 and 100 nm, and lengths of 100 nm. Using Poisson-Nernst-Planck calculations, we quantitatively predicted the magnitude of the current blockade of phytoglycogen NPs by including a “hardness parameter” term to describe the degree to which the NPs occlude the nanochannel, and found good agreement with neutron scattering measurements. The NPs diffused through the nanochannels under pure three-dimensional Brownian motion, and diffusion coefficients were measured in quantitative agreement with dynamic light scattering.

*This work was supported by the NSF Polymers program (DMR-1651002).

M71.00020: A photo-responsive protein-polymer bioconjugate for control of a model protein JUSTIN HORN (Presenter), CHEN CHEN, ALLIE OBERMEYER, Columbia University — Stimuli-responsive bioconjugates have been investigated as a means of controlling protein behavior through conjugation of a responsive polymer to a protein. These bioconjugates have been used in many applications including purification and recovery of proteins, biosensing, and control over protein oligomer formation. We have prepared stimuli-responsive bioconjugates to provide spatiotemporal control over enzymatic activity through a covalently linked photo-responsive copolymer. Photo-responsiveness was conferred through an azobenzene-containing monomer which undergoes a light-induced cis-trans isomerization. Controlled radical polymerization was used to create a panel of polymers of varying size and azobenzene monomer content which was assayed for its ability to allow photo-control using a model protein, alkaline phosphatase (phoA). Site-specific bioconjugation of these photo-responsive polymers was achieved through introduction of a cysteine residue to wild-type phoA which reacted with the maleimide-functionalized responsive polymer. In addition to screening the influence of polymer size and composition, several conjugation sites on the protein were tested to probe the effect of distance to the active site on photo-responsivity.
M71.00021: Secondary structure drives self-assembly in weakly segregated globular protein-rod block copolymers*  HELEN YAO (Presenter), Massachusetts Institute of Technology MIT, KAI SHENG, The Scripps Research Institute, JIALING SUN, SHUPENG YAN, YINGQIN HOU, HUA LU, Peking University, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Protein-polymer bioconjugates combine protein functionality with polymer material properties and block copolymer self-assembly. The effect of polymer block secondary structure and chirality on solution-state self-assembly was studied using bioconjugates with a globular protein block (enhanced green fluorescent protein, or eGFP) and a poly(amino acid) (PAA) block with varying chirality. Block copolymers were synthesized by NCA polymerization, followed by native chemical ligation to eGFP. Homochiral $L$- and $D$- type PAAs formed $\alpha$-helices, while an achiral random copolymer of $L$- and $D$- type monomers was structureless. All bioconjugates with an $\alpha$-helical block self-assembled into lamellae with similar phase diagrams regardless of chirality type. However, bioconjugates with an achiral block remained disordered at all concentrations and temperatures measured. This was due to a non-repulsive interaction between the flexible achiral PAA and eGFP. Thus, incorporation of secondary structure into the polymer block can increase the effective segregation strength between blocks and drive self-assembly even with weak to no repulsion between blocks.

*This work is funded by DOE Award DE-SC0007106 and MIT International Science and Technology Initiatives (MISTI) China Program (award number 2116580).

M71.00022: Computationally designed coiled coil peptide bundle chains with positive charges: Self-assembly and click conjugation  YAO TANG (Presenter), Univ of Delaware, RUI GUO, JEFFERY G SAVEN, University of Pennsylvania, CHRISTOPHER J. KLOXIN, DARRIN JOHN POCHAN, Univ of Delaware — Computational design has been employed to predict peptide primary structure that will intermolecularly assemble into different net positively charged coiled coils nanostructures. Stable, robust, tetrahedral anti-parallel peptide bundles with net charges varying from 0 to +32 are self-assembled from the computationally designed 29-amino-acid peptides. In this research, +4 charged peptides are synthesized via solid phase peptide synthesis (SPPS) and modified with cysteine or maleimide on the N-termini of single peptides. Those two modified peptides are respectively self-assembled into 4 x 2nm cylindrical peptide bundles through non-covalent interactions and conjugated via Thiol-Michael ‘click’ react to form coiled coil bundle chains with extreme rigidity. The size and morphology of coiled coil bundle chains self-assembled under various temperatures, pH and solvent conditions are investigated by techniques such as Transmission electron microscopy (TEM) and circular dichroism (CD) spectroscopy. The self-assembled peptide bundles can be further used as building blocks to construct new 1-D nanomaterials. The effect of salt and pH on the solution behavior of the positively charged coiled coil chains will be also discussed.
M71.00023: Self-Assembly of Protein-based Block Copolymers – A Minimal Coarse-grained Model* AKASH ARORA (Presenter), HELEN YAO, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Protein-based block copolymers self-assemble into various nanostructures that are instrumental in developing next-generation biocatalysts and biosensors. Phase behavior of such block copolymers depends upon several parameters: temperature, blocks volume fractions, conjugate concentration in solution, protein shape and charge density, and multiple binary interaction parameters. In this work, a highly coarse-grained dumbbell model is developed in which protein is represented as a hard sphere linked to a soft sphere denoting a flexible polymer coil. Molecular dynamics simulations are performed with both implicit and explicit solvent. It is observed that such a simple model, incorporating primarily the various binary interactions, forms all the different morphologies that are observed experimentally. Interestingly, the model also predicts a lyotropic re-entrant order-disorder transition that is peculiar to protein-based block copolymers compared to coil-coil block copolymers. Integral-equation state theories are used to compute the solvent-mediated interactions to understand the origin of re-entrant transition. This work sheds light on the key factors governing the phase behavior of protein-based block copolymer solutions.

*This work is supported by the Department of Energy (DOE).

M71.00024: Tuning stoichiometry and physical interactions of peptide rigid rods through ‘click’ chemistry of computationally designed coiled coil* YI SHI (Presenter), Materials Science and Engineering, University of Delaware, RUI GUO, JACQUELYN BLUM, JEFFERY G SAVEN, University of Pennsylvania, CHRISTOPHER J. KLOXIN, DARRIN JOHN POCHAN, Materials Science and Engineering, University of Delaware — With computational design, peptide sequences can be customized to form specific solution self-assembly structures and to promote interactions that favor formation of unique structures such as nanotubes, needles, 2D plates. A recent publication of our collaborative group has shown that peptide rigid rods of various lengths can be formed from conjugation of N-terminal modified, anti-parallel, tetrameric coiled coil bundles by thiol-Michael reaction. Lyotropic liquid crystal behavior was observed and strong mechanical properties were expected from these peptide rods. In this work, further investigation into fine-tuning liquid crystal behavior of peptide rods and improving ‘click’ chemistry stoichiometry were carried out with computationally designed sequences. Highly charged coiled coil sequences were designed to showcase a tunable liquid crystal behavior through changing solution conditions and parallel coiled coil were designed to have inherent 1:1 stoichiometry at each end of bundle for long rods formation. Coiled coil design and preliminary results will be discussed.

*Department of Energy: DOE DE-SC0019355
M71.00025: In Situ SANS on Gelatinization of Polysaccharides  HOWARD WANG (Presenter), XIN ZHANG, FENG JIANG, ROBERT BRIBER, University of Maryland, College Park — It is desirable to understand, design and control the pathway of food preparation and consumption for the benefit of human health. Gelatinization occurs when starch/water mixtures are heated and native crystalline structures melt. The transport and distribution of water among polysaccharide molecules play a key role in the process of gelatinization. We have carried out in situ small angle neutron scattering measurements on rice grains in various aqueous solutions. Data imply the role of porosity and capillarity in the initial water uptake and the subsequent gelatinization kinetics. The interfacial tension between water and polysaccharides would alter the gelatinization process.

M71.00026: Directed Self-Assembly of Fluorine-Containing High-χ Block Copolymers using Top Coat and Electric Field  SEONGJUN JO (Presenter), SEUNGBAE JEON, TAESUK JUN, DU YEOL RYU, Yonsei University — Directed self-assembly (DSA) of block copolymers (BCPs) have been attractive for “bottom-up” approach lithographical applications. BCPs can form nanoscale structures spontaneously in long-range alignment with small feature down to 5 nm. In this study, we report a newly designed fluorine containing BCPs (polystyrene-b-poly(2,2,2-trifluoroethyl acrylate)) which the Flory-Huggins interaction parameter (χ) was above 0.2. Film experiments were demonstrated on a neutralized substrate where a sub-10 nm perpendicular lamellar morphology was observed with simple thermal annealing using the top coat strategies. The neutral conditions of the top coats for the BCP top surface was tuned by the same monomer of the BCP and the orientation was confirmed by AFM and GISAXS. Electric field was applied for the DSA, observing a long-range alignments without neither chemoepitaxy nor graphoepitaxy.

M71.00027: SCFT Study on Topological Defects of Symmetric Block Copolymers*  TIANYI HU (Presenter), WEI-HUA LI, State Key Laboratory of Molecular Engineering of Polymers, Department of Macromolecular Science, Fudan Univ, Shanghai, China — Block copolymers, as typical soft material, have a long relaxation time and are highly susceptible to thermal fluctuations, and thus their self-assembly is often accompanied by the occurrence of a variety of defects. At present, most research focuses on some simple defects in AB diblock copolymer melts, and there are few studies on the influence of block copolymer architectures on defect stability. Herein, the stability of various defects in (AB)_n linear and A_n B_n star block copolymer systems is investigated by self-consistent field theory (SCFT) and string method. We calculate the excess free energy of different defects and barriers of defect-removal in different symmetric block copolymers with the same effective segregation. The comparison of excess free energy between different defects indicate that the creation of a defect with more disconnections cost higher free energy. Moreover, our results demonstrate that (i) whether for linear or star block copolymer systems, the relationship between n and the excess free energy of a defect of the block copolymer is not monotonic and (ii) the same defect has different minimum free-energy path in different block copolymer systems.

**M71.00028: Emergence of multi-stranded helices by the self-assembly of a new AB-type multiblock copolymer under cylindrical confinement**

LIXUN ZHANG (Presenter), Department of Macromolecular Science, State Key Laboratory of Molecular Engineering of Polymers, Fudan University, Fudan Univ, Shanghai, China — Novel nanostructures can emerge from the self-assembly of block copolymers under geometrical confinements due to the modification to the competition between interfacial energy and stretching energy. In particular, it is very appealing that helical structures can be formed by achiral AB deblock copolymers under cylindrical confinement. However, helical structures with strands more than two are rarely discovered. In previous works, most of block copolymers are hexagonal cylinder-forming in bulk. Herein, we consider a new AB-type multiblock copolymer, whose bulk cylindrical phase can be regulated by the architecture from hexagonal lattice to tetragonal one or even a graphene-like lattice. Our self-consistent field theory calculations suggest that this copolymer under cylindrical confinement can form helical structures with strands varying between 1 and 6. Our work provides a facile way for the fabrication of helical structures with a large number of strands.

**M71.00029: Gyroidal Thin Films from Block Copolymer Self-Assembly as Structural Directing Templates for Fabrication of Mesostructured Crystalline Inorganic Materials**

FEI YU (Presenter), QI ZHANG, ULRICH WIESNER, Cornell University — Amphiphilic block copolymers swelled by carbon precursors self-assemble into bicontinuous gyroid mesophases (space group 214) compressed along <110> on Si wafers upon quenching after solvent vapor annealing. After pyrolysis in inert atmosphere, the resulting textured, mesoporous, and gyroidal carbon thin films are backfilled with amorphous Si (a-Si). The poor tolerance of carbon toward high temperature in air and the high melting points of inorganic materials present a seemingly insurmountable challenge in preparing crystalline mesostructured Si in the carbon templates. The stability of the carbon templates is significantly enhanced, however, when employing nanosecond transient laser heating. Melting and recrystallization of Si (a-Si melting point ~1250 °C) during this ultrafast, highly non-equilibrium process allow conformal template backfilling so that the templates' mesostructural order is inherited by the crystalized Si, which otherwise has little access to mesoscale ordering. Non-equilibrium transient laser technology in conjunction with block copolymer self-assembly in thin films opens up opportunities in fabricating materials for applications in catalysis, photonics, and beyond.

M71.00030: Unusual Phase Behavior by Blending Star-Shaped Block Copolymer and Linear Block Copolymer* YEOSEONG SEO (Presenter), SEONGHYEON AHN, SO YEONG PARK, JAEYONG LEE, Department of Chemical Engineering, Pohang Univ of Sci & Tech, WEI-HUA LI, Department of Macromolecular Science, Fudan University, JINKON KIM, Department of Chemical Engineering, Pohang Univ of Sci & Tech — Generally the block copolymer shows the arrangement of hexagonal patterns cylinder when volume fraction of one block is larger than that of the other. However, since all processes in the semiconductor business are geared to the rectilinear structure, it is needed to rework with time and money to apply block copolymer to the semiconductor business. Therefore, creating different structure from that of general block copolymer like square array structure or asymmetric lamellae has great significance in lithography applications. Here, we synthesized star-shaped poly polystyrene-block-poly(4-thydroxystyrene) (PS-b-PHS) and linear polystyrene-block-poly(2-vinyl pyridine) (PS-b-P2VP) and blended them in various proportions to observe the structures. Because the molecular weight of the PS on the core of star polymer is much smaller than that of the PS in linear polymer, the spacing between cylinders is limited and the large configurational entropy is formed, which leads block copolymer to have different structure.

M71.00031: WITHDRAWN ABSTRACT —

M71.00032: High $\chi$-low $N$ fluorine-based block copolymers for sub-10 nm lithography CIAN CUMMINS (Presenter), DANIELE MANTIONE, FEDERICO CRUCIANI, Laboratoire de Chimie des Polymères Organiques, University of Bordeaux, VIRGINIE PONSINET, Centre de Recherche Paul Pascal, University of Bordeaux, GUILLAUME FLEURY, GEORGES HADZIOANNOU, Laboratoire de Chimie des Polymères Organiques, University of Bordeaux — We will discuss the attractive properties of high $\chi$-low $N$ fluoro based BCPs and illustrate their utility for next-generation nanolithography. The synthesis, physical characterization and thin film self-assembly of a series of lamellar and cylindrical fluorine based BCPs will be described. Total BCP molecular weights ranging from 39 kg mol$^{-1}$ to 7 kg mol$^{-1}$ were synthesized using reversible-addition-fragmentation chain-transfer (RAFT) polymerization. Tailoring the fluorine containing blocks here resulted in a similar surface free energy to the well-studied polymethylmethacrylate (~ 41 mN/m) based BCPs thereby making orientational control in thin films more attractive. Solvo-thermal vapor annealing and thermal annealing of films were evaluated with a view to standardised industry methods. Period sizes ranged from 48 nm down to 14 nm with observed feature sizes as small as 7 nm. We also demonstrate the integration feasibility of our new fluorine based BCPs using sequential infiltration synthesis to form alumina nanowire hardmasks. The favorable BCP characteristics detailed here provide a versatile material option to the current library of available BCPs for nanolithography.
M71.00033: Development of Shape-Tunable Monodisperse Block Copolymer Particles through Particle Restructuring by Solvent Vapor Annealing  JAE MAN SHIN, EUN JI KIM (Presenter), YOUNG JUN LEE, MINGOO KIM, KANG HEE KU, JUNHYUK LEE, YONGJOO KIM, HONGSEOK YUN, KAIIST, KIN LIAO, Khalifa University, CRAIG J HAWKER, UCSB, BUMJOON KIM, KAIST — Uniformity and controllability of size, shape, and internal structure of block copolymer (BCP) particle are important to determine their functionality. Here, we introduce the particle restructuring by solvent engineering (PRSE) strategy to transform the size-controlled, monodisperse BCP spheres into non-spherical BCP particles with well-defined internal structure. PRSE process starts with generating monodisperse BCP spheres in a wide range of particle size using membrane emulsification. Then, successful shape transformation into non-spherical prolate and oblate was demonstrated while maintaining the monodispersity of particle size. PRSE can be applied generally to various functional BCPs including polystyrene-\textit{block}-poly(1,4-butadiene) (PS-\textit{b}-PB), polystyrene-\textit{block}-polydimethylsiloxane (PS-\textit{b}-PDMS), and polystyrene-\textit{block}-poly(4-vinylpyridine) (PS-\textit{b}-P4VP). Therefore, it allows an effective control of aspect ratio (AR) of the particles over a wide range, which was supported by theoretical calculation describing particle elongation. Further investigation on transformation kinetics during the PRSE showed that the morphological transformation was driven by reorientation of BCP domains, and it was strongly associated with overall molecular weight of the BCP and the annealing time.

M71.00034: Assessing the Capabilities of the Sharp-Interface Gradient-Based Theoretical Framework for the Simulation of Free-Surface Block Copolymers  DANIIL BOCHKOV (Presenter), FREDERIC GIBOU, University of California, Santa Barbara — Recently a sharp-interface gradient-based theoretical framework for the simulation of free-surface block copolymers within the Self-Consistent Field Theory was proposed [1,2]. In this talk, we present the results for the simulation of step edges in polymer thin films using this method. First, in the case of relatively low values of the polymer-air surface tension the results are compared to those obtained using the conventional approach based on adding `air molecules" to the system and discuss the differences in morphologies produced by the two methods. Then, we analyze the morphologies of step edges and construct phase diagrams in the case of high (more realistic) surface tensions, which are not easily accessible by the conventional approach.

M71.00035: Self-Assembly in Large Molecular Weight Block Copolymers for Dual Metal Nanodot Patterning and Optical Applications  ELEANOR MULLEN (Presenter), Trinity Coll —

Block copolymers (BCPs) have the potential to revolutionise the manufacturing of nanotechnology primarily due to their ability to self-assemble into spatially ordered nanodomains, resulting in nanoscale patterning. High molecular weight co-polymers poly(styrene-b-2-vinylpyridine) (PS-b-P2VP) and polystyrene-b-polyethylene oxide (PS-b-PEO) are used to form self-assembled patterns that act as a polymer template. This polymer template is infiltrated with the inorganic materials gold (Au) and silver (Ag). Polymer template removal leaves behind inorganic metal nanodots that exhibits surface plasmonic (SP) resonance effects that are particularly applicable for optical applications. The shape and chemical composition of metallic nanodots can be controlled by UV ozone or plasma etching removal of the polymer. It is found that dual metal nanodot arrays of Au and Ag can be used to suppress silicon reflectivity. Micelles of Au and Ag exhibit plasmonic resonance in the 400-600nm range that can be determined by the Au/Ag ratio. The transmission spectra for single metal nanodot arrays show SP dips at 430± 25nm for Au and 550 ±25nm for Ag. The resulting nanodot size, patterning and metal composition provides a low cost means of producing optical filters of tuneable plasmonic resonance effects.

M71.00036: Morphological Changes in Block Copolymer Thin Films Driven by Complex Coacervation*  HURSH SUREKA (Presenter), BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Block copolymer thin films have been proposed as a method for immobilizing target molecules on a nanostructured scaffold. The use of a charged-neutral block copolymer (BC) enables the incorporation of oppositely charged molecules into thin films of the material. However, incorporation of oppositely charged macromolecules can trigger a phase change via coacervation. In this work, the effect of polyanion strength on the structure of BC self-assembly in thin films is examined. Complexation with the strong synthetic model polyanion, polystyrene sulfonate, leads to precipitation, while complexation with the weak synthetic model polyanion, poly(acrylic acid), leads to micellization. This difference in phenomena is likely driven by the ability of the weaker polyanion to charge modulate. The weakest polyanion tested was a model protein, amylase, which showed a rich set of phase behavior dependent on the blending ratio between the protein and the BC. The protein’s charge density is significantly lower than that of the synthetic polymers, which leads to weaker interactions between the protein and the BC by comparison. As a result, the structure of the BC is less disrupted by the protein than by the synthetic polymers at moderate loading (up to ~30 wt%).

M71.00037: Self-assembly of Block Copolymers with Ionic Liquid Crystals in Thin Films

CHUQING YUAN (Presenter), Department of Chemical and Biomolecular Engineering, University of Houston, PRADIP BHOWMIK, Department of Chemistry, University of Nevada, Las Vegas, ALAMGIR KARIM, Department of Chemical and Biomolecular Engineering, University of Houston — Block copolymers (BCPs) self-assembly leads to plenty of promising applications in the area of electronics and energy storage. Thus, improving the ordering of BCP is crucial to optimize its performance in different applications. Adding ionic liquids (ILs) to BCPs has been reported a facile method to realize fast ordering because of its plasticization effect and wetting characteristics tunability. With similar chemical structure to ILs, ionic liquid crystals (ILCs) are liquid-crystalline salts also consisting of cations and anions. Differently, liquid-crystalline nature and thermotropic transition provide ILC with more fascinating features than IL when it is added to BCP. However, BCP/ILC system has not been well studied as BCP/IL system does. In this study, the effect of ILC additives on the self-assembly of BCP, PS-b-PMMA, under different annealing conditions has been investigated by using atomic force microscopy (AFM), grazing-incidence small-angle X-ray scattering (GISAXS), and time-of-flight secondary ion mass spectrometry (ToF-SIMS). We observed a drastic change of ILC selective swelling behavior during its thermotropic transition. Moreover, it can be highlighted that ILC enhances the ordering in BCP without enlarging the domain size after the zone annealing.

M71.00038: Influence of Charge Sequence on the Adsorption of Polydispersed and Monodispersed Polyelectrolytes onto Monodispersed Polyelectrolyte Brush

VAIDYANATHAN SETHURAMAN (Presenter), KEVIN D DORFMAN, University of Minnesota — We use coarse-grained molecular dynamics to elucidate the role of charge sequence on the adsorption efficacy of oppositely charged free monodispersed and polydispersed polyelectrolytes on to a polyelectrolyte brush. We consider four different model systems wherein the free and the brush polyelectrolytes can have either brush or alternating charge sequence. Our model treats the polyelectrolytes in a bath of implicit solvent, excess salt and explicit counterions. For monodisperse systems, the adsorption efficiency is highest when both the free and the brush polyelectrolytes possess a block charge sequence, and it is lowest when both the free and the brush polyelectrolytes possess an alternating charge sequence. By computing the free energy, internal energy and entropy of adsorption using umbrella sampling methods, we find that the origin of the differences in adsorption efficiency for different charge sequences in monodispersed systems is enthalpic. Additionally, equilibrium conformations for different charge sequences reinforce the results obtained from energetic calculations. We also show the changes in adsorption efficacy as a result of polydispersity in the free polyelectrolytes.

M71.00039: X-ray scattering characterization of polystyrene chains tagged with a single quaternary ammonium group per chain.* SANGWOO LEE (Presenter), Chemical and Biological Engineering, Rensselaer Polytechnic Institute, SUNGMIN PARK, CHULSUNG BAE, Chemistry and Chemical Biology; and Chemical and Biological Engineering, Rensselaer Polytechnic Institute, LIWEN CHEN, Chemical and Biological Engineering, Rensselaer Polytechnic Institute — Polymers containing a moderate amount of covalently bound ionic groups are widely used as membrane materials for electrochemical energy conversion devices such as fuel cells and electrolyzers. The performance of these ion-containing polymers largely depends on the microstructures, especially the structures of ion aggregates. To investigate the effects of the local chemical environment of ionic groups to the ionic aggregate and chain structures, we synthesized and characterized polystyrene chains containing a single quaternary ammonium group at the end of chains, in the middle of the chains, and right next to the secondary-butyl initiator motif using amino-functionalized diphenylethylene monomer. X-ray scattering characterization reveals three structural features of these model polystyrene chains. First, the domain spacing between ion aggregates changes with the location of the ionic groups in chains. Second, ionic groups stretch the polystyrene chains. Third, all polystyrene chains even without an ionic group display strong upturn curves in the small-angle domain, and the features of the upturn curves vary with the location of ionic groups in chains and processing pathways.

M71.00040: Transport through ionic layers in sulfonated telechelic polyethylenes* BENJAMIN PAREN (Presenter), University of Pennsylvania, MANUEL HAEUSSLER, PATRICK RATHENOW, STEFAN MECKING, University of Konstanz, KAREN WINEY, University of Pennsylvania — We present a set of sulfonated telechelic polyethylene ionomers that demonstrate ion transport of metal cations within ionic aggregates in a crystalline polymer matrix. These precise ionomers consist of 23 or 48 backbone carbons with sulfonic acid end groups that are fully neutralized by a counterion, Li⁺ or Na⁺. Depending on spacer length and counterion, these telechelics exhibit multiple order-order transitions at T<Tₘ and order-disorder transitions at T~Tₘ, with melting points up to 300°C, as evident in both differential scanning calorimetry and X-ray scattering. At room temperature, the most common morphology is well-defined nanoscale ionic layers with a crystalline polymer backbone. The temperature-dependent ionic conductivity is characterized using electrical impedance spectroscopy. While ion transport appears decoupled from the polymer backbone at T<Tₘ under certain conditions, the conductivity remains quite low.

M71.00041: Current-induced morphological changes in block copolymer electrolytes
WHITNEY LOO (Presenter), MICHAEL GALLUZZO, University of California, Berkeley, CHENHUI ZHU, Advanced Light Source, Lawrence Berkeley National Lab, NITASH BALSARA, University of California, Berkeley — Block copolymers are attractive electrolyte materials for lithium metal batteries due to their ability to microphase separate into distinct ion-conducting and mechanically-reinforcing domains on the nanometer-length-scale. Although the formation of current-induced gradient crystals has been previously shown when the material was heated above the glass transition temperature, $T_g$, of the mechanically-reinforcing block, it has been previously assumed that these equilibrium morphologies remain intact throughout polarization under the $T_g$, e.g. at 90 °C. In-situ small angle X-ray scattering (SAXS) experiments were used to probe morphology and electrochemical impedance spectroscopy (EIS) was used to quantify the bulk resistance of the electrolyte throughout cycles of cell polarization and subsequent cell relaxation of lithium-lithium symmetric cells as a function of polarization voltage. The electrolyte is comprised of a polystyrene–$b$-poly(ethylene oxide), PS-b-PEO, copolymer mixed with a lithium salt that forms hexagonally packed PS cylinders in a matrix of salt-containing PEO in the absence of current. We hypothesize that the formation of salt-concentration gradients within the electrolyte from the cell polarization drive the changes seen in morphology and resistance.

M71.00042: Polymer Electrolytes with Abundant Hydrogen Bonding Sites
RUIYANG WANG (Presenter), MOON JEONG PARK, Pohang Univ of Sci & Tech — Coulombic and/or dipolar interactions of polymers with embedded salts offer ion conduction across the polymer chains. Such polymers can be used in a wide range of electrochemical devices such as lithium batteries, fuel cells, and ionic actuators. Key challenges in developing practically viable devices based on polymer electrolytes are high conductivity, mechanical strength, and electrochemical stability. In this study, new polymer electrolytes possessing abundant hydrogen bonding sites for simultaneous achievement of high conductivity and improved mechanical properties. Owing to the high dielectric constant of such polymers, enhanced degree of ion dissociation and high ionic conductivity were obtained. In particular, with added inorganic salts, the hydrogen bonding sites in polymer structure effectively stabilize anion, thereby retarding the anion diffusion. This is connected to improved cation transference number of the resultant polymer electrolytes.
M71.00043: The Effect of Host Incompatibility and Polarity Contrast on Ion Transport in Ternary Polymer-Polymer-Salt Blend Electrolytes  BILL WHEATLE (Presenter), ERICK F. FUENTES, NATHANIEL A LYND, VENKATRAGHAVAN GANESAN, University of Texas at Austin — Conventional lithium-ion battery electrolytes are typically formed by blending high polarity and high mobility small-molecule components. These electrolytes tend to have ionic conductivities higher than those formed from either component alone. This is hypothesized to arise from a molecular-level synergy between miscible components. In short, molecular simulations have suggested that lithium ion solvation is dominated by the high polarity component. The solvated ions are then able to diffuse through a medium dominated by the high mobility component.

We hypothesize that similar effects can be seen in miscible polymeric blend electrolytes (PBEs) containing a high polarity and high mobility component. We have previously shown that increasing host polarity both improves solvation strength and slows dynamics. We thus investigate the role of changing the polarity of the nominally high polarity polymer on ionic conduction. Further, we study the influence of PBE miscibility on transport by varying the bare interaction parameter between polymer hosts. As hypothesized, we find that ionic conduction can be improved with increased miscibility and at intermediate levels of polarity contrast. We preliminarily investigate the effect of host molecular weight contrast on ionic transport.

M71.00044: Ion Transport in Ether-Based Polymer Electrolytes  YOUNGWOO CHOO (Presenter), Lawrence Berkeley National Laboratory, RACHEL SNYDER, BROOKS ABEL, Cornell University, NEEL SHAH, Lawrence Berkeley National Laboratory, GEOFFREY COATES, Cornell University, NITASH BALSARA, Lawrence Berkeley National Laboratory — Polymer electrolytes, typically poly(ethylene oxide) (PEO) mixed with a lithium salt, have emerged as promising solid electrolytes for lithium ion batteries. However, polymer electrolytes still exhibit lower conductivities than commercial liquid electrolytes. We report a novel ether-based polymer, poly(diethylene oxide-alt-oxymethylene), (P(2EO-MO)), which was synthesized via cationic ring-opening polymerization of the cyclic acetal monomer, 1,3,6-trioxocane. The polymer electrolytes, which are mixtures of P(2EO-MO) and various concentrations of lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salt, were characterized by electrochemical methods. P(2EO-MO)/LiTFSI exhibits lower ionic conductivity than PEO/LiTFSI due to increasing glass transition temperatures in the presence of lithium salts. However, the steady-state transference number of P(2EO-MO)/LiTFSI is significantly higher than that of PEO/LiTFSI at most salt concentrations. We investigate the thermodynamic factor and steady-state current of P(2EO-MO)/LiTFSI as a function of salt concentration and compare the results to PEO/LiTFSI. This work suggests that the overall efficacy of ion transport in P(2EO-MO) is greater than that in PEO, and P(2EO-MO) is a favorable electrolyte for lithium ion batteries.

*JCESR (DOE-BES)
M71.00045: Entropic transport of interacting Brownian particles in a channel with reflecting boundaries*  NARENDER KHATRI (Presenter), P. S. BURADA, Department of Physics, Indian Institute of Technology Kharagpur, Kharagpur - 721302, India — The entropic transport of overdamped biased Brownian particles in a symmetric channel is investigated numerically considering both the no-flow and the reflection boundary conditions at the channel boundaries. The constrained dynamics yields a scaling parameter f, which is a ratio of the work done to the particles to available thermal energy. The distinct transport features are observed with reflection boundary conditions, for example, the nonlinear mobility exhibits a nonmonotonic behavior as a function of the scaling parameter f, and the effective diffusion coefficient exhibits a rapidly increasing behavior at higher f, which are not observed with no-flow boundary conditions. We show that the transport properties can be significantly influenced by the nature of reflection, i.e., elastic or inelastic. In doing so, we identify that both the nonlinear mobility and the effective diffusion coefficient can be enhanced with inelastic reflection boundary conditions. In addition, by including the short range interaction force between the Brownian particles, the mobility decreases, and the effective diffusion coefficient increases for the optimal values of f.

*This work was supported by the Indian Institute of Technology Kharagpur under the Grant No. IIT/SRIC/PHY/TAB/2015-16/114.

M71.00046: Shear-induced Counterion Redistribution of a Single Polyelectrolyte*  KAIKAI ZHENG, KUO CHEN, JIANG ZHAO (Presenter), Institute of Chemistry, Chinese Academy of Sciences — The counterion distribution of a model polyelectrolyte, sodium polystyrene sulfonate (NaPSS), as a function of shear rate is investigated at single molecular level. The fluorescence resonance energy transfer (FRET) between the fluorescence donor attached at the charged PSS- chain and the positively charged acceptor as the counterion probes shows the increase of average counterion-chain distance, indicating the expansion of counterion cloud by shear. Such a process is further verified by the emission spectra of the pH-responsive fluorophore labeled at PSS- chain end, showing the local pH value is shifted to higher values by shear. The shear-induced counterion release or counterion cloud expansion is attributed to alternation of the electric filed distribution inside the solution and the overlap of electric fields of multiple PSS- chains in the process of creating inhomogeneity in concentration inside the PSS- solution by shear.

*Project supported by the National Natural Science Foundation of China (21833012).
**M71.00047: Through-plane Structural Analysis of Engineered Nafion Surfaces**

NATALIE LINNELL SCHWAB (Presenter), Materials Science and Engineering, University of Maryland, College Park, YUANCHAO LI, TRUNG VAN NGUYEN, Chemical and Petroleum Engineering, University of Kansas, ROBERT BRIBER, Materials Science and Engineering, University of Maryland, College Park, JOSEPH A. DURA, Center for Neutron Research, National Institute of Standards and Technology — The thin-film structures of Nafion, a model perfluorinated ionomer, impact practical advances in proton-exchange membrane fuel cells (PEMFCs). Engineered Nafion surfaces were developed by Dowd et al. to reversibly and permanently alter the surface composition and wettability of Nafion [a]. Using neutron reflectometry (NR), we probe the through-plane structure of surface-treated Nafion thin-films with sub-Ångstrom resolution. Humidity-related layers of phase-separated lamellae were observed in Nafion thin-films at Au, Pt, and SiO$_2$ interfaces by Dura et al. and DeCaluwe et al. [b,c].

We develop and apply titanium nitride (TiN) substrates to minimize the neutron scattering contrast to similar Nafion-TiN interface structures, thus optimizing the sensitivity of NR to the thickness, roughness, and scattering-length density (SLD) of the engineered Nafion surfaces. The engineered Nafion thin-films are assessed in dry (0% RH) and wet (92% RH) conditions in H$_2$O and D$_2$O vapor to independently determine water content and polymer density, before and after surface modification. Additionally, we evaluate the formation structures at the Nafion-TiN interface.

*This work was supported by NIST cooperative agreement 70NANB17H301.

**M71.00048: Single-ion polymers based on ion-conducting crystalline phases**

JAEMIN MIN (Presenter), MOON JEONG PARK, Pohang Univ of Sci & Tech — Recently, single-ion conducting polymers have extensively been studied as future polymer electrolytes owing to the minimized device polarization at a given dc voltage. In this study, we investigate single-ion conducting polymers containing zwitterions. Based on computational calculations, design and synthesis of zwitterion were carried out to modulate intermolecular interactions in single-ion polymers via controlling dipolar orientation of ionic moieties. With balanced Coulombic and dipolar interactions, well-defined ionic crystals were formed within the ionic phases. Particularly, nanoconfinements given by the use of acid-tethred block copolymer matrix were a key to induce the crystallization of ionic moieties. Hierarchical self-assembly of the zwitterion-containing single-ion polymers was further characterized with a focus on the structure-transport relationship.
M71.00049: On the Transference Numbers and Inverse Haven Ratios of Ionic Liquids and Polymeric Ionic Liquids
ZIDAN ZHANG (Presenter), BILL WHEATLE, University of Texas at Austin, JAKUB KRAJNIAK, KU Leuven, JORDAN R KEITH, VENKATRAGHAVAN GANESAN, University of Texas at Austin — In this study, we used atomistic computer simulations within a non-equilibrium molecular dynamics framework to probe the transference number and inverse Haven ratio of ionic liquids and polymerized ionic liquids. In contrast to the conventional expectations, we find that the transference number is a constant at approximately 0.5 and independent of the degree of polymerization (DP). The inverse Haven ratio increases first with increasing DP and then decreases at larger DP. We demonstrate that such results arise as a consequence of the strong cation-cation correlated motions. Together, such findings challenge the premise underlying the pursuit of single ion conductors as a means towards enhanced transference numbers.

M71.00050: Comparing Ion Conductivity and Transference Number of Single-ion and Salt-doped Block Copolymer Electrolytes*
KUAN-HSUAN SHEN (Presenter), LISA HALL, Ohio State Univ - Columbus — Nanostructured block copolymer electrolytes with both ion conductive and mechanically robust microphases are strong candidates for solid battery electrolytes. However, their performance is limited by their low cation transference number (fractional contribution of the cation to the overall conductivity). Experimental work has showed a potential route of increasing transference number by tethering anions to the polymer backbone of the conducting segment of block copolymers. Due to the synthetic challenges of such materials, the design space has yet to be well explored. It is unclear how to optimize their conductivity and under what conditions these single-ion block copolymer electrolytes can more efficiently conduct lithium ion than the salt-doped materials. In this work, we perform coarse-grained molecular dynamics simulations with an applied electric field to calculate ion conductivity and transference number in both single-ion and salt-doped block copolymers. We aim to show how the choices of molecular weight, ion loading, and anion type impact ion transport to guide design of new materials.

*This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Award DE-SC0014209.
M71.00051: Enhanced ion transport in block polymer electrolytes through the manipulation of salt and monomer segment distributions  PRIYANKA KETKAR (Presenter), MELODY A MORRIS, SEUNG HYUN SUNG, Chemical and Biomolecular Engineering, University of Delaware, JOSEPH A. DURA, NIST Center for Neutron Research, National Institute of Standards and Technology, RYAN NIEUWENGAAL, Materials Science and Engineering Division, National Institute of Standards and Technology, THOMAS EPPS, Chemical and Biomolecular Engineering, University of Delaware — Solid block polymer (BP) electrolytes for lithium-ion batteries can address safety and performance concerns present in conventional liquid-state electrolytes, but the ion transport in BPs requires significant improvement to meet the demands of current and future battery applications. Transport properties in nanostructured BP electrolytes can be enhanced through the modification of salt and monomer segment distributions within the ion-conducting domain. We explored two methods to tune these distributions: the synthesis of polystyrene-block-poly(oligo-oxyethylene methacrylate) (PS-b-POEM) BPs with gradient or random copolymer regions at the chemical junction between the PS and POEM blocks (i.e., tapered block polymers) and the blending of POEM homopolymers of different molecular weights into PS-b-POEM BPs. For both methods, we connected the structural characteristics, such as the salt and monomer segment distributions, determined by X-ray and neutron reflectivity, to the segmental and ion dynamics measured through differential scanning calorimetry, $^7$Li solid-state NMR, and AC impedance spectroscopy. These results elucidated design parameters in the synthesis and fabrication of BP electrolytes that can increase ionic conductivity.

M71.00052: Investigation of proton conductivity in polymer nanocomposite films  SANKET KADULKAR (Presenter), VIKRAM LAKHANPAL, DELIA MILLIRON, THOMAS TRUSKETT, VENKATRAGHAVAN GANESAN, University of Texas at Austin — Proton-conducting membranes and solid electrolytes are critical components in many electrochemical devices, and the performance of such devices is often limited by proton transport. In this work, we study proton conductivity in polymer nanocomposite films. We experimentally observe multifold increase in proton conductivity in a composite of poly(ethylene oxide) (PEO) and cerium oxide (CeO$_2$) nanocrystals, in comparison to their individual counterparts. Employing kinetic Monte Carlo simulations, we model proton transport in such systems. Our results reveal the significance of percolation and connectivity of filler/polymer interface in such systems, with further scope for improving conductivity by tuning the morphology of nanocrystals. We also study the overall proton conductivity at different nanocrystal compositions, predicting an optimum composition for maximum proton conductivity.

*Support for this research was provided by the National Science Foundation through the Center for Dynamics and Control of Materials: an NSF MRSEC under Cooperative Agreement No. DMR-1720595.
M71.00053: The effects of processing method on conductivity and dielectric relaxations in PVDF blended with a zwitterionic copolymer* ANDREW CLARK (Presenter), MIRIAM SALCEDO, NELAKA DILSHAN GOVINNA, SAM LOUNDER, AYSE ASATEKIN, PEGGY CEBE, Tufts Univ — The conductivity and relaxation dynamics of poly(vinylidene fluoride) (PVDF) blended with a random copolymer of methyl methacrylate and sulfobetaine-2-vinylpyridine (PMMA-r-SB2VP) were investigated. Films were prepared using two processing methods, compression molding and doctor blading from solution. Scanning electron microscopy revealed morphological differences between the films, with the doctor bladed films demonstrating a porous microstructure, while FTIR revealed the presence of different crystallographic phases for the films. Dielectric relaxation in the temperature range from 30 °C to 140 °C showed several relaxations in compression molded films due to the motion of dipoles in the PVDF crystal phase, segmental relaxations of PMMA, as well as a unique relaxation seen only in the blends. Blends demonstrated higher conductivity then the neat PVDF and copolymer. Doctor bladed films showed a large decrease in the dielectric constant and conductivity as well as different relaxation behavior compared to the compression molded films. These differences suggest that influence of the different processing techniques on the molecular environment plays a significant role on the dielectric properties of these PVDF zwitterionic copolymer blends.

*NSF DMR-1608125

M71.00054: Gyroid Morphologies in Single-Ion Conducting Polymers and the Consequences for Ion Conductivity JINSEOK PARK (Presenter), University of Pennsylvania, ANNE STAIGER, CHRISTINA RANK, STEFAN MECKING, University of Konstanz, KAREN WINEY, University of Pennsylvania — The morphology of self-assembled ionic aggregates influences the ion transport in single-ion conducting polymers. Recently, our group reported that polymers with sulfosuccinate units containing sulfonate groups with their counterions (Li⁺, Na⁺, and Cs⁺) and precisely separated by 23 methylene units form ordered ionic aggregate morphologies (layered, gyroid, and hexagonal). In these ionomers, the gyroid morphology exhibits higher ion conductivity than layered and hexagonal ionic aggregates morphologies, demonstrating the importance of bicontinuous ion-containing channels for enhanced ion conductivity. These gyroid morphologies were reported at relatively high temperatures (120°C - 130°C) that are coincident with the melting point of the crystalline polyethylene unit. To produce the gyroid phase in a lower temperature range, polymers with shorter polyethylene units are being explored and results will be discussed using a phase diagram with volume fraction of sulfosuccinate units ($f_{polar}$) and temperature, similar to conventional block copolymer phase diagrams. This study endeavors to provide design strategies for single-ion conducting polymers with controlled ionic aggregate morphologies and enhanced ion conducting properties.
M71.00055: Understanding the interactions of polyols with hexafluoroisopropanol containing polynorbornene biobutanol membranes using QCM-D*  SIYUAN LI (Presenter), Univ of Akron, BRYAN VOGT, Chemical Engineering, Pennsylvania State University — Polymer membranes offer a low-cost path to separate bio-products. However, interactions of the membrane with components in the fermentation broth can alter its performance. Here we describe how ppm levels of polyl surfactant designed to inhibit foaming of the broth can dramatically swell and plasticizing the polynorbornene copolymers in the bio-butanol separation. *in-situ* quartz crystal microbalance with dissipation (QCM-D) enable the quantification of both the swelling and rheological properties. We examined the molecular-weight-dependent sorption behavior of 10ppm of polyethylene glycol (PEG) and polypropylene glycol (PPG) for a series of copolymer membranes that all contain 50 mol% hexafluoroisopropanol norbornene and 50 mol% alkyl (methyl to decyl) norbornene. Changing the alkyl side length only modestly impacts the swelling behavior, which is consistent with hydrogen bonding between hydroxy groups driving the sorption. It shows that PPG, not PEG, is the primary cause for the enhanced swelling. Increasing molecular weight of the PPG leads to increased swelling (entropic effect) but also slower the sorption rate (size effect). These results illustrate that details about components added to the broth can dramatically affect the membrane properties.

M71.00056: Self-assembly of Linear Block Copolymers and Bottlebrush Block Copolymers in Thin Films*  MINGQIU HU (Presenter), Univ of Mass - Amherst, DARREN SMITH, Department of Chemistry, University at Buffalo, DUK MAN YU, Univ of Mass - Amherst, XINDI LI, JAVID RZAYEV, Department of Chemistry, University at Buffalo, THOMAS RUSSELL, Univ of Mass - Amherst — Semiconductor device fabrication has been developing rapidly in recent years. It's been harder to keep up with Moore's law since top-down photolithography is approaching the diffraction limit. Self-assembly of block copolymers is a promising solution for its highly reproducible self-assembly, great diversity of morphology, good etching contrast, economic efficiency and recipes compatible for industrialization. Well-aligned self-assembled patterns with sub-10 nm feature size and good etching contrast in thin films have been achieved in recent years. However, poor solubility, microdomain orientation and high energy barrier for defect annihilation remain from their application. We developed a series of linear block copolymers and bottlebrush block copolymers containing ketal groups as side chains for low-χ to high-χ conversion in the solid state. Self-assembled lamellar and cylindrical morphologies, with a 5.4 nm full pitch have been obtained in the bulk and 9.4 nm full pitch in thin films, which is among the smallest domains obtained so far.

**M71.00057: Macrorheology and particle tracking to study tracer transport, viscoelasticity and network structure of mucin and mucin-like biopolymer solutions**  JOSHUA TAMAYO (Presenter), ARVIND GOPINATH, University of California, Merced — Passive microrheology using single-particle and multi-particle techniques can be used to assess the local transport, mechanical properties and network structure of biopolymer laden biological fluids. Using single particle tracking (SPT) and multiple particle tracking (MPT) passive microrheology, we probe the dynamics of tracer particles ranging from 0.1 to 10 microns in size in mucin-like Carboxy Methylcellulose (CMC) solutions and in re-constituted mucin solutions. Tracking and linking algorithms implemented in MATLAB and Python reconstruct 2-dimensional trajectories from sequential list of particle coordinates. Corrected data is used to calculate the distributions of displacements and velocities, ensemble averaged mean square displacement, and particle velocity autocorrelations from which we extract diffusion coefficients of the particles and tracer-size dependent viscoelastic properties of the medium. Passive microrheology combined with macrorheology studies and confocal derived connectivity and morphology measurements provide a base state to understand the dynamics of living active materials such Candida albicans biofilms.

**M71.00058: Rheological Scaling of Imidazolium-Based Polyelectrolyte in Ionic Liquid Semidilute Solutions**  ATSUSHI MATSUMOTO (Presenter), AMY QING SHEN, Okinawa Inst of Sci & Tech — Polymerized ionic liquids (PILs) are a special type of polyelectrolytes with ionic liquid moieties covalently attached to a polymer backbone. Existing studies show that electrostatic interactions play a dominant role in determining the viscoelastic properties of ordinary polyelectrolytes. Recently, we found that the charge underscreening effect, in which the screening length increases with increasing the ion concentration, resulted in expanding PIL chains at high ion concentrations in the dilute regime. In this study, we investigate the effect of charge underscreening on the rheological properties of PILs in the semidilute unentangled regime by using a model system consisting of a PIL (PC$_4$–TFSI) in a mixture of an ionic liquid (BmimTFSI) and a non-ionic solvent (DMF). We observe: i) both specific viscosity $\eta_{sp}$ and relaxation time $\lambda$ are initially constants at low ion concentrations $c_s$ and then decrease with increasing $c_s$ at an intermediate $c_s$. ii) both $\eta_{sp}$ and $\lambda$ increase with increasing $c_s$. This result indicates that the charge underscreening effect is still dominant in the semidilute unentangled regime. We capture the observed trend by proposing and validating a modified scaling law accounting for the dependence of correlation length on $c_s$. 
M71.00059: Rheological Properties of Bare and Grafted Nanoparticle Polymer Networks*  
YI FENG (Presenter), PINAR AKCORA, Stevens Inst of Tech — This study investigates the rheological properties of crosslinked poly(methyl methacrylate) (PMMA) composites with bare and grafted nanoparticle constituents. We will present the influence of crosslinking density and particle loading on linear rheological properties of PMMA networks. These results will be compared with the PMMA-grafted particles in crosslinked PMMA matrices. Effects of including the short linear chains into crosslinked composites of bare and grafted nanoparticles will be discussed. Topological constraints of crosslinked matrix will be compared to the crosslinked grafted nanoparticles to understand the addition of free chains and entanglements in these two different system networks.

*NSF CMMI MEP program Grant No.1825250

M71.00060: Effect of topological constraints in semidilute polymer solutions under planar extensional flow*  
CHARLES YOUNG, CHARLES SING (Presenter), University of Illinois at Urbana-Champaign — Polymer solution dynamics and rheology are relevant to a wide range of processing methods. Developing an understanding of the polymer conformational dynamics and the emergent material properties is challenging because of the interplay of hydrodynamic interactions (HI), excluded volume, and topological constraints driven by concentration and polymer architecture. This is particularly true in extensional flow, which strongly deforms the polymers from their equilibrium conformations. Using a new technique for rapid Brownian dynamics (BD) simulation which we call the iterative conformational averaging (CA) method, we investigate the dynamics and rheology of linear, comb, and ring polymer solutions at concentrations increasing from the dilute limit into the semidilute regime. We apply step strain rate planar extensional flow and quantify the dynamics in startup, at steady state, and after flow cessation via conformational distributions and the polymer contribution to extensional viscosity. We show that flow enhances intermolecular HI and topological interactions, resulting in transient intermolecular entanglements. We investigate the effect of these constraints on polymer stretching and the transient solution stress.

*We acknowledge support from NSF grant CBET-1803757.
M71.00061: The effects of the structure of a confinement on the ejection rate of a polymer chain from a nanopore*  CHUNG BIN PARK (Presenter), BONG JUNE SUNG, Sogang Univ — Conformations of DNA inside the phage are crucial to the ejection dynamics of the DNA. The equilibrium conformation of DNA inside the viral capsid is determined by the shape of the capsid (confinement): a concentric spool DNA and a folded twist DNA are considered equilibrium conformations in a spherical capsid and an elongated capsid, respectively. Because there are a variety of viral capsids in nature, the correlation between the capsid shape and the ejection dynamics should be a topic of interest. In this study, we investigate the effects of the capsid shape on the conformation of a polymer and its ejection rate by performing Langevin Dynamics simulations. We employed two different types of capsid: 1) sphere and 2) cube capsids. We find that a polymer chain ejects out of the capsid faster in case of the sphere than the cube capsid and that the ejection rate becomes faster by up to 35% as the rigidity of the polymer increases. The segments of the polymer near the wall of the capsid travel faster than other segments, regardless of the capsid shape. However, a larger fraction of the monomers are distributed near the wall in case of the sphere capsid than the cube capsid.

M71.00062: Interfacial Dynamics Governs the Mechanical Properties of Nanoconfined Glassy Polymers  WENJIE XIA (Presenter), North Dakota State Univ — Understanding the mechanical properties of nanoconfined glassy polymers is essential in design of nanostructured soft materials. Here, we investigate the mechanical properties of free-standing polymer thin films by employing an atomistically informed coarse-grained (CG) modeling approach. By examining three representative CG polymer models, i.e., polystyrene (PS), poly(methyl methacrylate) (PMMA), and poly(1-ethylcyclopentyl methacrylate) (PECPMA), we show that the elastic moduli of nanoscale thin films are substantially reduced with decreasing film thickness compared to their bulk values at their glassy state. Specifically, the PS and PMMA films exhibit similar size-dependent elastic responses and their film moduli are reduced compared to bulk values at a thickness of less than 40 nm, whereas, for PECPMA, the length scale where elastic modulus deviates from the bulk value is much larger. The local molecular stiffness within the films assessed by Debye-Waller factor further reveals a gradient a softer interfacial layer having a size of only a few nanometers. Based on our simulations, a bilayer composite model is employed to predict the elastic moduli of thin films, which uncovers the size scaling relationship that universally holds for all three polymers.
M71.00063: Surface and bulk dynamics of compressed polystyrene films: A β-NMR study
DEREK FUJIMOTO (Presenter), University of British Columbia, OWEN BRAZIL, Trinity College Dublin, ARIS CHATZICHRISTOS, MARTIN H DEHN, VICTORIA L. KARNER, ROBERT F KIEFL, PHILIP C. P. LEVY, RYAN M. L. MCFADDEN, University of British Columbia, IAIN MCKENZIE, GERALD MORRIS, MARTIN H DEHN, MONIKA K STACHURA, TRIUMF, JOHN TICKNOR, W ANDREW MACFARLANE, University of British Columbia, GRAHAM CROSS, Trinity College Dublin — Glasses gradually densify as they relax towards equilibrium, and in doing so, their spectral density of molecular fluctuations is modified. In polystyrene (PS), only a few percent increase in density is equivalent to the passage of millions of years. To access this regime, we have plastically deformed a PS thin film with nanoimprint lithography, resulting in permanent compactification without rejuvenation. We present depth-resolved $^8\text{Li}^+$ β-NMR measurements in PS films and discuss the dynamical effects of the mechanical processing. β-NMR is a technique sensitive to nanosecond molecular dynamics through the spin-lattice relaxation of a short-lived radioisotope. Because the isotope is implanted as a low-energy ion beam, the depth is controllable with nanometer-scale resolution. This has allowed β-NMR to directly probe the dynamics in glassy polymer thin films near both the free and buried interfaces.

M71.00064: Reduction of Dielectric Signal of the Interfacial Segmental Dynamics in Polymer Nanocomposites*
IVAN POPOV (Presenter), Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, BOBBY CARROLL, Department of Physics, University of Tennessee, Knoxville, Tennessee 37996, USA, VERA BOCHAROVA, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, ANNE-CAROLINE GENIX, Laboratoire Charles Coulomb, Université de Montpellier, CNRS, F-34095, France, SHIWANG CHENG, Department of Chemical Engineering and Materials Science, Michigan State University, East Lansing, Michigan 48824, USA, AIRAT KHAMZIN, Kazan Federal University, Institute of Physics, 420008, Kremlevskaya str.18, Kazan, Tatarstan, Russia, ALEXANDER KISLIUK, ALEXEI SOKOLOV, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — In this study we focus on polymer nanocomposites (PNCs) with dispersed silica core nanoparticles. We examine the dielectric strength and relaxation behavior of segmental dynamics in the interfacial polymer layer surrounding silica nanoparticles. The presented analysis reveals the significant drop in the dielectric strength, and its anomalous temperature dependence in polymer layer adsorbed to nanoparticles. We ascribe the observed effect to the restricted amplitude of segmental relaxation in the interfacial/adsorbed layer. The theoretical model explaining the unusual temperature dependence of dielectric strength is presented. Our results provide new view on discussion of dynamics in interfacial layer in PNC that may be applied to the thin polymer films as well: Not only characteristic time scale, but also amplitude of structural relaxation can be strongly affected by the presence of an interface.

**M71.00065: The Influence of Polymer and Ion Solvation on Counter-ion Cloud Formation and Charge Fluctuations in Highly Charged Polyelectrolytes**  
**JACK DOUGLAS (Presenter), National Institute of Standards and Technology, ALEXANDROS CHREMOS, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health** — We investigate the influence of solvent affinity to counter-ions and to the polyelectrolyte (PE) backbone on the charge distribution about highly charged flexible polymer chains based on coarse-grained molecular dynamics simulations that include both explicit counter-ions and solvent. Based on this framework, we find that the competitive solvation of ions and PE chains leads to an extended “cloud” of counterions about the polymers that cannot be understood without modeling the solvent explicitly. The counter-ion cloud is highly dynamic and fluctuations of the charge can be expected to great influence the polarizability of PEs in solution. After reviewing recent findings on the influence of molecular topology and interactions on the average size of the counter-ion cloud, we estimated the PE potential of the mean interaction to determine the influence of the counterion-cloud and charge fluctuation effects on inter-PE interactions. Consistent with the Kirkwood-Schumaker theory, we find evidence that charge fluctuations gives rise to a long range attractive interaction having a $1/r^2$ asymptotic decay at large interpolymer separation distances $r$ in the case of strongly hydrating counterions and a PE backbone that is not strongly hydrating, a model of relevance to many synthetic PEs.

**M71.00066: Reflection band-gap for a transversely stretched composite cholesteric elastomer**  
**GUILLERMO REYES (Presenter), ADRIAN REYES, Univ Nacl Autonoma de Mexico** — We have studied the conduction of electromagnetic waves, impinging normally in a composite cholesteric elastomer slab, doped with metallic inclusions, aleatory distributed in the structure. We performed a theoretical and numerical model, that allow us to obtain the reflection and transmission spectra, when the system is under the action of mechanical forces in transverse direction respect to cholesteric axis. We have found that by stretching transversely the elastomer slab after the critical value of stretching in which the helical structure gets unwind, it transform from a discriminatory circular filter to a polarization independent device. Intervals of conversion from right to left circularly polarized waves in the reflection spectra, are alternated with regions of resembling transmission of both circularly polarized waves. The spectra of the pure cholesteric elastomer can be modulated specially nearby the metallic resonance where the transmittances are greatly damped and reflection is considerably increased.
M71.00067: Structure Instability in Particle Filled Elastomeric Polymer Composite Under Tensile Stress  LANFANG LI (Presenter), Emulsion Polymer Institute, Lehigh Univ, WEI GUO, Oriental Yuhong North American LLC, ZHIYU JIANG, CHONG SHEN, Physics Department and Emulsion Polymers Institute, Lehigh Univ, WILLIE LAU, Oriental Yuhong North American LLC, H DANIEL OU-YANG, Physics Department and Emulsion Polymers Institute, Lehigh Univ — The buckling instability and crease development in elastomeric soft material under compression has been experimentally and theoretically studied over the past decades[1]. The structural instability of such material under tensile stress, however, has not been well understood. In this work, we present the structure instability of a polymer particle composite under tensile stress. It is observed that periodic undulation in sample surface develops as the tensile stress increases, manifested as linear ridges and valleys on the sample surface perpendicular to the direction of tension. The undulation is reversible at small strains. There is a memory effect in the undulation location at repeated strain applications. At large enough strain, the material eventually fractures from crack developed at one of the valley regions from the undulation structure.

M71.00068: Thermo-electro-mechanical and Rheological Properties of Rubber Composites Filled with \(sp^2\)-Hybridized Different Carbon Fillers*  EMIL FERNANDO (Presenter), THUSITHA ETAMPAWALA, LALEEN KARUNANAYAKE, Department of Polymer Science, University of Sri Jayewardenepura, Sri Lanka, DHARANI ABYESINGHE, AMANDA EKANAYAKE, NARAYANA SIRIMUTHU, Department of Chemistry, University of Sri Jayewardenepura, Sri Lanka, A R KUMARASINHGE, Department of Physics, University of Sri Jayewardenepura, Sri Lanka, DILHARA EDIRISINGHE, Department of Rubber Technology and Development, Rubber Research Institute, Sri Lanka — Rubber composites (RC) with enhanced thermo-electric properties are widely used in applications such as in flexible electrodes and solid tyres. In this work, the effect of carbon black (CB), multiwall carbon nano tubes (MWCNT) and natural graphite on thermal, electrical, mechanical and rheological properties of RC was studied. In all these fillers, carbon mainly has \(sp^2\) hybridization. When the MWCNT loading was increased from 5 to 60 phr, the electrical conductivity of RC increased by four orders of magnitude. At 60 phr MWCNT loading showed five orders of magnitude higher electrical conductivity than CB added sample. The graphite loaded RCs were nonconductive. Hardness, elastic modulus, tensile and tearing strengths increased gradually with the increase of filler loadings. The variation of modulus of graphite-loaded samples was subtle. Interestingly addition of graphite showed higher elongation at break than that of pristine rubber. Viscoelastic characteristics showed that MWCNT added samples have least time and graphite added samples have highest time for curing compared to CB loaded samples. Although carbon-based fillers responsible for a significant improvement in their overall properties type of filler controls the extent to which the property changed.

Aqueous pigment dispersions: The thermodynamics of hierarchical aggregation*  
ANDREW J MULDERIG (Presenter), KABIR RISHI, GREG BEAUCAGE, Univ of Cincinnati
— Many industrially important materials aggregate to form nanoscale mass-fractal structures. Unlike sintered aggregates such as fumed silica, aqueous pigment-based inks often consist of weakly bound nanoparticles stabilized by a surfactant that can break apart and re-form balancing mixing energy and the reduction in surface energy with aggregation. Rapid thermal motion of small elemental crystallites lead to dense primary particle clusters with slower thermal motion that aggregate into ramified mass fractals. It is proposed that the hierarchical structure relies on subtle and competitive equilibria between different hierarchical structural levels. In the context of the removal of a subunit from a cluster, the thermodynamics of nanoparticle hierarchical equilibria was explored on surfactant-stabilized pigment dispersions using the Vogtt Theory. Reversible nanoparticle aggregation could be described solely from the degree of aggregation and the volume fraction. In this case, the hierarchical thermodynamics at each of three structural levels is dominated by solubility of the nonionic dispersing surfactant that decreases with temperature (LCST).

A model nanocomposite designed to understand the interfacial behavior in a novel thermally stiffening nanocomposite*  
CHEN GONG (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, KRISTINA NGUYEN, Biomedical Engineering, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical and Materials Engineering, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — A novel polymer-adsorbed silica-reinforced nanocomposite with a heterogeneous structure was recently shown to have thermal-stiffening behavior. Although the macroscopic properties of this nanocomposite were characterized via rheological experiments, the structure and dynamics at the matrix-nanofiller interface remain to be investigated. In the current study, we use a simplified 2D system to mimic the complex 3D structure of the nanocomposite. The simplified sandwich structure consists of a flat silica substrate, a thin layer of adsorbed high glass transition temperature polymer (PMMA, P2VP, and PC), and a final layer of PEO. Modulated Differential Scanning Calorimetry (MDSC) and Thermogravimetric Analysis (TGA) experiments indicated that the conformation and the relaxation in the confined environment surrounded by the hydroxyl group-rich silica surface and flexible PEO chains were significantly altered. Besides, by carefully changing the thickness, annealing condition, and molecular weight, different trends were observed which corresponds to different possible mechanisms. The results are of great help in understanding the previous real nanocomposite results and they also provide some strategies to design nanocomposites with desired properties.

*Supported by NSF Grant 1825254.
M71.00071: Compatibility/incompatibility in surface-modified, aggregated, precipitated silica nanocomposites*  LAHARI PALLERLA (Presenter), KABIR RISHI, GREG BEAUCAGE, Univ of Cincinnati — Industrially relevant products often display a complex multi-level hierarchical, nano-to macro-scale structure. Control over this complex multi-hierarchical structure can be achieved through manipulation of filler-polymer compatibility/incompatibility such as by varying the silanol surface density, by chemically-tailoring the surface, and by grafting low molecular weight polymers. These modifications control dispersion and the associated emergent multi-hierarchy. Kinetic dispersion in reinforced elastomers has been likened to thermal dispersion leading to a pseudo-thermodynamic model.[1,2] The dispersion of modified fillers is quantified using this approach. These interactions can be classified as weak and strong depending on the presence of correlations. Interactions and dispersion are modeled using a random-phase or a modified Born-Green approach. Surface alteration was linked to the emergence of a multi-hierarchy. From the mesh size and packing of an emergent network, the state of dispersion and the interaction potential for coarse-grain simulations were determined.

M71.00072: New Insights into Hierarchical Structures in Polymer Nanocomposites: A Dissipative Particle Dynamics (DPD) Simulation Study*  ASHISH GOGIA, Univ of Dayton, KABIR RISHI, ALEX M MCGLASSON, GREG BEAUCAGE, University of Cincinnati, VIKRAM KUPPA (Presenter), Univ of Dayton — Polymeric systems such as natural rubber used in car and truck tires require the addition of suitable additives for the enhancement of numerous properties, including reinforcement and durability. The behavior of such fillers, (carbon black, silica, and metal oxides and some combination thereof), and their influence on nanocomposite effectiveness, depends on the filler structure, the interaction between filler-polymer matrix as well as the processing history. To understand this problem, we perform Dissipative Particle Dynamics (DPD) simulation of these blends, varying polymer-polymer, filler-filler, and polymer-filler interaction energy. We will discuss the effects of interaction strength, the scaling of polymer chains, and methods to quantify the filler percolation threshold and mesh size as a function of filler concentration. The simulation results are also validated against small angle x-ray scattering data. Additionally, the effect of such agglomerates on the structural and dynamical properties of the nanocomposites, measured via the radial distribution, mean square displacement, and autocorrelation function are also explored.

*Funding from the National Science Foundation via awards NSF CMMI-1635865 and NSF CMMI-1636036 is gratefully acknowledged.
M71.00073: Localizing Genesis in Polydomain Liquid Crystal Elastomers  

HAYDEN FOWLER (Presenter), BRIAN R DONOVAN, JOSELLE MCCracken, FRANCISCO LOPEZ JIMENEZ, TIMOTHY J WHITE, University of Colorado, Boulder — Programming the local orientation of liquid crystal elastomers (LCEs) is a differentiated approach to prepare monolithic material compositions with localized deformation. Our prior efforts prepared LCEs with surface-enforced spatial variations in orientation to localize deformation when the LCEs were subjected to directional load. However, because these surface alignment methods included regions of planar orientation, the deformation of these programmed LCEs is inherently directional. The absence of macroscopic orientation in polydomain LCEs results in uniform, nonlinear deformation in all axes (omnidirectional soft elasticity). Here, we exploit the distinct mechanical response of polydomain LCEs prepared with isotropic or nematic genesis. By localizing the polydomain genesis via masked photopolymerizations conducted at different temperatures, we detail the preparation of main-chain, polydomain LCEs that are homogeneous in composition but exhibit spatially localized programmability in their mechanical response that is uniform in all directions.

*The authors recognize financial support from the University of Colorado Boulder. H.E.F. recognizes Fellowship support from the Department of Education program “Graduate Assistantships in Areas of National Need” (GAANN).

M71.00074: Optical reconfiguration of the blue phase in liquid crystalline elastomers  

KYLE SCHLAFMANN (Presenter), TIMOTHY J WHITE, University of Colorado, Boulder — Liquid crystalline elastomers (LCEs) have been a topic of significant interest, largely motivated by their compelling performance as material actuators. Here, we detail distinctive optical reconfiguration of solid LCE compositions based on the cubic blue phases. These phases are retained in the LCE composition and exhibit selective reflection attributable to a periodic lattice superstructure. Strain-induced tuning of the selective reflection is detailed, associated with dimensional changes to lattice parameters. These materials exhibit mechanical properties that diverge from those observed within cholesteric LCEs. The influence of preparation conditions on the retention of the blue phase as well as processing conditions to increase platelet size will be discussed.
M71.00075: Predicting Stress-Strain Behavior of Thermoplastic Elastomer by Theoretical Calculation and Deep Learning*

TAKESHI AOYAGI (Presenter), CD-FMat, National Institute of Advanced Industrial Science and Technology (AIST) — Thermoplastic elastomer (TPE) is a typical industrial product where the microphase separation of block copolymer is utilized. This elastic behavior is one of the examples where the phase separated structure affects the physical properties. However, it is not simple to find the relation between complicate phase separated structure and stress-strain behavior. To tackle the problem, we applied coarse-grained simulation and deep learning technique. Stress-strain curve of various phase separated structures of ABA type triblock copolymers, where A blocks and B blocks form glassy domain and rubbery domain respectively, are investigated by the collaborative simulation of self-consistent field theory and coarse-grained molecular dynamics. Furthermore, we applied deep learning approach to make regression between the phase separated structure and stress-strain (S-S) behavior obtained by the computational simulation. The prediction of S-S behavior using trained deep learning network showed reasonably good results, and was very fast comparing to the computationally intensive simulation.

M71.00076: BigSMILES: A Digitalization Scheme for Data-Driven Macromolecules Research*

TZYY-SHYANG LIN (Presenter), BRADLEY OLSEN, Massachusetts Institute of Technology MIT — In polymer research, a major hurdle preventing the adoption of data-driven approaches to modeling is the lack of a general digitalization scheme for polymeric systems. To address this issue, a digitalization scheme is proposed that consists of two components: first, a structurally based line notation that specifies how different repeating units interconnect to form polymers, and second, a data format that quantitatively specifies the distributional properties associated with the structure presented in the first part. The new line notation, BigSMILES, built on top of the popular line notation SMILES, encodes the chemical structures of polymeric fragments with “stochastic objects” that specify the constituent repeating units and the permissible set of connectivity patterns between them. Along with the accompanying data standard, BigSMILES provides a compact, machine-friendly yet versatile route to digitally encode and report polymeric materials. It is hoped that the proposed scheme can be easily utilized by both material scientist and modelling experts to enable rapid development of data-driven polymers research.

**M71.00077: Achieving Atomic Scale Resolution of Metastable Polymers in Solution using Machine Learning**  
THOMAS OWEIDA (Presenter), North Carolina State University, HO SHIN KIM, Pacific Northwest National Laboratory, JOHNNY DONALD, YAROSLAVA YINGLING, North Carolina State University — Single-stranded DNA (ssDNA) is a metastable biopolymer that plays an important role in biological processes and has shown promise for applications in medicine and DNA nanotechnology. Understanding the structure of ssDNA in solution can provide a framework on how to control and manipulate the self-assembly and structure of ssDNA-based materials. Typically, experimental methods such as Small Angle X-ray Scattering (SAXS) are used to resolve conformational distributions of ssDNA; however, the low resolution does not provide enough information on structural details. We have developed a new method that utilizes molecular dynamic (MD) simulations in conjunction with machine learning (ML) that can obtain converged structures of metastable polymers. This study specifically performs MD simulations on ssDNA and evaluates the conformational landscape with respect to SAXS. ML methods are first used to obtain a comprehensive collection of possible ssDNA structures through simulation and subsequently used to optimize which group of individual chains closely match experimental SAXS curves. Ultimately, this process lets us break down the ensemble average embedded in SAXS and find the most probable group of metastable conformations in solution with structures defined at the atomic scale.

**M71.00078: Structural Prediction and Inverse Design by a Strongly Correlated Neural Network**  
JIANFENG LI, Fudan University, JEFF CHEN (Presenter), University of Waterloo — Macromolecules contain molecular units as the coding information for their correlated structures in physical dimensions. The relationship between these two features is governed by the interaction energies of the involved molecular units and their encoded sequences. We present a neural network algorithm that treats molecular units themselves as neural networks, which has the flexibility to allow each unit to respond to its own environment and to influence others in the system. Through a deep neural network and a self-consistent procedure, molecular units in the network establish a strong correlation to produce the desirable features in the physical world. The proposed framework is applied to the HP model. Both the forward problem of predicting folded structures from given sequences and the inverse problem of predicting required sequences for a given structure are examined.
**M71.00079: High-throughput study of mechanical properties of organic stable glasses by nanoindentation**  SARAH WOLF (Presenter), SAGE FULCO, AIXI ZHANG, YI JIN, SHIVAJEE GOVIND, HAOQIANG ZHAO, PATRICK WALSH, KEVIN TURNER, ZAHRA FAKHRAAI, University of Pennsylvania —

Glasses with enhanced stability over ordinary glasses have been formed by the process of Physical Vapor Deposition using a sufficiently slow deposition rate and appropriate temperatures. These stable glasses have been shown to exhibit higher density, lower enthalpy, and better kinetic stability over ordinary glasses, and are typically optically birefringent. These properties depend on the temperature at which the substrate is held during deposition, with temperatures near \(.85T_g\) (glass transition temperature) producing the most stable glasses. Given such exceptional properties, it is of interest to further investigate how the properties of stable glasses vary with deposition temperature and compare to those of ordinary glasses. In particular, the mechanical properties of these glasses remain relatively under-investigated. Nanoindentation is a useful technique for determination of mechanical properties, though it can present a problem of surface detection in cases of soft surfaces. Correcting for this, and using a temperature gradient sample for high-throughput acquisition of data, mechanical properties are obtained for several organic glass-formers in order to explore the relationship between chemical structure, deposition temperature, and mechanical properties of stable glasses.

**M71.00080: Photovoltaic and Electrical Properties of Diketopyrrolopyrrole Based Organic Semiconductors**  MAJHARUL HOQUE (Presenter), ANDREW LEVINE, SAUL BLAIN, JOSEPH HAMMER, VISHAL NARANG, ADAM BRAUNSCHWEIG, MILAN BEGLIARBEKOV, The Graduate Center, City University of New York —

Methylated-diketopyrrolopyrrole (MeDPP) is a small molecule, air-stable organic semiconductor with relatively high mobility, which is capable of undergoing excitonic singlet fission. Here we study the electrical transport and optical properties of MeDPP-based field effect transistors and photovoltaic devices. Using the magnetic field dependence of photocurrent in MeDPP solar cells we present strong evidence of efficient harvesting of charge carriers from triplet excitons. These results suggest that MeDPP is a promising candidate for high efficiency, air stable photovoltaic devices.

*NSF CREST IDEALS*
M71.00081: Low-temperature carrier transport of purely organic radicals embedded in double tunnel junctions* TUHIN BASU (Presenter), RYOMA HAYAKAWA, International Center for Materials Nanoarchiteconics (WPI-MANA), National Institute for Materials Science (NIMS), 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan, MIKHAIL KABDULOV, THOMAS HUHN, Department of Chemistry, University of Konstanz, 78457 Konstanz, Germany, NAHO TSUNETOMO, KAZUHIRO MARUMOTO, Division of Materials Science, University of Tsukuba, Tsukuba, Ibaraki 305-8573, Japan, YUTAKA WAKAYAMA, International Center for Materials Nanoarchiteconics (WPI-MANA), National Institute for Materials Science (NIMS), 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan — Purely organic radicals hold promise for molecular spintronics because the molecules have weak spin-orbit coupling and the feature is expected to achieve long spin relaxation time [1]. In this work, we evaluated the carrier transport through stable oligo(p-phenylene ethynylene)-based radical molecules (TEMPO-OPE) at cryogenic temperature (<20 K). A striking point of our device is that molecules are embedded in insulating layer of a metal–oxide–silicon (MOS) structure, where the structure acts as a double-tunnel junction [2]. Obvious stepwise currents were observed in the current-voltage measurements. Furthermore, the peak positions in differential conductance curves were consistent with the molecular orbitals of the TEMPO-OPE. These results clarify that the molecules still keep their radical characters even in solid-state devices. Our proposed device therefore paves the way to realize new molecular spintronics devices with further prospect of the integration into current silicon device.

M71.00082: Glass Transition Temperature from the Chemical Structure of Conjugated Polymers* RENXUAN XIE (Presenter), ENRIQUE D GOMEZ, Chemical Engineering, Pennsylvania State University, University Park, RALPH COLBY, Materials Science and Engineering, Pennsylvania State University, University Park — The glass transition temperature ($T_g$) is a key property that dictates the applicability of conjugated polymers. The $T_g$ demarks the transition into a brittle glassy state, making its accurate prediction for conjugated polymers crucial for the design of soft, stretchable, or flexible electronics. In this work, only one adjustable parameter is used to build a relationship between the $T_g$ and the molecular structure of 32 semiflexible (mostly conjugated) polymers that differ drastically in aromatic backbone and alkyl side chain chemistry. An effective mobility value, $m$, is calculated using an assigned atomic mobility value within each repeat unit. The only adjustable parameter in the calculation of $m$ is the ratio of mobility between conjugated and non-conjugated atoms; the value for this ratio is supported by results from molecular dynamics simulations. We show that $m$ correlates strongly to the $T_g$, and that this simple method predicts the $T_g$ with a root-mean-square error of 13 K for alkylated conjugated polymers.

*NSF DMREF-1629006
M71.00083: Investigating vapor doping dynamics in poly(3-alkylthiophenes) using *in situ* technique

MARK DITUSA (Presenter), GARRETT GROCKE, TENGZHOU MA, SHRAYESH PATEL, University of Chicago — For conjugated polymers to be utilized in future organic electronic technology, their conductivity must be able to be controlled. Molecular doping has been used for this purpose, but details of this process are not well understood. Here, we report on a study of vapor doped poly(3-alkylthiophenes), a conjugated-polymer system that has been widely characterized. We use traditional dopant 2,3,5,6-Tetrafluoro-7,7,8,8-tetracyanoquinodimethane and its less fluorinated cousins, along with poly(3-alkylthiophenes) with varying sidechain length, to probe how HOMO-LUMO overlap and spacing of the polymer affects the dynamics of the vapor doping process. These results are enhanced with characterization of the materials energetically and structurally at various time-points throughout the doping process. Spectroscopies such as UV-Vis, FTIR, and Raman give insight to the efficiency and mechanism of doping. This study shows how these techniques can be leveraged to probe how variables such as polymer structure, strength of dopant, and processing affect the final properties of molecularly-doped conjugated polymers.

M71.00084: Mechanism of charge transfer and separation in polymer/nonfullerene acceptor organic solar cells

NOZOMI OHTA (Presenter), Japan Women's Univ-Facul Sci, KOICHI YAMASHITA, Elements Strategy Initiative for Catalysts and Batteries, Kyoto University, AZUSA MURAOKA, Japan Women's Univ-Facul Sci — Recently, in the research fields on the organic solar cells (OSCs), it has been reported that it succeeded in synthesizing polymer/nonfullerene acceptor OSCs, and showed the power conversion efficiency (PCE) higher than polymer/fullerene type. Also, it was reported that nonfullerene acceptors were successfully fluorinated and showed higher PCE than non-fluorinated nonfullerene types. In this study, from the viewpoint of electronic structure, absorption spectrum, and HOMO–LUMO gap, we consider the mechanism of charge transfer and separation in polymer/nonfullerene acceptor OSCs, using time dependent density functional theory method.

We compared the absorption spectra and HOMO–LUMO gap of the PTB7/ITIC complex with those of the fullerene PTB7/PC_{71}BM complex, with those of the non-fluorinated nonfullerene PTB7/IT-4F complex. It turns out that nonfullerene type has an absorption band in the longer wavelength region compared to the fullerene type. Moreover, fluorination causes the absorption band to be slightly red shifted. In the nonfullerene type, Voc is reduced, but the PCE is increased. Therefore, the improvement in PCE is due to the Jsc improvement due to the increase in light absorption of nonfullerene acceptor.
**M71.00085: Towards the prediction and design of low-glass transition Donor-Acceptor semiconducting polymers**

SONG ZHANG (Presenter), Polymer Science and Engineering, Univ of Southern Mississippi, AMIRHADI ALESADI, Civil and Environmental Engineering, north dakota state university, SIMON RONDEAU-GAGNE, department of chemistry and biochemistry, University of Windsor, WENJIE XIA, Civil and Environmental Engineering, north dakota state university, XIAODAN GU, Polymer Science and Engineering, Univ of Southern Mississippi — Past efforts on conjugated polymers, especially donor-acceptor (D-A) type polymers have mainly focused on the understanding of their structure-optoelectronic property relationship. However, the designing rule for fabricating soft and deformable semiconducting polymers is largely neglected. Here, we report a predictive linear model to quantitatively connect the glass transition behavior of D-A polymers to the flexibility of polymer chains, which is further verified through molecular dynamics simulation. The thermomechanical performance was characterized through pseudo-free-standing tensile test, thin film DMA and verified by AC-chip calorimetry. X-ray scattering and solution neutron scattering were applied to investigate the thin film morphology and polymer chain rigidity for further proof. This model shows its guidance role in molecular engineering of a low-glass transition pristine polymer with high mechanical deformability (~ 100%).

**M71.00086: Tuning side chains to affect phase behavior and charge mobilities of PCPDTBT donor-acceptor conjugated polymers**

JAMES SUTJANTO (Presenter), ENRIQUE D GOMEZ, Chemical Engineering, Pennsylvania State University — Elucidating the critical components of molecular design would accelerate the implementation of conjugated polymers for electronic and energy applications. Using a donor-acceptor alternating copolymer based on a polycyclopentadithiophene benzothiadiazole backbone (PCPDTBT), we modify side chains to perturb phase behavior and charge mobilities in organic field-effect transistors. We use both branched and linear side chains of varying length and observe changes in glass transition temperatures, melting temperatures and liquid crystalline clearing temperatures using a combination of calorimetry, rheology, and X-ray scattering. Fabricating and testing field-effect transistors with PCPDTBT as the active layer yield field-effect mobilities that depend on the side chain substituent. Optimizing side chain composition and architecture is likely crucial to achieve remarkable charge mobilities of 10 cm^2/Vs that is observed with devices based on PCPDTBT.

M71.00087: The Impact of Illumination on the Photoluminescence and Depth Profile of MEH-PPV/dPS Thin Films  JOSHUA MONCADA (Presenter), University of Tennessee, TANGUY TERLIER, RAFAEL VERDUZCO, Rice University, MARK DADMUN, University of Tennessee — This study focuses on the changes in photoluminescence and film structure due to white light exposure during annealing of conjugated polymer blend thin films. Previous studies in our group have shown that annealing similar polymer blend thin films above the T_g of the polymers in a dark or illuminated environment alters the film structure. These structural changes should influence the photoluminescence (PL) activity observed for the film. The present work aims to investigate the correlation between light exposure, film morphology and photoluminescence for four film compositions, 5, 20, 35, and 50% MEH-PPV. The PL of the films are measured using Raman microscopy, which showed differences in PL activity depending on illumination during annealing at 125 °C. Samples that are exposed to light during annealing exhibited lower PL. Time-of-Flight Secondary Ion Mass Spectroscopy provides the depth profile of the films that enables the correlation of the film’s morphology and depth profile to the observed PL.

M71.00088: Controlling the Backbone Flexibility of Conjugated Polymer to Achieve Superior Backbone Tensile Alignment  LUKE GALUSKA (Presenter), Polymer Science and Engineering, Univ of Southern Mississippi, WILLIAM MCNUTT, Chemistry, Purdue University, ZHIYUAN QIAN, SONG ZHANG, SUJATA DHAKAL, ZHIQIANG CAO, Polymer Science and Engineering, Univ of Southern Mississippi, JIANGUO MEI, Chemistry, Purdue University, XIAODAN GU, Polymer Science and Engineering, Univ of Southern Mississippi — Recent reports have shown increased interest in the capacity of conjugation-break spacers (CBS) to soften relatively rod-like conjugated polymers (CP) while maintaining charge mobility. Here, we provide a holistic approach to understand the thermomechanical influence of CBS length on an n-type NDI-based conjugated polymer, denoted by PNDI-Cx. CBS lengths are varied from C0 (fully conjugated) to C7 with the CBS engineered into each repeat unit for systematic evaluation. Solution small angle neutron scattering and melt shear rheology were employed to provide the first quantitative evidence of CBS influence over CP chain rigidity and entanglement molecular weight (M_e), demonstrating an increase in chain flexibility, as well as a M_e independent of CBS length. Thermomechanical property, including: modulus, glass transition temperature, and melting temperature were all shown to decrease with increasing CBS length, while a high ductility was observed for PNDI-C4 which we attribute to a large number of entanglements. Furthermore, a high degree of backbone alignment was observed upon strain through GIXD, polarized UV-vis, and AFM. We will also discuss coalignment in a blend system of PNDI-C0 (tie-chain) in a ductile PNDI-C4 (matrix) to yield enhanced charge mobilities.
M71.00089: Photoabsorption of acceptor molecules in non-fullerene type organic thin film solar cells  SUMIRE IKEYAMA (Presenter), NOZOMI OHTA, Japan Women’s Univ-Facul Sci, KOICHI YAMASHITA, Kyoto University, Elements Strategy Initiative for Catalysts and Batteries, AZUSA MURAOKA, Japan Women’s Univ-Facul Sci — The π-conjugated system is important as a semiconductor material in organic electronics such as organic light emitting diodes, field effect transistors, and organic solar cells (OSCs). Organic semiconductors can adjust the energy levels of HOMO and LUMO, so it is also possible to adjust the relative energy between the molecular orbital of the organic semiconductor and the Fermi level of the metal electrode. Therefore, selective insertion/transport of holes/electrons is essential to the realization of organic devices. Recently, it has been reported that the bulk heterojunction OSCs, which contain fluorinated naphtho[1,2-c:5,6-c’]bis[1,2,5]thiadiazole-based non-fullerene acceptors has a better photovoltaic performance. In this study, we theoretically investigate the effects of fluorine atoms on the properties and photovoltaic performance from the perspective of molecular structure, HOMO-LUMO energy gap, and absorption spectrum. FNTz-Teh-FA was found to have a lower LUMO energy. Therefore, by fluorine substitution, it is expected that $J_{SC}$ will be increased, and charge separation will be enhanced. These results provide the key to develop new organic semiconductors with the application of donor-acceptor type donors and non-fullerene acceptor materials in OSCs.

M71.00090: Controlling mixed Li/electronic conduction in conjugated polymeric ionic liquids through the addition of ionic and electronic dopants  DONGWOOK LEE, DAKOTA RAWLINGS (Presenter), University of California, Santa Barbara, IOAN-BOGDAN MAGDAU, California Institute of Technology, ELAYNE THOMAS, University of California, Santa Barbara, THOMAS MILLER, California Institute of Technology, RAM SESHADRI, RACHEL A SEGALMAN, University of California, Santa Barbara — Conjugated polymeric ionic liquids (conjugated PILs) may be useful in electrochemical applications, owing to their potential for simultaneous ionic and electronic conductivity. The addition of ionic and electronic dopants is essential to control the mixed conductivity, although the doping design rules remain largely unknown. Here, we investigate the roles of LiBF$_4$ as an ionic dopant and NOBF$_4$ as an electronic dopant on the overall mixed conduction of a model conjugated PIL, P3HT(Im$^+$)BF$_4^-$. The thiophene backbone is selected to allow hole conduction while the ionic (Im$^+$)BF$_4^-$ sidechain solvates mobile ions. The addition of either the ionic dopant LiBF$_4$ or the electronic dopant NOBF$_4$ leads to a simultaneous increase in the mixed conductivity. Improvements in ionic conduction by LiBF$_4$ and NOBF$_4$ can be interpreted as a result of plasticization and increased mobile ion density respectively. The enhanced electronic conductivity is thought to proceed from oxidative or Lewis acid doping of the polymer backbone by NOBF$_4$ or LiBF$_4$ respectively. Molecular dynamics simulation will reveal the role of LiBF$_4$ to enhanced electronic conductivity. This study offers a new insight on the impact of ionic and electronic dopants on mixed conduction and future optimization of conjugated PILs.
M71.00092: Effect of pH on the phase behavior of multiple proteins in oppositely charged weak polyelectrolyte solution  RITUPARNA SAMANTA (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — We discuss the effect of pH on the phase behavior of weakly dissociating proteins in the presence of oppositely charged polyelectrolytes. We have used a hybrid methodology of coarse-grained single chain mean field simulation with constant pH method in a semi-grand canonical framework to include the fluctuating charge of the proteins and polyelectrolytes. Using the characteristics of the resulting phase behavior pertaining to multiple proteins and several polyelectrolytes, we compare the results due to charge regulation and equivalent fixed charge distribution on proteins.

M71.00093: Effect of divalent ions on mixtures of like-charged polyelectrolytes  CARLOS LOPEZ (Presenter), Physical Chemistry, RWTH Aachen — We study the rheology of mixtures of carboxymethyl cellulose and polyacrylate, two anionic polyelectrolytes in the presence of monovalent and divalent ions of the alkaline earth group. $\text{M}^{2+}$ are shown to promote interactions between the two systems, the nature of which depends on the specific interactions between the carboxyate groups and the metal cations. Addition of NaPA to $\text{M}^{2+}$CMC in salt-free solution leads to a non-monotonic dependence of the viscosity, entanglement modulus and longest relaxation time of the mixtures, presumably arising from an interplay of single chain collapse due to electrostatic screening and network strengthening resulting from associative interactions.

M71.00094: Interpolymer Hydrogen Bonding in the Presence of a Low-Molecular Competitor  ALIAKSEI ALIAKSEYEU (Presenter), VIKTOR SELIN, Materials Science and Engineering, Texas A&M University, JOHN F ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, SVETLANA SUKHISHVILI, Materials Science and Engineering, Texas A&M University — We examine the effect of dimethyl sulfoxide (DMSO) on binding enthalpy, strength of association between hydrogen-bonding polymers (poly(methacrylic) acid, PMAA), and polyvinylpyrrolidone, PVP) and their deposition within layer-by-layer (LbL) films, In solution, isothermal titration calorimetry (ITC) showed that the addition of DMSO to aqueous solutions resulted in a switching in enthalpy of binding from endothermic to exothermic. In good agreement with the ITC data, the growth mode of PVP/PMAA LbL films changed from linear to exponential with an increase in DMSO content. Neutron reflectometry (NR) studies showed that while LbL films constructed from DMSO-free solutions were stratified, significant layer intermixing occurred in the films constructed from polymer solutions with high DMSO content. This study demonstrates a facile means to control binding of polymer components and structure of assembled films in hydrogen-bonded systems.
ALEXANDER E. MARRAS (Presenter), JEFFREY VIEREGG, MATTHEW TIRRELL, Pritzker School of Molecular Engineering, University of Chicago — Polyelectrolyte complex micelles (PCMs) are widely used in the delivery of hydrophilic payloads. As oppositely charged polyelectrolytes assemble, counterions are liberated, however, when counterion concentrations are sufficiently high they prevent, or disrupt, polyelectrolyte complexation. Measuring complex stability versus salt provides a metric for the strength of ion pairing between polymers. PCM attributes are also strongly dependent on the size and chemical structure of each polymer block. Neutral blocks drive nanoscale phase separation while charged blocks control micelle core size and stability. An understanding of physical property behavior controlled by block size, chemistry, and salt conditions is crucial when designing for use in dynamic or biological environments and provide a greater understanding of the physics of polyelectrolyte assembly. In this work, we use small angle x-ray scattering, light scattering, and electron microscopy to determine scaling behaviors of micelle shape, size, and stability for many commonly used polyelectrolytes.

*National Institute of Standards and Technology, Center for Hierarchical Materials Design (CHiMaD) award 70NANB14H012. Advanced Photon Source, Department of Energy Office of Science User Facility Contract No. DE-AC02-06CH11357.

CONNOR BILCHAK (Presenter), Department of Chemistry, University of Pennsylvania, SHAWN MAGUIRE, THERESA TSAGGARIS, SAMUEL WELBORN, JOHN CORSI, ERIC DETSI, Department of Materials Science and Engineering, University of Pennsylvania, JAMIE FORD, Nanoscale Characterization Facility, Singh Center for Nanotechnology, University of Pennsylvania, JAMES PRESSLY, Department of Materials Science and Engineering, University of Pennsylvania, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania, RUSSELL COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — Most research on polymer composites has focused on the addition of discrete nanofiller to a polymer matrix to enhance properties. However many applications would benefit from a percolated network of the organic or inorganic phase, such as ion conductivity. This work focuses on the development of bicontinuous materials created by infiltrating polymer into nanoporous gold (NPG) thin films. The optical properties of the NPG, characterized via ellipsometry, are reminiscent to those of gold nanorods exhibiting a plasmon peak, which is controllable through the ligament size. Polymer films of amorphous Poly(Styrene) and Poly(2-Vinyl Pyridine) which have different affinities for the gold scaffold, are infiltrated into the NPG through thermal annealing, which provides further control over the optical response. A range of chain molecular weights are studied to probe the relation between chain radius of gyration and average NPG pore size and its effect on film properties. The polymer chains in the confined pores exhibit a slowdown in segmental dynamics measured through the glass transition temperature. The broad tunability of these hybrids represents a unique template for designing functional network composite structures from flexible electronics to fuel cell membranes.

**M71.00097: Morphological Effects on Ionic Conductivity in Solid Polymer Nanocomposite Electrolytes**

SHAWN MAGUIRE (Presenter), Materials Science & Engineering, University of Pennsylvania, ANDREEA-MARIA PANA, Chemical and Biomolecular Engineering, University of Pennsylvania, HYUN-SU LEE, Materials Science & Engineering, University of Pennsylvania, PATRICE RANNOU, MANUEL MARÉCHAL, UMR5819-SyMMES (CNRS/CEA/UGA), French National Centre for Scientific Research (CNRS), KOHJI OHNO, Polymer Chemistry, Kyoto University, RUSSELL COMPOSTO, Materials Science & Engineering, University of Pennsylvania — Perfluorosulfonic acid (PFSA) polymers, such as the benchmark Nafion®, are consistently used as proton exchange membranes (PEMs) in fuel cells and batteries. However, PFSA polymers’ high price, environmental safety issues and reduced lifetime have motivated the search for adequate alternatives. This work investigates two systems: a neat sulfonated polystyrene random copolymer (PS-S\_x) and a blend of PS-Sx mixed with sulfonated PS grafted iron oxide nanoparticles (PS-S\_x NP). Random copolymer films were characterized with electrochemical impedance spectroscopy (EIS). Conductivity values were determined for PS-S\_x with sulfonation levels ranging from 0.7mol% to 47.9mol% as a function of relative humidity (RH, 30%, 60%, 90%) at 40°C. The highest sulfonation level of PS showed a conductivity value of 0.04 S/cm at 90% RH, half that of Nafion®. The conductivity of the binary composite is investigated as a function of film morphology (i.e. discrete or percolated NP domains) and characterized through small-angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). These morphologies aim to provide increased mechanical strength and ionic conductivity compared to pure PS-S\_x systems, and offer insights into ion mobility through percolated domains.

*NSF PIRE - 1545884

**M71.00098: Spectroscopic Investigations of PEO Based Polymers and Nanofibers**

MIRCEA CHIPARA (Presenter), MOHAMMED UDDIN, OMOSOLA ORIRETAN, ELAMIN IBRAHIM, KAREN LOZANO, CARLOS DELGADO, DORINA CHIPARA, University of Texas Rio Grande Valley — Polyethylene oxide (PEO) is a special polymer, soluble in both water and some organic solvents (such as chloroform). Fullerenes are not soluble in water but are soluble in chloroform. These features have been exploited in the study of the effect of solvent and nanofiller nature on the morphology and crystalline structure of PEO. Both “bulk” samples and mats of PEO nanofibers obtained by force spinning from solutions of PEO in water or chloroform have been investigated by spectroscopic techniques (Raman, UV-VIS, X-Ray diffraction). X-Ray investigations were focused on the crystallites’ size, the unit crystal parameters, and potential stress effects as revealed by the dependence of the X-Ray line position and width on the spinning rate, PEO concentration in the solvent, and Sn load. Additional information regarding crystalline phases and the mechanical stresses/strains in PEO polymers and mats of nanofibers have been obtained by Raman spectroscopy, using as excitation both a green (583 nm) and a red (785 nm) laser. The dependence of the position of Raman lines on spinning rate and nanofiller concentrations investigated in detail.

**M71.00099: Deformation Mechanisms of Polyolefin Hard-Elastic Films during Uniaxial Stretching**

YUANFEI LIN (Presenter), South China Univ of Tech, LIANGBIN LI, University of Science and Technology of China — Polyolefin hard-elastic films composed of highly oriented lamellar stacks can serve as one ideal sample to study the intrinsic deformation mechanisms of lamellar stacks, the basic structural and deformation unit in semi-crystalline polymers. With the quick development of synchrotron radiation X-ray scattering techniques, we were able to track the structural evolutions of hard-elastic polyolefin films during uniaxial stretching with the aid of a home-made tensile device. The effects of strain, strain rate and temperature on the nonlinear mechanical behavior and structural evolution of oriented lamellar stacks were systematically studied. And the different dominant deformation mechanisms, including microphase separation within interlamellar amorphous, microbuckling behaviors, crystal slipping and melting-recrystallization, dominate in different external tensile fields. The roadmap of microstructural evolutions of oriented lamellar stacks was constructed in temperature-strain space, which might aid to guiding the real processing of high-performance polymer films.

**M71.00100: The Rheology of Crystallizing Polymers: Towards a Universal Description**

KALMAN MIGLER (Presenter), DEBRA AUDUS, National Institute of Standards and Technology — A longstanding goal in polymer rheology is to develop a physical picture that relates the growth of mechanical moduli during polymer crystallization to that of structure. We have recently shown that the rheology is dominated by the formation and growth of the spherulitic superstructures. Here, we aim to develop a universal description of the process by exploring the roles of temperature, surface and bulk nucleation densities, and gap thickness. We study the model system of isotactic polypropylene (iPP) through simultaneous mechanical rheology and optical microscopy, with augmentation by deterministic reconstruction and stochastic simulations. We collapse the variable space by considering two scaled parameters; one related to bulk nucleation density and the other to surface.
M71.00101: Suppression of crystallization in thin films of cellulose acetates and its effect on gas transport characteristics*  HAIQING LIN (Presenter), State Univ of NY - Buffalo — This study elucidates the discrepancy in gas permeability between bulk films and asymmetric membranes of semi-crystalline cellulose acetates (CAs) from perspectives of thickness-confinement and crystallization suppression. CAs are the workhorse membrane materials for industrial CO₂/CH₄ separation. Bulk films of CAs often exhibit CO₂ permeability values of 1.8-6.6 Barrers at 35 °C, which correspond to permeance values of 36-132 GPU for asymmetric membranes with assumed selective layers of 50 nm. However, commercial CA membranes can have CO₂ permeance values as high as 200 GPU with a CO₂/CH₄ selectivity comparable to the bulk polymers. We hypothesize that as the CA films become thinner, the thickness confinement inhibits crystallization and thus increases gas permeability while retaining gas selectivity. To validate this hypothesis, freestanding cellulose diacetate (CDA) films with thicknesses ranging from 218 nm to 20 µm were prepared, and their crystallinity was determined using Differential Scanning Calorimetry and Wide-angle X-ray Diffraction. Crystallinity can be suppressed by the decrease in the film thickness. Gas solubility and permeability can be satisfactorily correlated with the crystallinity using the empirical equations available in the literature.

M71.00102: Prefreezing of Different Folding States of Linear Polyethylene on Graphite
OLEKSANDR DOLYNCHUK (Presenter), ANN-KRISTIN FLIEGER, THOMAS THURN-ALBRECHT, Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg — Prefreezing is the interface induced crystallization of a melt on a solid substrate. In contrast to heterogeneous nucleation, prefreezing is an equilibrium phenomenon that refers to the reversible and abrupt formation of a crystalline layer at a temperature $T_{\text{max}}$ above the bulk melting point $T_m$. Recent experimental results evidenced that thin films of oligomeric linear polyethylene prefrozen on graphite have a complex structure consisting of a thin layer of extended chain (EC) crystals directly at the graphite and folded chain (FC) crystals on top of this layer. Temperature dependent AFM experiments showed that EC crystals prefreeze at a higher $T_{\text{max}}$ than that of FC crystals: $T_{\text{max,EC}} > T_{\text{max,FC}}$. To explain this behavior, we extend the recently developed phenomenological theory of prefreezing to the case when a melt can crystallize in phases of different thermal stability with melting temperatures $T_{m1} > T_{m2}$. Our analytical results indicate that while the more stable crystal phase prefreezes at a higher temperature $T_{\text{max}1}$, prefreezing of the less stable phase is thermodynamically preferred at lower temperatures, $T_{\text{max}2} < T_{\text{max}1}$. This behavior is in contrast to bulk crystallization, where crystallization of the less stable FC crystals is often kinetically preferred.
M71.00103: Epitaxial Crystallization of PE Atop Graphene by Vapor Deposition  YUCHENG WANG (Presenter), RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Epitaxial crystallization of polymers is a fascinating phenomenon that drives crystal structures under lattice matching conditions as a result of the interfacial interactions between specific pairs of a polymer and an underlayer material. However, fundamental investigations of epitaxial crystallization are impeded by the difficulties in preparing uniform ultrathin polymer layers and fine tuning of the film thickness, especially for polymers with low solvent solubility or fast crystallization kinetics such as polyethylene (PE). In this study, exploiting a physical vapor deposition technique, an additive bottom-up approach that is attracting more interest in processing polymers, we demonstrate the ability to achieve better film quality and control of layer thicknesses. By applying the flexible control of substrate temperature and deposition time to the model system of PE epitaxial growth atop graphene substrates, we determine how temperature and film thickness influence crystal structure and lamellar orientation. Characterization include grazing incidence x-ray diffraction (GIXD), TEM and AFM.

M71.00104: Chiral Recognition of Poly(Lactic Acid) Stereocomplex*  TOSHIKAZU MIYOSHI (Presenter), WEI CHEN, Univ of Akron — Chiral recognition is a very important concept for structural formation of stereocomplex (SC) of right and left handed helices. A well known system is Poly(Lactic acid) SC. Recently, re-investigation of X-ray fiber diffraction proposed that there is no chiral recognition in PLA SC. In this work, solid-state NMR spectroscopy can be used to study both chain-packing and folding structure of PLA SC by $^{13}$C isotope labeling and Double quantum (DQ) spectroscopy. $^{13}$C CPMAS NMR spectra supported by isotope labeling technique provides stoichiometry of L:D in the SC phase in varied mixing ratio in the blends. DQ spectroscopy provides detailed packing structure as well as chain-folding structure. Uniqueness of intermolecular packing (chiral recognition) in SC will be highlighted.

*NSF DMR Polymers 1708999

M71.00105: Chain-Level Structure of Semi-crystalline Polymer in Thermodynamically Stable Crystal and Quenched Glass*  YI ZHANG (Presenter), FAN JIN, TOSHIKAZU MIYOSHI, Univ of Akron — Crystallization of long polymer chains changes random coil state to folded structure in thin crystal lamellae. In this work, we will study chain-level structure of $^{13}$C CH$_3$ labeled Poly (Lactic Acid) with diverse molecular weights in thermodynamically stable a crystal and quenched glass by using Solid-state NMR spectroscopy. Molecular weight effect on folding event and crystallization will be discussed.

*NSF DMR Polymers 1708999
**M71.00106: Nanoindentation of nanocomposites**  SURESH AHUJA (Presenter), materials, xerox corporation — The spray coatings were dried and the dried coatings were subjected to nano-indentation using a nano-indenter made by Hysitron. Contact area was calibrated by using silica and polycarbonate of known modulus and hardness. This work on nano-indentation of polycarbonate containing nano-particles of silica shows that there is an increase in modulus and hardness up to a certain concentration threshold in concentration. As the level of silica increases beyond a threshold level, aggregates form which results in weakening of the structure. Polymer silica interface is found to be weak as silica is non-interacting promoting interfacial slip at silica-matrix junctions. At critical stress level for silica-polymer interfacial slip is reached and filler-matrix debonding (sliding) is activated resulting in a decrease in the composite's stiffness. Departure from the analytical composite models is analyzed in terms of interface adhesion between nanofiller and polymer matrix. Results on polycarbonates are compared with those of nanocomposites of polyesters where the effect of composite hardness and modulus depended on dispersion of nano-filler in polycarbonate or polyester. Experimental results are compared against analytical models.

**M71.00107: Physical Aging in Anhydride-Cured DGEBA Epoxy**  CATHERINE GROVES (Presenter), JAMIE M KROPKA, Sandia National Laboratories, JOHN MCCOY, New Mexico Tech — In amorphous polymers, there is a temperature \( T_g \) reached upon cooling at which the thermal energy is insufficient to allow for molecular rearrangements on the time scale of the temperature change. At this point, the material becomes kinetically trapped in a glassy, non-equilibrium state characterized by excess free volume and enthalpy. Physical aging occurs as a material is held below \( T_g \) and begins to relax towards equilibrium. This relaxation can change the properties of the material and is important to understand when considering the long-term reliability in applications. In this work, the physical aging of an anhydride (Aradur 917, Huntsman) cured DGEBA resin (EPON 828, Hexion) was investigated. Four sets of samples were held between 8°C and 35°C below \( T_g \) (132°C) for 0 to 4000 hours. The properties of these samples were tested through uniaxial compression and differential scanning calorimetry to observe the changes in yield stress and heat capacity.

M71.00108: Accelerated aging of an epoxy glass under elevated temperatures and compressive stresses* NOAH WHITE (Presenter), STEPHAN COMEAU, GABE ARECHEDERRA, JOHN MCCOY, New Mexico Tech, JAMIE M KROPKA, Sandia National Laboratories — The aging of the diglycidyl ether of bisphenol-A (DGEBA) cured with diethanolamine was studied both in its "neat" state and filled (at 50 vol%) with glass microballoons (D32-4500, 3M). Cylindrical test samples were compressed uniaxially and the stress-strain curves were analyzed for materials properties (principally the maximum, or yield, stress). Samples were oven-aged at five sub-Tg temperatures for extended times before testing at their aging temperatures and a range of strain rates. As the glass densifies during aging, the yield stress increases. The effect of applying uniaxial stress to the samples during aging is also studied. The samples are held at ~70% of the yield stress over periods of time (up to 24 hrs.), unloaded and then reloaded through yield. The recovery strain and yield stress are found. The yield stress is found to increase and the recovery strain to decrease as aging time increases. The rate of increase of the yield stress is compared to the oven-aged tests.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia LLC, a wholly owned subsidiary of Honeywell International Inc. for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

M71.00109: Metallization of Chiral and Grooved Polymers at Nanoscale ANTHONY GRAY (Presenter), KYRA FULEIHAN, BENJAMIN SCHUTSKY, CHRISTOPHER LA FOND, MEGHAN EVANS, PETR V SHIBAEV, Physics and Engineering Physics, Fordham University — Different types of polymers with chiral or grooved pattern on the surface were covered (decorated) with metal nanoparticles (silver, gold, nickel, etc.) or thin metal films (silver) in order to create surfaces with increased light reflection and to study possible plasmonic effects arising from ordered arrangement of nanoparticles and metal films. Decorated surfaces were inspected under the microscope and studied by atomic force microscopy (AFM). It was shown that for chiral surfaces the nanoparticles tend to arrange themselves along the spirals not only on the surfaces of original chiral polymers with focal conic domains but also on their replicas made from different polymers. Changes in light scattering and transmission were attributed to the presence of metal inclusions on the surface and are discussed in detail.
M71.00110: Apparent effect of crosslinker concentration on structure and dynamics of polymeric microgels* KIRIL STRELETZKY (Presenter), SAMANTHA C TIETJEN, Cleveland State University, SAMANTHA R HUDSON, Hiram College — The effect of the amount of crosslinker on the structure and dynamics of polysaccharide microgels synthesized in a surfactant solution was studied below and above volume phase transition. When the relative amount of crosslinker was varied by a factor of a hundred, three apparent behavioral regimes emerged from static and dynamic light scattering measurements. At low crosslinker concentrations, microgel behavior was found to be consistent with homogenously crosslinked microgels that displayed uniform reversible deswelling above the transition temperature. These microgels became more diffusive with temperature increase. At high crosslinker concentrations, microgels showed an unusual temperature dependence and signs of inhomogeneous crosslinking. In this regime, microgels grew in size and became less diffusive with increase in temperature. At intermediate crosslinker concentrations, microgels didn't show significant dependence of their size on temperature except for a reproducible jump in size at the transition temperature. The apparent regimes are likely due to nonuniform crosslinker distribution in the polymer microgel, which leads to nonuniform density of microgel particles, especially at large concentrations of the crosslinker.

M71.00111: Guided Design of Composite Graphene-Polymer Foams: From Graphene Stabilized Emulsion to Electrically Conductive Foams* ZILU WANG, YUAN TIAN (Presenter), HEYI LIANG, ANDREY DOBRYNIN, Polymer Science, The University of Akron, DOUGLAS ADAMSON, Chemistry, University of Connecticut — The surface activity of graphene enabled synthesis of composite polymer/graphene foams showing a strong coupling between electrical and mechanical foam properties. To develop a general framework for computationally driven design of composite polymer/graphene foams we use large scale coarse-grained molecular dynamics simulations. In particular, we study the affinity of the 2D elastic graphene-like sheets (G-sheets) to the interface between two immiscible solvents. The established envelop of interaction parameters was used to model emulsion polymerization resulting in polymeric foams which cells are coated with elastic G-sheets (G-shells). Upon uniaxial deformation or under foam swelling conditions, the percolating network of the G-sheets coating foam cells breaks down. This break down is manifested as an increase of the foam's electrical resistance. The disruption of the graphene networks occurs through crack formation of the G-shells covering the surfaces of the polymeric foam cells. The results of the computer simulations are compared with corresponding experimental studies of the graphene stabilized emulsions and of mechanical and electrical properties of composite graphene/polymer foams.

M71.00112: Designing Polymer Nanocomposites for Membrane Gas Separation: an Integrated Experimental and Modeling Approach*  HAIQING LIN (Presenter), State Univ of NY - Buffalo — Membrane technology is an energy-efficient approach for pre-combustion CO₂ capture and H₂ purification. Conventional membranes are based on rigid polymers with strong size sieving ability, such as poly[2,2'-(m-phenylene)-5,5'-bisbenzimidazole] (PBI) that provides high H₂/CO₂ diffusion selectivity. In this study, we demonstrate enhanced H₂ sorption and diffusion in PBI films with embedded palladium (Pd) nanoparticles, which have strong affinity towards H₂. Pd nanoparticles with uniform diameters of 6 - 8 nm are prepared via a hot-injection colloidal synthesis. The loading of Pd nanoparticles in PBI increases H₂ sorption by almost 1,000 times, and at high Pd loadings, the Pd nanoparticles may form fast channels allowing the H₂ molecules to jump from one particle to another and thus increasing the effective H₂ diffusivity. For example, adding 70 wt.% Pd in PBI increases H₂ permeability from 25 to 70 Barrers, and H₂/CO₂ selectivity from 13 to 29 at 150 °C. Such performance is above the Robeson's upper bound for H₂/CO₂ separation, demonstrating the potential of these new materials for industrial H₂/CO₂ separation. The gas transport in these PBI-Pd nanocomposites is being modeled using computational fluid dynamics (CFD) to elucidate the mechanisms for the facilitated H₂ transport.

M71.00113: Fabrication of Carbonized Block Copolymer Particles for Cathode Catalyst of Proton Exchange Membrane Fuel Cell  YOUNG JUN LEE (Presenter), JUHYUK CHOI, HYUNJOO LEE, BUMJOON KIM, KAIST — A porous carbon particle attracted great attention as supporting material for electrocatalyst due to its high conductivity and large surface area. Herein, we demonstrate a robust strategy to carbonize block copolymer (BCP) particles with maintained their size and morphology using etchable BCP (i.e., polystyrene-block-polydimethylsiloxane (PS-b-PDMS)). Key of generating porous carbon material is to introduce cross-linking, which can enhance the thermal stability of linear BCP during carbonization. We produced monodisperse cylinder-forming BCP particles using membrane emulsification, followed by cross-linking and carbonization. We confirmed that its morphology and size distribution is well maintained after carbonization. Moreover, we demonstrate carbonized BCP (cBCP) particles as a supporting material of electrocatalyst with depositing low amount (1 wt%) of platinum (Pt) catalyst on the cBCP particles (Pt@cBCP). Pt@cBCP showed 3.6 times-higher mass activity than commercial Pt/C catalyst in oxygen reduction reaction (ORR). Moreover, we confirmed the advantages of the porous structure by comparing them with a nonporous carbon sphere.
M71.00114: Effects of Heterogeneous Segmental Friction on the Decoupling of Segmental and Chain Dynamics  
WALTER YOUNG (Presenter), Polymer Science & Engineering, University of Massachusetts Amherst, JOESPHER P. SAEZ, Chemical Engineering, University of Massachusetts Amherst, THOMAS D. KUMLIN, Chemistry, University of Massachusetts Amherst, REIKA KATSUMATA, Polymer Science & Engineering, University of Massachusetts Amherst — Segmental and chain dynamics often deviate from Rouse model predictions due to dynamic heterogeneity introduced by interfaces or temperature reduction. However, the effect of heterogeneous segmental friction on such multi-scale dynamics of polymers remains poorly understood. This work aims to elucidate a possible mechanism for the decoupling of segmental and entire chain motion by systematically altering segmental friction in statistical copolymers. A model statistical copolymer of styrene and 2-vinyl pyridine (2VP) is loaded with amine functionalized silsesquioxane nanoparticles. These nanoparticles form hydrogen bonds with 2VP, while not interacting strongly with styrene monomers. Thus, the heterogeneous polymer architecture leads to heterogeneous segment-nanoparticle friction. Segmental relaxation is studied by differential scanning calorimetry, while the chain relaxation is studied by rheology. These measurements suggest that segmental and entire chain dynamics are slowed due to increasing copolymer-nanoparticle friction by increasing nanoparticle loading and/or increasing the 2VP content of the polymer. The relationship between segmental and entire chain dynamics of these copolymer/nanoparticle composites will be discussed in this presentation.

M71.00115: Effect of Softness of Polymer Grafted Nanoparticles on the Co-assembly Behavior in 3D Confined Nanoparticle/Block Copolymer Hybrid System  
MENG XU (Presenter), HONGSEOK YUN, KANG HEE KU, BUMJOON KIM, KAIST — Controlling the spatial alignment of inorganic nanoparticles (NPs) within polymer matrix is of great importance due to its great potential for building novel hybrid materials. Herein, we demonstrate the precise spatial distribution tuning of softness-controlled polystyrene-grafted Au NPs (Au@PS) within polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP) particles. The softness of Au NPs was controlled by changing the ratio of the PS ligand length to the inorganic core size. The hybrid particles produced via solvent-evaporative emulsions led to the formation of spherical PS-b-P4VP particles with radially-stacked lamellar morphology, while the spatial distributions of Au@PS NPs showed strong dependence on the softness of Au@PS NPs within PS-b-P4VP particles. Au@PS showing the characteristics of hard spheres were excluded from the block copolymer domains and formed well-ordered hexagonal packing on the particle surface. In stark contrast, Au@PS with the characteristics of soft spheres hierarchically stacked within the inner favorable domains and showed stronger selectivity to the domains which close to the center of onion particles. Finally, the phenomena will be explained by considering the entropic interactions between the BCP chains and PS ligands on Au surface.
**M71.00116: Interconnected Nanoporous Polysulfone Membranes by Microphase Separation of Randomly End-linked Copolymer Networks**  
JAECHUL JU (Presenter), RYAN HAYWARD, Univ of Mass - Amherst — Co-continuous nanostructures have been widely studied in blends, block copolymers, interpenetrating networks (IPN), and other polymer architectures. In contrast to block copolymers where equilibrium self-assembly yields ordered co-continuous phases over only small regions of composition (~5 vol. %), microphase separation in randomly end-linked copolymer networks (RECNs) has been shown to provide a kinetically insensitive route to co-continuous nanostructures and interconnected nanoporous materials across broad ranges of composition. Previously, interconnected nanoporous polystyrene (PS) materials were realized by selective etching of polylactic acid (PLA) in co-continuous PS/PLA RECNs. However, the resulting nanoporous PS structures have proven too brittle to be applied as membranes. To overcome this, we extend the concept to an engineering polymer, polysulfone (PSU), and generate co-continuous PSU/PLA RECNs and interconnected nanoporous PSU. We demonstrate that co-continuous PSU/PLA displays better mechanical properties than co-continuous PS/PLA, and that the resulting interconnected nanoporous PSU structures offer potential for applications as nanoporous templates and membranes.

**M71.00117: Brush Structure of Polymer Grafted SiO₂ Nanoparticles Measured with Neutron Scattering**  
YUAN WEI (Presenter), MICHAEL HORE, Case Western Reserve University — Polymer chains are grafted to nanoparticles (NPs) surfaces for a variety of purposes, including altering their solubility and dispersion within a polymer matrix. Here, we have grafted either poly(methyl acrylate) (PMA) or poly(N-isopropylacrylamide) to $d \approx 10$ nm SiO₂ nanoparticles, and measured the structure of the brush with small-angle neutron scattering (SANS). For moderate grafting densities ($\sigma \approx 0.3 \text{ nm}^{-2}$), high molecular weight polymers adopt two primary conformations. Polymer chains near the NP core are stretched in the concentrated polymer brush region (CPB). Farther away from the core, polymer chains are less confined and the conformation becomes more ideal in the semi-dilute polymer brush region (SDPB). To highlight scattering from these two regions, we took advantage of selective deuteration and contrast matching. SANS measurements are analyzed using the “core-chain-chain” form factor that we recently developed. We compare and contrast the conformation of poly(methyl acrylate) in a good solvent to that of PNIPAM in both D₂O and ethanol-d₆, in which PNIPAM has LCST and UCST behavior, respectively.

M71.00118: Quantum metamaterials from block copolymers: synthetic pathways to and emergent properties of superconducting gyroids from triblock terpolymer nanocomposites

PETER BEAUCAGE (Presenter), Materials Science & Engineering, Cornell University — The last three decades have established block copolymer self-assembly as a scalable route to complex morphologies with exquisite control over the resulting mesostructures. The incorporation of inorganic nanoparticles into these materials has produced record-setting solar cells, batteries, and other devices. However, most of these applications make little use of the crystallographically ordered and highly topologically complex nature of the resulting domains. This unique strength of block copolymers has been shown in simulations to result in emergent properties including negative refractive indices in the visible and circularly polarized light propagation. The primary barrier to realization of these properties has been a lack of synthetic approaches to produce electronic-grade materials, such as superconductors, using block copolymer self-assembly. Using thermal treatments of PI-b-PS-b-PEO triblock terpolymer-niobium oxide nanocomposites, we develop synthetic routes to niobium carbonitride superconductors whose transition temperature varies with morphology and confinement, a first example of the plethora of emergent phenomena we expect from this exciting new class of quantum metamaterials.

*PAB thanks the NIST-NRC postdoctoral fellowship and the NSF GRFP (DGE-1650442) for support.

M71.00119: Deformation-Structure Correlations in Glassy Polymer-Grafted Nanoparticle Assemblies

ALLEN SCHANTZ, Air Force Research Lab - WPAFB, FLORIAN KÄFER, Cornell University, JINHO HYON, Rice University, JASON STREIT, Air Force Research Lab - WPAFB, CHRISTOPHER OBER, Cornell University, EDWIN THOMAS, Rice University, LAWRENCE DRUMM, RICHARD ARTHUR VAIA (Presenter), Air Force Research Lab - WPAFB — Composites made from polymer-grafted nanoparticles (PGNs) with entangled canopies can avoid the nanoparticle aggregation common in polymer-nanoparticle blends, and have allowed mechanically robust designs for structural, separation, electronic, and optical applications. Recent studies have elucidated the relationship between PGN architecture (graft density $\Sigma$, graft degree of polymerization $N$, and nanoparticle core radius $r_0$) and the retention of mechanical strength and polymer-like plasticity (i.e. crazing) below $T_g$. In parallel, the ARGET-ATRP emulsion-polymerization method has expanded the available composition and quantity of PGNs. Herein, we discuss the correlations between the structure of PGN assemblies derived from ARGET-ATRP and their elasticity, plasticity, and failure mechanisms, with a focus on elucidating the impact of secondary interactions within and between canopies, and the impact of core shape and composition.
M71.00120: Controlling Morphology of Self Assembling Nanocrystalline Reinforcing Domains by Grafting Density Design*  
AARUSHI SRIVASTAVA, JOHN MEYERHOFER, YIHONG ZHAO, Univ of Akron, SUSANA TEIXEIRA, National Institute of Standards and Technology, LI JIA, MARK FOSTER, WENHAN ZHAO (Presenter), Univ of Akron — Thermoplastic elastomers (TPEs) attain good mechanical performance by virtue of hard, reinforcing domains resulting from microphase separation of two immiscible, covalently connected parts of the chains. The use of monodisperse hard segments with a strong tendency to self-assemble into β-sheet secondary structures via cooperative multiple hydrogen bonds has received attention as a strategy for forming reinforcing domains. The β-alanine trimer grafted polyisobutylene (βA_3-g-PIB) studied here are TPEs. The β-sheet crystals provide physical crosslinks and reinforcement, and the PIB chains provide elasticity. In molecular designs f-PIB-g-βA_3 and p-PIB-g-βA_3 the chain tethering density on the surfaces of the β-sheet crystals was varied to change the long dimension of the reinforcing domains. Small Angle X-ray Scattering (SAXS) and Small Angle Neutron Scattering (SANS) measurements reveal that indeed when the chain tethering at the crystal surface is more crowded the domain dimension in the direction of β sheet stacking is reduced from over 200 nm to less than 10 nm, so all three domain dimensions are truly “nano”. SANS of samples swollen with deuterated cyclohexane show that portions of the backbone near the grafting points are stretched

M71.00121: Influence of Graft Chain Properties on Polymer Grafted Nanocomposites*  
ANDREW EHLERS (Presenter), Materials Science and Engineering, Rensselaer Polytechnic Institute, PINAR AKCORA, Chemical Engineering and Materials Science, Stevens Institute of Technology, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — The viscoelastic behavior of polymer grafted nanocomposites (PGNs) with significantly different glass transition temperatures (T_g) between the graft and matrix polymers is investigated with molecular dynamics simulations. The effect of the dynamic coupling of the grafted and matrix polymer chains is studied by molecular dynamics simulations. These types of PGNs have been shown to have reversible and repeatable stiffening behavior upon heating (Senses, E.; Isherwood, A.; Akcora, P. ACS Appl. Mater. Interfaces 2015, 7, 14682). This unique thermal stiffening behavior was attributed to the dynamic coupling of the high-T_g adsorbed chains and low-T_g matrix chains. The PGN studied in the current work consists of a nanoparticle with grafted high-T_g polymer chains in a low T_g polymer matrix. The influence of the matrix density on viscoelastic properties is investigated to identify the mechanism of the observed stiffening in these types of PGNs. The influence of the graft properties (density and length) is also investigated to identify the mechanism of the aforementioned stiffening behavior.

M71.00122: Development of a CVD assisted PLD system for growing atomic monolayers
SINJAN MAJUMDER (Presenter), DAVID MARK CORNELISON, KARTIK GHOSH, Missouri State Univ —
The fundamental step for development of semiconductors involves stacking of layers of thin films of materials with desired properties on a particular substrate. PLD is a technique employed for growing thin films using laser ablation of a target material. CVD is an alternate method used to deposit solid materials from a gaseous phase. However, combining these two techniques can enhance plume, gas and laser interaction to facilitate the growth of novel materials with new properties. Conformity and purity play pivotal roles in the thin film growth process. While working under Ultra-high vaccum can eliminate impurities, on the other hand, proper screening and thermal activation of the plasma of ablated materials ensures a smooth registration of the film with the substrate. In order to control the ratio of CVD to PLD action, we use an optical chopper. We also aim at studying the effect of substrate, temperature and carrier gas on the resulting film. For analysis and characterization of the developed film, we employ standard techniques like SEM, XRD, Raman spectroscopy, fluorescence and profilometry. For initial proof of concept, we demonstrate growing a metal nitride.

M71.00123: Nonlinear Elasticity and Swelling of Comb and Bottlebrush Networks*
MICHAEL JACOBS (Presenter), HEYI LIANG, Polymer Science, University of Akron, ERFAN DASHTIMOGHADAM, BENJAMIN MORGAN, SERGEI SHEIKO, Chemistry, University of North Carolina, ANDREY DOBRYNIN, Polymer Science, University of Akron — We use a combination of analytical calculations, coarse-grained molecular dynamics simulations and experiments to elucidate the effect of branched architecture on swelling of comb-like and bottlebrush networks. The equilibrium swelling ratio of such networks is shown to be larger than that of conventional linear chain networks as a result of two effects: architectural disentanglement of network strands and amplification of polymer-solvent interactions by side chains. For networks of brush-like strands with poly(dimethyl siloxane) side chains in toluene, we achieve a swelling ratio of $Q = 30$, which is larger than that of linear chain networks with the same strand length. All of the studied systems, including linear chain, comb, and bottlebrush networks, follow a universal scaling relation, $G(Q) \sim Q^{-\delta}$, between the shear modulus $G(Q)$ and swelling ratio $Q$ with scaling exponents $\delta = 2.6\pm0.08$ (simulations) and $\delta = 2.6\pm0.12$ (experiments). These values agree with the theoretically predicted exponent $\delta = 8/3$, confirming dominant contribution of three body interactions to the osmotic pressure which drives network swelling.

Gelation of DGEBA epoxy in the presence of a tertiary amine for temperatures above and below the ceiling temperature

JOHN MCCOY (Presenter), CATHERINE T. HOUSE, New Mexico Tech, JAMIE M KROPKA, Sandia National Labs — DGEBA epoxy is reacted with the curative diethanolamine (DEA). DEA has a single secondary amine that reacts rapidly with epoxide forming a non-crosslinked adduct in about 30 minutes under normal, 70°C, cure conditions. The subsequent crosslinking reaction is much slower, taking 24 hrs. at 70°C to near completion for the standard DGEBA/DEA mix. Cures at elevated temperature (above ~80°C) display a slowing of the overall rate of reaction in a "ceiling temperature" effect which results from a series of reactions associated with the zwitterion driven addition reaction. Here we measure the gel point across a wide range of temperature. At low temperatures, a simple bubble viscometer is used, while traditional rheology is employed for high temperature tests. We find that the extent of cure at gelation is 42±3% for all cases. We show that our measurements are in good agreement with predictions of Carothers and Flory-Stockmayer Theories of gelation.

The effect of water sorption, high temperature aging, and cooling rate on the calorimetric signature of the aging of an epoxy glass

STEPHAN COMEAU (Presenter), BRANDON MCREYNOLDS, TAYLOR LE, JOHN MCCOY, New Mexico Tech, JAMIE M KROPKA, Sandia National Laboratories — Stephan Comeau, Brandon McReynolds, Taylor Le, John D. McCoy, Jamie M. Kropka 2
American Physical Society March Meeting 2020
New Mexico Institute of Mining and Technology
2) Sandia National Laboratories

The cure of DGEBA with diethanolamine results in an epoxy that is susceptible to complex aging signatures. Aging at room temperature (about 50°C below Tg) and ambient humidity results in three distinct features: a pre-Tg peak starting 30°C below Tg, a broad post-Tg Shoulder from Tg (75°C) to 175°C, and a decrease in Cp between 175°C and 200°C (chemical aging). Unlike the other features the high-T decrease in Cp persists after the first heat. Extended isothermal holds at 200°C remove the high-T decrease in Cp and slightly increase the Tg (indicating additional cure). Water soaked samples and samples stored in sub ambient conditions, show an evolving pre-Tg peak and an evolving post Tg-shoulder. The pre-Tg peak also occurs in Samples rapidly cooled (10°C/min) from above Tg and then aged.

M71.00126: Introducing imide-based functional groups for enhanced self-healing properties of polyurethane*  HEE JEONG PARK (Presenter), Dankook University, SUNG WOO HONG, Korea Institute of Industrial Technology, DONG HYUN LEE, Dankook University — A functional polyurethane with imide moiety (PUI) is synthesized and the self-healing properties are compared with conventional polyurethane (PU). As the imide-based molecules with either mono-hydroxyl or di-hydroxyl groups are added to the mixtures of reactants including polyols and cross-linkers, the imide groups are successfully incorporated to the polyurethane chains. Therefore, while the mono-hydroxyl imide-based molecules give only interacting sites to PU chains, the di-hydroxyl imide-based molecules provide both interacting sites and chemical crosslinks. Interestingly, despite a small amount of the imide moiety in polyurethane, it is observed that the self-healing properties are drastically enhanced as compared to those of PU. Especially, PUI based on imide derivative with di-hydroxyl groups exhibits more excellent self-healing performances compared with that with mono-hydroxyl groups because of the unique intermolecular networks of reversible interactions and chemical crosslinks.

*This research was supported by Gyeonggi Regional Research Center (GRRC) program (GRRC DANKOOK 2016-B02 / GRRC DANKOOK 2017-B01), Korea Institute for Advancement of Technology (KIAT) grant funded by the Korea Government (MOTIE)(P0002007, The Competency Development Program for Industry Specialist).

M71.00127: Relationship of Local Strain-Field and shape of Crack-tip in the Dynamic Crack of Filled Elastomers  THANH-TAM MAI (Presenter), KENJI URAYAMA, Kyoto Institute of Technology — The correlation between the crack-tip shape and local strain-field in the dynamic crack with both subsonic ($V < C_s$) and supersonic ($V < C_s$) motion of filled elastomers is investigated, where $V$ and $C_s$ are crack-growth rates and shear wave speed. The shape of the crack-tip is characterized by the deviation from the parabolic shape ($\delta$) and the opening displacement (CTOD). The strain-field around the crack-tip is calculated by the two-dimensional digital image correlation technique (DIC) on the basis of the speckle images captured by a high-speed camera. The vertical strain field ($e_{yy}$) near the crack-tip can be characterized by the relation $e_{yy} \sim (1/r)^{\alpha}$, known as a crack-tip singularity. We discuss the correlation between the features of the local strain field ($\alpha$ and strain field distribution) and those of the crack-tip shape ($\delta$ and CTOD).
M71.00128: From quantum mechanics to viscoelasticity: A multiscale modeling and characterization of radical initiated modification of polyolefin in molten state  WEIZHONG ZOU (Presenter), Massachusetts Institute of Technology, AMBER TUPPER, Cooper-Standard Automotive Inc., NATHAN REBELLO, WONTAE JOO, DUMINDA S. RANASINGHE, TZYY-SHYANG LIN, Massachusetts Institute of Technology, GENDING JI, Cooper-Standard Automotive Inc., SARAH KHANNICHE, BRADLEY OLSEN, WILLIAM H. GREEN, Massachusetts Institute of Technology, KRISH GOPALAN, CHRISTOPHER COUCH, Cooper-Standard Automotive Inc. — Multiscale approaches for peroxide-initiated grafting of vinyl silane monomers to polyolefins have been investigated with the intention of the development of a mechanistic model for the synthesis of functional copolymers by melt phase processing. A comprehensive mechanistic view of the complex radical mediated reactions is achieved by determining the reaction kinetics through both quantum theory and model compound study. Our results clearly show that the overall mechanism is dominated by grafting single monomer of vinyl silane to hydrocarbon substrates, rather than forming localized or homopolymer grafts, and this occurs at the expense of polymer crosslinking due to the termination of radicals via combination. A fundamental kinetic model is therefore established to depict the general chemistry involving all the critical reactions in modification of molten polymer and their relationships to processing conditions. Combined Fourier transformation infrared spectroscopy with gel permeation chromatography, the further implement of this kinetic model to our recently-developed topology-based viscoelastic model allows, for the first time, to estimate both the yield of graft content and the change of rheological properties during the synthesis of polyolefin graft copolymer in molten state.

M71.00129: Electro-mechanical transduction of ionoelastomer junctions* MATTHEW MCBRIDE (Presenter), HYEONG JUN KIM, Univ of Mass - Amherst, BAOHONG CHEN, ZHIGANG SUO, Harvard Univesity, RYAN HAYWARD, Univ of Mass - Amherst — Ionoelastomers are an emerging class of ion conducting materials wherein one of the ionic moieties of an ionic liquid pair is covalently attached to a polymer backbone, leading to solid-state electrolytes that selectively conduct ions of one charge. Herein, two oppositely charged ionoelastomers were prepared based on 1-ethyl-3-methyl imidazolium (3-sulfopropyl) acrylate (ES) and (1–(2–acryloyloxy–ethyl)–3–buthyl–imidazolium bis(trifluoromethane) sulfonimides (AT). At the interface of ES/AT, an ‘ionic double layer’ (IDL) is formed due to diffusion of mobile ions away from the interfacial region, resulting in a build-up of excess fixed charges with a capacitance of ~ 1 mF/cm$^2$. Thanks to the highly elastic properties of ILEs, along with stretchable electrodes based on embedded carbon nanotubes or graphene, ILE diodes can be repeatedly deformed to large strains (~ 100%) without failure. Remarkably, we have found that uniaxial stretching of an ILE diode produces a spike in the open circuit voltage, or correspondingly a current when the system is connected to an electrical load. This effect can be used for strain sensing or energy harvesting, especially for ambient mechanical energy sources with relatively low frequency and large strain.

*Funding from NSF through grant DMR-1609972
M71.00130: Comparison of the mesh size for semi-dilute worm-like micelles obtained through rheology, neutron scattering, cryo-TEM, and theory.  

HANQIU JIANG (Presenter), The China Spallation Neutron Source (CSNS), Institute of High Energy Physics, KABIR RISHI, GREG BEAUCAGE, KARSTEN VOGTT, Univ of Cincinnati — Worm-like micelles (WLMs) are amphiphilic structures that display viscoelastic properties due to entanglement of robust thread or hair-like morphology. In the semi-dilute regime, the properties of wormlike micelle solutions are no longer governed by the features of individual micelles but rather by the emergent inter-micellar structure reflected in a transient network characterize by the mesh size. A new approach was developed to obtain the mesh size information from small-angle neutron scattering (SANS) data. This observed mesh size was compared with those obtained through rheology, cryo-TEM and by theory. The different physical origins of these values are discussed. The corresponding osmotic pressure was also calculated based on the mesh size from SANS at various salt concentrations and temperatures. It was used to predict concentration and thermal critical points which correspond with observed phase separation. Reasonable agreement was found for the dynamic, structural, and theoretical mesh size, sufficient to support structural interpretations of rheological data which form a basis for theoretical predictions of the complex rheology displayed by WLM systems.

M71.00131: Nonlinear shear flow experiments suggest no missing physics in slip-link models of entangled polymer melts  

DIEGO BECERRA, ANDRES CORDOBA, Chemical Engineering, Universidad de Concepcion, JAY SCHIEBER (Presenter), Illinois Institute of Technology — The idea that the dynamics of concentrated, high-molecular weight polymers are largely governed by entanglements is now widely accepted and typically interpreted through the tube model. However, recent work has shown that tube models can not predict the maximum strain, of polymer melts under start-up of shear flow at high Rouse-Weissenberg numbers. Based on these observations it has been suggested that there are physics missing in the tube theory. Here, we show that the slip-link model can predict all the features observed in start-up of shear experiments for melts and solutions of various chemistries (PS, PI, PBD, SBR) and for various numbers of entanglements. Specifically we use the the open-source GPU implementation of the clustered fixed slip-link model, and perform simulations for the startup of shear flow for melts with 14 and 30 entanglements. We find that the maximum strain depends weakly on the number of entanglements and that it does not necessarily follow a single power law, in agreement with data. Moreover, a master curve is obtained for the shear stress normalized by its peak value vs. strain normalized by its value at the maximum stress, also in agreement with experiments.

**M71.00132: Electrical Properties of Hafnium Dioxide**  
CHRISTOPHER ROBLEDO (Presenter), KARTIK GHOSH, SANCHALI DAS, ZACHARY LEUTY, Missouri State Univ — Since the discovery of graphene in 2004, there has been a renewed interest in 2D materials—which have the potential to increase efficiency and speed, and decrease cost, size, and power consumption within electronic devices. Current insulating material, such as silicon dioxide, limits our ability to comply with Moore's Law—which predicts that the number of transistors within an integrated circuit doubles about every 2 years. To scale devices even further, hafnium dioxide (hafnia) has shown to be a suitable replacement in the gate oxide insulating layer in complementary metal oxide semiconductor devices due to its comprehensive performance. Atomic Layer Deposition of hafnia was grown and annealed at various temperatures between 1-2 hours and its electrical characteristics were examined. Results show that with an annealing temperature of 700°C for 1 hour, the crystallinity of the bulk material improved significantly compared to lower temperatures regardless of the annealing time. Results also show that the capacitance remains nearly constant with increasing voltage frequency. Also, the dielectric loss remains the lowest in the same sample. However, the decrease in impedance shows no significant improvement among other samples annealed at different temperatures.

**M71.00133: Biaxial Stretching of Nearly Critical Gels with Extremely Sparse Network Structures**  
TAKUMA AOYAMA (Presenter), NAOTO YAMADA, KENJI URAYAMA, Kyoto Inst of Tech — Nearly critical gels, which are obtained slightly beyond the gel point, have very low modulus due to their extremely sparse network structures. The nonlinear elasticity of such sparse polymer networks is intriguing, but their very low modulus has prevented the characterization of the large deformation behavior. The present study investigates the biaxial stress-strain behavior of nearly critical gels by means of a custom-built tensile tester optimized for soft gels. The biaxial data show that the cross-effect of strains becomes smaller as the gels approach the gelation point, and that the effect vanishes in the nearly critical gels.

**M71.00134: Capturing change in microstructure of physically assembled gels as a function of temperature and strain using in-situ RheoSAXS technique**  
ROSA MARIA BADANI PRADO (Presenter), SATISH MISHRA, Mississippi State Univ, WESLEY ROTH BURGHAHRT, Northwestern University, SANTANU KUNDU, Mississippi State Univ — The mechanical properties of physically assembled gels depend on their microstructure. During large deformation, gel microstructure changes leading to a change in their mechanical properties. Here, we have considered two gels that consist of 10% and 20%(w/w) of poly(styrene)-poly(isoprene)-poly(styrene) [PS-PI-PS] in mineral oil, a midblock selective solvent. At room temperature, collapsed PS-blocks form aggregates, which are bridged by the PI-chains resulting in a three-dimensional gel. We capture the microstructural transformation as a function of temperature in a RheoSAXS setup. The scattering data capturing the change in gel microstructure subjected to oscillatory shear-strain was collected in the 1-2 plane. Strain amplitude values of 10, 100, and 300% were applied on the gels, therefore we have been able to collect data both at small and large strain amplitude. At high strain amplitude, an elliptical two-dimensional scattering pattern has been observed indicating structural orientation along the applied strain direction. To quantify such orientation, we have estimated the anisotropic factor as a function of strain from these patterns.
M71.00135: The Geometric State of a Solid-Solid Interface  THOMAS PILVELAIT (Presenter), School of Engineering and Applied Sciences, Harvard University, SAM DILLAVOU, Physics, Harvard University, SHMUEL RUBINSTEIN, School of Engineering and Applied Sciences, Harvard University — The evolution of a static frictional interface is surprisingly elaborate. It is well known that the frictional strength of a solid-solid interface changes with normal load, but it also evolves in another way: slowly over time, in a process known as ‘aging.’ The effects of aging and a change in normal load on an interface are traditionally seen as unimportant, if they are assumed to exist at all. In a glass-silicone rubber interface, we hold the real area of contact constant over time and demonstrate the existence of differences between these two types of evolution as well as their dependence on contact geometry. This suggests that a frictional interface cannot be fully described by the real area of contact, or any such instantaneous variable, as different configurations of the same interface could all have the same total real area of contact. As the real area of contact is often used as a proxy for frictional strength, these results have important implications for contemporary models of friction, such as the widely used Rate and State Laws.

M71.00136: Surface Micro Replicas of Self-Assembled Chiral Polymers and Grooves  KYRA FULEIHAN (Presenter), CHRISTOPHER LA FOND, PETR V SHIBAEV, ANTHONY GRAY, BENJAMIN SCHUTSKY, MEGHAN EVANS, Fordham University — Transparent polymer replicas of different surface patterns appearing on chiral surfaces and gratings are created and studied at nanoscale by atomic force microscopy (AFM), infra-red (IR) spectroscopy and optical methods. Replicated polymers were represented by chiral cholesteric glassy materials with focal conic domains [1] and isotropic networks with grooved surfaces. Polymer replicas were successfully prepared from different types of glassy polymers by direct deposition from either solution or melt, creating novel opportunities for designing novel nanostructures. Different methods of replica preparation employed and optimal strategies leading to the most effective transfer of chiral surface patterns and grooves were developed and discussed. Studies of light scattering and reflection from polymer replicas were conducted in order to evaluate their suitability for subsequent metallization and design of optical metamaterials.

[1] Surface reconstruction of chiral glassy oligomers under the action of volatile organic compounds (VOCs)

M71.00137: Interactions and Competitive Adsorption at Solid/Liquid Interface

NITYANSHU KUMAR (Presenter), SUKHMANJOT KAUR, Univ of Akron, RAJAT KUMAR, Biomedical Engineering, Stony Brook University, SARANSHU SINGLA, MICHAEL C WILSON, SELEMON BEKELE, MESFIN TSIGE, ALI N DHINOJWALA, Univ of Akron — Broadness in vibrational spectrum is usually associated with heterogeneity of surrounding environment. At solid/liquid interface, surface-sensitive sum-frequency generation spectroscopy (SFG) has shown wide distributions of frequency shifts of sapphire surface hydroxyl groups with several liquids in contact. Even though the shifts were associated with the interfacial interactions, the origin of variation and a physical picture of interfacial interactions are elusive in experiments. To better understand the interfacial interactions, we perform molecular dynamics (MD) simulations of liquid molecules (acetone, chloroform, and dimethylformamide) in contact with sapphire. The energy distribution profiles from MD correlate well with the experimental SFG spectra, highlighting the ability to interpret spectroscopic features with the physical insights gained from MD simulations. Further, we use MD simulations to gain insights into the preferential adsorption of acetone from acetone-chloroform binary mixtures on sapphire. The current study paves the way for the theoretical understanding of adsorption, which can benefit the development of new technologies in adhesion, coatings, and medicine.

*We acknowledge financial support from NSF (partly by NSF-CHE 1506275 and NSF DMR-1610483).

M71.00138: Nanoparticles as Universal Adhesives

RYAN SAYKO (Presenter), University of Akron, ZHEN CAO, MIT, HEYI LIANG, ANDREY DOBRYNIN, University of Akron — Nanoparticles are shown to be able to act as effective adhesives capable of binding two soft materials together. We performed coarse-grained molecular dynamics simulations to study contact mechanics of hard and soft nanoparticles at the interfaces between two elastic surfaces. Our simulations have shown that a nanoparticle at the interface between two elastic substrates could be in a bridging or Pickering state. The degree of penetration of a nanoparticle into a substrate is shown to be determined by nanoparticle size, strength of nanoparticle-substrate interactions and nanoparticle and substrate elastic properties. Using the Weighted Histogram Analysis Method, we calculated the potential of mean force for separation of two substrates which interface was reinforced by deformable nanoparticles. These simulations show that interface reinforcement is a function of nanoparticle size and elastic modulus. In particular we have shown that the softest nanoparticles are most effective in interface reinforcement demonstrating about eight times increase in the work of adhesion.
M71.00139: Does Flexoelectricity Drive Triboelectricity?*  CHRISTOPHER MIZZI (Presenter), ALEX Y.W. LIN, LAURENCE D. MARKS, Northwestern University — Since the first reports of friction-induced static electricity in 600 B.C., the phenomenon of triboelectricity has fascinated, and perplexed, generations of scientists. While much progress has been made in the ensuing centuries regarding the nature and identification of charged species transferred during tribocharging, a universal thermodynamic driver for charge transfer has not been found. We identify flexoelectric potential differences induced by inhomogeneous strains at nanoscale asperities as the thermodynamic driver for tribocharge separation [PRL 123, 116103 (2019)]. Using single asperity elastic contact models, we show that nanoscale flexoelectric potential differences of 1–10 V or larger arise during indentation and pull-off. Importantly, we also demonstrate our model agrees with several experimental observations including bipolar charging during stick slip, inhomogeneous tribocharge patterns, charging between similar materials, and surface charge density measurements.

M71.00140: Unravelling the Behaviour of Brush Block Nanocomposites at Ultrahigh Strain Rates*  SRAVYA NUGURI (Presenter), ANURAAG GANGINERI PADMANABAN, JAE-HWANG LEE, JAMES J WATKINS, Univ of Mass - Amherst — Poly(tert-butyl acrylate)-block-polyethylene oxide (PtBA-b-PEO) brush block (BB) copolymers offer rapid self-assembly kinetics and ready access to long-range order. Taking advantage of cooperative self-assembly using hydrogen bonding additives, we incorporate phenol formaldehyde (Resol) resins into the PEO block to create a crosslinked network, and thus enable formation of alternating soft (PtBA) and hard (Resol crosslinked) multi-layered films. We then explore ultrahigh strain rate behaviour (>10^6 s^{-1}) of these BB nanocomposites films using Laser Induced Projectile Impact Test (LIPIT). Rigid spherical alumina particles of 15-25 µm in diameter are accelerated towards these composites with velocities ranging from 50 to 450 m/s and the corresponding impact and residual flight paths are captured by ultrafast stroboscopic imaging with exposure times of less than 1 ps. We analyse the change in kinetic energies, the deformation depth as measured by profilometry, and scanning electron microscopy images to interpret real-time deformation propagation across the BB nanocomposite.

*This work is supported by the Army Research Lab.
M71.00141: Guided Design of Strain-Adaptive Polymer Networks*  HEYI LIANG (Presenter), ANDREY DOBRYNIN, Univ of Akron, MOHAMMAD VATANKHAH-VARNOSFADERANI, ANDREW N. KEITH, SERGEI SHEIKO, Department of Chemistry, University of North Carolina at Chapel Hill — Mimicking the mechanical behavior of biological tissues is crucial for medical implants and wearable electronic devices. Many biological tissues are supersoft at small deformations (Young's Modulus $E_0<10$ kPa) and stiffens as deformation increases. This combination of softness and nonlinear elasticity cannot be duplicated by synthetic elastomers composed of linear polymers. Graft polymers (combs or bottlebrushes), consisting of linear backbones with grafted side chains, endow polymeric materials with diluted backbone entanglements and backbones pre-stretching due to steric repulsions between side chains. These distinct features pave the way for the design of supersoft materials with controllable nonlinear elasticity. Such materials can be prepared by chemical crosslinking of graft polymers or by self-assembly of linear-bottlebrush-linear triblock copolymers. We have developed a design strategy to encode the nonlinear mechanical response of soft materials through the architecture of graft polymer networks by changing the strand length, side chain length, side chains grafting density and block lengths. Materials replicas of jellyfish, artery and skin tissues based on poly(dimethylsiloxane) bottlebrushes were synthesized to verify the design approach.

M71.00142: A Comparative Study of Hydrogen Bond Organization between Hyperbranched Polymers and Dendrimers Based on bis-MPA*  BEIBEI CHEN (Presenter), SAMANTHA DAYMON, MALIHA N. SYED, Univ of Southern Mississippi, OLUWAPELUMI KAREEM, MCKENNA REDDING, Tulane University, BRIAN OLSON, Univ of Southern Mississippi, SCOTT M GRAYSON, Tulane University, SERGEI NAZARENKO, Univ of Southern Mississippi — Physical properties hyperbranched polymers (HBPs) based on 2,2-bis(hydroxymethyl) propionic acid (bis-MPA), which have been widely studied, are largely determined by the hydrogen bonds (H-bonds). However, similar studies have not yet been extended to bis-MPA based dendrimers which require considerable synthetic efforts. In this study, hydrogen bond organization and interrelated structural order formation of a bis-MPA based second-generation dendrimer (D2) were investigated in comparison with its HBP analogue (HBP2). WAXS spectra of both polymers showed similar structural ordering originated from clustering of multiple hydroxyl groups mediated via H-bonds. MD simulations well predicted the WAXS spectra and revealed ‘chain-like’ clusters of different lengths from single H-bond associations to clusters containing tens of hydroxyls. D2 showed higher propensity of forming long clusters than HBP2 indicating terminal hydroxyls are more capable of forming long associations than linear ones. Meanwhile, an additional narrow peak which superimposed on the amorphous halo was only observed on the WAXS spectra of HBP2. The origin of this narrow peak was assigned to a pseudo-hexagonal mesophase formed by linear chain segments.

M71.00143: Unusual Protein Adsorption Phenomena on Ultrathin Homopolymer Films
YUTO KOGA (Presenter), Cornell University, YASHASVI BAJAJ, DANIEL SALATTO, ZHIXING HUANG, Stony Brook University, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, DMYTRO NYKYPANCHUK, Brookhaven National Laboratory, MAYA ENDOH, TAD KOGA, Stony Brook University — Recently, we designed a new anti-fouling polymer nanolayer of a few nanometer-thick composed of non-charged homopolymer chains physically adsorbed onto a solid [1]. Interestingly, the anti-fouling property of this polymer nanolayer emerged regardless of the degree of hydrophilicity of the polymers against a model protein (bovine serum albumin (BSA). However, it was observed that 50 nm-thick spin-cast thin films composed of the same homopolymers showed BSA adsorption. To shed light on the anti-fouling/fouling switching between the nanolayer and thin film, BSA adsorption was studied on a series of ultrathin films of different thicknesses (2-200 nm in thickness) using polystyrene, poly(2-vinyl pyridine), polybutadiene, poly(methyl methacrylate), and polypropylene. Additionally, we examined the adsorption behavior of another protein, Fibrinogen, to see generality/differences in the anti-fouling/fouling switching. To quantify the protein adsorption, photon counting spectrofluorometry along with the fluorescence-labeled proteins was utilized. We will discuss the universal anti-fouling/fouling switching as a function of film thickness regardless of the polymer and protein choice.

M71.00144: Unravelling the mechanism behind adhesion failure events at the polymer-solid interfaces
ZHIXING HUANG (Presenter), DANIEL SALATTO, JUSTIN CHEUNG, MAYA ENDOH, TAD KOGA, State Univ of NY - Stony Brook — Polymer thin films on solid substrates play a crucial role in nanocomposite materials as well as protective industrial coatings. In particular, polymethylpentene (PMP) has been reported to have a wide array of very promising properties such as high heat tolerance (melting point of 220°C) and resistance to a variety of both inorganic and organic chemicals and materials. In this presentation, we chose PMP thin films on a weakly attractive silicon substrates as a rational model to understand the mechanism of adhesion failure at the solid interface. We will discuss the critical role of a physically adsorbed polymer layer (“adsorbed nanolayer“) at the polymer-substrate interface in the adhesion failure event.
M71.00145: Phase behavior of disk-coil block copolymers under cylindrical confinement: Curvature-induced structural frustrations*  MIN YOUNG HA (Presenter), Seoul Natl Univ, YONGJOO KIM, Korea Advanced Institute of Science and Technology, WON BO LEE, Seoul Natl Univ — We explore the self-assembly of disk-coil block copolymers (BCPs) confined within a cylinder using molecular dynamics simulations. We obtained concentric lamellar structures with a different number of alternating disk-rich and coil-rich bilayers as a function of the cylinder diameter and coil length. Our study focuses on the curvature-induced structural behavior in the disk-rich domain after self-assembly, investigated by local density distribution $P(r)$ and orientational distribution $G(r, \theta)$. In the inner layers of the cylinder-confined system, both $P(r)$ and $G(r, \theta)$ show characteristic asymmetry within a bilayer, directly contrasted to its bulk and slab-confined counterparts. We successfully attribute the curvature-induced structural behavior of disks to (1) packing frustration of disks, and (2) asymmetric stretching of coils to regions with different curvatures of a bilayer. Our results are important to understand the self-assembly of BCPs containing rigid motif in confinement, such as the self-assembly of bacteriochlorophyll confined by lipid layer to form a chlorosome, the photosynthetic antennae complex found in nature.

*This research was supported by National Research Foundation of Korea (NRF) Grants funded by Korean Government (NRF-2015R1A5A1036133, NRF-2017R1A6A3A04009006).

M71.00146: Disordered Assemblies of Rubber Bands as a Model of Polymer Rings  NICOLAS GARCIA (Presenter), Institut Laue-Langevin, 71 Avenue des Martyrs, 38042 Grenoble, France, LEOPOLDO R GOMEZ, Department of Physics, UNS - IFISUR - CONICET, Bahía Blanca, Argentina, THORSTEN POESCHEL, MSS, Friedrich-Alexander Universität Erlangen-Nürnberg, Germany — A comprehensive understanding of the packing structure of dense assemblies of semiflexible rings is not only fundamental for the dynamical description of polymer rings but also key to understand biopackaging, such as observed in the circular DNA of viruses or genome folding.

In this work, we use X-ray tomography to study disordered packings of rubber bands in a cylindrical container as a simple model of semiflexible polymer rings. Using advanced computational tools, we study the geometrical and topological features of disordered packings of rubber bands at a single ring-level. The degree of entanglement in the structures is quantified through minimal surfaces and generalized Voronoi tessellations. We found that assemblies of short bands assume a liquid-like disordered structure, with short-range orientational order, revealing a minor influence of the container. In the case of longer bands, the confinement causes folded configurations, and the bands interpenetrate and entangle. Most of the systems are found to display a threading network that percolates the system. Surprisingly, for long bands whose diameter doubles the diameter of the container, we observe that all bands interpenetrate each other in a complex fully-entangled structure.
M71.00147: Multiple arms star polymer translocation from a cylindrical cavity subject to a pulling force  MESAY TILAHUN ABEBE, YERGOU TATEK (Presenter), Addis Ababa Univ — A Langevin dynamics computer simulation is used to investigate the dynamics of star polymer translocation from a cylindrical cavity (tube), which is connected to a plane wall having a circular nanopore along the tube axis. Star polymers of different masses and number of arms or functionalities are considered in the present study. The translocation is carried out by applying an external pulling force which is exerted only on the end monomer of one arm. For a strong pulling force regime and for a given functionality, the translocation time exhibits a power law dependence on the polymer mass where the exponent is found to be close to 2. We have also found that the translocation dynamics of chains of constant mass but varying functionality is significantly affected by the pore radius. For wider pores, the translocation time decreases continuously as the number of arms increases, while in the case of smaller pores, the average exit time shows a non-monotonic behavior with a minimum around a critical functionality $f_c$. In addition, the translocation dynamics was also investigated in terms of tube length and tube aspect ratio.

M71.00148: The Cononsolvency Effects: A Coarse Grained Simulation Study  JING ZONG (Presenter), DONG MENG, Mississippi State Univ — One puzzling phenomenon about polymer conformations in a mixture of solvents is the cononsolvency effect -- polymers in a good solvent undergo reentrant coil-to-globule-to-coil transition upon addition of a good cosolvent. Recent studies have suggested the generic nature of the cononsolvency effect independent of chemically specific details of the polymer and solvents. In this study, we first reinforce such claim by showing that a coarse-grained soft model frequently used in studying polymers is able to reproduce the reentrant transition at the single-chain level, provided that solvents are treated explicitly. In our Monte Carlo simulations, the coil-to-globule-to-coil transition occurs as the chemical potential of polymers in solution decreases upon increasing the cosolvent fraction, ruling out increasingly worse solvent quality as the cause of collapse. To further our microscopic understanding, we apply the soft model to studying conformational responses of surface-grafted polymers under the cononsolvency effect. By analyzing the inter-polymer density correlations, we illustrate the highly correlated nature of polymer clustering mediated by the cosolvents. Conformational responses of high grafting density brushes will also be discussed in the context of smart sensor surfaces.
M71.00149: Detection of Hip Infections Using an Injectable Hydrogel Based Synovial Fluid pH Sensor*  SACHINDRA KIRIDENA (Presenter), UTHPALA WIJAYARATNA, MD. ARIFUZZAMAN, JEFFREY N. ANKER, Clemson University — A hydrogel-based sensor was developed which could be attached to prosthetic hips prior to implantation, to measure pH in the joint fluid in order to detect, monitor, and study infection. A common complication of hip surgeries are post-surgery infections. Delayed diagnosis would lead to reduced function, increased morbidity and may require more complex surgeries. Therefore, early detection of infections is important for successful management of hip infections. In order to detect infection biomarkers, the joint is aspirated and the synovial fluid is analyzed. However, joint aspiration performed by a radiologist under fluoroscopy or ultrasound guidance is painful and is impractical for routine screening or serial monitoring during treatment. The developed synovial fluid sensor provides a method of early detection and monitoring of hip infections using plain radiography. The sensor is made of a pH responsive polyacrylic acid-based hydrogel and the response was determined from the radiograph by measuring the position of a radio-dense tantalum bead embedded in the hydrogel. Thus, the developed sensor could be used as a potential X-ray imaging functional chemical sensor.

M71.00150: WITHDRAWN ABSTRACT —

M71.00151: Shape-Switchable Block Copolymer Particles Exhibiting Light-Responsive Surfactants  KANG HEE KU, MIT, JUNHYUK LEE, YOUNG JUN LEE (Presenter), BUMJOON KIM, KAIST — Particles capable of changing their shape in response to external light irradiation may serve as promising bio-inspired, smart materials for clinical and biomedical applications due to their remarkable spatial/temporal resolution. Herein, we report polystyrene-block-poly(2-vinylpyridine) (PS-b-P2VP) block copolymer (BCP) particles exhibiting shape and morphological transition induced by light irradiation. Key of forming light-dependent BCP particles is to design surfactants containing light-active groups (i.e., nitrobenzyl ester and coumarin ester), which can light-dependently modulate interfacial activity. With irradiating light, a sphere with onion-like inner morphology changes to prolate or oblate ellipsoids with axially stacked nanostructures. In addition, wavelength-selective shape transformation of BCP particles is achieved by a mixture of two light-active surfactants, which respond to the light with different wavelengths (i.e., 254 and 420 nm). Moreover, we demonstrate the color- and shape-changing particles in response to the light, which can be achieved by the use of light-emitting, photo-responsive surfactants. Finally, we integrate shape-switchable BCP particles into a hydrogel film to demonstrate the modulation of the particle shape in sub-micrometer resolution.
M71.00152: Configurational contribution to the Soret effect of a protein ligand system*  
JUTTA LUETTMER-STRATHMANN (Presenter), Physics and Chemistry, University of Akron — Many of the biological functions of proteins are closely associated with their ability to bind ligands. Since binding state and conformation of a protein affect its response to a temperature gradient, they may be probed with thermophoresis. In recent years, thermophoretic techniques to investigate biomolecular interactions, quantify ligand binding, and probe conformational changes have become established. To develop a better understanding of the mechanisms underlying the thermophoretic behavior of proteins and ligands, we employ a simple, off-lattice model for a protein and ligand in explicit solvent. To investigate the partitioning of the particles in a temperature gradient, we perform Wang-Landau type simulations in a divided simulation box and construct the density of states over a two-dimensional state space. This method gives us access to the entropy and energy of the divided system and allows us to estimate the configurational contribution to the Soret coefficient. For dilute solutions of hydrophobic proteins, we find that a hard-sphere solvent model captures important aspects of protein-ligand interactions and allows us to relate the binding energy to the change in Soret coefficient upon ligand binding.

M71.00153: Packing density, homogeneity, and regularity: quantitative correlations between topology and thermoresponsive morphology of PNIPAM-co-PAA microgel coatings*  
CAMDEN CUTRIGHT (Presenter), North Carolina State University, ZACH BROTHERTON, Chemical Engineering, University of Texas- Austin, JAKE HARRIS, LANDON ALEXANDER, KAIHANG SHI, SAAD KHAN, JAN GENZER, STEFANO MENEGATTI, North Carolina State University — We investigated the formation of monolayers of microgel particles comprising poly[(N-isopropylacrylamide)-co-(acrylic acid)] on solid substrates, their surface morphology, and stimuli-responsiveness. Crosslinked microgels with different composition were produced showing a range of response in swelling with temperature and pH. Microgels were deposited on silicon wafers primed with a bilayer of poly(octadecene-alt-maleic anhydride) and polyethyleneimine. The characterization of the microgel-coated wafers led to the identification of three metrics describing microgel arrangement: density (ρ); heterogeneity (H), which correlates strongly with ρ and depends on deposition temperature and pH; and packing efficiency (PE), which portrays the regularity of microgel arrangement and exhibits no correlation with ρ nor H. The values of ρ, H, and PE calculated for in silico models of microgel coatings confirmed that these three metrics portray distinct characteristics of surface topology. Finally, laser profilometry showed that microgel coatings respond to thermal stimuli with sensible variations in surface roughness; which correlate strongly with ρ and H, and to a lesser extent with PE.

M71.00154: Magnetically Induced Self–Healing in Iron Oxide–Poly(ethylene oxide) Nanocomposites

DONOVAN WEIBLEN (Presenter), SARAH DALAKOS, Materials Science and Engineering, Rensselaer Polytechnic Institute, CHARLOTTE TEUNISSE, Mechanical, Aerospace, and Nuclear Engineering, Rensselaer Polytechnic Institute, VANESSA R SWEPSON, Chemistry and Chemical Biology, Rensselaer Polytechnic Institute, GRACE L GIONTA, Chemical and Biological Engineering, Rensselaer Polytechnic Institute, DENIZ RENDE, Center for Materials, Devices, and Integrated Systems, Rensselaer Polytechnic Institute, RAHMI OZISIK, Materials Science and Engineering, Rensselaer Polytechnic Institute — Current research aims to quantify self-healing capabilities of iron oxide (Fe₃O₄) nanoparticle (NP) infused poly(ethylene oxide) (PEO). Iron oxide NPs of varying surface chemistries (bare, aminopropyl triethoxysilane coated, and polyethylene glycol α–, ω–diphosphate coated) are used to prepare nanocomposites of varying concentrations less than 1% by weight. Each sample, in the form of a cylindrical disc, is indented using a LECO M400 Microindenter at five different locations between the center and edge. The indentation site is examined before and after being placed in an alternate magnetic field (AMF) to induce healing. The micrographs of each indent were collected with an Olympus PMEG microscope at the same imaging parameters. Healing efficiency is quantified using visual and software-based image analysis, identifying the percentage of healing as a function nanoparticle concentration and surface chemistry. Multiple methods of software-based image analysis were developed to perform this analysis. Nanoindentation experiments were also carried out to evaluate impact of surface coating and concentration on mechanical properties and viscoelastic behavior of these nanocomposites.

*This material is based upon work supported by NSF Grant 1825254.

M71.00155: Tuning Diblock Copolymer Morphologies by Stimuli-Responsive Supramolecular Interactions

XIANGYU ZHANG (Presenter), JING ZONG, DONG MENG, Mississippi State Univ — Ability to tune the microstructures formed by block copolymers via easy-to-use physical approaches offers additional handles to the materials for practical applications. One common approach is through adding homopolymers, which induces morphological changes due to preferential partitioning of homopolymers into specific micro-domains. Recently, supramolecular forces that are chemistry-specific and stimuli-responsive have been exploited to enable stimuli-switchable morphologies. To offer microscopic insights into this process, here we present a simulation study of diblock copolymers blended with homopolymers that are associative to one of the blocks through supramolecular forces. By manipulating the manner of associations, we investigate structural changes induced by supramolecular complexations, and to elucidate the differences from the counterpart van der Waals (VDW) force-driven systems. It is found that the homopolymer-receiving microdomain exhibits non-monotonic size changes accompanied by cluster formation as preferential partitioning occurs. Dynamics analysis suggests that both morphologies and supramolecular binding kinetics exert significant influence on the diffusion of homopolymers across the microdomains, implicative of the extent of “responsiveness” of such materials.
**M71.00156: Water Dynamics and Poly(N-isopropyl acrylamide) Co-nonsolvency in Water-Methanol Solutions at Variable Temperature and Pressure**

BART-JAN NIEBUUR, Physics Department, Technical University of Munich, WIEBKE LOHSTROH, Heinz Maier-Leibnitz Zentrum (MLZ), TU Munich, CHIA-HSIN KO, Physics Department, Technical University of Munich, MARIE-SOUSAI APPAVOU, Jülich Centre for Neutron Science at MLZ, TU Munich, ALFONS SCHULTE (Presenter), Physics Department, Univ of Central Florida, CHRISTINE PAPADAKIS, Physics Department, Technical University of Munich — The phase behavior of 25 % poly(N-isopropyl acrylamide) (PNIPAM) in a 80:20 v/v water methanol mixture is investigated by quasi-elastic neutron scattering (QENS) and Raman spectroscopy at variable temperature and pressure with focus on the co-nonsolvency effect. The susceptibility spectra span the frequency range from 2 GHz to 2 THz at momentum transfers between 0.2 to 1.7 Å⁻¹ and reveal the relaxation peak of the hydration water near 10 GHz, in addition to the known processes of bulk water. The solvent phase is enriched with methanol at high pressure, implying that water is preferentially adsorbed at the chains. The exchange of methanol with water takes place mainly at the hydrophilic Amide groups of PNIPAM. The hydrophobic hydration of alkyl groups in the side chain and the backbone of the polymer in the presence of methanol is reduced at ambient and high pressure. In the two-phase region the preferential adsorption of water at the chains is diminished.

**M71.00157: Phase behavior and self-assembly of liquid-crystalline block copolymers in nematic solvents**

CHANGYEON LEE (Presenter), University of Pennsylvania, DENNIS NDAYA, REUBEN BOSIRE, RAJESWARI M. KASI, University of Connecticut, CHINEDUM OSUJI, University of Pennsylvania — Block copolymers (BCP) are an attractive class of materials that can be utilized for active/stimuli-responsive/adaptive materials. The performance of BCPs in various target applications largely relies on their controlled, long-range assembly with high fidelity. In this context, liquid-crystalline BCP (LC BCP) is a compelling material platform because of its ability to control the directional and positional arrangement by leveraging the nature of the LC block. While ranging successful examples have been showcased using LC BCPs in recent years, one may envision that incorporating LC BCPs into other material systems can be the next step forward to open up new possibilities for formulating multi-functional materials. However, neither the fundamental studies on these blend systems nor their useful functionality has been rarely reported thus far. Here, we present the phase behavior and self-assembly of LC BCPs in the blends with other LC materials such as labile mesogens and lamellae-forming block molecules. We demonstrate that LC BCPs are co-assembled with other LC materials with preserving or shifting their original phases as a function of the composition. It is also demonstrated that the blended LC materials can be aligned uniaxially under the magnetic-field.
M71.00158: Toward molecular modeling of ductility and drawablity of semi-crystalline polymers*  

MASOUD RAZAVI (Presenter), SHIQING WANG, Univ of Akron — We contrast the mechanical responses of different crystallizable polymers such as PLA, PET, PA and PS in their respective amorphous and semicrystalline states using uniaxial extension and compression at varying temperatures below and above $T_g$. Coherent phenomenology will be presented in terms of the stress response to ongoing deformation, stress relaxation behavior from both preyield and postyield, creep and real-time POM images, aiming to develop a detailed understanding of the mechanical/structural interactions between amorphous and crystalline regions. Through these experiments, we expect to gain more insights regarding the molecular mechanisms for ductility ($T < T_g$)/drawability ($T > T_g$) and effective strategies to avoid brittleness/non-drawability.

*This work is supported by NSF (DMR-1905870) and ACS PRF# 60897-ND7.

M71.00159: Probing the Impact of Polymer Hydrophobicity on Solution and Hydrated Surface Conformation*  

AUDRA DESTEFANO (Presenter), SALLY JIAO, Chemical Engineering, University of California, Santa Barbara, MIKAYLA BARRY, SEGOLENE ANTOINE, Materials, University of California, Santa Barbara, TIMOTHY KELLER, Chemistry, University of California, Santa Barbara, SCOTT SHELL, Chemical Engineering, University of California, Santa Barbara, SONGI HAN, Chemistry, University of California, Santa Barbara, RACHEL A SEGALMAN, Chemical Engineering, University of California, Santa Barbara — Sequence controlled polypeptoids provide a valueable platform for systematic study of molecular level changes in polymer patterning and chemistry; however limitations in our understanding of sequence effects on polymer conformation and challenges in modeling polypeptoids persist. In this work, distributions of end-to-end distances calculated with molecular dynamics (MD) simulations are compared to those obtained experimentally via Double Electron Electron Resonance (DEER) spectroscopy. This pulsed electron paramagnetic resonance technique determines a distribution of distances between spin labels placed at each end of a polymer chain, providing insight on sequence-conformation relationships and validation of existing simulation force fields. Together, MD and DEER provide a methodology for understanding the impact of polymer sequence and chemistry on polymer conformation as well as confidence in MD prediction of other properties, such as local hydration dynamics at polymer surfaces.

*This work was supported as part of the Center for Materials for Water and Energy Systems (M-WET), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #DE-SC0019272.
M71.00160: Unfolding of Polymer Thin Films on Liquid Surfaces*  R. KONANE BAY (Presenter), Polymer Science and Engineering, University of Massachusetts Amherst, KLARA ZARYBNICKA, JOSEF JANCAR, Brno University of Technology, ALFRED J CROSBY, Polymer Science and Engineering, University of Massachusetts Amherst — Ultrathin polymer films are difficult to handle. Liquid support layers are often used to ease the manipulation of these films. However, removing the film from the liquid support leads to the fluid draining from the interface, and without the liquid, the polymer interface adheres to itself, forming a crumpled film. The polymer thin film will remain crumpled or tear due to the adhesion forces being higher than the strength of the film. Here, we report a processing method to allow for reversible folding and unfolding of ultrathin polymer films from liquid surfaces. We explain the folding and unfolding mechanism through tuning the surface interactions at the polymer-liquid interface. We demonstrate the ability to fold and unfold several types of polymer thin films on different liquid surfaces.

M71.00161: Polymers in confinement: Free energy scaling and folding transitions*  MARK TAYLOR (Presenter), ANTONIA SIKON, TROY PRUNTY, Dept. of Physics, Hiram College — Geometric confinement of a polymer chain results in loss of conformational entropy. For an athermal polymer the associated free energy increase is expected to exhibit power law scaling with an exponent that depends on confinement dimensionality. For a chain that can fold into a compact native state, confinement primarily reduces the number of possible unfolded states, thereby providing entropic stabilization of the folded state and allowing for the possibility of confinement driven folding [1]. Here we investigate these confinement effects for flexible hard-sphere (HS) and square-well (SW) sphere chains (where the latter exhibit all-or-none folding characteristic of many small proteins [2]). We use a Wang-Landau simulation approach to construct the partition function for a polymer confined within a hard-wall slit, a cylindrical pore, and both a cylindrical and spherical cavity. Scaling analysis of the HS-chains shows significant finite size effects. For the confined SW-chain, isothermal reduction of the confinement dimension can induce folding, unfolding, or crystallite restructuring. Scaling results and phase diagrams will be presented. M71.00162: Tunable Assembling of Soft Polymer Janus Nanoparticle at Liquid Interface*
YUFENG JIANG (Presenter), University of California, Berkeley, RAMZI CHAKROUN, ANDRÉ GRÖSCHEL, Physical Chemistry and Center for Nanointegration (CENIDE), University of Duisburg Essen, THOMAS RUSSELL, Polymer Science and Engineering, University of Massachusetts Amherst — We present a study on the assembly of polymeric Janus nanoparticles (pJNPs) at the toluene/water interface. The soft spherical polymeric Janus nanoparticles pJNPs, made by cross-linking polystyrene-block-polybutadiene-block-poly(methyl methacrylate) (PS-PB-PMMA), show a high interfacial activity where the preferential affinity of the PMMA to the aqueous phase causes a spreading of the PMMA block at the interface, even though neither component is soluble in water. The Janus character is later tailored by substituting the PMMA domain to poly-tert-butylmethacrylate (PtBMA) or poly(methacrylic acid)(PMAA) to probe the influence of Janus balance (solvophilic-to-solvophobic balance) to areal density of assemblies of JNPs at the liquid interface and the response of the assemblies to a compression. We investigated the influence of structural asymmetry of JNPs on the assembly, packing, stability and responsiveness of pJNP assemblies by varying the PS-to-PB-to-PMMA ratio. We demonstrate the potential of structure one liquid structure in another by using JNPs complex with salt at liquid interface to obtain bi-continuous liquids.

M71.00163: Mussel inspired polymers for flexible electronics applications*
ELENI PAPANANOU (Presenter), University of California, Santa Barbara, REIKA KATSUMATA, polymer science and engineering, university of massachusetts amherst, RUBAYN GOH, University of California, Santa Barbara, FENG LIU, MINGQI LI, PETER TREFONAS, Electronic Materials, Dupont, RACHEL A SEGALMAN, University of California, Santa Barbara — Electroless plating of solid metals from a solution onto a catalytically active surface has been widely used in the printed circuit board industry for production of wiring layers and inter-layer (via) connections. Smooth substrate surfaces, like polyimide (PI) for flexible electronics applications, are particularly challenging as the electrolessly plated metal tends not to adhere to the surface. It is therefore desirable to develop new chemistries that can be used for adhesion promotion between the polyimide substrate and the deposited copper. Herein, we introduce a mussel-inspired universal adhesive moiety, dopamine, as a side group to a water soluble polymer backbone and demonstrate its application as an adhesion promotion layer for electroless plating of flexible substrates. When the polymer is deposited on a substrate surface, the DOPA moiety reacts with the substrate and adheres to it while the polymer chain extends and folds to generate a smoother outer surface through minimizing the surface energy, creating a smooth and uniform coat of deposited copper.

*Dupont Electronic Materials University Partnership Initiative
M71.00164: Study of a passive enhancement architecture for FRET-enabled molecular communication.*  MATTHEW HAWKINS (Presenter), HEMALI P RATHNAYAKE, JOSEPH M STAROBIN, Univ of NC - Greensboro — Nanomachine technology has advanced by improving complexity and function yet, their future value relies upon superior control and communication; this requires reliable and highly efficient networks. Data transfer techniques of global networks are not scalable for nanomachines, and thus a different approach is needed. Non-radiative energy transfer offers high efficiency, localized, and rapid signal transfer: Förster Resonant Energy Transfer is one of such promising paradigms. Application of light-induced FRET, by combining donor/acceptor pairs with a nanostructure architecture, creates nanosecond signaling data transfer to highly specified locations. Developed through novel, arene-based, donor/acceptor moieties - integrated into a thin-film device designed for signal enhancement - a theoretical and experimental approach has been developed and implemented for tuning scattered excitation energy for increased absorption by the donor for higher energy transfer to the acceptor. This architecture results in increased energy transfer and overall higher output of acceptor emission passively increasing the signaling performance and feasibility of application to molecular communication.

M71.00165: Charge density gradients of polyelectrolyte thin films generated by diffusion and reaction in the vapor phase  YEONGUN KO (Presenter), JAN GENZER, North Carolina State University — We present fabrication and characterization of charge density gradients on polymeric thin films. Tertiary amines in poly(2-dimethylaminoethyl methacrylate) (PDMAEMA) thin films were quaternized with methyl iodide (MI) through vapor phase diffusion and reaction. The quaternized PDMAEMA (qPDMAEMA), a strong polyelectrolyte, bears permanent charges. The degree of quaternization (DQ) was characterized by FT-IR spectra as well as a refractive index from ellipsometry at elevated temperature to minimize moisture uptake. The resulting films have position-dependent gradients of charge density. The gradient location on the sample depends on process time and concentration of MI. We discovered that the diffusion of MI through air is the rate-limiting step for the entire process. The vapor phase reaction allows for creating charge density gradients in both grafted PDMAEMA brushes and non-grafted PDMAEMA films. In addition, we also evaluated the coefficient of thermal expansion (CTE) and thermo-optic coefficient (TOC) as a function of DQ and showed their linear relationship.
M71.00166: Spontaneous degrafting of weak and strong polycationic brushes in aqueous buffer solutions  JAN GENZER (Presenter), YEONGUN KO, North Carolina State University, YUANCHAO LI, Sun Yat-Sen University — Polymers grafted to substrates have usually been considered to be stable because of the covalent bonds that anchor the macromolecules to the substrate. Several recent reports have reported on degrafting polymers from substrates under specific conditions. We have conducted a systematic study of degrafting polycationic brushes with different degrees of quaternization (DQ), molecular weight, grafting density, which have been incubated in buffer solutions (pH 4, 7.4, and 9) with the same ionic strength (0.05 M). We also explored the effect of the bonding environment at the anchoring point of the polymer graft on the overall stability of polymer assemblies on the substrate. The major findings in this study are: 1) Degrafting of polycationic grafts from flat silica substrate increases with increasing DQ of the polymer, 2) Polymer degrafting likely occurs both in the initiator ester group and the silane head-group at the silicon substrate, 3) The degrafting kinetics can be described by time-dependent rate constant modeled by stretched exponential function.

M71.00167: Structure of Irreversibly Adsorbed Star Polymer Layers*  GIZEM KIREVIYASI (Presenter), Department of Chemistry, Bogazici University, DAVID UHRIG, KUNLUN HONG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, BULENT AKGUN, Department of Chemistry, Bogazici University — Viscosity, glass-transition temperature, and diffusivity of polymer chains in thin films deviate from bulk values due to the presence of adsorbed polymer chains on the substrate. The structure of irreversibly adsorbed layers (IALs) formed by linear chains has been extensively investigated and found to be composed of two layers: high density inner layer in which chains are flattened and bulk-like density outer layer in which chains adopted more tail and loop conformations. However, the role of chain branching on the structure of adsorbed layer is not clear.

Well-defined linear polystyrene (PS), 4-arm and 8-arm star PS chains with the same total molecular weight, and 8-arm star PS with different molecular weights are used to elucidate the effect of polymer architecture on the structure of IAL by ellipsometry, X-ray reflectivity (XR) and atomic force microscopy measurements. Our results indicated that the normalized layer thickness increases as the number of arms increases and arm length decreases on both SiOₓ and Si-H surfaces. Adsorbed star polymers formed thicker layers on Si-H surfaces compared to SiOₓ surfaces. Adsorbed layer thickness is found to be a function of initial film thickness up to 100 nm.

M71.00168: Visualization of interface effect on the molecular morphology in block copolymer thin films by SVSEM tomography  AMANDA SUAREZ (Presenter), XUEYAN FENG, EDWIN THOMAS, Rice University — Applications of block copolymer thin films include their use in lithography, photonics and biomedical devices, and is in large part, due to their internal nanostructures. Thin films are particularly sensitive to surface confinement effects, which on one hand enriches the molecular assembly while on the other hand can produce distortions of the structure from thermodynamically stable symmetries. Here, we study polystyrene-b-poly(2-vinylpyridine) thin films with different microdomain morphologies (double gyroid, lamella, disordered network). By applying Slice-and-View scanning electron microscopy (SVSEM) tomography, the domain structures, distortions, and defects within the polymer films can be measured over large areas/volumes and the influence of the field of the interface (substrate/film and film/air) on the molecular assembly morphologies examined.

M71.00169: Universal cohesive law governing interaction between nanoparticles in hairy nanoparticle assemblies*  NITIN HANSOGE (Presenter), AGAM GUPTA, SINAN KETEN, Northwestern University — Polymer-grafted nanoparticle assemblies have significant advantages over traditional nanocomposites as they overcome the dispersion issues, attain high structural order and allow accurate tailoring of mechanical properties. Modeling these assemblies using atomistic or even coarse-grained molecular dynamics simulations is quite challenging due to spatiotemporal limitations. To overcome this challenge, in this work, we develop a universal cohesive law that governs the interaction between nanoparticles in these assemblies. This effective interatomic potential is based on the strain energy density between two nanoparticles modeled as plates. We find that the potential consists of empirical constants dependent on polymer fragility, molecular weight and grafting density. Using these design parameters, we were able to collapse all the strain energy curves into a universal curve governing the interaction between nanoparticles. By eliminating the need to explicitly model polymer beads, we can simulate micron scale systems of these hairy nanoparticle assemblies without the loss of underlying physics.

**M71.00170: Recyclable Bio-based Thermoset Furan-Epoxy Networks via Diels-Alder Crosslinks**

LUC LE (Presenter), KARL JACOB, KYRIAKI KALAITZIDOU, Georgia Inst of Tech — Strong and lightweight thermoset polymeric can be used for many structural applications. However, thermoset materials may cause significant environmental problems since many of such materials cannot be recycled and have to be stored in landfills. Thus, thermoset that can be recycled, or even renewed will have a substantial impact on reducing the adverse environmental impact of such materials. Renewable polymer composite is a promising path for reducing environmental pollution while improving the sustainability of such materials for the long future. By introducing the thermo-reversible covalent bonds in the molecular network, the thermoset material can be reprocessed upon a suitable thermal trigger. One of the most effective reversible covalent bonds is the Diels Alder (DA) bond between furan and maleimide because of its relatively fast kinetics and mild reaction conditions. In this work, the reversible DA networks were prepared from bio-based furan grafting on epoxy and maleimides crosslinkers of different structures. The kinetics and thermodynamics properties of the dynamic network were studied following the evolution of structure formation and dissociation.

**M71.00172: Ordering kinetics and steady state in Active Nematic with quenched disorder**

SAMEER KUMAR (Presenter), SHARDHA MISHRA, Indian Institute of Technology (BHU) —

A finite disorder in an active liquid crystal has a significant effect on the ordering dynamics and the steady-state. System of self-propelled apolar particles with nematic interaction is one of the way to understand the defect topology and their dynamics in an active liquid crystal and hence, the ordering kinetics in the system. We construct a two-dimensional monolayer of self-propelled apolar particles with the quenched inhomogeneous field. We write hydrodynamic equations of motion for the hydrodynamics fields, viz. density $\rho$ and orientation $Q$ in a coarse-grained description with the addition of finite quenched disorder. We found that, although the presence of disorder in the system slows down the ordering dynamics, static and dynamic scaling properties remains the same. Our study will motivate experimentalists to verify results and may find applications in living and artificial systems in the presence of inhomogeneous quenched disorder.

M71.00173: Multicellular Magnetotactic Bacteria under an Applied Magnetic Field Form Active Crystals  ALEJANDRA ROSSELLI (Presenter), ALEXANDER PETROFF, BENJAMIN ROQUE, Clark University — Multicellular Magnetotactic Bacteria (MMB) of the species Magnetoglobus multicellularis live in spherical colonies composed of 10-50 individual bacteria. These bacteria are the known known obligately multicellular bacteria. The colony swims as a single unit parallel to the Earth’s magnetic field. When a magnetic field is oriented normal to a glass surface, aggregates accumulate into a monolayer on the glass surface. As the magnitude of magnetic field increases, the density of the colonies increases. At a critical field strength, the mean free path of the colonies shrinks to the radius of a single colony. The colonies display a crystalline packing. Unlike previous examples of active crystals (e.g., with colloids and fast swimming bacteria), these bacteria spontaneously detach and reincorporate into the structure at rates dependent on the strength of the applied field. As a result, active crystals composed of MMB display numerous vacancies. We describe the dynamics is this new state of active matter and compare them to active crystals and active super-critical fluids.

M71.00174: Polar flock with bond disorder*  JAY SINGH (Presenter), Indian Institute of Technology (BHU), SUDIPTA PATTANAYAK, Physics, A.S.N.B.C.B.S Kolkata, SHRADHA MISHRA, Indian Institute of Technology (BHU) — Understanding the collective behaviour of self-propelled particles (SPP’s) is an active area of research. Although collection of SPP’s are made of similar particles. But each individual can differ due to their much details of biological complexity. We focus on difference in interaction ability with neighbours. Hence in this study we introduced a collection of SPP’s interecting through a short range Vicsek type alignment interaction, but strength of alignment is different for different particle and obtained from random distribution. Equalibrium analog of one model is XY-model with bond disorder. we find that presence of such bond disorder, long range ordering (L.R.O) remains unchanged as for clean system. Also ordering kinetics remain uneffected but large disorder.

*I would like to thank MHRD (Govt. of India) and iit bhu for their financial support in this work.
**M71.00175: Measuring Force Fluctuations and Diffusion in Active Baths**

**HUNTER SEYFORTH** (Presenter), **WYLIE AHMED**, **MAURICIO GOMEZ**, California State University, Fullerton — Actively driven systems such as suspensions of active colloids, bacteria, and enzymes have been observed to enhance diffusion at the microscopic scale. Active suspensions also exhibit anomalous mechanical properties that are not observed in typical equilibrium fluids. To investigate the interplay between enhanced diffusion and fluid response we measure fluctuations of forces, motion, and viscosity in active baths composed of actively swimming bacteria. To do so, we use two approaches: (1) Differential Dynamic Microscopy, to analyze motion in the form of image intensity fluctuations to quantify decorrelations of the active suspension. (2) Optical tweezers, to trap suspended colloids and measure the force fluctuation spectrum due to non-equilibrium fluctuations of the active bath. We quantify the space-time correlations and calculate the energy dissipated by non-equilibrium processes to extract information about the system.

**M71.00176: role of annulus confinement on 2D active nematic behaviour**

**ZAHRA ZAREI** (Presenter), **MICHAEL M NORTON**, **CHAITANYA JOSHI**, **MICHAEL HAGAN**, **SETH FRADEN**, Brandeis Univ — Defects play an important role in active-matter systems. They are nucleated because of the bend instability and in steady state are continuously created and annihilated. In this study we investigate a 2D active nematic confined in an annulus, which exhibits a rich dynamical behavior of the plus and minus half defects. The confinement effectively transforms the turbulent dynamics of the active nematic into coherent flow. We measure the positional-orientational distribution of defects in different confinements. We define three different states for the defects based on their positions and orientations, and calculate their transition rates.

*MRSEC*

**M71.00177: Physical Basis for Coordination among Bacterial Cells in a Proto-Multicellular Colony**

**BENJAMIN ROQUE** (Presenter), **ALEXANDER PETROFF**, **ALEJANDRA ROSSELLI**, Clark University — Multi-cellular Magnetotactic Bacteria are the only known obligately multi-cellular bacteria. Cells live within a colony composed of 10-50 cells. Each cell precipitates a magnetic crystal. The average magnetic moment of the colony aligns with the Earth’s magnetic field. The outer surface of each cell is covered in about 30 flagella. Colonies move as a single unit as individual cells in the colony rotate their flagella. It is not understood how cells in a colony align their magnetosomes, how this order is maintained during division, or how cells coordinate their flagella to exert a force parallel to their average magnetic moment. Here, we propose a physical mechanism to show this coordination may arise without direct cell-cell communication. We use published data to show that the organization of the cells in a colony is consistent with a Fibonacci packing. Next, we show that coupling chemotaxis to magnetotaxis allows cells to exert a net force parallel to the average magnetic moment of the colony. These results give insight into the evolution of complex life by showing that cells in a protomulticellular organism may coordinate their behaviors through purely physical mechanisms before the evolution of shared chemical signaling pathways.
M71.00178: Near-surface Motion of Bacteria in Polymer Solutions

DING CAO (Presenter), Chinese Univ of Hong Kong — Many bacteria live on solid-liquid interface and they are surrounded by polymers that naturally exist or excreted by themselves. Polymers may facilitate the formation of biofilm by protecting bacteria from external stress. In addition, the interactions between swimming bacteria, polymer and surface are crucial for dynamic processes of bacteria such as surface attachment and dispersal. Here we will present our preliminary work on how polymers may affect the single cell motion pattern near solid surfaces and assist the spreading of bacterial colony.

*This work was supported by the Research Grants Council of Hong Kong SAR (RGC numbers 2130439, 2130493 and 2130613), and from the National Natural Science Foundation of China (NSFC 21473152).

M71.00179: Evolutionary game theory of sticky motile bacteria

GURDIP UPPAL, DERVIS VURAL (Presenter), University of Notre Dame — Bacteria typically reside in heterogeneous environments with varying nutrition and toxin profiles. Motile cells can gain an advantage over non-motile cells by migrating to more favorable environments. Since motility is energetically costly, cells must optimize their swimming speed and behavior to maximize their fitness. Here we look at how cheating strategies might evolve where slow or non-motile microbes exploit faster ones by sticking together and "hitching a ride." We theoretically and computationally study the effects of sticking on the evolution of run speed in a controlled chemostat environment. We find stickiness allows slow cheaters to dominate only at intermediate distance between nutrition sources. In contrast, for long run durations slow microbes do gain a small advantage from sticking, but only get so far before falling behind; and for short run durations it is best for no one to swim.

M71.00180: Failure propagation in multicellular tissues as mediated by advective flow

GURDIP UPPAL, GOKHAN BAHCECIIOGLU, PINAR ZORLUTUNA, DERVIS VURAL (Presenter), University of Notre Dame — Aging is not just due to the death of cells but due to systemic failures due to the accumulation of malfunctions in a network of interdependent components. Here we experimentally and theoretically study how failure propagates in a synthetic multicellular tissue, as mediated by cooperative factors transported by diffusion as well as advective flow. We first experimentally show that fluid flow induces a reduced death rate upstream. Based on this observation, we then develop a model where cells secrete cooperative factors that enhance their survival which diffuse, decay, and advect in space according to the laws of fluid dynamics. From this model, we derive further predictions for the conditions for which a propagating front of failure should form, and its velocity.

*We Acknowledge National Science Foundation grant CBET-1805157
M71.00181: Aggregation Dynamics of Active Spinning Superparamagnetic Particles in Dense Passive Media  JOSHUA STEIMEL (Presenter), Univ of the Pacific, JUAN ARAGONES, Universidad Autonoma de Madrid, DANIEL MADERA, SAGE MORELAND, Univ of the Pacific, ALFREDO ALEXANDER-KATZ, MIT — Active matter systems exhibit emergent non-equilibrium dynamical phenomenon which is driven by the activity-induced effective interactions between active particles or units. Here we study aggregation dynamics of many active spinning superparamagnetic particles, spinners, embedded in a dense complex 2D colloidal monolayer of passive particles. Utilizing coarse grained Lattice-Boltzmann simulations and experiments we observed that the aggregation of dynamics of active spinning particles resemble classical 2D Cahn-Hilliard coarsening. The spinners will aggregate and display Cahn-Hilliard coarsening when the passive monolayer is dense enough so that it behaves elastically and when the spinner activity exceeds a minimum activity threshold. For the concentrations investigated here the cluster size scaling is independent of the number of active units. We also observe a critical cluster size which maximizes spinner aggregation by minimizing viscous drag through the dense passive monolayer while maximizing the stress applied on the passive medium. In simulations, we can create ternary mixtures of co-rotating, counter-rotating, and passive particles. The aggregation behavior of such mixtures show distinct aggregates of co and counter-rotating spinners.

M71.00182: Confinement effect on active turbulent dynamics*  YUHAO WANG (Presenter), Chinese Univ of Hong Kong — Dense bacterial suspensions organize into mesoscale active turbulent vortices when confined in quasi-2D or 3D chambers. The spatial and temporal length scale of the turbulent vortices is dependent not only on the active fluid itself but also on the rheological properties of the confinement interface. Moreover, the turbulent vortices transform into a single spiral vortex state when the confinement size reaches the turbulent correlation length. Here we discuss the confinement interface and dimension effects on active turbulent dynamics and hence the macroscale behavior. This study is aiming to provide physical insights for designing environments of controllable collective motion and active assembly.

*This work was supported by the Research Grants Council of Hong Kong SAR (RGC numbers 2130439, 2130493, and 2130613), and from the National Natural Science Foundation of China (NSFC 21473152).
M71.00183: Statistical mechanical sum rules for active colloids at surfaces - a touch of equilibrium*  RENÉ WITTMANN (Presenter), HHU Düsseldorf, FRANK SMALLENBURG, Univ. Paris-Sud, Univ. Paris-Saclay, JOSEPH BRADER, Université de Fribourg — We study the mechanical properties of active particles in the presence of curved walls by computer simulation of Active Brownian Particles (ABPs), Active Ornstein-Uhlenbeck Particles (AOUPs) and a passive system with effective interactions. The effective theory admits analytic results for pressure, surface tension and adsorption of an active ideal gas at a two-dimensional circular wall. It further predicts that an equilibrium sum rule also holds for active fluids, which we confirm numerically for both ABPs and AOUPs in the limit of small curvature.

More precisely, we find within each model that the slope of the pressure as a function of the curvature equals the surface tension and adsorption (up to an effective temperature scale) on a planar wall. Intriguingly, the explicit value of these coefficients is model-dependent, which can be explained by the different velocity distributions.

We also discuss the influence of interactions and find that the effect of curvature on the wall pressure is reduced when increasing the density. Within numerical accuracy, the equality of the slope of the pressure and the planar surface tension appears to hold at finite density.

*Funding by the DFG: LO 418/20-2

M71.00184: Capillary Forces on a Janus Sphere Straddling a Liquid-Gas Interface*  SHENGFENG CHENG (Presenter), YANFEI TANG, Virginia Tech — Particles with a patterned surface can exhibit interesting packing and self-assembly behavior. One class of such particles is Janus particles whose surfaces are divided into two halves with distinct physical properties. We compute the capillary forces on a Janus sphere, one side of which is solvophobic while the other is solvophilic, straddling a liquid-gas interface via molecular dynamics simulations. In equilibrium, the liquid-gas interface is flat in the horizontal plane and intersects with the equator of the Janus sphere, with its solvophilic side immersed in the liquid. When the Janus sphere is pulled or pushed out of its equilibrium position along the vertical direction, a capillary rise or fall occurs but the contact line is first pinned at the equator. The contact line only starts to slide when the apparent contact angle becomes equal to the acute (obtuse) contact angle on the solvophilic (solvophobic) side for the Janus sphere pulled upward (pushed downward). An analytical model is developed to explain the observation. The capillary force on a Janus sphere oriented upside-down with the solvophobic side submerged in the liquid is also computed with simulations and possible metastable configurations are found.

**M71.00185: Achieving highly ordered nanoparticle structures in polymer solution without chemical grafting**  
SOL MI OH (Presenter), SO YOUN Y KIM, Ulsan Natl Inst of Sci & Tech —  
Nanoparticle arrays with highly ordered structures have drawn great attention based on their potentials to improve the physical properties compared to the randomly oriented structures. However, it is often difficult to disperse nanoparticles in order in a neat polymer matrix keeping the liquid-like processability, thus requiring complicated and time expensive laborious procedures. In this work, we report that nanoparticles can be highly ordered by simply dispersing them in poly(ethylene glycol) derivative solution. Without chemical grafting, the strong hydrogen bonding between nanoparticles and the PEG complex could retain the superstructures in the liquid-phase with excess amount of water. The systematic investigation is carried out by varying molecular weight/concentration of polymers/nanoparticles and temperature with small-angle X-ray scattering and oscillatory rheometry experiments.

**M71.00186: Sticky diffusion: How to achieve complex motion with random sticky feet ?**  
SOPHIE MARBACH (Presenter), Courant Institute of Mathematical Sciences, JEANA(AOJIE) ZHENG, DAVID J PINE, NYU, Center for Soft Matter Research, MIRANDA HOLMES-CERFON, Courant Institute of Mathematical Sciences —  
Beating equilibrium diffusion is a paradigm challenge that biological or artificial systems of small particles have to face to achieve complex functions. Some cells (like leucocytes) use ligand-receptor contacts (sticky feet) to crawl and roll along vessels. Sticky DNA (another type of sticky feet) is coated on colloids to design programmable interactions and long-range assembly features. The dynamics of such sticky motion are complex as sticky events (attaching/detaching) often occur on very short time scales that affect the overall motion of the particle on much longer time scales, and makes predictions challenging. Here we present analytical predictions in several cases (with different geometries of sticky feet). We rationalize what parameters control diffusion and how they can be compared to existing systems. We investigate furthermore how complex motion like rolling may be favored compared to lateral motion.
M71.00187: Droplets of Colloidal Ferromagnetic Nanoplates*  MIN SHUAI, XI CHEN, CHEOL PARK (Presenter), JOSEPH E MACLENNAN, MATTHEW A. GLASER, NOEL ANTHONY CLARK, University of Colorado, Boulder — Disk-shaped, ferromagnetic barium hexaferrite nanoplates in isotropic solvents exhibit a first-order transition from a paramagnetic isotropic (I) phase to a ferromagnetic nematic (N_F) phase for sufficiently high volume fractions [Nat Comm, 7: 10394, 2016]. In samples prepared at a volume fraction within the I – N_F coexistence range, it is possible to create metastable dispersions of oblate spheroidal N_F droplets in an isotropic background. Magnetostatic interactions strongly favor tangential alignment of the N_F magnetization field and the corresponding nematic director field along lines of latitude. However, such a circumferential director configuration requires the formation of a +1 disclination line along the symmetry axis of the droplet, with a correspondingly large elastic free energy cost. The formation of a disclination line is avoided through the escape of the polar director field into the third dimension, giving rise to spontaneously chiral droplets whose handedness is determined by the sign of twist of the magnetization. Coalescence of droplets leads to highly complex morphologies that depend on the polar and chiral structure of the constituent droplets.

M71.00188: Elucidation of Structural Information of Colloidal Assemblies from Binary Particles using Scattering Techniques*  ANVAY PATIL (Presenter), SARANSHU SINGLA, Polymer Science, The University of Akron, ZIYING HU, Chemistry, Northwestern University, JING-JIN SONG, Materials Science & Engineering, University of California San Diego, MARKUS BLEUEL, Center for Neutron Research, National Institute of Standards and Technology, NATHAN C. GIANNESCHI, Chemistry, Northwestern University, SUNIL K SINHA, Physics, University of California San Diego, ALI N DHINOJWALA, Polymer Science, The University of Akron — Self-assembly plays an important role in materials and life sciences, for example, in production of structural colors in various taxa, folding and assembly of proteins in living cells, and creation of metamaterials by self-assembly of complex nanostructures. Previously we have reported a simple one-pot emulsion-based process to form photonic colloidal assemblies called supraballs. In this work, we have measured the small angle neutron scattering from supraball assemblies constructed using binary mixtures of melanin and silica particles. The neutron scattering results can be used to determine the various partial structure factors of the nanoparticles, which is important in understanding scattering of visible light. Designing tunable structural colors is of interest for many applications including cosmetics, paints, and food colorings.

*This work is supported by Air Force Office of Scientific Research (FA9550-18-1-0142) and access to vSANS was provided by the Center for High Resolution Neutron Scattering (DMR-1508249) at the National Institute of Standards and Technology.
M71.00189: Dynamical processes of interstitial diffusion in a two-dimensional colloidal crystal
SUNGCHEOL KIM, Watson Research Center, IBM Research, LICHAO YU, Google, ALEXANDROS PERTSINIDIS, Sloan-Kettering Cancer Institute, XINSHENG LING (Presenter), Brown University — We report the first study of the dynamical processes of interstitials in a 2D colloidal crystal. The diffusion constants of both mono- and di-interstitials are measured, and found to be significantly larger than those of vacancies. Di-interstitials are clearly slower than mono-interstitials. We found that, by plotting the accumulative positions of 5- and 7-fold disclinations relative to the center-of-mass position of the defect, a 6-fold symmetric pattern emerges for mono-interstitials. This is indicative of an equilibrium behavior that satisfies local detailed balance that the lattice remains elastic and can be thermally excited between lattice configurations reversibly. However, for di-interstitials the 6-fold symmetry is not observed in the same time window, the local lattice distortions are too severe to recover quickly. This observation suggests a possible route to creating local melting of a lattice (similarly one can create local melting by creating di-vacancies). This work opens up a new avenue for microscopic studies of the dynamics of melting in colloidal model systems.

M71.00190: Glass Transition in PEO-C$_{60}$ Nanocomposites
OMOSOLA ORIRETAN, DORINA CHIPARA, MOHAMMED UDDIN, DANNA CAPITANACHI AVILA, KAREN LOZANO, MIRCEA CHIPARA (Presenter), University of Texas Rio Grande Valley — Nanocomposites of polyethylene oxide (PEO) loaded by various amounts of fullerenes have been prepared by dissolving PEO into a given solvent and homogenizing the PEO-solvent solution by stirring. Fullerenes nanoparticles have been added to the PEO solution, then the mixture was stirred for about 1 h at 1,000 rotations per minute followed by a 30 minutes high power sonication. The homogenized mixture/solution was poured on microscope slides and the solvent was removed in an oven at 90 °C, for 12 hours. The complete removal of the solvent was confirmed by TGA. Two solvents: deionized water and chloroform were used. The nanofiller is not soluble in water but is soluble in chloroform, opening thus the door towards a refined understanding of the differences between a nanocomposite and a molecular dispersion. The as-obtained nanocomposites were investigated by using a TA Instruments Q 50 DSC at various heating and cooling cycles with rates ranging between 5 °C/min to 30 °C/min. The research is focused on the effect of the heating/cooling rates, solvent type, and concentration of fullerenes on the glass transition temperature of PEO-C$_{60}$ nanocomposites.

M71.00191: Hierarchically Organized Chiral Supraparticles of Twisted Gold-Cysteine Sheets

PRASHANT KUMAR (Presenter), YUEFEI WANG, WENFENG JIANG, NICHOLAS KOTOV, Univ of Michigan - Ann Arbor — The structural complexity of composite biomaterials and mineralized particles arises from hierarchical ordering of inorganic building blocks over multiple scales. While empirical observations of complex structures from nanoparticles are abundant, assembly mechanisms leading to their geometrical complexity are still puzzling especially for non-uniformly sized components. Here, we report the assembly of hierarchically organized particles (HOPs) with twisted spikes and other morphologies from polydispersed Au-Cys nanoplatelets. Complexity of HOPs is comparable to biological counterparts as enumerated by graph theory methods. Their intricate hierarchical organization emerges from competing electrostatic and elastic restrictions that render assembly pathways primarily dependent on nanoparticle symmetry rather than size. Upon varying the enantiomeric excess and synthesis temperature, a large family of colloids with complex architectures and unusual chiroptical and chemical properties are explored.

M71.00192: Terahertz time-domain spectroscopic study on an oxide glass with entropic elasticity

JEONGHYUK KIM (Presenter), TATSUYA MORI, Division of Materials Science, University of Tsukuba, SEIJI INABA, Research Center, AGC Incorporated, TAKANARI KASHIWAGI, Division of Materials Science, University of Tsukuba, YASUHIRO FUJII, Department of Physical Sciences, Ritsumeikan University, SUGURU KITANI, HITOSHI KAWAJI, Materials and Structures Laboratory, Tokyo Institute of Technology, AKITOSHI KOREEDA, Department of Physical Sciences, Ritsumeikan University, SOO HAN OH, JAE-HYEON KO, Department of Physics, Hallym University, SEIJI KOJIMA, Division of Materials Science, University of Tsukuba — For disordered systems, universal excitation called boson peak appears in the terahertz range. In addition, for polymeric glasses, fractal dynamics, so-called fracton, is expected to appear above boson peak frequency as a result of self-similarity of monomer unit. In this study, we performed terahertz time-domain spectroscopy on an oxide glass with entropic elasticity: mixed alkali metal metaphosphate glass with the chemical composition Li$_{0.25}$Na$_{0.25}$K$_{0.25}$Cs$_{0.25}$PO$_3$, to detect the boson peak and fracton. Obtained spectra are compared with results of low-frequency Raman scattering and low-temperature specific heat measurement.

M71.00193: Proton Conductivity in Protic Ionic Liquids (PILs)

AMANDA YOUNG-GONZALES (Presenter), ALEXEI SOKOLOV, SHENG ZHAO, University of Tennessee, Knoxville — Protic ionic liquids (PILs) have attracted significant attention due to their promising properties and potential use in various applications. Recent studies revealed strong decoupling of proton conductivity from structure relaxation in a mixture of lidocaine with phosphoric acid, $^1$ in which the proton conductivity of this mixture even exceeds that of phosphoric acid at the same viscosity. In this study, we selected bases that exhibit similar properties to lidocaine to facilitate the formation of hydrogen bonded networks to promote high proton diffusivity. Using broadband dielectric spectroscopy (BDS), the conductivity relaxation of several different mixtures with phosphoric acid can be compared and used to determine the best structures for increased conductivity.

**M71.00194: Self-limiting electrospray deposition on polymer masks**  
LIN LEI (Presenter), ARIELLE MARIE GAMBOA, CHRISTIANNA KUZNETSOVA, SUNSHINE LITTLECREEK, JINGREN WANG, QINGZE ZOU, JEFFREY ZAHN, JONATHAN SINGER, Rutgers University, New Brunswick — Electrospray deposition (ESD) can produce monodisperse generations of droplets down to hundreds of nanometers in diameter by applying high voltage to liquids flowing through capillaries. This deposition method has been combined with insulated stencil masks for fabricating micro patterns by spraying nanoparticles, polymers, or biomaterials. To optimize the fabrication process for micro coatings, a self-limiting electrospray deposition (SLED) method has recently been developed. Here we combine SLED with a pre-existing polymer film to study the fundamental behavior of this process in a bilayer geometry. SLED has been observed when insulating materials are sprayed onto conductive substrates. A thickness-limited film will occur when charge accumulates and repels the arrival of additional charged droplets. In this study, polystyrene (PS) and Parylene C thin films of varying thicknesses are utilized as insulated spraying substrates. Polyvinypyrrolidone (PVP), a thermoplastic polymer is sprayed to investigate the SLED behavior on the pre-deposited insulating films. Moreover, to examine the effects of in-plane confinement on the spray, a microhole array patterned onto the PS thin film by focused laser spike (FLaSk) dewetting was sprayed with PVP in the SLED mode.

**M71.00195: Contact singularity between curved dielectric surfaces**  
HUADA LIAN (Presenter), JIAN QIN, Stanford Univ — The induced polarization charges density on two dielectric surfaces in proximity appear to diverge as separation decrease. This diverging charge density cannot be resolved by the conventional numerical methods or series expansions because the surface charges demand ever-increasing spatial resolution that becomes intractable in the near-contact regime. We analyze the asymptotic behavior of this contact singularity by adopting the 'lubrication' approximation, and demonstrate explicitly the singular dependence on the gap distance and the curvature of two approaching surfaces. The result agrees with the known logarithmic singularity for conducting surfaces and, for dielectric surfaces, provides a means for isolating the singularity and calculating the cohesive energy for ensembles of dielectric particles in close contact.
M71.00196: Programmable Multistable Mechanisms for Locomotion* MOHAMED ZANATY (Presenter), Harvard University, PATRICK FLÜCKIGER, ILAN VARDI, SIMON HENEIN, EPFL — We characterized the stability behavior of a multistable mechanism and applied the results to create a new locomotion mechanism based on serially connected bistable beams. The beams of our mechanisms have axial loads that can tune their stiffness and thereby modify the number and location of the stable states. This mechanism is an instance of programmable multistable mechanisms introduced in our previous work.

Using analytical modeling, numerical simulation, and experimental measurements, we demonstrated how the transition sequence between the stable states depends on the beams' axial loads. We exploited this property to produce locomotion with a highly simplified control system. We applied our concept to construct a skating robot, where velocity can be tuned by varying beam stiffness.

M71.00197: Jamming in a bubble raft: order, disorder and glassy behavior* KLEBERT FEITOSA (Presenter), CHRISTOPHER EATON, ANDREW JOYCE, BRIAN C SEYMOUR, CHRISTINE O'DEA, Dept. of Physics and Astronomy, James Madison University — Soap bubbles floating at an air-liquid interface form stable aggregates resulting from capillary attraction between bubbles. Under external forcing the aggregates unjam and experience plastic events. By using bubble shape deformations as a proxy for the stress, we correlate bubble rearrangements with the stress field as the raft is subject to uniaxial oscillatory compression between parallel plates. We find that most rearrangement events occur immediately after a turning point in the cycle when the stress field changes direction and is most heterogeneous. We also compute metrics from tessellations of polygonal regions set by idealized contact points as well as particle bond orientations and analyze their statistics at different stages of the cycle.

M71.00198: Systematic control of anisotropy and percolation in patchy particle gels  JAKE SONG (Presenter), Massachusetts Institute of Technology MIT, BRIAN LYNCH, MEHEDI RIZVI, North Carolina State University, JAN ILAVSKY, Argonne National Laboratory, DAVID MANKUS, Massachusetts Institute of Technology MIT, JOSEPH TRACY, North Carolina State University, NIELS HOLTEN-ANDERSEN, GARETH H MCKINLEY, Massachusetts Institute of Technology MIT — Patchy particle interactions enable the design of so-called ‘equilibrium gels’, a system where arrest is achieved without an underlying phase separation, resulting in structurally equilibrated gels which do not undergo coarsening-induced aging. We show that nanoparticle-incorporated supramolecular hydrogels - consisting of reversibly polymer-grafted metallic nanoparticles which are cross-linked with end-functionalized polymers – exhibit behaviour consistent with systems undergoing equilibrium arrest. We show that the interaction patchiness of this system can be controlled through the ratio of polymeric linkers to nanoparticles, thus resulting in a canonical system with tunable self-assembly, local structural anisotropy, and mechanical percolation thresholds. Moreover, we show that the addition of metal ions as a second competitive reversible cross-linking species results in the stabilization of locally anisotropic nanoparticle structures, thus resulting in a globally anisotropic structure and a dramatic reduction in the mechanical percolation threshold of the nanoparticle network in the hydrogel. These findings allow the systematic design of stable particle gels with tunable morphology and rigidity.

M71.00199: Effect of chain architecture on self-diffusion in a model associative network.* IRINA MAHMAD RASID (Presenter), NIELS HOLTEN-ANDERSEN, BRADLEY OLSEN, Massachusetts Institute of Technology MIT — Associative networks are ubiquitous both in natural and synthetic materials, and self-diffusion within these networks dictates many of their desirable properties such as self-healing and stress relaxation. Self-diffusion studies of various associative networks have shown that over length scales of several times the radius of gyration, the dynamics of the network lead to the observation of an apparent super-diffusive regime prior to transitioning to the Fickian regime at larger length scales. In this work, the effect of chain architecture was investigated by comparing the self-diffusion of a random copolymer with one where the stickers are clustered at the end of the chain. Since the chemical composition of the model associative networks is kept constant, this approach allows for a more direct comparison of the role of chain architecture. The insights gained from this study will improve our understanding of the effect of sticker distribution on the transport properties of natural and synthetic associative networks and how it could impact the macroscopic properties that rely on these processes.

M71.00200: Chiral Elastic Waveguide  OSWALDO ADAPTA (Presenter), ADRIAN REYES, National Autonomous University of Mexico — In this work, we investigate the propagation of elastic transverse and longitudinal waves in a helical medium through a cylindrical waveguide. By solving the Navier-Cauchy equations together with the constitutive equations for a helical medium. By assuming quasi-planar waves, we reduce our system to a set of ordinary differential equations. We have obtained the band structure of the system and the propagation parameters by imposing the corresponding boundary conditions for vacuum outside the waveguide. We also calculate the corresponding strain and stress distributions within the waveguide. We discuss our result and address our conclusions.

M71.00201: Binary Clay – Graphene Oxide Liquid Crystals*  BARBARA PACAKOVA (Presenter), Dept. of Physics, NTNU Trondheim, ROMULO TENORIO, Comissão Nacional de Energia Nuclear - (CNEN) and Centro Regional de Ciências Nucleares - (CRCN), Brazil, MARIAN MATEJDES, Bayerisches Polymer Institut und Lehrstuhl für Anorganische Chemie 1, Universität Bayreuth, Bayreuth, Germany, YVES MEHEUST, Geosciences Rennes, Université Rennes 1, Rennes, France, PAULO BRITO, Dept. of Physics, NTNU Trondheim, JOSEF BREU, Bayerisches Polymer Institut und Lehrstuhl für Anorganische Chemie 1, Universität Bayreuth, Bayreuth, Germany, JON OTTO FOSSUM, Dept. of Physics, NTNU Trondheim — Colloidal suspensions (CS) of electrically charged nanosheets (NSTs) form liquid crystalline phases in polar solvents, such as graphene oxide\(^1\) or clays\(^2,3\). Self organization of NSTs due to competing van der Waals attraction and electrostatic repulsion forces can form several coexisting phases such as isotropic (I), nematic (N) or lamellar (L). Several single-component CS\(^1,2\) exhibit transition from I to N liquid crystalline phase; moreover, existence of L phase for CS of electrically charged NSTs has been observed recently\(^4\).

In contrary, complexity of binary CS (BCS) of charged NSTs can result in multi-phase systems. This study is focused on BCS of negatively charged synthetic clay\(^5\) and graphene oxide, serving as promising precursor for fabrication of clay-graphene oxide mixed ionic-electronic conductors. Results obtained using X-ray diffraction (SAXS, WAXS) and imaging (optical, MRI) techniques will be discussed, emphasizing formation of N and mixed-domain states.

M71.00202: Chiral Composite Networks for Sensing Volatile Organic Compounds Towards Liquid Crystal Nose (LC-nose).  MEGHAN EVANS (Presenter), BENJAMIN SCHUTSKY, ANTHONY GRAY, KYRA FULEIHAN, CHRISTOPHER LA FOND, PETR V SHIBAEV, Fordham University — Composite chiral networks were prepared by co-polymerization of cholesteric siloxane monomers with low molar mass monomers bearing hydrogen bonding, polar and non-polar side groups (acrylic acid, vinylpyridine, benzyl acrylate, and aliphatic acids). Polymerization was conducted between two plastic plates at elevated temperatures when compounds formed chiral liquid crystalline state. After polymerization thin polymer films were formed, the upper plastic film was peeled off and the surface of polymer composite was exposed to a particular VOC. The response of polymer films to VOCs (spectral shift of the selective reflection band) was studied by spectroscopic methods and morphological surface changes were studied by atomic force microscopy (AFM). It was shown that by varying the composition of materials it is possible to change their sensitivity to polar and non-polar VOCs. The mechanism of this sensitivity was also studied by modeling both gas diffusion inside the polymer and polymer optical properties. The selectivity of the whole system can be further improved by comparing relative spectral and color changes of a few polymer films simultaneously. Thus, the prototype of LC-nose based on polymer networks could be created.

M71.00203: Environmentally Sensitive Optical Fibers and Waveguides Based on Hydrogen-Bonding Compounds  BENJAMIN SCHUTSKY (Presenter), ANTHONY GRAY, KYRA FULEIHAN, CHRISTOPHER LA FOND, MEGHAN EVANS, PETR V SHIBAEV, Fordham University — Novel optical fibers and waveguides were designed and created from blends of hydrogen bonding compounds (polyvinyl alcohol, polyvinylpyridine, acrylic acid) with glassy polymers and low molar mass liquid crystals. Optical fibers display significant birefringence in their cores since the drawing procedure of the fibers lead to the higher concentration and orientation of liquid crystal inside the core of the fiber. The fibers were studied by differential scanning calorimetry and optical methods. It was shown that fibers gain additional stability if they are physically crosslinked with diacidic low molar mass compounds (sebacic acid). Optical response of the fibers (changes in propagating light intensity or additional leakage of light) to the action of volatile organic compounds (VOCs) was studied and discussed for different types of polar and non-polar VOCs. It was found that optical response depends on structural reorganization of the fibers that starts in the outer layer and then propagates towards the core in a way similar to the response of liquid crystals [1].

M71.00204: Optics of multilayered cholesteric liquid crystals with disorder: towards LC-nose.  EMAIYAH GULLATT (Presenter), PETR V SHIBAEV, OLEKSIY ROSLYAK, JOSEPH PLUMITALLO, Fordham University, UPALI APARAJITA, Borough of Manhattan Community College — Optical properties of multilayered disordered cholesteric liquid crystals (CLC) with different types of disorders were performed by employing 4x4 matrix method in order to simulate a diffusion of volatile organic compound (VOC) molecules inside the cholesteric material. A simulated CLC consisted of three layers, the central layer being unaffected by VOCs and two outer layers being subjected to diffusion of VOC molecules. The diffusion of VOCs inside the CLC was simulated by changing either the order parameter or helical pitch of the two outer layers of the CLC. The results were compared with experiments of VOC diffusion in a number of CLC systems. It was determined that the change of order parameter plays an important role in liquid CLCs and change of helical pitch mostly affects CLC polymers. The applicability of these calculations for designing artificial LC-nose [1] is discussed.

[1] Liquid crystal nose, chiral case: towards increased selectivity and low detection limits

Liquid Crystals, 1-9

M71.00205: Verifying XY-Model Predictions for Topological Defects in Films of Smectic Liquid Crystals*  CHEOL PARK (Presenter), ADAM GREEN, STIAN HOWARD, ERIC MINOR, JOSEPH E MACLENNAN, MATTHEW GLASER, NOEL ANTHONY CLARK, Physics and Soft Materials Research Center, University of Colorado Boulder — We describe experiments exploring the applicability of the XY model to defect-rich smectic C liquid crystal films. Topological defects in the orientation field are created by rapidly deflating a hemispherical `bubble' of a molecularly thin film, resulting in a flat film with a high density of defects. The subsequent pair-wise annihilation of these defects is captured with sub-millisecond resolution using high-speed, polarized light video microscopy. The simplest theoretical description of the orientation field, the XY model, makes specific predictions about the annihilation dynamics, predicting sub-logarithmic scaling of the number of defects present at short times and logarithmic scaling at longer times. Progress towards verifying the applicability of the XY model to these systems at early times has been stymied by experimentally difficulties in tracking the defects. Through improvements in illumination and by leveraging recent advances in machine-learning, we can now identify and track individual defects at early times, allowing us to confirm the predictions of the XY model.

M71.00206: Study of a cylindrical fiber cored by a double twisted chiral nematic.
FERNANDO MAGANA, GERARDO-JORGE VAZQUEZ FONSECA (Presenter), ADRIAN REYES, LAURA PALOMARES PALOMARES, Univ Nacl Autonoma de Mexico — We study a region of the space where an electromagnetic field is propagating within a waveguide consisting of a material having double helix as found in some chiral nematic materials such as blue phases. We establish the electromagnetic equation governing the dynamics of the propagating modes. We found the band structure of the mentioned modes, the profiles field amplitudes and the Poynting vector distributions versus the radius of the fiber. We discuss the composition and conditions for the modes to propagate.

M71.00207: Deformation of structurally chiral polymer stabilized networks in electrically tunable filters*
BRIAN P RADKA (Presenter), TIMOTHY J WHITE, Chemical and Biological Engineering, University of Colorado, Boulder — The cholesteric liquid crystalline phase self-organizes into a helical structure. In the planar orientation, the periodicity naturally exhibits a selective interference reflection. Dynamic optical responses observable as red-shifting tuning, blue-shifting tuning, or bandwidth broadening can be achieved under an electrical field with the inclusion of a polymer network. Our recent research activities have focused on further elucidating the fundamental electrochemical response of the ion-mediated deformation of the polymer stabilizing network in the cholesteric phase. A variety of liquid crystalline and non-liquid crystalline monomers are selected in order to determine how intermolecular forces and liquid crystalline interactions affect the performance of the material. Multiphoton fluorescent imaging is used to visualize pitch and polymer network deformation. The correlated influence of photopolymerization conditions and ionic impurities will be discussed.

M71.00208: Electro-optical switching and order parameter measurements of dual-frequency nematic liquid crystals: regimes of thin and thick cells.
OLHA MELNYK (Presenter), University of Colorado, Colorado Springs, YURIY GARBOVSKIY, Central Connecticut State University, ANATOLIY GLUSHCHENKO, University of Colorado, Colorado Springs — Liquid crystals utilized in conventional display applications typically have a layer thickness of less than 10 µm. However, emerging non-display applications of liquid crystals require thicker material layer with faster response. Electro-optical performance of relatively thin liquid crystal cells is well-documented, but little is known about the properties of thicker layers. Also to address the need for the fast electro-optical switching a dual frequency liquid crystals are investigated. We are presenting the electro-optical response of dual-frequency nematic liquid crystals using a broad range of the cell thickness (2–200 µm). Two regimes of electro-optical switching of dual-frequency nematics are observed and analyzed. To uncover the origin of the observed two regimes of electro-optical switching, measurements of the orientational order parameter of dual frequency nematic liquid crystals were carried out over the same range of thicknesses. The non-monotonous dependence of the order parameter $S$ on the cell thickness obtained for relatively thin layers (< 60 µm), and is followed by a rapid monotonous decay for thicker (60-200 µm) samples. This provides a basis for understanding of two regimes of electro-optical switching of thin and thick layers of dual frequency nematics.
M71.00209: Assembly of microparticles in disclination of LCLCs confined to cylindrical capillaries. SUJIN LEE (Presenter), ELSA REICHMANIS, JUNG O PARK, MOHAN SRINIVASARAO, Georgia Inst of Tech — We investigate the assembly of microparticles in nematic lyotropic chromonic liquid crystals (LCLCs) confined to cylindrical capillaries. Two line defects with double helical configuration is observed for Sunset Yellow FCF with the homeotropic anchoring being obtained by parylene-N coating. Here, we show that disclinations in Sunset Yellow FCF can act as templates for particle dispersions. Additionally, we use magnetic micropaticles to study effect of external magnetic fields on the lclcs. The observed assemblies extend our understanding of the structure of disclinations and ability to design the architectures of soft materials.

M71.00210: Predicting the Steady Flow of a Fluid with Particles by Deep Learning* HIROTO OZAKI (Presenter), TAKESHI AOYAGI, CD-FMat, AIST — Computational Fluid Dynamics (CFD) simulation has the potential for application in material science. In these applications, a common study object is a highly viscous fluid that passes structures in the microscale. However, its computational cost is a barrier to application. Meanwhile, some recent studies successfully reduced the computational cost of CFD by utilizing machine learning and deep learning techniques [1, 2].

Using deep learning, the authors predicted the steady flow around a large number of particles and examined the effectiveness of the prediction for the study of materials development. The particle-fluid interaction is computed using the Smoothed Profile Method [3]. After learning the flow that passes the particles obtained by iterative calculation, the deep learning quickly and accurately predicted the flow of the system with unknown particle concentration and arrangement. The fluid force applied to each particle was also accurately predicted.

M71.00211: Deep Convolutional Neural Network for Tomographic Reconstruction of Strain

MATTHEW CONNOLLY (Presenter), DAMIAN LAURIA, National Institute of Standards and Technology Boulder — The neutron transmission Bragg edge method has gained interest over the past decade as a technique for providing a fast, high spatial-resolution and high sample penetration mapping of strain. Since its advent, there has been a strong desire to extend the transmission Bragg edge method to provide a full 3D tomographic reconstruction of the full strain tensor. However, it has been shown that traditional tomographic reconstruction algorithms are, in general, unable to provide a unique solution as the mathematical problem of inversion of Bragg edge data is ill-posed. The major complication of strain tomography compared to traditional scalar tomography is the directional dependence of the strain tensor. Deep Convolutional Neural Networks (DCNNs) have shown success in scalar tomographic reconstruction, in particular for cases in which scalar tomography is ill-posed (e.g. when sample exposure or rotation is limited). We show that DCNNs can be extended to perform tomographic reconstruction of strain tensors based on neutron transmission Bragg edge data. We show three training strategies and a DCNN architecture with success in reconstructing 2D strain fields. Additionally, we explore the advancements necessary to make a fully generalizable model for tomographic reconstruction of strain.

M71.00212: Machine learning for detecting microscopic parameters characterizing mechanical properties of liquid crystal elastomers*

HIDEO DOI (Presenter), KAZUAKI TAKAHASHI, Research Center for Computational Design of Advanced Functional Materials, National Institute of Advanced Industrial Science and Technology (AIST), HARUKA YASUOKA, KENJI TAGASHIRA, Research Association of High-Throughput Design and Development for Advanced Functional Materials, JUNICHI FUKUDA, Faculty of Science, Kyushu University, TAKESHI AOYAGI, Research Center for Computational Design of Advanced Functional Materials, National Institute of Advanced Industrial Science and Technology (AIST) — Liquid crystal elastomers (LCE) are of great scientific and technical interest because of the potential of sensors and soft actuators. Molecular dynamics (MD) simulation is a promising means to clarify macroscopic deformation of LCE from a microscopic viewpoint, however, a detection of major parameters characterizing the deformation is difficult because there are many microscopic parameters. Therefore, a systematic analysis should be done for detecting the relation between microscopic parameters and mechanical properties. In this study, a machine learning (ML) approach is used to explore the relation between microscopic characteristics and mechanical parameters. With these models, we perform MD simulations and compute stress-strain curves. Then a regression analysis with random forest method to explain the difference of stress-strain curves is performed with 20 types of microscopic parameters. The ML results reveal the effective set of data descriptors that predict well the stress-strain curves. Therefore, ML technique has a capability to overcome the difficulty to manually explain the complex relation between microscopic parameters and macroscopic properties.

**M71.00213: Predicting Soft Matter Evolution Using Machine Learning**  ZITONG ZHANG  
(Presenter), Tsinghua University, BO LI, STEVE GRANICK, Institute for Basic Science — Soft matter including colloids, polymers and granular material display behavior and self-organization that are difficult and sometimes impossible to predict due to complex interactions with the environment, which itself can change and self-organize. The traditional approach to understand these problems is to study structural evolution by theory and experiment. We are taking the different approach of machine learning. We build convolutional neural networks (CNNs) to process the large amounts of data. We are applying these new tools to direct imaging in rheo-optics, to fitness evaluation of cell growth when they pass near obstacles, and to ecological microsystems with soft matter flavor. The common element is to predict properties varying with time.

**M71.00214: Confined filaments in soft vesicles - case of sickle red blood cells**  ARABINDA BEHERA (Presenter), GAURAV KUMAR, ANIRBAN SAIN, Physics, Indian Institute Of Technology Bombay — Abnormal shapes of red blood cells (RBC) have been associated with various diseases. Diverse RBC shapes have also been intriguing for membrane biophysics. In our work, we focus on sickle-shaped RBC which form due to abnormal growth of semi-rigid Hemoglobin (HbS) fibers confined in RBC. Using the area difference elasticity (ADE) model for RBC and worm-like chain model for the confined HbS fibers, we explore shape deformations at equilibrium using Monte-Carlo simulation. We show while a single HbS fiber is not rigid enough to produce sickle-like deformation, a fiber bundle can do so. We also consider multiple disjoint filaments and find that confinement can generate multipolar RBC shapes and can even promote helical filament conformations which have not been discussed before. We show that the same model, when applied to microtubules confined in phospholipid vesicles, predicts vesicle tubulation. In addition, we reproduce tube collapse transition and tennis racket type vesicle shapes, as reported in experiments. We conclude that with a decrease in the surface area to volume ratio, and membrane rigidity, the vesicle prefers tubulation over sickling.

*We thank the University Grant Commission, India, and IRCC-IIT Bombay for financial support.

**M71.00215: AZO-modified lipids bilayer and their dynamics associated with optical stimulation.**  CINTIA MENENDEZ (Presenter), Pritzker School of Molecular Engineerin, The University of Chicago, ARASH MANAFIRAD, ANTHONY DUPRAT DINSMORE, Department of Physics, University of Massachusetts, JUAN DE PABLO, Pritzker School of Molecular Engineerin, The University of Chicago — In this work we have studied the dynamics of membranes with azo-modified lipids from molecular scales (atomistic molecular dynamics simulations) to vesicle scale (experimental work), with the aim of increasing understanding regarding steady states, elastic constants and membrane permeability. We have found that vesicles dilate and become flexible and much more permeable as a result of trans-to-cis conversion. Therefore, to the best of our knowledge, these are the first studies to look at the membrane dynamics associated with optical stimulation. In addition, the relative energies of cis and trans states were theoretically determined. Finally, it is worth to highlight that this combined studies (computational and experimental work) open new avenues regarding rational molecular design in order to tune response.

M71.00216: Enhanced diffusion of tracer microspheres in a temporally fluctuating porous structure  
RAPHAEL SARFATI (Presenter), CHRISTOPHER P CALDERON, DANIEL K SCHWARTZ, 
University of Colorado, Boulder — Transport in porous materials is at the center of a wide range of natural and industrial processes. While many studies have focused on the properties of porosity with spatial fluctuations, much less is known about the effects of temporal fluctuations in the medium's structure. We have designed a simple experimental system aimed at investigating the transport properties of a crystalline porous material made of a hexagonal lattice of 2um spheres, which are either static, or fluctuating in time about an average position (dynamic). Using complementary illumination, we can image and track both diffusive tracers (100-400nm) and lattice spheres. We compare the transport properties of the static and dynamic lattices with similar average densities and find that diffusion is significantly faster within the dynamic lattice. We hypothesize that this might be due to a combination of different effects. First, the motion of lattice spheres could reduce the hydrodynamic hindrance of the tracers, and increase diffusivity within a cavity. Second, fluctuations in pore sizes, induced by the fluctuations in distances between adjacent spheres, could permit a higher transition rate between cavities than a fixed pore size of the same mean value. We present results relating to these two effects.

M71.00217: Fibers on the surface of thermo-responsive gels induce controllable formation of helical structure  
TAO ZHANG (Presenter), VICTOR V YASHIN, ANNA BALAZS, Univ of Pittsburgh — We use computational modeling and analytical calculation to investigate the behavior of gel-fiber long thin films; we specifically show that the arrangement of fibers localization on the outer surface of the sample provides a powerful means of tailoring the overall shape of the sample, as to form helical structure with controlled chirality. We focus on thermo-responsive gels, which exhibit a lower critical solubility temperature (LCST) and thus shrink when heated above a certain temperature. The stiff fibers are attached to this gel and inhibit the nearby network from undergoing the heat-induced collapse. Away from the fibers, however, the network can readily shrink in response to the increased temperature. This competition between the constrained regions and the unconstrained regions of the heated gel regulates the structural evolution and final geometry of the sample. Our simulations use the gel lattice spring model (gLSM) to determine how the temperature, arrangement and number of the fibers control the bending and twisting of thin ribbons. Our comprehensive 3D analytical calculation incorporates elasticity, differential geometry, and variational principles.
M71.00218: Curved Geometries from Planar Director Fields: Solving the Two-Dimensional Inverse Problem*  ITAY GRINIASTY (Presenter), Laboratory of Atomic and Solid State Physics, Cornell University, EFI EFRATI, HILLEL AHARONI, Weizmann Institute of Science — Thin nematic elastomers, composite hydrogels, and plant tissues are among many systems that display uniform anisotropic deformation upon external actuation. In these materials, the spatial orientation variation of a local director field induces intricate global shape changes. Despite extensive efforts, until recently there was no general solution to the inverse design problem: How to design a director field that deforms exactly into a desired surface geometry upon actuation, or whether such a field exists. In this work, we phrase this inverse problem as a hyperbolic system of differential equations. We prove that the inverse problem is locally integrable, provide an algorithm for its integration, and derive bounds on global solutions. We classify the set of director fields that deform into a given surface, thus paving the way to finding optimized fields.

M71.00219: Elastic-Viscoplastic transition in a modified Soft Glassy Rheology model*  JUN DONG PARK (Presenter), Kumoh Inst of Tech — The elastic-viscoplastic transition of glassy materials is studied with a modified Soft Glassy Rheology (SGR) model that is newly suggested for more accurate description of rheological behavior of glassy materials. The modified SGR model incorporates sophisticated features of glassy materials, such as collective dynamics. The modified SGR model demonstrates different elastic-viscoplastic transitions depending on conditions such as methods of glassy dynamics description, flow conditions, and shear history. The rheological transition of SGR model under startup shear is interpreted in terms of local strain distribution change that represents physical state change. Based on the findings, we interrogate how various features of glassy dynamics affect the elastic-viscoplastic transition in glassy materials and discuss effective ways to describe glassy materials. Our results provide some clue to understand the physical origin of the elastic-viscoplastic transition in glassy materials.

M71.00220: Bifurcated yielding response of aging fibrillar networks  
RYAN POLING-SKUTVIK (Presenter), CHINEDUM OSUJI, University of Pennsylvania — Yielding in disordered materials occurs with a remarkably broad variety of characteristics and remains a poorly understood phenomenon. Here, we investigate the yielding and aging behavior of disordered fibrillar networks of cellulose nanofibrils (CNF), micron-sized semiflexible fibers with aspect ratios >100. At high concentrations, CNF form dense physical networks that support finite stresses and in which terminal relaxations are suppressed. We observe a strong decrease in the yield strain of the networks with increasing volume fraction ($\gamma_y \sim \phi^{-2}$). Further, we observe a strong aging response of the system after an initial yielding event. Subsequent yielding occurs at a time $t_y$ that depends sensitively on the magnitude of applied stress and the aging time $t_w$ between initial yielding and reapplication of stress. The yield time diverges at finite waiting times for small stresses and asymptotes towards a finite yield time at large stresses, with bifurcation around a critical stress that is similar to the yield stress of the system. The waiting time at which the yield time diverges increases with applied stress below the critical stress, indicating that the bifurcation is rooted in the rate of thermally driven network restructuring relative to stress-driven de-structuring.

M71.00221: Yielding of FCC crystals at zero deformation rate: evidence for hidden transition  
PASWA NATH (Presenter), TIFR Centre for Interdisciplinary Sciences — Despite much effort, no theory, consistent with all rigorous thermodynamic constraints, has been derived that can predict the yield point of a real solid. An exact result states that the free energy of any material, made up of entities interacting with short ranged forces, cannot depend on the shape of the boundary. This implies that crystalline solids are guaranteed to yield at infinitesimal stresses when deformed at vanishing rates. Here we present our work on yielding of an ideal FCC solid in the strictly zero strain rate limit. In this limit, the yield point vanishes for infinitely large systems. Earlier, we showed, for an ideal 2d triangular crystal that the yielding phenomena is a dynamic consequence of a hidden first order phase transition. Our calculations of the free energy of such solids also show that the solid phase is always metastable at any finite temperature and infinitesimal deformation. Our prediction for the dynamical yield points agree with MD simulations for a wide range of deformation rates. We describe, here, our extension of this previous work to the initially defect-free FCC crystal. We discuss about commensuration, finite-size effects and consequences of systematically introduced disorders as random interactions of varying strength in such solids.
**M71.00222: Interfacial Thermodynamics of Surfactants at Elevated Pressure**  
ZACHARY HINTON (Presenter), NICOLAS ALVAREZ, Department of Chemical and Biological Engineering, Drexel University — While surfactant use under elevated pressures is not a novel field, experimental measurements of surfactants in extreme environments is lacking in the literature. Thermodynamically, pressure impacts the concentration of surfactants at a pressurized interface, thus affecting the interfacial tension. The relationship between the concentration, pressure, and interfacial tension for a given surfactant has not been measured sufficiently for nearly any surfactant. In this work we use a novel high pressure microtensiometer to probe surfactant transport and equilibrium thermodynamics at the water-CO$_2$ vapor interface. We show that surfactant isotherms are highly dependent on pressure illustrating that key thermodynamic and kinetic parameters are strong functions of pressure. Furthermore, we show that surfactant performance is significantly decreased at elevated pressures. We outline the importance of experimental measurements of surfactant behavior on predicting high pressure performance of a variety of surfactant chemistries.

**M71.00223: Role of solvent identity in impact-activated solidification of dense suspensions**  
LIANG ZHAO (Presenter), MICHAEL VAN DER NAALD, GRAYSON JACKSON, HEINRICH M. JAEGGER, University of Chicago — Applied stress can drive flowing suspensions of solid particles in a Newtonian liquid into a shear-jammed solid state. Beyond steady state rheology, recent work demonstrated that high-speed ultrasound imaging could be used to visualize transient flow fields generated by impact and track the propagation of “jamming fronts” in optically opaque cornstarch suspensions [1][2]. We here use this ultrasound imaging technique to reconstruct the flow fields caused by impact of dense suspensions containing silica nanoparticles in polymeric liquids. We find that the solvent molecular weight plays an important role in mediating frictional contacts between particles required for shear jamming. [1] E. Han, I. R. Peters and H. M. Jaeger. High-speed ultrasound imaging in dense suspensions reveals impact-activated solidification due to dynamic shear jamming. *Nat Commun*, 7:12243, 2016.  
**M71.00224: Colloidal Assembly at Curved Liquid-Liquid Interface**  
ZICHEN LING (Presenter), Chemical Engineering, Wayne State University, NAMITA SHOKEEN, Physics and Astronomy, Wayne State University, YINGXI ELAINE ZHU, Chemical Engineering, Wayne State University, ASHIS MUKHOPADHYAY, Physics and Astronomy, Wayne State University — Colloidal particles can readily assemble into crystalline structure under confinement. When confined on a flat surface, spherical particles can pack efficiently with an arrangement of hexagons. However, the regular hexagonal packing configuration could be disrupted on a curved surface with resulting formation of defects. In this study, we investigated the self-assembled crystallography of fluorescence labeled polystyrene (PS) microspheres at lutidine-water interfaces, where liquid-liquid separation occurs as increasing the temperature to exceed the critical solution temperature of the mixture around 27-28 °C. We determined the assembled packing microstructure of PS microspheres at the liquid-liquid interface of varied curvature by direct confocal microscopic particle tracking. We observed disordered-to-crystalline structural transition in self-assembled PS colloidal monolayer at curved liquid-liquid interfaces when a critical curvature is exceeded.

**M71.00225: Unique assembly structures of amphiphilic Janus particles in ionic liquid solutions**  
AYUNA TSYRENOVA, MUHAMMAD FAROOQ, JARED ANDERSON, SHAN JIANG (Presenter), Iowa State University — Janus particles assemble into remarkable superstructures due to different chemistry on the two sides of a single particle. The directional interactions present new structures and the ensuing physics are essential to the formation of intriguing clusters, chains and crystals. Our recent experiments demonstrate unique assemblies of Janus particles in ionic liquid solutions that have never been observed before. Despite extensive studies focused on purified Janus particles, their self-organization in the presence of surface-active molecules has not been systematically studied. The intriguing orientation correlation and crystal structures formed in this multicomponent system cannot be explained by the current theory. Our central hypothesis is that the association of surface active molecules with Janus spheres, especially the boundary on the particle surface dividing the two sides, can effectively modulate the interactions among Janus particles and alter their assembly behaviors. The results provide critical information regarding new phenomena observed through experimentation and offer guidance for future applications of Janus particles.

JESSICA BICKEL (Presenter), KIRIL STRELETZKY, Cleveland State University — Researchers at Cleveland State University's Department of Physics and Department of Chemical & Biomedical Engineering collaboratively study the unique properties and applications of soft matter materials. Together, we are in our third year of an NSF-sponsored Research Experiences for Undergraduates (REU) site on Synthesis, Assembly and Characterization of Soft Matter Systems. The objective of our site is to involve undergraduate physics and engineering majors in meaningful interdisciplinary research projects within soft matter science and engineering. A primary focus of our site is to encourage students to continue in STEM fields as either graduate students or workforce members. CSU’s focus on Engaged Learning has cultivated a strong culture of support for undergraduate research, and REU participants benefit from this culture. Students receive one-on-one mentoring from experienced faculty and participate in a variety of professional development opportunities. This poster will give an overview of the student research accomplishments over the last three years. It will also discuss the benefits of the experience to both students and faculty mentors.

CSU Office of Research

M71.00227: Introducing Mutations in an artificial self-replication system*  

HENG NI, FENG ZHOU (Presenter), RUOJIE SHA, NADRIAN C SEEMAN, PAUL M CHAIKIN, New York Univ NYU — We have started a study of Darwinian evolution using an artificial self-replication system of DNA origami dimer rafts. By introducing a small error (3 bases) in the sticky-ends recognition strands, there is a small chance for the system to mutate templating a different dimer raft which can replicate itself effectively starting a new species. The mutation rate is small, but the mutated nanostructure shares the same replication ability as the original dimers. Although the original dimers are dominant at the beginning of self-replication, after many replication cycles we should have an equal mixture of mutated and original dimers. In addition, we can modify the mutated structures with the capability of growing faster, then after many replication cycles, the mutated species will take over the system. We can use the functionality of the different species to affect this takeover. Mutation and population domination by the fittest species would amount to natural selection in this artificial system.

*This research has been primarily supported by DOE DE-SC0007991 and DE-SC0000989.
M71.00228: Flow-induced fracture in freestanding wet colloidal pillars*  JUSTIN BEROZ
(Presenter), ALVIN T.L. TAN, KENNETH N KAMRIN, JOHN HART, Massachusetts Institute of Technology
MIT — Self-assembly of colloidal particles is an attractive means to create materials with engineered properties by controlling the hierarchy of particle composition, size, ordering and macroscopic form. We recently demonstrated a direct-write method [1] that enables self-assembly of colloidal particles from liquid suspension into centimeter-scale freestanding crystalline structures by utilizing a combination of evaporation-driven liquid flow and capillary attraction. However, in a subset of the structures we constructed, cracks formed during drying, throughout the height and at the free end. We detail our observations and explain how the Darcy flow of liquid through the structure drives fracture, despite the structure being compressed by a uniform capillary pressure at its surface. We derive a criterion for the presence and spacing between cracks, based on an energy scaling argument, that compares favorably with our experiments. This work ultimately provides a guideline for constructing crack-free 3D colloidal structures, which can potentially achieve complex freeform macroscale geometries.

M71.00229: Block copolymer assemblies under 3D confinement: from spherical boundary to continuous network template  XUEYAN FENG (Presenter), WENPENG SHAN, Rice University, ABBY JUHL, Air Force Research Laboratory, INBAL WEISBORD, TAMAR SEGAL-PERETZ, Technion, EDWIN THOMAS, Rice University — Depending on the interplay between polymer chain stretching and interfacial energy of the intermaterial dividing surface (IMDS), different self-assembled block copolymer nanostructures can be achieved. Directed self assembly in 2D employing confinement via walls, posts and various surface treatments can improve long range order and induce new microdomain patterns. By applying templates with spatially varying 3D geometric boundary conditions, block copolymers have the possibility to form a host of new morphologies and complex, hierarchical block polymer/template 3D ordered composites. The self-assembly behaviors of a bulk phase lamella-forming polystyrene-b-polydimethylsiloxane diblock copolymer within different 3D confinement boundary conditions are presented. The 3D confinement varies from that of within a simple sphere to occupation of the connected void space of a complex 3D network template. By taking advantage of Slice-and-View scanning electron microscope tomography, large volume 3D information of the polymer/template assemblies can be produced at high resolution. The domain morphology, IMDS curvature, polymer chain stretching, and morphological defects are discussed.
M71.00230: Hydrodynamically-driven assembly of nanoparticles in an anisotropic media
STIVEN VILLADA GIL, Universidad Nacional de Colombia sede Medellín, Politécnico Colombiano Jaime Isaza Cadavid, VIVIANA PALACIO-BETANCUR (Presenter), Institute for Molecular Engineering, University of Chicago, JULIO C. ARMAS-PÉREZ, División de Ciencias e Ingenierías, Campus León, Universidad de Guanajuato, JUAN P. HERNÁNDEZ-ORTIZ, Departamento de Materiales y Minerales, Universidad Nacional de Colombia sede Medellín, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago.

Argonne National Laboratory —
Nanoparticle (NP) self-assembly in liquid crystals (LCs) depends on the elasticity of the material to form arrays with crystalline symmetry. These arrays can be tuned via the anchoring of the NP, and the orientation of the director field, effectively using the defects around the NP as sites for assembly. Additionally, confinement and hydrodynamic fields can also be used to control the assembly. Scenarios often consider one, two, or three NPs under various flow regimes and in moderate confinement. The simulations presented here use the Stark-Lubensky formalism, where the Landau-de Gennes free energy functional is coupled with the momentum balance through a Poisson-bracket formulation. To describe NP-LC suspensions, a transient three-dimensional Galerkin finite element framework was implemented to achieve a numerical solution. We show that, independent of NP anchoring, defects are displaced in the up-stream direction, ultimately forming a hedgehog defect. The assembly mechanism for a pair of NPs is modified in the large Ericksen regime, where the NPs show an unexpected non-monotonic tendency to aggregate. The modifications to the defect structure and the free energy landscape open a new avenue to the directed assembly of NPs immersed in LC under conditions far from equilibrium.

M71.00231: Knitting Patterns of Pentasil Chains reveal MFI-MEL Heterostructures in Two-Dimensional Zeolite Nanosheets
PRASHANT KUMAR (Presenter), NEEL RANGNEKAR, HAO XU, EVGENII FETISOV, J. ILJA SIEPMANN, TRAIAN DUMITRICA, University of Minnesota, MICHAEL TSAPATSIS, John Hopkins University, K. ANDRE MKHOYAN, University of Minnesota —
The zeolite MFI is a widely used catalyst and adsorbent, which also holds promise as a thin film membrane for the separation of hydrocarbon isomers and other difficult to separate mixtures. The discovery of nm-thick 2-dimensional (2D) MFI nanosheets has enabled methods for thin film zeolite fabrication that open new horizons for membrane science and engineering. However, the crystal structure of 2D-MFI nanosheets and its relationship to separation performance remain elusive. Using transmission electron microscopy, we find that one- to few-unit-cells wide intergrowths of the zeolite MEL exist within 2D-MFI. We identify the planar distribution of these 1-dimensional (1D) or near-1D-MEL domains, and show that a fraction of individual nanosheets have high MEL content while the majority of nanosheets are MEL-free. Atomistic simulations suggest that commensurate knitting of 1D-MEL within 2D-MFI creates more rigid and highly selective pores as compared to those in pristine MFI nanosheets and permeation experiments show an unprecedented separation factor of 60 using an industrially relevant (undiluted 1 bar xylene mixture) feed.
M71.00232: Structural and mechanical properties of nucleic acid nanotubes: A combined all-atom and coarse-grained molecular dynamics study*  SUPRIYO NASKAR (Presenter), HIMANSHU JOSHI, MOUNIKA GOSIKA, Indian Institute of Science - Dept of Physics, BANANI CHAKRABORTY, Department of Chemical Engineering, Indian Institute of Science, NADRIAN C SEEMAN, Department of Chemistry, New York University, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — In this work, we introduce a computational framework to model nucleic acid nanotubes and estimate their mechanical properties using various levels of theory. Using atomistic molecular dynamics (MD) simulations, we report the enhancement of the structural and mechanical stability of DNA nanotube (DNT) by changing the salt concentrations. The calculated persistence length \( L_p \) of the DNTs is \( \sim 1-2 \) μm which is an order of magnitude higher than that of a single dsDNA. DNTs have stretch modulus \( \gamma \) value in the range of \( \sim 6-8 \) nN. We find that, with the gradual increment of salt concentration, an increase in \( L_p \) and \( \gamma \) which reaffirms the structural and mechanical stability of the DNT at higher salt concentrations. We also model DNT using two widely used coarse-grain (CG) models – namely Martini and oxDNA. We compare and contrast the all-atom MD and experimental results with the results obtained using these CG models. We also propose a model of hexagonal nanotubes made of dsRNA connected by double crossover at different positions. The calculated \( \gamma \) and \( L_p \) of the in silico modeled RNTs are in the same range of values as in the case of DNTs. Using helicoidal parameters of individual base pairs, we explain the relative flexibility and rigidity of the RNTs having different sequences.

*CSIR IISc

M71.00233: Role of Chirality in Self-Assembly of Amino Acid Tryptophan on Au (111)  YONGCHAN JEONG (Presenter), JUNGPIL SEO, Daegu Gyeongbuk Institute of Science and Technology — Proteins only use single L-enantiomer of amino acids owing to the homochirality in a living system. Interestingly, a small amount of tryptophan (Trp), which is one of the essential amino acids, is required in the proteins. We studied the self-assembly of Trp on Au (111) using scanning tunneling microscopy and density functional theory. When single Trp enantiomers were deposited on Au (111), we confirmed 1D chain structures. The deposition of racemic mixture of two opposite Trp enantiomers also built chain structures, but these structures differed from those formed by single Trp enantiomers. In the self-assembly of two opposite Trp enantiomers, the absence of the single Trp enantiomers-formed chain structures is because the heterochiral configurations were more favorable energetically than the homochiral ones. In the heterochiral chain structures, an enantiomer obstructed the access between amino and carboxyl groups in the opposite enantiomers, resulting in the hindrance of formation of peptide bonding between the opposite enantiomers. From these results, we can estimate that proteins utilize a small amount of Trp to avoid the disturbance of peptide bonding formation. In addition, our study also will contribute to the understanding for origin of homochirality in a living system.
M71.00234: Biomimetic Tunable Disordered Photonic Structures via Programmable Polymer Blend Phase-Separation  
ASRITHA NALLAPANENI, University of Akron, MARKUS BLEUEL, NIST, JAN ILAVSKY, CHENHUI ZHU, ANL, MATTHEW SHAWKEY, University of Ghent, ALAMGIR KARIM (Presenter), University of Houston — Biopolymers such as proteins undergo self-assembly resulting in complex hierarchical structures with well-defined structure and fascinating multi-functional properties. For example, disordered photonic structures in avian birds are responsible for white and blue non-iridescent colors. These structures are thought to arise from phase-separation between β-keratin and cytoplasm during cell growth and the degree of disorder determines coloration. We utilized temperature-induced phase-separation in polymer blends as an approach to attain multi-functional non-iridescent structural colors similar to nature. We further examined the dynamics of phase-separation to gain insights into the molecular self-assembly process and understand the temporal-evolution of structural and optical disorder. Our results indicate that structural disorder scales with domain-size as well as phase-separation time and a strong direct correlation between structural and optical disorder is observed. Tunable disordered photonics can also be obtained simply by tuning the molecular weight of the polymer blend components. In future photonic designs, it is important to exercise good control on structural disorder at multiple length scales in order to obtain tunable visible colors with multi-functionality.

M71.00235: Oscillatory Microdroplet Constituted Urea Biosensor Stimulated by Acoustic Waves*  
SIDDHARTH THAKUR (Presenter), Department of Chemical Engineering, Indian Inst of Tech-Guwahati, MITRADIP BHATTACHARJEE, Centre for Nanotechnology, Indian Institute of Technology Guwahati, ASHOK KUMAR DASMAHAPATRA, Department of Chemical Engineering, Indian Inst of Tech-Guwahati, DIPANKAR BANDYOPADHYAY, Centre for Nanotechnology, Indian Institute of Technology Guwahati — A proof of concept microdroplet based urea biosensor has been presented that employs a facile but robust detection technique. To substantiate, variation in electrical resistance across a 10 µL salt-laden water microdroplet placed on a glass substrate was observed when it was subjected to sinusoidal acoustic waves at its natural frequency, ~ 320 Hz. For the biosensing application, the conducting water microdroplet was loaded with a suspension of urease-linked gold/cadmium sulfide nanocomposite. Upon adding urea solution in the droplet under the influence of acoustic waves, the changing electrical resistance could be effectively correlated with the changing urea concentration. Higher reaction rate was observed owing to the presence of nanocomposites which provided enzymatic stability and higher interfacial area. Also, the confined droplet geometry resulted in formation of vortices that improved the mixing characteristics. A calibration chart was prepared across a wide range of urea concentrations that was employed for working with unknown human serum samples.

M71.00236: Proton Dynamics of CsH$_2$PO$_4$ Solid Acid using $^1$H and $^{31}$P Magic Angle Spinning Nuclear Magnetic Resonance (MAS-NMR)  SE-HUN KIM (Presenter), Jeju National University — This study investigated hydrogen-bonded CsH$_2$PO$_4$ (CDP) solid acid using $^1$H and $^{31}$P high-resolution nuclear magnetic resonance (NMR). Below the superprotonic phase transition temperature, the temperature dependence of the H NMR spectra was observed with two different hydrogen-bonded networks in the CDP structure. The systematic evolution of the lineshape with temperature dependence indicates hydrogen hopping in the chemical structure of hydrogen-bonded networks in a solid acid lattice. The proton conduction under two types of hydrogen-bonds—interchain and intrachain—in CsH$_2$PO$_4$ in the chemical environments of PO$_4$ tetrahedra is discussed.

M71.00237: Distinguishing protein aggregates from contaminants in viscous mixtures with holographic video microscopy*  LAURA PHILIPS (Presenter), ANNEMARIE WINTERS, MARY ANN ODETE, FOOK C CHEONG, Spheryx, Inc — We demonstrate how holographic video microscopy detects, counts, and characterizes individual sub-visible protein aggregates ranging in diameter from 0.5 μm – 10 μm in concentrations and viscosities typical of biologic pharmaceutical formulations. Protein aggregates are distinguished from other contaminants that are found in pharmaceutical manufacturing, including silicon oil emulsion droplets, air bubbles, tungsten metal particles and breakdown products of industry standard surfactants. A study was also performed comparing the holographic signatures of protein aggregates and other contaminants in solvents of different viscosities. These results differentiates uniform spherical particles from particles composed of an irregularly shaped aggregation of proteins. Holographic characterization’s unique ability to measure refractive index provides a basis for differentiating protein aggregates from contaminants. For example, silicone oil droplets are clearly distinguished from protein aggregates on the basis of refractive index, even when they have the same size.

*Supported by the NSF, Award #1631815 7, NIH, Award #R44TR001590.
M71.00238: Gripping, Catching, and Conveying with a Soft, Toroidal Hydrostat*  SAMUEL ROOT (Presenter), GEORGE M. WHITESIDES, Harvard University — This work describes how a toroidal hydrostat can be used to perform three functions found in both living and engineered systems: gripping, catching, and conveying. We first demonstrate a gripping mechanism that uses the inversion characteristic of the toroid to encapsulate and grip onto objects under a uniform hydrostatic pressure. Using this mechanism, we demonstrate gripping forces ranging from 1-80 N, depending (in a predictable way) on the geometry and material properties of the system. We next demonstrate a catching mechanism akin to that of a chameleon's tongue: the elasticity of the membrane is used to store mechanical energy and drive a rapid acceleration to capture moving objects out of the air. Finally, we show how the toroidal topology can be exploited to construct a soft conveying mechanism that continuously inverts and passes objects through its center—serving a similar function to that of esophageal peristalsis, while eliminating the requirement of a lubricated interface. In general, we show that the use of inflatable topological structures comprising soft polymeric films is a promising approach to designing soft robotic actuators with novel, bio-inspired functionality.

M71.00239: Comparison of the Helmholtz, Gibbs, and Collective-modes methods to obtain nonaffine elastic constants*  BINGYU CUI (Presenter), EUGENE M TERENTJEV, Univ of Cambridge — We review and compare the Born-Huang and the Lemaitre-Maloney's theories that lead to analytical expressions for elastic constants, accounting for affine and nonaffine deformations in a lattice. The Born-Huang method is based on Helmholtz energy while the Lemaitre-Maloney's formalism focus on Gibbs force. Although starting from different perspectives, in the linear elastic limit, and in equilibrium, elastic material constants must be the same in all these methods. This is explicitly verified on examples of linear chains, and numerical simulation of a non-centrosymmetric crystal.

*B. C acknowledges the financial support of CSCCambridge Scholarship.
M71.00240: Hydrodynamics and rheology of a vesicle doublet suspension*  BRYAN QUAIFE, Scientific Computing, Florida State University, YUAN-NAN YOUNG (Presenter), New Jersey Inst of Tech — The dynamics of an adhesive two-dimensional vesicle doublet under various flow conditions is investigated numerically using a boundary integral method. In a quiescent flow, two nearby vesicles move slowly toward each other under the adhesive potential, pushing out fluid between them to form a vesicle doublet at equilibrium. A lubrication analysis on such draining of a thin film gives the dependencies of draining time on adhesion strength and separation distance, which are in good agreement with numerical results. In a planar extensional flow, a stable vesicle doublet forms only when two vesicles collide head-on. In a microfluid trap where the stagnation of an extensional flow is dynamically placed in the middle of a vesicle doublet through an active control loop, novel dynamics of a vesicle doublet are observed. Numerical simulations show that there exists a critical extensional flow rate above which adhesive interaction is overcome by the diverging stream, thus providing a simple method to measure the adhesion strength between two vesicles. In a planar shear flow, numerical simulations reveal that a vesicle doublet may form provided that the adhesion strength is sufficiently large at a given vesicle reduced area.

M71.00241: Continuum modeling of colloid-polymer mixtures in microgravity*  LAUREN BARNES (Presenter), BORIS KHUSID, LOU KONDIC, New Jersey Inst of Tech, WILLIAM V MEYER, NASA Glenn Research Center, ANAND OZA, New Jersey Inst of Tech — We present a continuum model of colloid-polymer mixtures in a microgravity environment. Such mixtures are an archetype for phase transition processes, but the variety of observed colloidal structures remain poorly understood. We construct, analyze and numerically simulate a phase-field model for structure evolution in colloid-polymer mixtures. The model consists of the Cahn-Hilliard equation, which describes phase separation processes in multicomponent mixtures, coupled with the Stokes equation for the viscous fluid flow. The results of the model will be compared against experiments performed on the International Space Station, using data available on the NASA Physical Sciences Informatics system.

*We acknowledge support from the NASA Physical Science Research Program.

M71.00242: STATISTICAL AND NONLINEAR PHYSICS —
**M71.00243: Understanding Fundamental Principles of Emergent Collective Behavior from Simple Bristlebots**  SKANDA VIVEK (Presenter), SAIRAM TANGIRALA, Georgia Gwinnett College — While it's known that simple interactions between active constituents reproduces collective phenomena such as flocking and schooling, there is a lack of comprehensive understanding of emergent collective behaviors arising from different kinds of interactions, increasingly relevant in the modern era. Take connected vehicles as an example: increasingly sophisticated sensors and software are being used to make complex decisions, and a basic understanding of how these changes in vehicular interactions in turn affects collective behaviors such as traffic is unknown. We built a model platform for studying various emergent collective behaviors in the real world, using customizable low-cost bristlebots. We find that certain intrinsic behaviors of the bristlebots such as shape and confinement significantly affect collective behaviors. Ultimately, our system provides an accessible, low-cost model to experimentally study and understand fundamental principles of collective behavior, highly relevant in the modern era.

**M71.00244: Energy Stability of Gravitationally Interacting Rods and Dumbbells**  MELITA F WILES (Presenter), JOHN LINDNER, College of Wooster — We extend classic dynamical results for two or three gravitationally interacting point masses to ideal rods and dumbbells. We derive equilibrium configurations by demanding that the vector of first derivatives of energy at constant angular momentum vanish. We investigate their stability by checking if the spectrum of the Hessian matrix of second derivatives is positive. The additional degrees of freedom allow the objects to store and exchange angular momentum and enable us to elucidate the behavior of non-spherical celestial bodies like asteroids and comet nuclei.

*Funded in part by NSF DMR-1852095

**M71.00245: A Continuous-time, Analog Approach to Boolean Satisfiability Problems**  SHUBHA RAJ KHAREL (Presenter), FERENC MOLNAR, ZOLTAN TOROCZKAI, Physics, University of Notre Dame — Recently, a continuous-time, deterministic analog solver based on ordinary differential equations was introduced, to solve Boolean satisfiability (SAT) problems, a family of discrete constraint satisfaction problems. As SAT is NP-complete, efficient algorithms would benefit solving a large number of decision type problems, both within industry and the sciences. Here we present a detailed analysis of the performance of this continuous-time solver and several variants of it, implemented on digital machines, on hard random SAT and very hard Ramsey-type coloring problems. We also present a randomization theorem connecting the entropy generation rate of the dynamics with solution time and problem hardness.

*Funding: NSF CCF-1644368 and 1640081, and by SRC-NRI Nanoelectronics Research Initiative 2698.004
M71.00246: Weighted Network Analysis of Biologically Relevant Chemical Spaces* MARIKO ITO (Presenter), TAKAAKI OHNISHI, Graduate School of Information Science and Technology, The University of Tokyo — In cheminformatics, network representations of the space of compounds have been suggested extensively. Among these, the threshold-network consists of nodes representing molecules. In this network representation, two molecules are connected by a link if the Tanimoto coefficient, a similarity measure, between them exceeds a preset threshold. However, the topology of the threshold-network is affected significantly by the preset threshold. In this study, we collected the data of biologically relevant compounds and bioactivities. We defined the weighted network where the weight of each link between the nodes equals the Tanimoto coefficient between the bioactive compounds (nodes) without using the threshold. We investigated the relationship between the strength of the link connection and the bioactivity closeness in the weighted networks. We found that compounds with significantly high or low bioactivity have a stronger connection than those in the overall network.

M71.00247: Modeling the Response of Rayleigh-Van der Pol Oscillators to Stochastic Excitation Near the Hopf Bifurcation BINGSHEN LU (Presenter), MASOUD ASADI-ZEYDABADI, RANDALL TAGG, Physics, University of Colorado Denver — The Rayleigh-van der Pol equation for nonlinear oscillation has been a useful model for studying critical behavior near a Hopf bifurcation, including effects of external forcing and noise. Moreover, this equation has been found to be a good model of the long-term behavior of an experimental system consisting of the Wien bridge oscillator. We will describe work to study measures of noise variance, phase relations and other features of this combined model and experimental system, extended to coupling of two or more oscillators.

M71.00248: Granular Crystallization Driven by Dynamic Jamming Front KUN XUE (Presenter), JIARUI LI, Beijing Institute of Technology — Mono-dispersed particle systems under moderate vibration or continuous shearing are prone to form crystallized packing structures. Our grain scale simulations also find a collection of initially unjammed mono-dispersed particles would jammed into ordered packing structures by uniaxial compression via a rake. The crystallization degree, indicated by the local order of individual particles and the number of ordered particles, is found to be strongly influenced by the inter-particle friction. For the smooth particles, crystallization ensues the propagating jamming front regardless of the disorder degree of initial particle arrangement. A trivial friction (m = 0.01) suffices to markedly reduce the crystallization degree from above 90% to 68% thanks to the emergence of shear bands. An increased friction (m = 0.3) induces profuse shear bands, contributing to a significant reduction of crystallization degree (below 40%) which is also correlated with the initial disorder degree. As expected, the order-to-disorder transition of jammed structure induced by increasing particle friction dictates the jammed packing fraction and consequently the dynamic of jamming front. We also reveal mechanisms underlying the dynamic crystallization and its degeneration due to the elevated particle friction.
M71.00249: Self-Entanglement of a Tumbled Circular Chain  BEATRICE SOH (Presenter), Massachusetts Institute of Technology MIT, ALEXANDER KLOTZ, California State University, Long Beach, PATRICK DOYLE, Massachusetts Institute of Technology MIT — The spontaneous knotting of linear chains has been well studied, but little attention has been given to the self-entanglement of chains with more complex topologies. In this work, we perform experiments with granular chains that undergo tumbling motion to investigate the self-entanglement of circular chains, which lack the chain ends essential for forming knots. We study the entanglement probability and types of self-entanglements formed on linear and circular chains, using the well-studied self-entanglements on a linear chain to frame our understanding of self-entanglements on a circular chain. We describe a characterization method that views a self-entangled circular chain as a link of two components and use it to characterize the self-entanglements on circular chains with known topological descriptors from knot theory. By examining the formation pathway of several self-entanglements, we infer a general mechanism for the self-entanglement of circular chains.

M71.00250: Effect of mechanical coupling on the synchronization regimes of coupled optomechanical systems  XUEWEI ZHANG (Presenter), Texas A&M University, Kingsville — The objective of this work is to investigate the effect of mechanical coupling strength on the bistable synchronization regimes of two coupled optomechanical systems. Classically, the system is described by an effective Kuramoto-type model. Quantum mechanically, the system has been defined by a Hamiltonian and can be studied using semi-classical Langevin equation method. Previous research concluded that the quantum fluctuations are responsible for the appearance of the bistable synchronization regime. In this work, it is shown that, at some critical value of mechanical coupling, the synchronization can be bistable even in the absence of quantum fluctuation. Further, the numerical results of systems with detuning and thermal noise are obtained. These results collectively are used to extract a statistical measure that differentiate bistable synchronous states and unsynchronous states.

M71.00251: Instability power laws and planes from the variational principle*  JUSTIN BEROZ (Presenter), JOHN HART, JOHN W M BUSH, Massachusetts Institute of Technology MIT — Stable thermodynamic equilibrium of a physical system exists for a finite range of its physical parameters. Beyond this range, the system may transition to a dynamical one or undergo a phase change; determining the stability limit is often challenging for complex and nonlinear systems. We show that, for a broad range of physical systems, the stability limit may be formulated in terms of physical parameters that are independent with respect to an arbitrary variation of the system. Consequently, the stability limit is simply a power law if the thermodynamic potential describing the system comprises only two energy quantities; if comprised of more than two quantities, the stability limit is generally represented as a plane. Our result is shown to be valid for several solid, fluid and gas systems, and is especially useful for determining the stability limit of systems for which no analytical solution exists. As an example of the latter, we experimentally and theoretically investigate the stability limit of a liquid droplet exposed to an electric and gravitational field. The connection with statistical physics is also discussed.

M71.00252: The conditions leading to dry lumps and dry granular jets when dispersing grains across a liquid-air interface* XIN YI ONG, CPE, U.Surrey, SPENCER E. TAYLOR, Chemistry, U.Surrey, MARCO RAMAIOLI (Presenter), UMR 782, Institut National Recherche Agronomique (INRA) — Avoiding the formation of dry lumps when dispersing powders into water is key for many industrial processes.

This study identifies experimentally the conditions leading to i) the dispersion of individual grains ii) the formation of a dry lump or iii) the formation of a dry granular jet when pouring grains onto a liquid-air interface by varying systematically grain size, density, contact angle and the grain flow rate.

Once a granular island is formed onto an interface, it can grow till reaching a maximum number of grains, above which either individual grains leave the interface or the whole island sinks. These two phenomena are governed by a different scaling law and a critical Bond number can be identified, above which grains disperse. The latter depends on two dimensionless numbers: the relative grain density and on their contact angle. Conversely, the formation of dry granular jets depends on the dimensionless kinetic energy of the grains when impacting the interface and on their contact angle.

A physical interpretation is provided to explain common practical strategies used to promote grain dispersion in industrial processes.

M71.00253: Processing and Characterization of Ultralow-Binder-Content Particulate Composites* KIWON OH, YU QIAO (Presenter), University of California, San Diego — We developed the technique of compaction self-assembly (CSA), through which ultralow-binder-content (UBC) particulate composites were produced, with the binder content (c) in the range from 2 to 8 wt.%. In CSA, a high pressure is applied on premixed binder and granular filler, so that the material is densified and the binder is self-assembled into polymer micro-agglomerations (PMA) at critical load-carrying locations. Such a microstructure minimizes the system redundancy. The flexural strength of the UBC composite is ~25 MPa and the compressive strength is more than 50 MPa. This technology may find important applications for advanced pharmaceutical manufacturing, green cement, energy storage materials, among others.

**M71.00254: Automated Measurement of the Profile of an Avalanching Conical Bead Pile**
BENNETT W ANDERSON (Presenter), SUSAN LEHMAN, College of Wooster — A conical bead pile subject to slow driving is used as a model system to experimentally investigate critical behavior in a granular system. The pile is composed of roughly 20,000 steel beads, 3 mm in diameter; we drive the pile by adding one bead at a time to the pile apex. We record the changes in pile mass over the course of tens of thousands of bead drops to characterize the distribution of avalanche sizes. To better understand the dynamic effect of individual avalanches, we now capture a profile image of the pile at every bead drop. By automating analysis of the images in Matlab, we can track changes in the overall height of the pile as well as variations in the angle of repose as the pile responds to each bead drop. In our previous work, we have characterized the changes in avalanche size distribution as we tune the cohesion in the system. Specifically, as cohesion is added, the size and number of the largest avalanches in the system increase. Using the new profile measurements, we investigate the effect of cohesion on the overall angle of repose as well as the variation in the angle. We find larger variations in the angle of repose as the cohesion is increased, and we correlate these variations with the mass of individual avalanches.

**M71.00255: Onset of dynamic jamming in granular medium subject to explosion**
KUN XUE (Presenter), PANPAN HAN, Beijing Institute of Technology — The dynamic jamming of granular media consisting of glass spheres subjected to explosion is investigated experimentally via a radial heleshaw cell connected with a vertical shock tube. The evolution of velocity fields as well as the resulting strain rate fields are attained via the imaging technique, namely Particle Image Velocimetry (PIV). As the expanding internal surface accelerates outwards, a highly localized and exponentially decayed flow field is induced and becomes increasingly diffusional with an increased decay length. The end of the acceleration phase of the advancing internal surface corresponds to the transition of exponentially decayed flows to a jammed band with largely constant velocity in the wake of a circular dynamic jamming front across the thickness of which a large velocity gradient is discerned. The onset of a steady dynamic jamming commences from the transition of flow fields. Afterwards, most compression and shear deformations occur throughout the thickness of the jamming front in a highly heterogeneous manner in contrast with the deformation mode in the prior transient period. The statistical analysis of strain fields reveals a characteristic length scale which may well arise from the grain-scale heterogeneity of granular materials.
**M71.00256: Multi-functional Tw-Kagomé lattices: Tuning by pruning mechanical metamaterials** DANILO LIARTE (Presenter), Cornell University, OLAF STENULL, TOM LUBENSKY, University of Pennsylvania — We study phonon and elastic properties of randomly-diluted twisted-Kagome lattices with tunable structures that include auxetics with negative Poisson ratios. Intelligent protocols to tune the Poisson ratio of elastic networks can be used in the design of metamaterials with flexible mechanical properties. Here we introduce two periodic lattice models that access negative values of the Poisson ratio, one of which accesses the full range from -1 to +1. Besides tunable auxetic transitions, these models exhibit rich critical phenomena that include rigidity percolation (where both the bulk $B$ and shear $G$ moduli continuously vanish), jamming (where $B$ undergoes a discontinuous jump and $G$ grows continuously from zero), shear-jamming (where $G$ undergoes a discontinuous jump and $B$ grows continuously from zero), and “double jamming” (where both $B$ and $G$ undergo a discontinuous jump).

**M71.00257: Visualizing the Interfacial Jamming of Nanoparticles on a Liquid Surface**

ZACHARY FINK (Presenter), SATYAM SRIVASTAVA, Univ of Mass - Amherst, PAUL Y KIM, Lawrence Berkeley National Laboratory, ALEXANDER E RIBBE, DAVID HOAGLAND, THOMAS RUSSELL, Univ of Mass - Amherst — Two-dimensional assemblies of nanoparticles (NPs) are model systems for studying jamming and vitrification, with slowed dynamics, rate dependence, and dynamic heterogeneities. We developed a scanning electron microscopy (SEM) technique to image NP assemblies on a nonvolatile ionic liquid (IL) droplet where areal density, $\varphi$, is well-controlled. SEM precisely images the real time location of each NP on the droplet surface, allowing NP dynamics to be determined as a function of $\varphi$. The packing structure and interactions between NPs can be rigorously measured as assemblies transition from the liquid state to the glassy or jammed state. Here, monodisperse PEGylated silica NPs and gold NP tracers (100-250 nm) were cast on the surface of 1-ethyl-3-methylimidazolium ethyl sulfate IL and imaged. By measuring the mean square displacement as a function of time, NP diffusion coefficients were found and compared with phenomenological models. Assembled structures were also analyzed at each $\varphi$ by order parameters $<\psi_6>$ and $T^*$, Voronoi tessellation, and pair correlation functions. The results show that as $\varphi$ increases, NPs diffuse more slowly and their assembly transitions from a liquid-like structure to a crystalline structure.

M71.00258: Extreme Energy-Absorbing Metamaterials Based on Liquid Crystal Elastomers*
SEUNG-YEOL JEON, ZEYU ZHU, Johns Hopkins University, CHRISTOPHER YAKACKI, University of Colorado, Denver, THAO NGUYEN, SUNG KANG (Presenter), Johns Hopkins University — Liquid crystal elastomers (LCEs) are fascinating materials for energy dissipation, due to their extreme damping behavior emerging from an internal degree of freedom of LC molecules, which is coupled to elastic deformations of polymer network. Here, we report metamaterials composed of LCE beams for extreme energy absorption. We have synthesized LCEs through a two-stage thiol-acrylate reaction to consider the effects of the alignment of LC molecules within LCE beam elements. The energy-absorbing capability of metamaterials consisting of bistable beams with differently arranged LC molecules was characterized at strain rates from $10^{-4}$/s to $10^{3}$/s and it followed a power-law relation. We observed that metamaterials based on LCE showed increase of the energy absorption at a higher strain rate. Moreover, the strain-rate dependency could be tuned by LCEs with different degree of alignment. We envision that our study can contribute to harnessing the interplay between snapping-based architectures and enhance dissipation of LCEs to enable the metamaterials with extreme energy-absorbing capabilities.

M71.00259: Valley Hall In-Plane Edge States as Building Blocks for Elastodynamic Logic Circuits*
JIHONG MA (Presenter), Department of Civil, Environmental, and Geo- Engineering, University of Minnesota - Twin Cities, KAI SUN, Department of Physics, University of Michigan, STEFANO GONELLA, Department of Civil, Environmental, and Geo- Engineering, University of Minnesota - Twin Cities — Although waveguiding is vital in mechanical signal processing and energy harvesting, conventional techniques are prone to significant backscattering from corners or junctions. Inspired by the quantum Valley Hall effect, we create and study topologically protected in-plane waveguides that are immune to backscattering. In addition, the waveguides are exploited to realize multi-interface junctions that act as logic ports with unconventional wave-manipulation capabilities, including asymmetric transport, energy trapping and rerouting, and mechanical signal delaying. These ports can ultimately serve as the building blocks for a practically endless array of elastodynamic circuits.

M71.00260: Brownian Motions in Two Dimensions under Non-harmonic Potentials: Nonequilibrium Steady-State Dynamics  
HSIN CHANG (Presenter), CHI-LUN LEE, PIK-YIN LAI, YUNG-FU CHEN, Natl Central Univ — A Brownian gyrator features a two-dimensional random particle under a harmonic potential, while random thermal kicks are of distinct temperatures along the two axes [Filliger and Reimann, Phys. Rev. Lett. 99, 230602 (2007)]. In our current work, we replace the harmonic potential by other types of potentials, and we investigate the nonequilibrium steady states (NESS) through simulation studies. In contrast to the Brownian-gyrator case, where the average flux circulates along the probability contour, our results for the non-harmonic cases do not follow this signature. Moreover, the violation of this feature exists even near the potential energy minima, where the harmonic approximation work. For the special case with a symmetric quartic potential, we provide a simple argument for this less intuitive behavior.

M71.00261: Time-reversal-invariant scaling of light propagation in one-dimensional non-Hermitian systems*  
JOSE HERNANDEZ (Presenter), LI GE, CUNY College of Staten Island — Light propagation through a normal medium is determined not only by the real part of the refractive index but also by its imaginary part, which represents optical gain and loss. Therefore, two media with different gain and loss landscapes can have very different transmission and reflection spectra, even when their real parts of the refractive index are identical. Here we show that while this observation is true for an arbitrary one-dimensional medium with refractive index n(x) and its time-reversed partner with refractive index n*(x), there exists a universal scaling that gives identical transmittance and reflectance in these corresponding systems. Interestingly, the scaled transmittance and reflectance reduce to their standard, unscaled forms in a time-reversal-invariant system, i.e., one without gain or loss.

M71.00262: Examining Human Unipedal Quiet Stance: Temporal Correlations in the Jerk Record*  MATTHEW SEMAK (Presenter), NOAH J BLAIR, Physics and Astronomy, University of Northern Colorado, GARY HEISE, School of Sport and Exercise Science, University of Northern Colorado — We investigated the quality of smoothness during human unipedal quiet stance. Smoothness is quantified by the time rate of change of the accelerations, or jerks, associated with the motion of the foot and can be seen as being indicative of how controlled the balance process is. To become more acquainted with this as a quantity, we wanted to establish whether it can be modeled as a (stationary) stochastic process and, if so, explore its temporal scaling behavior. Specifically, our study focused on the jerk concerning the center-of-pressure (COP) for each foot. Data were collected via a force plate for individuals attempting to maintain upright posture using one leg (with eyes open). Positive tests for stochasticity allowed us to treat the time series as a stochastic process and, given this, we took the jerk to be proportional to the increment of the force realizations. Detrended fluctuation analysis (of various orders) was the primary tool used to explore scaling behavior. Results suggest that both the medial-lateral and anterior-posterior components of the jerk display persistent and antipersistent correlations which can be modeled by fractional Gaussian noise over three different temporal scaling regions.

M71.00263: Morphological Properties of Shrinkage-Induced Crack Patterns*  SHIN-ICHI ITO (Presenter), The University of Tokyo, SATOSHI YUKAWA, Osaka University — We investigate morphological properties of shrinkage-induced crack patterns, which are observed such as on cooling lava and drying soil, through numerical simulations of a phase-field (PF) model. Since our PF model does not require any assumptions related to crack nucleations and numerical lattice configurations, we can investigate the pattern formations that purely depend on material/external parameters. We find that our PF model shows various types of pattern formations depending on a shrinkage rate and material constants, and in particular, the shrinkage rate provides a significantly qualitative difference in the pattern formations. Cellular patterns resulting from sequential fragmentations of straight cracks can be observed when using a slow shrinkage rate, while random network patterns resulting from connections of micro cracks that appear simultaneously can be observed when using a rapid shrinkage rate. We quantify the difference of the pattern formations statistically, and explain the origin of the difference on the basis of a simple continuum theory of a thin layer of viscoelastic material.

M71.00264: Reaction-diffusion waves interacting with fractals, spirals, and concave & soft obstacles*  
YANG YU (Presenter), CHASE A FULLER, MARGARET K. MCGUIRE, NIKLAS MANZ, JOHN LINDNER, College of Wooster — We simulate the recovery and delay of reaction-diffusion wave fronts colliding with various obstacles in narrow two-dimensional channels by numerically integrating the two-variable Tyson-Fife reduction of the three-variable Oregonator model of the chemical Belousov-Zhabotinsky reaction. We investigate the influence of obstacles on the wave front's shape and its recovery after passing around/through fractals (e.g. Hilbert curve, Peano curve, inverse Sierpinsky carpet), Archimedian spirals, and convex & concave polygons by plotting the wave front's left most point and delay versus time. We find that wave fronts behave the same when propagating through symmetric obstacles (e.g., Hilbert curve and Sierpinski carpet) at specific angles, which is in contrast to non-symmetric obstacles such as the Peano curve. At long times, wave fronts follow the same power-law recovery behavior as previously observed for convex obstacles. We also construct two types of chemical clocks, using illumination gradients with the light-sensitive reaction term or using space-dependent diffusion constants in the diffusion term.

M71.00265: Reaction-Diffusion Waves as a Black Hole Event Horizon Analogue*  
SAMUEL CAVENDER (Presenter), SAMUEL NASH, MARC E. MANHEIM, NIKLAS MANZ, College of Wooster — Hydrodynamic systems have been build to model the interaction between electromagnetic waves and black/white hole event horizons using gravity waves in water tanks as they behave analogously to electromagnetic waves traveling through space-time. We present a further scaled-down table-top size experiment using a chemical reaction-diffusion (RD) system, the Belousov-Zhabotinsky (RD) reaction. These RD waves propagate forward without any mass transport. When moving in a channel with a flow-rate gradient it is possible to achieve a situation when the medium's flow rate equals the propagation speed of the BZ wave front, creating the illusion of a stationary wave, the black/white hole horizon.

M71.00266: Harvesting energy from the thermal motion of gas molecules in gravity  
TOM ZHU (Presenter), Tom Zhu — This presentation will describe how to produce energy, e.g. electricity, from the thermal motion of gas molecules under the effect of the gravity. We will describe the motion of the gas molecules in the gravity, and the consequence of such motion. We will shown the conditions for making use of the thermal motion of the gas molecules to produce electricity.
M71.00267: Transport and Dynamical Properties of Two-Dimensional One Component Plasma  
VASSILIOS FESSATIDIS (Presenter), Department of Physics & Engineering Physics, Fordham University, Bronx, New York, KARE N. PATHAK, Department of Physics, Panjab University, Chandigarh-160014, India, GIRIJA DUBEY, Department of Earth & Physical Sciences, York College-CUNY, New York & Fordham University, Bronx, New York, GODFREY GUMBS, Department of Physics & Astronomy, Hunter College-CUNY, New York — We present a new theoretical model based on Fick's law for calculating the diffusion constant for a two-dimensional (2D) one-component plasma in the presence or absence of magnetic field. Both 1/r and ln(r) potentials are employed in conjunction with various values of coupling parameters. Our model predicts diffusion constants in agreement with recent simulation results. We also present detailed comparison of our results with those obtained from other theoretical models. Additionally, we compare our transport coefficients for the 1/r and ln(r) potentials for 2D systems.

M71.00268: Two-Scale Factor Universality in O$_2$ and H$_2$*  
DERECK MORGADO (Presenter), CHRISTIAN G HAWKINS, ANA OPRISAN, College of Charleston, GURUNATH GANDIKOTA, DENIS CHATAIN, Universite Grenoble Alpes, YVES GARRABOS, Universite de Bordeaux, DANIEL A BEYSENS, Laboratoire de Physique et Mécanique des Milieux Hétérogènes — Video images are increasingly used in science, supplanting current methods such as light scattering by a statistical evaluation of the images. In this paper, it is shown that light turbidity data, a quantity due to density-induced refractive index fluctuations, can be directly obtained from image analysis. We fitted the turbidity data to a theoretical expression that allowed us to estimate the critical amplitudes of isothermal compressibility and correlation length. Images of an oxygen-filled cell and a hydrogen-filled cell were taken near their respective critical temperatures of 155 and 33 K. Images for Hydrogen were analyzed and values of isothermal compressibility and fluctuation correlation lengths obtained from turbidity fitting were compared against literature values. In order to go very close to the critical point, the fluids are placed under weightlessness using a magnetic levitation device. Our data analysis shows a large sensitivity of the fitting parameters to the refractive index value and to even minute density deviations from criticality.

M71.00269: A Computational Study of The Villin Headpiece Subdomain HP36: The Effect of Hydration on Side Chain Dynamics in the Hydrophobic Core* TANJA KOVACEVIC (Presenter), Chemistry, University of Colorado Denver, JILLIAN OVIEDO, Biochemistry, University of Colorado Denver, LILIYA VUGMEYSTER, HAI LIN, Chemistry, University of Colorado Denver — Hydrophobic side-chain interactions are considered the major dynamic force in the folding of globular proteins and aggregation of non-globular proteins. Due to its small size, a villin headpiece subdomain HP36 is an ideal system to compute the influence of hydrophobic side-chain interaction on protein stability. Alzheimer’s has been attributed to the interactions between the hydrophobic side chains, such as phenylalanine, to drive beta-amyloid (AB) aggregation. Molecular modeling is used to gain insight into how protein-protein interactions and flexibility of the hydrophobic core are altered with the hydration level of HP36. The calculated free energy profiles will be used to estimate the rate constant for ring flipping and determine the effects of relative solvation on transition frequencies, lifetimes, and populations of the residues. These results can have implications on the hydrophobic residue interactions that drives the aggregation of AB plaques in patients with Alzheimer’s.

M71.00270: Theoretical modelling of stock price dynamics in stock markets using a phynance approach.* LEONARD MUSHUNJE (Presenter), Applied Mathematics and Statistics, Midlands State University — This paper presented time to time price dynamics associated with stock assets within stock markets. Our conjecture was that, stock prices are stochastic and time variant and as such they do attain and posses different values from time to time. We aimed to model the old way phenomenon of stock price dynamics using a distinct model from the physics field. We used the two-forms of Schrodinger equation and identified the one which best describes the dynamic nature of stocks. Our results suggested that, stock price dynamics can well be modelled and presented using the time independent Schrödinger equation (SE) with traceable stock price changes. This supported our conjecture as stock prices are traditionally known to be stochastic in nature and normally they are non-stationary. Additionally, we objectified to suggest another unique way of solving the Schrödinger equation contextualized into our case. We derived the solution using Frobenious method and the method of undetermined factors borrowed from ordinary differential equations. Fortunately, all the chosen methods proved to work well and to provide significant solutions. We therefore concluded that stock prices are non-stationary and recommend the wider use of such physics models.

*I have no funding yet.
M71.00271: Market crashes as second-order phase transitions*  JACK SARKISSIAN (Presenter), Algostox Trading — We study the behavior of ensemble features of financial markets during crash periods to see if they exhibit the behavior typical for second-order phase transitions. We find that during market crashes the order parameter (defined as the ensemble-average correlation) sharply increases and fluctuations (defined as ensemble volatility) exhibit a spike. In addition, the hysteresis effect is observed for correlations and drawdown (market drop) and a similar effect exists for trading volume and drawdown. These facts point that during crashes the markets not only resemble, but undergo a second-order phase transition. Market phases can be identified on a trading volume vs drawdown diagram as regions with high and low order parameter. While market dynamics has a self-coordinated nature, the two inputs on phase diagram are measurable directly from the markets.

*None

M71.00272: Policies for allocation of information in task-oriented groups: elitism and egalitarianism outperform welfarism  SANDRO MARTINELLI REIA, Instituto de Física de São Carlos, Universidade Estadual de São Paulo, PAULO FREITAS GOMES (Presenter), Universidade Federal de Goiás, JOSÉ FERNANDO FONTANARI, Instituto de Física de São Carlos, Universidade Estadual de São Paulo — Communication is probably the most controllable factor that are known to impact on the problem-solving capability of task-forces. In the case connections are costly, it is needed a better policy to allocate them to the individuals. We use an agent-based model to study how distinct allocation policies affect the performance of a group of agents whose task is to find the global maxima of NK fitness landscapes. The larger the influence neighborhood of an agent, more information it receives. We find that the elitist policy in which agents with above-average fitness have their influence neighborhoods amplified is optimal for smooth landscapes, provided the group size is not too small. For rugged landscapes, however, the elitist policy can perform very poorly for certain group sizes. In addition, we find that the egalitarian policy, in which the size of the influence neighborhood is the same for all agents, is optimal for both smooth and rugged landscapes in the case of small groups. The welfarist policy, in which the actions of the elitist policy are reversed, is always suboptimal, i.e., depending on the group size it is outperformed by either the elitist or the egalitarian policies.

M71.00273: Digital sustainability: A high dimensional ML problem  DEEDER AURONGZEB (Presenter), Johns Hopkins University — The Brundtland report states sustainability as : “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (World Commission on Environment and Development 1987, p. 37). However, due to serious asymmetry of knowledge and technology around the world with digital (know how) based economy, a high dimensional definition is needed before we can begin to address this issue. We show that digital sustainability is a sparse high dimensional problem with independent features. We use framework by Friedman, J.H. Data Mining and Knowledge Discovery (1997) 1: 55., to minimize digital sustainability problem and suggest a ML framework.
M71.00274: Themodynamical aspects of self-similar relaxation evolution of dense star clusters  
YUTA ITO (Presenter), The Graduate Center, City University of New York — Occurrence of negative heat capacity has been predicted and reported for various systems of particles and objects. Examples are granular gases, plasmas, atomic- and molecular- clusters, self-gravitating systems (black holes, stars, star clusters), ... The Antonov's pioneering work assumed an isothermal sphere (a self-gravitating system described by Maxwellian distribution function of particles at constant temperature) enclosed by an adiabatic wall. The work showed no maximum entropy state can be achieved for the sphere beyond a certain large-density contrast between the center and edge. Without the wall, the system expands and particles flow from the dense core to the ambient. Due to the negative heat capacity and conservation of energy/particle, the core heats up and shrinks while the ambient gets sparse and elongates. Such toy model has helped astrophysicists/astronomers to understand the structures of dense star clusters (e.g. globular cluster). More sophisticated models have predicted the clusters can evolve in a self-similar fashion at the late stage of relaxation evolution. The present work discusses the thermodynamical aspects of the self-similar-evolution model compared to classical models, such as the isothermal sphere, polytropic sphere and King model.

M71.00275: Steady-state thermodynamics: reservoir independence*  
LEONARDO CALAZANS (Presenter), RONALD DICKMAN, Univ Fed de Minas Gerais — For stochastic lattice models in spatially uniform nonequilibrium steady states, a thermodynamic temperature T and chemical potential μ can be defined via coexistence with heat and particle reservoirs. Here we ask whether the values so obtained depend on the nature of the exchange between system and reservoir. For example, a stochastic particle reservoir is usually taken to insert or remove a single particle in each exchange, but one may also consider a reservoir that inserts or removes a pair of particles in each event. In equilibrium, equivalence of pair and single-particle reservoirs is guaranteed by the canonical form of the probability distribution on configuration space. We examine whether this equivalence persists in nonequilibrium steady states.

M71.00276: Graphlet Degree correlations reveal evidence of partial spatial embedding in complex networks*  
JOSHUA PARKER (Presenter), RAJEEV AGRAWAL, U.S. Army Engineer Research and Development Center — By virtue of most complex networks being comprised of real world objects or entities that can be assigned a location, the interactions that drive edge formation and network growth are affected by the spatial arrangement of the network's nodes. This means that most networks can be considered "partially embedded" in space, and the degree to which the network is embedded is determined by network growth rules. We utilize recent advances in network alignment techniques based on "Graphlet Degree Similarity" (GDS) to quantify how topological quantities change due to varying levels of spatial embedding in simulated complex networks. We demonstrate that the graphlet degree cross correlation matrix can be used to quantify the level of spatial embedding, and discuss how similar measures can be used to investigate the spatial hierarchy of complex networks.
*Funding provided by the Engineer Research and Development Center, which is a division of the US Army Corps of Engineers
M71.00277: Non-equilibrium statistical physics of systems with finite heat baths*  DAVID WOLPERT (Presenter), Santa Fe Inst, JAN KORBEL, Complexity Science Hub Vienna — In this presentation I analyze the thermodynamics of a system connected to a single, finite heat bath. I concentrate on the case where the work reservoir can only change the Hamiltonian of the system, not the Hamiltonian of the bath, nor the interaction Hamiltonian coupling the system to the bath. In order to apply the tools of conventional stochastic thermodynamics, I assume that the system is coupled to a second, infinite heat reservoir, in addition to the finite heat bath. I prove that in this scenario the entropy production rate of the joint system—finite—bath is lower-bounded by the rate of change of the mutual information between the system and the finite bath. This means that while it is possible to use a semi-static process to simultaneously extract the no-nequlibrium free energy of the system considered by itself, together with the non-equilibrium free energy of the finite bath considered by itself, it is impossible to at the same time extract the free energy stored in the mutual information of those two systems.

*This work was supported by the Santa Fe Institute, and by Grant No. CHE-1648973 from the NSF.

M71.00278: Maximizing free energy gain*  ARTEMY KOLCHINSKY (Presenter), Santa Fe Inst, IMAN MARVIAN, Duke, CAN GOKLER, ZI-WEN LIU, PETER SHOR, OLES SHTANKO, KEVIN THOMPSON, MIT, DAVID WOLPERT, Santa Fe Inst, SETH LLOYD, MIT — Maximizing the amount of free energy that a system extracts from its environment is important for a wide variety of physical, biological and technological processes, from energy harvesting processes such as photosynthesis to energy storage systems such as fuels and batteries. We extend recent results from non-equilibrium thermodynamics to derive closed-form expressions for the maximum amount of free energy that a system can extract from its environment over the course of a fixed process. We also analyze how our bounds on extractable free energy vary with the initial distribution of the states of the system. Simple equations allow us to compare the amount of free energy that can be extracted under the optimal initial distribution with that for a sub-optimal initial distribution. We show that the problem of finding that optimal initial distribution is convex and solvable via gradient descent. We demonstrate our results by analyzing how the amount of extractable free energy varies with the initial distribution of a simple Szilard engine.

M71.00279: FLUID DYNAMICS —

M71.00280: WITHDRAWN ABSTRACT —
**M71.00281: Drop breakup in yield stress fluids**  
JUAN REIMONDO (Presenter), Texas Tech Univ, JOSEFA GUERRERO MILLAN, Augusta University, YA-WEN CHANG, Texas Tech Univ — We study the production of droplets inside yield stress fluids (YSFs) using an extrusion-based 3D printer device. Microgel-based YSFs have recently gained traction in 3D printing applications due to their ability to be molded when stresses are applied, followed by immediate solidification to hold shapes when stresses are removed. The capillary breakup of an immiscible Newtonian fluid inside a YSF can be eliminated completely when the yield stress of the YSF is sufficiently high. This contrasts with simple liquids, where the dispersed phase of co-flowing streams always breaks into spherical droplets. There is, however, and intermediate regime where the evolution of capillary breakup and shape relaxation of drops is arrested, resulting in droplets of non-spherical shapes. By carefully tuning the flow and shear parameters, we demonstrate precision control of dispersed drop shapes through simple physical parameters in ‘co-flowing’ streams of a Newtonian fluid and a surrounding YSF.

**M71.00282: Interfacial thermodynamics of spherical liquid nanodroplets: Molecular understanding of surface tension via hydrogen bond network**  
QHWAN KIM (Presenter), WONHO JHE, Seoul National University — Surface tension plays a important role in nucleation of atmospheric liquid droplets. Especially, understanding of interfacial thermodynamics of the 1 nm scale nucleus is essential for characterization of nucleation such as the activation energy barrier. Despite theoretical and experimental studies performed for decades, determination of surface tension of the nanodroplet is still a topic of ongoing controversies. Here, we investigate surface tension of spherical nanodroplets by both molecular dynamics and density functional theory, and find that surface tension decreases appreciably below 1 nm diameter, whose analytic expression is derived from the Tolman's equation. In particular, analysis of the free energy of nanodroplets shows that the change of surface tension originates from the configurational energy of molecules, which is evidenced by the disrupted hydrogen bond network of nanodroplet. Our results may further illuminate the molecular mechanisms of the interface-related phenomena associated with molecular fluctuations such as ice nucleation or biomolecule adsorption where the macroscopic thermodynamic quantities are ill-defined.

M71.00283: Hydrodynamic Analog for Spontaneous Emission Radiation  JUSTIN EDWARDS (Presenter), YU CHE HO, LUIS GRAVE DE PERALTA, Texas Tech Univ — It has been shown that a drop of fluid can be made to bounce on a vertically oscillating bath of fluid. These droplets, known as “walkers”, couple to the waves they generate and are propelled forward. When a variation of depth in the fluid bath is introduced it creates a difference in potential; droplets crossing the barrier must do so on a transmitted exponentially decaying wave. We have created a system which spontaneously generates walker droplets to simulate particles leaving a potential well. Previous studies of walker droplets have used forcing amplitudes just below the Faraday instability threshold to study the drop’s path about the fluid bath. In this system we use a forcing amplitude well above the threshold in order to generate walker droplets autonomously. The droplets then tunnel across a potential barrier to a damped region where the fluid is below the instability threshold. The formation of these droplets and their resulting kinetic energy is related to the amplitude and frequency of the driving oscillation. We present a statistical study of droplet emission from a potential well. The system could provide an analog to radioactivity in which particles spontaneously tunnel across a potential barrier, showing promise for future analysis.

M71.00284: Ejection of individual microparticles from an electrified meniscus*  JUSTIN BEROZ (Presenter), KAIHAO ZHANG, HENRY MERROW, JOHN W M BUSH, JOHN HART, Massachusetts Institute of Technology MIT — On-demand production of 2D and 3D parts with complex geometries and/or high value material requirements is significant to many industries, and a broad goal of additive manufacturing. State-of-the-art methods for metal, ceramic, and advanced engineering materials typically utilize powder feedstocks, and the dimensional resolution of parts is limited to several particle diameters or larger, which limits precision applications. To address this challenge, we present a method to direct-write individual microparticles onto substrates using an electrohydrodynamic process. A liquid droplet, confined at an orifice and containing microparticles on its surface, is electrified, resulting in the dynamic ejection of individual microparticles from the droplet’s apex. We experimentally detail the electrohydrodynamic process of particle ejection and the parameter regime for which particles print individually. Scaling for ejection speed, liquid entrainment on the particle and satellite droplet formation are also discussed.

*Financial support provided by grants from BAE Systems, MIT Deshpande Center, MIT Lincoln Laboratory (FA8721-05-C-0002) and NSF (CMMI-1346638 to A.J.H., CMMI- 1727565 to J.W.M.B.)
M71.00285: Observing phase separation of temperature-responsive colloids under shear*
JOHN BRADY (Presenter), RYAN J. MCGORTY, Univ of San Diego — We use colloidal microgel particles, PNIPAM and PNIPMAM, in a colloid-polymer system to study phase separation. We synthesize particles of various sizes and characterize their temperature-tunable size with differential dynamic microscopy. When these colloidal particles are mixed with a depletant we observe fluid-fluid phase separation as well as gelation. The process of phase separation is observed using a custom-built light-sheet microscope. With a two-color fluorescent labeling scheme we can track single colloidal particles as well as the phases that emerge as an originally-mixed sample phase separates. Furthermore, we observe our samples under shear in both a custom-built cylindrical shear cell with our light-sheet microscope and in a commercial rheometer using brightfield microscopy. Studying the behavior of multiphase systems like our colloid-polymer samples strengthens our understanding of non-equilibrium thermodynamics while providing novel routes for structuring complex fluids.

M71.00286: Bravais lattice structures settling in viscous media: scaling of terminal velocity with porosity*
SEBASTIAN BÜRGER, Univ Leipzig, RAHUL CHAJWA (Presenter), Fluid Dynamics and Turbulence, International Centre for Theoretical Sciences TIFR, Survey no. 151, Bengaluru 560089, GANGA SRINIVASA PRASATH, Harvard School of Engineering and Applied Sciences, 29 Oxford Street, Cambridge, MA 02138, USA, RAMA GOVINDARAJAN, Fluid Dynamics and Turbulence, International Centre for Theoretical Sciences TIFR, Survey no. 151, Bengaluru 560089 — The settling velocity of porous objects in Stokes flow depends on their geometry. Complex geometries of such objects occur in nature and technology, such as marine snow, particles in pulmonary drug delivery, chemical catalysts and pollen grains. To model the fundamental building blocks of porous geometries, we conduct experiments on sedimentation of various Bravais lattice unit-cell structures at low Reynolds numbers (\( \sim 10^{-4} \)), where each structure consists of equally sized spheres connected by thin rods. For each of these structures, porosity becomes a function of the lattice parameter. We show that the sedimentation behaviour of all Bravais lattices can be collapsed when the settling velocity is scaled using the number of particles in the lattice. A ball-and-stick model using Stokesian hydrodynamic kernel for spheres and slender-body theory for connecting rods, captures the settling behaviour accurately. We perform PIV measurements of flow inside these structures to understand the dependence of permeability on porosity and also the validity of our theoretical model. Our experiments and calculations pave the way for understanding sedimentation of systems closer to reality by introducing disorder in the lattice.

M71.00287: Wave damping of a sloshing wave by an interacting turbulent vortex flow*  
CLAUDIO FALCON (Presenter), Univ de Chile, FRANCISCO REYES, Universidad de Santiago, VICENTE TORREJÓN, Univ de Chile — We report on the enhancement of the hydrodynamic damping of gravity waves at the surface of a fluid layer as they interact with a turbulent vortex flow in a sloshing experiment. Gravity surface waves are excited by oscillating horizontally a square container holding our working fluid (water). At the bottom of the container, 4 impellers in a quadrupole configuration generate a vortex array at high Reynolds number, which interact with the wave. We measure the surface fluctuations using different optical non-intrusive methods and the local velocity of the flow. In our experimental range, we show that as we increase the angular velocity of the impellers, the gravity wave amplitude decreases without changing the oscillation frequency nor generating transverse modes. This wave dissipation enhancement is contrasted with the increase of the turbulent velocity fluctuations from PIV measurements. To rationalize the damping enhancement a periodically forced shallow water model including viscous terms is presented, which is used to calculate the sloshing wave resonance curve as a function of the turbulent fluctuations. From these measurements we compute the dependence of the shallow water viscous friction coefficient

M71.00288: WITHDRAWN ABSTRACT —

M71.00289: A mathematical model of mitochondrial calcium-phosphate dissolution as a mechanism for persistent post-CSD vasoconstriction*  
SHIXIN XU, Duke Kunshan University, JOSHUA CHANG (Presenter), CARSON C CHOW, National Institutes of Health - NIH, HUAXIONG HUANG, York University — Cortical spreading depolarization (CSD) is the propagation of a relatively slow wave in cortical brain tissue that is linked to a number of pathological conditions such as stroke and migraine. Most of the existing literature investigates the dynamics of short term phenomena such as the depolarization and repolarization of membrane potentials or large ion shifts. Here, we focus on the clinically-relevant hour-long state of neurovascular malfunction in the wake of CSDs. This dysfunctional state involves widespread vasoconstriction and a general disruption of neurovascular coupling. We demonstrate, using a mathematical model, that dissolution of calcium that has aggregated within the mitochondria of vascular smooth muscle cells can drive an hour-long disruption. We determine the rate of calcium clearance as well as the dynamical implications on overall blood flow. Based on reaction stoichiometry, we quantify a possible impact of calcium phosphate dissolution on the maintenance of F0F1-ATP synthase activity.

M71.00290: Light-Driven Ballistic Nanoparticle Swimmers*  EUNGYU LEE, TENGFEI LUO (Presenter), University of Notre Dame — Directed high-speed motion of nanoscale objects in fluids can have a wide range of applications. However, directed movement and high speed in the nanoscale are rarely compatible. Light is a convenient source that can drive nano objects to move by applying optical pushing forces due to momentum conservation when photons are scattered off the objects. In theory, optical forces from a planewave can also be “negative” that pull objects against the light propagation direction in a homogeneous medium if some unique optical configurations of the objects can be realized, but this is yet to be demonstrated. Nevertheless, these optical forces are too weak to enable fast-moving swimmers in fluids. Here, we report ballistic plasmonic Au nanoparticle (NP) swimmers with unprecedented speeds (~397,000 mm s\(^{-1}\)) realized by both optical pushing and pulling forces from a single Gaussian laser beam. The Au NP excited by the laser at the surface plasmon resonance (SPR) peak interact with the NP both thermally and optically, leading unique conditions for ballistic movements and “negative” optical forces.

M71.00291: Enhancing propulsion efficiency of biomimetic elastic propulsor using hybrid actuation*  ERSAN DEMIRER, FIKAYO OSHINOWO (Presenter), ALEXANDER ALEXEEV, Georgia Institute of Technology — Bio-inspired propulsion of a robotic swimmer can be achieved by periodic actuation of an elastic caudal fin. We use three-dimensional computer simulations to probe how the hydrodynamic performance of a caudal fin can be enhanced by combining two distinct types of fin actuation. The fin is represented by an elastic rectangular plate that is actuated at the base to perform sinusoidal oscillations. The actuation frequency is set to match the fundamental frequency of the plate yielding the maximum bending amplitude. In addition to this plunging actuation, the plate is actuated by a distributed bending moment with the magnitude that periodically changes in time with the same frequency as the fin base. We introduced a phase difference between the base and the internal actuation and investigate the resultant hydrodynamic thrust and efficiency. We compared the hybrid fin actuation to the base actuation and to the internal actuation to identify the parameter space in which the synergetic effects of the two action mechanisms are the most beneficial for swimmer propulsion.

*This work is supported by NSF CBET 1705739
M71.00292: Scattering of a fast-swimming bacterium off of a surface: Methods  SCHUYLER MCDONOUGH (Presenter), BENJAMIN ROQUE, ALEXANDER PETROFF, Physics, Clark University — Thiovulum majus is the fastest known bacteria. In its natural habitat, near the penetration depth of oxygen in salt marsh sediment, these bacteria create fluid flows that pull nutrient-rich water through the pore space. As cells navigate the pore space in which they live, they frequently collide with grains of sand. To better understand the ecology of these microbes, we investigate the dynamics of a collision of a T. majus with a solid surface. This presentation focuses on the experimental techniques needed to perform these measurements. These bacteria cannot be grown in pure culture. We first describe how we enrich T. majus from mud, collected from a Massachusetts salt marsh. Next, we analyze the motion of these cells in a microfluidic device. This device confines the motion of cells to two dimensions. We present techniques that allow us to track several thousand collisions between fast swimming cells and the chamber walls. We show that there are two types of collisions. If a cell approaches the wall at a glancing angle, it initially turns to swim parallel to the wall and then returns to the fluid. In the case of head-on collision, the cell becomes hydrodynamically bound to the surface.

M71.00293: WITHDRAWN ABSTRACT  —

M71.00294: Distinguishing Complex Locomotory Patterns in C. elegans*  SUSANNAH ZHANG (Presenter), Physics and Astronomy Department, University of Georgia, JENNY MAGNES, Physics and Astronomy Department, Vassar College, HAROLD HASTINGS, Physics Department, Bard College at Simon's Rock, KATHLEEN SUSMAN, Department of Biology, Vassar College, MIRANDA R HULSEY-VINCENT, Physics and Astronomy Department, Vassar College — Caenorhabditis elegans, more commonly known as C. elegans, are transparent nematodes approximately 1 mm long that inhabit soil in temperate environments. C. elegans have 302 neurons that are similar in form and function to that of humans. This similarity and the small number of neurons has spiked the interest of neurological and biological communities. With over 70 phenotypes, it is possible to quantitatively distinguish many C. elegans phenotypes according to different locomotory patterns. Time-Dependent Diffraction by oversampling provides information about the locomotion in the form of a single time-series; nevertheless, visually the different locomotion types are indistinguishable. We investigate the locomotion of two types of C. elegans, Wildtype (N2) and Roller (OH7547), using Recurrence Plots (RP) to analyze the complex dynamics collected. This method of analysis allows us to keep all of the dynamics of motion since every point in the diffraction pattern is a superposition of light rays diffracted from each point on the worm. Through the RPs, we dive deeper into the difference between locomotory patterns to be able to separate these two types of C. elegans.

**M71.00295: Comparison between direct experimental measures of surface excess concentration in surfactant solutions with estimates based on the Gibbs Adsorption Isotherm**

ERNESTO HERNÁNDEZ-ZAPATA (Presenter), Recursos de la Tierra, Universidad Autónoma Metropolitana, LUCIANO MARTÍNEZ-BALBUENA, Departamento de Física, Universidad de Sonora, ARACELI ARTEAGA-JIMÉNEZ, Centro de Investigación en Ciencia Aplicada y Tecnología Avanzada, Instituto Politécnico Nacional, CÉSAR MÁRQUEZ-BELTRÁN, Instituto de Física, Benemérita Universidad Autónoma de Puebla — Recently, Menger et al [J. Am. Chem. Soc. 131 (30): 10380 (2009)] have suggested that the Gibbs Isotherm Method (GIM) is not the best way to estimate surfactant surface excess concentration from surface-tension measurements at the air-water interface. Important experimental techniques, such as Neutron Reflectivity and the radiotracer method, have arisen in recent years helping to clarify the controversy. This is because they are able to measure the surface excess concentration without the use of the GIM. We review the best available surface-tension data for some ionic and nonionic surfactants, and apply the GIM to them in order to directly compare with Neutron Reflectivity and radiotracer data [Adv. Coll. Int. Sci. 247: 178 (2017)]. As the thermodynamic theory behind the GIM predicts the agreement is good for concentrations smaller than the CMC, both for ionic and nonionic surfactants. In the case of nonionic surfactants, we found also a good agreement for concentrations larger than the CMC.

---

**M71.00296: Solvent diffusivity and viscosity in graphene oxide membrane for water-ethanol separation**

GOBIN ACHARYA (Presenter), PETER HOFFMANN, Wayne State Univ — Graphene oxide (GO) membranes were recently suggested for applications in separation of ethanol from water using a vapor permeation method. Understanding microscopic diffusivity of water and ethanol in graphene oxide membranes is important for separations applications. It is also important to study the anisotropy of water and ethanol diffusivity between the direction perpendicular to the plane and in-plane direction. We used quasielastic neutron scattering (QENS) to measure the temperature dependence of the diffusivity of water and ethanol, and its anisotropy by the utilization of Q-dependence of QENS signals obtained from BASIS at Oak Ridge National Lab. We will also discuss how dynamic measurements from QENS can be correlated with atomic force microscopy measurements of the temperature dependence of viscosity in water/ethanol confined in GO.

*We thank Wayne State University for funding and ORNL for providing access to BASIS through a user proposal.*

**M71.00297: BIOLOGICAL PHYSICS**
M71.00298: Estimating the posture of coiled and overlapping worms using a neural network  
AVELINO JAVER, JENS RITTSCHER, University of Oxford, ANDRE BROWN (Presenter), Imperial College London — The first step in studying postural dynamics is typically animal tracking. A range of deep learning approaches have proven effective for human posture tracking and several groups have adapted these methods to laboratory animals. These methods typically detect key points on the body and they work particularly well for jointed animals where there are clear landmarks. For tracking the nematode worm *C. elegans*, some challenges remain. We generated a manually annotated data set with tens of thousands of frames including coiled and overlapping worms to train a neural network to find equidistant points along the worm midlines. During training we rely on simple image synthesis augmentations and use priors that incorporate the worm morphology into the loss function. We show that the new algorithm performs well with challenging backgrounds, for coiled worms, and for multiple overlapping worms. We apply the network to mating, a behaviour that necessarily involves overlapping worms.

M71.00299: Piezoelectric based sensor development to measure sound intensity in aquatic environments.*  
ELIJAH WATERS (Presenter), Physics and Astronomy, Georgia Southern University, SILVIU C. SARARU, MIHAELA T. UDRISTIOIU, Sciences, University of Craiova, VINOTH SITTARAMANE, Biology, Georgia Southern University, DRAGOS AMARIE, Physics and Astronomy, Georgia Southern University — When aquatic animals are presented with unfamiliar environments they tend to alter their behavior. To gain insight on such behavioral actions and changes there is a need for a submersible sensor designed to measure sound intensity given by the specimen. Our device builds around the property of a piezoelectric element that gives off an electrical signal when undergoing mechanical stress. This small signal is then boosted by means of a pre-amplifier connected to the piezo element within the device's housing. In experimentation, the device is placed in a position that allows for exposure of the piezo element surface into the aquatic environment. A clear gel containing the animal's food or prey within is applied on the surface. In an attempt to get food, or attack, the animal will strike, thus apply a force on the piezo. This provides the mechanical stress needed to gain the electrical signal that is recorded into a digital audio workstation (DAW) as audio. DAW is used to analyze the audio in decibels over time. Software is used to process the data as sound intensity produced by the specimen and quantify the striking intensity. Being able to measure these changes in behavioral habits we would be able to study embryonic learning.

*Office of Research, Georgia Southern University
M71.00300: Epigenetic regulation enhances stability of somatic differentiation state*
TIANCHI CHEN (Presenter), MUHAMMAD ALI AL-RADHAWI, EDUARDO SONTAG, Northeastern University — Stem cell treatments, such as those affecting the states of the network of pluripotency genes, are expected to play a central role in future personalized medicine. The genetic regulatory network consisting of the Oct4, Nanog, and TET transcription factors (TF's) is understood to control cell fate, specifically the transitions between somatic and pluripotent states. In the classical view, the steady states of a dynamical system modeling the genes, mRNAs, and proteins in this network are identified with the above two types of states. In this work, we investigate the role of epigenetic regulation in further stabilizing the two states. Specifically, we present a mathematical model that combines TF's and DNA methylation, which is one of the most important forms of epigenetic regulation. Our starting point is a mechanistic model formulated in the language of chemical reaction networks that describe promoter binding together with transcription/translation. We conclude that the effective rate of DNA methylation increases stability (relative size of the basin of attraction) of the somatic cell state, while increasing DNA demethylation rate, which is controlled by Nanog-guided TET protein, increases stability of the pluripotent state.

*NSF 1716623

M71.00301: Characterizing the spread of the effect of mutations on the protein-protein interaction network
ANUSH DEVADHASAN (Presenter), ITALO FARIA DO VALLE, Northeastern University, ISTVAN KOVACS, Physics, Northwestern University, ALBERT L BARABASI, Northeastern University — Networks can serve as a powerful tool for dissecting phenomena in complex biological systems. Of particular interest in biology is the effect of mutations on the resulting phenotype. Although numerous prior studies address this for specific cases, a generalized mechanistic theory of the phenotypic effect of mutation-induced perturbations does not exist. Here we identify patterns and principles characterizing the spread of the effect of mutations on the protein-protein interaction (PPI) network. Specifically, we propose network-based laws to identify differentially expressed genes (DEGs) following loss-of-function (LOF) mutation by studying the interplay between the topology of the PPI network and its response following node removal. We utilize cell line gene expression data following LOF mutation to evaluate network measures involving the DEGs and the knocked-out gene (KOG). We find that for 26/53 genes the DEGs form a statistically significant connected subgraph in a PPI network comprised of interactions curated from literature. Furthermore, we find that DEGs are significantly proximal to the KOG in 10/53 cases. This work contributes fundamental systems-level observations which may be exploited for the development of a predictive framework for general use in biological research.
M71.00302: Human Gene Expression and the Protein-Protein Interaction Network: Identification of Potential Disease Module Association to Differential Gene Expression for Patient-to-Drug Matching  AYDIN WELLS (Presenter), Northeastern University, DEISY MORSELLI GYSI, Center for Complex Network Research, ALBERT L BARABASI, Northeastern University — The relationship between human gene expression (GE) and precision medicine applications is central in understanding how patients are affected by and how to better treat a disease. Even though it is of extreme importance, this knowledge is still absent from almost any disease analysis resulting in misdiagnosis and mistreatment based on symptomatic and physical observation criteria devoid of high throughput sequencing technologies. By detecting disease modules in the protein-protein interaction (PPI) network, along with the identification of patient differential GE sets (DGE), we can suggest effective individual treatment options. Here, we collect public RNA sequencing data for a diverse population and arrange unique GE patient profiles. DGEs are computed using machine learning techniques and are identified within the PPI network, where disease modules can be pinpointed. Those modules can be used for disease classification specific to expression levels and cohort phenotype. By elucidating these interactions using network approaches with an individual patient's features, human diseases can be identified not by peripheral approaches, but by a personal genetic diagnosis; essentially redefining disease diagnostics from a “one size fits all” philosophy, to a “one size fits you” reality.

M71.00303: Effects of Stochasticity in Biological Oscillators  CHAITRA AGRAHAR (Presenter), Physics, UIC, MICHAEL RUST, University of Chicago — Many processes need to occur periodically for proper functioning of the cell, despite fluctuations in its environment. A cell must remain robust against irrelevant fluctuations, while simultaneously responding to relevant cues. We study how network topologies optimize the trade-off between maintaining robust oscillations and biosynthetic expenditure.

Many studies concur that motifs with positive and negative feedback are most robust to variations in the deterministic limit [1, 2], and in the stochastic regime [3, 4]. However, there is no mechanistic understanding for predicting the performance of different topologies.

Our findings suggest that deterministic amplitude, along with the distribution of angular velocities along the phase-space orbit of dynamical variables can lead to a mechanistic understanding of this trade-off. Regulation mechanisms and tuning of interaction strengths play a pivotal role in this optimization.

**M71.00304: Multivalent Binding of Patterned Polymers**  
EMIKO ZUMBRO (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology MIT — Using inspiration from biology, we can leverage multivalent binding to enhance weak, monovalent binding between molecules. Synthetic glycopolymers have been shown to successfully bind to viruses and toxic proteins. This binding indicates that multivalent polymers are a promising tool for inhibiting target attachment to and subsequent infection of cells. Previous work from our group focused on how structural features of uniform binding site polymers create high affinity and specificity to a single target. In contrast, real synthetic polymers might find it desirable to have multiple binding moieties along the chain. Multiple binding site types allow polymers to target multiple species creating broad-spectrum binding or allow for tracking or imaging in addition to targeted binding. Heterogeneity in binding site patterns can also be a byproduct of chemical synthesis methods. We use a reactive-binding, Brownian dynamics simulation and machine learning to examine how patterning of heterogeneous binding sites along a polymer chain controls binding of a multivalent polymer. Our results provide direction for the rational design of multivalent binders.

*The authors were supported by the Department of Defense through the National Defense Science & Engineering Graduate Fellowship Program.*

**M71.00305: Using structural adaptations in plants for desalination**  
ADAM WOOD (Presenter), RAGHAV GARG, KYLE JUSTUS, TZAHI COHEN-KARNI, ALAN RUSSELL, PHILIP R LEDUC, Carnegie Mellon Univ — Biologically-inspired abiotic systems are becoming a central pillar in how we respond to critical grand challenges that accompany exponential population growth, uncontrolled climate change and the reality that 96.5% of the water on the planet is saltwater. One fascinating biologic adaptation to saltwater is the growth of mangrove trees in brackish swamps and along the coasts. Through salt exclusion, the mangrove maintains a near freshwater flow from roots to leaves for survival. One abiotic approach to water desalination is capacitive deionization (CDI), which uses electrostatic force to adsorb ions from a feed stream to a pair of charged electrodes. In this work, we use one-step carbonization of mangrove roots with developed aerenchyma tissue to enable highly-permeable, freestanding flow-through (FT) CDI electrodes. We demonstrate the use of the intact carbonized mangrove roots as electrodes in a FT-CDI system. We also show that the structure of carbonized aerenchyma from mangrove roots reduces the resistance to water flow through the electrodes by 65-fold relative to carbonized plant structure lacking this biological adaptation (woody biomass). These findings have implications in a range of fields including desalination, bioinspired materials, and plant-structure functionality.
M71.00306: Correlative Atomic Force Microscopy and Photo-Activated Localization Microscopy of Nano-cellulose Fibrils from Tunicate and Poplar*  LIN KANG (Presenter), CONGZHOU WANG, Nanoscience and Nanoengineering, South Dakota School of Mines & Technology, SHI-YOU DING, Department of Plant Biology, Michigan State University, STEVE SMITH, Nanoscience and Nanoengineering, South Dakota School of Mines & Technology — The molecular structure of cellulose in its native nano-fibril form is difficult to characterize and consequently still not well understood. We report simultaneous Atomic Force Microscopy (AFM) and Photo-Activated Localization Microscopy (PALM) of cellulose nano-fibrils (CNFs) from Tunicate and Poplar. PeakForce Quantitative Nanomechanical Mapping (PFQNM) is employed to characterize sample stiffness and modulus mapping. To complement the AFM measurements, the nano-fibrils were exposed to recombinant family 3 Carbohydrate Binding Modules (CBM3) specifically binding to the hydrophobic surface of crystalline CNF. The CBM3 was also tagged with a photoactivatable fluorescent protein PA-mCherry to allow super resolution imaging by PALM. We compare the distribution of CBM binding sites to the nano-fibril topography to draw conclusions about the degree of crystallinity of the elemental CNF and the distribution of amorphous areas within the CNF and at morphological kinks, which show a non-Gaussian distribution related to the crystallographic planes of cellulose.

*Funded by the National Science Foundation (DMR 1206908 BMAT).

M71.00307: The SWCNT-DNA hybrid for imaging and vector delivery applications A. Adesina, S. Pourianejad, T. Ignatova Nanoscience Department, University of North Carolina at Greensboro, Greensboro, NC, USA* ADEYINKA ADESINA (Presenter), Univ of NC - Greensboro — Single Wall Carbon Nanotubes (SWCNTs), being quasi-one-dimensional materials, are extensively investigated for intracellular imaging and bio-sensing applications since discovery of the hybridization of ssDNA molecules to SWCNTs. When functionalized, SWCNT can be introduced within the cell and co-localized with the sub-cellular organelles. SWCNTs exhibit resonance Raman scattering, with sharp, high intensity Raman peaks quite different from that of the hybrid or the cell itself. Raman signal of SWCNTs is chirality specific hence it can be used for nanotube identification and to assess their aggregation in cell environment. The long-term intracellular studies of SWCNTs within neural stem cells have been conducted using micro-Raman spectroscopy indicating the viability of SWCNTs as an efficient tracking agent. Additionally, we investigated the affinity of the ssDNA for SWCNT in presence of complementary strand. Here, the results on the equilibrium and dynamic study of DNA displacement from the nanotube surface, temperature dependence, Manning-Oosawa counterion condensation, and pH variation will be presented.

M71.00308: Investigating Zika Virus RNA Conformational Switching using Molecular Dynamics* NAOMI BRANDT (Presenter), RNA Institute, University at Albany (SUNY), SIMI KAUR, Chemistry Department, University at Albany (SUNY), ALAN CHEN, Chemistry Department, RNA Institute, University at Albany (SUNY) — Previous attempts at modeling RNA folding for relatively large systems have demonstrated limited sampling of conformation space due to the presence of kinetic traps. In this work, we used a novel method of molecular dynamics simulations, a 2D replica exchange protocol in which RNA replicas cycle through both temperature variations and base-pairing restraint strength using experimentally determined base-pairing patterns. This method refines the energy landscape, biasing the structure to preserve only the most stable conformations at low temperatures.

Using this approach, we designed all-atom models of sections of the 3’ untranslated region of Zika Virus RNA in order to predict pseudoknot formation between the 3’ dumbbell region and other nearby structures. The dumbbell is theorized to be a driving mechanism that allows switching between the translation and replication phases of the RNA lifecycle. From our simulations, we were able to infer the kinetic and structural favorability of proposed pseudoknots, and investigate potential intermediaries required to trigger switching.

*This work was supported by NIH Grant 1R35GM13346901.

M71.00309: Restraint-Biased 2D Molecular Dynamics Simulations SIMRANPREET KAUR (Presenter), PARISA EBRAHIMI, Chemistry, SUNY Albany, NAOMI BRANDT, RNA Institute, SUNY Albany, ALAN CHEN, Chemistry and RNA Institute, SUNY Albany — Although recent experimental and computational advances have strived to understand RNA structure-function relationships, the roles of many RNAs are dependent upon a complex network of motifs, including hairpins, internal loops, pseudoknots and long-range contacts, that are not easily captured by these methods. Ab-initio modeling using all atom molecular dynamics simulations is limited by the available energy functions and the required sampling of an extensive conformational space. We have developed a hybrid replica exchange method that incorporates secondary structure information from experiments in the form of piecewise linear-harmonic distance restraints (bias forces) to efficiently fold RNA in 3D detail. This sharpens the free energy landscape by reducing the number of conformations that satisfy an optimum 3D fold. Replica exchange conducted in both temperature and position space, where replicas with variable bias forces and temperatures run in parallel and periodically swap, also allows molecules to overcome kinetic barriers surrounding local minima. A range of possible structures are uncovered from higher temperatures, but only the most stable conformations are retained at lower temperatures.
M71.00310: Flow Analysis and UniverScope: complementary techniques to monitor spheroid growth* SHANJIDA KHAN (Presenter), Drew University — The Bioimaging & Optofluidics laboratory has developed an encapsulation technique that allows to produce multicellular spheroids as model tissue at a very high throughput and controlled manner. To monitor the growth of spheroids, we use two complementary techniques. The first one relies on an image-free analysis of the light absorbed by the spheroids; the second one consists of building a microscope that allows parallelized imaging of spheroids in physiological conditions. These two methods are aimed at measuring the spheroid radius as a function of time and at gaining insight into the fate of cells within the spheroids.

*This research was funded in part by National Science Foundation - REU and the Department of Physics in Lehigh University. I would like to thank Dr. Pierre Guillot and H.D. Ou-Yang who made arrangements for me to work in Laboratoire Photonique Numérique et Nanosciences at the Institut d'Optique Graduate School. Finally, I would like to thank Dr. Pierre Nassoy who had oversight of this research.

M71.00311: Expanding Without Exploding: Measuring and Modeling the Biomechanics of Pollen Hydration KARI MILLER, ANDERS CARLSSON (Presenter), ELIZABETH HASWELL, Washington University, St. Louis — To carry male gametes to female plants, pollen grains must undergo desiccation. They subsequently rehydrate before extending a tube to fertilize the egg cell. Hydration involves dramatic changes in both the turgor pressure and cell wall properties of the pollen. Little is known about the mechanics of hydration, especially the mechanisms that allow the pollen grain to tolerate the large forces that occur. Here we combine mathematical modeling with experimental data to clarify the role of a membrane-bound tension-sensitive ion channel (MSL8) during hydration. This channel is known to be essential for pollen survival during hydration, but its exact role is not known. New data presented here reveal that MSL8 contributes to rapid stabilization of the pollen grain volume during hydration. In the absence of MSL8, the pollen grain continues to expand indefinitely, often leading to overexpansion and bursting. We develop a mathematical model of rehydration dynamics embodying the interplay between turgor pressure, cell wall mechanics, membrane mechanics, and tension-sensitive channels. This model finds, consistent with the data, that the absence of tension-sensitive channels causes continued expansion of the cell.
M71.00312: Interaction of Electromagnetic Radiation with DNA  DAVID ORTEGA (Presenter), SAMINA MASOOD, University of Houston, Clear Lake — Cells are known to be affected significantly due to constant exposure to electromagnetic radiation. DNA can be damaged with electromagnetic waves in a variety of ways. Cellular multiplication plays an important role in the survival of life. This multiplication involves a chain of DNA replication going through several steps including auto-repair mechanisms to protect DNA from damages. These repair mechanisms range from specific "locate and repair" systems to "damage tolerance" repairs. With many damage events per cell per day the errors that do make it through the repair process are seen as mutations to the genetic code and may be expressed as changes in morphology. Applying an appropriately modified Jaynes-Cummings model with an extra potential we re-investigate the DNA replication considering the entangled states of the nucleotide. Interaction of DNA with radiation is studied as an interaction of matter with electromagnetic waves. This approach is used to measure the probability of changes in morphology due to the interaction of DNA with radiation.

M71.00313: Polymerization Characteristics of Different Microtubules’ Interaction with Tau Protein and Taxol*  JANE BRESLIN (Presenter), IBUKUNOLUWA AKINTOLA, MITRA SHOJANIA FEIZABADI, Seton Hall Univ — We previously reported that the interaction of one of the microtubule-associated protein (MAP), tau protein, is significantly different on two different types of microtubules; brain microtubules versus human breast cancer microtubules in vitro. These two types of microtubules are distinct from one another due to structural differences that exist in beta-tubulin isotype distributions. In addition, microtubules are known as one of the best targets for anti-cancer drugs such as Taxol. It is known that the direct interaction of Taxol with tubulin or microtubules changes the polymerization specifications of them. Due to the existence of Tau protein in brain cells and some breast cancer cells, it is important to study how the presence of both Tau protein and Taxol may affect the polymerization specifications of these two structurally different microtubules. In this study, we explain the outcomes of our experiments in identifying the distinct polymerization properties of Tau protein and Taxol interacting with different beta-tubulin isotypes in these two types of microtubules.

M71.00314: A Nano-Technology Approach to Screen the Charge of Molecular Motors

RAMIZ ALEJILAT (Presenter), ALEXIS DUFFY, MITRA SHOJANIA FEIZABADI, Seton Hall Univ — A better understanding of the nature of the electrostatic interactions between molecular motors and microtubules requires a thorough examination of, not only the charge of microtubules, but molecular motors as well. Several reported studies have been conducted to screen and evaluate the charge of microtubules in vitro. However, our knowledge about the electric charge of molecular motors is still limited to the evaluation of the association rate they express in conjunction with microtubules.

With the goal of screening and evaluating the charge that molecular motors carry, we have designed a nanotechnology-based method. In this approach, the charge of motors can be screened in vitro by monitoring their behavior inside a uniform electric field. This novel in vitro approach minimizes the cellular factors that can potentially interfere with evaluating the charge of motors, leading to a better capability of evaluating the charge of these bio-motors in a more exclusive framework.

*We acknowledge the funding from Clare Boothe Luce for Alexis Duffy.

M71.00315: Optical Imaging of Magnetic Particle Rotation in High Viscosity Fluids

RIVER GASSEN (Presenter), DENNIS THOMPKINS, GUY HAGEN, KATHRIN SPENDIER, BioFrontiers, UCCS — The purpose of this experiment is to study the oscillation and rotation of nanoparticles in fluids of different viscosities. The investigations have practical applications to the medical field, specifically drug delivery through high viscosity fluids like mucus. Magnetic barium hexaferrite (BaFe12O19) and iron oxide (Fe3O4) particles were suspended in distilled water or various glycerol concentrations. The mixtures had a concentration of 2.50mg/ml for the BaFe12O19 and 1.00mg/ml for Fe3O4. Magnetic particles were exposed to oscillating or rotating magnetic fields and imaged with an optical microscope. Time-varying magnetic fields ranging from 10Hz to 180Hz are created by pairs of home-made wire coils that insert into the microscope. Magnetic field amplitudes can be varied from 0-12 mT. The resulting measured frequency of the particle oscillation or rotation equaled the drive frequency when the drive frequency was less than half the frame rate. For high viscosity fluids, higher magnetic field strength was necessary for particle motion. Further investigation will need to be done to determine how the viscosity, particle size, and drive frequency impact the movement of the particles, going from oscillating at the driving frequency to no particle motion.

**M71.00316: The Dynamics of Human Society Evolution**
RAM POUDEL (Presenter), Tribhuvan University, JON MCGOWAN, University of Massachusetts Amherst — Human society is an open system that evolves by coupling with various known and unknown (energy) fluxes. How do these dynamics precisely unfold? Energetics may provide further insights. We expand on Navier-Stokes’ approach to study non-equilibrium dynamics in a field that evolves with time. Based on the ‘social field theory’, an induction of the classical field theories, we define social force, social energy and Hamiltonian of an individual in a society. The equations for the evolution of an individual and society are sketched based on the time-dependent Hamiltonian that includes power dynamics. In this paper, we will demonstrate that Lotka-Volterra type equations can be derived from the Hamiltonian equation in the social field.
Keywords: evolution; energetics; social field theory; capital; capabilities.

*We did not seek any funding for this research. RP acknowledges a sabbatical granted by the Institute of Engineering, Tribhuvan University.*

**M71.00317: Ecological mechanisms of direct and indirect bacteriotherapies in generalized Lotka-Volterra systems**
ERIC JONES (Presenter), JEAN M CARLSON, University of California, Santa Barbara — Over the last two decades, an association between microbiome composition and some human diseases has been unambiguously established. The correlation between gut microbe composition and these diseases has prompted medical interest into bacteriotherapies, which seek to modify the gut microbiome composition in the hopes of treating the correlated disease. In this work we use generalized Lotka-Volterra (gLV) models to probe the ecological mechanisms through which these bacteriotherapies function. We first describe direct bacteriotherapies, which drive a microbiome to a target state via an instantaneous influx of foreign microbes (e.g. probiotics or fecal microbiota transplantation). Then, we present a novel control framework for indirect bacteriotherapies, which drive a microbiome to a target state by deliberately modifying its environment (e.g. diet, acidity, or nutrients). These dual control methods for gLV systems, interpreted as bacteriotherapies, could eventually inform personalized medicine for the microbiome.

M71.00318: Competing for Resources: on the Emergence of Property Rights  CLELIA DE MULATIER (Presenter), University of Pennsylvania, CRISTINA PINNERI, Max Planck Institute for Intelligent SystemsMax Planck Institute for Intelligent Systems, Tübingen, Germany, MATTEO MARSILI, International Centre for Theoretical Physics — A game theory approach to the evolution of animal conflicts has shown that choosing an initial asymmetric feature, such as first come first served, to settle a contest is evolutionarily stable, as it avoids the costs of animal fights. In this context, we investigate the optimal strategies of a population of non-aggressive agents competing for multiple resources. Resources provide different payoffs and can only be exploited by one agent at a time. If an agent tries a resource that turns out to be occupied, it then looks for another resource, which has a cost. We show theoretically and numerically that this system admits two types of Nash equilibria. In an under-crowded system, resources are equally shared between agents; our reinforcement learning simulations find multiple optimal solutions, where agents each exploit different sets of resources but all earn the same average payoff. The average strategy of these agents matches with the theoretical mean-field solution. Over-crowded systems are instead conducive to the emergence of inequality; some agents can earn more than the others by establishing themselves as property owner of a medium-payoff resource. In the reinforcement learning simulations, such lucky agents emerge naturally from their random learning experience.

M71.00319: A model to explain the propagation of small dysfunctional mitochondrial DNAs in budding yeast  CHRISTOPHER NUNN (Presenter), SIDHARTHA GOYAL, Univ of Toronto — Mitochondrial DNA (mtDNA) in budding yeast is unstable, resulting in a high rate of spontaneous respiratory-deficient mutants [1]. These respiratory-deficient mutants (called petites) can, however, grow on fermentable media. A petite cell often contains small, incomplete mtDNA fragments, that replicate and pass on from generation to generation with no known function in the cell. These selfish mtDNAs often do better than wild type mtDNA and outcompete (suppress) them if they are present together in a cell [2]. The features that allow these selfish mtDNAs to outcompete wild type mtDNA, as well as the potential for mechanisms that select against selfish mtDNAs remains to be fully characterized. To address these questions we have characterized a set of spontaneous petite mitochondrial genomes, and developed a model to explain what features of their structure inform their suppressivity when mixed with wild type mtDNA.

M71.00320: Information costs in the control of protein synthesis  REBECCA ROUSSEAU (Presenter), Physics, California Institute of Technology, WILLIAM S BIALEK, Physics, Princeton University — Efficient protein synthesis depends on the availability of charged tRNA molecules. With 61 different codons, shifting the balance among the tRNA abundances can lead to large changes in the protein synthesis rate. Previous theoretical work has asked about the optimization of these abundances, and there is some evidence that regulatory mechanisms bring cells close to this optimum, on average. We formulate the tradeoff between the precision of control and the efficiency of synthesis, asking for the maximum entropy distribution of tRNA abundances that is consistent with a desired mean rate of protein synthesis. Our analysis, using data from *E. coli*, indicates that reasonable synthesis rates are consistent only with rather low entropies, so that the cell's regulatory mechanisms must encode a large amount of information about the “correct” tRNA abundances.

M71.00321: Contours information and the perception of various visual illusions*  EE HOU YONG (Presenter), Nanyang Technological University — The simplicity principle states that the human visual system prefers the simplest interpretation. However, the conventional coding models could not resolve a contradiction between the global minimum principle and the local minimum principle. By quantitatively evaluating information content along the contours under our framework, it is shown that the most plausible interpretation of a stimulus (the one correctly predicted by local minimum principle) possesses the lowest information globally, hence resolves the contradiction. This model could also explain the perception of various visual illusions including Kanizsa illusions, Ehrenstein illusions and Rubin's vase via estimating the lower bound of the spread parameter of the von Mises distribution governing human visual expectation. This provides new insight into the celebrated simplicity principle and could serve as a fundamental explanation of the perception of illusory boundaries and the bi-stability of perceptual grouping.

M71.00322: The robust bioinformatic analysis of the protein sequences with phase behavior
ALEKSANDRA ELZBIETA BADACZEWSKA-DAWID (Presenter), DAVIT POTOYAN, Iowa State University — Liquid-liquid phase separation (LLPS) of many proteins is critical in the biological function of membrane-less organelles. Reversible nature of biomolecular PS in cells suggests that phases of proteins and nucleic acids are like to be tightly regulated. Post-translational modifications and single-residue mutations have been shown to lead to the dissolution of biomolecular droplets or phase transition into aggregated forms. Based on the wealth of experimental data, it reasonable to expect that the PS of proteins is highly sequence-specific. To reveal common motifs of protein sequences that promote PS, we have carried out large-scale statistical analysis of phase separating protein deposited in the LLPSDB database. For each motif, the most significant interactions have been identified (e.g. charge, hydropathy, polarity, pi-stacking). The bioinformatic analysis provides us with crucial knowledge about sequence conservation, secondary structure preferences, aggregation tendency, post-translational modification prediction, and binding affinity. The long-term goal of our research is the creation of a publically accessible database that would be used by both experimentalists for designing controlled mutations and for computationally-oriented scientists for developing new modeling tools.

M71.00323: Reentrant Liquid Condensation of Ribonucleoprotein–RNA Complexes
MURALIKRISHNA RAJU (Presenter), RABIA LAGHMACH, DAVIT POTOYAN, Iowa State University — Intracellular Ribonucleoprotein (RNP) granules are membrane-less liquid condensates that dynamically form, dissolve, and mature into a gel-like state in response to a changing cellular environment. RNP condensation is largely governed by attractive inter-chain interactions mediated by low-complexity domains. Using an archetypal disordered RNP, fused in sarcoma (FUS), here we employ atomistic simulations to study how RNA, a primary component of RNP granules, can modulate the phase behavior of RNPs by controlling both droplet assembly and dissolution. Electrostatic interactions are found to be the primary driving force behind condensate formation. Monotonically increasing RNA concentration initially leads to droplet assembly via complex coacervation and subsequently triggers an RNP charge inversion, which promotes disassembly. We construct phase diagrams based on Droplet density and Shannon entropy calculations, wherein three distinct regimes can be identified based on RNA and peptide concentrations. Increasing salt concentration is found to inhibit the formation of liquid condensates and narrow the coexistence region. The internal organization and dynamics of the condensates are investigated as a function of RNA/peptide concentrations, RNA chain length and salt concentration.
M71.00324: Liquid-liquid phase separation driven compartmentalization of reactive nucleoplasm  RABIA LAGHMACH (Presenter), MURALIKRISHNA RAJU, DAVIT POTOYAN, Iowa State University — Organization and regulation of intracellular biochemistry are achieved by compartmentalizing biomolecules through the liquid-liquid phase separation process (LLPS) and its associated chemical reactions into membrane-bound and membrane-less organelles. The LLPS of proteins/RNA within the nucleus plays a crucial role in the gene regulation of eukaryotic cells. Here, we present a reaction-diffusion model of transcription which connects the phase separation of proteins-RNA mixture inside nucleoplasm with transcriptional and catalytic reactions. Our model shows the existence of a variety of complex protein-RNA patterns that arise from the competition between different mechanisms including LLPS, biomolecular interactions, and biochemical reactions. The protein-RNA pattern formation is strongly dependent on the interplay of time-scales for diffusion, transcription, and translation. Under appropriate kinetic regimes, we can dramatically accelerate or slow down the phase-separation process, thereby leading to arrested phases.

M71.00325: Liquid-liquid phase separation driven compartmentalization of reactive nucleoplasm  RABIA LAGHMACH (Presenter), MURALIKRISHNA RAJU, DAVIT POTOYAN, Iowa State University — Organization and regulation of intracellular biochemistry are achieved by compartmentalizing biomolecules through the liquid-liquid phase separation process (LLPS) and its associated chemical reactions into membrane-bound and membrane-less organelles. The LLPS of proteins/RNA within the nucleus plays a crucial role in the gene regulation of eukaryotic cells. Here, we present a reaction-diffusion model of transcription which connects the phase separation of proteins-RNA mixture inside nucleoplasm with transcriptional and catalytic reactions. Our model shows the existence of a variety of complex protein-RNA patterns that arise from the competition between different mechanisms including LLPS, biomolecular interactions, and biochemical reactions. The protein-RNA pattern formation is strongly dependent on the interplay of time-scales for diffusion, transcription, and translation. Under appropriate kinetic regimes, we can dramatically accelerate or slow down the phase-separation process, thereby leading to arrested phases.

M71.00326: Complex Coacervate Core Micelles for Protein Delivery  RACHEL KAPELNER (Presenter), ALLIE OBERMEYER, Columbia University — Proteins are an increasingly important class of therapeutics. There are, however, several challenges in the development and production of protein based therapeutics. These include relative temperature sensitivity and propensity to aggregate at therapeutically relevant concentrations, both of which contribute to the their relatively short shelf-life and short circulation times. Previous work has developed protein delivery platforms that increase circulation time while maintaining protein activity, but suffer several shortcomings such as low-levels of protein loading and controlled release. To address these limitations, we have investigated the use of block-polyelectrolytes to form complex coacervate core micelles (C3Ms) to be used as a protein delivery vehicle. While C3Ms allow for controlled protein loading and release, they also have the potential to improve protein stability at therapeutically relevant concentrations and increased temperatures. In this work, we identified protein and polymer design parameters that govern complex coacervation of model proteins to form C3Ms that remain phase separated under physiological conditions and study how incorporation of proteins in C3Ms influences protein stability and delivery to cells.
M71.00327: The role of epigenetics and microenvironment in breast cancer evolution

J. ROBERTO ROMERO-ARIAS (Presenter), Mathematics and Mechanics, Institute for Research in Applied Mathematics and Systems, UNAM, GUILLERMO RAMÍREZ-SANTIAGO, CALOS GONZÁLEZ-CASTRO, Institute of Mathematics, UNAM Juriquilla — Cancer is a disease driven by aberrant signaling pathways that control and maintain the malignant phenotype. Among the different aspects that drive these aberrant behavior are epigenetic changes that favor the uncontrolled growth and longer survival of malignant cells. These molecular changes affect microenvironment and cellular function subjecting cells to stress due to the lack of sufficient nutrients (glucose) and oxygen. On the other hand, estrogens have been found to play a major role in promoting the proliferation of both normal and neoplastic cells and they are believed to stimulate the occurrence of neoplastic mutations. Here, we incorporate these biological processes into a quantitative model to understand how microenvironmental conditions affect genetic dynamics and phenotypic diversity. Our results suggest that the evolution of malignancy and heterogeneity in a tumor arise and can be controlled by local epigenetic changes. This yields support to the believe that controlling local microenvironmental aspects might prevent the further development of a tumor.

M71.00328: Geometry and mechanics of a model epithelium with irregular cells and a clonal inclusion

DIEGO A CONTRERAS, VINCENT HAKIM (Presenter), FRANCIS CORSON, Ecole Normale Superieure — An important role in the modeling of epithelial tissue mechanics has been played by vertex models, with cells idealized as polygons, and tricellular junctions as vertices joined by straight interfaces. Numerical simulations of these models in the presence of cell divisions display geometrically irregular cells, similar to those of epithelia, even when cell properties are homogeneous. Yet existing theoretical analyses are mostly confined to the mechanics of regular hexagonal lattices. We develop an analytical description of geometrically disordered vertex models. We first quantify, in numerical simulations, geometrical properties such as the distributions of cell areas and perimeters, and mechanical properties such as the tissue bulk and shear moduli, with different sources of disorder, e.g. different division rules or simply relaxation in the presence of noise. We then develop a simple mean-field description that accounts for these properties. Finally, we apply our analytical description to a simple case of interest in different biological contexts: a clonal group of cells with material properties that differ from the surrounding tissue and that may also grow at a different rate. We compare our results with data obtained on epidermis differentiation in flies.

**M71.00329: Chemotaxis of Tumor Spheroids in 3D Extracellular Matrices**

YOUNG JOON SUH (Presenter), YU LING HUANG, Cornell University, JEFFREY SEGALL, Albert Einstein College of Medicine, MINGMING WU, Cornell University — Cytokine-mediated tumor migration (chemotaxis) plays a crucial role in cancer metastasis. Previous studies have explored the chemotactic behavior of single cells embedded within 3D extracellular matrices (ECM). However, due to the vastly different nature of single cells and tumors, a single cell 3D model cannot recapitulate the in vivo tumor invasion behavior. In this talk, we will present a 3D tumor spheroid model for tumor chemotaxis studies. Breast tumor spheroids using MDA-MB-231 cells were engineered and embedded within a collagen matrix. Tumor spheroid dynamics were imaged and analyzed when subjected to well-defined cytokine (Epidermal growth factor, hEGF) gradients provided by a microfluidic platform. Differential behavior of single tumor cell and spheroid chemotaxis will be discussed.

**M71.00330: On the mechanical principles of biofilm formation**

JING YAN, QIUTING ZHANG, JAPINDER NIJJER (Presenter), Molecular Cellular and Developmental Biology, Yale University — Bacteria, once thought to be solitary and asocial, can grow in large, dynamic, multi-cellular communities known as biofilms, which consist of bacteria embedded in an extracellular matrix. However, the manner in which these three-dimensional, surface-adhered communities are built in space and time still remains to be shown. Using the human pathogen *Vibrio Cholerae* as model biofilm former, we examine the growth of biofilms from single founder cells to mature three-dimensional colonies. We find that biofilms grow from disordered, two-dimensional layers into three-dimensional structures with long-range order consisting of vertically aligned cores and horizontally aligned periphery. Using agent-based modelling, we find that verticalization occurs due to mechanical instabilities at the cell-scale and we quantitatively test these predictions by varying the cell lengths, surface roughness and osmotic conditions.

**M71.00331: WITHDRAWN ABSTRACT**

**M71.00332: Probing tissue mechanical properties in Drosophila embryos using magnetic tweezers**

AN PHAM (Presenter), Department of Physics and Soft Matter Center, Duke University, DANIEL P KIEHART, Department of Biology, Duke University, CHRISTOPH F. SCHMIDT, Department of Physics and Soft Matter Center, Duke University — The amnioserosa is a single-cell-deep epithelial cell sheet that contracts during dorsal closure in Drosophila melanogaster embryos. Displacement can be easily observed by microscopy and strains can be inferred from UV laser ablation experiments. The material properties of the amnioserosa and surrounding cell layers, however, remain elusive, which challenges a complete understanding of the driving forces in developing tissues. We have constructed an experiment to quantify mechanical properties of the amnioserosa cells during dorsal closure using magnetic tweezers. Complex shear moduli of the tissues are directly measured by exerting calibrated magnetic forces and observing displacements of bound magnetic beads.
M71.00333: Interpretation of Phase Boundary Fluctuation Spectra in Biological Membranes with Nanoscale Organization*  
SAHITHYA IYER (Presenter), Indian Institute of Science, ARCHIT NEGI, Department of Physics, Indian Institute of Technology, Bombay, ANAND SRIVASTAVA, Indian Institute of Science — In this work, we use a computationally less expensive and more automated Support Vector Machine algorithm to detect simple and complex interfaces in atomistic and coarse-grained molecular simulation trajectories of phase separating lipid bilayer systems. We find that the power spectral density of the interfacial height fluctuations and in turn line tension of the systems depends on the order parameter used to identify the intrinsic interface. To highlight the effect of length scale used to identify the interface on the fluctuation spectra, we perform a convolution of the boundaries identified at molecular resolution with a 2D Gaussian function of variance equal to the experimental resolution limit. The region of fluctuation spectra that scales according to capillary wave theory formalism relies on the complexity of the interfacial geometry, which may not always be detected at experimental resolutions. We propose that the different $q$-regimes in the fluctuation spectra can be used to characterize mode dependent interfacial tensions to understand the interfaces beyond the linear line tension calculations.

M71.00334: External Forces generated by the Attachment between embryonic Tissue and Egg Shell affect Gastrulation in Insects  
STEFAN MUENSTER (Presenter), Max-Planck-Institute of Molecular Cell Biology and Genetics, ALEXANDER MIETKE, Max-Planck-Institute for Physics of Complex Systems, AKANKSHA JAIN, PAVEL TOMANCAK, STEPHAN GRILL, Max-Planck-Institute of Molecular Cell Biology and Genetics — Gastrulation is a critical step during the development of multicellular organisms in which a single-layered tissue converts into the multi-layered germband. This shape change is characterized by tissue folding and large-scale tissue flow. The myosin-dependent forces that underlie this process have been increasingly investigated; however, thus far, a possible interaction between the moving tissue and the rigid shell surrounding the embryo has been neglected. Here, we present our quantitative findings on the physical mechanisms governing gastrulation in the red flour beetle, Tribolium castaneum. We investigated the forces expected within the tissue given the myosin distribution observed by multi-view light-sheet microscopy and discovered that an additional external force must be counteracting this tissue-intrinsic contractility. We then identified that a specific part of the tissue tightly adheres to the outer rigid shell. This attachment is mediated by a specific integrin whose knock-down leads to a complete loss of the counter-force. Moreover, in the fruit fly Drosophila melanogaster, knock-down of another integrin leads to a severe twist of the germband, suggesting that the integrin-mediated interaction between tissue and vitelline envelope may be conserved in insects.
M71.00335: Size and shape control dynamics in an early diverging animal* PRANAV VYAS (Presenter), MANU PRAKASH, Bioengineering, Stanford University — Animals have traditionally been characterized as clonal cell populations with complex tissue architectures which have specific developmental programs that guide the morphogenesis of organs and in turn whole animals. On the other hand, very early diverging metazoans display simple tissue architecture with a lesser division of labour that allows high plasticity and scalability. High plasticity in such tissues allows dynamic shape changes at time scales of ~five minutes and a scalable tissue architecture allows size variation of over two orders of magnitude. For such tissues, size and shape are deeply interdependent due to physical constraints. Using high throughput long term scanning microscopy, we collect datasets on shape and size variation in lab culture conditions and quantify their temporal trajectories. Using perturbations to these 'natural' trajectories, we decouple size and shape parameters to decipher the principles that the system uses to exercise control over growth. Utilizing large datasets and growth-based models, our study provides abstract principles that would have governed size and shape control in very primitive `animal-like' multicellular clusters.

M71.00336: Single-Chain Variable Fragment Bearing Silica Nanoparticle Evaluation in HER2+ Over Expressing Tumor Tissues Using Optical Super-Resolution Microscopy* JOSHUA HINCKLEY (Presenter), NIRMALYA BAG, JACOB ERSTLING, ULRICH WIESNER, Cornell University — Active targeting of therapeutics or imaging probes to cancer cells is the primary pharmacological strategy in cancer therapy and diagnostics. Recent years have witnessed a boom in nanotechnologies, such as antibody-functionalized nanoparticles, in cancer theranostics which provide unique advantages over standard treatments. However, nanomedicine has is currently suffering from a lack of characterization and quantitative methods that provide understanding of the complex interactions in tumor tissues. The challenge in making quantitative methods for large samples usually lies in cost and availability of equipment. However, optical microscopy is a well-established and relatively low-cost alternative which is equipped, due to various super-resolution techniques, with the capability to study objects smaller than 100 nm. Here we demonstrate the use of coordinate base colocalization and nearest neighbor distance analysis with optical super-resolution microscopy to determine the quality of nanomedicine targeting using HER2 overexpressing tumor tissues.

*This study was funded by MedImmune and grants from the National Institutes of Health (U54 CA199081-01 to M.S.B. and U.W.) and Sloan Kettering Institute (Core Grant P30 CA008748CCSG).
M71.00337: Exploring the Dynamics of Biological Macromolecules at Angstrom Scale

ZAHRA ALAVI, CALVIN FOSS (Presenter), Loyola Marymount Univ — This research project plans to study Guanylate Kinase (GK) using nano-rheological techniques. These biological macromolecules will be immersed in solutions with different solvents in order to observe how the conformational dynamics of the molecules change.

An oscillatory force will be applied by attaching enzymes to a gold-coated surface and to gold nanoparticles. An additional gold-coated surface will be placed on top of the setup in order to create a parallel plate capacitor configuration. An oscillatory voltage will then be applied across the capacitor to drive the gold nanoparticles and exert a force on the enzymes. The setup will detect the ensemble averaged movement of the enzymes at the Angstrom scale in order to measure the conformational dynamics.

The specific goals of this research project include the following: creating a one-of-a-kind experimental setup which will be useful for a plethora of other experiments in the future, deforming enzymes and recording their levels of deformation, changing what enzymes and solvents are used, and comparing data from the experiments. The results of the enzymes’ viscoelastic behavior which will be useful for further research in the fields of Biophysics, Biology, and Chemistry.

M71.00338: Effect of Carbon Nanotubes on The Propagation of Neural Signals*

AHMED ELRASHIDY (Presenter), GARY PENNINGTON, JOHN LEVENTIS, Towson Univ —

Studies have shown that carbon nanotubes scaffolds promote the growth of neurons along the nanotube axis and also enhance neural signaling. In addition carbon nanotubes have been successfully incorporated into cells as transmembrane channels and as bridges connecting with the intracellular and intercellular microtubule scaffolds which function as cellular transportation highways. Based on laboratory experiments in the literature, it is clear that carbon nanotubes will play an ever increasing role in neurological research acting to enhance properties or to serve in a sensing capacity.

To investigate the effects of nanotubes on neuron properties, we report finite element based simulations of voltage pulse propagation along neural membranes in the presence of incorporated carbon nanotubes. Results will be used to help determine the origin of neural enhancement in neuron-nanotube complexes and to look for mechanisms by which a nanotube proximal to a neuron may act as a sensor allowing imaging of neural signals.

M71.00339: Dynamical Model of Cytokines in Rheumatoid Arthritis in the Presence of Additive Noise  TIMOTHY DUREN (Presenter), MASoud ASADI-ZEYDABADI, RANDAll TAGG, University of Colorado, Denver, COLIn O’DONNELL, CHRISTOPHER COLLORA, KEVIN DEANE, University of Colorado Anschutz Medical Campus — A dynamical model from Baker et. al* is used to explore the possibility of predicting onset of Rheumatoid Arthritis. The model is based on nonlinear interaction of pro-inflammatory and anti-inflammatory cytokines. In the model, a parameter measures the effect of the pro-inflammatory cytokine concentration on further growth of pro-inflammatory cytokines. As this parameter increases, a healthy state jumps to a disease state through a fold bifurcation. By adding noise to the model, we observe precursor flickering and large-scale fluctuations that might appear clinically as early clues to incipient onset. *M. Baker, S. Denman-Johnson, and M. R. Owen, “Mathematical modelling of cytokine-mediated inflammation in rheumatoid arthritis” Mathematical Medicine and Biology (2013) 30, 311–337

M71.00341: A synthetic transcriptional counter*  TIANCHI CHEN (Presenter), MUHAMMAD ALI AL-RADHAWI, Bioengineering, Northeastern University, CHRISTOPHER VOIGT, Biological Engineering, MIT, EDUARDO SONTAG, Bioengineering, Northeastern University — Elementary sequential logic circuits have been proposed in synthetic biology. The long-term goal is to obtain more complex circuits, capable of finite-automaton computation, in analogy to central processing units in digital computers. We design here a single bit counter, i.e. a parity checker, that can be implemented with current technology by a genetic circuit. When excited by a sequence of N sufficiently separated pulses of an external input (which might be a chemical inducer or a physical signal such as light at a specific frequency), the network will produce an output to indicate whether the number N of pulses seen so far is even or odd. Our circuit is the key component of a distributed-computation m-bit counter, in which a count modulo 2^m of the observed number N of pulses is stored and displayed. The m-bit counter can be in principle assembled from a set of m single-bit counters, together with additional gates that implement "carry" operations. In this design, communication among cells could be biologically implemented by diffusing chemicals (for example, quorum-sensing molecules).

M71.00342: Dose-rate effects in the radiation induced mutation of Drosophila*  TAKAHIRO WADA (Presenter), TOMONORI OHNISHI, Kansai Univ, YUICHIRO MANABE, MASAKO BANDO, Osaka Univ. — We proposed a mathematical model to study the biological effects of radiation which we call WAM model. (1) An important feature of the model is that it can describe the dose-rate dependence of the effects of radiation. We succeeded in reproducing the existing data of dose/dose-rate dependence of mutation frequencies of 5 species including animals and plants. (2) We hope to develop the model to describe the whole process from mutation to cancer generation.

In 1926, Herman Muller conducted the famous experiments of the radiation-induced mutation in Drosophila, which shows a linear increase with the total dose. Later, Purdom and McSheehy irradiated Drosophila with much lower dose rate to find out if there is a dose-rate dependence in the mutation frequency. (3) Here, we reexamine their data with WAM model and found that the data is reproduced well with our model. We will discuss the possible dose-rate dependence of the radiation-induced mutation frequency in Drosophila.

M71.00343: Understanding Base Pairing Interactions in Aqueous Environment*  RONGPENG LI (Presenter), CHI H MAK, Univ of Southern California — Base pairing plays a pivotal role in DNA functions. But while the complementarity between Watson-Crick matched bases is conventionally believed to arise from the different number of hydrogen bonds in G|C pairs versus A|T, the energetics of these hydrogen bonds are heavily renormalized by the aqueous solvent. We computationally extracted the solvent components of the free energy, entropy and enthalpy for canonical and some wobble and stacked base pairs. For all of them, the solvent's contribution to the base pairing free energy appears to be exclusively destabilizing. While the direct hydrogen bonding interactions in the G|C pair is much stronger than A|T, the thermodynamic resistance produced by the solvent also pushes back more forcefully against G|C pair formation compared to A|T, generating a difference in thermodynamic stability of only ~1 kcal/mol between them. We have profiled the density of water molecules in the solvent adjacent to the bases and observed a decrease in the solvent's entropy as a result of a "freezing" transition where waters are recruited into the gap between the bases to compensate for the unsatisfied hydrogen bonds between them.

M71.00344: **Stochastic Lattice Model of the RAD51 Nucleoprotein Filament Formation on Single-Stranded DNA**

MARY SUTTON, Univ of Northern Iowa, COLLEEN CALDWELL, MARIA SPIES, Biochemistry, University of Iowa, ALI TABEI (Presenter), Univ of Northern Iowa — Homologous recombination (HR) is one of the most enigmatic processes in DNA metabolism and is a fundamental driver of evolution. Its central step involves the search for homology between two DNA molecules and the subsequent exchange of the DNA strands. We use a Monte Carlo model to study the statistics and dynamics of the recombinase filament nucleation, extension, and disassembly. We use our developed computational toolbox for analyzing single-molecule data to build a predictive model to test different binding hypotheses.

M71.00345: *In silico* studies of “DNA Flossing” through a Double-Nanopore system

ANIKET BHATTACHARYA (Presenter), SWARNADEEP SETH, Univ of Central Florida — We carry out *in silico* study of “DNA Flossing” (X. Liu et al., bioRxiv: http://dx.doi.org/10.1101/77817) in a model Double Nanopore Device, where the DNA conformations oscillates back and forth from one nanocavity to the other while translocating through a double nanopore when the linear segment between the nanopores gets scanned. We simulate the conditions for efficient multiple scans as well as the reduction of the variance in measurement of genomic length from these scans. In particular, we vary the dimensions of the cavities, the distance between the nanopores, and nature of the feedback forces to optimize the measurement of genomic lengths through flossing mechanism.

M71.00346: Loss of CTCF loops on human interphase chromosome organization

DAVIN JEONG (Presenter), GUANG SHI, DAVE THIRUMALAI, University of Texas at Austin — Chromatin looping, mediated by CTCFs, is a widespread principle in chromatin folding. Despite many studies that elucidate the importance of the insulator protein CTCF and cohesin complex in regulating genome folding, how chromatin loops determine the overall genome organization is unclear. We created a Chromosome Copolymer Model (CCM) to investigate the impact of CTCF loop loss on human interphase chromatin organization. We show that chromatin folding associated with loop domains is extended with a decrease in the number of CTCF loops. Surprisingly, the degree of epigenetic compartmentalization increases. In contrast, local topological associating domain (TAD) is only affected by removal of adjacent CTCF loop. Furthermore, deletion of some CTCF loops causes abnormal contacts between certain insulated loci with adjacent TADs merging, while others do not, indicating that CTCF loop is required to form a subset of TADs. The TADs whose formations are mainly driven by underlying epigenetic states have minimal dependence on CTCF loops. Moreover, our results employing complete CTCF depletion are in good agreement with experiments, supporting that cohesin is necessary for the formation of CTCF loops.
M71.00347: Role of Liquid-Liquid Phase Separation in Organization and Regulation of Chromatin MURALIKRISHNA RAJU (Presenter), ALEKSANDRA ELZBIETA BADACZEWSKA-DAWID, DAVIT POTOYAN, Iowa State University — Genomic DNA is densely compacted in the nucleus of eukaryotic cells into chromatin. However, mechanisms that regulate the assembly and compaction of the genome remain unclear. Here we employ atomistic simulations to study how histone tail-driven interactions drive liquid-liquid phase separation (LLPS) of archetypal DNA-histone mixtures, resulting in formation of mesoscale condensates. The role of histones H1, H2a, H2b, H3 and H4 are individually explored under a range of physiological salt concentrations. Histone H1 is found to play a critical role in chromatin organization by promoting LLPS, denser compaction and slower dynamics within the condensates. Electrostatic interactions are found to be the primary driving force behind condensate formation and consequently histone acetylation is found to inhibit LLPS. We construct phase diagrams based on Droplet density and Shannon entropy calculations, wherein distinct regimes can be identified based on histone concentrations. The spatial organization and dynamics of the droplets are investigated as a function of histone concentrations, DNA chain length and salt concentration.

M71.00348: Nuclear chromatin patterns: modeling dynamics of intra-chromatin interactions and its impact on structure organization RABIA LAGHMACH (Presenter), Iowa State University, MICHELE DI PIERRO, Center for Theoretical Biological Physics, Rice University, DAVIT POTOYAN, Iowa State University — The description of chromatin organization and its dynamics, at a large scale, are functionally important factors in the genome regulation function. Growing evidence suggests that chromatin within the nucleus has a liquid-like behavior mediated by phase separation into micro-droplets with distinct transcriptional states. The formation and spatial arrangement of chromatin droplets within the nucleus depending on their transcriptional states either active (euchromatin) or inactive (constitutive and facultative heterochromatin) genes are important features of the nuclear architecture. Understating mechanisms that control the dynamics and spatiotemporal regulation of droplets formation is a possible way to elucidate the relationship between nuclear architecture and gene regulation. Here, we introduce a mesoscale liquid model of nucleus (MELON) that incorporates dynamic of interactions between A-B-C chromatin compartments of the nucleus, as well as the affinity between constitutive heterochromatin and Lamina at the nuclear envelope and nucleus deformation. Using MELON framework, we show that phase separation together with surface tension effects and nuclear shape deformation is sufficient for recapitulating large-scale morphology and dynamics of chromatin along the life cycle of cells.
M71.00349: United we stand, divided we fall: Response to antibiotics in a bacterial swarm* 
HARSHITHA SHANKAR KOTIAN (Presenter), HITHYSINI K. N., AMITH ZAFAL ABDULLA, VARSHA SINGH, MANOJ M VARMA, Indian Institute of Science — Bacterial swarms consist of millions of bacterial cells collectively colonizing a nutrient rich agar plate. *Pseudomonas aeruginosa* is a bacterial species in which swarming is modulated by the interplay of surfactant driven fluid flow and chemotactic motility of individual cells, leading to the formation of a sparse branched pattern over the agar plate. The branches of the swarm do not intersect due to repulsive forces from the surfactant gradients. However, when an antibiotic drop is added near one of the growing branches, its growth gets arrested and the neighbouring branches intersect to join this branch. This is quite non-intuitive as the bacterial cells move towards the branch exposed to antibiotic as opposed to escaping the area to protect themselves. Moreover, this behaviour requires a complex signalling mechanism as the bacterial cells cannot directly sense the antibiotic as they lack the receptors specific to the antibiotic (gentamicin). We present experimental data and a mathematical model to unravel the mechanism behind this behaviour. Our findings reveal that stress on the bacterial community drives them into collaborating with each other to demonstrate collective resistance and avoidance of antibiotic toxicity.

M71.00350: Delay embedding of low-dimensional attractors of local field potentials from optogenetic data* 
XANDRE CLEMENTSMITH (Presenter), SORinel OPRISAN, College of Charleston, TAMAS TOMPA, ANTONIETA LAVIN, Medical University of South Carolina — We investigated the effect of acute cocaine injection in conjunction with dopamine (DA) receptor antagonists on the medial prefrontal cortex (mPFC). In his study we used D1-like receptors antagonist SCH 23390 or D2-like receptors antagonists sulpiride. The goal of the study was to determine the changes in the gamma oscillations and their relationship to short term neuroadaptation that may mediate addiction. In this study we used 17 mice and recorded optogenetically evoked local field potentials (LFPs) in vivo. The optical stimulus was a brief 10 ms laser light pulse. Data preprocessing involved computing a Euclidian distance-based dendrogram to separate the 100 trials for each animal in disjoint clusters. The classifier is not perfect as it gives a minimum 20% overlap between the control data and DA receptor antagonists trials. We used the delay-embedding method to reconstruct neural activity attractor. The lag time was determined both using the correlation time and the mutual information methods.

M71.00351: System identification in the brain: inferring ARMA dynamics from sensory data
 TIBERIU TESILEANU (Presenter), CCB, Flatiron Institute, SAMANEH NASIRI, Emory University, ANIRVAN M SENGUPTA, Rutgers University, DMITRI CHKLOVSKII, CCB, Flatiron Institute — Sensory information reaches the brain as a stream with non-trivial correlations across time. In a generative model, these correlations can be seen as the result of a dynamical system acting on a white noise source signal. Learning the parameters describing this system enables a variety of applications, from detecting changes in the input dynamics to inferring dynamical rules in the environment.

Here we present biologically plausible neural networks for performing system identification from time series data. The starting point is the mutual information between the past and the future, which in the case of one-dimensional Gaussian signals is equal to a kind of cepstral norm. By searching for the autoregressive moving-average (ARMA) filter that minimizes this mutual information, we develop algorithms that learn an inverse model to the dynamical system generating the data. Employing update rules based on Givens rotations we ensure that our algorithms work online, an essential ingredient to maintain biological plausibility. We also look for implementations that rely on local learning rules, such that synaptic updates only require information that is available to them from pre- and post- synaptic activity.

M71.00352: Dynamics of multi-domain bio-macromolecules by neutron scattering  LAURA-ROXANA STINGACIU (Presenter), Oak Ridge National Lab, RALF BIEHL, ANDREAS STADLER, JCNS, Juelich Research Center — Conformational ensembles of synthetic polymers and intrinsic disorder in proteins are both aspects of the varying degree of order and disorder that are crucial for the properties of macromolecules. Neutron scattering techniques, in particular small angle scattering and neutron spin echo, have an important contributions to understand conformation and dynamics of macromolecules with regards to polymer physics. The possibility for altering and defining accessible conformational spaces through localized or intermediate and long-range interactions of segments along a polypeptide chain are limited by chain stiffness and local hydrodynamic friction. Our research aims for a deeper understanding of this challenging topic. We will present the dynamics of several bimolecular species based on results of neutron scattering and the comparison with secondary and segmental relaxations, Rouse and reptation dynamics in polymers, with emphasis on the significant difference between dynamics of random coil of synthetic polymers and the dynamics of globular proteins.
M71.00353: Decoupling Effect between Dynamics of Proteins and their Hydration Water at Elevated Temperature  
LIRONG ZHENG (Presenter), ZHUO LIU, LIANG HONG, Shanghai Jiao Tong Univ — Water, as a life solvent, is primary to the energy transfer, biomacromolecules assembly, biological reaction and so on. Particularly, the dynamical transition at ~200 K in proteins, which hydration water is essential for, leads the state of proteins from rigid, nonfunctional state to flexible, functional state. So far, a large number of studies have suggested that the dynamical transition at ~200 K is coupled to the activation of translational motion of the hydration water on the protein's surface, i.e., the dynamics of proteins and that of their hydration water are coupled. However, by performing elastic neutron scattering experiments of atomic dynamics of proteins with different secondary structures under various instrumental resolutions, we surprisingly find that the dynamics of proteins and that of their hydration water molecules show a resolution-independent and a resolution-dependent behavior at elevated temperature, respectively. These results suggest that there actually exists the decoupling effect between dynamics of proteins and that of their hydration water at elevated temperature, and gives a new comprehension in protein dynamical transition.

M71.00354: A new heteropolymer theory to describe conformation of Intrinsically Disordered Proteins  
JONATHAN HUIHUI (Presenter), TAYLOR FIRMAN, KINGSHUK GHOSH, Univ of Denver — Intrinsically Disordered Proteins (IDPs) perform many vital functions and yet have no native structure. This is in contrary to the commonly held notion that protein sequence determines the unique folded structure that in turn dictates the function of the protein. IDPs exhibit an ensemble of conformation, instead of a unique folded structure, making them amenable to tools of polymer statistical physics. Presently, homopolymer theories are commonly used in order to describe the conformation of IDPs. However, IDPs consist of amino acids of different chemical properties, including positive and negative charges. We present a novel heteropolymer theory to describe the sequence specific conformational ensemble of IDPs. Our theory provides rich ensemble average distance maps that are more informative about conformation than coarse-grain measures like radius of gyration or scaling exponents. We will showcase application of this novel analytical theory – benchmarked against all-atom simulations – to multiple naturally occurring IDPs. We highlight how biology can achieve variability with the ability to induce drastic conformational changes by making concise changes in the sequence — termed as hot spots -- such as post-translational modifications (PTMs), often used as a regulator.
M71.00355: Into the Vast Unknown: Structure-Function Relationships in Uncharacterized Bacteriophage Proteins*  KRISTA FREEMAN (Presenter), SAEED BINSABAAN, ANDREW VANDERMARK, GRAHAM HATFULL, Univ of Pittsburgh — With an estimated global population of $10^{31}$ particles, bacteriophages (viruses that infect bacterial hosts) are Earth's most abundant biological entities. Billions of years of evolution have granted phages unparalleled genetic diversity and given rise to a vast collection of genes. We have sequenced and analyzed the genomes of over 3,000 phages and sorted their hundreds of thousands of encoded proteins into phamilies. The functions of over 70% of these protein phamilies are unknown, with a complete dearth of functionally informative sequence-based homology for guidance. We hypothesize that these hypothetical phage proteins represent an unexplored reservoir of genetic, functional, and possibly structural novelty. To address this, we have developed a research pipeline to structurally and functionally characterize subsets of phage-encoded proteins. We have successfully advanced a number of proteins through various stages of this pipeline, which combines bioinformatics, molecular biology, biochemistry and biophysical approaches. This presentation will address our progress on elucidating structure-function relationships in these bacteriophage proteins.

M71.00356: The Impact of Deep Eutectic Solvent on the Structural Stability of Myoglobin*  LINH PHAM (Presenter), JOSE L BANUELOS, SUPRIYO RAY, University of Texas, El Paso, JENNIFER KIST, GARY BAKER, Department of Chemistry, University of Missouri- Columbia — The stability of Myoglobin (Mb) in hydrated Deep Eutectic Solvent (DES) is investigated as a function of temperature and DES concentration. Determining the effect of DES on protein structure can lead to understanding the properties of DES, and allow their use to expand to cost-effective, and simple synthesis applications. Mb in 2 DESs: 35% wt glyceline-water and 5% wt reline-water and the resulting structure were compared to Mb in water. Small Angle X-ray Scattering results show that Mb's tertiary structure remains relatively unchanged in both DESs until the temperature reaches 80°C (for glyceline) and 70°C (for reline) at which globular structure of Mb starts to gradually unfold. However, in water, Mb's tertiary structure unfolds slowly and linearly with temperature until reaching a major transition at 80°C. In addition, circular dichroism spectroscopy measurements show that Mb loses substantially more secondary structures with increased temperature in DES mixtures than in water solvent, yet DES allows better recovery of Mb secondary structure.

*This work was supported by Office of the Provost, Campus Office of Undergraduates Research Initiatives (COURI) under the Summer Undergraduate Research Program Assistantship (SURPASS) of the University of Texas at El Paso.
M71.00357: Adaptive Sampling of Markov-state models with MD Simulations to assess the rates of biologically relevant processes*  JOHN OSSYRA (Presenter), University of Tennessee, Knoxville, ADA SEDOVA, JEREMY SMITH, Oak Ridge National Laboratory — It is a challenge for classical molecular dynamics to directly simulate the time and length scales of biologically relevant processes. Incomplete sampling makes the calculation of macroscopic observables such as rates for major state transitions difficult to estimate correctly. A number of techniques bias the energy landscape to accelerate processes that are difficult to reach with direct simulation. However the altered landscape introduces artifacts that obscure rate estimates. Here we show how adaptive-sampling workflows that iteratively redirect swarms of trajectories can enhance the sampling of the slowest kinetic processes. Markov-state models are then adaptively refined with continual updates from these parallel swarms resulting in unbiased, well-sampled estimates of kinetic rates. We demonstrate how this method can be applied to provide long-timescale kinetics for atomistic simulations of protein-protein interactions.

*This work was supported from a Laboratory Directed Research and Development award from the US Department of Energy.

M71.00358: Data-Driven Modeling of Discrete Synchronization in Firefly Swarms  RAPHAEL SARFATI, JULIE HAYES, ORIT PELEG (Presenter), University of Colorado Boulder — Fireflies are a landmark example of synchronization in nature. During mating season, males of synchronous firefly species flash in unison within swarms containing tens of thousands of individuals. This magnificent display inspired numerous mathematical models that aim to explain how global synchronous patterns emerge from local interaction rules. However, experimental data to validate these models has been rarely reported. To address this gap, we obtained quantitative measurements of the spatiotemporal flashing pattern of synchronous firefly swarms. Using the North American synchronous firefly species *Photinus carolinus* as a model system, we recorded the flashing patterns of the fireflies in their natural habitat as well as within light controlled environments, and for the first time, we were able to perform a 3D reconstruction of the synchronous flashing positions of thousands of individuals. This talk will focus on analysis of the spatiotemporal patterns observed in our experiments and connecting it to mathematical models that account for the species specific discontinuous flash pattern, short range spatial correlations, and spatial mixing due to movement of individuals within the swarm.
M71.00359: A Quest for a Science of Social Dynamics* RAM POUDEL (Presenter), Tribhuvan University — Humans are social beings. Social interactions inform the state of an individual in society. We proposed a new social field theory in order to define the state in terms of Hamiltonian of an individual. In a multi-dimensional social field, social interactions are conceived in terms of the energetic exchanges of various fluxes including information. Such exchanges govern the change of states of an individual. The transport equations of change for an individual and ensemble of individuals include source terms and power dynamics. For an ensemble of individuals, the equation takes a form of an implicit Fokker-Planck equation. A target of this paper is to formulate the “equations of motion for social systems” Wolfgang Weidlich has long sought for. Lotka-Volterra equations can be derived from the proposed equations of motion for the social field.

*We did not seek any funding for this research. RP acknowledges a sabbatical granted by the Institute of Engineering, Tribhuvan University.

M71.00360: Physics of the Brain. Treatment of Neurological Diseases via the Brain Waves, Using the Multi-photon Pulsed-operated Fiber Lasers in the Ultraviolet Range of Frequencies.* V. ALEXANDER STEFAN (Presenter), Institute for Advanced Physics Studies, Stefan University — The novel study of the brain waves (BW)[1] in connection to neurological diseases is proposed. It is based on the pulsed-operated (amplitude modulation) multi-photon (frequency modulation) fiber-laser interaction with the brain neuro-topion (the neurological disease area).[2] The repetition frequency, Ω, (5-100 pulses per second) matches the frequency of a particular brain wave, Ω_{BW}. The tunable fiber laser frequencies, Δω (multi photon operation), are in the ultraviolet frequency range, thus enabling monitoring of the electrical charge dynamics in the neuro-topion of a particular disease within the 10s of milliseconds.

*Supported by, The American Society for Laser Neuroscience (Stefan University).
M71.00361: Dynamics of timescales on complex lattices  GECIA BRAVO-HERMSDORFF, AHMED EL HADY (Presenter), Princeton University — A popular idea in biology is that the intrinsic timescale of an individual “unit” plays a crucial role in the information processed by the system as whole. For example, it has been proposed that the intrinsic timescales of single neurons in different brain areas are related to functional differences between these areas. However, disentangling between intrinsic and collective timescales remains a highly nontrivial task, and could benefit by drawing intuition from simple physical toy models. To this end, we consider the prototypical model of collective temporal behavior: kinetic Ising models, where identical units are connected with a given topology, and neighboring units stochastically interact with one another. We analyze how the behavior of such models is altered when considering many aspects relevant to their computational implementation, namely, finite temporal resolution, topological connectivity, and finite system size. Not coincidentally, these considerations have biological analogues. For example, the clock speed of processor is functionally similar to an “inverse refractory period” of a neuron. While locality of interactions can be exploited for parallel simulation of physical systems, the diversity of topologies in biological systems is key to their expressive power.

M71.00362: Development of control in brain networks over temporal and spatial scales using graph models LINDSAY M. SMITH (Presenter), HARANG JU, DANIELLE BASSETT, University of Pennsylvania — Regions of the human brain vary in their capacity to control whole brain activity, in large part due to their location in the underlying structural network of interconnections crisscrossing the cortex. Recent work suggests that this capacity for control differs across spatial and temporal scales of the brain’s dynamics and can be formally probed using the Laplacian eigenspectrum of the brain’s structural network. Yet how such spatiotemporal control might differ from one human to another, potentially supporting and explaining differences in cognitive function, remains unclear. Here, we address this question by measuring several summary statistics of spatiotemporal control from human brain network architecture, as reflected in diffusion tensor imaging data acquired from 882 youth between the ages of 8 years and 22 years. We found that distinct features of network topology are correlated with a region’s capacity to enact distinct control strategies, and we investigate these relationships as a function of discrete timescales, from markedly slow modes of dynamics to relatively swift modes of dynamics. Our results provide insight into how local variation in connectivity gives rise to distinct processes of global control as a function of timescales over modes of activity.
M71.00363: Kinesin Model for Brownian Dynamics Simulations of Stepping Efficiency

MATT MURROW (Presenter), Physics & Astronomy, Vanderbilt University, JUTTA LUETTMER-STRATHMANN, Physics and Chemistry, University of Akron — The motor protein kinesin plays an integral role in cell function, transporting, for example, cargo from the center to the periphery of a cell. Kinesin molecules have been shown experimentally to walk along microtubules in a hand-over-hand stepping motion, carrying their cargo eight nanometers per step. However, details of the stepping process are still under investigation. Kinesins are difficult to study with atomistic simulations due to the size of the proteins and the long time-scales involved. In this work we develop a 3D model of kinesin stepping on a rigid microtubule substrate that can be simulated efficiently with Brownian dynamics simulations. The interactions governing the motor protein conformations and the interactions between kinesin sites and the microtubule sites are designed to reproduce important aspects of the biological system. We perform simulations spanning many kinesin steps to investigate the stepping efficiency of the motor protein for different neck linkers. We find that neck linkers close to the wild-type length yield a stepping efficiency of about 90%, in agreement with experimental data. In addition, we find that increasing the neck-linker length leads to a decrease in efficiency, as has also been observed in experiments.

M71.00364: Correlating synaptic vesicle motion to cytoskeletal structure of the presynapse and axon.

BRIA STORR (Presenter), Univ of Alabama - Birmingham, MICHAEL W GRAMLICH, Physics Department, Auburn University — Two neurons communicate via release of neurotransmitter from a presynapse of one neuron to a post-synapse of another. This neurotransmitter is carried from the inside of the presynapse to the membrane of the presynapse using a presynaptic vesicle. The transport mechanics of presynaptic vesicles thus influences presynaptic communication. Presynaptic vesicles undergo many types of motion, but it is still unclear how their motion corresponds to the overall structure of the synapse. High resolution fluorescence microscopy has recently been shown to be an effective tool to understand vesicle motion. We take advantage of recent three-dimensional microscopy experiments and develop a three-dimensional computational analysis method of single vesicle motion in live cells. We use the computational method to classify types of motion, then distinguish different types of motion relative to the known structure of the synapse observed. We show that this approach can distinguish types of vesicles motion relative to the synapse. This method also allows us to take a closer look at the vesicles when the motion is directed.
M71.00365: A micromechanical model for interactions of curvature sensing septin filaments with membrane  WENZHENG SHI, KEVIN S CANNON, AMY S GLADFELTER, EHSSAN NAZOCKDAST (Presenter), Univ of NC - Chapel Hill — Cells reconfigure their shape in micron-scale in response to internal and external forces. Septins are filament-forming GTP-binding proteins that can sense curvature in micron-scale by preferentially accumulating in membrane regions with high curvature. Yet, the underlying mechanisms by which a nanoscopic septin hetero-octamer senses curvature in micron-scale remains unclear. We combine biophysical modeling and experiments and propose a micromechanical model for interactions of septin filaments with membranes. We propose that the rate of attachment of septins filaments to membranes is controlled by a combination of membrane's thermal and stored elastic energy, while the rate of detachment is controlled by the bending energy of the curved membrane-bound septin filaments. Moreover, our model predicts a qualitative change in septins curvature sensing as they assemble into micron-scale filaments in larger concentrations. We verify these predictions experimentally, by measuring the attachment/detachment kinetics under different bulk concentrations of septins on beads of different radii, covered with lipid bilayer.

M71.00366: One-dimensional contact process with both temporal and spatial disorder  XUECHENG YE (Presenter), THOMAS VOJTA, Missouri Univ of Sci & Tech — We investigate the non-equilibrium phase transition in the contact process under the influence of both temporal and spatial disorder using large-scale Monte-Carlo simulations. Spatial disorder alone is known to lead to an exotic infinite-randomness critical point [1]. More recently, it was shown that temporal disorders also produces unconventional critical behavior dubbed infinite-noise critical behavior [2]. We perform a series of simulations adding weak temporal disorder to a spatially disordered space and vice versa. We find that the critical behavior remains unchanged by these perturbation, in agreement with the generalized Harris criteria [3]. We then focus on the case where both temporal and spatial disorder are strong.

M71.00367: Modeling Swimming Microorganisms using Macroscopic Experiments*  MACKENZIE CONKLING, JACOB PFALLER, BRUCE RODENBORN (Presenter), Centre College — The swimming of microorganisms is typically analyzed using biological experiments or numerical simulations because the Reynolds number is much less than one. Our research group uses model macroscopic experiments with typical length scales of ~ 10 cm, but match the low Reynolds number of microorganisms by using a highly viscous silicone oil. The fluid has a viscosity that is $10^5$ larger than water but with approximately the same density. We can therefore build laboratory scale robotic swimmers and model microorganisms that are typically ~10 μm. We can also explore fundamental theories such as our project to build a laboratory scale three-link swimmer to test theoretical predictions (Purcell 1977, Hatton et al. 2013).

M71.00368: Single molecule force spectroscopy to determine specific receptor densities on live cancer cells under varying conditions*  RAMESH CHANDRA TRIPATHI (Presenter), PETER HOFFMANN, Wayne State Univ — We have used atomic force microscopy to study the single-molecule interaction between the ligand and receptors in live cancer cells under different conditions. We particularly focused on discoidin domain receptors (DDR), an important player in cancer metastasis. DDRs are receptors that dimerize in response to collagen and initiate a signaling chain within the cell. To mimic the cancer environment, we constructed gel substrates of varying stiffness and collagen concentration. The goal of the research is to determine receptor levels, dynamics and interactions as a function of cell type and environment. Using an improved AFM analysis method, we were able to determine not only binding probability and kinetic parameters, but also ligand densities. We will present preliminary results from this research.

*We acknowledge the Richard Barber foundation and Wayne State University for funding for this research.

M71.00369: CHEMICAL PHYSICS —

M71.00370: Photoprotective properties of a eumelanin building block: Ultrafast excited state relaxation dynamics in 5,6-dihydroxyindole  SARITA SHRESTHA (Presenter), University of Georgia — Skin plays the significant role in protection of body from ultraviolet radiation. The protection is primarily done by a type of pigment called eumelanin. Eumelanin chromophores absorb the energy of the radiation, and through internal conversion, dissipate them quickly in the form of heat. The process takes place in femtosecond time scales. A bottom-up approach is used to study the photophysics of eumelanin which focuses on individual building blocks to gather the overall information of the complex system. Time-Resolved Photoelectron Spectroscopy (TRPES) is implemented to understand the underlying excited state relaxation mechanism in 5,6-dihydroxyindole. This method allows to see the associated dynamics in terms of photoelectron kinetic energy.

M71.00371: Fabrication of CFO@C Core/Shell Nanoparticles by Pulsed Laser Ablation  JOY ROY (Presenter), KARTIK GHOSH, Missouri State Univ — A considerable research work is going on worldwide among the therapeutic scientific communities to use magnetic nanoparticles (NPs) for drug delivery system. Challenges to use those NPs for such in vivo applications successfully, are-biocompatibility and functionality of those NPs and control over the complex drug release system. In this project, we synthesized carbon coated cobalt ferrite (CFO) core shell nanoparticles (CSNPs) by ablating a solution of toluene and cobalt ferrite NPs with varying number of pulsed laser shots. The structure of the CSNPs was further investigated through X-ray diffraction, UV-VIS, Raman spectra and also with the high-resolution transmission electron microscopy (TEM). The XRD analysis shows that the inner structure of CFO is intact after the laser shots. Raman spectra confirms that with increasing laser shots the G band peak for Carbon becomes more prominent which infers to the crystallinity of carbon. Preliminary TEM line scan data concludes that laser ablation technique is quite efficient to manufacture carbon coated magnetic metal oxide CSNPs.

M71.00372: WITHDRAWN ABSTRACT —
M71.00373:Kinetic compensation effect due to the variation in the concentration of an additive

NAYELI ZUNIGA-HANSEN (Presenter), Louisiana State University, Baton Rouge, LEO SILBERT, Central New Mexico Community College, MARIA CALBI, University of Denver — As part of a systematic study on the kinetic compensation effect, we use kinetic Monte Carlo simulations to study the effects of the change in the concentration of a chemical species in the Arrhenius parameters - effective activation energy $E_a$, and preexponential factor $\nu$ - during the thermal desorption of a binary mixture of interacting and non-interacting adsorbates from two dimensional ordered and disordered surfaces. A chemical additive, such as a catalyst, can have an effect in the overall rate at which a process occurs. In this study we quantify the transient variations in the Arrhenius parameters when the concentration of one of the chemical species in the mixture, which is treated as an additive, is varied. The purpose is to observe if a compensation effect and/or isokinetic relation occur when this 'experimental parameter' is altered. We expect our results to help advance the understanding of the microscopic origins of compensation effects in our system of study but also in other fields where these effects have been reported.

M71.00374: Probing structure-property relationships of BODIPY dimers on the efficiency for symmetry breaking charge transfer

LAURA ESTERGREEN (Presenter), Univ of Southern California, SEAN ROBERTS, University of Texas at Austin, MIKE KELLOGG, AUSTIN R MENCKE, Univ of Southern California, NADIA KOROVINA, National Renewable Energy Laboratory, MARK E THOMPSON, STEPHEN EDMUND BRADFORTH, Univ of Southern California — Symmetry breaking charge transfer (SBCT) is the process in which a pair of identical chromophores are coupled such that post excitation an exciton (electron-hole pair) can dissociate between the two chromophores. The product is an uncoupled, spatially separated electron and hole pair, reducing the probability of recombination. The resulting uncoupled charges from SBCT are beneficial for photoelectrochemical and photovoltaic applications. BODIPY dimers have been shown to undergo SBCT in femto-to-pico-second timescales\(^1\). The dipyrrinato dimer analogues have also been studied and shown to undergo SBCT where they are ligated via the nitrogen termini through a zinc (II) center\(^2\). Herein the BODIPY and dipyrrinato dimers are analyzed to understand the effect of different bridging methods and increased substituents on the efficiency of SBCT. Efficiency in the context of this analysis is the rate of formation and longevity of the SBCT state. We find that direct linkage where torsion is not sterically hindered results in the fastest SBCT formation and that orthogonally fixed geometries result in the slowest decay times of the SBCT state.

M71.00375: Stimulated Raman spectroscopy for characterizing two-dimensional crystals
HWANSOO JEON (Presenter), SUNMIN RYU, Pohang Univ of Sci & Tech — Two-dimensional dielectric materials such as hexagonal BN and mica give very weak signals in conventional spontaneous Raman scattering using visible excitation lasers. In this work, we report a micro-spectroscopy setup for stimulated Raman scattering (SRS), which gives a substantial increase in overall sensitivity. Pump and Stokes beams with temporal width of a few ps were prepared by spectrally slicing 200 fs pulses from an optical parametric oscillator. The pulse slicer acting as a narrow band-pass filter consisted of a grating (1200 grooves/mm), a cylindrical lens, a mirror, and a mechanical slit that were arranged in the 4f-configuration. Whereas the Stokes pulses were fixed at 1040 nm with a bandwidth of 0.7 nm, the pump pulses were varied from 734 nm to 998 nm for the Raman shift in the range of 400 ~ 4000 cm⁻¹. The pump beam intensity-modulated by interaction with the Stokes beam in thin hexagonal BN crystals was detected with a photodiode connected to a lock-in amplifier. The sensitivity of the SRS setup and its spatial resolution in raster-scan imaging will be presented.

M71.00376: WITHDRAWN ABSTRACT

M71.00377: Visualization of orbital free models of Kinetic Energy density in solids
BRIELLE TILSON (Presenter), ANTONIO CANCIO, Ball State University — The metaGGA functional for describing the exchange-correlation (XC) energy in density functional theory (DFT) is conventionally constructed as a functional dependent on the density, density gradient, and kinetic energy density (KED). The addition of the KED makes metaGGA's a more accurate functional than ones that use the density and its gradient alone but also more computationally expensive for some applications such as ab initio molecular dynamics simulations. The calculation of the XC energy in meta-GGAs can be made less expensive by replacing the explicit orbital dependence in the KED with expressions involving only the particle density and its gradient and Laplacian. We test the validity of recent deorbitalization strategies in the literature by visualizing their predictions for the KED and related quantities, and comparing these to exact calculations. For an effective test, we perform these calculations on ionic, semiconductor, simple metal, and transition metal solids to see how well the KED for these different binding topologies can be represented by a single metaGGA model in terms of the scaled gradient and Laplacian of the density. The calculations of exact KED and electron density are done with the ABINIT DFT plane-wave pseudopotential code.
M71.00378: Bayesian Calibration assisted by Markov Chain Monte Carlo in DFT+U for Iron Compounds

ALDO H ROMERO, DAVID S. MEBANE, PEDRAM TAVADZE, REESE BOUCHER

(Presenter), West Virginia Univ — Density Functional Theory (DFT) revolutionized condensed matter physics by mapping the electron problem solved by the Schrodinger's Equation to a series of mean field electron independent equations. In DFT, the most crucial approximation is from the exchange correlation functional. Although many have attempted the development of accurate functionals, they all fail to reproduce the behavior of strongly correlated materials when kinetic energy is as large as the Coulomb interaction. To solve this problem, local exchange correlation functionals are corrected by a Hubbard term. This is DFT+U which depends on two extra parameters, U (on-site coulomb interaction) and J (on-site exchange interaction). These parameters are usually fitted from experimental values or obtained by using density functional perturbation theory. Either way the quality of the parameter values can only be assessed by comparing to experimental data. In this work, we use uncertainty quantification methods to study the dependence of different experimental observables where we evaluate the relevance of errors by utilizing Bayesian Calibration facilitated by Markov Chain Monte Carlo simulation with a number of strongly correlated materials.

*NSF, O'Brien Fund of the WVU Energy Institute, Spruce Supercomputer, WVU SURE

M71.00379: Accurate effective potential for density amplitude and the corresponding Kohn-Sham exchange-correlation potential calculated from approximate wavefunctions

ASHISH KUMAR (Presenter), Physics, Indian Insitute of Technology Kanpur, U.P., Indian, 208016, RABEET SINGH, Physical sciences, National Institute of Science Education and. Research, Jatni, Odisha-752050., MANOJ K HARBOLA, Physics, Indian Insitute of Technology Kanpur, U.P., Indian, 208016 — It is well known that direct inversion of an accurate but approximate density leads to KS exchange-correlation potential which has spuriously large deviations from the exact one. On the other hand, a different approach which employs wavefunction directly to obtain KS exchange-correlation potential is found to lead to potentials close to the exact one. This approach utilises the Levy-Perdew-Sahni expression for the effective potential used in the equation for the square root of the density.

We present why the Kohn-Sham exchange-correlation potential obtained by using an approximate wavefunction in the Levy-Perdew-Sahni expression for effective potential is accurate while the direct inversion of density associated with the same wavefunction may lead to pathological features in it. By analysing the Levy-Perdew-Sahni equation, we show that quantities like effective and exchange-correlation potentials, calculated from approximate wavefunctions are free from spurious features and close to the corresponding exact ones. The study also suggests possibility of a new approach for the calculation of accurate densities from approximate wavefunctions. These densities are closer to the exact ones than those obtained from the wavefunction directly.
M71.00380: Mechanical and electronic properties of mechanically-bent monolayer transition metal dichalcogenides (MX$_2$) in the ground state using SCAN density functional*  

NIRAJ NEPAL (Presenter), Temple Univ, LI-PING YU, University of Maine, QIMIN YAN, ADRIENN RUZSINSZKY, Temple Univ — As an alternative to graphene, transition metal dichalcogenides (TMD) have gained a lot of interest as promising candidates for future flexible nano-electronics due to the mechanical and electronic properties related to their high flexibility [1]. Though the TMD thin layers have a promising future, traditional methods of tuning the band gap such as doping with impurities or contact engineering suffer strong Fermi-level pinning or even damage the materials. However, due to the high bending and in-plane stiffness, thin monolayer MoS$_2$ can be bend mechanically to tune the bandgap as well as reducing Fermi level pinning to some extent [2]. In this work [3], we extend the study to exploring the other TMD monolayers corresponding to transition metals from groups IV to X in the periodic table in the ground state, using the recently developed meta-GGA SCAN.

M71.00381: A simple self-interaction correction to the RPA+ correlation energy*  

SHIQI RUAN (Presenter), Temple Univ, TIM GOULD, Griffith University, ADRIENN RUZSINSZKY, Temple Univ — The exchange energy of the Random Phase Approximation is exact for a many-body ground state, but the correlation energy is often overestimated. The error comes from the poor description of the short-range correlation. The RPA+ approximation [1] largely reduces this error for atoms, for the jellium surface and for the uniform electron gas by adding a local or semi-local correction. While the RPA+ is accurate for the total energies of atoms, it fails for single-electron systems like stretched H$^{2+}$, and systems where spin-polarization plays a significant role such as ionization energies, electron affinities, and atomization energies. In this work, we have introduced a simple correction to the RPA+ correlation energy to make the new gRPA+ [2] approximation exact for single-electron systems. We are assessing this computationally feasible approximation beyond RPA for various molecular test sets and we analyze the impact of self-interaction correction.

*Work was supported by National Science Foundation under Grant No. DMR-1553022.
**M71.00382: Quasiparticle energies of the uniform electron gas**

PRADEEP BHETWAL (Presenter), ANDREW PONENTO, ALEXANDER TRACKMAN, JOHN P. PERDEW, Temple Univ —

The uniform electron gas (UEG) model is the simplest model of a metal, a large volume of electrons subject to a uniform background of positive charge. Existing parametrizations of the UEG correlation energy allow us to perform calculations in Kohn-Sham density functional theory (KS-DFT). While the Kohn-Sham and generalized Kohn-Sham orbital energy eigenvalues are not single-particle excitation energies [1,2], how well do they predict the occupied bandwidth of the uniform electron gas or of alkali metals like Na? In this work, we aim to answer this question using the local spin density approximation (LSDA), the Perdew-Burke-Ernzerhof generalized gradient approximation (PBE GGA), and the PBE0 hybrid functional (with 25% of Hartree-Fock exchange). We benchmark our DFT values against the results of higher-level theories and experiment.

**M71.00383: Pressure-induced New Oxidation States**

GUOCHUN YANG (Presenter), Department of Physics, Northeast Normal University —

The formalism of the oxidation state of atoms in compounds is a key concept in chemistry. Finding novel compounds containing elements with unusually high oxidation states allows a deeper understanding of chemical behavior of elements. On the other hand, high oxidation state compounds usually bring new types of bonds with interesting physical and chemical properties. Thus, the preparation of compounds with unusual oxidation states becomes an attractive topic in chemistry and condensed-matter physics. Gold (Au) is a well-known fascinating element, but still hides interesting surprises to be discovered, especially for oxidation state. Here, we propose that high pressure becomes a controllable method for preparing high negative oxidation state of Au through its reaction with lithium. Au acts as a 6p-element in dense lithium aurides. Moreover, we identify two hitherto unknown stoichiometric compounds, AuF4 and AuF6, exhibiting typical molecular crystal character, in which Au demonstrates +4 and +6 oxidation states. On other hand, we also achieve several compounds with unusual stoichiometry such as IrF₈, IF₈, and BaF₅.

ABHISHEK AGGARWAL (Presenter), Department of Physics, Indian Institute of Science, SAIENTAN BAG, Institute of Nanotechnology, Karlsruhe Institute of Technology, RAVINDRA VENKATRAMANI, Department of Chemical Sciences, Tata Institute of Fundamental Research, MANISH JAIN, PRABAL K MAITI, Department of Physics, Indian Institute of Science — Double-stranded DNA (dsDNA) and dsRNA hold great promises in molecular electronics. We characterize the charge transport properties of dsRNA for different sequences and compare them with similar sequences of dsDNA in two extreme charge transport regimes - incoherent charge hopping regime and coherent electron transport regime. We find that the relative conductance of A-form dsRNA and B-form dsDNA depends on the mechanism of charge transport. This is attributed to various structural differences in dsDNA and dsRNA. We also study the effect of stretching and propose a method to detect conformational changes using electrical measurements. Despite the twist-stretch coupling of dsRNA and dsDNA being different under external force, dsRNA shows similar structural polymorphism to dsDNA under different pulling protocols. Our atomistic MD simulations show that overstretching dsRNA along the 3’ ends (OS3) leads to the emergence of S-RNA whereas overstretching along the 5’ ends (OS5) leads to melting of dsRNA. Using the dsRNA morphology from pulling MD simulations, we use a multiscale method involving ab initio DFT calculations and Kinetic Monte Carlo (KMC) simulations to estimate the conductance of dsRNA and find that the conformational changes drastically affect its conductance.

M71.00385: Tuning the adsorption properties of transition metal dichalcogenides (TMD) monolayer by bending* SANTOSH NEUPANE (Presenter), NIRAJI NEPAL, ADRIENN RUZSINSZKY, Temple Univ — Due to their exceptional catalytic performance, there has been a growing interest in understanding the adsorption properties of transition metal dichalcogenide (TMD) monolayers. Previous studies focused on tuning the adsorption energies and distances in these 2D materials using mechanical strain as well as doping with impurities. Besides that, 2D materials are highly flexible. Moreover, some recent works [1,2] have shown the importance of mechanical bending for tuning various mechanical and electronic properties of TMD monolayers. Using first-principles calculations, we report the effect of mechanical bending on the adsorption properties of the monolayers using a single hydrogen atom as the adsorbate.

Work is supported as part of the Center for Complex Materials from First Principles (CCM), an Energy Frontier Research Center supported by the U.S. Department of Energy (DOE), Basic Energy Sciences (BES), under Award No. DE-SC0012575.

M71.00386: WITHDRAWN ABSTRACT —
M71.00387: WITHDRAWN ABSTRACT —
M71.00388: Modelling the electronic kinetic energy density and Pauli potential by orbital free density functional theory.  BISHAL THAPA (Presenter), ANTONIO CANCIO, Ball State University —

In Kohn Sham density functional theory, the kinetic energy (KE) functional is described by fictitious Kohn-Sham (KS) orbitals. This causes a computational bottleneck for large systems that require many KS orbitals. Much recent research is going into Orbital-Free Density Functional Theory (OFDFT), which models the Kinetic Energy as a functional of density and other ingredients that are derived from density directly, avoiding the need for orbitals. There are reasonable OFDFT models for Kinetic Energy at the meta-GGA level, such the Perdew-Constantin model [1], that properly treat the nonnegativity constraint for the Pauli contribution to the KED, which describes the correction to the von-Weizsäcker KED, which describes the KE of a single electron pair. However, an issue arises of Pauli potentials that are not physically reasonable and difficult to find convergent solutions for. Our goal is to construct meta-GGA level models with potentials which vary smoothly. We test them against calculations of the exact Kohn-Sham KE density and potential for atoms, with atomic densities constructed from the fhi98pp code. As another design goal we will try to incorporate the calculation of linear response.

M71.00389: Stable Structures and NMR Analysis of (Na)$n$ with pore size in hard carbon by DFT calculations  AYANE SUZAKI (Presenter), AZUSA MURAOKA, Japan Women's Univ-Facul Sci, KOICHI YAMASHITA, Kyoto University, Elements Strategy Initiative for Catalysts and Batteries — The lithium ion batteries (LIB) which are a typical secondary batteries, is widely used as an energy storage system by having high voltage, good charge and discharge cycles. However, due to problems with the resources and costs of lithium in LIB, there is a growing interest in resource-rich sodium-ion batteries (NIB) with equivalent electrode potential. In recent years, a NIB using a Na metal oxide as the positive electrode and hard carbon (HC) as the negative electrode has attracted attention in particular. To develop a NIB with high capacity, high efficiency, long life, and acceptable safety, it is essential to elucidate the state of the sodium ion and the mechanism of charge and discharge on the electrode. The states of sodium electrochemically inserted in HC samples have been experimentally reported using solid 23Na NMR. In this study, in order to study the correlation of NMR shift of Na clusters (n = 1-8) with pore size in HC and structure, DFT calculations are performed at B3LYP/6-31G(d) level using the Gaussian 16. From NMR analysis it can be seen that the value of chemical shielding shifts significantly depending on the strength of bonding between Na atoms and the size of clusters.
M71.00390: Investigation the nature of CO2 binding to borophene $\chi_3$  FARIDEH ZERGANI (Presenter), Kashan University — Global warming following the release of greenhouse gases, especially CO2, is one of the important areas of research to adsorption of CO2 to remove it from the environment. But the CO2 binding to the surfaces is weak, and scientists want to correct this defect. Here we used borophene $\chi_3$ as a novel 2D material with the hole density ($\eta=1/4$) and investigated the nature of CO2 binding to its surface. DFT calculations and plane-wave basis set with the ultrasoft pseudopotentials were used in the quantum espresso. The GGA approximation with PBE functional was applied for the electron exchange-correlation energy. The VDW interactions were taken into account using the DFT-D2 method. The binding site for CO2 was determined and the adsorption energy and electronic properties of the $\chi_3$-CO2 were analyzed. The calculated binding energy (~0.2eV) and distance of CO2 to the surface (~3.5Å) indicated weak adsorption. The charge density differences calculation shows the charge depletion between the boron sheet and CO2. The Bader charges analysis shows that the CO2 tends to capture electrons from boron atoms during the adsorption. Therefore, because of the electron deficiency of the surface, the CO2 physisorbed. Therefore, to achieve stronger adsorption, the surface modifications were needed.

M71.00391: Theoretical study of charge and discharge process and NMR in Na ion battery anode material Sn  KEI KUDO, AZUSA MURAOKA (Presenter), Japan Women’s Univ-Facul Sci, MASANORI KANEKO, KOICHI YAMASHITA, Kyoto University, Elements Strategy Initiative for Catalysts and Batteries — Sn can be used as an anode material for secondary battery Na ion batteries because it can work with Na with a composition ratio of up to $\text{Na}_{15}\text{Sn}_4$ by alloying with Na. For practical application, it was reported from both experiments and calculations that there were multiple plateaus in the charging curve of Na-Sn system based on the structural change in the sodiation/desodiation process of Na-Sn system. In this study, we investigated the detailed mechanism of charge and discharge processes in Sn anodes by theoretically clarifying the structural changes, charge and discharge curves, and $^{23}\text{Na}$ NMR chemical shift properties of the anode material Sn in Na ion batteries. We used VASP-5.3.2 to optimize the structure of Na-Sn systems with different composition ratios during the charge/discharge process, and calculated their formation energy. The boundary composition ratio was clarified from the charging curve obtained by estimating the change in potential with respect to the Na/Sn composition ratio. We calculated chemical shift tensors for Na-Sn system, Na and NaCl by GIPAW method. As a result of theoretical calculation of the $^{23}\text{Na}$ chemical shift, it was possible to obtain a number of shielding effect values corresponding to the number of independent Na sites in each Na-Sn composition.
M71.00392: Alternative diffusion Monte Carlo methods for fermions*  
OTO KOHULAK, Department of Physics, University of Ostrava, MATUS DUBECKY (Presenter), Advanced Technologies Research Institute, Slovak University of Technology in Bratislava — Current continuum diffusion Monte Carlo methods for fermions are limited by the sign-problem, or, fixed-node approximation, computationally inefficient in cases that require far more than single determinant to reliably describe leading correlations. We devise and critically examine some alternative approaches that enable maintaining Fermi statistics within continuum DMC simulations.

*We acknowledge financial support by the Czech Science Foundation (18-24321Y), and Slovak Research and Development Agency (APVV-18-0161).

M71.00393: Self-Interaction correction using Fermi-Lowdin orbitals: Methodology and Parallelization*  
LUIS BASURTO (Presenter), YOH YAMAMOTO, CARLOS DIAZ, TUNNA BARUAH, RAJENDRA ZOPE, Physics, University of Texas at El Paso — Density functional theory is a popular electronic structure method that can handle comparatively much larger systems than quantum chemical methods. However, density functional approximations suffer from self-interaction errors which limits its reliability for certain properties. The Perdew-Zunger (PZ) self-interaction correction (SIC) method removes self-interaction on an orbital by orbital basis and is computationally expensive. Recent implementation of Fermi-Lowdin orbital based SIC (FLOSIC) is a promising method that removes many computational complexities of PZ-SIC. We present some details of the FLOSIC methodology and present parallelization strategies using MPI+MPI and recent shared memory features of MPI-3 to make efficient use of large supercomputers. Using this implementation, we achieved parallel efficiency above 80% for 3360 processors. Applications of the FLOSIC method using the FLOSIC code on water clusters and carbon fullerenes will be presented.

*US DOE under grants DE-SC0018331 and DE-SC0006818
M71.00394: Synthesis of carbon nanodots from caramelized glucose solutions  HARSH UPPALA (Presenter), DAVID SIDEBOTTOM, Creighton University — Carbon nanodots are a class of zero-dimensional carbon-based nanoparticles that have been used increasingly in the fields of bioimaging, drug delivery, and optronics. Despite their popularity, carbon nanodots remain difficult to isolate when synthesized by a bottom-up approach, especially through the thermal treatment of carbohydrate solutions due to the presence of many molecular byproducts which result from the Maillard reaction [1].

We investigated multiple possible methods of purification of glucose solutions [2]. Glucose solutions were heated at 120 °C for a period of 48 hours to produce carbon nanodots. We found that dialysis combined with solid phase extraction preserved the photoluminescent properties of dissolved carbon nanodots, while eliminating measurable traces of other chemical byproducts, as measured by Fourier-Transform IR spectroscopy, Carbon-NMR, and Hydrogen-NMR.

M71.00395: Synthesis and Characterization of Barium Titanate and Carbon-based core-shell nanoparticles  MOUDIP NANDI (Presenter), KARTIK GHOSH, CHRISTOPHER ROBLEDO, Missouri State Univ — Core-shell nanoparticles (CSNP) have diverse applications such as biology and electronic field of studies. Among so many oxide nanoparticles, Barium Titanate nanoparticles are of current interest due to their good electronic and ferroelectric properties.

There are some studies based on the synthesis and characterization of oxide-oxide and oxide-sulfide based core-shell nanoparticles. Here we are trying to synthesize and characterize oxide-carbide based core-shell nanoparticles, where the core is made of Barium Titanate and the shell is made of Carbon. There are various synthesis approaches like hydrothermal synthesis, sol-gel method, emulsion polymerization etc to produce core-shell nanoparticles, here we have synthesized these core-shell nanoparticles with a unique method. The shell is made of Carbon which is a biocompatible element and it can be used as a connector between organic and inorganic materials. Shell made of carbon shows interesting optical properties and they can be useful for biosensing and optoelectronic applications. We used different methods like XRD, RAMAN, SEM, and TEM to characterize and analyze these CSNP. Some of the findings will be discussed here.
M71.00396: A Gd@C$_{82}$-based single electron transistor device with ferroelectric-like switching behavior  FENGQI SONG (Presenter), KANGKANG ZHANG, Nanjing Univ — Ferroelectricity arises from permanent dipole and has led to technology innovation in memory devices. However, maintaining ferroelectricity at nanoscale is challenging, greatly limits its application in nanoscale devices. Here we report the gate-controlled switching between two sets of single-electron characteristic stability diagrams in the electrical transport of a Gd@C$_{82}$-based single molecular device. It is operated in a hysteresis-like loop with a coercive gate field of up to 0.5 V/nm. The theoretical calculations attribute the two diagrams to the energy levels of two trapping states of the Gd atom in the C$_{82}$ cage, which possess two different permanent electrical dipole configurations. The switching thus originates from the electrical field driven dipole flipping and demonstrate the ferroelectricity at the single molecule level.

M71.00397: Evolution of plasmonic response of individual size-selected Au clusters from nanoscale to atomic-scale  FENGQI SONG (Presenter), SIQI LU, Nanjing Univ — We have studied the evolution of plasmonic response of individual size-selected Au clusters by scanning transmission electron microscopy-electron energy loss spectrum (STEM-EELS) from nanoscale to atomic scale. The clusters are prepared and selected by magnetron sputtering time-of-flight cluster source to get an atomic number precision. To distinguish surface and bulk plasmon mode, we put the electron beam at the edge or center of clusters, where we can get a pure surface mode or a mixture of surface and bulk mode. Both surface and bulk mode exist when the gold clusters are large enough. However when the atom numbers decrease to 887, the bulk mode disappears abruptly while the surface mode still appears. The surface mode excitation probability of a single incident electron shows a square relationship versus atom numbers from 70000 to 300, but deviates from it when the atom number reaches 175. What's more, a new peak higher than surface mode appears when the gold clusters are smaller than Au$_{500}$. After a slight redshift from Au$_{70000}$ to Au$_{887}$, an obvious blue-shift happens in the range Au$_{887}$ to Au$_{300}$, showing a combined influence between quantum size effect and classical size effect of electron mean free path.
Infrared Spectroscopy Investigation of Ammonium Sulfate at Low Temperatures

LUCAS EHINGER (Presenter), Seattle Univ, KRISHNA KHAREL, OZGE GUNAYDIN-SEN, Lamar University, AMAL B AL-WAHISH, University of Washington — We present a comprehensive study of ammonium sulfate between 30 and 300K using Fourier transform infrared (FTIR) spectroscopy, differential scanning calorimetry (DSC) and neutron powder diffraction (NPD) to investigate the paraelectric to ferroelectric phase transition. Heat capacity measurements taken with DSC show a clear anomaly at the phase transition (223 K). This phase transition in ammonium sulfate is associated with temperature dependent hydrogen bonding and presents an interesting and challenging research area.¹ We characterize the hydrogen bonds at different-temperatures and compare our NPD at room temperature with previously reported results². We then analyze FTIR spectral features of the sample and demonstrate their temperature dependent displacement.

Activation of CO₂ at chromia-nanocluster-modified rutile and anatase TiO₂

MICHAEL NOLAN, Tyndall National Institute, MARCO FRONZI (Presenter), IRCRE, Xi'an Jiaotong University — Converting CO₂ to fuels is required to enable the production of sustainable fuels and to contribute to alleviating CO₂ emissions. In considering the conversion of CO₂, the initial step of adsorption and activation by the catalyst is crucial. In addressing this difficult problem, we have examined how nanoclusters of reducible metal oxides supported on TiO₂ can promote CO₂ activation. In this paper we present density functional theory (DFT) simulations of CO₂ activation on heterostructures composed of clean or hydroxylated extended rutile and anatase TiO₂ surfaces modified with chromia nanoclusters. Our results highlight that a metal oxide support modified with reducible metal oxide nanoclusters can activate CO₂, thus helping to overcome difficulties associated with the difficult first step in CO₂ conversion.
M71.00400: Logarithmic Expansion of Swellable Organosilica Material*  
BRIAN P CORBIN, JOHN LINDNER (Presenter), PAUL A BONVALLET, College of Wooster — Swellable organically modified silica (SOMS) is a matrix of crosslinked polysilsesquioxanes that undergoes rapid reversible swelling upon contact with organic solvents. This material has applications in environmental remediation, catalysis, and personal care products. We demonstrate that SOMS exhibits a logarithmic stress-strain relationship when it swells. Using a two-piston force sensor, we measured the swelling force exerted by various samples of SOMS when treated with acetone. As the mass of SOMS inside the force-measurement apparatus increases, the force generated by the swelling also increases, up to a maximum value of approximately 180 N at 650 mg of SOMS. However, the rate-of-change of the force generated by SOMS decreases at larger masses, implying that SOMS is dynamic rather than static. A data collapse of two different SOMS samples (Osorb® and Cyclasorb®) shows that the underlying behavior of SOMS is uniform across sample types.

*Research supported by NSF DMR-1852095

M71.00401: Carrier Injection Mechanisms in Diketopyrrolopyrrole Organic Semiconductors  
SHAWN KILPATRICK (Presenter), VISHAL NARANG, ANDREW LEVINE, MAJHARUL HOQUE, ADAM BRAUNSCHWEIG, MILAN BEGLIARBEKOV, NanoScience, CUNY Advanced Science Research Center — Organic semiconductors based on diketopyrrolopyrrole (DPP) are a new class of small molecule semiconductors which are air-stable, possess relatively high mobilities, and have been recently shown to undergo excitonic singlet fission. Realizing high quality (Ohmic) contacts to DPP is essential for the fabrication of high quality devices. In this work we use a combination of scanning Kelvin probe microscopy and electrical transport measurements to spatially map the work function in several DPP-based semiconductors and study the carrier injection mechanism in thermally evaporated DPP films.

M71.00402: Novel phase transitions as bridges for broken ergodicity in confined colloidal prisms*  
PRAJWAL BANGALORE PRAKASH (Presenter), FERNANDO A ESCOBEDO, Cornell University — We used Monte Carlo simulations to study the assembly behavior of square and hexagonal prisms under quasi-2D confinement separations, within a hard-wall slit. Our results for hexagonal prisms revealed two types of first order phase transitions at increasing concentration: 1) solid-solid transition (6-fold → 4-fold symmetry solid) occurring through lattice symmetry breaking, and 2) solid to dense-liquid (disorder) to solid. The predicted dense-liquid has a density intermediate to those of the two solid phases and high translational/orientational mobility. We showed that similar phase behavior can be expected for other n-gonal prisms (n > 6). For square prisms, we observed a solid-solid phase transition where a square lattice spacing rearrangement gives rise to a polycrystalline phase with multiple locally ordered domains. These unusual phase transitions are attributed to the broken ergodicity associated with a dynamically disconnected rotational phase space accessible to the particles. As an experimentally viable strategy to dynamically bridge those rotational states observed for hard-slit phase behavior, we also investigated and validated a soft-repulsive wall model.

*Partial funding support from NSF awards CBET-1907369 and 1402117
M71.00403: Non-Adiabatic Molecular Dynamics of Molecules in the Presence of Strong Light-Matter Interactions*  YU ZHANG (Presenter), TAMMIE NELSON, SERGEI TRETIAK, Theoretical Division, Los Alamos National Laboratory — The mixing between the light and matter characters modifies the photophysical and photochemical properties. In this work, a theoretical model and an efficient numerical method for studying the dynamics of molecules strongly interacting with quantum light are developed based on non-adiabatic excited-state molecular dynamics. The methodology was employed to study the cis-trans photoisomerization of a realistic molecule in a cavity. Numerical simulations demonstrate that the photochemical reactions can be controlled by tuning the properties of the cavity. In the calculated example, the isomerization is suppressed when polaritonic states develop a local minimum on the lower polaritonic state. Moreover, the observed reduction of isomerization is tunable via the photon energy and light-molecule coupling strength. But the fluctuation in transition dipole screens the effect of light-matter, which makes it harder to tune the photochemical properties via the coupling strength.

*The work at Los Alamos National Laboratory (LANL) was supported by the LANL Directed Research and Development Funds. This research used resources provided by the LANL Institutional Computing (IC) Program. LANL is operated by Triad National Security, LLC, for the NNSA of the U.S. DOE (Contract No. 89233218NCA000001).

M71.00404: Strong plasmon-molecule coupling at the nanoscale revealed by first-principles modeling*  TUOMAS ROSSI (Presenter), PAUL ERHART, TIMUR SHEGAI, Department of Physics, Chalmers University of Technology, TOMASZ ANTOSIEWICZ, Faculty of Physics, University of Warsaw — Strong light-matter interactions in both the single-emitter and collective strong coupling regimes attract significant interest due to emerging applications in quantum optics as well as opportunities for modifying material-related properties. Exploration of these phenomena is theoretically challenging, as polaritons exist at the intersection between quantum optics, solid state physics, and quantum chemistry. In this presentation, we shed light on nanoscale polaritons in small strongly-coupled plasmon-molecule systems by using time-dependent density-functional theory (TDDFT) [1]. By analyzing the electron-hole transitions involved in the excitation process, we dissect the symmetric and antisymmetric polaritonic modes caused by strong coupling between plasmon and molecular excitation, resulting in Rabi oscillations in time domain. Our results indicate that cavity quantum electrodynamics description holds down to resonators of a few cubic nanometers in size. In a broader perspective, first-principles methods enable parameter-free in-depth studies of polaritonic systems for emerging applications.

High-order harmonics generated from a quasi-one-dimensional hexagonal solid*  
GUOPING ZHANG (Presenter), Y. H. BAI, Indiana State University — High harmonic generation has attracted enormous attentions. Here we report a completely new kind of harmonics in a quasi-one-dimensional and hexagonal barium titanium sulfide: Under circularly polarized laser excitation, harmonics are generated only at first, fifth, seventh and eleventh orders. These magic harmonics appear only with circularly polarized light, not with linearly polarized light. Neither cubic nor tetragonal cells have magic harmonics even with circularly polarized light. Through a careful group-theory analysis, we find that two subgroups of symmetry operations unique to the hexagonal symmetry cancel out third and ninth harmonics. This feature presents a rare opportunity to develop HHG into a crystal-structure characterization tool for phase transitions between hexagonal and nonhexagonal structures.

M71.00406: Deciphering photoacidity by following electronic charge distribution changes along the photoacid Förster cycle with picosecond nitrogen K-edge x-ray absorption spectroscopy

SEBASTIAN ECKERT, MARC-OLIVER WINGHART, CARLO KLEINE, JAN LUDWIG, MARIA EKIMOVA, Max Born Inst, AMBAR BANERJEE, Department of Physics, Stockholm University, JESSICA HARICH, Institute for Nanostructure and Solid State Physics, University of Hamburg, ROLF MITZNER, Institute for Methods and Instrumentation for Synchrotron Radiation Research, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, DANIEL AMINOV, EHUD PINES, Department of Chemistry, Ben Gurion University of the Negev, NILS HUSE, Institute for Nanostructure and Solid State Physics, University of Hamburg, PHILIPPE WERNET, Department of Physics and Astronomy, Uppsala University, MICHAEL ODELIUS, Department of Physics, Stockholm University, ERIK T. J. NIBBERING (Presenter), Max Born Inst — Photoacids are molecular systems that show a strong increase in acidity in the first electronic excited state. The underlying mechanisms for photoacidity and photobasicity have until now remained unsolved. We use picosecond N K-edge x-ray absorption spectroscopy to determine how the transient electronic-structure changes and hydrogen-bond dynamics determine the acidity of a prototypical photoacid, 8-aminopyrene-1,3,6-trisulfonate (APTS), in aqueous solution. We follow in time the characteristic spectroscopic signatures of N-H σ* and N-lone pair interactions of the proton donating functional amine group as well as aromatic pyrene π* anti-bonding orbitals of APTS along the different stages in the Förster photocycle. With our flatjet system for x-ray absorption spectroscopy in transmission and with the picosecond x-ray pulses at BESSY II (in multibunch mode), we elucidate how UV excitation converts the photoacid into the conjugate photobase form on a time scale of 150 ps, followed by electronic excited state fluorescence decay on nanosecond time scales. With these results we demonstrate that a systematic electronic-structural approach to the ultrafast dynamics of photoacids in aqueous solution can be established.
M71.00407: Microscopic study of proton kinetic energy anomaly for confined water*

MOHAMMAD MOID (Presenter), Indian Institute of Science - Dept of Physics, YACOV FINKELSTEIN, Nuclear Research Center-Negev, Beer-Sheva, RAYMOND MOREH, Department of Physics, Ben-Gurion University of the Negev, Beer-Sheva, PRABAL K MAITI, Indian Institute of Science - Dept of Physics — Several anomalies, related to structural and dynamical transition, have been reported for water at different thermodynamic conditions and environments. Of particular interest, the reported anomalies of the proton mean kinetic energy, Ke(H), in nanoconfined water, as measured by deep inelastic neutron scattering (DINS), are a longstanding problem related to proton dynamics in hydrogen-bonded systems. We used classical MD method to deduce Ke(H) by calculating the proton vibrational density of states, H-VDOS, for the case of water inside single wall carbon nanotubes (SWCNT) of varying diameters. The mean vibrational density of states (VDOS) of protons in water nanoconfined inside single wall carbon nanotubes (SWCNTs) is calculated as a function of temperature and SWCNT diameter, D\text{CNT}. The calculated VDOS are utilized for deducing the mean kinetic energy of the water protons, Ke(H), by treating each phonon state as a quantum harmonic oscillator. The calculation depicts a strong confinement effect as reflected in the drop of the value of Ke(H) at 5K for D\text{CNT} < ~12Å, while absent for larger diameters. The results also reveal a very significant blue and red shifts of the stretching and bending modes respectively compared to those in bulk ice, in agreement with experiment.

M71.00408: Evidence of topologically non-trivial phase trough unusual Shubnikov-de Haas oscillations*

JOÃO VITOR IGNÁCIO COSTA (Presenter), Sao Carlos Institute of Physics at the University of Sao Paulo, DENIS CANDIDO, Department of Physics and Astronomy and Optical Science and Technology Center, University of Iowa, SIGURDUR INGI ERLINGSSON, School of Science and Engineering, Reykjavik University, CARLOS EGUES, Sao Carlos Institute of Physics at the University of Sao Paulo — Topological features in bulk related phenomena are still an uncharted territory as opposed to edge and surface effects, making Shubnikov-de Haas (SdH) oscillations an interesting phenomenon to explore in topological systems. Here we investigate the bulk magneto-oscillations in connection with topological bands of 2D systems. We describe our systems by the BHZ model [1] and use a convenient trace formula [2] to describe the density of states of broadened Landau levels within a phenomenological Drude-like transport description. Our preliminary results show unusual beatings in the SdH oscillations for the topological regime, which are absent in the trivial regime. These can be traced back to the coexistence of both electron- and hole-like carriers, present in the “Mexican hat” band structures. This suggests SdH oscillations as a possible bulk probe for the non-trivial band topology of 2D systems.

M71.00409: Stacking-type dependence of topological phase transitions in a superlattice of topological and normal insulators*  
GUN SANG JEON (Presenter), Department of Physics, EWHA Woman's Univ — We consider a superlattice of topological and normal insulating layers. It is known that topological phase transitions occurs with the variation of the interlayer hopping when two-dimensional quantum spin Hall insulator is hybridized with the normal insulators in the AA-type stacking. We examine how the nature of topological phase transition changes depending on the stacking type. The resulting phase diagram exhibits rich phases such as semimetal and topological ones. The properties of the edge states are also investigated in the sample of finite width. Finally we discuss the topological features of alternately stacked layers of topological and normal insulators.

M71.00410: The physical basis of using MRI to detect cancer  
DONALD CHANG (Presenter), Hong Kong University of Science and Technology — Nowadays, the most effective way of detecting cancer in a patient is using MRI (Magnetic Resonance Imaging). This technique is based on the measurement of hydrogen nuclear spin signal of water molecules inside the body. During the development of the MRI technique, it needed to overcome two major difficulties: (1) How to produce a contrast between water molecules inside the cell and the extra-cellular water? (2) How to differentiate the water signals contributed by cancer cells from those contributed by normal cells? These difficulties were resolved mainly through the discovery that the relaxation times of water protons inside the cells are very different from those of the extra-cellular water. Furthermore, the relaxation times of water molecules in normal cells are found to be significantly different from those in the cancerous cells. In this presentation, I will give a concise review of the evidence for these discoveries. Finally, I will discuss the possible physical basis that may account for the relaxation time difference between different cells.

M71.00411: Influence of self-heating on noise of SiGe heterojunction bipolar transistors at cryogenic temperatures  
NACHIKET NAIK (Presenter), AUSTIN MINNICH, Caltech — Cryogenic low noise transistor amplifiers (LNA) at microwave frequencies have long been of interest for radio astronomy and more recently for quantum computers. While high electron mobility transistors have been the primary device of choice for these applications, SiGe HBTs are increasingly competitive due to increases in cutoff frequency and their relatively high yield. However, an understanding of the influence of self-heating on noise at cryogenic temperatures is lacking. In this work, we report noise measurements on SiGe HBT LNAs from 4 – 50 K. The influence of self-heating on the temperature of electrons at the base-emitter junction is evaluated by comparing measurements in vacuum with those in liquid Helium baths. Our work helps to identify a path for SiGe HBTs to achieve noise figures competitive with those of HEMTs.
M71.00412: Transfer of Linear and Angular Momentum from Evanescent Fields of an Optical Fiber to Isotropic and Anisotropic Dipolar Spheres.* DUSTIN SAVELLI (Presenter), Ohio State Univ - Columbus, ARIEL XIE, CODY LEARY, Physics, College of Wooster — We calculate the force and torque on a transparent isotropic dipolar sphere due to the higher-order evanescent field modes propagating outside a few-mode optical fiber immersed in water. After applying these results to find the orbital trajectory and spin dynamics of an isotropic sphere, we then use perturbation theory to calculate the orbital trajectory of a weakly anisotropic sphere.

*We would like to thank the National Science Foundation for their NSF grant #1852095

M71.00413: Capacitive Compactness and Surface Charge Density Variation in Pluronic (F-127) Micelles using Small-Angle X-ray Scattering TAHMIDA IQBAL (Presenter), JOSE L BANUELOS, Physics, University of Texas at El Paso — The spatial extent of a charged colloid or an electrode is usually characterized by its Debye length which is independent of important physical features including colloidal charge and electrostatic ion correlations. To describe the colloidal stability of electrified nanoparticles more accurately we need tools to study the structure of the electrical double layer. Colloidal particles can be used in diverse technological applications involving colloidal stability of charged solutions, or storage capacity of electrical energy in batteries or supercapacitors. Capacitive compactness is a novel description of the diffuse electrical double layer extension in terms of an effective capacitor and has ability to consider important physical characteristics of the solute. We have chosen Pluronic F-127 in this work because it is a temperature responsive triblock copolymer with well-known adsorption and colloidal properties. In this work, we studied the surface charge density of Pluronic F-127 micelles at different concentration and pH to understand how interparticle interactions relate to capacitive compactness. Small-angle x-ray scattering results were used to analyze the micelle-micelle structure factor and relate it to pH dependent changes in the capacitive compactness.

M71.00414: WITHDRAWN ABSTRACT
M71.00415: Nano Spray-Dried Block Copolymer Nanoparticles and Their Transformation into Hybrid and Inorganic Nanoparticles  INBAL WEISBORD (Presenter), NETA SHOMRAT, Chemical Engineering, Technion - Israel Institute of Technology, HEN MOSHE, ALEJANDRO SOSNIK, Materials Science and Engineering, Technion - Israel Institute of Technology, TAMAR SEGAL-PERETZ, Chemical Engineering, Technion - Israel Institute of Technology — Block copolymers (BCPs) self-assemble into highly ordered structures with periodicities of 5-50 nm. When BCP self-assembly is confined in macro and nano spheres various morphologies can be achieved by tailoring BCP chemical composition, solvent, and process parameters, making them attractive materials for applications like drug delivery and catalysis. So far, BCP NPs were mainly fabricated through emulsion-based methods. However, there is need to develop novel, potentially scalable, BCP NP fabrication methods which will enable new NP morphologies. We present a new route for BCP NP fabrication through BCP confinement in sprayed nanodroplets using Nano Spray-Drying (NSD). PS-b-PMMA and PS-b-PVP were NSD from toluene and chloroform. SEM and TEM were used to study the effects of BCP chemistry, solvent, and NSD process parameters on BCP NP morphology. Following NSD, BCP NPs were suspended in non-solvents and solvent annealed with chloroform to tune internal NP morphology. Finally, hybrid organic-inorganic particles were created through Sequential Infiltration Synthesis (SIS), a method that enables growth of metal-oxides within polymers. Using SIS, alumina and zinc-oxide were selectively grown in BCP polar domains, transforming the BCP NP into hybrid or BCP-templated inorganic NPs.

M71.00416: Fabrication of low dimensional oxide thin films using cuprates as sacrificial layers  YAO-WEN CHANG (Presenter), JHIH-BANG YI, CHUN-CHIEN CHIU, YU-CHEN LIU, JAN-CHI YANG, Department of Physics, National Cheng Kung University — The characteristics and functionalities of complex oxide caught a lot of attention recently. For oxide perovskite thin film, an available modulation is to form heterostructure. Applying different perovskite allows strain manipulating and other effects that would change the characteristic which form a unique system. Unfortunately, not all kinds of complex oxide are acceptable to heterostructure. To give a wider range of combination for oxides, freestanding membrane was developed. La$_{0.7}$Sr$_{0.3}$MnO$_3$ and Sr$_3$Al$_2$O$_6$ are the two commonly used buffer layer. By etching the buffer layer, the thin film that deposit after the buffer layer can be separated from the substrate. In this work, we used YBa$_2$Cu$_3$O$_{7-x}$ as a buffer layer, this method takes less time etching but maintain a fine freestanding membrane for later procedure. Furthermore, the process allows us to separate materials like La$_{0.7}$Sr$_{0.3}$MnO$_3$ with acid etchant because of the time etching YBa$_2$Cu$_3$O$_{7-x}$ takes a few minutes while etching La$_{0.7}$Sr$_{0.3}$MnO$_3$ takes a few hours. Our goal is to develop a universal freestanding method that could applied to all kind of materials which could give access to more combination of complex oxide thin films.

Session N01 APS: Planned Giving Luncheon (12:15pm - 1:45pm) 204
12:15PM N01.00001: Planned Giving Luncheon (12:15pm - 1:45pm) — Discover opportunities for creative gift arrangements that offer immediate tax benefits for you, and long-term benefits for the science community. Join the APS Development Office for a conversation facilitated by:

David Morrison, Partner; Prosperion Financial Advisors
and
Brian B. Schwartz, Ph.D., Professor of Physics; Brooklyn College and The Graduate Center of CUNY

Light refreshments and handouts will be provided. This session is free to members of APS and their guests. You do not need to be registered for the March Meeting to attend.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P00 APS: Kavli Foundation Special Symposium: Frontiers of Computation: Machine Learning and Quantum Computing

2:30PM P00.00001: Vignettes of machine learning in the natural sciences [Invited] PATRICK F RILEY (Presenter), Google Accelerated Science, Google, LLC — The promise of machine learning to aid in scientific discovery is now a frequent topic in journals and conferences. For the last 5 years, the Google Accelerated Science team has been partnering with scientists in a variety of natural science fields to make this promise a reality. I’ll sample a few of our achievements with examples in scientific computing and molecular design while also highlighting the current and future challenges in the effective use of machine learning in the sciences.

3:06PM P00.00002: Machine Learning and the Complexity of Quantum Simulation [Invited] ROGER MELKO (Presenter), University of Waterloo — Computational approaches to condensed matter have long influenced the theoretical development of quantum many-body physics. For example, quantum Monte Carlo (QMC) ties our understanding of the computational efficiency of simulating quantum systems to the sign structure of the Hamiltonian. The Density Matrix Renormalization Group motivated the modern field of Tensor Networks (TNs), which relate computational efficiency to the entanglement entropy of a wavefunction. This trend now continues with the rapidly-developing field of machine learning, which has introduced a host of new strategies and architectures for the simulation and data-driven reconstruction of quantum many-body systems. Over the last three years, progress has been made in framing various machine learning approaches within the context of traditional methods such as QMC or TNs; however, it has also become apparent that some aspects differ substantially. In this talk I will provide an overview of the landscape of machine learning strategies in simulating quantum systems. I will speculate on how our theoretical framework of quantum many-body physics can influence the development of new machine learning strategies, and vice versa.
In recent years, machine learning methods such as "deep learning" have proven enormously successful for tasks such as image classification, voice recognition, and more. Despite their effectiveness for big-data classification problems, these methods have had limited success for time series prediction, especially for complex systems like those we see in weather, solar activity, and even brain dynamics. In this talk, I will discuss how a Reservoir Computer (RC) - a special kind of artificial neural network that offers a "universal" dynamical system - can draw on its own internal complex dynamics in order to forecast systems like the weather, far beyond the time horizon of other methods. Like many other machine learning architectures, the RC provides a knowledge-free approach because it builds forecasts purely from past measurements without any specific knowledge of the system dynamics. By building a new approach that judiciously combines the knowledge-free prediction of the RC with a knowledge-based model, we demonstrate a further, dramatic, improvement in forecasting complex systems. This hybrid approach can given us new insights into the weaknesses of our knowledge-based models and also reveal limitations in our machine learning system, guiding improvements in both knowledge-free and knowledge-based prediction techniques.

Decades of efforts in improving computing power and experimental instrumentation were driven by our desire to better understand the complex problem of quantum emergence. However, increasing volume and variety of data made available to us today present new challenges. I will discuss how these challenges can be embraced and turned into opportunities by employing machine learning. It is important to note that the scientific questions in the field of electronic quantum matter require fundamentally new approaches to data science for two reasons: (1) quantum mechanical imaging of electronic behavior is probabilistic, (2) inference from data should be subject to fundamental laws governing microscopic interactions. Hence machine learning quantum emergence requires collective wisdom of data science and condensed matter physics. I will review rapidly developing efforts by the community in using machine learning to solve problems and gain new insight. I will then present my group's results on the machine-learning-based analysis of complex experimental data on quantum matter.

*I acknowledge support by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering under Award DE-SC0018946, DOE and the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875).
4:54PM P00.00005: Quantum computing: Current status and future prospects [Invited]  JOHN PRESKILL (Presenter), Caltech — Noisy Intermediate-Scale Quantum (NISQ) technology is now becoming available for the first time. Quantum computers with of order 100 qubits may be able to perform tasks which surpass the capabilities of today's classical digital computers, but noise in quantum gates will limit the size of quantum circuits that can be executed reliably. NISQ devices will be useful tools for exploring many-body quantum physics, and may have other useful applications, but the 100-qubit quantum computer will not change the world right away --- we should regard it as a significant step toward the more powerful quantum technologies of the future. Quantum technologists should continue to strive for more accurate quantum gates and, eventually, fully fault-tolerant quantum computing.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P01 DAMOP: Precision measurements for fundamental physics, interferometry, and trapped ions 103 - Norman Yao, University of California, Berkeley

2:30PM P01.00001: JILA’s search for the electron’s electric dipole moment: a novel approach to searches for new physics  TANYA ROUSSY (Presenter), WILLIAM B CAIRNCROSS, DANIEL A PALKEN, BENJAMIN M BRUBAKER, DANIEL N GRESH, JILA and The University of Colorado, Boulder, MATTHEW GRAU, Institute for Quantum Electronics, ETH Zurich, KEVIN COSSEL, National Institute of Standards and Technology, KIA BOON NG, YUVAL SHAGAM, YAN ZHOU, JILA and The University of Colorado, Boulder, VICTOR FLAMBAUM, University of New South Wales, JUN YE, ERIC A. CORNELL, JILA and The University of Colorado, Boulder — We are probing TeV-scale physics with a unique tabletop experiment which combines trapped molecular ions, rotating bias fields, orientation-resolved detection, and over a dozen lasers to both measure the electron's electric dipole moment and constrain potential dark matter candidates. In this talk I will introduce the essence of our measurement as well as our methods for constraining both dark matter and parity-violating physics.
Towards a More Sensitive Measurement of the Atomic Electric Dipole Moment of Radium-225

Permanent atomic electric dipole moments (EDMs) violate parity (P) and time reversal (T), and, assuming CPT symmetry, combined charge-conjugation and parity transformation (CP). Observable EDMs are enhanced in large-Z atoms with octupole-deformed, or pear-shaped, nuclei. Radium-225 has a significantly larger octupole deformation than nuclei used in other EDM experiments. In the Ra EDM experiment, radium atoms are vaporized, slowed, trapped, and transported to a science chamber between two high voltage electrodes. The first measurements of the upper limit of the EDM of Radium-225 were carried out in 2014 and 2015. For the second generation of measurements (2019—2020), upgrades to the atom detection method and applied electric field magnitude will improve our measurement sensitivity by up to two orders of magnitude. Additionally, we validated plans for a better longitudinal atom slower by experimentally verifying critical theorized branching ratios. The new slower is expected to provide an order of magnitude improvement in measurement sensitivity.

*Work funded by MSU and US DOE Office of Science, Office of Physics, DOE Oak Ridge Institute for Science and Education, and DOE National Nuclear Security Administration under contracts DE-AC02-06CH11357, DE-SC0014664, and NSSC DE-NA0003180.

Modeling a dual-Sagnac interferometer for rotation sensing

A recent experiment performed in the group of Cass Sackett, implemented a dual Sagnac interferometer for rotation sensing using a Bose-Einstein condensate confined in an harmonic potential. The condensate is first split into two pieces using standing-wave Bragg lasers and then allowed to fly apart until the two pieces come to a stop. These two pieces are then split again along a perpendicular direction creating two pairs of condensates moving around a circle in opposite directions. They re-overlap after one trip around the circle at which point they are split a third time and the number of stationary atoms is measured. We have simulated this experiment using a model based on the Lagrangian Variational Method where the condensate pieces are represented by Gaussian clouds. We have mapped out the region of validity of this model by direct numerical simulation using the 3D Gross-Pitaevskii equation. In addition to performing simulations under experimental conditions where the number of atoms was N=10⁴, we also simulated the interferometer operation for larger condensates where atom-atom interactions must be accounted for.

3:06PM P01.00004: Mechanism for producing smooth flow by stirring a racetrack BEC*
MARK EDWARDS (Presenter), DANIEL FOGARTY, Georgia Southern University, CHARLES CLARK, National Institute of Standards and Technology — We studied the production of smooth flow in a Bose-Einstein-condensed (BEC) gas in a racetrack atom-circuit potential. The BEC is confined into a thin horizontal sheet by laser light. The racetrack potential is a channel having two straight channels connected by circular endcaps. The system is assumed to follow the Gross-Pitaevskii model. Flow is produced by stirring the BEC with a rectangular barrier. We have studied in-depth how flow is produced by this stirring. As the barrier strength increases, a backflow develops in the barrier region producing a vortex/anti-vortex pair. The outside vortex circulates like the stir. Above a critical barrier height, the vortices swap places. This generates two disturbances: (1) the vortex/antivortex pair moves off in the anti-stir direction and (2) a compression wave moving the other way. This repeats until the flow produced overtakes the barrier speed. Each new unit of flow creates another pair of disturbances. These disturbances convert the localized circulation of the vortices into macroscopic flow around the racetrack. The flow oscillates around this value until the barrier falls below the critical value determining the final flow.

*This work was supported in part by the US National Science Foundation grant no. PHY-1707776.

3:18PM P01.00005: Phase-sensitive amplification and SU(1,1) interferometry via multimode four-wave mixing*
ERIN KNUTSON (Presenter), J. SAM CROSS, SARA WYLLIE, RYAN T GLASSER, Tulane Univ — We demonstrate a useful phase dependence in a multi-pump four-wave mixing configuration. We find that, for certain phase values, the intensity noise of an output mode is lower than that of its phase-insensitive counterpart. This lower-noise amplification has been demonstrated previously in atomic four wave mixing, but only with the use of significantly more complex experimental configurations, e.g. dual homodyne detection or cascaded vapor cells. Additionally, our method naturally results in four beams that can be quantum correlated with one another.
These findings have obvious applications in the simplification of quantum optical experiments that involve the generation or amplification of more than two correlated modes. Additionally, we describe how this result may be employed in a “touchless” or interaction-free SU(1,1) interferometry scheme, wherein a phase measurement may be made remotely on a pair of modes without introducing loss or destroying any squeezing between them.

*We acknowledge support from the National Science Foundation Graduate Research Fellowship under Grant No. DGE-1154145, and from the Louisiana State Board of Regents.
3:30PM P01.00006: Search for non-Newtonian gravity with optically-levitated microspheres*
CHARLES P BLAKEMORE, ALEXANDER FIEGUTH (Presenter), AKIO KAWASAKI, DENZAL MARTIN, NADAV PRIEL, ALEXANDER D RIDER, GIORGIO GRATTA, Stanford Univ — The universal law of gravity has undergone stringent tests for a long time over a significant range of length scale, from an atomic scale to a planetary scale. Of particular interest is the short distance regime, where modifications to Newtonian gravity may arise from axion-like particles and extra dimensions. We have constructed an ultra-sensitive force sensor based on optically-levitated microspheres with a force sensitivity of $\sim 10^{-17}$ N/\(\sqrt{\text{Hz}}\) for the purpose of investigating non-Newtonian forces in the 1-100 \(\mu\text{m}\) range. Microspheres interact with a variable-density attractor mass made by alternating silicon and gold segments with periodicity of $\sim 50$ \(\mu\text{m}\). The attractor can be located as close as a few \(\mu\text{m}\) to a microsphere. We report on the characterization of this system, its sensitivity, and preliminary results. Further technological developments to reduce background are investigated to provide orders of magnitude improvement in the sensitivity, going beyond current constraints on non-Newtonian interactions.

*This work was supported, in part, by NSF grants PHY1502156 and PHY1802952, ONR grant N00014-18-1-2409, and the Heising-Simons Foundation.

3:42PM P01.00007: Ultrasensitive torque detection and ultrafast rotation with an optically levitated nanoparticle*
JONGHOON AHN (Presenter), ZHUJING XU, JAEHOON BANG, PENG JU, XINGYU GAO, TONGCANG LI, Purdue Univ — Torque sensors have enabled great accomplishments in physics including the discovery of Coulomb's law and Cavendish's first determination of the gravitational constant, and is widely used for studies such as small-scale magnetism and the Casimir effect. Here, we develop an ultrasensitive torque sensor with an optically levitated nanoparticle in vacuum and experimentally demonstrate a torque sensitivity of \((4.2 \pm 1.2) \times 10^{-27}\) Nm / \(\sqrt{\text{Hz}}\) at room temperature [1] without the need of complex nanofabrication or cryogenic cooling. With the optically levitated particles, we are also able to achieve a record high mechanical rotation exceeding 5 GHz [1,2]. Our calculations suggest our torque sensor will allow detection of vacuum friction near a surface under realistic conditions.

*We are grateful to supports from the Office of Naval Research under grant No. N00014-18-1-2371, the NSF under grant No. PHY-1555035, and the DARPA NLM program.
Towards mass sensing using cavity optomechanics readout

EWA REJ (Presenter), MERT YUKSEL, WARREN FON, MATTHEW MATHENY, MICHAEL ROUKES, California Institute of Technology — The minute size of nanoelectromechanical systems (NEMS), combined with their large quality factors, has provided a large class of sensors capable of measuring the properties of single molecules. In particular, NEMS have allowed the mass of individual adsorbed molecules, such as protein complexes, to be measured. I will present results showing NEMS based mass spectrometry of individual proteins and explain how the mass resolution is governed by the phase noise of the system, with contributions from the resonator itself, readout circuitry and thermomechanical noise. I will outline our new approach based on a superconducting cavity optomechanics readout scheme for improved sensor performance. The transduction by cavity optomechanics is expected to greatly reduce system phase noise as readout-self heating is minimal. This will directly yield improved resolution in detecting the spatial mass distribution of individual analytes.

Searching for scalar dark matter with compact mechanical resonators*

JACK MANLEY (Presenter), RUSSELL STUMP, University of Delaware, DALZIEL WILSON, University of Arizona, DANIEL GRIN, Haverford College, SWATI SINGH, University of Delaware — We discuss the viability of laboratory-scale mechanical resonators as detectors for ultralight scalar dark matter. The signal we investigate is an atomic strain due to modulation of the fine structure constant and the lepton mass at the Compton frequency of dark matter particles. The resulting stress can drive an elastic body with breathing modes, producing displacements that are accessible with opto- or electromechanical readout techniques. To address the unknown mass of dark matter particles (which determines their Compton frequency), we consider various resonator designs operating at kHz to MHz frequencies, corresponding to $10^{-12}$-$10^{-5}$ eV particle mass. Current resonant-mass gravitational wave detectors that have been repurposed as dark matter detectors weigh ~$10^3$ kg. We find that a large unexplored parameter space can be accessed with ultra-high-Q, cryogenically-cooled, cm-scale mechanical resonators possessing ~$10^7$ times smaller mass[1].

4:18PM P01.00010: Realization of a second-generation scheme for dissipative entanglement of hyperfine beryllium-ion qubits* DANIEL COLE (Presenter), STEPHEN D ERICKSON, Time & Frequency Division, National Institute of Standards and Technology Boulder, KARL HORN, Department of Physics, Universität Kassel, FLORENTIN REITER, Institute for Quantum Electronics, ETH Zürich, PANYU HOU, JENNY WU, Time & Frequency Division, National Institute of Standards and Technology Boulder, CHRISTIANE KOCH, Department of Physics, Freie Universität Berlin, ANDREW C WILSON, DIETRICH LEIBFRIED, Time & Frequency Division, National Institute of Standards and Technology Boulder — The generation of entanglement using engineered dissipation has recently attracted attention because this approach can be competitive in fidelity and robustness against noise when compared with methods of entanglement generation based on controlled unitary evolution, and can enable optical pumping directly into entangled resource states for quantum protocols [1]. In a dissipative entanglement generation scheme, population is trapped in a target entangled state through evolution according to dissipative dynamics that have the target state as a steady state. We will discuss the generation of entangled states of hyperfine beryllium-ion qubits using engineered dissipation. In particular, we will present experimental realization of a ‘second generation’ scheme for dissipative production of an entangled singlet state that offers an improvement in speed and fidelity, along with reduced experimental complexity [2]. This scheme involves engineering suitable spin-motion couplings in the Hamiltonian, which are then combined with dissipation in the form of pumping to and decay from an electronic excited state.

IARPA LogiQ Program

4:30PM P01.00011: Surface-science studies of electric-field noise from ion-trap electrodes DUSTIN HITE (Presenter), KYLE MCKAY, PHILIP KENT, DAVID PAPPAS, National Institute of Standards and Technology Boulder — Heating of the motional modes of ions in a rf Paul trap is a major obstacle to trapped-ion quantum information processing (QIP). It is caused by electric-field noise from the surface of the trap electrodes, which couples to the ions’ net charge. A better understanding of the physical origin of this surface noise will help to mitigate this heating in trapped-ion QIP applications. To aid in tackling this problem, our group has constructed a one-of-a-kind trapped-ion surface probe, where the ion is used to measure noise from the surfaces of nearby samples positioned into close proximity. This novel surface probe is operated in situ with traditional surface science tools, namely SPM, XPS, and SPA-LEED, where the sample is transferred from instrument to instrument in vacuum. Various treatments to the sample surfaces will elucidate possible origins of the noise. For example, in situ cleaning of the trap electrodes by Ar-ion bombardment reduces this noise by 1 – 2 orders of magnitude. In this talk, I will describe the composition and surface-potential landscape of typical as-fabricated and treated ion-trap electrodes and show results where we have demonstrated the efficacy to use trapped ions as a probe to nearby surfaces.
Towards Improved Quantum Simulations and Sensing via Parametric Amplification  
MATTHEW AFFOLTER (Presenter), ELENA JORDAN, KEVIN A. GILMORE, SHAUN BURD, JOHN JACOB BOLLINGER, NIST - Boulder — Improving spin coherence is a fundamental challenge in quantum simulations and sensing experiments on trapped ions. Here we discuss preliminary experiments attempting to enhance spin-motion coupling in large ion crystals via parametric amplification without a reduction in the spin coherence. These experiments are performed on 2D crystal arrays of over a hundred Be\(^+\) ions confined in a Penning trap. This device has been used to perform quantum simulations and sense displacements of the ion crystal that are small compared to the ground state zero-point fluctuations\(^1\). By modulating the trapping potential at twice the center-of-mass mode frequency, we squeeze the motional mode, which can enhance spin-motion coupling while maintaining the spin coherence. This should enable higher fidelity simulations and improve our sensitivity to small displacements.

Quantum measurement and many-body dynamics for the Dicke model  
YUNJIN CHOI (Presenter), SHANE KELLY, SHAN-WEN TSAI, University of California, Riverside — The Dicke model (DM) is a well-suited system for exploring enhanced metrology and quantum information processing. An entangled spin-boson cat-state in the DM is obtained when the spin and boson degrees of freedom interact in the strong coupling limit. This entangled spin-boson cat-state is a metrological resource to the spin cat-state in terms of the spin degrees of freedom. However, it is difficult to experimentally explore features of coherence of the entangled spin-boson cat state, and it is hard to control and measure the boson and spin degrees of freedom simultaneously. Treating the spin subsystem as the main system of interest, we consider the bosonic degrees of freedom as an environment that can be controlled and probed to some extent. We investigate a measurement process on the bosonic system to extract partial information about the spin system. The degree to which the spin system is affected by such a measurement can be controlled by the coupling strength between the spin and boson systems. We also discuss the measurement context on the bosonic system to preserve or retrieve coherence of the spin subsystem.
Study of the mechanical loss of amorphous mirror coatings for gravitational wave detectors using two level system model

JUN JIANG (Presenter), ALEC MISHKIN, University of Florida, KIRAN PRASAI, RICCARDO BASSIRI, MARTIN M. FEJER, Stanford University, HAI-PING CHENG, University of Florida — For future generation of laser interferometer gravitational-wave observatory (LIGO), thermal noise from amorphous mirror coatings will be a limiting noise source in the most-sensitive frequency band (about 150 Hz). In our previous studies, two level system (TLS) model was used to study the mechanical loss of the pure and doped amorphous SiO$_2$, Ta$_2$O$_5$ coatings. With reverse Monte Carlo (RMC) method, we generate amorphous models for both as-deposited and heat treated samples based on measurements of grazing-incidence pair distribution function (GI-PDF). In this work, we further refine the RMC models of 50% ZrO$_2$ doped Ta$_2$O$_5$ with first-principles atomic structure relaxation and improve the previous TLS model by correctly taking into account two relaxation times associated with one asymmetrical TLS transition. From the mechanical loss calculation based on these models, we find that annealing will partially eliminate voids (or pores) larger than 200 Å$^3$ and smaller than 100 Å$^3$ making the atomic structures more uniform, which is correlated with high mechanical loss at low temperature.

This work is supported by the NSF through grants PHY-1707870 and PHY-1404110.

Atomic Tritium Production and Trapping for Neutrino Mass Measurement in Project 8

ALEC LINDMAN (Presenter), Johannes-Gutenberg Univ — Project 8 is a phased experiment using tritium β decay to investigate the absolute neutrino mass. Good energy precision, high statistics, and well-controlled systematics are required to reach an electron antineutrino mass limit of ≤ 40 meV. Our technique, Cyclotron Radiation Emission Spectroscopy (CRES), has achieved eV-scale resolution at 17.8 keV, near the tritium endpoint. Project 8 was the first to observe the fW-scale radiation from individual electrons. The event rate in CRES scales with volume; we will instrument our fiducial volume with a spatially-resolving antenna array, eliminating pileup. Project 8 will be the first laboratory neutrino mass experiment to use atomic tritium (T). Decay of a T$_2$ molecule excites rovibrational states that smear the observed energy by 1 eV. The decay of T, however, has an energy smearing of ≤ 0.1 eV. Our baseline calls for trapping 30 mK atomic tritium in a 2-T-deep, 10+-m$^3$ superconducting magnetic bottle. I will discuss our approach to this large-volume atomic CRES experiment, focusing on production and handling techniques for recombination-prone tritium atoms.

This work is supported by the US DOE Office of Nuclear Physics, the US NSF, the PRISMA+ Cluster of Excellence at the University of Mainz, and internal investments at all institutions.
2:30PM P02.00001: Pressure-temperature-magnetic field phase diagram of the molecule-based multiferroic (CH$_3)_2$NH$_2$]Mn(HCOO)$_3$ AMANDA CLUNE (Presenter), NATHAN HARMS, KENNETH R O’NEAL, KEVIN ARTHUR SMITH, KENDALL HUGHEY, Chemistry, University of Tennessee, Knoxville, DIMUTHU OBEYSEKERA, JUNJIE YANG, Physics, Central Michigan University, JOHN HADDOCK, NARESH S DALAL, Chemistry and Biochemistry, Florida State University, ZHENXIAN LIU, Civil and Environmental Engineering, The George Washington University, JANICE LYNN MUSFELDT, Chemistry, University of Tennessee, Knoxville — We employ high pressure susceptibility and vibration spectroscopy to reveal the properties of (CH$_3)_2$NH$_2$]Mn(HCOO)$_3$. Combining with prior high field work, we unveil the $P$-$T$-$H$ phase diagram of this molecule-based multiferroic. Specifically, we focus on the behavior of the formate bending mode across the order-disorder temperature to expose the role of the formate ligand in the framework stability and symmetry.

2:42PM P02.00002: A new pulse-magnetic field diamond anvil cell* DANIEL JACKSON (Presenter), MUN K. CHAN, Pulse Field Facility, National High Magnetic Field Laboratory, Los Alamos National Laboratory — Measurements in extreme conditions provide valuable insight into material properties. Combining high magnetic field, high pressure, and cryogenics allows for smooth tuning of parameters in a 3-dimensional phase space. The highest magnetic fields are generated using pulse-field magnets and provide more than twice the maximum field compared to direct-current magnets, 100 T vs 45 T. However, pulse fields invariably generate eddy currents in any conductive parts. A diamond anvil cell (DAC) was designed with slits to reduce eddy current loop area. The DAC was machined out of titanium, a poor thermal conductor, and was machined using a tabletop 5-axis CNC. I will present preliminary results from measurements in pulse field at high pressure, and details of the design of the cell.

DEJ would like to thank Jon Betts, Fedor Balikerev and Dan Sun for help with development of these capabilities.
The Role of Hydrogen Bonding in Aromatic Molecular Crystals at High Pressures*  
HANNAH SHELTON (Presenter), Physics Division, Lawrence Livermore National Laboratory,  
PRZEMYSŁAW DERA, Hawaii Institute of Geophysics and Planetology, University of Hawaii at Manoa,  
SERGEY TKACHEV, GSECARS, University of Chicago, TOMMY YONG, Department of Earth Sciences, University of Hawaii at Manoa — Noncovalent interactions wield remarkable control in molecular crystals, which can alter properties such as impact sensitivity and chemical reactivity. The presence of hydrogen bonding has been shown to stabilize organic molecular crystals against pressure-dependent polymorphism and amorphization. These effects can be seen in melamine (C\textsubscript{3}H\textsubscript{6}N\textsubscript{6}; 1,3,5-triazine-2,4,6-triamine) and resorcinol (C\textsubscript{6}H\textsubscript{6}O\textsubscript{2}; 1,3-dihydroxybenzene), which are used industrially to produce laminates, adhesives, and flame retardants. Melamine is chemically and structurally similar to many energetic materials, including TATB and RDX. In the crystalline state melamine forms corrugated sheets of individual molecules linked by extensive intra- and inter-plane N-H hydrogen bonds. In comparison, resorcinol has less hydrogen bonding ability as only two hydroxyl groups form intermolecular links. At high pressure, melamine experiences a symmetry change from monoclinic to triclinic above approximately 36 GPa in helium. Conversely, resorcinol remains crystalline to only approximately 6 GPa. Examining the high-pressure intermolecular interactions in these compounds may allow their improved utilization as chemical feedstocks and analogues for related energetic compounds.

*Prepared by LLNL under Contract DE-AC52-07NA27344.

Tuning Octahedral Tilting of Ruddlesden-Popper Chalcogenide via Pressure  
SHANYUAN NIU (Presenter), FENG KE, Stanford University, BOYANG ZHAO, JAYAKANTH RAVICHANDRAN, University of Southern California, YU LIN, WENDY MAO, Stanford University — Transition metal perovskite chalcogenides (TMPCs) are currently of substantial interest as a class of emerging semiconductors for optoelectronic and photonic applications. Ruddlesden-Popper (RP) phases of perovskite chalcogenides have been predicted to be promising candidates to achieve ferroelectric semiconductors with static polar order. Hybrid improper ferroelectricity can be realized in such n=2 RP compounds with $a^-a^-c^+$ tilt system as Ba\textsubscript{3}Zr\textsubscript{2}S\textsubscript{7} via coupling of out-of-phase octahedral tilting around in-plane directions and in-phase rotation mode around the stacking direction. However, experimentally obtained Ba\textsubscript{3}Zr\textsubscript{2}S\textsubscript{7} is in a higher symmetry centrosymmetric phase with only one octahedral tilting mode. Pressure offers a unique perspective to drive such octahedral tilting and study the phase transitions. We report the high-pressure study of Ba\textsubscript{3}Zr\textsubscript{2}S\textsubscript{7} up to 50 GPa using diamond anvil cells. In-situ Raman spectroscopy and X-ray diffraction analysis are carried out to probe the structural changes. Structural transitions of Ba\textsubscript{3}Zr\textsubscript{2}S\textsubscript{7} under pressure have been observed. Efforts in stabilizing the low-symmetry phases with hybrid improper ferroelectricity will also be discussed.
High Hydrostatic Pressure (0.5–2.5 GPa) Synthesis and Properties of Bulk “nnx” Rare-Earth Nickel Oxides ($R_nNi_nO_x$)*

SARA J IRVINE (Presenter), GREGORIO PONTI, QUINN D. B. TIMMERS, ZACHARY P. KUKLINSKI, JOHN MARKERT, Department of Physics, University of Texas at Austin — We have undertaken rare-earth and alkaline-earth substitutions in known nickel oxide phases, and a search for new such phases, using a hot press. We prepared starting materials both by ambient solid-state reaction (650°C–975°C) and by using high-oxygen-pressure (150–200 bar), high-temperature ($T \approx 1000°C$) syntheses, producing either nominal-composition mixed-phase $RNiO_x$ materials, or the nearly-simple-perovskite $RNiO_3$ phases, respectively. We then subjected such parent materials [$R = Pr, Nd, (La,Y)$], as well as hole- and electron-doped varieties, to high quasi-hydrostatic pressures using a hot piston-cylinder apparatus (5–25 kbar, i.e., 0.5–2.5 GPa) at high temperatures (950°C–1050°C). The technique¹ can include oxidizers (KClO₄), or can be naturally reducing, the latter augmentable by hydrogen. We report product phases; initial syntheses have provided specimens with decreases in undesired starting phases. Our study of other nickelate phases, e.g., $R_3Ni_3O_7$ and infinite-layer $RNiO_2$, with this technique is ongoing, exploring both steric effects and hole- ($Sr^{2+}$) and electron-doping ($Ce^{4+}$) in targeted $R_nNi_nO_x$ structures.

Superconductivity of platinum hydride PtH*

TAKAHIRO MATSUOKA (Presenter), JIAM, University of Tennessee, Knoxville, MASAHIRO HISHIDA, Department of Materials Science and Technology, Gifu University, KEIJI KUNO, Environmental and Renewable Energy Systems Division, Gifu University, NAOHISA HIRAO, YASUO OHISHI, Japan Synchrotron Radiation Research Institute (JASRI), SHIGEO SASAKI, Department of Electrical, Electronic and Computer Engineering, Faculty of Engineering, Gifu University, KAZUSHI TAKAHAMA, KATSUYA SHIMIZU, Center for Science and Technology under Extreme Conditions, Osaka University — Pt has a strong electron-phonon (e-p) coupling [1]. On the other hand, the 5d conduction electrons show strong spin fluctuations on the short length and time scales, which suppress the superconductivity. In PtH, hybridization between Pt 5$d$ and H 1$s$ [2] and the resulting strengthened e-p coupling and $T_c$ above 10 K have been predicted [2-5]. We report the ac magnetic susceptibility, electrical resistance, and x-ray diffraction measurements of PtH in diamond anvil cells. At 30 GPa, when PtH is in a $P6_3/mmc$ structure, PtH exhibits the superconducting transition at 7 K. The observed $T_c$ is higher than that of powdered Pt by more than three orders of magnitude. It is suggested that the noble metal hydrides possibly have higher $T_c$ than elements.

**3:42PM P02.00007: O\textsuperscript{1} earthquake-like precursors: a MaxEnt-\(\mu\)SR MgO study**  
CAROLUS BOEKEMA (Presenter), CARLOS MORANTE, MINA TAVAKOLZADEH, San Jose State University, FRIEDEMANN T FREUND, NASA, AMES — Earthquake-like precursor O\textsuperscript{1} effects [1,2] are studied by analyzing Muon-Spin-Resonance (\(\mu\)SR) MgO data using Maximum Entropy (ME). [3,4] MgO is ideal due to its presence in the Earth's crust: O\textsuperscript{1} or positive-hole formation results from a 2-stage break-up of an O anion pair under high-T or high-P conditions. [2] As T increases above room temperature (RT) a small O-ion \% is predicted to produce an O\textsuperscript{1} state.[2] ME analysis of transverse field (TF; 100 Oe) \(\mu\)SR data of a 3N-MgO single crystal show above RT a Gaussian signal at 1.36 MHz and a Lorentzian signal at 1.4 MHz. For similar oxides like MnO, TF\(\mu\)SR show only the \(\mu\)O Gaussian signal, as positive muons probe near negative O ions. [3,4] The extra 1.4-MHz MgO signal indicates the existence of extended O 2p states. [1, 2] Between 200 & 400 °C where O\textsuperscript{1} formation occurs, we find evidence of a missing (3rd \(\mu\)SR) fraction. The relation of O-valency effects and earthquake-like precursors is discussed. 1] FT Freund, Nat Hazards Earth Sys Sci 7(2007) 1. 2] FT Freund et al, Phys Chem Earth 31(2006) 389. 3] C Boekema and MC Browne, MaxEnt 2008, AIP Conf Proc #1073 p260. 4] S Lee et al, HUIC Educ, Math & Eng Tech Conf, Uo HI (2013).

**3:54PM P02.00008: Relaxation, Viscosity and Density Scaling of the Hydrogen-bonded System Glycerol at Pressures above 5 GPa**  
WILLIAM OLIVER (Presenter), KEVIN W LYON, Univ of Arkansas-Fayetteville — Using Tg(P) data for glycerol up to very high pressures of 6.7 GPa, we reanalyze viscosity and relaxation data taken by several groups over different temperature and pressure ranges, constraining these earlier data with our isochronous Tg(P) curve. This analysis allows new insights into the pressure dependence of fragility in such glass forming systems over pressure ranges in which the hydrogen bonded network is broken up. Attempts at thermodynamic scaling are also discussed for glycerol over this large pressure range.

**4:06PM P02.00009: Observation of nine-fold coordinated amorphous TiO$_2$ at high pressures**

YU SHU (Presenter), High Pressure Collaborative Access Team, X-ray Division, Argonne Natl Lab, YOSHIOKONO, Geodynamics Research Center, Ehime University, GUOYIN SHEN, High Pressure Collaborative Access Team, X-ray Division, Argonne Natl Lab, YANBIN WANG, Center for Advanced Radiation Sources, The University of Chicago, ROSTISLAV HRUBIAK, High Pressure Collaborative Access Team, X-ray Division, Argonne Natl Lab — Understanding pressure-induced structural changes in amorphous dioxides (a-AO$_2$) is of great importance in many fields of science. Here we report new experimental results of high pressure polyamorphism in amorphous TiO$_2$ (a-TiO$_2$) with the Ti-O coordination number (CN) close to 9. Our experimental data show that CN increases from 7.2 at 15.7 GPa, to 8.8 at 70.2 GPa, and finally reaches a plateau ~8.9 at pressures up to 85.7 GPa. We find that CN of both crystalline TiO$_2$ and a-TiO$_2$ follows a similar and systematic dependence on the ratio ($\gamma$) of the ionic radii of Ti and O. The $\gamma$ of a-TiO$_2$ is 0.614 at 15.7 GPa, which is similar to that of baddeleyite-type TiO$_2$ (~0.61), and increases continuously with pressure. At 70.2 GPa, $\gamma$ of a-TiO$_2$ is 0.701, which is similar to that of cotunnite-type TiO$_2$ (~0.693). It appears that the CN=9 plateau of a-TiO$_2$ correlates to the cotunnite-type and Fe$_2$P-type polymorphs, which have the same CN=9 but correspond to different $\gamma$ values. This CN-$\gamma$ relationship is applicable to other a-AO$_2$ of a-SiO$_2$ and a-GeO$_2$. All three compounds show surprisingly consistent between CN and $\gamma$, implying a unified relation between CN and $\gamma$ in a-AO$_2$. The established CN-$\gamma$ relationship may be used to predict the compression behavior of a-AO$_2$ compounds to extreme conditions.

**4:18PM P02.00010: Enhancing broadband emission in indirect bandgap lead halide perovskites by hydrostatic pressure**

SHENYU DAI (Presenter), College of Electronics & Information Engineering, Sichuan University, ZHAOJUN QIN, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, VIKTOR G. HADJIEV, Texas Center for Superconductivity, University of Houston, CHONG WANG, School of Materials Science and Engineering, Yunnan University, ZHIMING M. WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, GUOYING FENG, College of Electronics & Information Engineering, Sichuan University, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston — Although broadband emission caused by self-trapped excitons (STE) has been widely studied in direct bandgap perovskites, few attention has been paid to indirect bandgap perovskites. Here we report that indirect bandgap all-inorganic perovskite exhibits typical STE induced broadband emission. We use diamond anvil cell to study the response of optical properties of 2D perovskite microplates to hydrostatic pressure. The broadband emission intensity increases significantly with increasing pressure, and the peak position is largely blue-shifted by 650 meV. The mechanism of these phenomena is discussed using experimental methods and theoretical calculations. This work shows a potential method to control and utilize indirect bandgap perovskites materials in optoelectronic devices.
Molecular-Like Equilibrium Behavior of Anatase Nanoparticles in Compressed Hydrothermal Conditions

HENGZHONG ZHANG (Presenter), Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, JINYUAN YAN, MARTIN KUNZ, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, California 94720, United States, BIN CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, JILLIAN F. BANFIELD, Department of Earth and Planetary Science, University of California, Berkeley, California 94720, United States — Nanocrystals are intermediate in size between molecules and micron-scale crystallites. They usually exhibit size-dependent properties and behaviors that are closer to the latter than the former. However, in this work, we found that small titania nanoparticles present molecular-like phase equilibrium behavior under compressed hydrothermal conditions, as evidenced by the fact that both the phase contents and particle sizes of involved titania nanoparticles can increase or decrease in response to altered temperature and/or pressure applied to shift a phase equilibrium. Thermodynamic analysis showed that the phase content of a solid nanophase contributes to the free energy change of the phase equilibrium, in contrast to the textbook knowledge that the thermodynamic activity of a pure solid phase equals one and as such the phase content of a pure solid phase makes no contribution to the equilibrium. This result suggests that much more frequent and stronger collisions among nanoparticles at high-T&P conditions can enhance the energy transfer among individual nanoparticles in a fluid, making them behave collectively more like solute molecules in a solution. This finding renews our understanding of the physical-chemical properties of nanoparticles with strong interparticle interactions.

Study on refractive index, EOS and polarizability of atomic, molecular and mixed gases at high pressures up to 60 MPa

CHENGJUN LI (Presenter), Institute of Fluid Physics, China Academy of Engineering Physics — The refractive index of initially transparent gases at high pressures is very important for shock velocity measurements in shock compression experiment since the measured shock velocity has to be modified by the refractivity of the initial sample. In this work, by using optical frequency domain interferometer (OFDI), we measured the refractive index of atomic (He, Ne, Ar, Kr, Xe), molecular (H2, D2, O2, N2, CO, CH4) and mixed gases (H2-D2, H2+Ar, D2+He, He-Ar, He-Xe) up to 60 MPa. The EOS of part of above gases were measured experimentally, while others were calculated. The polarizability of different gases were derived from their refractive index and density according to Lorentz-Lorenz formula. The mixing rule below 60 MPa were verified by the experimental results of mixed gases investigated in this work.
4:54PM P02.00013: Quasi One-Dimensional Compound and Superconductivity Induced by Pressure*  JINLONG ZHU (Presenter), Southern University of Science and Technology, JUN ZHANG, hpstar, XIANCHENG WANG, CHANGQING JIN, EX5, Institute of Physics, Chinese Academy of Sciences — Ba$_3$TiTe$_5$ was synthesized at HP/HT with infinite face-sharing octahedral TiTe$_6$ chains and Te chains along the c axis, exhibiting a strong 1D characteristic structure. The calculations confirmed the 1D conductor characterization, and can be considered a starting point to explore the exotic physics induced by pressure to move the 1D conductor to a high-dimensional metal. High-pressure techniques were employed to study the emerging physics dependent on interchain hopping, such as the Umklapp scattering effect, spin/charge density wave, superconductivity and non-Fermi liquid behavior. Finally, a complete phase diagram was plotted. The superconductivity emerges at 9GPa, near which the Umklapp gap is mostly suppressed. $T_c$ is enhanced and reaches a maximum of 6K at 37 GPa, where the SDW or CDW is completely suppressed, and a non-Fermi liquid behavior appears. Our results suggest that the appearance of superconductivity is associated with the fluctuation due to the suppression of the Umklapp gap and that the enhancement of the $T_c$ is related to the fluctuation of the SDW or CDW.

*National Key R&D Program of China under grant no. 2018YFA0305700, 2017YFA0302900, and 2015CB921300; NSFC under grant no. 11474344; National Natural Science Foundation of China (Grant no. U1530402)

5:06PM P02.00014: Non-uniform thermal gradient evolution in thermally cycled ytterbium silicate-silicon environmental barrier coatings  DAVID OLSON (Presenter), JEROEN DEIJKERS, KATHLEEN QUIAMBAO, JOHN T GASKINS, ELIZABETH OPILA, HAYDN N G WADLEY, PATRICK HOPKINS, Univ of Virginia — The primary purpose of barrier coating materials is to protect underlying media from harsh temperatures and/or environmental conditions that pose to undermine the performance of a system. Thus, materials with high thermomechanical stability and low thermal conductivity are choice candidates as thermal/environmental barrier coating top coats. Systems that implement a ytterbium-disilicate have shown to be promising candidates for next generation gas turbine engines. However, a robust examination of the microscale structural and thermal effects has yet to be performed over a range of cycling conditions. Considering the multi-phase, anisotropic constituents of such systems, a robust understanding of these mechanisms is necessary. In this work, we examine the microstructural and thermal evolution in ytterbium silicate-silicon environmental barrier coatings. The coating system cannot be defined by a single thermal conductivity, as local variations in thermal conductivity arise due to these multi-phase, anisotropic systems. Understanding the evolution and distribution of the thermal gradients associated with high-temperature steam-cycling is necessary for the continued development of these materials as hot-section components in gas-turbine engines.
Understanding the structural dynamics of ultrafast laser-induced melting is important for applications ranging from laser micromachining to warm dense matter experiments. Direct experimental observations of ultrafast melting have previously not been possible because of the small time and length scales involved. However, recent advances in ultrafast-electron-diffraction (UED) techniques [1] have opened up an exciting opportunity to study the transient atomic dynamics with femtosecond temporal resolution.

Here we report on the melting dynamics studies of femtosecond-laser irradiated metallic nanofilms with UED at relativistic energies. In our experiments, we employed 400nm, 130fs (FWHM) laser pulses as the heater and 3.2MeV, 350fs (FWHM) electrons as the probe. With this pump-probe technique, we have recently resolved for the first time the transition between heterogeneous and homogeneous melting regimes in warm dense gold [2]. These results provided a direct testing to predictions from molecular-dynamics (MD) simulations and revealed the melting sensitivity to nucleation seeds. We have also applied this technique to study the melting dynamics of tungsten with externally-driven defects from radiation damage [3]. We found that radiation-damaged tungsten liquefied at a lower temperature than pristine tungsten. Combining the experimental data with MD simulations allowed us to quantify, for the first time, how the ultrafast melting process is affected by radiation damage.

*This work is supported by DOE Office of Science, Fusion Energy Science under FWP 100182, and the DOE BES Accelerator and Detector R&D program.
3:06PM P03.00002: Nuclear Quantum Effects in Two-temperature Hydrogen via Orbital-free DFT Path Integral MD*  
SAM TRICKEY (Presenter), University of Florida, DONGDONG KANG, Physics, National University of Defense Technology, KAI LUO, Geophysical Laboratory, Carnegie Institution of Washington, VALENTIN KARASIEV, Laboratory for Laser Energetics, Univ. of Rochester, KEITH RUNGE, Materials Science and Engineering, Univ. of Arizona — Among systems at extreme conditions, hydrogen is special: its small nuclear mass implicates significant nuclear quantum effects (NQEs). An increasingly important set of extreme-condition systems has electrons driven to temperature $T_e$ far from the ion temperature $T_i$. For such two-temperature hydrogen, we report path integral molecular dynamics calculations driven by state-of-the-art orbital-free DFT calculations for the electrons. When the ratio of the ionic thermal de Broglie wavelength to their mean distance is larger than about 0.35, the ionic radial distribution function is strongly affected by NQEs. Moreover, NQEs induce a substantial increase in both the ionic and electronic pressures.

3:18PM P03.00003: A new capability for large-scale linear scaling Kohn Sham DFT calculations for materials at high temperatures.*  
SEBASTIEN HAMEL (Presenter), Lawrence Livermore Natl Lab, MANDY BETHKENHAGEN, Physics, University of Rostock, JOHN PASK, Lawrence Livermore Natl Lab, PHANISH SURYANARAYANA, Georgia Tech, BABAK SADIGH, Lawrence Livermore Natl Lab — We developed a new capability for the accurate and efficient quantum simulation of material properties across an extreme range of densities, pressures and temperatures. This code, SQDFT, enables the use of full Kohn-Sham quantum molecular dynamics from the condensed matter regime, through the warm dense matter regime and into the plasma regime, well beyond the previous state-of-the-art which was restricted to temperatures below approximately 100 000 Kelvins. We demonstrate this new capability by calculating the Hugoniot curve of different materials up to millions of degrees Kelvin and Gigabar of pressure and investigating the structural and transport properties of the materials under these extreme conditions. We also present a performance study of our SQDFT code on various supercomputing platforms. SQDFT scales linearly with system size which allows us to run full Kohn-Sham QMD simulations with several thousand of atoms.

*Funding Acknowledgement: This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. We gratefully acknowledge support from the Laboratory Directed Research and Development Program.
**3:30PM P03.00004: Atom-in-jellium equations of state and melt curves in the white dwarf regime**

DAMIAN SWIFT (Presenter), THOMAS LOCKARD, SEBASTIEN HAMEL, CHRISTINE J WU, LORIN BENEDICT, PHILIP A STERNE, HEATHER WHITLEY, Lawrence Livermore Natl Lab — Atom-in-jellium calculations of the electron states, and perturbative calculations of the Einstein frequency, were used to construct equations of state (EOS) from around $10^{-5}$ to $10^{7}$ g/cm$^3$ and $10^{-4}$ to $10^{6}$ eV for elements relevant to white dwarf (WD) stars. This is the widest range reported for self-consistent electronic shell structure calculations. Elements of the same ratio of atomic weight to atomic number were predicted to asymptote to the same T = 0 isotherm. A generalized Lindemann criterion based on the amplitude of the jellium oscillations, previously used to extrapolate melt curves for metals, was found to reproduce previous thermodynamic studies of the melt curve of the one component plasma with a choice of vibration amplitude consistent with low pressure results. For elements for which low pressure melting satisfies the same amplitude criterion, such as Al, this melt model thus gives a likely estimate of the melt curve over the full range of normal electronic matter; for the other elements, it provides a useful constraint on the melt locus.

*Work performed under the auspices of the U.S. Department of Energy under contract DE-AC52-07NA27344.

**3:42PM P03.00005: First Principles Calculations of the Equation of State of MgSiO$_3$ in the Gigabar Regime**

FELIPE GONZALEZ (Presenter), Department of Earth and Planetary Science, University of California, Berkeley, FRANCOIS SOUBIRAN, Laboratoire de geologie de Lyon, CNRS UMR 5276, Ecole Normale Superieure de Lyon, HENRY PETERSON, BURKHARD MILITZER, Department of Earth and Planetary Science, University of California, Berkeley — The equation of state (EOS) of silicates at extreme conditions is of significant interest in planetary science and high-pressure physics. Using path integral Monte Carlo (PIMC) and density functional theory molecular dynamics (DFT-MD) simulations, we study the properties of MgSiO$_3$ enstatite in the regime of warm dense matter. We generate a consistent equation of state for MgSiO$_3$ over a wide range of temperature and density conditions, ranging from $10^4$ to $10^8$ K and 0.1- to 20-fold the ambient density. An analysis of the structural and thermodynamic properties of the liquid is provided as L and K shell electrons are ionized with increasing temperature and pressure. The shock Hugoniot curve, that we derived from our EOS, is in very good agreement with the experimental data available for megabar pressures. In the gigabar regime, shock experiments are predicted to reach maximal compression. We analyze the shape of the Hugoniot curve under these conditions and demonstrated that the shock compression is controlled by the ionization of L and K shell electrons of the three nuclei.

3:54PM P03.00006: Ionization Potential Depression in Dense Plasmas Predicted with Ab Initio Methods  BURKHARD MILITZER (Presenter), University of California, Berkeley, MAXIMILIAN BÖHME, Helmholtz-Zentrum Dresden-Rossendorf, GERARD MASSACRIER, Ecole Normale Superieure de Lyon, JAN VORBERGER, Helmholtz-Zentrum Dresden-Rossendorf, FRANCOIS SOUBIRAN, Ecole Normale Superieure de Lyon — The degree of ionization is an important quantity that directly affects the equation of state of plasmas as well as their optical and transport properties. At high density, the electronic states are affected by the interaction with nearby particles. In energy space, bound states are pushed closer to the continuous spectrum of free-particle states. These changes are typically encapsulated in the terms of ionization potential depression (IPD). An accurate description of IPD becomes important when spectroscopic measurements are employed to determine the thermodynamic state of plasmas. In their seminal work, Stewart and Pyatt (SP) have developed an analytical model to describe the IPD. However, in Physical Review E 97 (2018) 063207, diverging trends between SP predictions and ab initio results were reported for hot, dense aluminum. Here, we report results from a comprehensive set of density functional molecular dynamics simulations that were designed to study the IPD of different materials under various thermodynamic conditions. We analyze the strengths and weaknesses of SP models and discuss possible reasons why they may become unreliable at high density.

4:06PM P03.00007: High Temperature Density Functional Theory Calculations*  PATRICK HOLLEBON (Presenter), TRAVIS SJOSTROM, Los Alamos National Laboratory — Kohn-Sham density functional theory calculations are widely used as an accurate ab-initio approach to solving the many-body problem in the warm dense matter regime, encompassing conditions approximately ranging from 0.1 to 50 times solid density and temperatures from 0.5 to 100 eV. Nonetheless computational costs can quickly become prohibitive with rising temperature due to the growing number of partially occupied states involved. This is particularly pertinent for accurate molecular dynamics simulation that require large box sizes and timescales to reach convergence. For these reasons, orbital-free methods are an attractive alternative for temperatures beyond approximately 10 eV, however the increased computational efficiency of simple kinetic energy functionals comes at the cost of physical accuracy. Here we present a hybrid approach in which the Kohn-Sham equation is solved for the low-lying states only, whilst an orbital-free method is applied to describe the remaining electrons. Our hybrid methods are used to perform equation of state calculations in the warm dense matter regime which we then benchmark against conventional Kohn-Sham calculations.

*This work has been supported by the U.S Department of Energy and Los Alamos National Laboratory LDRD.
4:18PM P03.00008: Electron-thermal contribution to the equation of state model based on two-temperature quantum molecular dynamics simulations* LIN YANG (Presenter), JOHN EMRICH KLEPEIS, PHILIP A STERNE, HEATHER D WHITLEY, Lawrence Livermore Natl Lab, SHUAI ZHANG, Laboratory for Laser Energetics, University of Rochester — We present results using two-temperature quantum molecular dynamics (QMD) simulations to identify the electron-thermal contributions to the equation of state (EOS) and make comparison with the Purgatorio-based model. The two-temperature approach treats the electron and the ion temperature independently in a QMD simulation. We applied the method to some low-Z materials (B, BN, and B$_4$C) and a high-Z transition-metal oxide at temperatures ranging from room temperature to $10^6$ K and 1 to 5 times compression in densities. Our results suggest that the electron-thermal contribution begins to dominate around $1.2 \times 10^5$ K (10 eV) and is material as well as density dependent. For each material, we identify the temperature-density regime where the electron-thermal contribution is independent of ionic configurations. We illustrate our findings by comparing electron pressure and specific heat with Purgatorio-based model.

*Work performed under the auspices of LLNL under Contract DE-AC52-07NA27344.

4:30PM P03.00009: Atom-in-jellium equations of state for high Z elements TOM LOCKARD (Presenter), LORIN BENEDICT, CHRISTINE J WU, PHILIP A STERNE, DAMIAN SWIFT, Lawrence Livermore Natl Lab — We have previously reported atom-in-jellium (AJ) predictions of the equation of state (EOS) and melt locus of low- and mid-Z elements. Here we report equivalent results for a selection of high Z elements that are also under experimental investigation at high energy density facilities. In comparison with previous EOS models for these substances, based on Thomas-Fermi theory, the shock Hugoniot exhibits structures corresponding to the ionization of successive electron shells. Proportionately, the difference from TF theory is less than was found for lower Z elements, though it can still amount to a factor ~2 in pressure as each ionization occurs. The broad trend of the Hugoniot is however closer to TF predictions than was observed at lower Z. The cold curve and ambient isochore deduced from AJ calculations is generally quite close to the corresponding TF calculation.
4:42PM P03.00010: Multiscale Simulation Method for Plasma Flows  ABDOURAHMANE DIAW  
(Presenter), JEFF HAACK, MIKE MCKERNS MCKERNS, ROBERT PAVEL, Los Alamos National Laboratory — In high-energy density flows, a number of dynamical and structural data is needed to be collected at the microscale using first principles calculations. Experimental results and their analysis, on the other hand, are determined by measurements at the macro-scale in space over long scales in time. Thus, one major disparity that is currently inhibiting progress in this area is the extrapolation of microscale information into macroscopically relevant scales. Inertial confinement fusion experiments, for example, are fundamentally multi-physics in nature; understanding the connection between experimental observables, and the underlying microphysics, is needed to fully assess capsule performance. In this work, we use uncertainty quantification driven learning algorithms coupled with directed sampling to automate the learning of a multiscale model that is valid for both atomistic processes and continuum phenomena. The multiscale framework couples a molecular dynamics with a Boltzmann kinetic model to describe mesoscale phenomena, and which is tuned by minimizing the model error. We will discuss the code written to build a valid multiscale model relevant to high-energy density experiments, and how that tool may be leveraged to facilitate the learning of plasma models.

4:54PM P03.00011: Spin-orbit coupling in first-principles optical and X-ray spectroscopy spectra under WDM conditions  NILS BROUWER, VANINA RECOULES, MARC TORRENT  
(Presenter), CEA, DAM, DIF. France — The prediction and analysis of optical and X-Ray spectra of materials under WDM conditions is of great scientific interest. The Kubo-Greenwood (KG) formula associated with the Projector Augmented-Wave (PAW) approach [1] has proven its efficiency to compute these spectra and has been implemented in a few DFT codes, including the ABINIT code [2]. One important aspect when treating optical and X-Ray spectroscopy, especially for heavier elements, is the spin-orbit coupling (SOC).

We present some improvements in the implementation of the calculation of optical and X-Ray spectra. Spinors are now treated explicitly; SOC is added in the velocity operator and is taken into account in the dipole matrix elements in the KG formula. We are now able to predict the spin-orbit splitting and the ratio of the X-ray absorption edges correctly.

We present two applications in the WDM regime. We show that the inclusion of SOC allows for the correct description of the splitting and branching ratio of the L2/L3 edge in copper. We also show that SOC has a small and visible -- but still not sufficient -- effect on the optical properties of gold. We explore other options to improve the optical spectra of gold.

**5:06PM P03.00012: Quasi-isentropic compression of strongly nonideal plasmas: correlations, degeneracy and plasma phase transitions**  
VLADIMIR E. FORTOV (Presenter), Joint Institute for High Temperatures of Russian Academy of Sciences, RADII I. IL'KAEV, Federal State Unitary Enterprise RUSSIAN FEDERAL NUCLEAR CENTER - All-Russian Research Institute of Experimental Physics, MIKHAIL I. KULISH, Institute of Problems of Chemical Physics of Russian Academy of Sciences, PAVEL R. LEVASHOV, Joint Institute for High Temperatures of Russian Academy of Sciences, VIKTOR B. MINTSEV, Institute of Problems of Chemical Physics of Russian Academy of Sciences, MIKHAIL A. MOCHALOV, Federal State Unitary Enterprise RUSSIAN FEDERAL NUCLEAR CENTER - All-Russian Research Institute of Experimental Physics, DMITRY N. NIKOLAEV, Institute of Problems of Chemical Physics of Russian Academy of Sciences, VLADIMIR V. STEGAILOV, Joint Institute for High Temperatures of Russian Academy of Sciences — A series of experiments with intense quasi-isentropic compression of the plasma D2 and He were carried out to get strongly coupled nonideal plasma. Two-stage spherical explosively driven devices were used in these experiments. Recordary high parameters of strongly coupled deuterium plasma were obtained in the experiments: pressures up to 18 TPa and density up to 14 g/cc. Helium plasma was compressed ~ 200 times up to density of 8 g/cc and pressures of P ~ 5 TPa. Remarkable features of helium and deuterium plasma behaviour at these extremely high pressures, temperatures and densities are discussed with the use of nonideal plasma models as well as of the results of computer simulation calculations using first principle approaches. The different theoretical models of plasma phase transitions are discussed in comparison with shock wave experiments. Exclusively important role of quantum degeneracy effects as well as of strong correlation effects is analysed on the basis of the experimental data obtained.

**5:18PM P03.00013: Measurement of the fs laser-induced structural modification process inside transparent materials**  
LIN ZHANG (Presenter), ZHICHENG ZHONG, HAO JIANG, SHIYUAN LIU, Huazhong University of Science & Technology — Femtosecond laser pulses can cause structural modification when focused inside transparent material, which can be used in the formation of optical waveguides, 3D micromachining and other photonic machining applications. However, the structural modification process of the material is still unclear, which often occurs in the picosecond scale.  
Here, we proposed a pump-probe based method to detect the laser-induced structural modification process inside transparent material. A fs laser pulse was acted as the pump pulse and focused inside fused silica, while a linear chirped pulse was adopted to probe the pump area. According to the mapping relationship between time and frequency of the chirped pulse, we have obtained the time dependent refractive index change process and the structural modification process in a single shot measurement. Results show that the volume and refractive index of the modified area gradually increase with time. Besides, we also observed the static structure after the experiment, and the microscopic image shows a donut-like structure was formed at the shock region, a void surrounded by a compressed shell, which is consistent with the micro-explosion theory.

**Wednesday, March 4, 2020 2:30 PM - 5:18 PM**
Multiexciton quantum interference in semiconductor nanocrystal quantum dots*  
HIROKAZU TAHARA (Presenter), MASANORI SAKAMOTO, TOSHIHARU TERANISHI, YOSHIHIKO KANEMITSU, Institute for Chemical Research, Kyoto University — Semiconductor nanocrystal quantum dots are one of the most suitable materials to examine strongly confined electron-hole pairs. It is desired to clarify their multiple carrier dynamics such as carrier multiplication and charged exciton properties. Here, we studied ultrafast multiexciton dynamics immediately after photoexcitation using quantum interference measurements [1]. The dipole oscillations containing single excitons, biexcitons, and triexcitons were observed by using the phase-locked interference detection method in transient absorption spectroscopy. We found that multiexcitons form harmonic quantum coherence, i.e., dipole oscillations with integer multiples of the exciton resonance frequency [2]. The coherent dynamics also play an important role in photogeneration processes of multiexcitons [3]. These results provide a deep understanding of multiexciton dynamics leading to advanced optoelectronic devices.

Ultrafast molecular dynamics of strongly adsorbed species on oxide surface  
MD AFJAL KHAN PATHAN (Presenter), AAKASH GUPTA, MIHAI E. VAIDA, Univ of Central Florida — In this contribution, the ultrafast dynamics of molecules strongly attached to oxide surfaces are studied using the femtosecond pump-probe mass spectrometry technique. As a model system, the molecular dynamics of CD₃I with random orientations on amorphous CeO₂ thin films is studied. The reaction dynamics is monitored through the detection of reaction intermediates and final products with time-, mass-, and kinetic-energy resolution. In contrast to the previous studies on surface-aligned CD₃I on crystalline oxide films, in the current investigation, in which CD₃I has random adsorption geometries, the CD₃⁺ and I⁺ transient signal intensities decay after the radicals are formed. The decay time constant of I⁺ (8.0 ps) coincided with the formation dynamics of a new peak at mass 254 amu corresponding to I₂⁺. The decay time constant of CD₃⁺ (2.5 ps) coincides with the formation dynamics of a new peak at 144.5 amu, corresponding to a highly energetic CD₃I⁺, which is reformed at the surface due to the increased collision between the I and CD₃ fragments, facilitated by the random adsorption geometry of the CD₃I molecules. In addition, power dependence measurements and kinetic energy-resolved mass spectra are employed to gain insights into the surface reaction dynamics.
2:54PM P06.00003: Phase-resolved 2D coherent spectra of exciton-polaritons and biexcitons in a semiconductor microcavity*  JAGANNATH PAUL (Presenter), JARED K WAHLSTRAND, Nanoscale Spectroscopy Group, National Institute of Standards and Technology, ALAN BRISTOW, Department of Physics and Astronomy, West Virginia University — Monolithic semiconductor microcavities host exciton-polaritons when the exciton modes are near cavity resonance. The light-matter interactions increase and the electronic states are modified by strong coupling. Biexcitons are still present and interact with the lower polariton branch [1]. Many-body effects, such as excitation-induced dephasing and shifts, appear clearly in phase-resolved 2D coherent spectra (2DCS) in bare quantum well systems. However, to date published 2DCS in microcavity systems have examined the amplitude of the signal without the phase information. This is in part due to the strength and complexity of the optical interaction with the macroscopic sample. Here we use an experimental method that allows for capturing phase-resolved 2DCS for numerous polarization [2]. Measurements are performed on a sample containing an InGaAs quantum well as a function of the detuning between the cavity and exciton modes. Analysis of both the polariton and biexciton modes is reported.

3:06PM P06.00004: Ultrafast thermal response of bismuth and indium nanoparticles near their melting points*  HUI XIONG, YUELI ZHANG, HANI ELSAYED-ALI (Presenter), Old Dominion University — The thermal response of Bi and In nanoparticles on carbon film and In nanoparticles embedded in Al are studied by ultrafast electron diffraction (UED) with a temporal resolution up to ~1.5 ps. The results show that the thermal response of nanoparticles near their melting points upon excitation by the femtosecond laser pulses deviates from that by heating under equilibrium conditions. A subset of the Bi nanoparticles and the In nanoparticles embedded in Al shows crystal integrity above their bulk melting points, consistent with transient superheating. For the Bi nanoparticles, this may be attributed to faceting of some of the nanoparticles, while for the embedded In nanoparticles the In/Al interface may suppress the growth of the In surface molten layer. We also investigated the anisotropic thermal expansion of the nanoparticles by measuring the angular shift of the diffraction peaks with UED.

*This study is based on research supported by the National Science Foundation under Grant No. 1708717.
3:18PM P06.00005: PT-Symmetry in Colloidal Quantum Dot Microdisk Lasers with Engineered Notches*  QINGJI ZENG (Presenter), EVAN LAFALE, University of Utah, ZHIQUN LIN, VLADIMIR V TSUKRUK, Georgia Institute of Technology, VALY VARDENY, University of Utah — Whispering gallery mode resonators are susceptible to parasitic splitting of clockwise and counterclockwise modes due to the sensitivity of optical modes to perturbations of the circular resonator boundary. This makes them useful devices for optical sensing and allow for evanescently coupling of modes of different resonators. We have studied laser mode behavior when a notch is engineered into the boundary of circular microdisk resonator based on colloidal quantum dots. We found substantive reduction of the parasitic mode splitting and enhanced emission directionality for resonators with by tuning the size of the notch. We also investigated the effects of Parity-Time (PT) symmetry in evanescently coupled microdisk pairs with variation of the gain and loss induced by the optical pump. We demonstrate that the exceptional point behavior of these systems can be controlled by the size of the engineered notch.

3:30PM P06.00006: Photogeneration and recombination dynamics of trions and biexcitons in CsPbX$_3$ nanocrystals revealed by double-pump transient-absorption spectroscopy*  ETSUKI KOBAYAMA (Presenter), SATOSHI NAKAHARA, HIROKAZU TAHARA, TOKUHISA KAWAKI, MASAKI SARUYAMA, RYOTA SATO, TOSHIHIKO TERANISHI, YOSHIHIKO KANEMITSU, Kyoto Univ — Lead halide perovskite nanocrystals (NCs) attract much attention because of their excellent optical properties such as high photoluminescence quantum yields. However, detailed dynamical processes of excitons, trions, and biexcitons have not been understood yet [1]. Here, we investigate the photogeneration and recombination dynamics of trions and biexcitons in all-inorganic perovskite CsPbX$_3$ (X = Cl, Br, I) NCs by conducting double-pump transient-absorption spectroscopy. In this method, the population of trions and biexcitons in NCs can be controlled by changing excitation intensity and time interval of two pump pulses. We revealed that Auger recombination of biexcitons and radiative and nonradiative recombination of trions determines ionization and neutralization processes in halide perovskite NCs [2]. In addition, we examined the difference in optical gain between single- and double-pump conditions. Our findings provide essential insights for low-threshold lasing.

*Part of this work was supported by JSPS KAKENHI (Grant No. 19H05465 and 18K13481).
3:42PM P06.00007: Observation and control of a photoinduced terahertz plasmonic mode in InAs mushroom arrays* SIEKHL RUBAIAT UL HAQUE (Presenter), Physics, University Of California, San Diego, XIAOGUANG ZHAO, Mechanical Engineering, Boston university, JINGDI ZHANG, Physics, Hong Kong University of Science and Technology, STEPHEN MARCH, SETH BANK, Electrical & Computer Engineering, The University of Texas at Austin, XIN ZHANG, Mechanical Engineering, Boston university, RICHARD AVERITT, Physics, University Of California, San Diego — Optical tuning of complex materials paves the ways towards control of macroscopic properties while also providing insight into novel physics under non-equilibrium conditions. We report the observation and control of a plasmonic resonance via photoexcitation in InAs mushroom metamaterial arrays. This is accomplished using optical pump broadband THz probe spectroscopy. A dramatic blueshift of plasmon resonance occurs (from ~1 to 7 THz) with increasing photoexcitation fluence. Clear signatures of plasmon-optical phonon coupling are observed, in agreement with simulations. In this presentation, we will clarify how the mushroom geometry provides dielectric isolation, thereby enabling broad photoinduced plasmonic tunability.

*The authors acknowledge funding from the Defense Advanced Research Projects Agency (DARPA), Defense Sciences Office (DSO) under the Driven Nonequilibrium Quantum Systems (DRINQS) program, grant number D18AC00014.

3:54PM P06.00008: Mapping out transient topological states in graphene by dichroic time-resolved photoemission* MICHAEL SCHUELER (Presenter), Stanford Univ, UMBERTO DE GIOVANNINI, HANNES HUEBENER, ANGEL RUBIO, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany, PHILIPP WERNER, University of Fribourg, THOMAS DEVEREAUX, Stanford Univ — We study the build-up of the Floquet-Chern insulator state in graphene and its implications in time- and angle-resolved photoemission (ARPES). In particular, we show that the circular dichroism in the angular distribution is directly related to the induced pseudospin texture and thus the Berry curvature of the Floquet band structure. Our conclusions are corroborated by realistic time-dependent simulation under experimentally relevant conditions. Including electron-electron and electron-phonon scattering, we reveal the crucial role of scattering mechanisms for the effective thermalization of the Floquet band structure. These calculations are combined with accurate onestep calculations, yielding an excellent description of the circular dichroism in ARPES (CD-ARPES). Albeit the system is highly excited, we show that CD-ARPES provides the unique possibility of discerning light-engineered topological properties of the effective band structure and the Floquet side bands.

*We acknowledge financial support from the Swiss National Science Foundation via NCCR MARVEL and the European Research Council via ERC-2015-AdG-694097 and ERC Consolidator Grant No. 724103, and the Alexander von Humboldt Foundation for its support with a Lynen scholarship.
**4:06PM P06.00009: Time Resolved Investigation of Coherent Surface Phonon Polaritons**

PIERRE-ADRIEN MANTE (Presenter), Lund Univ/Lund Inst of Tech — The sub-wavelength confinement and enhanced electric field created by plasmons render accessible precise sensing and strong coupling at room temperature. [1, 2] However, the high frequency and short lifetime of plasmons inhibit the full potential of this technology and substitutes with longer lifetime and that can be studied in the time domain are being sought-after. [3] Here, we propose and demonstrate an experimental approach using femtosecond pump-probe spectroscopy allowing the time-domain study of surface phonon polaritons. We first build a theoretical framework for the generation and detection of these modes that we verify experimentally. By comparing experiments and Finite Difference Time Domain simulations we highlight that dark and bright modes are simultaneously generated. Thanks to this time-domain method, we then investigate mode dependent decay and energy transfer to the environment. Our observations open the way to deeper investigations of the role of coherence in the rich polariton physics.

*Grant 2017-05150 from the Swedish Research Council (VR).*

**4:18PM P06.00010: Superconducting Higgs Mode Metamaterials**

IAN HAMMOCK (Presenter), KELSON KAJ, SHEIKH RUBAIAT UL HAQUE, Physics, University of California, San Diego, CHUNXU CHEN, XIAOGUANG ZHAO, Mechanical Engineering, Boston University, KEVIN A CREMIN, GUFENG ZHANG, JACOB S SCHALCH, Physics, University of California, San Diego, JINGDI ZHANG, Physics, The Hong Kong University of Science and Technology, XIN ZHANG, Mechanical Engineering, Boston University, RICHARD AVERITT, Physics, University of California, San Diego — In this work, we investigate the possibility of using metamaterials to couple to the Higgs amplitude mode in an optimally doped thin film cuprate superconductor, YBa$_2$Cu$_3$O$_{7-d}$ (YBCO). To coherently drive the condensate amplitude, we employ table top high-field terahertz radiation coupled with field enhancement metamaterials (that also serve as a bandpass filter). We utilize a metamaterial “tape” design that allows us to adhere the subwavelength resonators to the YBCO film without the need for photolithography. We will describe the design of the metamaterial tapes and present our preliminary experimental results using these tapes to access non-equilibrium order parameter dynamics in superconductors.

*The authors acknowledge funding from the DARPA DSO under the Driven Nonequilibrium Quantum Systems (DRINQS) program, grant number D18AC00014*
4:30PM P06.00011: Plasmonic nano-focused spectroscopy and imaging: from few-fs dynamics to a new regime of nonlinear nano-optics  
YIJIAN CAI (Presenter), TAO JIANG, University of Colorado, Boulder, VASILY KRAVTSOV, ITMO University, MARKUS B. RASCHKE, University of Colorado, Boulder — Probing ultrafast dynamics and coherence with nm-fs spatio-temporal resolution is of crucial importance for understanding quantum coherence at the nanoscale and further advancing nonlinear optical applications. However, ultrafast nanoimaging has long been experimentally challenging. Our unique approach of combining grating coupled plasmonic nanofocusing with scanning probe techniques enables nonlinear optical imaging with nanometer spatial and femtosecond temporal resolution. We will discuss how spatial nano-confinement and near-field momenta provide new pathways for enhancing nonlinear frequency conversion where, e.g., plasmonic gradient-field effects amplify dipole-forbidden nonlinear responses. We further demonstrate non-local enhancement in four-wave mixing in graphene associated with Doppler broadening due to the broad distribution of near-field momenta. By implementing both spatio-spectral and spatio-temporal nanoimaging we can resolve the few-fs dynamics of electron coherence in graphene. We discuss the extension of these studies to other layered materials like transition metal dichalcogenides, providing insight into the heterogeneity of nanoscale electronic properties, enhanced frequency conversion, and roles of associated band structures, defects and grain boundaries.

4:42PM P06.00012: Terahertz Quasiparticle Dynamics and Control in Ca$_3$Ru$_2$O$_7$*  
KELSON KAJ (Presenter), KEVIN A CREMIN, Physics, University of California, San Diego, YU WANG, Physics, Pennsylvania State University, IAN HAMMOCK, MUSTAFA ALI, RUBAIAT HAQUE, GUFENG ZHANG, PETER KISSIN, Physics, University of California, San Diego, YAKUN YUAN, Materials Science and Engineering, Pennsylvania State University, DANIELO PUGGIONI, Materials Science and Engineering, Northwestern University, VENKATRAMAN GOPALAN, Materials Science and Engineering, Pennsylvania State University, ZHIQIANG MAO, Physics, Pennsylvania State University, JAMES RONDINELLI, Materials Science and Engineering, Northwestern University, RICHARD AVERITT, Physics, University of California, San Diego — We have investigated the terahertz electrodynamics of single crystals of the Ruddlesden-Popper ruthenate Ca$_3$Ru$_2$O$_7$ using optical-pump terahertz-probe spectroscopy. This correlated semimetal orders antiferromagnetically at $T_N = 56$ K, with the opening of a pseudogap (~2 THz) at $T_C = 48$ K. We predict that Ca$_3$Ru$_2$O$_7$ exhibits novel non-equilibrium states, with the possibility that excitation of c-axis apical oxygen phonons could result in novel phases absent from the equilibrium phase diagram. In the present study, we have investigated near-IR changes in the THz reflectivity following near-infrared excitation. We observe clear signatures of pseudogap dynamics in the spectrally resolved dynamics. In this presentation, we will present a detailed account of these dynamics along with an update of the phonon driven electrodynamic response.

4:54PM P06.00013: Topological light for the control of skyrmionic textures and spin waves*

MASAHIRO SATO (Presenter), Department of Physics, Ibaraki University, HIROYUKI FUJITA, Institute for Solid State Physics, University of Tokyo — Topological light is the laser whose wave front has a geometric singularity, and a typical one is the vortex beam carrying orbital angular momentum. Its several applications have been intensively studied in optics, while its potential have not been explored well in condensed-matter physics. Very recently, such structural lights have been gradually applied to find new photo-induced phenomena in solids. In the last few years, we have theoretically proposed ways of controlling magnetism with topological light [1-4]. Among them, I would like to report two proposals: a systematic way of creating ring-type spin textures such as skyrmioniums by applying high-frequency vortex beams to chiral magnets [1], and spin-wave resonance driven by terahertz vortex beams in ordered magnets [2]. These offer ways of printing the information about the beam onto magnets. [1] Fujita and MS, PRB 95, 054421 (2017). [2] Fujita, and MS, PRB 96, 060407(R) (2017). [3] Fujita and MS, Sci. Rep. 8, 15738 (2018). [4] Fujita, Tada, and MS, New. J. Phys. 21, 073010 (2019).

* M. S. was supported by Grant-in-Aid for Scientific Research on Innovative Area, “Nano Spin Conversion Science” (Grant No. 17H05174) and “Quantum Liquid Crystals” (Grant No. 19H05825) as well as JSPS KAKENHI (Grants No. 17K05513 and No. 15H02117).

5:06PM P06.00014: Low-Temperature Phases of Er$_{1-x}$Y$_x$FeO$_3$ Mapped Out by Terahertz Time-Domain Spectroscopy

NICOLAS MARQUEZ PERACA (Presenter), Department of Physics and Astronomy, Rice University, XINWEI LI, Department of Electrical and Computer Engineering, Rice University, MOTOAKI BAMBA, Department of Physics, Kyoto University, CHIEN-LUNG HUANG, Department of Physics and Astronomy, Rice University, NING YUAN, Department of Physics, Shanghai University, GARY T NOE, Department of Electrical and Computer Engineering, Rice University, EMILIA MOROSAN, Department of Physics and Astronomy, Rice University, SHIXUN CAO, Department of Physics, Shanghai University, JUNICHIRO KONO, Department of Physics and Astronomy, Rice University — When the strength of coupling between an ensemble of two-level atoms and a single mode of light becomes a significant fraction of the natural frequencies in the system, a novel regime of light-matter interaction, known as the ultrastrong coupling regime, emerges. As the coupling is further increased, a quantum phase transition, referred to as the superradiant phase transition (SRPT), is theoretically predicted to occur. To date, a SRPT in thermal equilibrium has never been realized experimentally, and even its observability is a topic of ongoing debate in the literature. However, there remains a strong possibility to observe a phase transition analogous to the SRPT in magnetically ordered systems, which would provide new insight into the underlying physics behind the original photon SRPT. In the present work, we performed an extensive study of the low-temperature phases of Er$_{1-x}$Y$_x$FeO$_3$ as a function of temperature, magnetic field and x through terahertz time-domain magneto-spectroscopy. Through comparison with our detailed calculations, we found that there is a phase transition that can be interpreted as a magnon analogue of the SRPT in an extended Dicke model and that the cooperative coupling of spins and magnons plays a key role in the experimental realization of this phenomenon.
Quantum sensing beyond the standard quantum limit with 2D arrays of trapped ions

Kevin Gilmore (Presenter), Matthew Affolter, Elena Jordan, NIST Boulder, Robert J. Lewis-Swan, Diego Barberena, Athreya Shankar, Murray J Holland, Ana Maria Rey, University of Colorado, Boulder, John Jacob Bollinger, NIST Boulder — Quantum sensing protocols using trapped-ions can enable detection of weak electric fields (<1 nV/m) by sensing displacements surpassing the Standard Quantum Limit (SQL) – the sensitivity achievable with a coherent state. We present experiments investigating the limits of electric field sensing via the excitation of the center-of-mass (COM) motion of 100s of ions in a 2D crystal. By coupling the mechanical motion of the ions to their spin states by way of an optical potential, the displacement of the ion crystal can be read out via the spin state [1].

Recently, phase stabilization of this optical potential has improved the sensitivity by an order of magnitude. Probing on resonance with the COM mode provides the maximum sensitivity to electric fields. Using a scheme that cancels the thermal and zero-point motion ideally allows for detection of displacements ~15 dB below the SQL. Currently, frequency fluctuations of the COM mode limit this sensitivity to ~5 dB below the SQL. With future improvements, we predict electric field sensitivities of ~1 nV/m. Electric fields of this size may be produced by dark matter candidates: axion and hidden photon dark matter in the neV (MHz) regime has not been experimentally explored at this level.

Spin-squeezing using optimized parametric driving

PETER GROSZKOWSKI (Presenter), Pritzker School of Molecular Engineering, University of Chicago, CATHERINE LEROUX, University of Sherbrooke, LUKE GOVIA, Raytheon BBN Technologies, AASHISH CLERK, Pritzker School of Molecular Engineering, University of Chicago — Spin-squeezed states are desirable for meteorological applications as they allow for sensing beyond the standard quantum limit. A variety of mechanisms for generating such states have been proposed theoretically, and in some cases, realized experimentally. Nevertheless, approaches that reach the Heisenberg-limited scaling (eg. 'two-axis twist') often require elaborate experimental setups, making them difficult to realize in practice, while ones that are more experimentally viable, (eg. 'one-axis-twist') have sub-optimal scaling. In this talk we consider a parametrically driven cavity, coupled to a spin ensemble. We show that a careful control of the parametric drive detuning and amplitude can let one achieve Heisenberg-limited scaling. We also discuss the impact of dissipation on performance. Our approach is general enough to be experimentally viable in a variety of systems including spin ensembles coupled to superconducting microwave cavities (e.g. [1]), but also spins that are strain-coupled to a nanomechanical resonator (e.g. [2,3]).

Detecting spin polarization in 2D MoSe2 with nitrogen vacancy centers in diamond

BO DWYER (Presenter), TROND I ANDERSEN, GIOVANNI SCURI, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Materials Science, PHILIP KIM, HONGKUN PARK, MIKHAIL LUKIN, Harvard University — Since the isolation of monolayer graphene, the catalog of exfoliatable two dimensional materials has grown to include materials with a host of properties, including semiconductors, ferromagnets, and even superconductors. Of particular interest are the transition metal dichalcogenides (TMDCs), which in the monolayer limit are direct band gap semiconductors that support tightly bound excitons. Due to spin orbit coupling and a lack of inversion symmetry, spins in the two inequivalent K valleys are polarized, which has led to great interest in TMDCs for spin- and valley-tronic applications. While the spin properties of TMDCs have been studied with optical techniques, these offer limited spatial resolution and are difficult to extract quantitative values from. We report on progress towards the measurement of optically induced spin polarization in hole doped MoSe2 using nitrogen vacancy centers in diamond as nanoscale magnetic field probes. The close proximity of these sensors, coupled with available superresolution techniques, will enable nanoscale imaging and quantification of other exotic phenomena in TMDs such as the valley hall effect and imaging of Moire superlattice TMDC structures.

3:06PM P07.00004: Observation of ac Photocurrent Vortices in Monolayer MoS$_2$ Using NV Centers* PAUL JERGER (Presenter), Pritzker School of Molecular Engineering, University of Chicago, BRIAN ZHOU, Department of Physics, Boston College, KAN-HENG LEE, MASAYA FUKAMI, FAUZIA MUJID, JIWOONG PARK, DAVID AWSCHALOM, Pritzker School of Molecular Engineering, University of Chicago — Photocurrents are central to understanding the interaction of light with matter. Although widely used, transport-based detection cannot resolve the spatial distribution of photocurrents and can suffer from low photocarrier collection efficiency. We demonstrate a contact-free method to spatially resolve photocurrents using nitrogen-vacancy (NV) centers in diamond, and discover that optical excitation of MoS$_2$ produces photocurrent vortices via the Nernst effect. We use a near-surface ensemble of NV centers to map the magnetic field profile of photocurrents in a monolayer of MoS$_2$ transferred onto the diamond surface. By synchronizing pulsed photoexcitation with NV ac magnetometry, we perform a quantum lock-in measurement to resolve time-dependent photocurrent densities as small as 20 nA/µm. Spatiotemporal measurements reveal a photocurrent rise time dependent on the sample's thermal properties. This work establishes a novel probe for optoelectronic phenomena, ideally suited to two-dimensional materials, for which making contacts is challenging and can alter the intrinsic material properties.

3:18PM P07.00005: Electric Field Sensing Using an NV Center Under Perpendicular Magnetic Field ZIWEI QIU (Presenter), ASSAF HAMO, URI VOOL, ANDREW PIERCE, RUOLAN XUE, TONY ZHOU, AMIR YACOBY, Harvard University — Nitrogen-vacancy (NV) centers in diamond can sense locally both magnetic and electric fields and hence may offer unique insight into strongly correlated matter. While NV magnetic sensing is well established, NV electric sensing is not yet widely utilized. Here we explored electric field sensing using an NV in the presence of a strong magnetic field acting perpendicular to the NV axis. We use shallow NVs (~20nm below the surface) in bulk diamonds and nanotips to explore the optimal conditions for electric field sensing. Under a perpendicular field, the original spin states mix into bright and dark states. These states hybridize with the $^{15}$N nuclear spin due to hyperfine interaction, giving rise to periodic modulations in the spin-echo signal. Surprisingly, this hyperfine coupling strength appears to be tunable by the magnitude of the perpendicular field and is linear at least up to 200G. These findings may offer a new pathway for prolonging the coherence of the nuclear spin.
3:30PM P07.00006: Diamond parabolic reflectors for nanoscale quantum sensing  BRENDAH SHIELDS (Presenter), NATASCHA HEDRICH, DOMINIK ROHNER, MARIETTA BATZER, PATRICK MALETINSKY, University of Basel — The nitrogen-vacancy (NV) center in diamond is an atomic-scale atom-like system with an electronic spin that can be initialized and detected optically, making it an exceptional system for quantum sensing of magnetic phenomena requiring high field sensitivity, fine spatial resolution, quantitative imagery [1, 2]. A particularly powerful approach is to incorporate the NV sensor in a scanning probe, allowing for nanometer spatial resolution. Key challenges for such a system are to ensure high collection efficiency and NV-sample spacing below a few 10s of nm.

We address these challenges with all-diamond parabolic scanning probes containing single NVs. The parabolic shape redirects 80% of the NV emission into a strongly collimated mode [3]. To achieve a small NV-sample spacing we truncate the probe apex such that the NV sits at the focus of the parabola for optimal collection efficiency while achieving a tip-to-sample spacing of < 50 nm. We demonstrate the performance of these scanning probes through magnetometry on antiferromagnetic, thin-film Cr$_2$O$_3$ [4].

3:42PM P07.00007: Extending the quantum coherence of a near-surface qubit by coherently driving the paramagnetic surface environment*  DOLEV BLUVSTEIN (Presenter), ZHIRAN ZHANG, CLAIRE MCLELLAN, NICOLAS RYAN WILLIAMS, ANIA JAYICH, Physics, University of California, Santa Barbara — Surfaces enable useful functionalities for quantum systems, e.g., as interfaces to sensing targets, but often result in surface-induced decoherence where unpaired electron spins are common culprits. Here we show that the coherence time of a near-surface qubit is increased by coherent radio-frequency driving of surface electron spins, where we use a diamond nitrogen-vacancy (NV) center as a model qubit [1]. This technique is complementary to other methods of suppressing decoherence and, importantly, requires no additional materials processing or control of the qubit. Further, by combining driving with the increased magnetic susceptibility of the double-quantum basis, we realize an overall fivefold sensitivity enhancement in NV magnetometry. Informed by our results, we discuss a path toward relaxation-limited coherence times for near-surface NV centers. The surface-spin driving technique presented here is broadly applicable to a wide variety of qubit platforms afflicted by surface-induced decoherence.

3:54PM P07.00008: Observation of a quantum phase from classical rotation of a single spin
ALEXANDER WOOD (Presenter), LLOYD C. L. HOLLENBERG, ROBERT E SCHOLTEN, ANDY M MARTIN, School of Physics, University of Melbourne — The theory of angular momentum connects physical rotations and quantum spins together at a fundamental level. Physical rotation of a quantum system will therefore affect fundamental quantum operations, such as spin rotations in projective Hilbert space, but these effects are subtle and experimentally challenging to observe due to the fragility of quantum coherence. Here we report a measurement of a single-electron-spin phase shift arising directly from physical rotation, without transduction through magnetic fields or ancillary spins. This phase shift is observed by measuring the difference between the phase of a microwave driving field and that of a rotating two-level electron spin system, a phase difference that can accumulate nonlinearly in time. We detect the nonlinear phase using spin-echo interferometry of a single nitrogen-vacancy qubit in a diamond rotating at 200,000 rpm. Our measurements demonstrate the fundamental connections between spin, physical rotation and quantum phase, and will be applicable in schemes where the rotational degree of freedom of a quantum system is not fixed, such as spin-based rotation sensors and trapped nanoparticles containing spins.

4:06PM P07.00009: Long-living coherences and magnetic sensing with strongly-coupled quantum spins driven by pulse trains
VIATCHESLAV DOBROVITSKI (Presenter), WALTER HAHN, QuTech, Delft University of Technology — The systems comprised of a large number of strongly coupled quantum spins, driven by trains of 180° pulses, often demonstrate long-living quantum coherences, extending far beyond the "usual" coherence decay time (e.g. Hahn echo decay time) [1-3]. This effect is generic for various spin systems in different dimensions, from 1D to ∞-D (where every spin is coupled to all others), and the appearance of the long-living coherences is associated with the accumulated effect of the spin dynamics during the pulses (such as rotation angle deviating from 180°, or finite pulse width).

In this work, we present the protocols that employ the long-living coherences for quantum-assisted sensing of ac magnetic fields. In these protocols the pulse polarity is periodically changed, thus modulating the effect of pulses, so that the resulting long-living coherence oscillates in time with the frequency depending on the ac magnetic field. We also discuss application of such protocols beyong sensing of ac magnetic fields, to other quantum-assisted metrology tasks.

4:18PM P07.00010: Phase-estimation optimization in GaAs quantum dots* ANGEL GUTIERREZ-RUBIO (Presenter), PETER STANO, DANIEL LOSS, RIKEN — We address the optimization of phase estimation in the context of GaAs quantum dots [1]. This allows to track the hyperfine field in real time with maximum precision, quenching the main dephasing source. We prove that the mean entropy is the ultimate figure of merit to be minimized for such a purpose, in contrast to the ubiquitous use of the variance in the literature [2,3]. In accordance, non-adaptive and feedback strategies for the tunable interaction times are devised. Whereas global optimization is out of reach, we provide with the optimal offline strategy among the class of memoryless patterns. Remarkably, it indefinitely sustains its maximum precision despite frequency fluctuations and is robust in terms of self consistency. Moreover, we devise a computationally feasible online method to improve the precision for a given non-adaptive strategy, which could be applied to the experimental realization of Kitaev's algorithm. Finally, the scaling of the achieved precision beyond the shot-noise limit is discussed.

4:30PM P07.00011: Imaging the crossover between ohmic and hydrodynamic electron flow in graphene with a single spin magnetometer* ALEC JENKINS, SUSANNE BAUMANN, SIMON A MEYNEILL, HAOXIN ZHOU, DAIPENG YANG (Presenter), Department of Physics, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ANDREW LUCAS, Department of Physics, University of Colorado, Boulder, ANDREA YOUNG, ANIA JAYICH, Department of Physics, University of California, Santa Barbara — In conventional conductors, transport is typically dominated by electron-phonon and electron-impurity scattering, giving rise to a direct proportionality between current and electric field known as Ohm's law. In ultra-clean graphene devices where the momentum-conserving electron-electron interaction dominates, transport is expected to obey hydrodynamics in which the electrons behave like a classical fluid. By measuring the stray magnetic field created by the current flow, we directly image the crossover from ohmic to viscous flow in a high mobility graphene constriction using nitrogen-vacancy center magnetometry. At room temperature, current flow concentrates at the edges of the constriction regardless of carrier density, indicating ohmic transport. However, below 200K, we observe a crossover into the viscous flow where the current concentrates at the center of the constriction. Our imaging technique provides a direct observation of collision-dominated electron transport.

*We acknowledge support from NSF CAREER Grant No. DMR-1810544
CHARLOTTE BOETTCHER (Presenter), URI VOOL, Harvard University, JOEL WANG, Physics, MIT, GREG CALUSINE, DAVID K KIM, DANNA ROSENBERG, JONILYN YODER, MIT Lincoln Lab, AMIR YACOBY, Harvard University, WILLIAM OLIVER, Physics, MIT — High-impedance superconducting resonators are important tools for quantum information and quantum sensing, as their resilience to magnetic fields and their highly concentrated local electric fields allow for strong coupling to small defects.

We propose to use this technique to study condensed-matter systems, and particularly the properties of graphene in the quantum Hall regime. In the dispersive regime, a change in the density-of-states of graphene will affect the resonator mode, allowing for RF detection.

We will present a design of titanium nitride resonators, optimized for high electric and magnetic coupling, resilient to in-plane magnetic field up to several Tesla. In addition, we will discuss the hybrid devices combining such resonators with a graphene-hBN stack.

TIM HUGO TAMINIAU (Presenter), Delft University of Technology — Nuclear magnetic resonance (NMR) is a powerful method for determining the structure of molecules and proteins. While conventional NMR requires averaging over large ensembles, recent progress with single-spin quantum sensors has created the prospect of magnetic imaging of individual molecules and other spin systems. As an initial step towards this goal, isolated nuclear spins and spin pairs have been mapped. However, large clusters of interacting spins — such as found in molecules — result in highly complex spectra. Imaging these complex systems is an outstanding challenge due to the required high spectral resolution and efficient spatial reconstruction with sub-angstrom precision. Here we develop such atomic-scale imaging using a single nitrogen-vacancy (NV) centre as a quantum sensor, and demonstrate it on a model system of 27 coupled 13C nuclear spins in a diamond. We present a new multidimensional spectroscopy method that isolates individual nuclear spin interactions with high spectral resolution (< 80 mHz) and high accuracy (2 mHz). We show that these interactions encode the composition and interconnectivity of the cluster, and develop methods to extract the 3D structure of the cluster with sub-angstrom resolution. These results demonstrate a key capability towards magnetic imaging of individual molecules and other complex spin systems.

2:30PM P08.00001: Projecting NISQ-era quantum advantage with QAOA

GIAN GIACOMO GUERRESCHI (Presenter), Intel Corp - Santa Clara, JASON LARKIN, DANIEL JUSTICE, Software Engineering Institute, Carnegie Mellon University — A major milestone in quantum computing research is the demonstration of quantum supremacy, where some computation is performed by a quantum computer that is unfeasible classically. Recently, the efforts culminated in the experiment by Google's quantum teams and collaborators of sampling from random circuits. However, it is important to recognize that supremacy demonstrations based on artificial tasks bring very limited advantage for practical applications. A common problem used in benchmarking high performance computing is MaxCut, with applications in domains such as machine scheduling, image recognition, electronic circuit layout, and others. Maxcut has been used extensively, both theoretically and experimentally, to assess the performance of the hybrid Quantum Approximate Optimization Algorithm (QAOA), one of the leading candidates to demonstrate quantum advantage in the NISQ era. Here we project the performance of QAOA by considering the challenges due to its variational and stochastic nature and compare it with several among the best performing classical solvers in terms of time to solution and quality. The results demonstrate the importance of algorithm and problem selection and we discuss the performance data in the context of projecting NISQ-era quantum advantage.

2:42PM P08.00002: Small-parameter and operator series approaches for quantum approximate optimization*

STUART HADFIELD (Presenter), TAD HOGG, ELEANOR RIEFFEL, NASA Ames Research Center, Quantum AI Lab (QuAIL) — We show a calculus for analyzing algorithms based on quantum alternating operator ansatze, in particular the quantum approximate optimization algorithm (QAOA). Our framework relates cost gradient operators, derived from the cost and mixing Hamiltonians, to classical cost difference functions that reflect cost function structure. For QAOA we show an exact series expansion in the algorithm parameters and cost gradient operators. This enables analysis in different parameter regimes which yields novel insights. In the small-parameter regime, for single-layer QAOA-1 the leading-order change in solution probability is determined by cost differences; for sufficiently small parameters probability provably flows from lower to higher cost states on average (or vice versa via parameter selection). On the other hand, we derive a classical random algorithm which emulates QAOA-1 in the same small-parameter regime, i.e. outputs samples with the same probabilities up to small error. Our results apply generally under minimal cost function assumptions. For deeper QAOA-p circuits we derive analogous results in several settings. We discuss applications to performance, parameter setting, and design of more effective QAOA mixing operators.

Reinforcement Learning for Finding QAOA Parameters

YURI ALEXEEV (Presenter), Argonne Natl Lab, SAMI KHAIRY, Department of Electrical and Computer Engineering, Illinois Institute of Technology, RUSLAN SHAYDULIN, Clemson University, LUKASZ CINCIO, Los Alamos National Laboratory, PRASANNA BALAPRAKASH, Argonne Natl Lab — Quantum Approximate Optimization Algorithm (QAOA) is an important variational hybrid quantum-classical algorithm for approximately solving combinatorial optimization problems on NISQ devices. The quality of the solution obtained by QAOA depends on the performance of the classical optimizer used to optimize the variational parameters, but finding these optimal parameters can be hard to achieve. To address this problem, we formulate the problem of finding optimal QAOA parameters as a learning task in which the knowledge gained from solving training instances can be leveraged to find high-quality solutions for unseen test instances using two machine learning based approaches. We used reinforcement learning (RL) framework to learn a policy network to optimize QAOA circuits and a kernel density estimation (KDE) technique to learn a generative model of optimal QAOA parameters. In both approaches, the training procedure is performed on the small-sized problem instances, which can be simulated on a classical computer; yet the learned RL policy and the generative model can be used to efficiently solve larger problems. Our proposed RL and KDE based approaches reduce the optimality gap by factors up to 30 when compared to other commonly used standard optimizers.

Quantum approximate optimization of the exact-cover problem on a superconducting quantum processor

ANDREAS BENGTSSON (Presenter), PONTUS VIKSTÅL, CHRISTOPHER WARREN, Microtechnology and Nanoscience, Chalmers University of Technology, MARIKA SVENSSON, Computer Science and Engineering, Chalmers University of Technology, GÖRAN JOHANSSON, PER DELSING, GIULIA FERRINI, JONAS BYLANDER, Microtechnology and Nanoscience, Chalmers University of Technology — Superconducting qubits are one of the leading technologies for building useful quantum processors. Currently available devices, where error correction and fault tolerance is not yet possible, are usually referred to as noisy intermediate-scale quantum (NISQ) devices. Such processors hold yet great promise, for instance they might allow for running heuristic quantum algorithms solving combinatorial optimization. On small-scale quantum processors, these algorithms serve as important technology demonstrators. Here, we use the quantum approximate optimization algorithm (QAOA) to solve small instances of the NP-complete exact-cover problem. This problem has many real-world applications, such as work-shift scheduling and tail assignment for airlines. We implement the QAOA on our hardware platform consisting of two superconducting transmon qubits and one parametrically modulated coupler. We explore iteration levels of the algorithm up to two, and compare the performance of three different black-box optimizers. Our results show that the exact-cover problem can be solved by the QAOA with high success probability.
The QAOA is one of the candidates for quantum algorithms which might outperform classical approaches, while being amenable to NISQ devices. The target application for this approach is finding approximate solutions to combinatorial optimization problems. Since real world combinatorial optimization problems almost always have hard constraint, the algorithm was generalized to the Quantum Alternating Operator Ansatz. This approach consists of two alternating operators. First the phase separation operator which stems from the original cost function and second, a suitable mixing operator which explores the whole feasible subspace while conserving the hard constraints.

In this work, we present a Quantum Alternating Operator Ansatz for the problem of optimal assignment of airplanes to gates in a large airport hub. This is a hard operational planning problem with real world impact. We investigate several problem variations and their different relationships to NP-hard graph coloring problems. Our primary contribution is the development of novel mixing operators for the different problem settings and facilitate efficient QAOA implementation. For each case we analyse the quantum resource requirements and discuss the feasibility of using real-world problem input data.
3:30PM P08.00006: Probing topological defect formation in a quantum annealer  YUKI BANDO, Tokyo Institute of Technology, Nagatsuta-cho, Midori-ku, Yokohama 226-8503, Japan, FERNANDO J. GÓMEZ-RUIZ, 2. Saitama Medical University, Moroyama, Saitama 350-0495, Japan, DANIEL A LIDAR, 5. University of Southern California, Los Angeles, California 90089, USA, ADOLFO DEL CAMPO (Presenter), 2. Donostia International Physics Center, E-20018 San Sebastián, Spain, HIDETOSHI NISHIMORI, Tokyo Institute of Technology, Nagatsuta-cho, Midori-ku, Yokohama 226-8503, Japan — When a quantum phase transition is crossed in finite time, the breakdown of adiabatic dynamics leads to the formation of topological defects. The average density of defects scales with the quench rate following a universal power-law predicted by the Kibble-Zurek mechanism. The later provides useful heuristics for adiabatic quantum computation. Physics beyond the Kibble-Zurek mechanism can be probed by characterizing the full counting statistics of topological defects. We argue that the distribution of the number of defects generally follows a Poisson binomial distribution with all cumulants exhibiting a universal power-law scaling with the quench rate. As an example, we report the exact kink number distribution in the transverse-field quantum Ising model. For this system, we test kink statistics in a D-Wave machine and show that the study of the kink number distribution can be used to benchmark the performance of a quantum processor.

3:42PM P08.00007: Simulations of the Ising Model on a Shastry-Sutherland Lattice by Quantum Annealing* PAUL KAIRYS (Presenter), University of Tennessee, Knoxville, KELLY BOOTHBY, ISIL OZFIDAN, JACK RAYMOND, ANDREW D KING, D-Wave Systems, Inc., ARNAB BANERJEE, TRAVIS HUMBLE, Oak Ridge National Laboratory — The Ising Hamiltonian offers a versatile model for studying the microscopic behavior of several material systems. We study an Ising Hamiltonian on a geometrically-frustrated Shastry-Sutherland lattice, which has been used to explain the magnetic properties of the rare-earth tetraborides. Variants of this model can produce a complex phase diagram with emergent fractional magnetization plateaus. We present a novel embedding of the lattice into the D-Wave 2000Q processor and use forward and reverse annealing to compute the phase diagram and probe the magnetization plateaus in the classical limit of zero transverse field. Empirical results enable us to calculate the static structure factor in the different phases and critical regimes opening opportunities for direct comparisons to reciprocal-space experimental techniques. Using quantum Monte-Carlo calculations to validate our results, this work indicates that quantum annealing provides a versatile method of material simulation that can accelerate scientific discovery.

3:54PM P08.00008: Excited-state search by quantum annealing toward quantum chemistry calculations* YUYA SEKI (Presenter), YUICHIRO MATSUZAKI, SHIRO KAWABATA, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science & Technology (AIST) — We report two methods to obtain an excited state of a spin-1/2 system using quantum annealing (QA) and adiabatic quantum computation (AQC), and evaluate their performance based on the fidelity of the output states. Although QA and AQC has been developed to search ground states of Ising Hamiltonians, excited state is also required when we analyze quantum systems such as electrons in molecules. We propose two methods to obtain the excited states: methods using non-adiabatic transition and adiabatic transition. It is unclear which method is better under noisy environment. In order to compare the methods, we numerically solved the Lindblad master equation for a certain simple model, and compared their fidelity of output states. As a result, we found that the output of method using adiabatic transition was as high fidelity as the other even when the problem seemed to be difficult for the adiabatic method.

**4:06PM P08.00009: Isomer Search on the D-Wave Quantum Annealer**

*SUSAN MNISZEWSKI (Presenter), Los Alamos National Laboratory, JASON TERRY, University of Georgia, PROSPER AKROBOTU, University of Texas at Dallas, CHRISTIAN F. A. NEGRE, Los Alamos National Laboratory — Isomer search or molecule enumeration refers to the problem of finding all the isomers for a given molecule. Many classical search methods have been developed in order to tackle this problem. However, the availability of quantum computing architectures has given us the opportunity to address this problem with new (quantum) techniques. This paper describes a procedure for determining all the structural isomers of alkanes. We first formulate the problem as a quadratic unconstrained binary optimization (QUBO) problem. We use the D-Wave quantum annealer to enumerate all structural isomers of all alkanes with fewer carbon atoms (n < 10) than Decane (C10H22). The number of isomer solutions increases with the number of carbon atoms. We find that the sampling time needed to identify all solutions scales linearly with the number of carbon atoms in the alkane. We probe the problem further by employing reverse annealing as well as a perturbed QUBO Hamiltonian and find that the combination of these two methods significantly reduces the number of samples required to find all isomers.

*This research has been funded by Los Alamos National Laboratory (LANL) Laboratory Directed Research and Development (LDRD). And additionally by the National Science Foundation (NSF).*

**4:18PM P08.00010: Exploring phase transitions in a quantum dimer using a quantum annealer**

*BIBEK POKHAREL (Presenter), Univ of Southern California, KABUKI TAKADA, HIDETOSHI NISHIMORI, Tokyo Institute of Technology, DANIEL A LIDAR, Univ of Southern California — It is well known that problems with exponentially decreasing gaps can cause adiabatic quantum computation (AQC) to fail. However, this does not imply that open-system quantum annealing (QA) will also fail for these problems. We consider an archetypical problem that is classically trivial, but difficult for AQC: an Ising ladder exhibiting a first-order phase transition with an exponentially closing gap, and a second-order phase transition with a polynomially closing gap. We investigate the performance of QA at these quantum phase transitions/ gap scalings theoretically using open quantum systems theory and experimentally using the D-Wave quantum annealer.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.*
4:30PM P08.00011: Solving the Graph Isomorphism Problem on a Quantum Annealer* ZOE GONZALEZ IZQUIERDO (Presenter), ITAY HEN, Univ of Southern California, RUILIN ZHOU, Northwestern University — The Graph Isomorphism (GI) problem—the task of deciding whether two graphs are isomorphic—has garnered considerable interest both for its wide range of applications in industry and for its particular computational complexity. One possible approach is measuring certain graph invariants—quantities that remain unchanged under vertex relabeling. While a complete graph invariant that would unequivocally distinguish non-isomorphic graphs is yet unknown, the energy spectrum of the quantum Ising Hamiltonian is a possible candidate. This is the Hamiltonian implemented by commercially available quantum annealers, making quantum annealing a natural tool for solving certain hard instances of the GI problem. Following the lead of previous work, we use a D-Wave quantum annealer to distinguish between pairs of graphs with the same classical Ising spectrum by gathering statistics on the energy and other observables. We show that introducing a pause at intermediate points in the anneal yields clearly different results for graphs that had previously been undistinguishable using standard annealing schedules.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050.

4:42PM P08.00012: Optimizing annealing parameters using genetic algorithms* SAMUEL STROMSWOLD (Presenter), QuAIL, NASA Ames Research Center, FILIP WUDARSKI, USRA - Univ Space Rsch Assoc, ELEANOR RIEFFEL, QuAIL, NASA Ames Research Center — Quantum annealing is an emerging technology that has the potential to be useful for solving combinatorial optimization problems such as maximum satisfiability. Prior work showed that annealing times [1] and inclusion of pauses [2] can significantly impact the probability of obtaining exact solutions. Less is known about leveraging other parameters such as flux biases implemented on the most recent D-Wave 2000Q annealer. We seek to bridge this gap by using genetic algorithms to select parameters. We explore various statistical measures, such as stochastic for ranking settings. Evaluations are performed using the Ames Research Center annealer.

4:54PM P08.00013: Quantum annealing applied to ionic diffusion analysis  KEISHU UCHIMURA, School of Materials Science, JAIST, TOM ICHIBHA, Physical Sciences Directorate, Oakridge National Laboratory, KOUSUKE NAKANO, Condensed matter theory, SISSA, KENTA HONGO, Research Center for Advanced Computing Infrastructure, JAIST, RYO MAEZONO (Presenter), School of Information Science, JAIST — We applied the quantum annealing framework to a problem of ionic diffusions in solids. The problem has been one of the important issues both in scientific and industrial sense in the field of materials science, which originally attracted interests in the microscopic analysis of mechanical strengths but is recently getting more active in exploring better batteries because the ionic diffusions as the charge carriers affect the efficiency in the solid electrolytes. We developed a scheme to formulate the problem in terms of the mapping into a quantum spin systems described by the Ising Hamiltonian. A key quantity to describe the diffusion can be evaluated from the output of annealing simulations, which has been quite difficult to be obtained by classical counterparts.

5:06PM P08.00014: Experimentally Testing Quantum Critical Dynamics Beyond the Kibble-Zurek Mechanism*  FERNANDO GOMEZ-RUIZ (Presenter), Physics, Donostia International Physics Center, JIN MING CUI, YUN-FENG HUANG, CHUAN-FENG LI, GUANG-CAN GUO, CAS Key Laboratory of Quantum Information, University of Science and Technology of China, ADOLFO DEL CAMPO, Physics, Donostia International Physics Center — We experimentally verify the distribution of kink pairs resulting from driving a one-dimensional quantum Ising chain through the paramagnet-ferromagnet quantum phase transition, using a single trapped ion as a quantum simulator in momentum space. The number of kink pairs after the transition follows a Poisson binomial distribution, in which all cumulants scale with a universal power-law as a function of the quench time in which the transition is crossed. We experimentally verified this scaling for the first cumulants and report deviations due to noise-induced dephasing of the trapped ion. Our results establish that the universal character of the critical dynamics can be extended beyond the paradigmatic Kibble-Zurek mechanism, which accounts for the mean kink number, to characterize the full probability distribution of topological defects.

5:18PM P08.00015: Quantum Simulations of Superconducting Flux Circuits* THOMAS HALVERSON (Presenter), Information Sciences Institute, University of Southern California, LALIT GUPTA, Department of Physics, University of Southern California, MOSHE GOLDSTEIN, School of Physics and Astronomy, Tel Aviv University, ITAY HEN, Information Sciences Institute, University of Southern California — One of the main avenues being explored as of late to obtain quantum speedups by annealing is that of quantum simulations, wherein one performs measurements mid-anneal. To that aim, there is a tremendous ongoing effort to fabricate superconducting flux circuits which are non-stoquastic in their qubit representation. Because of this these circuits are thought to be “unsimulatable” by classical approaches such as quantum Monte Carlo; however, we present the results of a study which aims to simulate the circuit Hamiltonian directly by utilizing an infinite Hilbert representation that is, in fact, stoquastic. Our approach obviates the reduction to a qubit representation and produces results that we feel are more in spirit with the experiential setup.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P09 DQI: Quantum Foundations II 106 - Mark Wilde, Louisiana State University, Baton Rouge - Tag(s): Focus

2:30PM P09.00001: Objectivity In Different Quantum Reference Frames* THAO LE (Presenter), University College London, PIOTR MIRONOWICZ, PAWEL HORODECKI, International Centre for Theory of Quantum Technologies, University of Gdansk — Quantum Darwinism and its frameworks describe objectivity of quantum systems via their information in the environment. However, the observation of these environments must be done with respect to a frame of reference. Given so, is objectivity consistent across different reference frames? Here, we take the quantum reference frame structure of [1] and consider the scenario where system and environment are static particles distributed across space. In this prescription, entanglement and coherence are interchangeable frame-dependent properties, and statistical mixedness and classical correlations are equivalently interchangeable. We find that the consistency of objectivity depends on the distinguishability of states in all relevant quantum reference frames, which in turn depends on non-degenerate relative separations, sharp localisation, and sufficiently large macro-fractions.

2:42PM P09.00002: The Nakano-Nishijima-Gell-Mann Formula From Galois Fields

SATOSHI TANDA (Presenter), TOMOO OHAGA, KEIJI NAKATSUGAWA, Applied Physics, Hokkaido University, TOSHIYUKI FUJII, Physics, Asahikawa Medical University, TOYOKI MATSUYAMA, Physics, Nara University of Education — If world has a finite compact space (\(I_{120}\): Poincare Dodecahedron) [1] and discrete coordinates [2,3], what happens? In this case, the problem of infinities in gravity and in the standard model might be avoided. To avoid this problem, quantum gravity theories such as the superstring theory or the loop quantum gravity are developing, but neither of those theories have been completed. We reconstruct the Nakano-Nishijima-Gell-Mann (NNG) formula by using a discrete Galois field without using continuous coordinate. When we reconstruct new theories with a Galois field, these new theories must satisfy fundamental conservation law related to unitary, Lorentz, and gauge invariance. Here, we reexamine previous model [2] using isospin \(I_z\). Consequently, instead of the NNG formula, we obtained the alternate formula \(Q = 2(n + I_z)\), where \(Q\) is charge number and \(n\) is multi-valuedness in Galois field. These results may be a starting point to develop a theory without many problems of infinity.

2:54PM P09.00003: Quantum Fields from Quantum Cellular Automata? A No-Go Theorem and a Path Forward

TODD BRUN (Presenter), LEONARD MLODINOW, Univ of Southern California — A quantum walk (QW) is a unitary analogue of a classical random walk, and a quantum cellular automaton (QCA) is a unitary analogue of a classical cellular automaton. QWs can be treated as the one-particle sector of a QCA. Since quantum walks on the body-centered cubic lattice give rise to relativistic wave equations in the long wavelength limit, it is natural to seek for QCAs that give rise to quantum field theories in a similar limit. We show that this can be done in one spatial dimension, with the QCA being naturally described in terms of creation and annihilation operators that create or destroy particle locally, evolve straightforwardly under the QCA unitary, and obey the usual anticommutation relations (ACR). However, generalizing this construction to two or more spatial dimensions fails: the requirements on the creation and annihilation operators are inconsistent with a local QCA. For a QCA to give rise to a quantum field theory in the long-wavelength limit, one must give up at least one of the desired properties. A likely choice is to give up the requirement that the creation and annihilation operators create and destroy localized states.
**3:06PM P09.00004: Quantum mechanics and the covariance of physical laws in quantum reference frames** [invited] FLAMINIA GIACOMINI (Presenter), Perimeter Inst for Theo Phys — In physics, every observation is made with respect to a frame of reference. Although reference frames are usually not considered as degrees of freedom, in all practical situations it is a physical system which constitutes a reference frame. Can a quantum system be considered as a reference frame and, if so, which description would it give of the world? In my talk, I will introduce a general method to quantise reference frame transformations, which generalises the usual reference frame transformation to a “superposition of coordinate transformations”. With this method, it is possible to describe states, measurement, and dynamical evolution in different quantum reference frames, without appealing to an external, absolute reference frame, and find that entanglement and superposition are frame-dependent features. The transformation also leads to a generalisation of the notion of covariance of dynamical physical laws, and to the possibility of defining the rest frame of a quantum system. This last feature allows us to find an operational definition of the relativistic spin of a Dirac particle, and to devise a "relativistic Stern-Gerlach experiment".

**3:42PM P09.00005: Quantum Mechanics of a Single Photon and the question of its Localizability in Space** HASSAN BABAEI (Presenter), Department of Physics, Univ of Illinois - Chicago, ALI MOSTAFAZADEH, Department of Mathematics and Physics, Koç University — We use the dynamical Maxwell equations to determine the space of state vectors of a single photon. We endow this space with a relativistically invariant positive-definite inner product to make it into a Hilbert space. We identify the Hamiltonian operator with the generator of time translations, construct momentum and helicity operators, and introduce a chirality (direction-of-time) operator. Next, we construct a position operator that has commuting components. These also commute with the helicity and chirality operators. We obtain the eigenstates of the position operator, which we identify with the localized states of the photon, and use them to determine photon's position wave function. The position wave function for the localized states has a delta-function singularity at a single point in space, but their electromagnetic fields diverge on a particular plane containing this point. This behavior turns out to be related to an implicit freedom in the choice of the position operator. Each choice for the position operator determines the plane at which the electromagnetic fields of a given localized state diverge.
**3:54PM P09.00006: Quantized Electromagnetic-Field Propagation in a General Non-Local and Non-Stationary Dispersive and Absorbing Medium**

VERNE JACOBS (Presenter), United States Naval Research Laboratory — We develop dynamical descriptions for the propagation of quantized electromagnetic fields, in the presence of environmental interactions. These descriptions are systematically and self-consistently developed in the complimentary Schrödinger and Heisenberg pictures. An open-systems (non-equilibrium) quantum-electrodynamics and quantum-statistical description is thereby provided for electromagnetic-field propagation in a general non-local and non-stationary dispersive and absorbing optical medium, including a fundamental microscopic treatment of decoherence and relaxation processes due to environmental collisional and electromagnetic interactions. Particular interest is centered on entangled states and other non-classical states of electromagnetic fields, which may be created by non-linear electromagnetic interactions and detected by the measurement of various electromagnetic-field correlation functions. Accordingly, we develop dynamical descriptions based on general forms of electromagnetic-field correlation functions involving both the electric-field and the magnetic-field components of the electromagnetic field, which are treated on an equal footing.

*Work supported by the Office of Naval Research through the Basic Research Program at The Naval Research Laboratory.

**4:06PM P09.00007: Probability arises from entropy in axiomatic information thermodynamics [Invited]**

MICHAEL WESTMORELAND (Presenter), Denison University — Axiomatic information thermodynamics (Entropy 2018, 20(4), 237) is a formal mathematical system that describes thermodynamic processes including those in which information is acquired, transformed or discarded. A central concept in the theory is the "eidostate", which is a simple array of possible states, including both thermodynamic macrostates and information records. Well-motivated axioms lead to an entropy function that describes the irreversibility of eidostate processes, and this function in turn leads to a unique probability measure for the states and records in a uniform eidostate. Does this development shed light on the kinds of reasoning available to physical agents that observe and intervene in the quantum world?

**4:42PM P09.00008: Emergence of the Born rule in quantum optics**

MORGAN WILLIAMSON (Presenter), BRIAN LA COUR, University of Texas at Austin — The Born rule provides a fundamental connection between theory and observation in quantum mechanics, yet its origin remains a mystery. We consider this problem within the context of quantum optics using only classical physics and the assumption of a quantum electrodynamic vacuum that is real rather than virtual. The connection to observation is made via classical intensity threshold detectors that are used as a simple, deterministic model of single-photon detection. By following standard experimental conventions of data analysis on discrete detection events, it can be shown that this model is capable of reproducing several observed phenomena thought to be uniquely quantum in nature.

*This work was supported by the Office of Naval Research under Grant No. N00014-14-1-2107.
Interaction-Free Energy Transfer  MORDECAI WAEGELL (Presenter), Institute for Quantum Studies, Chapman University, CYRIL ELOUARD, University of Rochester, BENJAMIN HUARD, Physics, Ecole Normale Superieure, ANDREW N JORDAN, University of Rochester — The interaction-free measurement scheme of Elitzur and Vaidman enables a probe particle to detect the presence of an object blocking one arm of a Mach-Zender (MZ) interferometer without the probe ever locally interacting with that object. THE MZ is tuned so that without the block, the dark port detector never fires. The presence of the block changes the interference pattern in the MZ, allowing the dark port to fire, in which case the block is detected while the probe traveled the unblocked arm. We consider a quantum block in the ground state of a confining potential, a superposition of inside and outside one arm of the MZ. When the dark port detector fires, the quantum block is localized inside the arm, which increases its energy. This energy is delivered by the probe even though it traveled the unblocked arm to reach the dark port, and we thus obtain interaction-free energy transfer. This effect obtains even though the coupling Hamiltonian is local.

Diffraction-based Interaction-Free Measurements*  SPENCER ROGERS (Presenter), University of Rochester, YAKIR AHARONOV, Chapman University, CYRIL ELOUARD, ANDREW N JORDAN, University of Rochester — We consider the problem of determining if a single-slit contains a bomb in its middle region using a single photon test. We notice that the quantum case allows the bomb to significantly increase the probability for the photon to reach certain detection positions, in particular the dark bands of the single-slit pattern. The bomb's presence can be inferred without exploding it when the photon lands at one of these positions. We thus find a diffractive extension to the interaction-free measurement protocol of Elitzur and Vaidman. In addition, we consider the role of time in interaction-free measurements. We find that, if the bomb is thought of as a measuring device which checks periodically if the photon is in its space, then it can only find the particle (and "explode") if its measurement rate is finite. The alternative is the Zeno limit, where the bomb acts like an infinite potential barrier. Critics of interaction-free measurement may find it interesting that the normal, non-Zeno bomb can be passed through without setting it off.

Quantum mysteries for anybody: Solved  WILLIAM STUCKEY (Presenter), Physics, Elizabethtown College — In 1981, Mermin published a now famous paper titled, "Bringing home the atomic world: Quantum mysteries for anybody." Therein, he presented the 'Mermin device' that illustrates the conundrum of entanglement per the spin singlet state for the "general reader." He then challenged the "physicist reader" to explain the way the device works "in terms meaningful to a general reader struggling with the dilemma raised by the device." I will show how conservation per no preferred reference frame (NPRF) answers that challenge, but still leaves a mystery for those who seek dynamical explanation via hidden variables or 'causal influences'. Since NPRF also underwrites the postulates of special relativity, we see a common theme between relativistic and non-relativistic modern physics.
Session P15 DFD DSOFT: Drop II 210/212 - Daphne Klotsa, University of North Carolina at Chapel Hill

2:30PM P15.00001: Microfluidics platform for generation of microparticles and capsules through Electrohydrodynamics  DANISH EQBAL, VENKAT GUNDABALA (Presenter), chemical engineering, Indian Institute of Technology Bombay — In this work we present a microfluidics based implementation of electrohydrodynamics for generation microparticles and capsules. Electric fields are applied through a novel interface-crossing of the precursor single and double emulsion droplet. The particles are alginate based and the capsules have oil core with alginate shell. The particle and capsule sizes were investigated as functions of the applied electric field strength, when the droplet generation happened in the electrodripping mode. It was observed that the obtained particle/capsule sizes were much lower than non-EHD methods and the monodispersity is much better than external EHD approaches. Thus we show an efficient approach that couples EHD with microfluidics to generate uniformly sized microparticles and microcapsules.

3:06PM P15.00002: Numerical Modeling of In-Situ Curing of a Photopolymerizing and Spreading Drop with Applications in 3D-Printing*  SIDDHARTHA DAS (Presenter), VISHAL SIVASANKAR, HARNOOR SACHAR, SHAYANDEV SINHA, University of Maryland, College Park, DANIEL HINES, Laboratory for Physical Sciences — The key to understand droplet-based direct writing (DW) printing processes like Aerosol Jet Printing (AJP), Ink-jet printing, syringe printing, etc. is to quantify the behavior of ink droplets during deposition. For instance, the resolution of the print depends on minimum drop radius and also to the extent of the droplet spread (spreading radius). In this study, we investigate the spreading behavior of a polymer drop in conditions similar to that of the Aerosol Jet Printing (AJP) process. Here, the drop is undergoing simultaneous spreading and photopolymerization with timescales of \( \tau_s \) and \( \tau_p \) respectively. We conduct a comparative study of the droplet behavior for two cases, \( \tau_s \ll \tau_p \), where the spreading is much faster than polymerization and \( \tau_s \sim \tau_p \), where the spreading and polymerization have similar timescales. Droplet spreading is unaffected by the polymerization process in the former case. However, in the latter case the spreading of the droplet is hindered by the polymerization process due to a tremendous increase in viscosity. We further study this complex thermo-fluid-solutal dynamics by comparing the time dependent curing profiles for the two cases.

*NextFlex Consortium, Laboratory for Physical Sciences
3:18PM P15.00003: A Comparative Study of the Pattern Formation in the Drying Protein Droplets suspended in the De-ionized water ANUSUYA PAL (Presenter), GERMANO S IANNACCHIONE, Worcester Polytech Inst — Pattern formation in drying bio-relevant systems continues to attract major attention of the researchers because of its medical applications. Here, an extensive description of drying evolution and the final patterns are presented, highlighting the concentration dependence (from 1 to 13 wt%) on two globular proteins, lysozyme (Lys) and bovine serum albumin (BSA) prepared in de-ionized water. The drying process starts with a constant contact radius mode and shifts to a mixed-mode where both contact radius and contact angle changes. The contact angle decreases monotonically, whereas, the contact radius exhibits two regimes: an initial linear, and a later non-linear regime. Unlike linear regime, the non-linear regime is faster for Lys droplets. This results in the formation of a `mound'-like structure and a new feature, a `dimple' is observed in this structure and found to be influenced by the initial concentration. The cracks which are only seen near the edge of BSA droplets, are spread throughout Lys droplets. In particular, Lys shows a hierarchy from delaminated to spiral cracks, and the spirals obey the well-known logarithmic equations. The mean crack spacing is found to be smaller than BSA droplets, and finally, these patterns are interpreted using a mechanical shear mechanism.

3:30PM P15.00004: Flow of Emulsions with Insoluble Surfactant through Porous Media JACOB GISSINGER (Presenter), ALEXANDER Z ZINCHENKO, ROBERT H DAVIS, Chemical and Biological Engineering, University of Colorado Boulder — While our understanding of surfactants' effect on single-drop dynamics has recently been improving, the general rheology of confined and contaminated emulsions remains less characterized. In particular, complex multiscale behavior results when the drop size is larger than granular interstices. In such cases, the emulsion cannot be treated as a single phase and a droplet-resolved model is required. A pressure-driven, concentrated emulsion flowing through a packed bed of spheres is modeled using a three-dimensional boundary-integral algorithm. The emulsion is initially monodisperse and uniformly coated with surfactant, and subsequently advected using a recently-developed robust algorithm for insoluble surfactant transport, with added options for complex equations of state as well as drop breakup. The ensemble-averaged permeabilities of the drop and continuous phases are studied versus degree of contamination and capillary number, with an emphasis on the effect of surfactant on the droplet-breakup cascade. The possibility of daughter drops having a significantly different surfactant concentration, and therefore capillary number, compared to the original drops results in particularly rich local and global dynamics.
MARINA MACHADO DE OLIVEIRA, Chemical Engineering, University of Wyoming, JOSEPH R MURPHY, Physics, University of Wyoming, JOHN ACKERMAN, Chemical Engineering, University of Wyoming, WILLIAM RICE, Physics, University of Wyoming, VLADIMIR ALVARADO (Presenter), Chemical Engineering, University of Wyoming — Ice adhesion measurements for impact ice are critical for solving important aerospace challenges. Previous measurements have shown that the ice adhesion on surfaces of apparently identical materials differ significantly under similar measuring conditions. This striking observation indicates that surface properties, e.g. roughness, may significantly affect ice formation and its adhesion response. Roughness properties can regulate the water-air-substrate contact-line dynamics. In this work, we focus on water-air contact angle hysteresis on metal substrates of interest, e.g. aluminum, using a pendant-drop system over a frequency range 0.1-10 Hz. Surface roughness of metal substrates is measured using confocal microscope profilometry. To establish a quantitative correlation between roughness and contact angle hysteresis, we analyzed the spatial roughness correlation function, including its angular dependency. Contact angle hysteresis results reveal a weak dependency on frequency, but a strong function on anisotropy, spatial correlation and surface roughness. The effect depends highly on drop size, which might explain differences in ice accretion under atmospheric conditions.

*We acknowledge funding support from NASA Grant WY-80NSS17M0049

GESSE ROURE (Presenter), ROBERT H DAVIS, Department of Chemical and Biological Engineering, University of Colorado, Boulder — The method of froth flotation by small air bubbles has been traditionally used in industry to capture fine minerals and other hydrophobic particles. This method, however, has shown to not be efficient for capturing smaller particles. The present work is motivated by a new agglomeration method proposed to overcome this lack of efficiency. It consists of mixing a particle suspension and saltwater-filled droplets covered with semi-permeable oil layers. The present work investigates the two-particle dynamics of a solid particle and an expanding semi-permeable spherical drop in an external pure extensional flow field. The computational results from the numerical integration determine a collision efficiency, which describes the influence of hydrodynamic interactions and osmotic flow on particle capture. An engulfment parameter measures the relative effects of droplet growth and convective flow.
Experiments in liquid-spray physics  
GARY LAPHAM (Presenter), Mathematics, Maine Maritime Academy, JOHN MCHUGH, Mechanical Engineering, University of New Hampshire — Waves on the ocean surface interacting with solid objects create complex and visually spectacular patterns of spray. The solid object can be a breakwater, drilling rig, or a ship. Another spray-related case is the presence of large industrial tanks of liquid, and often dangerous liquids, that exist throughout the world. These tanks are becoming obsolete in great numbers. When such tanks burst it is often catastrophic. Recent experience has shown, that when such tanks burst, the resulting spray may shoot several hundreds of meters from the tank —distances that are not readily explained. These tanks often have a wall or dam (containment barrier) surrounding them in an attempt to contain a violent breach or leakage. When the tank bursts it is akin to the dam-break problem. A wall of water rushes forth and impinges on the barrier creating spray. Previous experiments (McHugh and Watt, 1998) considered the related configuration of a solitary wave impinging on a vertical wall. Present experiments discussed will include tank experiments that more closely model the bursting tank case and smaller-scale experiments that attempt to identify some of the fundamental mechanisms of spray formation.

The Cheerios Effect under a thin elastic film  
CARMEN LEE (Presenter), ABIGAIL BULLER, KARI DALNOKI-VERESS, McMaster Univ — An air bubble placed in a liquid bath will rise through the bath until it reaches the liquid-air interface. The surface tension of the interface will keep the bubble from escaping into the air, but the bubble will in turn deform the flat interface. An equilibrium is reached between the buoyant force of the bubble and the surface tension of the liquid. Furthermore, an air bubble will move along the interface to reach a minimum in potential energy, in this case, the maximum height. Two bubbles in proximity to each other will attract each other due to the surface deformation from the other bubble. This mechanism is analogous to the famous Cheerios effect. Here, we examine the effect of replacing the liquid-air interface with a thin, elastic film. By floating a thin film onto the surface of a clean water bath, we can precisely place two monodisperse air bubbles below and observe the attraction between the bubbles, while altering the interface. We examine the effect of the thin film on the equilibrium position of the bubble as well as the attractive force between the two bubbles and present a theoretical model.
4:30PM P15.00009: Stability limit of electrified droplets and bubbles* JUSTIN BEROZ
(Presenter), JOHN HART, JOHN W M BUSH, Massachusetts Institute of Technology MIT — In many physical processes, including cloud electrification, electrospray and electrocoalescence, droplets and bubbles are exposed to electric fields and may either remain whole or burst in response to electrical stresses. Determining the stability limit of a droplet exposed to an external electric field has been a century-long mathematical challenge, and the only analytical treatment to date is an approximate calculation for a free-floating droplet. In this talk, we demonstrate, experimentally and theoretically, that the stability limit of a conducting droplet exposed to an external electric field is described by a power law with broad generality that applies to the cases in which the droplet is pinned or sliding on a conducting surface or free floating. The power law is simply derivable by the variational principle, provided the physical quantities defining the instability are selected to be independent of an arbitrary variation of the system. Practically, our finding provides a simple formula that captures the parameter range of bubbles and droplets that can be supported on electrified surfaces.

*Financial support provided by grants from BAE Systems, MIT Deshpande Center, MIT Lincoln Laboratory (FA8721-05-C-0002) and NSF (CMMI-1346638 to A.J.H., CMMI- 1727565 to J.W.M.B.)

4:42PM P15.00010: Superpropulsion of liquid droplets in sharpshooter insects* ELIO CHALLITA (Presenter), RAGHAV ACHARYA, Georgia Institute of Technology, RODRIGO KRUGNER, United States Department of Agriculture, SAAD BHAMLA, Georgia Institute of Technology — Sharpshooters are plant-sucking agricultural pests that constantly discharge large quantities of discrete water-based droplet excreta while feeding on plant’s xylem. Owing to a catapult-like mechanism powered by a biological spring located at their anal stylus, sharpshooters are able to blast away discrete droplet excrements at high accelerations reaching 200 m/s². Here, we unravel the propulsion mechanism exploited by sharpshooters that enables them to optimize the droplet ejection kinematics. Unlike the take-off speed of a rigid projectile that is set by maximum speed of the launching spring, we find that the elastic liquid droplets in sharpshooters can achieve take-off velocities that are up 3X faster than the underlying spring. This ‘superpropulsion’ behavior reveals that the frequency of the insect stylus is tightly tuned to the Rayleigh frequency of droplets \( f_0 \sim R^{-3/2} \), providing insight into the physical limits on the maximum size and speed droplets in these extraordinary insects.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P16 DQI: Multi-mode and 3D-Cavity Circuit QED Systems I Bruno Taketani, Univ Federal de Santa Catarina
SOPHIA SOSNINA (Presenter), JAMES WILLS, SIMONE D FASCIATI, SALHA JEBARI, GIULIO CAMPANARO, SHUXIANG CAO, PETER SPRING, TAKAHIRO TSUNODA, IAN YANG, PETER J LEEK, BRIAN VLASTAKIS, University of Oxford — Alternative qubit design is an active field of research in superconducting quantum systems. In particular, multi-mode quantum circuits can allow error-protected subspaces, nonlinear coupling for multi-qubit operations, and additional mechanisms for state readout or control. In this talk we introduce a simple multi-mode coaxial transmon qubit - a two-mode qubit with a dipole-like differential mode and a coaxial common mode. We discuss the qubit Hamiltonian, analyze its sensitivity to fabrication imperfections, and discuss the effects of quasi-particle tunnelling in this system. Finally, we consider extensions of the design to multi-qubit settings.

*This work was supported by the EPSRC, Oxford Quantum Circuits Ltd, and from the European Union's Horizon 2020 research and innovation programme under grant agreement MSCA-IF-EF-ST 832814.

JAMES WILLS (Presenter), SOPHIA SOSNINA, SIMONE D FASCIATI, SALHA JEBARI, GIULIO CAMPANARO, SHUXIANG CAO, PETER SPRING, TAKAHIRO TSUNODA, IAN YANG, PETER J LEEK, BRIAN VLASTAKIS, University of Oxford — We discuss experimental results on a multi-mode qubit operating within a coaxial circuit QED architecture. This device includes a two-mode coaxial transmon qubit with out-of-plane coupling to a coaxial LC resonator. We discuss the characterisation of devices using two-tone spectroscopy and coherence measurements. We observe a strong cross-Kerr coupling between the differential and common modes of the qubit, which results in a qutrit-like behavior. Finally, we investigate charge sensitivity in such a device, and discuss its potential as a novel probe of charge fluctuations in superconducting quantum systems.

*This work was supported by the EPSRC, Oxford Quantum Circuits Ltd, and from the European Union's Horizon 2020 research and innovation programme under grant agreement MSCA-IF-EF-ST 832814.
2:54PM P16.00003: Chiral cavity quantum electrodynamics in a 3D microwave lattice
coupled to a transmon qubit (Part 1)*  MARGARET PANETTA (Presenter), University of Chicago,
CLAI OWENS, California Institute of Technology, SRIVATSAN CHAKRAM, BRENDAN SAXBERG,
GABRIELLE ROBERTS, University of Chicago, RUICHAO MA, Purdue University, JONATHAN SIMON,
DAVID I SCHUSTER, University of Chicago — Recent advancements in the ability to create and
manipulate superconducting quantum systems have created an exciting opportunity to construct
from the ground up quantum materials tailored to host rich interactions. We have designed a
two-dimensional meta-material in which microwave photons inhabiting a lattice of
superconducting 3D microwave cavities interact strongly with ferrimagnets, realizing a quarter-
flux Hofstadter model for light. We perform state tomography on the lattice and demonstrate
chiral, time-reversal symmetry broken edge transport with lifetimes ~1000 times larger than the
site to site tunneling rate. This is the first photonic topological lattice platform compatible with
strong interactions. We have coupled a single transmon qubit to this lattice, enabling this
platform to study chiral cavity quantum electrodynamics. Here we discuss the design and testing
of this system and describe prospects for its application.

*This work was supported by the Chicago MRSEC, which is funded by NSF through grant DMR-
1420709; and by ARO Grant No. W911NF-15-1-0397. It was also based on work supported by the

DGE-1746045.

3:06PM P16.00004: Chiral cavity quantum electrodynamics in a 3D microwave lattice
coupled to a transmon qubit (Part 2)*  CLAI OWENS (Presenter), Applied Physics, California Institute
of Technology, MARGARET PANETTA, SRIVATSAN CHAKRAM, BRENDAN SAXBERG, GABRIELLE
ROBERTS, JONATHAN SIMON, DAVID I SCHUSTER, Physics, University of Chicago — We have
previously realized a chiral meta-material for microwave photons. We now describe our
work combining a single transmon with this topological lattice, achieving, for the first
time, a platform for chiral cavity quantum electrodynamics. We show strong coupling
between the qubit and the topological lattice. Using the qubit we prepare arbitrary
quantum states of the lattice edge modes and we can non-destructively measure their
photon occupation. Finally, we describe a path towards coupling a transmon to each site
of the lattice, enabling exploration of a Harper-Hubbard model which is anticipated to
support fractional Chern insulating many-body phases.

*This work was supported by the Chicago MRSEC, which is funded by NSF through grant
DMR-1420709; and by ARO Grant No. W911NF-15-1-0397. It was also based on work
supported by the National Science Foundation Graduate Research Fellowship under Grant
Nos. DGE-1144082 and DGE-1746045.
3:18PM P16.00005: Driving a Dark State Qubit in 3D Waveguide QED* MAXIMILIAN ZANNER (Presenter), CHRISTIAN M. F. SCHNEIDER, Univ of Innsbruck, MATHIEU L. JUAN, OSCAR GARGIULO, IQOQI, Austrian Academy of Sciences, STEFAN OLESCHKO, Univ of Innsbruck, ALEKSEI SHARAFIEV, IQOQI, Austrian Academy of Sciences, GERHARD KIRCHMAIR, Univ of Innsbruck — The collective behavior of coupled qubits in a waveguide leads to sub-radiant and superradiant states. This effect was extensively studied theoretically and experimentally over the last decade. The appearing dark states can be used to generate an effective two level system that has longer coherence times than a single qubit in the same physical configuration. We engineered a system that creates subradiant and superradiant states by using a direct dipole-dipole, as well as a waveguide-mediated interaction. We show experimentally that this two-qubit dark-state can be used as a qubit state even though it is embedded in an open system. Furthermore, we use the bright state to read out the qubit encoded in the dark state.

*FWF, ÖAW, ERC, DK ALM

3:30PM P16.00006: Universal control of superconducting cavities with weak nonlinearity* ALEC EICKBUSCH (Presenter), SALVATORE S ELDER, Yale University, PHILLIPE CAMPAGNE-IBARCQ, QUANTIC Team, INRIA Paris, ZHENGHAO DING, SHANTANU JHA, NICHOLAS FRATTINI, CHRISTA FLÜHMANN, LUIGI FRUNZIO, ROBERT SCHOELKOPF, MICHEL H. DEVORET, Yale University — In superconducting cavities, fast universal control usually requires an inherited Kerr nonlinearity on the order of a few kHz. However, in many bosonic quantum error correction codes, such nonlinearities corrupt encoded information, causing errors. Recently, we have engineered an effective quadrature coupling between a cavity and an ancillary qubit based on an arbitrarily weak native dispersive interaction through the use of large phase space displacements. In this talk, we extend the idea of using large displacements in a cavity's phase space to perform universal control of a superconducting cavity with Kerr nonlinearity on the order of 1 Hz. This control will pave the way toward more sophisticated quantum error correction protocols applied to nearly linear bosonic systems.

3:42PM P16.00007: Entangling Bosonic Modes via an Engineered Exchange Interaction*

[Invited] YVONNE GAO (Presenter), Natl Univ of Singapore, BRIAN LESTER, MICHEL H. DEVORET, LUIGI FRUNZIO, LIANG JIANG, STEVEN GIRVIN, ROBERT SCHOELKOPF, Yale University — The realization of robust universal quantum computation with any platform ultimately requires both the coherent storage of quantum information and (at least) one entangling operation between individual elements. The use of continuous-variable bosonic modes as the quantum element is a promising route to preserve the coherence of quantum information against naturally-occurring errors. However, operations between bosonic modes can be challenging. In analogy to the exchange interaction between discrete-variable spin systems, the exponential-SWAP unitary can coherently transfer the states between two bosonic modes, regardless of the chosen encoding, realizing a deterministic entangling operation in a programmable fashion. Here, we develop an efficient circuit to implement this unitary and realize the operation in a three-dimensional circuit QED architecture. We demonstrate high-quality deterministic entanglement between two cavity modes with several different encodings. Our results provide a crucial primitive necessary for universal quantum computation using bosonic modes.

4:18PM P16.00008: The Kerr-cat qubit: efficient readout and two-qubit gates*

NICHOLAS FRATTINI (Presenter), ALEXANDER GRIMM, SHRUTI PURI, CHAN U LEI, Yale University, MAZYAR MIRRAHIMI, QUANTIC team, Inria Paris, MICHEL H. DEVORET, Yale University — Superpositions of two opposite-phase coherent states in an oscillator, so-called Schrödinger cat states, can encode a noise-biased qubit, meaning a qubit with a strong protection against one error channel. Such a protected "cat qubit" has the ability to significantly reduce the overhead associated with quantum error correction in, for instance, a surface-code-style architecture. This overhead reduction relies on the ability to perform all gates in a manner that preserves the noise bias. In this talk, we review our implementation for the Kerr-cat qubit, which is based on the interplay between two-photon driving and Kerr nonlinearity. This scheme is compatible with fast, high-fidelity single qubit gates and achieves a strong noise bias. We will report on experimental improvements, the efficiency of the quantum non-demolition (QND) readout of this qubit, and our progress towards the realization of a noise-biased CNOT gate between two such Kerr-cat qubits.

4:30PM P16.00009: Multiplexed photon number measurement of a cavity using the fluorescence of a coupled qubit. * ANTOINE ESSIG (Presenter), QUENTIN FICHEUX, PERONNIN THEAU, NATHANAEL PIERRE COTTET, Université Lyon, ENS de Lyon, Université Claude Bernard, CNRS, Laboratoire de Physique, F-69342 Lyon, France, RAPHAEL LESCANNE, Laboratoire Pierre Aigrain, Département de physique de l'ENS, Ecole normale supérieure, PSL Research University, Université Paris Diderot, Sorbonne Paris Cité, Sorbonne Univer, ALAIN SARLETTE, PIERRE ROUCHON, Centre Automatique et Systèmes, Mines ParisTech, PSL Research University, 60 Boulevard Saint-Michel, 75272 Paris Cedex 6, France, ZAKI LEGHTAS, Laboratoire Pierre Aigrain, Département de physique de l'ENS, Ecole normale supérieure, PSL Research University, Université Paris Diderot, Sorbonne Paris Cité, Sorbonne Univer, BENJAMIN HUARD, Université Lyon, ENS de Lyon, Université Claude Bernard, CNRS, Laboratoire de Physique, F-69342 Lyon, France — Measuring the photon number of an electromagnetic mode in a quantum nondemolition manner is instrumental to control the quantum state of a cavity, detect photon emission or measure work. In the microwave domain it can be done using the dispersive coupling between the cavity of interest and a coupled Rydberg atom or superconducting circuit. This method has been used successfully to count up to about a dozen photons, to realize Quantum Zeno dynamics experiments, or count photon number parity. Yet this technique has constraints on the measurement time. In particular it increases with the maximal number of photons. In this contribution, we present a technique that avoids this constraint by using the resonant fluorescence of a qubit coupled to the resonator of interest and a multiplexing measurement of the fluorescence field. We show an experiment where an independent quantum state tomography can be performed on the resonator to compare the result of the conventional method to this new technique.

*We thank MIT Lincoln labs that provided us a Traveling Wave Amplifier. The project was supported by the foundation Simone et Cino Del Duca.

4:42PM P16.00010: Full characterization and universal control of a superconducting 3D transmon qudit* XIAN WU (Presenter), LUIS MARTINEZ, YANIV J ROSEN, JONATHAN L. DUBOIS, Lawrence Livermore Natl Lab — While high fidelity single qubit and two-qubit gates have been realized for transmons, use of higher levels as a quantum resource has not yet been systematically studied. Coherent control of these higher energy states offers a direct route to increasing the available quantum volume of a given quantum circuit. In addition, the increasing charge dispersion present in higher level states offers a unique tool for studying charge noise. Here, we use the lowest four levels of a 3D transmon as the quantum register, qudit, which is computational equivalent to two qubits. We measure the decoherence times for each of the excited state. We also demonstrate multiplexing readout and universal control of the qudit with a single drive line.

4:54PM P16.00011: Advancements in 3D cavity fabrication and design for improved multimode quantum memories*  ANDREW ORIANI (Presenter), SRIVATSAN CHAKRAM, KEVIN HE, ALEXANDER ANFEROV, AKASH DIXIT, JOHN CLAI OWENS, DAVID I SCHUSTER, University of Chicago — Superconducting multimode cavities can provide a hardware efficient means for quantum information storage and processing. To increase mode density, reduce cross-talk, and increase gate fidelities, it is important to build cavities with tailored mode spacing and very long coherence times. In this talk we present advances in materials processing and design of 3D microwave resonators to increase mode lifetimes beyond that of state-of-the-art aluminum cavities. This includes moving to higher Tc superconductors and quantifying the efficacy of various surface treatment procedures in reducing dissipative loss mechanisms. In doing so we will present a pathway for developing these cavities into novel 3D multimode architectures for next-generation randomly accessible quantum memories and processors.

*This research was supported by Samsung Advanced Institute of Technology Global Research Partnership.

5:06PM P16.00012: Towards strong multi-mode coupling between a transmon and a metamaterial resonator  SAGAR INDRAJEET (Presenter), Syracuse University, HAOZHI WANG, Quantum Electromagnetics Division, University of Colorado Boulder, B.L.T. PLOURDE, Syracuse University, MATTHEW D. LAHAYE, United States Air Force Research Laboratory, Rome, NY, MATTHEW D HUTCHINGS, Syracuse University, BRUNO TAKETANI, Univ Federal de Santa Catarina, FRANK WILHELM, Saarland University — A high density of modes can be produced using metamaterial resonant structures made from arrays of lumped circuit elements, to which a flux-tunable transmon qubit can be coupled. For such a system, we have measured the coupling strength of the qubit to multiple modes by tuning the flux and observing the splitting in the transmission of each mode. In these initial measurements, the coupling strengths were larger than the individual mode linewidths, but did not exceed the inter-mode spacing. We discuss approaches to decrease the mode spacing in this system and simulate the spectrum numerically. In addition, we discuss techniques for increasing the coupling strength between these modes and the transmon qubit. For appropriate parameters, we show that it will be to possible to reach the regime where the qubit can be coupled to multiple modes simultaneously, which will have applications in analog quantum simulations and multi-mode cQED.
Within the stopband, where the density of states is zero, no travelling modes are allowed through the waveguide. However, evanescent modes, exponentially localized around the atoms' position can give rise to atom-photon bound states as theoretically predicted in Ref. [1] and experimentally observed in a photonic crystal configuration on a chip [2]. Here, we report observation of an atom-photon bound state with a transmon qubit inserted in a three-dimensional rectangular waveguide. Rectangular waveguides naturally exhibit low-frequency cut-off and the atom-photon bound states shows stronger localization compared to a photonic crystal realization [3]. We provide evidence of exponential localization of the atom-photon bound states through spectroscopic measurements, study their radiative emission and coherent interaction.

Session P17 DQI: Quantum Computing with Donor Spins 203 - RUICHEN ZHAO,
National Institute of Standards and Technology Boulder - Tag(s): Focus
2:30PM P17.00001: Demonstration and benchmarking of electron and nuclear 2-qubit logic gates with implanted donors in silicon* [Invited] ANDREA MORELLO (Presenter), Univ of New South Wales — Ion-implanted $^{31}$P donors in silicon have attained 1-qubit gate fidelities >99.9% [1]. Here we present the realization of a 2-qubit CNOT gate between weakly J-coupled electron spins, deploying our proposal of using the nuclear spins to detune the individual qubit frequencies [2]. In a second experiment we realize a nuclear 2-qubit CNOT gate using a two-donor cluster where both $^{31}$P nuclei are hyperfine-coupled to the same electron. The CNOT gate is obtained by performing a CZ gate via a geometric phase imparted through a 2$\pi$ rotation of the electron, preceded and followed by $\pi/2$ gates on one of the nuclei [3]. Gate-Set Tomography benchmarks the fidelity of this universal gate set, which approaches the threshold for fault-tolerant quantum error correction.

3:06PM P17.00002: Driven dynamics of an electron coupled to spin-3/2 nuclei in quantum dots* ARIAN VEZVAEE (Presenter), Department of Physics, Virginia Tech, GIRISH SHARMA, School of Basic Sciences, Indian Institute of Technology Mandi, SOPHIA ECONOMOU, EDWIN BARNES, Department of Physics, Virginia Tech — The problem of hyperfine interaction between a confined electron in a self-assembled quantum dot and its surrounding nuclear spin environment features interesting physics. Driving of the electron spin leads to dynamic nuclear spin polarization of the bath, and feedback effects on the electron spin can qualitatively change its dynamics. While for most systems of interest the nuclei have a spin of 3/2 or higher, in which case quadrupolar terms are present, the majority of existing theoretical treatments assume a nuclear spin-1/2 bath. In this work, we present a comprehensive theoretical framework of a driven electron spin coupled to a nuclear spin-3/2 bath based on a mean-field approach, and we use it to study the effects of higher nuclear spin on dynamic nuclear polarization.

Long-time noise characteristics of an isotopically-enriched silicon nuclear spin bath

MATTHEW D GRACE (Presenter), WAYNE M WITZEL, Sandia National Laboratories —

Electron spin qubits in silicon are known to have long coherence times, especially in isotopically-enriched materials with few nuclear spins. As a variety of silicon qubit devices are explored experimentally, it is useful to have a theoretical understanding of noise characteristics as induced by nuclear spins to know when other noise sources should be suspected. We present a quantitative study of nuclear spin dynamics for moderately-sized baths over a range of timescales. We approximate the quantum dynamics by adapting the cluster-correlation expansion (CCE) technique to calculate bath “flip-flop” probabilities, improving the accuracy of simulations for longer timescales by introducing random, projective measurements throughout the time evolution as a semiclassical approximation. In this way, we are able to estimate the spectral density of noise induced by a nuclear spin bath for a wide range of frequencies and study the variation for different instances of nuclear spin samples. We present results of our modified CCE technique, comparing it to exact analytical and numerical solutions. SAND2019-12116A

A silicon quantum-dot-coupled nuclear spin qubit

BAS HENSEN, WISTER WEI HUANG, CHIH-HWAN YANG, KOK WAI CHAN, JUN YONEDA (Presenter), TUOMO I TANTTU, FAY E. HUDSON, ARNE LAUCHT, University of New South Wales, KOHEI M ITOH, Keio University, THADDEUS D LADD, HRL Laboratories, ANDREA MORELLO, ANDREW STEVEN DZURAK, University of New South Wales — Single nuclear spins in the solid state have long been envisaged as a platform for quantum computing. However, establishing long-range interactions between multiple dopants or defects is challenging. Conversely, in lithographically-defined quantum dots, tunable interdot electron tunneling allows direct coupling of electron spin-based qubits in neighboring dots. Moreover, compatibility with semiconductor fabrication techniques provides a compelling route to scaling. Unfortunately, hyperfine interactions are typically too weak to address single nuclei. In this presentation, we report that for electrons in silicon metal-oxide-semiconductor quantum dots the hyperfine interaction is sufficient to initialize, read-out and control single silicon-29 nuclear spins, yielding a combination of the long coherence times of nuclear spins with the flexibility and scalability of quantum dot systems. We demonstrate that the nuclear and electron spins can be entangled and that they both retain their coherence while moving the electron between quantum dots, paving the way to long range nuclear-nuclear entanglement via electron shuttling. Our results establish nuclear spins in quantum dots as a powerful new resource for quantum processing [1].

3:54PM P17.00006: Coherent electrical control of a single high-spin nucleus in silicon

MARK JOHNSON (Presenter), SERWAN ASAAD, VINCENT MOURIK, BENJAMIN JOECKER, UNSW Sydney, ANDREW BACZEWSKI, Sandia National Laboratories, HANNES ROLAND FIRGAU, MATEUSZ T MADZIK, VIVIEN SCHMITT, JARRYD PLA, FAY E. HUDSON, UNSW Sydney, KOHEI M ITOH, Keio University, JEFFREY C MCCALLUM, University of Melbourne, ANDREW STEVEN DZURAK, ARNE LAUCHT, ANDREA MORELLO, UNSW Sydney — We report the discovery of Nuclear Electric Resonance (NER) in a single 123 Sb donor, implanted in a silicon nanoelectronic device [1]. NER enables the coherent control of a high-spin nucleus through the electrical modulation of its quadrupole coupling. This effect was first proposed in the 1960s but never observed in a non-polar, non-piezoelectric material, or in a single atom. Our experiments are quantitatively matched by a microscopic theory that elucidates how an electric field distorts the bond orbital around the atom and results in a modulation of the electric field gradient at the nucleus. The observation of a large quadrupole splitting in a single 123 Sb nucleus paves the way to the realization of a quantum chaotic “kicked-top” model [2] or the encoding of quantum information in an 8-level nuclear spin qudit.

4:06PM P17.00007: Decoherence of Dipole Coupled Flip-Flop Qubits*  
JOHN TRUONG (Presenter), XUEDONG HU, State Univ of NY - Buffalo — A recent proposal for a scalable donor-based quantum computer scheme promises excellent coherence properties, fast qubit couplings and insensitivity to donor placement. The suggested system consists of two different types of qubits per donor: a flip-flop qubit consisting of the electron and nuclear spin states, and a charge qubit of the donor electron tunneling between the donor and an interface quantum dot. In this scheme, the qubits can be coupled to each other via the electric dipole interaction between their respective charge qubits. We study in detail this effective coupling, especially the effect of charge noise on two-qubit gates utilizing this coupling. We find that due to the proximity of the charge excited states to the flip-flop logical states, the presence of charge noise greatly reduces the fidelity of two-qubit operations. We calculate the qubit-noise interaction strengths, and identify leakage from the qubit Hilbert space as the main culprit of the reduced gate fidelity. We also explore different bias conditions to mitigate this decoherence channel.

*We thank support from US ARO.

4:18PM P17.00008: Full configuration interaction simulations of exchange coupled donors in silicon in an effective mass theory framework*  
BENJAMIN JOECKER (Presenter), Center for Quantum Computation and Communication Technology, University of New South Wales, ANDREW D. BACZEWSKI, Center for Computing Research, Sandia National Laboratories, JOHN K GAMBLE, Microsoft Research, JARRYD PLA, ANDREA MORELLO, Center for Quantum Computation and Communication Technology, University of New South Wales — Several proposals for multi-qubit gates with donor spin qubit in silicon rely on the exchange interaction, using either weak exchange and microwave pulses [1], or strong tunable exchange [2]. Designing the optimal devices to embody these control strategies requires accurate models of the dependence of the exchange interaction on lattice placement, orientations, and electric fields. Here, we use a full configuration interaction method within an established multivalley effective mass theory framework [3] to model the two-electron wavefunction for different donor configurations. In particular, we investigate the exchange interaction and valley population along different lattice orientations, and the tunability of exchange with external electric fields.

*Funded by the Australian Research Council (CE170100012) and the US Army Research Office (W911NF-17-1-0200). **4:30PM P17.00009: Simultaneous Comparison of Coulomb Blockade Linewidths of P Donor-based and MOS-based Si Quantum Dots**  
YANXUE HONG (Presenter), University of Maryland, College Park, ARUNA N RAMANAYAKA, MICHAEL DAVID STEWART, XIQIAO WANG, RANJIT KASHID, PRADEEP NAMBOODIRI, RICHARD SILVER, JOSHUA POMEROY, National Institute of Standards and Technology — In solid-state quantum computation, noise often presents a limitation for coherence or device integration. One indicator of the noise levels, the effective electron temperature ($T_{\text{eff}}$), must be as low as possible to enable high-fidelity coherent measurements. High $T_{\text{eff}}$ in the measurement may come from noise sources extrinsic to the device or from intrinsic noise in the device, which can be measured by the broadening of Coulomb blockade peaks. To study the extrinsic systematic noise origins and the intrinsic lattice couplings, here we report on the comparison of $T_{\text{eff}}$ on two different quantum dot systems, P donor-based and MOS-based Si quantum dots simultaneously measured using the same measurement setup on the same platform. T-dependent and bias-dependent conductance are measured in different cryogenic setups over temperatures ranging from 10 mK to 25 K. The $T_{\text{eff}}$ is extracted using a theoretical model. By initially rearranging ground configuration and noise filtering, we have successfully reduced the $T_{\text{eff}}$ in a dilution refrigerator with 10 mK base temperature to $< 0.5$ K.

**4:42PM P17.00010: Evaluating effective mass models of the phosphorous donor in silicon**

LUKE PENDO (Presenter), XUEDONG HU, State Univ of NY - Buffalo — Evaluating effective mass models of a phosphorus donor in silicon is made difficult by conflation of mathematical and physical approximations. We propose a scheme to solve a class of effective mass models with high precision. We construct donor electron states using envelope functions expanded in freely extensible basis sets equipped with tunable parameters. With these states, we compute the expectation values of both the donor's energy as well as the energy variance. We variationally optimize the parameters of these basis states to find stationary points of the energy functional, with variance of the expectation energy used to evaluate the precision of our candidate eigenstates. In this manner, we can find exact energy eigenstates of the implied Hamiltonian of an effective mass model.

To improve the physical verisimilitude of a given effective mass model, we evaluate models of the donor atom’s Coulomb potential, in particular considering the effects of a dielectric constant with dynamic response. We present a phenomenological pseudopotential for exchange and correlation effects from the donor's valence electrons. Finally, we include symmetry breaking perturbations, in particular the effect of an electric field upon the donor electron.

*Acknowledgment: We thank support by US ARO.*
4:54PM P17.00011: A two-qubit gate between phosphorus donor electrons in silicon

YU HE, SAMUEL KEITH GORMAN (Presenter), DANIEL J KEITH, LUDWIK KRANZ, JORIS GERHARD KEIZER, MICHELLE Y SIMMONS, Univ of New South Wales — Electron spin qubits formed by atoms in silicon have large orbital energies and weak spin-orbit coupling giving rise to isolated electron spin ground states with seconds long coherence times. The exchange interaction promises fast two-qubit gate operations between single-spin qubits. Until now, creating a tunable exchange interaction between two electrons bound to phosphorus atom qubits has not been possible. This reflects the challenges in knowing how far apart to place the atoms to turn on and off the exchange interaction, whilst aligning atomic circuitry for high fidelity independent read out of the spins. Here we report a ~800 ps √SWAP gate between phosphorus donor electron spin qubits in silicon with independent ~94 % fidelity single shot spin read-out. By engineering qubit placement on the atomic scale, we provide a route to the realisation and efficient characterisation of multi-qubit quantum circuits based on donor qubits in silicon.

*The research was supported by the Australian Research Council Centre of Excellence for Quantum Computation and Communication Technology (CE170100012), the US Army Research Office (W911NF-17-1-0202) and Silicon Quantum Computing Pty Ltd. This work was performed in part at the NSW node of the Australian National Fabrication Facility.

5:06PM P17.00012: Donor-bound excitons in Cl doped ZnSe quantum wells

AZIZ KARASAHIN (Presenter), University of Maryland, College Park, MARVIN MARCO JANSEN, ALEXANDER PAWLIS, Peter Grünberg Institut PGI-9, EDO WAKS, University of Maryland, College Park — Quantum information processing heavily depends on the ability to generate the high number of indistinguishable single photons and to interface them with long-lived coherent spin states. Quantum dots as emerged as promising scalable solid-state platforms by offering bright photon emissions. However, epitaxially grown quantum dots are not immune to size variations and they suffer short coherence times due to interactions with host material nuclear spin bath.

Quantum emission from electron-bound to F donor impurities in bulk ZnSe and ZnSe quantum wells are shown previously. Unlike quantum dots, these emitters show small inhomogeneous broadening\(^1\), short decay times\(^1\), and long-coherence times\(^2\). Together with the possibility of spin purification of the host material, donor impurities in such quantum wells may open the possibility to generate efficient spin-photon interfaces.

Here we investigate emission properties of donor bound excitons in Cl doped ZnSe/ZnMgSe quantum wells. Spectral properties of emitters are investigated in cryogenic temperatures. Time-resolved fluorescence experiments show that these emitters exhibit sub-nanosecond decay times. Second-order time-correlation measurements prove the single-photon emission.
Spins in semiconductor quantum dots are among the leading candidates for quantum computing. To lift spin degeneracy, a large in-plane magnetic field is applied. This has sizable effects on the confined electron, allowing the shape and orientation of the orbitals to be inferred in this way, see Camenzind et al. PRL112, 207701 (2019).

Here, we present experiments studying the effect of the strength and direction of in-plane magnetic fields on the spin structure of an electron in a gated GaAs quantum dot. We have measured an anisotropic correction of about 7% and an isotropic correction pushing the average g-factor 10-15% below the bulk value |g|=0.44. The experiment is compared to theory by Stano et al. PRB98, 195314 (2018), finding rather good agreement. The anisotropic correction is given by the Dresselhaus spin-orbit coupling, matching well using a coefficient of 10.6 eVÅ. The isotropic term is dominated by the well-known Rashba term and an additional 43-term appearing in finite B-field. These corrections are predicted to depend strongly on the thickness of the wave function in the z-direction perpendicular to the 2D gas, and may also depend on the strength of the in-plane field.

2:42PM P20.00002: Rotating Cylinder as a Flow Split Controller in a Rectangular T-channel: Power-Law Fluids  
ANAMIKA MAURYA (Presenter), NAVEEN TIWARI, Chemical Engineering Department, IIT Kanpur, R.P. CHHABRA, Chemical Engineering Department, IIT Ropar — The present work endeavours to understand numerically the flow characteristics of power-law fluids in a rectangular T-channel over a wide range of conditions: power-law index \(0.2 \leq n \leq 1\), the rotational velocity of the cylinder \((-5 \leq \alpha \leq 5\) at \(Re = 45\). A rotating cylinder (both in the clockwise \((\alpha > 0)\) and anticlockwise \((\alpha < 0)\)) placed at the T-junctions is used here as a flow rate controlling strategy from the channel outlets. The flow is assumed to be steady, laminar and incompressible. The detailed flow kinematics has been visualized in terms of streamline patterns, flow-split ratio (i.e., the ratio of the main branch flow rate to the side branch flow rate), hydrodynamic forces (total and its pressure component) over the cylinder surface and torque (due to the force required to maintain the cylinder rotation in the free stream of power-law fluid). The flow split ratio is seen to be significantly affected by the cylinder rotation while the stationary cylinder is found to divide the flow equally in both main and side branches. The total hydrodynamic force and its pressure coefficient are seen to be a strong function of cylinder rotation as well as the power-law index. The magnitude of the torque is seen to be independent of the direction of cylinder rotation.

2:54PM P20.00003: Scale resolving simulations of flow past a heated sphere using non-linear eddy viscosity closure  
SAGAR SAROHA, KRISHNENDU CHAKRABORTY, SAWAN SINHA (Presenter), Applied Mechanics, Indian Institute of Technology Delhi, SUNIL LAKSHMIPATHY, GexCon — The partially-averaged Navier-Stokes (PANS) method of turbulence computations has been employed in recent years to perform scale-resolving simulations of various canonical as well as flows of practical interest. While in most flows PANS shows improvements over the Reynolds-averaged Navier-Stokes (RANS) method, further scope of improvement still exists, especially in massively separated flows, wherein the linear eddy viscosity assumption is suspected to misrepresent some essential flow physics. With the motivation to address this shortcoming, we augment the PANS methodology using a non-linear (quadratic) constitutive equation. We examine the performance of this enhanced PANS methodology in flow past a heated sphere at Reynolds number of 10000. We find that the non-linear PANS methodology shows improvements over its conventional counterpart (PANS using linear eddy viscosity assumption) in terms of several hydrodynamic (drag and pressure profiles over the sphere surface, axial and transverse velocity profiles and wake structures), as well as some temperature-related flow features (mean temperature profiles around the sphere and Nusselt number). In this talk these results along with some pertinent explanations and insights will be presented.
**3:06PM P20.00004: Lattice Boltzmann Simulations of Magnetohydrodynamic Flows on a Rectangular Grid using a Central Moments Formulation**  
EMAN YAHIA (Presenter), KANNAN PREMNATH, University of Colorado, Denver — Simulations of magnetohydrodynamic (MHD) flows, especially in wall-bounded flows involving the resolution of Hartmann layers, are particularly effective with numerical techniques based on stretched grids. Lattice Boltzmann methods (LBMs) are highly parallelizable local algorithms based on collide-and-stream steps. Here, we extend a prior LBM formulation for MHD, which was constructed for square grids, to handle rectangular lattice grids. Our approach is based on augmenting the equilibria of a vector distribution function with terms involving the grid aspect ratio obtained via a Chapman-Enskog analysis in such a way that it consistently solves the magnetic induction equation. Similarly, the equilibria of another scalar distribution function representing the electrically conducting fluid motion subjected to the Lorentz force are extended with corrections terms based on the aspect ratio so that it correctly recovers its isotropy. For robust simulations, the collision steps of both the scalar and vector distribution functions are based on the relaxation of their central moments to the corresponding equilibria. Computations of various MHD flows at different Hartmann and magnetic Prandtl numbers based on our novel LB formulation demonstrates its accuracy and effectiveness.

**3:18PM P20.00005: Data-driven A priori analysis of sub-grid scale stress closures**  
AVIRAL PRAKASH (Presenter), KENNETH JANSEN, JOHN A EVANS, University of Colorado, Boulder — Better affordability of computational resources over the past decade has led to increased use of scale-resolving simulation techniques such as Large-Eddy Simulations (LES) by industries. These techniques involve the use of a model to account for the effect of small-scale unresolved turbulence structures on large scale resolved structures. The most commonly used models are often based on simplified assumptions such as gradient viscosity hypothesis and turbulence quasi-equilibrium and often fail to replicate higher-order statistics.

This talk will discuss the use of a data-driven approach i.e. neural nets for determining a functional mapping that governs the physics behind the problem. We present an A priori study conducted on the homogeneous isotropic turbulence to determine a model for modeling sub-grid scale stress tensor and compare it with common gradient-viscosity hypothesis based models. A comparison of higher-order statistics will shed light on the universality of small-scale turbulent flow structures as hypothesized by Kolmogorov 1941 theory. The importance of selecting correct input features and the design of the model form for obtaining a physically-consistent relation will also be discussed.
3:30PM P20.00006: Adaptive time-step selection in volume of fluid (VOF) simulations
ASHKAN DAVANLOU (Presenter), Siemens Digital Industries Software — In numerical simulations, Volume of Fluid (VOF) approach is a well-established method in capturing the interface and solving multiphase problems. However, choosing the appropriate time step can be a challenging task for majority of users both with commercial software as well as in house codes. Therefore, we implemented a CFL based time-step control that can target a given area such as the cells intersecting the free surface, such that the CFL limit can be imposed where it is needed. In addition, we keep the sub-steps constant. This enhancement is useful in casting, tank sloshing and marine applications.
In this presentation, we focus on a tank sloshing simulation with Simcenter STAR-CCM+ aiming to demonstrate the merits of using adaptive time-step for VOF multi step simulations. We highlight the add on value from two perspectives 1) reduction in overall computational time for a range of transient examples that are known to have non-constant timescales, 2) demonstrate an improvement in convergence compared to a constant time step set at the average of the variable timestep run.

3:42PM P20.00007: Control of Unstart Phenomenon in a Hydrogen Fuelled Scramjet model
ANCHAL VARSHNEY (Presenter), MEHUL VARSHNEY, MF BAIG, Aligarh Muslim University — The present work involves the development of a numerical methodology to model supersonic combustion using 8 species, 13-reaction chemical model. The governing equations of continuity, momentum, energy, and combustion(species conservation) have been solved using commercial code of Fluent. The methodology has been then used to model the unstart phenomenon in a scramjet engine. A control system based on the mitigation of unstart by leaking high-pressure fluid from the slots designed on the lower and sidewall of the scramjet has been studied[1]. The effect of the slot size position on control mechanism has been studied. The unstart is initiated by a) raising a solid flap downstream of the isolator b) heat release due to combustion of fuel. An automatic slot control mechanism has been suggested to control the unstart phenomenon. The effect of bleeding ratio through slots on engine performance parameters has also been explored.

3:54PM P20.00008: Experimental & CFD Analysis, Design & Optimisation of the Cooling System of a Formula Student Racecar
AYUSH MITTAL (Presenter), RWTH - Aachen, ANCHAL VARSHNEY, MEHUL VARSHNEY, Department of Mechanical Engineering, Aligarh Muslim University — FSAE cars witness a persistent problem of Engine overheating because of inefficient cooling system used. Paper emphasises on complete designing and analysis of the cooling system of FSAE Car along with the integration of Side-pods to increase residence time, heat transfer across the radiator and enhance engine cooling by natural convection. The stock radiator parameters were experimentally determined, theoretically confirmed and validated using CFD analysis. Features like fin density, heat transfer coefficient, flow rates, side-pod geometry, presence of gills, chimneys were analysed to design an optimised cooling system resulting in increased efficiency by over 150%.
Flow dynamics in an aneurysm: Effect of prolonged exercise  MEHUL VARSHNEY (Presenter), ABDULLAH Y. USMANI, Aligarh Muslim University — Present work involves the study of non-invasive treatment of unruptured Abdominal Aortic Aneurysm subjecting the patient to certain physiological level of heart. This technique was initially studied by Varshney et al. [1] Flow topology for 3-D axisymmetric and asymmetric aneurysm is studied under resting (Re=200), mild exercise (Re = 750) & moderate exercise (Re=1200) conditions. Pulsatile flow is given at inlet. Hemodynamic indicators are quantified in terms of time-averaged wall shear stress, oscillatory shear index. The trajectories of vortex-core movement (using Q-criterion) are correlated to pressure peaks attained at the wall. For symmetric aneurysm, it was seen that the resting condition manifests the aneurysmal wall to recirculating fluid for most of the cycle time. Moderate and high exercise exposes the aneurysmal wall and the distal end to high pressure, which otherwise has low intensity under mild activity Thus, mild exercise for a prolonged duration is effective in non-invasive symmetrical aneurysmal treatment. Similar study will be done for an asymmetric aneurysm.

Session P21 GERA: Semiconductors and Quantum Dots for Energy Applications 302

A Computational Survey of Semiconductors for Power Electronics
PRASHUN GORAI (Presenter), ROBERT W MCKINNEY, Colorado School of Mines, NANCY M HAEGEL, ANDRIY ZAKUTAYEV, National Renewable Energy Laboratory, VLADAN STEVANOVIC, Colorado School of Mines — Power electronics (PE) are used to control and convert electrical energy in a wide range of applications from consumer products to large-scale industrial equipment. While Si-based power devices account for the vast majority of the market, wide band gap semiconductors such as SiC, GaN, and Ga$_2$O$_3$ are starting to gain ground. However, these emerging materials face challenges due to either non-negligible defect densities, or high synthesis and processing costs, or poor thermal properties. We performed a broad computational search aimed at identifying promising materials for future power electronic devices beyond SiC, GaN, and Ga$_2$O$_3$. We consider 863 oxides, sulfides, nitrides, carbides, silicides, and borides reported in the crystallographic database and exhibit finite calculated band gaps. We utilize *ab initio* methods with models for intrinsic carrier mobility, and critical breakdown field to compute the Baliga figure of merit. We also compute the lattice thermal conductivity as a screening parameter. In addition to correctly identifying known power electronic materials, our survey has revealed a number of promising candidates exhibiting the desirable combination of high figure of merit and high lattice thermal conductivity, which we propose for further experimental investigations.
2:42 PM P21.00002: Towards efficient green emitters: Heteroepitaxial ZnGeN$_2$ on GaN by molecular beam epitaxy  MARSHALL TELLEKAMP (Presenter), CELESTE MELAMED, ANDREW NORMAN, ADELE TAMBOLI, National Renewable Energy Laboratory — GaN-based LEDs have revolutionized the lighting industry, yet phosphor converters are still required to achieve green and amber wavelengths in a white light emitter. The ‘green gap’ refers to this lack of efficient emitters from 510 nm – 610 nm. InGaN active layers theoretically can reach this range, however the increased In-content results in complications including phase separation and increased spontaneous polarization mismatch which leads to decreased radiative recombination efficiency. II-IV-N$_2$ materials are an optically relevant class of materials with direct gaps across the visible spectrum. ZnGeN$_2$ is nearly lattice matched to GaN, providing a direct route to device integration within a mature system, and can potentially enable green and amber emission at much lower lattice mismatch than InGaN. The heteroepitaxial growth of ZnGeN$_2$ on GaN by molecular beam epitaxy will be discussed, highlighting the impact of Zn desorption and interfacial surface energy on nucleation rate. Insights into growth regimes and limitations will be given, highlighting practical considerations for the characterization of potentially cation-disordered materials. Heterostructure growth represents a major step toward enabling hybrid III-N/II-IV-N$_2$ optical devices.

2:54 PM P21.00003: Combinatorial Investigation of Structural and Optical Properties of Cation-Disordered ZnGeN$_2$  CELESTE MELAMED (Presenter), REKHA SCHNEPF, Colorado School of Mines, JIE PAN, National Renewable Energy Laboratory, ALLISON MIS, Colorado School of Mines, RACHEL WOODS-ROBINSON, University of California, Berkeley, KAREN HEINSELMAN, National Renewable Energy Laboratory, JACOB CORDELL, Colorado School of Mines, JOHN PERKINS, STEPHAN LANY, National Renewable Energy Laboratory, ERIC TOBERER, Colorado School of Mines, ADELE TAMBOLI, National Renewable Energy Laboratory — In this work, we present a combinatorial study of sputtered ZnGeN$_2$ thin films with cross-cutting applications in fundamental materials science and novel device development. The II-IV-N$_2$ materials offer the possibility of groundbreaking optoelectronic properties through greater chemical and structural tunability than the III-Ns. ZnGeN$_2$ is lattice-matched to GaN and is predicted to exhibit a direct bandgap with strong absorption, but experimental studies to date report inconsistent optical properties. Additionally, minimal work has explored variation with cation composition, which has been shown to impact properties of other II-IV-N$_2$ materials. Here, we present a study of combinatorial ZnGeN$_2$ grown by RF co-sputtering. X-ray diffraction reveals phase-pure films in the expected cation-disordered wurtzite structure for cation compositions from 30% to 60% Zn/(Zn+Ge) and synthesis temperatures from 200°C to 600°C. Changes in crystallinity are explored as a function of cation composition, synthesis temperature, and in-situ and ex-situ annealing. Finally, spectroscopic ellipsometry is performed to investigate optical properties with changing synthesis conditions. This study reaffirms the potential for tunability of thin film ZnGeN$_2$ as a direct- and wide- bandgap optoelectronic material.
3:06PM P21.00004: Cathodoluminescence measurement of high bandgap CdTe-based devices  
AIDA TORABI (Presenter), CLAUDIA BECK, Texas A&M University, Central Texas, AMIT MUNSHI, CAREL REICH, WALAJABAD SAMPATH, Colorado State University, TAYLOR HARVEY, Texas A&M University, Central Texas — High band-gap CdTe-based devices are being developed as top films to be used in tandem solar cells. CdTe can be alloyed with Mg and Zn to form Cd$_x$Mg$_{1-x}$Te (CMT) or Cd$_x$Zn$_{1-x}$Te (CZT) to increase the band gap; however, doping and passivation of these films continue to be a fundamental challenge. Films exhibiting better recombination lifetimes have been demonstrated by incorporating Se in CMT and CZT to from quaternary alloys. A fundamental understanding of the film properties are needed for all these films to realize their potential as photovoltaic absorbers. Optical characterization is one method to understand and aid in the development of high band-gap CdTe films. Scanning electron mapping of the luminescence of these film gives insight into film composition, homogeneity, and crystal quality. Herein we present our study of the optical properties of these materials using cathodoluminescence(CL). Additionally, electron beam-induced current (EBIC) is measured and correlated to the optical response. Unexpected peak shift and secondary peak presence indicate potential phase segregation or trap state formation.

3:18PM P21.00005: Investigation of the photocorrosion of GaP, III-V photoanode in acid with in situ UV/vis spectroscopy*  
SAHAR PISHGAR (Presenter), Univ of Louisville, JOSHUA SPURGEON, Conn Center for Renewable Energy Research — Although III-V semiconductors are one of the most promising group of materials for high efficiency solar fuels applications, they are prone to self-corrosion in strongly acidic or alkaline solutions. In-situ Investigation of photo-corrosion process are now limited to very expensive and complicated methods that are not available in every lab. Developing methods that enable researchers to do in-situ study of photo-corrosion process could make a profound impact on this field. Herein we studied self-corrosion of GaP photoelectrodes, a promising III-V material for tandem top subcells, in acidic electrolyte via in-situ UV-Vis spectroscopy. In-situ measurement of concentration of dissolved Ga and P species that come off from the electrode to electrolyte, calculation of corrosion faradaic efficiency as a function of applied bias and time along with SEM and XPS characterization are utilized to expound the photo-corrosion process of n-GaP and p+-GaP photoelectrodes which have shown different corrosion behavior. In addition, TiO$_2$ protective layer was deposited on some samples to study the change in corrosion faradaic efficiency as a function of deposition parameters.

*Conn Center for Renewable Energy Research
3:30PM P21.00006: Influence of epitaxial anatase and rutile TiO\textsubscript{2} thin films as electron transport layers for perovskite solar cell

YEON SOO KIM (Presenter), HYE-JIN JIN, HYE RI JUNG, JIHYUN KIM, WILLIAM JO, EWHA Woman’s Univ — The effective electron transport layer (ETL) is essential for high-power conversion efficiency (PCE) of perovskite solar cell (PSC). TiO\textsubscript{2} is the most widely used material for ETL owing to proper band alignment, enough optical transmittance, and high electron mobility. There are two representative thermodynamically stable crystal phases of TiO\textsubscript{2}: anatase and rutile. However, it is still debated which phase is more effective for the ETL. To solve the concern, single-phase thin film is strongly needed. We deposited epitaxial anatase- and rutile-TiO\textsubscript{2} thin films on LaAlO\textsubscript{3} and g-sapphire substrate, respectively, using pulsed laser deposition technique. X-ray diffraction analysis shows that both films have high crystallinity. In addition, both phases of epitaxial Nb-doped TiO\textsubscript{2} films are grown in order to enhance carrier injection/extraction of ETL. The variation of chemical states of elements resulting from Nb dopants was observed by X-ray photoelectron spectra. Steady-state photoluminescence (PL) spectra and time-resolved PL reveals PSC with anatase-TiO\textsubscript{2} has more effective carrier transporting and charge separating than with rutile-TiO\textsubscript{2}. Finally, the photocurrent density-voltage (J-V) measurements were conducted for estimating PCE.

3:42PM P21.00007: First-Principles Calculation of Charge Carrier Mobility using Complex Band Structure

ANDREW V BROOKS (Presenter), YUE YU, DMITRY SKACHKOV, HAI-PING CHENG, XIAOGUANG ZHANG, University of Florida — We compute charge carrier mobilities from the complex band structure, using the Quantum Espresso suite and a previously developed method\textsuperscript{1}. Carriers with finite lifetimes due to scattering may be represented by Bloch states with complex energies. Our method determines the constant complex potential that must be added to a perfect crystal to induce the scattering effects seen in a crystal with defects, which we deduce from a series of complex band calculations. The mean scattering lifetime is computed from the imaginary part of this complex potential, and the carrier mobility is obtained from the scattering lifetime using the Boltzmann transport theory. Mobility is calculated for graphene, hybrid organic-inorganic perovskites, and 2D FeCl\textsubscript{2} half-metal system, as a function of temperature due to phonon scattering, impurity and absorbed molecules.

Towards Monolithically Integrated Thin Film Bypass Diodes

TIMOTHY SILVERMAN, LORELLE MANSFIELD, STEPHEN GLYNN, TIMOTHY REMO, KAREN BOWERS, BART STEEVENS, MATTHEW REESE (Presenter), National Renewable Energy Laboratory — Bypass diodes can make photovoltaic (PV) modules more resilient, for instance preventing local heating when one portion is shadowed and another is not. This is significant because hot spot formation due to partial shading can cause sudden, non-linear permanent degradation. Presently, if incorporated at all, bypass diodes must be integrated as discrete components. Thin film photovoltaics can be fabricated in a manner where by thoughtfully choosing growth and scribing order “monolithic” integration can be achieved. We will present electrical simulations of diodes placed in an edge configuration to highlight the tradeoffs of designing real-world modules considering such variables as lateral resistance, PV cells per diode, and diode leakage current. Simulations incorporate both optimal and experimentally grown thin film diode characteristics to allow the tradeoffs and areas for improvement to be better understood.

Injection-dependent non-radiative SRH recombination via interstitials and dislocations in multicrystalline Si

ANDREY SEMICHAEVSKY (Presenter), Lincoln University — This paper deals with models of NR carrier recombination in mc-Si, which limits the efficiency of photovoltaic conversion. Experimental minority lifetimes in Si show a variety of dependences on injection levels. Models of non-radiative recombination in silicon were proposed for point defects (e.g., Fe interstitials) and extended defects (e.g., dislocations). High-resolution measurements of carrier transport are technically difficult, so models are used instead to relate carrier recombination processes in mc-Si to minority carrier lifetimes. While the SRH recombination due to shallow and deep point defects may result in a lifetime dependence on concentration with a distinct maximum, the recombination via arrays of dislocations leads to a monotonically increasing lifetime with the carrier concentration.

The NSF HRD 1505377 grant was used to produce results in this presentation.
4:18PM P21.00010: Transition Metal Doped Quantum Dots for Photovoltaic Applications*
TRIEU LE (Presenter), Physics, State University of New York - Oswego, THILINI EKANAYAKA, Physics and Astronomy, University of Nebraska at Lincoln, ANNIKA NEUFELD-KREIDER, Physics, State University of New York - Oswego, ARCHIT DHINGRA, TAKASHI KOMESU, Physics and Astronomy, University of Nebraska at Lincoln, ANDREW J. YOST, Physics, Oklahoma State University, CAROLINA C. ILIE, Physics, State University of New York - Oswego — In recent years, semiconductor zinc sulfide (ZnS) quantum dots have been considerably studied for various applications such as light emitting diodes, flat panel display, UV sensor and solar cell application. We discuss herein the optical and transport properties of the transition metal doped quantum dots and optimize them for better photovoltaics. Zinc sulfide has an excellent optical and electronic performances due to its wide band gap. In addition, cobalt-nickel doped zinc sulfide brings a versatility of the band gap energy. This is corresponding to an enhancement in the photo-to-current efficiency of doped quantum dots in sensitized solar cell. In this study, we explore how the different dopants lead changes in the band gap and discuss the characteristic of these doped quantum dots. The absorption data shows that cobalt-nickel doped ZnS has the highest absorbance the visible range out of all the single and co-doped and tri-doped quantum dots which made it the best candidate for optoelectronic device fabrication.

4:30PM P21.00011: Glucose-Derived Carbon Nanodots in Dye-Sensitized Solar Cells to Increase Efficiency*
MAX MARKUSON-DIPRINCE (Presenter), HARSH UPPALA, GRACE DIRKS, LOGAN SMITH, JOHN VOSICKY, ANDREW G BARUTH, Creighton University — Although carbon nanodot isolation remains difficult due to the presence of molecular byproducts in a bottom-up synthesis approach using thermal treatment of carbohydrate solutions, their resultant photoluminescence shows promise for down-converting UV photons. In particular, excitation at 390nm results in significant luminescence from 490–540nm, with an excitation wavelength dependence of luminescence (peak absorption occurs at 290nm). Carbonaceous nanodot solutions were derived from high-concentration glucose solutions at 120°C for a 48 hour period and then incorporated into Ruthenium-based dye-sensitized solar cell devices to enhance external quantum efficiency for high energy photons. We found that dialysis combined with solid phase extraction retained photoluminescent properties while allowing for carbon dot isolation in acetonitrile, a soaking solvent for dye-sensitization of TiO₂ nanoparticles, with minimal measurable traces of other chemical byproducts. Successful purification processes, photoluminescence, external quantum efficiency, and J-V curves of these carbon dot-modified devices will be shown to verify this low-cost, earth abundant approach to efficiency enhancement of dye-sensitized solar cells.

4:42PM P21.00012: Nano-biohybrid Organisms: In-vivo Targeting of Enzymes with Quantum Dots for Light-Driven Renewable Biochemical Synthesis  JOHN BERTRAM (Presenter), PRASHANT NAGPAL, YUCHEN DING, University of Colorado, Boulder — Living cells do not interface naturally with nanoscale materials, although such artificial organisms can have unprecedented multifunctional properties, like wireless activation of enzyme function using electromagnetic stimuli. Realizing such interfacing in a nanobiohybrid organism (or nanorg) requires (1) chemical coupling via affinity binding and self-assembly, (2) the energetic coupling between optoelectronic states of artificial materials with the cellular process, and (3) the design of appropriate interfaces ensuring biocompatibility. We have shown that many different core–shell quantum dots (QDs) couple with targeted enzyme sites in bacteria. When illuminated by light, these QDs drive the renewable production of different biofuels and chemicals using carbon dioxide, water, and nitrogen (from air) as substrates. Together, these nanorgs catalyze light-induced air–water–CO2 reduction to synthesize biofuels like isopropanol, 2,3-butanediol, C11–C15 methyl ketone, hydrogen gas; and valued chemicals such as formic acid, ammonia, ethylene, and degradable bioplastics polyhydroxybutyrate. Therefore, these resting cells function as nano-microbial factories that synthesize valuable chemicals from abundant small molecules powered by the sun.

Ref: JACS, 2019, 141, 10272

4:54PM P21.00013: Building quantum dot-bacteria nano-biohybrids for light-driven renewable biochemical synthesis  YUCHEN DING (Presenter), JOHN BERTRAM, University of Colorado, Boulder — Live cells do not interface naturally with nanostructures, although such artificial organisms can have unprecedented multifunctional properties, like wireless activation of enzyme function using electromagnetic stimuli. Realizing such interfacing requires (1) chemical coupling via affinity binding and self-assembly, (2) energetic coupling between material optoelectronic states and the cellular process, and (3) design of appropriate interfaces ensuring biocompatibility. Here we show different core-shell quantum dots (QDs), with excitations ranging from UV to NIR, couple with targeted enzyme sites in bacteria. When illuminated by light, these QDs drive the renewable production of different biofuels and chemicals using CO2, water, and N2 as substrates. These QDs use their zinc-rich shell facets for affinity binding to the enzymes. Cysteine zwitterion ligands enable uptake through the cell, facilitating cell survival. Together, these nanorgs catalyze light-induced air-water-CO2 reduction with a high turnover number of \(~10^6\)-\(10^8\) (mols/mol of cells) to biofuels like C2H4, 2-propanol, 2,3-butanediol, methyl ketones, and H2; and chemicals such as formate, NH3, and bioplastics. Therefore, these resting cells function as nano-microbial factories powered by light. 
5:06PM P21.00014: Alcohol Synthesis on MoS$_2$-supported Gold Nanoparticle*  
TAO JIANG  
(Presenter), DUY LE, TALAT S. RAHMAN, Univ of Central Florida — Alcohol synthesis from syngas (CO, H$_2$) is an important part of an economy based on renewable fuels. Rational designing of efficient catalyst material for such synthesis is in great demand because of the limitation of the current state-of-the-art catalysts. We report our density functional theory based calculations of the hydrogenation of CO on 31-atom, bilayer Au cluster supported on single-layer MoS$_2$ (Au$_{31}$/MoS$_2$). In accordance with previous investigations [1], we found that the gold atoms at the edge were most affected by substrate interaction and had strong affinity for CO. Furthermore, molecular H$_2$ could only physisorb on Au$_{31}$/MoS$_2$ and the activation barrier of H$_2$ dissociation was 0.63 eV, lower than that on Au$_{13}$ [2]. We found that Au$_{31}$/MoS$_2$ offers excellent activity toward methanol synthesis, via two competitive reaction pathways: 1) CHO$^*$→CH$_2$O$^*$→CH$_3$O$^*$→CH$_3$OH$^*$; 2) CHO$^*$→CHOH$^*$→CH$_2$OH$^*$→CH$_3$OH$^*$, the former being kinetically more favorable. We compare our findings with that on Au$_{13}$ [2] to elucidate the influence of size and shape of nanoparticles on their catalytic performance.

5:18PM P21.00015: Analytical electron billiards model of geometric diodes  
JEREMY LOW  
(Presenter), JAMES P CUSTER JR., JAMES CAHOON, Univ of NC - Chapel Hill — Unlike traditional diodes that require a potential barrier to generate electrical asymmetry, geometric diodes operate simply by breaking the structural symmetry on a scale comparable to the mean-free-path length of charge carriers. This gives geometric diodes unique properties that allow them to function as long wavelength energy harvesters and ultra-high speed signal processors. These devices exhibit nonlinear charge transport that is largely dictated by geometric parameters and position-dependent mean-free-path. We aim to predict the device’s dependence on these parameters through analytically calculating the proportion of possible paths ballistic charge carriers can travel through the device. Trajectories of up to an arbitrary number of internal reflections are integrated over all space inside the device. To account for the effect of applied electric field on the electron momentum distribution, a spatial distribution weighted in one direction is used and the impact on diode asymmetry is evaluated. The model is able to simulate nonlinear charge transport in both 2D and 3D nanowire geometric diodes. The model has excellent agreement with experiment, matching trends of IV curve asymmetry versus geometric parameters in silicon nanowire geometric diodes.

Wednesday, March 4, 2020 2:30 PM - 5:30 PM

Session P22 DBIO GSNP DCOMP: Inference, Information, and Learning in Biophysics: I  
303 - Pankaj Mehta, Boston University
2:30PM P22.00001: What can and can't Machine Learning do for Physics? [Invited] PANKAJ MEHTA (Presenter), Physics, Boston Univ — This speaker is on last year's program for invited talk but in fact that talk was given by someone else, due to a death in the family, making him eligible this year.

3:06PM P22.00002: Coarse scale representation of spiking neural networks: from dynamics to backpropagation through spikes ANGEL YANGUAS-GIL (Presenter), Argonne National Laboratory — Leaky integrate and fire neurons have long been used as a model system to understand the dynamics of spiking neural networks, recently becoming the underlying model of neuromorphic chips such as Intel's Loihi. One of the interesting features of this type of models is the presence of an absolute refractory period, which essentially limits the maximum spike rate that can be attained by the system. This is also the largest time interval that guarantees that at most a single spike is produced per neuron. In this work we have explored the development of coarse scale representations of leaky integrate and fire neurons that operate at this timescale. Our coarse scale approximation is obtained by approximating spike arrival times as being homogeneously distributed over our time interval, and results on a discrete representation that exhibits equivalent dynamics on randomly connected networks. Moreover, the coarse scale model allows us to implement stochastic gradient descent methods for spiking neurons that take advantage of backpropagation. This provides a useful baseline with which to compare more bio-inspired approaches based on local learning rules, as well as the impact of different codings on the network's ability to learn and generalize.

3:18PM P22.00003: Towards a grammar of probabilistic models for large biological networks PHILIPP FLEIG (Presenter), University of Pennsylvania, ILYA M NEMENMAN, Emory University — Biological interaction networks such as biological neural networks, amino acid sequences in proteins, etc. are critical to the functioning of any living system. The trend of modern experiments is to record data with a rapidly increasing number of simultaneously measured network variables. Inferring models for such complex data is becoming increasingly more difficult, since one is confronted with a combinatorial explosion in the number of possible interactions between variables. Here we present first steps of an approach to overcome this obstacle. We investigate the question whether a small set of carefully chosen statistical models suffices to describe rich phenomenology in data of biological networks. As candidate models for this grammar we consider low-rank approximation, clustering, sparsity, etc.. We discuss the distribution of eigenvalues and pairwise correlations characteristic for each model, working under the assumption that they serve as key indicators for the phenomenology described by a model. We provide examples of modelling data of Ising spin systems and outline a vision for how combinations of models in the grammar cover a large part of model space occupied by biological networks.

*This work was supported in part by NIH Grant R01-NS099375 and NSF Grant BCS-1822677.
3:30PM P22.00004: Different noise assumptions yield qualitatively different landscapes and transition paths in gene regulation models*  JOHN VASTOLA (Presenter), WILLIAM R. HOLMES, Vanderbilt Univ — Intrinsic gene expression noise is a major source of phenotypic variability in cancer biology, and noise-induced transitions are thought to contribute to everything from developmental error correction to drug resistance. It is increasingly common to incorporate noise into mathematical models of gene networks, but limited experimental knowledge forces noise to be modeled in a phenomenological/approximate way. Do the different ad-hoc ways noise is included in these models qualitatively affect their predictions? Building on earlier work that analyzed one and two gene toy models, we present results on how noise assumptions affect landscapes and transition paths in models of the epithelial-to-mesenchymal transition (EMT) and early T cell development. We focus on two aspects of modeling noise: its functional form (constant/additive, multiplicative/linearly dependent on concentration, or the ‘canonical’ Gillespie-like prescription) and its symmetry (whether different genes have the same amount of noise). We find that different assumptions about noise can dramatically impact (i) the relative occupancy of different states, (ii) the stability/existence of intermediate states, and (iii) transition rates and paths.

3:42PM P22.00005: Stochastic Modelling of Dynein Motors on a One-Dimensional Lattice: Dynamics and Stationary State*  RIYA NANDI (Presenter), PRIYANKA ., Department of Physics & Center for Soft Matter and Biological Physics, Virginia Tech — The motion of molecular motors inside cells constitutes an exciting and biologically motivated non-equilibrium physics problem. Experimental studies in recent years have shown that dynein motors can move with variable step sizes along the microtubule, depending on the load and ATP concentration. Inspired by the dynamics of dyneins, we have developed a model of an exclusion process on a one-dimensional lattice, where the motors can move in the forward direction up to four steps depending on the load attached to it. We study the dynamics of the mean-square displacement, stationary state current, and gap distribution for both open and periodic boundary conditions. In the transient regime, the fluctuation grows as t.log(t) for the periodic boundary conditions and is ballistic for open boundary conditions. The gap distribution between the motors in the stationary state for periodic boundary conditions shows discrete peaks of exponentially decaying amplitude at multiples of four gap size. We have also verified these interesting results using a mean-field analysis.

3:54PM P22.00006: Limits to biochemical signalling in a changing environment as an inference problem*  THIERRY MORA (Presenter), Ecole Normale Superieure, ILYA M NEMENMAN, Physics, Emory — Cells must sense concentrations of external ligands as well as internal signalling molecules in order to adapt to environment changes and execute developmental programs. Berg and Purcell calculated an upper bound to the accuracy of concentration sensing by physical objects, due to the particle nature of molecules and finite sensor size. However, that bound assumed that the concentration to be sensed was constant. In realistic situations, concentrations may vary quickly over orders of magnitude. Here, we calculate a new bound to concentration sensing of a changing concentration by mapping the problem onto a field theory through Bayesian inference, which we solve using a Gaussian approximation. We find that the inverse square root dependency of the error as a function of concentration, ligand diffusivity, sensor size and time in the classical Berg and Purcell bound is replaced by a quartic root. The solution to the inference problem provides dynamical inference equations which can be mimicked by simple biochemical downstream networks, providing a plausible biological implementation of optimal inference.

4:06PM P22.00007: Human information processing in complex networks  CHRISTOPHER LYNN (Presenter), EVANGELIA PAPADOPOULOS, ARI KAHN, DANIELLE BASSETT, University of Pennsylvania — Humans communicate using systems of interconnected stimuli or concepts - from language and music to literature and science - yet it remains unclear if and how the structure of these networks supports the communication of information. Although information theory provides tools to quantify the information produced by a system, traditional metrics do not account for the inefficient and biased ways that humans process this information. Here we develop an analytical framework to study the information generated by a system as perceived by a human observer. We demonstrate experimentally that this perceived information depends critically on a system's network topology. Applying our framework to several real networks, we find that they communicate a large amount of information (having high entropy) and do so efficiently (maintaining low divergence from human expectations). Moreover, we show that such efficient communication arises in networks that are simultaneously heterogeneous, with high-degree hubs, and clustered, with tightly-connected modules - the two defining features of hierarchical organization. Together, these results suggest that many real networks are constrained by the pressures of information transmission, and that these pressures select for specific structural features.
4:18PM P22.00008: Information tradeoffs in sensing and sampling* CAROLINE HOLMES (Presenter), WILLIAM S BIALEK, Princeton University — Organisms sense the world through arrays of receptor cells. In some cases, such as the compound eyes of insects, these arrays are nearly crystalline. In other cases, including the human retina, sampling is much less regular. While ordered sampling typically gathers more information, this comes at the cost of specifying the positions of all the cells. We explore this tradeoff, asking about the maximum entropy of the sampling lattice that is consistent with gathering a certain amount of information from a Gaussian random signal; bits of sensory information are traded against bits of positional information. This problem maps to an equilibrium statistical mechanics problem for the positions of the receptor cells, with interactions that depend on the correlation structure of the input signal. In some limits we find that the information cost of disorder is surprisingly small. In other limits there are transitions where an ordered sampling lattice melts as we change the parameters of the sensory environment.

4:30PM P22.00009: Optical reservoir computing with tumor spheroids* DAVIDE PIERANGELI, Univ of Rome La Sapienza, VALENTINA PALMIERI, University Cattolica, GIULIA MARCUCCI, Univ of Rome La Sapienza, CHIARA MORICONI, GIORDANO PERINI, MARCO DE SPIRITO, MASSIMILIANO PAPI, University Cattolica, CLAUDIO CONTI (Presenter), Univ of Rome La Sapienza — Photonics enables the implementation of many modern neural network architectures, like deep learning and random neural networks. When a multiple scattering medium is adopted for mixing optical signals and perform computations, one can realize optically different conventional applications of artificial intelligence, like image recognition or time-series prediction. Optical reservoir computing may have other applications beyond computing. We demonstrate a random optical network realized by tumor spheroids. The tumor spheroids are samples of human tumors, like glioblastoma. The characterization of tumor spheroids is commonly done by optical imaging, and it is time-consuming and resource-demanding. We experimentally realize a random optical network that uses a tumor spheroid as a computing reservoir. We train the device by data from conventional imaging to infer tumor metabolism and the growth rate. After the training, the network can predict the time-dynamics of the metabolism and also the effect of hyperthermia and chemotherapy.[1] Our bio-random optical network represents a new kind of smart device for cancer morphodynamics and biophysical applications.

4:42PM P22.00010: Stochastic Force Inference* PIERRE RONCERAY (Presenter), Princeton University, ANNA FRISHMAN, Technion — Brownian dynamics is ubiquitous in biophysics, from the motion of single molecules and cytoskeletal filaments to effective models for cell and small animal behavior. We propose a principled framework, Stochastic Force Inference, for the inverse problem of Brownian dynamics: reconstruct spatially dependent force and diffusion fields from individual trajectories. It consists in a linear regression of these fields with a basis of smooth functions. We show that it is data efficient and successfully addresses the many challenges associated to real biological data: localization error, high dimensionality of phase space, out-of-equilibrium currents, multiplicative noise, complex force fields.

4:54PM P22.00011: Predicting the future from the past in visual object motion: optimal representations of mixed stochastic/deterministic trajectories* VEDANT SACHDEVA (Presenter), University of Chicago, ALEKSANDRA MARIA WALCZAK, THIERRY MORA, Ecole Normale Superieure, STEPHANIE PALMER, University of Chicago — Making predictions about the future state of the external world confers benefits to biological systems that can translate to increased fitness. This requires that sensory systems encode information about the stimulus in a manner suitable for prediction. However, physical constraints, such as finite metabolism and finite computing power, result in additional evolutionary pressures. These favor organisms that compress the representation of the input stimulus statistics along particular readout dimensions, creating an underlying tension between representing the statistics of a stimulus while preserving the information relevant to prediction. Here, we propose that the encoding scheme used by such biological systems can be predicted by the information bottleneck method. Using this technique, we can compute the optimal form of the encoding distribution for a variety of mixed stochastic and deterministic stimuli and demonstrate that these encoding distributions are optimized for prediction tasks at different timescales. We also consider the optimal encoding distribution when the underlying parameters of the stimulus evolve in time.

5:06PM P22.00012: Quantifying success and failure in simple models of large neural populations  LEENOY MESHULAM (Presenter), Massachusetts Institute of Technology MIT, JEFFREY GAUTHIER, Swarthmore College, CARLOS BRODY, DAVID TANK, WILLIAM S BIALEK, Princeton University — In statistical physics we routinely study models for collective behaviors that are simpler than the underlying microscopic mechanisms. In biological systems, one systematic implementation of this idea is the maximum entropy method, where we match some features of the data but otherwise the model has as little structure as possible. To understand whether this approach “works”, it would be attractive to have a testing ground where we could see the same model succeed or fail to describe different but related systems. Recent experiments monitor the activity of 1000+ cells in the mouse hippocampus as the animal runs through a virtual environment. The scale of these data allows us to construct models for many different subsets of neurons drawn out of the whole population. We test many predictions of these models, and find that quantitative agreement with experiment is best when the group of cells is spatially contiguous; if we draw the same number of cells at random from large regions, the agreement gets systematically worse. Strikingly, the different predictions fail in an ordered way, so we can rank the different collective behaviors of the network activity by the degree of difficulty in getting them right. This serves to make precise what it means for these models to work.

5:18PM P22.00013: Quantifying temporal information accumulation for biochemical signaling dynamics  YING TANG (Presenter), ADEWUNMI ADELAJA, Institute for Quantitative and Computational Biosciences, University of California, Los Angeles, XIAOFENG YE, Department of Applied Mathematics & Statistics, Johns Hopkins University, ERIC DEEDS, ROY WOLLMAN, ALEXANDER HOFFMANN, Institute for Quantitative and Computational Biosciences, University of California, Los Angeles — The temporal patterns of intracellular signaling contains information for cell decision making. When signaling is initiated by a stimulus, circuits that decode the temporal patterns to control biological effectors must make decisions based on available information within the timecourse. Quantifying information flow through signaling networks thus requires a dynamical framework to estimate information transmission in a time-dependent manner. We find that a type of stochastic process can be used to represent the signaling activities that show a high degree of cell-to-cell variability. Based on the model, we extract the time-dependent channel capacity of signaling pathways. When the transcription factor NFκB is activated by diverse immune threats in macrophages (e.g. virus, gram negative or positive bacteria, or cytokine), the channel capacity reaches 1 bit of information around 1 hour and 2 bits of information within 10 hours. By knocking down the feedback regulation in the signaling pathway, the information accumulation was reduced, which uncovers that information transmission is enhanced by feedback control. The result demonstrates that the method allows quantification on the learning rate of decoding circuits for rapid cellular decision making.

Session P23 DBIO GSNP: Physics of the Brain: Structure and Dynamics
II 304 - Marek Cieplak, Institute of Physics, Polish Academy of Sciences - Tag(s): Focus
When we make reach-directed movements to an object, like a cup, there is an infinite number of possible trajectories that an arm could take to go from its initial position to the final target. These are not given by solving Newton’s equations but are controlled by the brain. Humans show highly stereotyped random trajectories with hand velocity profiles that appear smooth to the naked eye. However, by using high definition motion capture MEM sensors we have found that at finer millisecond time scales, away from naked eye detection, the kinematic variables have clear random peak fluctuations that were unknown previously. We have been able to directly connect, in an individualized way, these random fluctuations to the nature of the Neurodevelopmental Disorders (NDD) of children with autism or attention hyperactive disorders. These random peak fluctuations are very different, though, in healthy individuals. In this lecture I will describe the nature of experiments we carry out, the importance of fully filtering out the external electronic noise from neuronal noise. We measure angular velocity, linear acceleration, and the time derivative of the acceleration, known as jerk of importance in human kinematics. Based on the data measured over thousands of arm movement trials we developed a detailed statistical analysis that allowed us to uncover quantitative NDD biomarkers that a posteriori agreed with the clinical diagnoses for each individual studied. We further hypothesize that the brain tries to minimize the associated stochastic kinematic variable fluctuations describing the motions. The identified biomarkers quantitatively determine the illness severity, that could be used as a diagnostic tool by clinicians.

Latent fields lead to emergence of scaling in simulated neurons

MIA MORRELL (Presenter), AUDREY SEDERBERG, ILYA M NEMENMAN, Emory University — Understanding activity of large populations of neurons is difficult due to the combinatorial complexity of possible cell-cell interactions. A remedy is to note that many systems may be macroscopically described with models simpler than the system's microscopic behavior. This has been probed via a coarse-graining procedure on experimental neural recordings, which shows over two decades of scaling in free energy, variance, eigenvalue spectra, and correlation time [1], hinting that a mouse hippocampus operates in a critical regime. We investigated whether this scaling behavior could be explained as a result of coupling the neural population to latent dynamic stimuli. We conducted simulations of conditionally independent binary neurons coupled to a small number of long-timescale stochastic fields with and without periodic spatial stimuli (depicting neural place cells) and replicated the coarse-graining shown in [1]. In a biologically relevant regime, we find that much of the observed scaling [1] may be recreated by this model. This suggests that aspects of the scaling may be explained by coupling to hidden dynamic processes, a ubiquitous trait of neural systems.
