10:00AM W41.00011: Anomalous Hall Effect sensor based on CoFeB with ultrahigh magnetic field detectability* YIOU ZHANG (Presenter), KANG WANG, GANG XIAO, Brown University — The anomalous Hall Effect (AHE) in ferromagnetic metals and alloys have been widely studied as a potential candidate for magnetic sensing applications, due to the relative easiness of fabrication, broad frequency response and lower intrinsic noise. Nevertheless, AHE sensor suffers from relatively low sensitivity in comparison with semiconductor Hall sensor. In this work, we have demonstrated that sensitivity of AHE sensor based on Ta/CoFeB/MgO/Ta multi-layer structure can be greatly enhanced, through engineering of magnetic anisotropy. By tuning thickness of CoFeB layer as well as the annealing temperature, ultra-high sensitivity (1000 V/A/T, comparable to that of semiconductor Hall sensor) and zero hysteresis can be achieved. We have also performed noise measurement over a broad frequency range. The low-frequency 1/f noise is found to strongly depend on input current and bias magnetic field, while the high-frequency white noise shows much weaker dependence. The best magnetic field detectability of our AHE sensor reaches 70 nT/rtHz at 1 Hz and 10 nT/rtHz at 1 kHz. Our work shows that AHE sensors are suitable for ultra-small magnetic field sensing applications.

*The work was supported by King Abdullah University of Science and Technology (KAUST) through the Sensor Initiative.
10:12AM W41.00012: Atomic antiferromagnetic domain wall propagation beyond the relativistic limit  
HUANHUAN YANG (Presenter), University of Electronic Science and Technology of China, 
HUAIYANG YUAN, Southern University of Science and Technology, MING YAN, Shanghai University, 
H. W. ZHANG, PENG YAN, University of Electronic Science and Technology of China — We theoretically investigate the dynamics of atomic domain walls (DWs) in antiferromagnets driven by a spin-orbit field. For a DW with a width of a few lattice constants, we identify a Peierls-like pinning effect, with the depinning field exponentially decaying with the DW width, so that a spin-orbit field moderately larger than the threshold can drive the propagation of an atomic DW in a stepwise manner. For a broad DW, the Peierls pinning is negligibly small. However, the external spin-orbit field can induce a fast DW propagation, accompanied by a significant shrinking of its width down to atomic scales. Before stepping into the pinning region, noticeable spin waves are emitted at the tail of the DW. The spin-wave emission event not only broadens the effective width of the DW but also pushes the DW velocity over the magnonic barrier, which is generally believed to be the relativistic limit of the DW speed. While the existing dynamic theory based on the continuum approximation fails in the atomic scale, we develop an energy conversion theory to interpret the DW dynamics beyond the relativistic limit.

10:24AM W41.00013: Transport signature of the BKT transition in 2D easy-plane magnets  
SU K BUM CHUNG (Presenter), Univ of Seoul, SE KWON KIM, Univ of Missouri — The theory of the Berezinskii-Kosterlitz-Thouless (BKT) phase transition was formulated to describe the 2D phase transition of easy-plane magnets as well as 2D superconductors and superfluids. The BKT transition being topological in nature, i.e. not characterized by a local order parameter, its detection has been challenging. The BKT transitions in the latter cases have been observed in experiments, much of which involves transport signatures, such as the current-voltage relation being non-linear below the BKT temperature and linear above the BTK temperature. By contrast, the experimental study of the solid-state 2D magnetic material emerged only in the last few years. The accompanied recent development of spin-transport measurements offers a tantalizing opportunity to discover novel transport phenomena of spin, which should be expected as the spin, unlike the particle number, is not conserved. In this Letter, we show here that this non-conservation of spin in the 2D easy-plane magnets leads to a distinct spin transport signature at the BKT transition, the crossover between the infinitely long-range spin transport and the exponentially decaying spin transport. We also present how this can be detected in the van der Waals easy-plane magnetic materials such as the monolayer NiPS$_3$. 
10:36AM W41.00014: Frequency Dependence of Magnetic and Magnetoelastic Properties of Magnetostrictive Materials for Multiferroic Antennae  PETER FINKEL (Presenter), United States Naval Research Laboratory, NICHOLAS JONES, NSWC, MARGO STARUCH, United States Naval Research Laboratory — Magnetoelectric (ME) resonators are of significant interest for pure mechanically driven antennae targeting the ULF/VLF radio frequency range. Direct coupling of magnetostrictive and piezoelectric phases in the ME composites enables time variable magnetic field generation with exceptionally low operational power requirements. A dynamic stress loading of the magnetoelastic/magnetostrictive material by piezoelectric element results in a fluctuating magnetic field. In this work we fully characterize magnetostrictive materials Fe_{81.6}Ga_{18.4} and Terfenol-D at high frequencies up to several kHz and studied the effect of eddy current losses that potentially curtail the magnetic response of the material. We evaluated the dynamic response of Galfenol rod up to 1000 Hz comparing both its sensing response (changing dynamic stresses) to its actuation response (changing dynamic magnetic fields) in both solid and laminated rods.

Tag(s): Focus
8:00AM W42.00001: Strong voltage-induced tunability of threshold current and frequency in spin Hall nano-oscillators [Invited] HIMANSHU FULARA (Presenter), MOHAMMAD ZAHEDINEJAD, ROMAN KHYMYN, MYKOLA DVORNIK, Physics, University of Gothenburg, 412 96 Gothenburg, Sweden, SHUNSUKE FUKAMI, SHUN KANAI, HIDEO OHNO, Laboratory for Nanoelectronics and Spintronics, Research Institute of Electrical Communication, Tohoku University, 2-1-1 Katahira, Aoba-ku, Sendai 980-8577, Japan, JOHAN AKERMAN, Physics, University of Gothenburg, 412 96 Gothenburg, Sweden — Spin Hall nano-oscillators (SHNOs) utilize pure spin currents to excite auto-oscillations at microwave frequencies in nanoscopic regions of magnetic thin films\(^1\)-\(^3\). Thanks to their wide frequency tunability\(^1,2\), their robust mutual synchronization in chains as well as in 2D arrays\(^1,3\), and their CMOS compatibility\(^2\), SHNOs have recently emerged as a promising spintronic device for neuromorphic computing\(^3\). While the SHNO frequency can be tuned with both current and external field, the lack of fine individual SHNO control in synchronized networks limits cognitive tasks in oscillator-based computing. It would be highly advantageous if an energy efficient route such as electrostatic gating can independently tune the SHNO characteristics in a synchronized network to perform more complex neuromorphic tasks\(^3,4\).

Here we demonstrate how electrostatic gating in nano-constriction based W(5nm)/CoFeB(1.7nm)/MgO(2nm) SHNOs can lead to substantial voltage-controlled tunability of threshold current and auto-oscillation frequency. High frequency microwave measurements show a large overall modulation of about 22% in threshold current with \(\Delta V_G = 4\, \text{V}\) and a moderate frequency tunability of 12 MHz/V. Our detailed analysis based on ST-FMR measurements combined with micromagnetic simulations unveil that the observed tunabilities are caused by minor voltage-induced changes in the perpendicular magnetic anisotropy, which, in our case, not only tunes the frequency but also significantly modifies the localization of the auto-oscillating mode resulting in a large change of the effective damping. Our demonstration introduces a new insight to critically control the effective damping and represents a significant step towards the realization of complex neuromorphic tasks\(^3,4\).

Large spin Hall effect in room-temperature sputtered W₃Ta thin films grown on SiO₂ and Al₂O₃

MOHSIN ZAMIR MINHAS (Presenter), BHARAT GROVER, ILYA KOSTANOVSKIY, STUART PARKIN, MAZHAR NAWAZ ALI, Max Planck Institute for Microstructure Physics — The spin Hall effect (SHE), in non-magnetic (NM) metals with strong spin-orbit coupling (SOC) has received much attention due to potential technological applications like magnetic random-access memory (MRAM) and spin-logic devices. Large spin Hall angles (SHA, the ratio of Jₛ/Jₖ) have been observed in materials like Pt and the metastable phase, β-W (a.k.a. W₃W in the A15-structure). Recently, W₃Ta (and other A15 compounds) was theoretically predicted to host an even larger intrinsic SHE than β-W, originating from the large spin Berry curvature of its electronic band structure. Here we report the SHE of W₄₋ₓTaₓ films including W₃Ta, deposited by DC magnetron co-sputtering on SiO₂ and Al₂O₃ substrates. Spin-torque ferromagnetic resonance (ST-FMR) and optically detected ferromagnetic resonance (ODFMR) techniques were used to measure the SHA of various W₄₋ₓTaₓ compositions and thicknesses with CoFeB as the magnetic layer. We find that W₃Ta in the A15 structure could be stabilized on both types of substrates at room temperature and hosts a large SHA in W₃Ta similar to theoretical predictions opening the door to facile device fabrication of Pt-free spintronic devices.

Critical spin fluctuation mechanism for the spin Hall effect

SATOSHI OKAMOTO (Presenter), Oak Ridge National Lab, TAKESHI EGAMI, Department of Materials Science and Engineering, University of Tennessee, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo — We propose mechanisms for the spin Hall effect in metallic systems arising from the coupling between conduction electrons and local magnetic moments that are dynamically fluctuating. We consider a microscopic model proposed by Kondo [1] for the coupling between electrons and local moments and describe the fluctuation of local moments using the self-consistent renormalization method by Moriya [2]. Both a side-jump-type mechanism and a skew-scattering-type mechanism naturally arise and give rise to a nontrivial temperature dependence in the spin Hall conductivity. This leads to the enhancement in the spin Hall conductivity at non-zero temperatures near the ferromagnetic instability [3]. The proposed mechanisms could be observed in 4d or 5d metallic compounds.

9:00AM W42.00004: Quantitative X-ray Imaging of Spin Accumulation due to the Spin Hall Effect in Ni<sub>x</sub>Cu<sub>1-x</sub> Nanowires  MARK KELLER (Presenter), MONIKA ARORA, JUSTIN SHAW, THOMAS SILVA, BASTIEN DASSONNEVILLE, National Institute of Standards and Technology Boulder, JOACHIM GRAEFE, Max Planck Institute for Intelligent Systems, MARKUS WEIGAND, Helmholtz-Zentrum Berlin für Materialien und Energie — We recently reported a spin Hall ratio \( \theta_{\text{SH}} = 1.05 \pm 0.18 \) in Ni<sub>60</sub>Cu<sub>40</sub>, an alloy that is nonmagnetic at room temperature, based on FMR measurements of unpatterned Ni<sub>80</sub>Fe<sub>20</sub> films deposited in a bilayer with the alloy [1]. Like previous studies of spin Hall effect (SHE) in heavy metals such as Pt and W, this work inferred spin accumulation indirectly, in this case from its effect on the FMR resonance. An alloy containing Ni enables scanning transmission x-ray microscopy (STXM) to directly image spin accumulation using circularly polarized x-rays tuned to the Ni L3 absorption edge. Importantly, this technique can quantify the spin accumulation without resorting to a theoretical model of spin transport. In wires of Ni<sub>60</sub>Cu<sub>35</sub>Al<sub>5</sub> with a cross section \( \approx 80 \text{ nm} \times 30 \text{ nm} \) and driven at a current density \( \approx 5 \times 10^{11} \text{ A/m}^2 \), fabricated on Si<sub>3</sub>N<sub>4</sub> membranes, we observed spin polarization along each wire edge in normal-incidence STXM images. The amount of spin accumulation is consistent with \( \theta_{\text{SH}} \approx 1 \) and it obeys three symmetries expected for SHE measured via STXM: 1) opposite sign on opposite edges of the wire, 2) opposite sign with reversal of the driving current, and 3) opposite sign with opposite x-ray helicity.

9:12AM W42.00005: Mutually synchronized 2D spin Hall nano-oscillator arrays with quality factors up to 170,000  JOHAN AKERMAN (Presenter), MOHAMMAD ZAHEDINEJAD, AHMAD AWAD, SHREYAS MURALIDHAR, ROMAN KHYMYN, HIMANSHU FULARA, HAMID MAZRAATI, MYKOLA DVORNIK, Goteborg Univ — Nano-constriction based Spin Hall nano-oscillators (SHNOs) have emerged as an attractive alternative to spin torque nano-oscillators [1,2], as their auto-oscillating mode exhibits substantial spatial expansion in out-of-plane fields [3], propagating spin waves can be generated [4], and long chains of nano-constrictions can be mutually synchronized [5]. Here we demonstrate that it is also possible to synchronize nano-constriction SHNOs in two dimensions. We fabricate 2D square SHNO arrays ranging from 2 x 2 to 10 x 10 constrictions and study their microwave signal properties in out-of-plane fields using both electrical measurements and Brillouin Light Scattering microscopy. We observe robust mutual synchronization in up to 8 x 8 arrays and find that their quality factor, \( Q = f/\Delta f \), increases in direct proportion to the number of mutually synchronized constrictions, with the largest arrays showing \( Q = 170,000 \).

9:24AM W42.00006: Magnetization-Independent Spin Hall Effect in Ferromagnetic Metals
JOSEPH MITTELSTAEDT (Presenter), ROBERT BUHRMAN, DANIEL RALPH, Physics, Cornell University —
The anomalous spin Hall effect, which creates charge-to-spin conversion in metallic ferromagnets, offers an exciting opportunity to generate spin currents for which the spin direction is controllable. Here we report spin-torque ferromagnetic resonance measurements of current-induced torques in ferromagnet-spacer-ferromagnet trilayers with NiFe, Co and CoFeB as our magnetic layers, allowing us to clearly separate signals from the different ferromagnetic layers. We observe signals with the symmetry of a magnetization-independent spin Hall effect with spin-to-charge efficiencies as large as 10% in NiFe, which is comparable to heavy metal-ferromagnet bilayers investigated previously. This research illustrates some of the competing effects which must be considered when investigating spin-to-charge conversion in ferromagnets, and also confirms that the spin current polarization and local magnetic moment in a ferromagnet do not need to be aligned.

9:36AM W42.00007: Maximizing the spin Hall ratio of Pt: Trade-off between intrinsic spin Hall conductivity and carrier lifetime
LIJUN ZHU (Presenter), Cornell University, LUJUN ZHU, Shaanxi Normal University, SHENGJIE SHI, Cornell University, MANLING SUI, Beijing University of Technology, DANIEL RALPH, ROBERT BUHRMAN, Cornell University — Spin Hall metals with high spin-torque efficiencies and relatively low resistivities are key for developing practical spin-orbit torque technologies (e.g. memories, oscillators, and logic). Pt-based spin Hall metals are the most attractive for such applications due to their relatively low resistivity, giant intrinsic spin Hall conductivity, easy growth, and ability to be readily integrated into experimental and/or manufacturing processes. This talk will report on an unambiguous determination of the intrinsic nature of spin Hall effect in Pt [1] and how the intrinsic spin Hall conductivity and spin Hall ratio of Pt varies with carrier lifetime, strain, and interruption of crystal order [2,3]. Based on this physical understanding, we have developed several low-resistivity spin Hall metals for spin-orbit torque technologies whose power consumption is estimated to be only 1% of that of the topological insulator Bi\textsubscript{x}Se\textsubscript{1-x} [4] based devices.

9:48 AM W42.00008: Spin pumping and non-uniform magnetic excitation in spin-torque FMR studies of the spin Hall effect  
RYAN TAPPING (Presenter), YONGXI OU, LUIS HENRIQUE VILELA-LEÃO, LIJUN ZHU, DANIEL C. RALPH, ROBERT BUHRMAN, Cornell University — Early on, spin-torque ferromagnetic resonance (ST-FMR) was used to establish an initially surprisingly strong spin Hall effect (SHE) in certain heavy metals (HM), and has since been widely deployed in the study of spin-orbit torques in HM/FM bilayers. However, there are questions as to whether ST-FMR always provides accurate, quantitative measures of the dampinglike spin-torque efficiency $\xi_{DL}$, principally because of the unsettled role of spin-pumping and the inverse SHE in ST-FMR, but also because of the assumption that only the uniform mode is excited. Here we report on an extensive ST-FMR study of Pt/FM and β-W/FM bilayers and HM/spacer/FM trilayers chosen such that the spin pumping effect is both strong and variable. We show that spin pumping, when significant, substracts from the antidamping torque signal, resulting in $\xi_{FMR} < \xi_{DL}$. In conjunction with the spin pumping model, the FMR studies also clearly indicate that there can be significant coupling of the incident spin current to non-uniform modes in the FM layer, which also contributes to a lower apparent $\xi_{DL}$. These results explain why ST-FMR often underestimates $\xi_{DL}$ in comparison to quasi-static second harmonic results, the latter of which are generally confirmed by ST switching of MTJs.

10:00 AM W42.00009: Electrical Measurement of Thermally Driven Spin Hall Voltage in Platinum with Permalloy contacts*  
SEONDO PARK (Presenter), YUN DANIEL PARK, Dept. of Physics and Astronomy, Seoul National University — A group of effects coupling spin current with heat has drawn considerable attention due to their large potential for applications in spin-caloritronics[1]. Recently, a new member of the family which converts thermal gradient into pure spin current in nonmagnetic conductors, named the spin Nernst effect, was observed. Here, we report a surprisingly large magnetic-field dependent voltage (<800 nV) across two permalloy contacts on a platinum channel patterned into a cross shape, while in the orthogonal channel, electrical current is utilized to create local thermal gradient by Joule heating. From finite element analysis as well as local electrical transport thermometry measurements, we estimate thermal gradients to be 1.5 K/micron near the permalloy contacts at electrical current of 10 mA. We will further discuss the origins of the large observed voltage by presenting several experimental results which we strongly feel rules out any unintended electrical effects such as spin Hall effect. [1] G. E. W. Bauer et al., Nat. Mat., 11, 391 (2012).

*This work was supported by National Research Foundation of Korea (2017R1E1A1A01074650).
Ferromagnetic materials can generate spin currents with controllable spin polarization via the anomalous spin Hall effect, a property potentially useful for driving spin torque oscillators (STOs), which have recently found applications for performing neurotrophic tasks. Iron rhodium (FeRh) exhibits a transition between a low-temperature antiferromagnetic (AFM) state and a high-temperature ferromagnetic (FM) state. For appropriate growth parameters, this transition can be found close to 300K, such that both the FM and AFM states are stable at room temperature, making it an ideal material to compare the effectiveness of FM and AFM spin sources for STOs. The transition also provides a high level of versatility for device design. We present measurements of the spin torque efficiency in iron rhodium as the temperature is varied to drive the FeRh through its magnetic transition. We compare FeRh's efficiency for driving STOs in the stable AFM and FM states at the same temperature, and compare the effectiveness of FeRh as a spin source with ordinary spin Hall materials.

*The work was supported as part of the Q-MEEN-C, an Energy Frontier Research Center funded by the U.S. Department of Energy.
**10:24AM W42.00011: Very high spin Hall conductivities and spin Hall ratios in epitaxial Iridium di-oxide films**  
ARNAB BOSE (Presenter), School of Applied and Engineering Physics, Cornell University, JOCIENNE NELSON, Department of Physics, Cornell University, Cornell University, XIYUE ZHANG, RAKSIT JAIN, SHENGJIE SHI, School of Applied and Engineering Physics, Cornell University, DARRELL SCHLOM, Department of Materials Science and Engineering, Cornell University, DANIEL C. RALPH, Department of Physics, Cornell University, Cornell University, DAVID MULLER, School of Applied and Engineering Physics, Cornell University, KYLE M SHEN, Department of Physics, Cornell University, Cornell University, ROBERT BUHRMAN, School of Applied and Engineering Physics, Cornell University — New metallic materials with exceptionally high spin Hall conductivities and accompanying high spin Hall ratios are desirable both to produce more efficient systems for spin-orbit torque applications and to further test the fundamental understanding of intrinsic spin-orbit interactions. A particularly interesting candidate for such research is the metallic rutile oxide Iridium di-oxide which angle resolved photoemission spectroscopy studies have shown exhibits Dirac nodal lines in the band structure, a feature that could enable a very high . Here we report spin-torque ferromagnetic resonance studies of the damping-like and field-like torques exerted on an adjacent ferromagnetic layer as the result of current flowing in epitaxial (110) and (001) IrO$_2$ films. The (110) films exhibit a damping-like torque efficiency $\approx 0.18$ at 293 K, which sets a lower bound for the spin Hall conductivity . The higher resistivity (~ 300 $\mu\Omega$-cm) (001) films exhibit even stronger spin-orbit torques, with ranging from ~0.45 at 293K to 0.8 at 30 K as decreases, behavior indicative of the dirty metal regime. The very high value for (001) IrO$_2$, ≥ , is both a challenge for current theoretical understanding and an exciting prospect for more efficient SOT applications.

**10:36AM W42.00012: Extrinsic Spin Hall Effect in Inhomogeneous Systems**  
TAKUMI FUNATO (Presenter), HIROSHI KOHNO, Science, Nagoya University — Interconversion between spin and charge signals is one of the most important processes in spintronics. This is done most commonly by the direct and inverse spin Hall effects (SHE). Recently, An et al. observed an enhanced charge-to-spin conversion, comparable to heavy metals, in naturally oxidized Cu (nox-Cu) [1]. Okano et al. reported a non-reciprocal charge-spin interconversion in nox-Cu [2]. The so-called spin-vorticity coupling (SVC) was suggested as the origin of these results.

In this work, we take a different approach and study the problem in terms of the extrinsic SHE in an inhomogeneous system. We model the nox-Cu system by nearly free electrons subject to impurities with spin-orbit interaction and with spatially modulated distribution. We calculate spin accumulation and spin current induced by an electric field using Kubo formula and discuss the relation between them. The results are summarized by a generalized spin diffusion equation with a spin source term given by the divergence of the spin Hall current. This source term can be put in a form of SVC only if the spin Hall angle is independent of impurity concentration, as in the case of skew scattering.

Large Spin Hall and Edelstein effects in Weyl semimetal WTe2 up to Room Temperature

BING ZHAO, DMITRII KHOKHRIAKOV, BOGDAN KARPIAK, MD ANAMUL HOQUE, SAROJ DASH (Presenter), Chalmers University of Technology, Sweden — The discovery of topological semimetals has revealed the opportunities to realize several extraordinary physical phenomena in condensed matter physics. Here, we report current-induced spin polarization, i.e. the spin Hall effect [1] and the Edelstein effect [2] and its inverse phenomenon in type-II Weyl semimetal WTe2 up to room temperature. In addition, to spin Hall and Rashba-Edelstein effects, our measurements also show an out-of-plane electrical field-induced spin polarization in WTe2 due to spin momentum locking of the spin-polarized bulk Fermi states [2]. These findings open opportunities for spin-orbit based spintronic technologies and possibilities for the realization of new states of topological matter with novel spin textures.

Session W43 DCOMP DMP: Computational Design and Discovery of Novel Materials VI: Machine Learning and High Throughput Computing 702 - Yuanxi Wang, Pennsylvania State University - Tag(s): Focus
**8:00AM W43.00001: New tools for detecting strong correlation in automated transition metal complex screening** [Invited]  
FANG LIU (Presenter), CHENRU DUAN, HEATHER J KULIK, Massachusetts Institute of Technology MIT — There are several prominent challenges in conducting quantum chemistry studies of transition metal complexes: generation of molecule structure, selection of electronic structure method, workflow control, and post-processing of simulation results. molSimplify is a user-friendly open-source toolkit that enables the seamless generation of candidate inorganic molecule structures, preparation, and execution of Density Functional Theory (DFT) calculations, and post-processing DFT results. Here we focus on extending the capability of molSimplify, enabling automated selection of electronic structure methods including both DFT and wavefunction based methods and automated control of simulations. For automatic method selection, we develop a python module, MultirefPredict, which is a high-level cross-platform workflow that calculates widely used multi-reference diagnostics for a given molecular system, without users handling the input and output of quantum chemistry packages. The backend of MultirefPredict supports several quantum chemistry packages based on both DFT and wavefunction theory methods, with calculation performed on both CPU and GPU. MultirefPredict guides a user to choose between single-reference and multi-reference based methods, which is essential for obtaining accurate results for transition metal-containing systems. For in-situ simulation control, we developed an automated workflow that checks the current status of geometry optimization using a “dynamic classifier” that predicts the probability of failure based on geometric and electronic structure information collected on the fly. This workflow terminates the simulation when it is predicted to fail, saving numerous computational resources. These open-source tools, which are accessible to the whole transition metal chemistry community, are anticipated to make transition metal chemistry simulation more automated and transparent.

**8:36AM W43.00002: High-throughput Design of Lead-free Organic-inorganic Lead Halide Semiconductors Beyond Perovskites**  
KESONG YANG (Presenter), YUHENG LI, University of California, San Diego — Organic-inorganic lead halide perovskites (including 2D hybrid perovskites) show great promise in optoelectronic applications such as light-emitting diodes and solar energy conversion. However, the poor stability and toxicity of lead halide perovskites severely limit their large-scale applications. In this talk, I am going to present our high-throughput design strategy of lead-free hybrid halide semiconductors with robust materials stability and desired material properties beyond perovskites. On the basis of 24 prototype structures that include perovskite and non-perovskite structures and several typical organic cations, a comprehensive quantum materials repository that contains 4507 hypothetical hybrid compounds was built using large-scale first-principles calculations. After a high-throughput screening of this repository, we have rapidly identified 23 candidates for light-emitting diodes and 13 candidates for solar energy conversion.

*National Science Foundation under award number ACI-1550404 and Global Research Outreach (GRO) Program of Samsung Advanced Institute of Technology under the award number 20164974.
8:48AM W43.00003: Perovskite Genomics: Optimizing the performance of large sets of perovskite materials with atomistic simulations  GIANAURELIO CUNIBERTI (Presenter), HAGEN ECKERT, FLORIAN PUMP, Chair Materials Science and Nanotechnology, TU Dresden, JOSUA VIETEN, MARTIN ROEB, CHRISTIAN SATTLER, Institute of Solar Research, German Aerospace Center (DLR) — Perovskites are ideal candidates to be applied in two-step redox cycles to convert, store and utilize energy from concentrated solar radiation by heating the perovskite materials to high temperatures (up to 1,500 °C) and thus transferring them to an energy-rich state. In a second step at lower temperatures, this energy can be used for a variety of chemical processes. As the overall performance of such redox materials is dominated by the diffusion rate of oxide ions through the constituting lattice, tuning the redox thermodynamics of such materials through composition adjustment allows the design of ideal perovskite materials. For an enhanced insight into the diffusion properties of a large set of perovskite materials, Molecular Dynamics simulations are applied for an efficient funneling of up to 58,000 candidate oxides to a few hundred for subsequent intensive studies. A major challenge lies in the generalization of the force field generation for datasets including large numbers of different oxides involving the characteristic electrostatic properties to be known for each material. To this end, we use data obtained by DFT stored in the database of the Materials Project. In this way, we are able to suggest materials with optimized and tailored dynamic properties.

9:00AM W43.00004: Computational discovery of semiconducting high-entropy chalcogenide alloys*  ZIHAO DENG (Presenter), LOGAN WILLIAMS, GUANGSHA SHI, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — High-entropy materials are formed by mixing typically five or more principal components into a single crystal structure. While significant progress has been made to synthesize entropy-stabilized metals and ceramics for structural applications, little attention has been paid to the discovery of new entropy-stabilized semiconductors. Here, we present a new class of entropy-stabilized semiconducting alloys based on the IV-VI binary chalcogenides, namely Ge_xSn_yPb_{1-x-y}S_zS_e_{1-t} high-entropy chalcogenides (HECs). By utilizing high-throughput first-principles calculations, we investigate the thermodynamic stability of HECs over their entire composition space, and show that more than 50% of the investigated compositions are stable with respect to phase segregation. We further studied the enthalpic effect of the individual elements via machine learning on the high-throughput data. Our work demonstrates the potential of entropy stabilization in the discovery of novel multicomponent semiconductor alloys.

*This work was supported by the National Science Foundation through Grant No. DMR-1561008 and used resources of the National Energy Research Scientific Computing (NERSC) Center, a Department of Energy Office of Science User Facility supported under Contract No. DEAC0205CH11231.
High-throughput discovery of metal-organic frameworks for cooperative CO2 adsorption

ERIC TAW (Presenter), Chemical Engineering, University of California, Berkeley, JEFFREY R LONG, Chemistry, University of California, Berkeley, JEFFREY B NEATON, Chemical Engineering, University of California, Berkeley, MACIEJ HARANCZYK, IMDEA Institute — Recently, a new class of post-synthetically modified metal-organic frameworks (MOFs) with non-Langmiur stepped isotherms have been discovered and tuned to reversibly and selectively adsorb CO2 under common flue gas conditions. However, very few MOFs are known to exhibit step-like isotherms, a result of a cooperative adsorption phenomenon. Here, we present a computational screening procedure to discover new CO2 adsorbent MOFs with the potential for step-like isotherms and cooperative adsorption. Our workflow is based on the hypothesis that the distance between accessible, undercoordinated metal sites is a key indicator for whether a MOF modified with ethylenediamine will exhibit cooperative adsorption. We screen the Computational-Ready Experimental MOF (CoRE-MOF) database using the fast marching algorithm to assess metal site distances given arbitrary pore geometries, and discuss candidate materials for experimental validation.

*This work is supported by the Department of Energy; computational resources provided by NETL.

Machine Learning Accelerated Discovery of Mixed Anion Materials

JIAHONG SHEN (Presenter), CHEOL WOO PARK, JIANGANG HE, CHRISTOPHER MARK WOLVERTON, Northwestern University — Mixed-anion materials are interesting counterparts to their more widely studied single-anion compounds due to the increased flexibility and tunability of properties afforded by the presence of multiple anions. Here, we demonstrate how computational approaches, based on DFT datasets can be combined with materials informatics and machine learning (ML) models to accelerate materials discovery. We utilize and compare a variety of materials representations, including a recently proposed improved crystal graph convolutional neural network (iCGCNN) model, and the Voronoi tessellation approach incorporated in the Materials-Agnostic Platform for Informatics and Exploration (MAGPIE). ML models are trained on a set of 450,000 DFT data prior calculated in the Open Quantum Materials Database (OQMD) and evaluated on a separate test set of 3,000 mixed-anion compounds where iCGCNN outperforms random forest models in predictive accuracy by ~300%. By introducing more mixed-anion compounds into the training set, the performance of the iCGCNN model is further improved, and it allows us to make predictions of a large number of stable (and hence, likely synthesizeable) new ternary oxychalcogenides, which are subsequently validated by DFT calculations.

*NSF MRSEC Grant No. DMR-1720139
9:36AM W43.00007: High-throughput Computational Study of Double Perovskite Oxides*
JIANGANG HE (Presenter), CHRISTOPHER MARK WOLVERTON, Northwestern University — Perovskite oxides have been intensively studied for decades due to the extraordinary variability of compositions and structures and their attractive applications in superconductivity, magnetoresistance, multiferroicity, catalysis, solid oxide fuel cells, and etc. Extending from single perovskite $\text{ABO}_3$ to double perovskite $\text{A}_2\text{BB'}\text{O}_6$ significantly increases the tunability towards the targeted physical and chemical properties. However, the number of possible compositions of double perovskite is prohibitively large to explore entirely experimentally. In this talk, we will present how to use a multi-step high-throughput computational method to screen $\sim 5000$ compositions of double perovskite $\text{A}_2\text{BB'}\text{O}_6$ ($\text{A}=$Ca, Sr, Ba, and La; $\text{B}$ and $\text{B'}$ are metal elements). With the $\sim 2000$ stable/metastable (and so likely synthesizable) compounds predicted by our calculations, we will show how statistical learning of the large dataset can capture the correlation among composition, stability, and crystal structure (i.e., cubic perovskite, distorted perovskite, and non-perovskite). The results will accelerate new double perovskite oxides prediction and discovery.

9:48AM W43.00008: Automated phase mapping of high throughput X-ray diffraction data
YIZHOU ZHU (Presenter), CHRISTOPHER MARK WOLVERTON, Northwestern University — Combinatorial synthesis and high-throughput characterization have become powerful tools to accelerate the discovery and design of novel materials. However, one key question in the high-throughput workflow is the phase mapping problem. Correct, automatic identification of the number, identity, and fraction of phases in XRD data is a crucial step to perform autonomous high-throughput characterization and establish further understanding on the composition-structure-property relationships. Traditional analysis performed manually could take days for a single material system, while an automatic solver, if lacks the domain-specific knowledge, is likely to give unphysical results. In this work, we demonstrate how we use phase diagrams generated based on DFT calculations databases, such as the Open Quantum Materials Database (OQMD), to provide domain-specific knowledge and enforce reasonable constraints. We show how DFT provides a good initial guess to phase mapping algorithms, we can address the “peak-shifting” caused by alloying behavior using machine learning techniques, and the method is capable of uncovering minor phases present in the XRD data. By combining first-principles calculations and machine learning techniques, our approach enables rapid phase identification and mapping.
A class of materials that has gained community attention recently is electrides. These rare materials stabilize “free” electrons, loosely bound to a low-dimensional cavity space, which act as anions to chemically stabilize the structure. This characteristic feature makes them highly desirable for applications such as battery anodes, superconductors, and topological electronics. However, very few electrides have been synthesized due to their chemical instability; they often undergo degradation in ambient conditions. Thus, a challenge in this field is to discover electrides with higher stability. In this work ternary electrides of the chemical species A-B-C were targeted; the choice of species and the stoichiometry between them allows a vast space within which to engineer compounds with enhanced stabilities and desirable properties. Properties of interest include magnetic, electronic carrier density, and band topology. A global structure search was performed with first-principles calculations to identify stable and metastable structures for a given composition. Highly parallelized GPU-accelerated DFT codes were used to explore the vast parameter space. Our database will guide experimental synthesis efforts of new ternary electrides with multidimensional functional properties.

Through employing the layered-crystal determination program based on the topology-scaling algorithm, 450 M_mN_nX_x (M, N = metal elements, X = S, Se) layered di-metal chalcogenides (LDCs) are identified from the 1602011 crystalline materials known in two Material Genome databases (Materials Project and OQMD). Their structures are classified into three types, standard structures, hetero-layered structures and large-cation intercalated layered structures. 312 cation-intercalated LDCs are hard to be exfoliated into few-layer 2D structures. In contrast, the other two types of structures may be exfoliated into stable few-layer 2D structures due to the weak inter-layer van der Waals interaction. The band structure screening identifies 24 semiconductors with small in-plane effective masses and thus high mobility of carriers. Furthermore, 83 found LDCs composed of the magnetic metal elements provide a new platform for search of 2D magnetic crystals. This work extends the search of layered materials from metal dichalcogenides to ternary chalcogenides and can serve as a map for the future discovery of novel 2D semiconductors and magnetic materials.
**10:24AM W43.00011: Effect of a Parameter in a Descriptor on the Efficiency of a Crystal Structure Search Using Bayesian Optimization**  
NOBUYA SATO (Presenter), National Institute of Advanced Industrial Science and Technology, TOMOKI YAMASHITA, National Institute for Materials Science, TAMIO OGUCHI, Osaka University, KOJI HUKUSHIMA, The University of Tokyo, TAKASHI MIYAKE, National Institute of Advanced Industrial Science and Technology — A crystal structure search method using Bayesian optimization (BO) has been developed recently. BO is a machine learning technique for the global optimization. It has been reported that the method can search a stable structure efficiently. In this method, a crystal structure is represented by a numerical vector referred to as a descriptor. Descriptors often have a parameter which should be predetermined. We reveal by case studies for crystalline silicon, silicon oxide, and yttrium–cobalt alloy that the efficiency of a crystal structure search depends heavily on a parameter value. Our analysis indicates that the efficiency is related to the distribution of the descriptor. Therefore, we introduce an information measure based on the descriptor distribution, which is evaluated only from a set of crystal structures. The measure succeeds in estimating a parameter value where the crystal structure search works efficiently, and thus, can be used to predetermine the value of a parameter.

**10:36AM W43.00012: An active-learning framework for the discovery of new crystalline materials**  
KIRSTEN WINTHER (Presenter), RAUL FLORES, Chemical Engineering, Stanford University, CHRISTOPHER PAOLUCCI, Chemical Engineering, University of Virginia, ANKIT JAIN, Mechanical Engineering, IIT Bombay, MICHAL BAJDICH, SUNCAT, SLAC National Accelerator Laboratory, THOMAS BLIGAARD, Department of Energy, Technical University of Denmark — A challenging problem in materials science is that the space of possible crystal structures is so vast that it is impossible to sample with brute-force screening approaches. However, electronic structure methods combined with machine-learning (ML) techniques have a huge potential to speed up the search [1][2], which hold a great promise for the discovery of novel materials and/or catalysts for energy applications. Here, we present a ML based active-learning framework to search for stable and meta-stable inorganic materials. It has already been applied to the discovery of new stable polymorphs of IrO, using a search space of experimentally observed crystal prototypes with element substitutions. We extend this search to hypothetical crystal structures that are generated with a crystal prototype enumeration scheme combined with a ML aided search for appropriate lattice parameters. Using a graph-theory based distinction, we identify a finite number of geometries to span a highly diverse material sub-space, which is used for the active-learning exploration.

10:48AM W43.00013: Unraveling nanoscale features controlling the diffusion of multi-component alloys through machine learning methods*  
S. MOHADESEH TAHERI-MOUSAVI (Presenter), S. SINA MOEINI-ARDAKANI, RYAN W. PENNY, JU LI, JOHN HART, Massachusetts Institute of Technology MIT — The immense compositional breadth of non-dilute multi-component alloys has made their well-targeted design extremely challenging. Yet, with the emergence of additive manufacturing which allows pointwise specification of the alloying components, new methods to predict alloy compositions and properties are needed. Here, we present a newly-developed numerical framework whereby a machine-learning algorithm supervised by atomistic-scale simulations is used to explore the nanoscale features controlling the diffusivity of atomic components in these heavily alloyed compounds. Analysis of all possible atomic configurations within a model medium-entropy alloy reveals how the size and cohesive energy of alloying elements alter the tendency of alloying elements to exchange their sites. Our developed theoretical model provides a pathway to calculate a macroscopic diffusivity rate from the information obtained from the nanoscale mechanisms. In the future, this approach can guide the selection of composition and processing parameters for conventional as well as additive manufacturing methods, and it could enable design of metals with tailored gradient diffusivity.

Session W44 DCOMP DMP: Electrons, Phonons, Electron Phophon Scattering, and Phononics VII 704 - Mu Wang, Nanjing University

8:00AM W44.00001: Nonperturbative Estimates of Electrical Current in 2D Dirac Systems - A MoS2 Example*  
DAVID N. CARVALHO (Presenter), NORDITA — The term “Dirac materials” refers to a large set of seemingly-disparate materials which share many universal properties and may be described by the Dirac equation. The effect of external time-dependent fields on their carrier dynamics is of great importance. However, due to the non-commutativity of the Dirac Hamiltonian in time domain, non-perturbative estimates of the propagator of a Dirac spinor are challenging to obtain.

Here, we propose an approach to construct observables, through the use of a suitable Magnus expansion and, with it, study the effect of shining light and deforming the sample on the produced current of arbitrary chemical potential and temperature. These two processes are captured by the coupling of electromagnetic and valley-dependent pseudo-electromagnetic fields. For appropriate excitation regimes, we show how (a) both fields create currents and (b) how these two fields can undergo interference and create both electrical and valley current and charge densities.

8:12AM W44.00002: Driven Imposters: Controlling Expectations in Solid State Systems

GERARD MCCAUL (Presenter), Physics, Tulane Univ, CHRISTOPHER ORTHODOXOU, Physics, King's College London, KURT JACOBS, Physics, University of Massachusetts, GEORGE BOOTH, Physics, King's College London, DENYS BONDAR, Physics, Tulane Univ — We present a model to control the observables of a general many-body electron system driven by an incident laser field. The main result is a non-linear, field free equation of motion for tracking observables, together with a constraint on the functional form of expectations which may be reproduced via tracking. As a first test, the strategy is used in the Fermi-Hubbard model to make the current expectation conform to an arbitrary function under a range of model parameters. Additionally, using two reference spectra for materials in the conducting and insulating regimes respectively, we demonstrate that using the developed tracking strategy allows one to make the dipole acceleration spectrum of each material mimic the reference spectra of the other, creating a 'driven imposter'.

*We are supported by the Air Force Office of Scientific Research (AFOSR), Young Investigator Research Program (grant FA9550-16-1-0254) and the Army Research Office (ARO) (grant W911NF-19-1-0377).

8:24AM W44.00003: Noise mediated mixing in a tunnel junction

SAMUEL HOULE (Presenter), EDOUARD PINOSOLLE, JOFFREY RIVARD, CHRISTIAN LUPIN, BERTRAND M REULET, Université de Sherbrooke — The microwave mixer is a key element in the detection of all sort of signals. It is based on a nonlinear element such as a semiconducting diode or a Josephson junction, and allows for example the downconversion of microwave signals to low frequency for digitization. In the quantum regime, the mixing of vacuum fluctuations with an ac excitation leads to the generation of squeezed microwaves.

A normal metal tunnel junction with a linear current-voltage cannot be used to mix signals. It has however been shown to generate squeezed vacuum thanks to another type of nonlinearity, that of noise vs. bias voltage. We demonstrate the use of a tunnel junction as a noise mediated mixer: the junction excited at two frequencies (around 20GHz) generates a noise which amplitude is modulated at the difference frequency. We compare our data with theoretical predictions of photon-assisted noise and observe small deviations that seem to indicate an extra frequency cutoff possibly related to the thermalization time of electrons in the electrodes.
Modeling Spontaneous Charge Transfer at Metal / Organic Hybrid Heterostructures

ONGUN OZCELIK (Presenter), YINGMIN LI, WEI XIONG, FRANCESCO PAESANI, University of California, San Diego — Hybrid heterostructures are crucial in photovoltaics where the overall efficiency of the materials are closely related to the level of charge transfer at their interfaces. Here, using a combined computational and experimental approach, we show that heterodyne vibrational sum frequency generation (HD-VSFG) measurements provide an effective way of monitoring the interfacial charge transfer in these heterostructures [1]. Using ab-initio quantum chemical calculations, we show that inducing regio-randomness into the organic polymer modifies the interfacial electronic states, level of hybridization and the electronic wave function of these materials. We present the HD-VSFG responses of the metal/P3HT heterojunctions containing both regio-regular and regio-random P3HT structures and show that the intensity of non-resonant signal is directly correlated with the computed electronic structure and the level of spontaneous charge transfer at these interfaces.

This research was supported by the National Science Foundation (NSF) through grant CHE-1808111.

Enhancement of superconductivity in organic-inorganic hybrid topological materials

HAOXIONG ZHANG (Presenter), AWABAIKEI ROUSULI, SHENGCHUN SHEN, KENAN ZHANG, CHONG WANG, LAIPENG LUO, JIZHANG WANG, YANG WU, YONG XU, DUAN WENHUI, HONG YAO, PU YU, SHUYUN ZHOU, Tsinghua University — Inducing or enhancing superconductivity in topological materials has attracted extensive research interests partly due to its fundamental importance toward topological superconductivity. Reducing the thickness of transition metal dichalcogenides has provided an important pathway to engineer superconductivity in topological matters, emergent superconductivity with $T_c \sim 0.82$ K in monolayer WTe$_2$ which also hosts intriguing high-temperature quantum spin Hall effect. However, such monolayer samples are often difficult to obtain and extremely sensitive in air. Here we report a generic, experimentally convenient approach to manipulate the interlayer coupling in bulk MoTe$_2$ and WTe$_2$ single crystals through organic cation intercalation. The as-formed organic-inorganic hybrid crystals exhibit dramatically enhanced superconductivity with $T_c$ of 7.0 K for intercalated MoTe$_2$ (as compared with 0.25 K for bulk crystal) and 2.3 K for intercalated WTe$_2$ (record high compared to monolayer WTe$_2$ and with greatly improved sample stability). This organic-cation-intercalation method can be readily applied to many other layered crystals, forming a promising research platform to manipulate their corresponding electronic states, including possible topological superconductivity with significantly enhanced $T_c$. 
9:00AM W44.00006: Pressure Control of Crystal Symmetry, Fermi Surface Reconstruction and Superconductivity in Weyl semimetal MoTe$_2$  TANER YILDIRIM (Presenter), National Institute of Standards and Technology, I-LIN LIU, Physics Department, University of Maryland, COLIN HEIKES, National Institute of Standards and Technology, CHRIS ECKBERG, TRISTIN METZ, SHENG RAN, Physics Department, University of Maryland, WILLIAM RATCLIFF, National Institute of Standards and Technology, JOHNPIERRE PAGLIONE, Physics Department, University of Maryland, NICHOLAS BUTCH, National Institute of Standards and Technology — Layered transition metal chalcogenides are promising hosts of electronic Weyl nodes and topological superconductivity. MoTe$_2$ is a striking example that harbors both non-centrosymmetric T$_d$ and centrosymmetric T' phases. In this talk we present neutron scattering and transport measurements along with Density functional theory (DFT) calculations to suggest a path towards the realization and control of these topological states of the type-II Weyl semimetal and superconductor MoTe$_2$ through the application of pressure [1]. DFT calculations reveal that the strength of the electron-phonon coupling is similar for both crystal structures. Finally, we show that there is a critical pressure characterized by unique coherent quantum oscillations, indicating that the change in topology between two phases give rise to a new topological interface state[2]. We present periodic and finite slab calculations of this new interface state which is in excellent agreement with the observed quantum oscillation frequencies.

9:12AM W44.00007: Discovering topological surface states of Dirac points in an acoustic crystal  HENGBIN CHENG (Presenter), Institute of Physics, Chinese Academy of Sciences/Beijing National Laboratory for Condensed Matter Physics, Beijing, China, YIXIN SHA, School of Electronics Engineering and Computer Science, Peking University, Beijing, China, RONGJUAN LIU, CHEN FANG, LING LU, Institute of Physics, Chinese Academy of Sciences/Beijing National Laboratory for Condensed Matter Physics, Beijing, China — Dirac materials, unlike the Weyl materials, have not been found in experiments to support intrinsic topological surface states, as the surface arcs in existing systems are unstable against symmetry-preserving perturbations. Utilizing the proposed glide and time-reversal symmetries, we theoretically design and experimentally verify an acoustic crystal of two frequency-isolated three-dimensional Dirac points with Z$_2$ monopole charges and four gapless helicoid surface sheets. Under symmetry breakings, the 3D ideal Dirac point breaks into Z$_2$ Weyl dipoles, Z$_2$ nodal rings or a full bandgap.
9:24AM W44.00008: Time-resolved x-ray diffraction study of acoustic phonons in TaAs
MIN-CHEOL LEE (Presenter), NICHOLAS SIRICA, Los Alamos National Laboratory, SAMUEL W. TEITELBAUM, MARIANO TRIGO, GILBERTO ANTONIO DE LA PEAN MUNOZ, Stanford PULSE Institute, SLAC National Accelerator Laboratory, VIKTOR KRAPIVIN, YIJING HUANG, DAVID A REIS, Department of Applied Physics, Stanford University, ALEXEI MAZNEV, JIAOJIAN SHI, KEITH ADAM NELSON, Department of Chemistry, Massachusetts Institute of Technology, ROXANNE TUTCHTON, JIAN-XIN ZHU, Los Alamos National Laboratory, XIANGGANG QIU, Institute of Physics, Chinese Academy of Sciences, DZMITRY YAROTSKI, ROHIT P PRASANKUMAR, Los Alamos National Laboratory — We utilized femtosecond x-ray pulses to investigate acoustic phonon oscillations in TaAs. We observed that time-resolved x-ray diffraction reveals coherent phonon oscillations of binary acoustic modes in truncation rod scattering. The phonon oscillations correspond to the transverse and longitudinal acoustic modes propagating along the surface normal vector. We suggest that the off-axis orientation of the surface normal makes it possible to observe the transverse phonon oscillation, in contrast to conventional laser-induced acoustic phonon oscillations due to a single longitudinal mode. We also found an asymmetric Fano-like feature in the longitudinal phonon oscillations, suggestive of strong electron-phonon coupling in TaAs.

9:36AM W44.00009: Spectral signatures of exciton-polarons in two-dimensional hybrid lead-halide perovskites
FELIX THOUIN (Presenter), CARLOS SILVA, Georgia Inst of Tech — Two-dimensional hybrid organic inorganic perovskites (2D-HOIPs) feature a previously unexplained excitonic fine-structure in their absorption and emission spectra. We here show using advanced optical probes that features within this fine-structure correspond to exciton-polarons of distinct polaronic nature. We first successfully reproduce their absorption spectrum by supposing distinct excitonic states with contrasting couplings to the lattice. This hypothesis is then unambiguously confirmed by high-resolution resonant impulsive Raman spectroscopy which reveals the polaronic nature of each excitons within this fine structure. We then show that their distinct polaronic nature drives the relaxation dynamics down this excitonic manifold. We also show that these effects protect the excitons from many-body interactions hinting at their importance in polaritonic microcavities based on these materials. Finally, we also observe stable biexcitons in these materials up to room temperature. Our conclusions are of broad fundamental importance to this class of materials which, due to the high degree of tunability of their crystalline structure, offer an ideal system on which to test models of exciton-polaronic effects.

* I acknowledge support from NSERC Canada and Quebec's FRQ:NT
9:48AM W44.00010: Density functional perturbation theory with subspace iteration  SAEED BOHLOUL (Presenter), VINCENT MICHAUD, NanoAcademic technologies, HONG GUO, McGill Univ — Density functional perturbation theory (DFPT) is a useful framework for calculating material responses that can be casted as total energy derivatives with respect to perturbation fields. These responses give access to important properties including the dynamical matrix, dielectric functions, optical properties, electron-phonon coupling, etc. A major advantage of DFPT is circumventing the computational burden of direct methods by replacing DFT supercell calculations, one for each possible perturbation, by a system of coupled linear equations for primitive cells which are solved self-consistently. Nevertheless, for unit cells containing a large number of atoms, solving this linear system becomes a major bottleneck. In this work, we report a new approach to overcome this bottleneck of DFPT, the perturbed Chebyshev-filtered subspace iteration (PCFSI) method, implemented in real space. It allows us to calculate responses of materials in much larger systems than was possible before. Dielectric functions and phonon spectra will be used as examples to demonstrate the impressive power of the PCFSI method.

10:00AM W44.00011: Theories, designs, and applications of thermal metamaterials* LIUJUN XU (Presenter), SHUAI YANG, JIPING HUANG, Fudan Univ — With the growing concerns about energy issues, many researchers have paid their attention to thermal management. This trend was mainly driven by the emerging field of thermal metamaterials in the last decade. This report mainly introduces the new progress of thermal metamaterials in three aspects: new functions, multi-particle systems, and intelligentization. The new functions include the thermal "golden touch" and the thermal Janus structures. The former is a method to extend the core property to the shell with an extremely small core fraction. The latter is essentially a core-shell structure whose core has two distinct thermal conductivities, and the mechanical rotation of the core can realize different functions. Multi-particle systems extend the core-shell design, and the multi-particle interaction helps us achieve thermal invisibility. Intelligentization means that the effective thermal conductivity of a shell is always the same as that of the environment.

*We acknowledge the financial support by the National Natural Science Foundation of China under Grant No. 11725521.
10:12AM W44.00012: Optical Properties of Complex Oxides RbFe(MoO$_4$)$_2$, RbFe(SO$_4$)$_2$, and RbFe(SeO$_4$)$_2$*

RACHEL OWEN (Presenter), ELIZABETH DRUEKE, CHARLOTTE ALBUNIO, Department of Physics, University of Michigan, ALEMAYEHU S ADMASU, Rutgers Center for Emergent Materials, Rutgers University, JUNJIE YANG, Department of Physics, New Jersey Institute of Technology, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials, Rutgers University, STEVEN THOMAS CUNDIFF, LIUYAN ZHAO, Department of Physics, University of Michigan — The structural and magnetic properties of the archetype type-II multiferroic RbFe(MoO$_4$)$_2$ have been well studied due to interest in the low temperature antiferromagnetic order and its coupling to the induced ferroelectric order. However, little is known about the optical properties of this complex oxide. There have been low energy spectroscopic characterizations, but no reported linear characterization up into the band edge. Here we explore a group of similar such complex oxides: RbFe(MoO$_4$)$_2$, RbFe(SO$_4$)$_2$, and RbFe(SeO$_4$)$_2$. Substitution of the A-site in RbFe(AO$_4$)$_2$ can result in comparable, spectrally tunable absorption features that appear below the optical transition band edges. Their absorption spectra show strikingly similar thickness and temperature dependence, despite their different growth conditions and electronic/magnetic properties. We further discuss the potential origin and impact of these tunable optical transition states in the RbFe(AO$_4$)$_2$ complex oxide family.

*NSF CAREER Grant No. DMR-1749774

10:24AM W44.00013: Nonlinear optics with ionizing radiation and ultrafast lasers: progress toward measuring the complete electric field of XFEL pulses

WILLIAM PETERS (Presenter), TRAVIS JONES, RICHARD L SANDBERG, PAMELA BOWLAN, Los Alamos National Laboratory — Newly developed X-ray free electron lasers (XFELs) promise to transform nearly all areas of modern science. However, there is a significant need for more sophisticated tools to measure the X-ray pulses themselves. Complete measurements of the pulse's electric field are needed to improve the light source technology and to enable new spectroscopy and scattering experiments. Here we describe measurement approaches in which an optical laser interacts with an interference pattern from the unknown XFEL pulse, referred to as a transient grating or as four wave mixing. This geometry largely isolates the instantaneous wave-mixing response necessary for the FROG algorithm and removes the long-lived response seen in other X-ray-pump optical-probe measurements. The measurement also transfers the phase information of the X-ray electric field onto a readily-detectable optical laser field, allowing us to fully characterize the unknown pulses with visible spectrometers and cameras. Crucially, our strategy promises to be broadly applicable across the entire energy range accessible by existing and planned XFEL facilities. Lab-scale UV demonstration experiments will be presented as well as results from an upcoming beam time at the FERMI soft X-ray FEL.
Critical Behaviors of Anderson Transitions in Three Dimensional Orthogonal Classes with Particle-hole Symmetries

XUNLONG LUO (Presenter), BAOLONG XU, Peking Univ., TOMI OHTSUKI, Sophia Univ., RYUICHI SHINDOU, Peking Univ. — From transfer-matrix calculation of localization lengths and their finite-size scaling analyses, we evaluate critical exponent of the Anderson transition in three dimensional (3D) orthogonal class with particle-hole symmetry, class CI, as $\nu = 1.16 \pm 0.14, 0.18$. We further study disorder-driven quantum phase transitions in the 3D nodal line Dirac semimetal model, which belongs to class BDI, and estimate critical exponent as $\nu = 0.80 \pm 0.02, 0.04$. From a comparison of the critical exponents, we conclude that a disorder-driven re-entrant insulator-metal transition from the topological insulator phase in the class BDI to the diffusive metal phase belongs to the same universality class as the Anderson transition in the 3D class BDI. We also discover a topological quantum critical point (TQCP) between one-dimensional (1D) class BDI topological insulator and Anderson insulator and showed that the re-entrant transition in the 3D model is connected to the TQCP in its 1D limit. We argue that an infinitesimally small disorder drives the nodal line Dirac semimetal in the clean limit to the diffusive metal.

Session W45 DCOMP: Quantum Manybody Systems and Computational Physics

8:00 AM W45.00001: Isometric Tensor Network Representation of String-Net Liquids

TOMOHIRO SOEJIMA (Presenter), KARTHIK SIVA, NICK BULTINCK, SHUBHAYU CHATTERJEE, University of California, Berkeley, FRANK POLLMANN, Physics, Technische Universitat Munchen, MICHAEL ZALETEL, University of California, Berkeley — Recently, a class of tensor networks called isometric tensor network states (isoTNS) was proposed which generalizes the canonical form of matrix product states to tensor networks in higher dimensions. While this ansatz allows for efficient numerical computations, it remained unclear which phases admit an isoTNS representation. In this work, we show that two-dimensional string-net liquids, which represent a wide variety of topological phases including discrete gauge theories, admit an exact isoTNS representation. We further show that the isometric form can be preserved after applying a finite depth local quantum circuit. Taken together, these results show that long-range entanglement by itself is not an obstruction to isoTNS representation and suggest that all two-dimensional gapped phases with gappable edges admit an isoTNS representation.

**8:12AM W45.00002: Dynamical phases of interacting Andre-Aubry-Harper model**  
YONG-CHAN YOO (Presenter), Condensed Matter Theory Center and Department of Physics, University of Maryland, College Park, JUNHYUN LEE, Condensed Matter Theory Center, Joint Quantum Institute and Department of Physics, University of Maryland, College Park, BRIAN SWINGLE, Condensed Matter Theory Center, Maryland Center for Fundamental Physics, Joint Center for Quantum Information and Computer Science, and Department of Physics, University of Maryland — The dynamics of non-integrable quantum many-body systems have received extensive attention for both theoretical and practical purposes. One important issue we address in this talk is the phase transition between thermal and many-body-localized states and the dynamical properties of their possible intermediate states. We calculate the non-equilibrium steady states (NESS) of the boundary-driven strongly interacting Andre-Aubry-Harper model by employing the time-evolving block decimation on matrix product density operators. The spin and energy transport properties of the system are obtained from the NESS, which reveals a rich phase diagram while tuning the quasiperiodic potential strength. We uncover an exotic dynamical phase following the thermal phase where the spin transport becomes sub-diffusive while the butterfly velocity remains non-zero, and also investigate the entanglement properties of each phase.

**8:24AM W45.00003: Topological signatures of Multipartite Entanglement**  
FABIO LINGUA (Presenter), Clark University, WEI WANG, Division of Condensed Matter, Max Planck Institute for the Physics of Complex Systems, LIANA SHPANI, BARBARA CAPOGROSSO-SANSONE, Clark University — We present a proposal to relate topological structure of worldline configurations to multipartite entanglement. Configurations result from the path-integral formulation of the density matrix in the limit of zero temperature. We consider hard-core bosons for which configurations, i.e. collections of particle paths, can be seen as geometric braids with a certain topological structure. We propose that properties of worldline configurations may realize a more comprehensive deciphering of multipartite entanglement. By means of Monte Carlo calculations, we study checkerboard, stripe, valence-bond solids, $Z_2$ topologically ordered spin liquid, and superfluid phase. We find that each ground-state is characterized by a certain `topological spectrum` which can be used to differentiate among different ground-states.

**8:36AM W45.00004: Dynamical properties of correlated many-body systems from Quantum Monte Carlo simulations**  
ETTORE VITALI (Presenter), PATRICK KELLY, ANNETTE LOPEZ, KAELYN DAUER, California State University, Fresno — I will discuss recent advances in the ab-initio study of correlated many-body quantum systems, and in particular the possibility to compute dynamical correlation functions from first principles using Quantum Monte Carlo techniques. Using the Hubbard model as an example, I will address the calculation of the spectral function, that can be experimentally measured in spectroscopy experiments, and the density structure factors, that can be measured in scattering experiments. The purpose is to allow us to directly compare the predictions of Quantum Monte Carlo techniques with experiments. I will present results for cold atomic Fermi systems in the BEC-BCS crossover in two and three dimensions and for cold atoms on optical lattices. I will also discuss results and perspectives for repulsive models, in connection with high-temperature superconductivity.
8:48AM W45.00005: Padé resummation of the linked cluster expansion of the many-particle path-integral.* ANISH BHARDWAJ (Presenter), Florida State University Tallahassee FL USA; National High Magnetic Field Laboratory FL USA, EFSTRATIOS MANOUSAKIS, Florida State University, Tallahassee, FL, USA; National High Magnetic Field Laboratory FL USA; University of Athens, Panepistimioupolis, Zografos, Athens, Greece — We have developed a quantum cluster expansion, analogous to the well-known Mayer cluster expansion for the classical partition function and the pair distribution function, and a quantum version of the virial expansion by starting from the many-body path-integral. We first derive the diagrammatic series expansion for the pair distribution function and show that the expansion is linked. This expansion can also be thought of as a power series expansion in the particle density. To resum the series, we use a Padé approximation scheme in momentum space, which is constrained to yield the calculated order by order expansion terms and the classical limit correctly. We have tested the approach on a Lennard-Jones and a hard-sphere system and our results agree very well with those obtained from the path-integral Monte Carlo. Our method has immediate application to the case of short-range hard-core potential where the established analytical and semi-analytical tools of many-body perturbation theory and quantum statistical mechanics cannot be applied in a straightforward manner.

*This work was supported in part by the U.S. National High Magnetic Field Laboratory, which is funded by NSF DMR-1157490 and the State of Florida

9:00AM W45.00006: An approach to discovering the low-energy space for effective quantum models of realistic systems.* BRIAN BUSEMEYER (Presenter), Center for Computational Quantum Physics, Flatiron Institute, JOAO N. B. RODRIGUES, Center for Natural Sciences and Humanities, Federal University of ABC - UFABC, SHIVESH PATHAK, LUCAS K. WAGNER, University of Illinois at Urbana-Champaign — Low-energy effective models can be powerful tools for understanding realistic systems, but in many cases it is difficult to quantify the accuracy of those models for a specific system. Density matrix downfolding (DMD) [1] is one approach to determining accurate effective models from first-principles many-body calculations, but requires a sample of low-energy wave functions with varying properties. We present a new method, constrained variational Monte Carlo, which targets low-energy wave functions while varying other properties, such as the average double-occupation of orbitals. We tested the approach on the hydrogen molecule at stretched and compressed bond lengths, and use it to explore how the low-energy space changes with bond length. For example, when the bond is stretched the low-energy space shifts such that interactions become necessary to accurately describe it. Models fitted to the generated states were solved and reproduced the exact low-energy spectrum of the first-principles Hamiltonian. The method provides a systematic many-body approach to exploring the low-energy space of realistic systems. [1] Changlani et al., J. Chem. Phys., 143, 10, 102814, (2015).

9:12AM W45.00007: Variational-Correlations Approach to Quantum Many-body Problems
ARBEL HAIM (Presenter), GIL REFAEL, Caltech — We investigate an approach for studying the ground state of a quantum many-body Hamiltonian that is based on treating the correlation functions as variational parameters. In this approach, the challenge set by the exponentially-large Hilbert space is circumvented by approximating the positivity of the density matrix, order-by-order, in a way that keeps track of a limited set of correlation functions. In particular, the density-matrix description is replaced by a correlation matrix whose dimension is kept linear in system size, to all orders of the approximation. Unlike the conventional variational principle which provides an upper bound on the ground-state energy, in this approach one obtains a lower bound instead. By treating several one-dimensional spin 1/2 Hamiltonians, we demonstrate the ability of this approach to produce long-range correlations, and a ground-state energy that converges to the exact result. Possible extensions, including to higher-excited states are discussed.

9:24AM W45.00008: Emergence of diffusive dynamics in an efficiently-solvable quantum lattice model  
JIE ZOU (Presenter), XIAOPENG LI, Department of Physics, Fudan University — Thermalization is a common phenomenon in nature, having a characteristic feature of irreversibility due to entropy increase. However, quantum mechanics, the principle for the microscopic world, is reversible. In past few decades, much effort has been devoted to this field in order to reconcile this conflict, and the eigenstate thermalization hypothesis has been proposed as one way to formulate quantum thermalization. In this talk, I will present our recent work on a one-dimension spinless hardcore fermion model with a variable range of interactions. We solve this problem by mapping it into a free fermion case, and we calculate its time evolution with an efficient Monte Carlo sampling algorithm. We observe that although our model is integrable in energy level spacing, the physical observables show certain thermalization behaviors. Furthermore, with increasing temperature, our system shows a crossover from ballistic to diffusive. It is worth mentioning that in our study we can reach a number of lattice sites of hundreds to thousands, much larger than typical numerical studies on quantum dynamics, which allows us to exclude finite-size artifacts.
Off-shell effective energy theory: a unified treatment of the Hubbard model from d=1 to d=∞
ZHENGQIAN CHENG (Presenter), CHRIS MARIANETTI, Columbia Univ — Here we propose an exact formalism, off-shell effective energy theory (OET), which provides a thermodynamic description of a generic quantum Hamiltonian. The OET is based on a partitioning of the Hamiltonian and a corresponding density matrix ansatz constructed from an off-shell extension of the equilibrium density matrix. To approximate OET, we introduce the central point expansion (CPE), which is an expansion of the density matrix ansatz, and we renormalize the CPE using a standard expansion of the ground state energy. We present dual realizations of OET based on a partitioning of the kinetic and potential energy, denoted as K and X, respectively. We showcase the OET for the one band Hubbard model in d=1, 2, and ∞ , showing favorable agreement with exact or state-of-the-art results over all parameter space; and a negligible computational cost. Physically, K describes the Fermi liquid, while X gives an analogous description of both the Luttinger liquid and the Mott insulator. Our approach should find broad applicability in lattice model Hamiltonians, in addition to real materials systems.

The Superfluid Pairing Gap for an Ultracold Atomic Unitary Fermi Gas
ANNETTE LOPEZ (Presenter), ETTORE VITALI, PATRICK KELLY, California State University, Fresno — We address the problem of computing the superfluid pairing gap of a fermionic cold gas from first principles. Cold atomic Fermi systems are unique laboratories to explore many-body systems, due to the unprecedented experimental control that can be currently achieved. The ability to provide robust theoretical predictions for cold atoms can have a significant impact in condensed matter physics, nuclear physics, and nuclear astrophysics. In particular, cold gases can shed light into some of the most mysterious physical systems in the universe, like the interiors of neutron stars. In this work we use unbiased Quantum Monte Carlo techniques interfaced with state of art analytic continuation technique to compute the spectral function of a unitary Fermi gas and the superfluid gap.
10:00AM W45.00011: Normalizing Cluster Wavefunctions in the Interstitial Region Within the Muffin-tin Approximation*  DANIEL GEBREMEDHIN (Presenter), CHARLES ALBERT WEATHERFORD, Florida A&M University, BRIAN WILSON, Lawrence Livermore Natnl Lab — In multi-scattering methods, overlap integrals of cluster wavefunctions for an interstitial region, which lies inside the Watson sphere and outside all the enclosed ionspheres, are discussed. When the potential inside this interstitial region is taken to be constant, and hence, obeys the Helmholtz equation, the resulting solutions are known to involve Bessel functions. Normalizing the cluster wavefunctions inside this intricate region naturally leads to two-center integrals of various Bessel-type functions. In this article, all of the numerous types of integrals that might arise are exhaustively presented. Analytical expressions that are suitable for efficient computation of the overlap integrals are worked out by employing known addition theorems for the Bessel functions. These integrals require careful attention as they otherwise lead to an artificial singularity that may not cancel. Results for sample implementations will be discussed.

10:12AM W45.00012: Temperature scaling in Monte Carlo nonequilibrium relaxation  YOSHIHIKO NONOMURA (Presenter), MANA, National Institute for Materials Science, YUSUKE TOMITA, College of Engineering, Shibaura Institute of Technology — The nonequilibrium relaxation (NER) method is an alternative approach to overcome the critical slowing down in Monte Carlo simulations. In local-update algorithms, NER is based on the power-law critical relaxation derived from the dynamical finite-size scaling (DFSS) theory, and off-critical scaling behaviors are also derived from the same formalism. In cluster-update algorithms, critical nonequilibrium relaxation is described by the stretched-exponential formula [1-4], which can be derived phenomenologically [5]. In the present talk, we show that off-critical scaling behaviors in cluster-update algorithms can be formulated by generalizing the nonequilibrium-to-equilibrium scaling [1,3-5]. By taking the magnetic susceptibility as an example, from the early-time critical relaxation, $\chi(t) \sim \exp(\alpha t^\beta)$, and the equilibrium behavior near the critical point $T_c$, $\chi(T) \sim (T-T_c)^\gamma$, we have $\chi(t,T) \sim (T-T_c)^\gamma f_{sc}(ct^\beta + \log(T-T_c)^\gamma)$ with a scaling function $f_{sc}(x)$. This scaling is confirmed numerically, and the one derived similarly in local-update algorithms holds better than that from DFSS.

10:24AM W45.00013: A statistical mechanics definition of the hydration shell of a membrane in an open system Molecular Dynamics Simulation. JOHN WHITTAKER (Presenter), LUIGI DELLE SITE, Freie Univ Berlin — Defining and quantifying the solvation shell of a biological macromolecule poses a major challenge, and even with state of the art equipment and methods, the question of the extent of hydration can vary depending on the quantity of interest, emphasizing the need for an unambiguous definition. The adaptive resolution simulation (AdResS) technique offers the unique ability to estimate the extent of the hydration shell around a biomolecule through the use of an open boundary atomistic system embedded within a thermodynamic reservoir of non-interacting, structureless particles. Here, we apply the latest AdResS scheme to the study of a pure DPPC membrane solvated in liquid water and determine that the mandatory solvation shell of a DPPC membrane extends to ~1.5 nm away from the DPPC phosphate headgroups, well beyond distances predicted from radial distribution functions.

10:36AM W45.00014: Topologically induced pre-scrambling and dynamical detection of topological phase transitions at infinite temperature* CEREN DAG (Presenter), Univ of Michigan - Ann Arbor, LUMING DUAN, Center for Quantum Information, IIIS, Tsinghua University, KAI SUN, Univ of Michigan - Ann Arbor — Out-of-time-order correlators (OTOCs) measured at infinite temperature are well-established tools to study quantum chaos in quantum many-body systems as well as information properties of black holes. Here we report that infinite-temperature OTOCs could also directly probe quantum phase transitions at zero temperature in contrast to common intuition. We reveal the mechanism that allows OTOC to prioritize the low energy effects over strong thermal fluctuations at infinite temperature and find that the mechanism is driven by topological degeneracy and hence is highly universal and robust, as long as the underlying system can be formulated in 1D Majorana basis. Using the Majorana representation, we analytically and numerically show that the infinite-temperature OTOCs detect the presence of Majorana zero modes at the ends of the chain that is associated with 1D Z2 topological order. Such sensitivity to zero modes introduces a new time-scale to the dynamics of non-integrable systems where the information scrambling temporarily freezes, suggesting a restricted scrambling for the topologically-protected quantum information. We dub the phenomenon as topologically induced pre-scrambling.

Session W46 GMAG: Low-Dimensional Magnetism and Single Molecule Magnets 708 - Selvan Demir, Michigan State Univ - Tag(s): Focus
Remarkable magnetic field effects in quasi-one dimensional Ising-like antiferromagnet BaCo$_2$V$_2$O$_8$ studied by neutron scattering [Invited] BEATRICE GRENIER (Presenter), Univ. Grenoble Alpes & CEA-Grenoble — BaCo$_2$V$_2$O$_8$ is a realization of a spin-1/2 Ising-like quasi-one dimensional antiferromagnet (AF) with fascinating static and dynamical behaviors. In zero-field, the weak interchain interactions stabilize below 5.6 K a peculiar Néel ordering, characterized by magnetic moments aligned along the chain c-axis and dressed with confined two spinon excitations [1,2]. We have explored the influence of an external magnetic field both on the AF ordering and on the spin dynamics by single-crystal neutron scattering. Different behaviors are observed for a transverse and a longitudinal magnetic field (i.e. perpendicular and parallel to the direction of the moments, respectively), nicely reproduced by TEBD numerical calculations.

In a transverse magnetic field $H$ // $b$, a staggered field is induced along the $a$ direction, due to the non-diagonal anisotropic $g$-tensor of BaCo$_2$V$_2$O$_8$. As a result, a high field novel phase settles above a critical field of 10 T, when the staggered field overcomes both the Ising anisotropy and the interchain coupling. The nature of the excitations is also strongly modified. As I will show, our results reveal the occurrence of a topological quantum phase transition between two types of solitonic topological objects [3].

In a longitudinal magnetic field $H$ // $c$, the Néel ordering turns at a critical field of 3.8 T into a longitudinal incommensurate (IC) one, with magnetic IC excitations, due to the Ising character of the system [1]. This phase has raised a strong interest as it is a unique example of the Tomonaga-Luttinger liquid (TLL) physics experimentally accessible under moderate magnetic field. I will present our results on the dispersion spectrum in this exotic phase together with its magnetic field dependence, in the light of the TLL theory [4].

8:36AM W46.00002: Comparison of magnetic disorder at low temperature in Ca$_3$Co$_2$O$_6$ and Ca$_3$Co$_{1.9}$Zn$_{0.1}$O$_6$*  
BENJAMIN WHITE (Presenter), ALEXANDER B. C. MANTILLA, JANI JESENOVEC, Central Washington University — The compound Ca$_3$Co$_2$O$_6$ undergoes a transition into a spin-density wave (SDW) state near 24 K. Below ~10 K, this unstable SDW state coexists with a nearly-degenerate commensurate antiferromagnetic state as well as short-range magnetic order. Clear signatures of this strong magnetic disorder have been observed in the response of entropy to changing magnetic field and temperature. We performed a calorimetry study of Ca$_3$Co$_2$O$_6$ and Ca$_3$Co$_{1.9}$Zn$_{0.1}$O$_6$ in order to compare their entropic responses at low temperature. Our results for Ca$_3$Co$_2$O$_6$ reveal that $\Delta S(T, H) = S(T, H) - S(T, H = 0)$ increases as either temperature or magnetic field increase. In contrast, $\Delta S$ data for Ca$_3$Co$_{1.9}$Zn$_{0.1}$O$_6$ were relatively unresponsive to changes in temperature or field, suggesting that Zn substitution may reduce the low-temperature magnetic disorder observed in Ca$_3$Co$_2$O$_6$. These results will be discussed within the context of two cases (Ca$_3$Co$_2$O$_6$ under applied pressure and Ca$_{2.75}$R$_{0.25}$Co$_2$O$_6$ ($R$ = Dy, Lu)) in which a single magnetic ground state is stabilized.

8:48AM W46.00003: Electronic and magnetic properties of the cluster magnet Ba$_3$LaRu$_2$O$_9$
QIANG CHEN (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, AMANDA CLUNE, Department of Chemistry, University of Tennessee, Knoxville, JIE MA, Department of Physics and Astronomy, Shanghai Jiaotong University, JINGUANG CHENG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, KEITH TADDEI, CLARINA RELOJ DELA CRUZ, MATTHEW STONE, ALEXANDER KOLESNIKOV, Neutron Scattering Division, Oak Ridge National Laboratory, JANICE LYNN MUSFELDT, Department of Chemistry, University of Tennessee, Knoxville, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, ADAM ACZEL, Neutron Scattering Division, Oak Ridge National Laboratory — Magnetic materials with electrons delocalized over small molecular clusters, so-called cluster Mott insulators, have recently attracted significant interest in the quest for novel magnetic properties. The extremely short metal-metal distances within the molecular clusters promote significant electron hopping, thus leading to the formation of unusual electronic ground state configurations based on quasi-molecular orbitals. In this talk, we discuss the electronic and magnetic properties of the cluster magnet Ba$_3$LaRu$_2$O$_9$. We present magnetic susceptibility and inelastic neutron scattering data supporting an unusual spin-3/2 per dimer electronic ground state that cannot be understood in a local moment picture. We also present bulk characterization, muon spin relaxation, neutron diffraction, and inelastic neutron scattering data that are indicative of an ordered state arising from a quasi-2D frustrated lattice of Ru dimer building blocks. Finally, we present preliminary results of Raman spectroscopy and neutron diffraction under pressure that reveal a coincident structural/spin state transition at ~1 GPa.
Large positive zero field splitting in the cluster magnet $\text{Ba}_3\text{CeRu}_2\text{O}_9$

ADAM ACZEL (Presenter), Oak Ridge National Lab, QIANG CHEN, SHIYU FAN, University of Tennessee, KEITH TADDEI, MATTHEW STONE, ALEXANDER KOLESNIKOV, Oak Ridge National Lab, JINGUANG CHENG, Chinese Academy of Sciences, JANICE LYNN MUSFELDT, HAIDONG ZHOU, University of Tennessee — We present the synthesis and magnetic characterization of a polycrystalline sample of the 6H-perovskite $\text{Ba}_3\text{CeRu}_2\text{O}_9$, which consists of Ru dimers based on face-sharing RuO$_6$ octahedra. Our low-temperature magnetic susceptibility, magnetization and neutron powder diffraction results reveal a non-magnetic singlet ground state for the dimers. Inelastic neutron scattering, infrared spectroscopy, and the magnetic susceptibility over a wide temperature range are best explained by a molecular orbital model with a zero-field splitting parameter $D \approx 85\text{meV}$ for the $S_{\text{tot}} \approx 1$ electronic ground state multiplet. This large value is likely due to strong mixing between this ground state multiplet and low-lying excited multiplets, arising from a sizable spin molecular orbital coupling combined with an axial distortion of the Ru$_2$O$_9$ units. Although the positive sign for the splitting ensures that $\text{Ba}_3\text{CeRu}_2\text{O}_9$ is not a single molecule magnet, our work suggests that the search for these interesting materials should be extended beyond $\text{Ba}_3\text{CeRu}_2\text{O}_9$ to other molecular magnets based on metal-metal bonding.

Lanthanide-based single molecule magnets through the prism of ab-initio calculations*

BORIS LEGUENNIC (Presenter), Institut des Sciences Chimiques de Rennes, University of Rennes 1 — In the beginning of the century, the emergence of lanthanide-based systems exhibiting slow relaxation of their magnetization opened a new chapter in the field of molecular magnetism. These so called Single-Molecule Magnets (SMMs) may find in a near future many important applications such as high-density data storage, molecular spintronic or quantum computing. Over the recent years, quantum chemical approaches, going from multiconfigurational wavefunction-based methodologies to (periodic) density functional theory have shown to be powerful tools to gain deep insight into electronic and magnetic features of such lanthanide-based SMMs. This presentation will focus on recent applications of such state-of-the-art computational protocols in the understanding of Ln-based SMMs behaviors.

*Project that has received funding from the European Research Council (ERC) under the European Unions Horizon 2020 research and innovation program (ERC-CoG MULTIPROSMM grant agreement N725184). French Research National Agency (ANR) is also acknowledged (grant ANR-19-CE29-0012-02).
Nature of hyperfine interactions in TbPc$_2$ single-molecule magnets: *Multireference ab-initio study*  
ALEKSANDER WYSOCKI (Presenter), KYUNGWHA PARK,  
Department of Physics, Virginia Tech — Lanthanide-based single-ion magnetic molecules can have large magnetic hyperfine interactions as well as large magnetic anisotropy. Recent experimental studies reported the tunability of these properties by changes of chemical environments or by application of external stimuli for device applications. In order to provide insight into the origin and mechanism of such tunability, here we investigate the magnetic hyperfine and nuclear quadrupole interactions of TbPc$_2$ single-molecule magnets using first-principles multireference methods including spin-orbit interaction. The microscopic Hamiltonian is mapped onto an effective Hamiltonian with an electronic pseudo-spin $S=1/2$. We discuss the physical origin of *ab-initio*-calculated hyperfine interaction parameters and their dependence on the experimental molecular geometry and structure distortions. We show the *ab-initio*-calculated electronic-nuclear spectrum and compare it with experimental data. We further analyze the role of the non-axial quadrupole interactions in the formation of avoided level crossings and magnetization dynamics.

A first-principles study of the phase stability and electronic properties of monolayer Vanadium-based Janus dichalcogenides  
DIBYENDU DEY (Presenter), ANTIA S. BOTANA, Arizona State Univ — We investigate the vibrational and electronic properties of 2D van der Waals Vanadium-based Janus dichalcogenides (VSSe, VSeTe, VSTe) at the monolayer level in both 2H and 1T phases by using first-principles calculations. We have found the 2H phase is energetically favorable in VSSe and VSeTe, whereas the 1T phase is lower in energy in VSTe. Within density functional theory, ferromagnetism (FM) allows splitting of the d-bands in the 2H phase with a trigonal prismatic environment, leading to a low-bandgap $S=1/2$ ferromagnetic insulator. On the other hand, no such splitting is observed in the distorted octahedral environment of the 1T phase, and the system remains metallic. In the presence of electronic correlations, we have found the magnetic ground state is FM for VSSe and VSeTe. On the contrary, a 120$^\circ$ canted AFM state is the magnetic ground state for VSTe. The semiconducting nature of FM two-dimensional Janus VSSe and VSeTe makes them potential materials for spintronics.
10:12AM W46.00008: Strong anisotropic spin-dipole coupling in electron-withdrawing Br-based system Cu$_2$(OH)$_3$Br*  
TATHAMAY BASU (Presenter), HEDA ZHANG, Michigan State Univ, ZHIYING ZHAO, Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences, XIANGLIN KE, Michigan State Univ — The compound Cu$_2$(OH)$_3$Br, belonging to an interesting hydroxyl salts of potential interests, crystallizes in monoclinic structure. This system consists of quasi-1D Cu-chains and undergoes complex antiferromagnetic ordering below around 10 K, with a magnetic field ($H$) induced spin-flop transitions below ordering. Here, we have investigated the detailed dielectric behavior of single crystalline compound in different orientations. We show that the temperature dependent dielectric constant clearly traces the magnetic ordering in presence of magnetic field, indicating the presence of magnetodielectric (MD) coupling. The MD coupling is further confirmed by isothermal $H$-dependent dielectric constant which captures the spin-flop transitions. These features are ascribable to electron withdrawing Br-atom to break the spatial inversion symmetry of the Cu-system, which creates local dipole moment and thereby governs strong MD coupling. This will create a path to design new magnetoelectric materials.

10:24AM W46.00009: Tailoring Non-Innocence in a Family of 2D Coordination Solids [Invited]  
KASPER PEDERSEN (Presenter), Department of Chemistry, Technical University of Denmark — Metal-organic frameworks (MOFs) and their non-porous analogues, coordination solids, constitute a new class of materials with highly multifaceted physical and chemical properties and virtually unlimited possibilities for synthetic modification and tuning. The realization of magnetic MOFs has been hampered by the large spatial separation between spin-carriers leading to magnetic order setting in at only low temperatures. A particularly attractive approach to magnetic MOFs is rooted in the use of radical ligands as spacers between paramagnetic metal ions, which alleviates the inter-metallic distance issue and have resulted in materials featuring extremely strong super-exchange interactions. Unfortunately, relatively few isolatable radical ligands possess the stability to allow their incorporation into MOF structures. An interesting approach to realize otherwise elusive radical ligands consists in the use of highly reducible metal ions, that will reduce even ligands considered wholly redox-inactive. We recently reported a quadratic, 2D coordination solid, CrCl$_2$(pyrazine)$_2$, that features Cr(III) and a partially reduced ligand scaffold, ensuing strong magnetic Cr(III)-radical exchange interactions [1].

In this talk, recent progress in the development of metal-organic solids with extremely strong magnetic exchange interactions will be presented. Focussing on a family of isostructural, quadratic 2D coordination solids, MX$_2$(pyrazine)$_2$, we show (1) how the occurrence of redox events between the metal ion, M, and the pyrazine ligand may be controlled by chemical tuning and external stimuli, and (2) how the macroscopic materials properties (magnetic, conductive, optical) relate to the redox state of the coordination solid.

8:00AM W47.00001: Coexistence of Magnetic Orders in Two-Dimensional Magnet CrI$_3$  

Ben Niu (Presenter), Tang Su, Brian A Francisco, Subhajit Ghosh, Fariborz Kargar, Xiong Huang, Mark I Lohmann, Junxue Li, Yadong Xu, University of California, Riverside, Di Wu, Department of Materials Science and Engineering, Nanjing University, Alexander Balandin, Jing Shi, Yongtao Cui, University of California, Riverside — The magnetic properties in two-dimensional van der Waals materials depend sensitively on structure. CrI$_3$, as an example, has been recently demonstrated to exhibit distinct magnetic properties depending on the layer thickness and stacking order. Bulk CrI$_3$ is ferromagnetic (FM) with a Curie temperature of 61 K and a rhombohedral layer stacking, while few-layer CrI$_3$ has a layered antiferromagnetic (AFM) phase with a lower ordering temperature of 45 K and a monoclinic stacking. In this work, we use cryogenic magnetic force microscopy to investigate CrI$_3$ flakes in the intermediate thickness range (25 – 200 nm) and find that the two types of magnetic orders can coexist in the same flake, with a layer of ~13 nm at each surface being in the layered AFM phase similar to few-layer CrI$_3$ and the rest in the bulk FM phase. The switching of the bulk moment proceeds through a remnant state with nearly compensated magnetic moment along the c-axis, indicating formation of c-axis domains allowed by a weak interlayer coupling strength in the rhombohedral phase.
8:12AM W47.00002: The honeycomb quantum Heisenberg ferromagnet model with anisotropic exchange interactions*  JOREN VANHERCK (Presenter), Physics Department, University of Antwerp, BART SOREE, Department of Electrical Engineering (ESAT), KU Leuven, WIM MAGNUS, Physics Department, University of Antwerp — Since the discovery of magnetism in single-layered CrI$_3$ about two years ago [1], research into the magnetic properties of this type of monolayer materials has ever been growing. However, a fundamental theory describing the origin of two-dimensional ferromagnetism, which is key in understanding its properties, is still missing.

We modelled these two-dimensional materials using a honeycomb quantum Heisenberg ferromagnet, accounting not only for the exchange interactions up to third nearest neighbours, but also allowing an overal exchange anisotropy. The latter turns out to be key for the ferromagnetic ordering. Here, we present analytical results that were obtained using double-time temperature-dependent Green's functions [2]. We furthermore discuss the influence of temperature, anisotropies and exchange constants on the resulting magnetization.

*We acknowledge funding from IMEC.

8:24AM W47.00003: Two-dimensional Ferromagnetic van der Waals CrX$_3$ (X=Cl, Br, I) Monolayers with Enhanced Anisotropy and Curie Temperature*  FENG XUE (Presenter), Fudan Univ, RUQIAN WU, UCI — Among the recently widely studied van der Waals layered magnets CrX$_3$ (X=Cl, Br, I), CrCl$_3$ monolayer (ML) is particularly puzzling as it is solely shown by experiments to have an in-plane magnetic easy axis and, furthermore, all of previous first-principles calculation results contradict this. Through systematical first-principles calculations, we unveil that its in-plane shape anisotropy that dominates over its weak perpendicular magnetocrystalline anisotropy is responsible for the in-plane magnetic easy axis of CrCl$_3$ ML. To tune the in-plane ferromagnetism of CrCl$_3$ ML into the desirable perpendicular one, we propose substituting Cr with isovalent tungsten (W). We find that CrWCl$_6$ has a strong perpendicular magnetic anisotropy and a high Curie temperature up to 76 K. Our work not only gives insight into understanding the two-dimensional ferromagnetism of van der Waals MLs but also sheds new light on engineering their performances for nanodevices.

*Work was supported by DOE-BES (Grant No. DE-FG02-05ER46237). Computer simulations were partially performed at the U.S. Department of Energy Supercomputer Facility (NERSC). F.X and Z.W. acknowledge support by the Basic Research Program of China under Grant No. 2015CB921400.
Spin wave excitations in van der Waals honeycomb ferromagnets

[Invited] JAE-HO CHUNG (Presenter), Korea Univ — Recent discoveries of robust two-dimensional magnetism brought about a great research interest in van der Waals ferromagnets [1]. Experimental observations of their spin wave excitations are important because the underlying spin Hamiltonian can provide crucial information regarding thermal stability of their long-range order. In this talk, we focus on honeycomb ferromagnets where linear Dirac crossings in their magnon bands similarly to the electronic band of graphene [2]. We used inelastic neutron scattering to observe spin wave excitations in CrI$_3$ and Cr$_2$Ge$_2$Te$_6$ single crystals, where robust ferromagnetism was observed in monolayers [1]. The spin wave band of CrI$_3$ at $T = 5$ K consisted of two distinctive bands of ferromagnetic excitations separated by a ~ 2 meV gap at the Dirac points [3]. These results can only be understood by considering a Heisenberg Hamiltonian with Dzyaloshinskii-Moriya interaction, thus providing experimental evidence that spin waves in CrI$_3$ can have robust topological properties. As the temperature was increased to and beyond $T_C = 61$ K, the anisotropy gap at the zone center vanished following the power law behavior whereas the stiffness of the spin waves remained finite. These results strongly indicate that the magnetic anisotropy plays a decisive role in determining the Curie temperature in CrI$_3$, which is in contrast with typical three-dimensional Heisenberg ferromagnets where exchange interactions controlling the Curie temperature. In comparison, Cr$_2$Ge$_2$Te$_6$ showed no evidence of Dirac gap but revealed the significant next nearest neighbor exchanges due to Ge ions. Finally, we will report the quantitative estimates of exchange parameters in their spin Hamiltonian, and compared their values with those of CrBr$_3$ and Cr$_2$Si$_2$Te$_6$.

Observation of 2D magnons in atomically thin CrI$_3$

JOHN CENKER (Presenter), BEVIN HUANG, Physics, University of Washington, NISHCHAY SURI, Physics, Carnegie Mellon University, PEARL THIJSSEN, AARON MILLER, Physics, University of Washington, MICHAEL MCGUIRE, Materials Science and Technology Division, Oak Ridge National Laboratory, DI XIAO, Physics, Carnegie Mellon University, XIAODONG XU, Physics, University of Washington — The collective excitations in magnetic materials, i.e. spin waves or magnons, may couple to inelastically scattered light. Despite the recent interest in two-dimensional (2D) van der Waals magnets, a direct observation of magnons in the monolayer limit is lacking. Here, we report the observation of 2D magnons in atomically thin CrI$_3$ by magneto-optical Raman measurements. In monolayer and bilayer CrI$_3$, we observe a sharp one-magnon feature at a zero-field energy of ~0.3 meV which blue-shifts with a g factor of 2. However, at the metamagnetic transition from the layered antiferromagnetic to spin-polarized state in bilayer, the magnon exhibits a discontinuous red-shift. This confirms that the magnetic anisotropy is much larger than the interlayer exchange in CrI$_3$. In addition, we observe a magnon feature at ~19 meV (~4.6 THz) for bilayer and thicker samples, significantly higher than $\Gamma$ point magnons in standard ferromagnetic systems, i.e. YIG. Our results establish CrI$_3$ as a potential candidate in miniaturized terahertz magnonic devices.
9:24AM W47.00006: Tuning Inelastic Light Scattering via Symmetry Control in 2D Magnet CrI$_3$

BEVIN HUANG (Presenter), JOHN CENKER, University of Washington, XIAOOU ZHANG, Physics, Carnegie Mellon University, ESSANCE RAY, TIANCHENG SONG, University of Washington, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, MICHAEL MCGUIRE, Materials Science and Technology Division, Oak Ridge National Laboratory, DI XIAO, Physics, Carnegie Mellon University, XIAODONG XU, University of Washington — The coupling between spin and charge degrees of freedom in a crystal imparts strong optical signatures on scattered electromagnetic waves. This has led to magneto-optical effects with a host of applications, from the sensitive detection of local magnetic order to data storage technologies. Here, we demonstrate a new magneto-optical effect: the tuning of inelastically scattered light through symmetry control in atomically thin chromium triiodide (CrI$_3$). In monolayers, we found an extraordinarily large magneto-optical Raman effect from an A$_{1g}$ phonon mode due to ferromagnetic order. The linearly polarized, inelastically scattered light rotates by ~40°, more than two orders of magnitude larger than the rotation from MOKE under the same experimental conditions. In CrI$_3$ bilayers, we show that the same A$_{1g}$ phonon mode becomes Davydov-split into two modes of opposite parity, exhibiting selection rules that depend on inversion symmetry and magnetic order. Applied magnetic and electric fields allow for magnetoelectrical control over these selection rules. Our work highlights the unique opportunities provided by 2D magnets for controlling underlying symmetries to manipulate Raman optical selection rules and for exploring emergent magneto-optical effects and spin-phonon coupled physics.

9:36AM W47.00007: Phonon-mediated magnetic order control of bilayer antiferromagnets*

MARTIN RODRIGUERZ-VEGA (Presenter), ZEXUN LIN, University of Texas at Austin, GAURAV CHAUDHARY, Physics, University of Chicago, ARITZ LEONARDO, University of the Basque Country, MAIA VERGNIORY, Donostia International Physics Center, GREG FIETE, Northeastern University — We study theoretically the effects of non-linear phonon processes after the ultra-fast photo-excitation of an infrared-active mode in the magnetic order of bilayer antiferromagnets. As a prototypical example, we consider bilayer CrI$_3$, a van der Waals crystal composed of ferromagnetic (FM) layers with out-of-plane magnetization. Between the layers, the exchange coupling is antiferromagnetic (AFM) in the ground state, as determined experimentally, and such coupling is connected with the relative stacking between the layers. We employ group theory methods to determine the nature of the phonons modes and their allowed non-linear coupling terms in the AFM groundstate. Then, we use first-principles calculations to determine their frequencies and coupling strengths. We then use those results as inputs for the phonon equations of motion after photo-excitation and find that the Raman modes involving relative movement between the layers have the potential to influence the interlayer exchange interaction. Finally, we comment on the feasibility of the experimental detection of the changes in the magnetic order.

9:48AM W47.00008: Strain effect on magnetism of atomically thin CrI₃  QIAN SONG (Presenter), CONNOR A OCCHIALINI, DIFEI ZHANG, JIARUI LI, ABRAHAM L LEVITAN, RICCARDO COMIN, Massachusetts Institute of Technology MIT — The structural stacking order plays an important role for the magnetic ground state of atomically thin CrI₃. While bulk crystals undergo a transition from Monoclinic structure at room temperature to Rhombohedral structure at low temperature, bilayer CrI₃ maintains a monoclinic structure for all temperatures. Despite several studies, the absence of a structural transition in bilayer CrI₃ remains to be understood. Here we report on the study of bilayer CrI₃ on different substrates, using Raman and magneto-optical Kerr effect measurements to reveal the interplay between epitaxial strain, lattice structure, and spin ordering. We find that the lattice mismatch and resulting strain between the substrate and the CrI₃ flakes has a dramatic impact on the structure of the atomically thin CrI₃.

10:00AM W47.00009: Intrinsic Ferromagnetism in 2D CrₓSe₁₋ₓ Crystals*  MENGYING BIAN (Presenter), KEKE HE, FAN SUN, PEIJIAN WANG, ALIREZA JALOULI, JONATHAN P BIRD, State Univ of NY - Buffalo, YANGLONG HOU, Peking University, HAO ZENG, State Univ of NY - Buffalo — In the last two years, several two-dimensional (2D) materials of magnetic order, including CrI₃ and Cr₂Ge₂Te₆, have been observed, which represents a breakthrough in the field of 2D magnetism and opens up opportunities for device applications integrating these magnets with other van der Waals (vdW) crystals. However, most of these materials are vdW structures which rely on the mechanical exfoliation technique to obtain ultra-thin flakes. Furthermore, most 2D magnets have poor stability and low magnetic transition temperature, which limit their practical application. To search for 2D materials with improved magnetic properties, one needs to look beyond vdW crystals. In this work, a 2D non-vdW magnetic material, CrₓSe₁₋ₓ, has been synthesized using an ambient pressure chemical vapor deposition method. The magnetic characterization demonstrated that the thin flakes exhibit ferromagnetic properties with ordering temperature above 250 K. These results may pave the way for practical applications of 2D magnets.

Temperature dependent study of magnetization dynamics in CrCl$_3$ – a layered antiferromagnet*  

SUPRIYA MANDAL (Presenter), LUCKY N. KAPOOR, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research (TIFR), SOHAM MANNI, Department of Physics, Indian Institute of Technology (IIT) Palakkad, MEGHAN P. PATANKAR, A. THAMIZHAVEL, MANDAR M DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research (TIFR) — Chromium trichloride (CrCl$_3$) is a layered antiferromagnet. Recently it has found renewed interest due to its antiferromagnetic resonance in GHz frequencies, two-dimensional (2D) layered structure with low cleavage energy and complex magnetization dynamics [1]. We report a detailed study of magnetization dynamics of bulk CrCl$_3$ placed on a coplanar waveguide (CPW) as a function of temperature. We observe prominent ferromagnetic, antiferromagnetic and paramagnetic resonances depending on temperature and in-plane magnetic field. We also observe magnon-magnon coupling and presence of multiple spin-wave modes by introducing an additional out-of-plane magnetic field by tilting the sample with respect to magnetic field direction. We extract useful system parameters and study their dependence on temperature and angle of tilting by fitting to experimental data. Ability to easily exfoliate 2D layers of CrCl$_3$ opens up possibility of coupling it to CPW resonators and application in antiferromagnetic spintronics and hybrid quantum systems.

Two-dimensional (2D) magnetic materials are of great current interest for their promising applications in spintronics. Here we propose the van der Waals (vdW) material $\text{VI}_3$ to be a 2D Ising ferromagnet (FM), using density functional calculations, crystal field level diagrams, superexchange model analyses, and Monte Carlo simulations. The $a_{1g}^1e_{-1}^1$ state in the trigonal crystal field turns out to be the ground state, and it gives rise to the 2D Ising FM due to a significant single ion anisotropy (SIA) associated with the $S_z=1$ and $L_z=-1$ state of $V^{3+}$ ions. Moreover, a tensile strain on the $\text{VI}_3$ monolayer further stabilizes the $a_{1g}^1e_{-1}^1$ ground state, and the enhanced FM superexchange and the strong SIA would raise the Curie temperature of the $\text{VI}_3$ monolayer from 70 K to 90-110 K under a 2.5-5% tensile strain. This prediction is worth a prompt experimental verification.

Two-dimensional magnetism in a van der Waals semiconductor

Since the recent discovery of ferromagnetism in exfoliated flakes of $\text{CrI}_3$ and $\text{Cr}_2\text{Ge}_2\text{Te}_6$, interest in two-dimensional (2D) ferromagnetic systems has increased. Previously predicted to be prohibited by thermal fluctuations, the existence of 2D magnetically ordered systems offers an ideal platform for examining novel quantum phenomena and opens up opportunities for emerging applications, including magneto-optic and magneto-electronic devices, spintronics, and quantum computing. For use in applications, there is a crucial need to develop 2D materials that simultaneously exhibit ferromagnetism and semiconducting behaviors. Towards this end, we recently synthesized an air stable van der Waals magnetic semiconductor. 2D sheets can be prepared through mechanical exfoliation for measurement and incorporation into more complex heterostructures. Using electrical transport, second harmonic generation spectroscopy, photoluminescence spectroscopy, and scanning tunneling spectroscopy, we investigate the electrical and magnetic properties of this material in the 2D limit. We present clear evidence of layered antiferromagnetic ordering at ~130K, below which the spins in each sheet are aligned ferromagnetically parallel to the plane while the interlayer coupling is antiferromagnetic.
W47.00013: Giant and nonreciprocal second harmonic generation from layered antiferromagnetism in bilayer CrI$_3$  
ZEYUAN SUN (Presenter), YANGFAN YI, Fudan University, TIANCHENG SONG, GENEVIEVE CLARK, BEVIN HUANG, University of Washington, YUWEI SHAN, SHUANG WU, DI HUANG, CHUNLEI GAO, ZHANGHAI CHEN, Fudan University, MICHAEL MCGUIRE, Oak Ridge National Laboratory, TING CAO, University of Washington, DI XIAO, Carnegie Mellon University, WEI-TAO LIU, Fudan University, WANG YAO, University of Hong Kong, XIAODONG XU, University of Washington, SHIWEI WU, Fudan University — Layered antiferromagnetism is the spatial arrangement of ferromagnetic layers with antiferromagnetic interlayer coupling. Recently, the van der Waals magnet, chromium triiodide (CrI$_3$), emerged as the first layered antiferromagnetic insulator in its few-layer form. In this talk, we present an emergent nonreciprocal second-order nonlinear optical effect in bilayer CrI$_3$. The observed second-harmonic generation (SHG) is giant: several orders of magnitude larger than known magnetization induced SHG and comparable to SHG in the best 2D nonlinear optical materials studied so far. We show that while the parent lattice of bilayer CrI$_3$ is centrosymmetric and thus does not contribute to the SHG signal, the observed nonreciprocal SHG originates purely from the layered antiferromagnetic order, which breaks both spatial inversion and time reversal symmetries. Furthermore, polarization-resolved measurements reveal the underlying C$_{2h}$ symmetry, and thus monoclinic stacking order in CrI$_3$ bilayers, providing key structural information for the microscopic origin of layered antiferromagnetism. Our results indicate that SHG is a highly sensitive probe of subtle magnetic orders and open up possibilities for the use of two-dimensional magnets in nonlinear and nonreciprocal optical devices.

Session W48 DCMP: Superconductivity: Theories and Models III  
Mile High Ballroom 1A - Volodymyr Turkowski, Univ of Central Florida

8:00AM W48.00001: On the equivalence of Peierls and Holstein models in perovskite structures  
YAU CHUEN YAM (Presenter), MONA BERCIU, GEORGE ALBERT SAWATZKY, University of British Columbia — We consider the effects of electron-phonon coupling in a perovskite ABO$_3$, modelled in terms of uncorrelated s-orbitals on the B sites that hybridize with ligand p-orbitals at the O sites. Both the s-p and the p-p hopping matrices are modulated by vibrations of the O, described as Einstein optical phonons. For a single B0$_6$ cluster, we show that the effects of this Peierls electron-phonon coupling are described well in terms of an effective Holstein model, which couples the carrier to the single "molecular" phonon with A1g symmetry. For a single polaron in an infinite crystal, however, we demonstrate that the Peierls model has sharp transitions as the coupling is varied, where the ground-state momentum jumps between different high-symmetry points of the Brillouin zone. Such transitions are impossible for a Holstein model, showing that there are regions of the parameter-space where the two types of models are not equivalent.
8:12AM W48.00002: Mottness induced phase fluctuation in overdoped superconducting cuprates  WEI KU (Presenter), ZIJIAN LANG, Tsung-Dao Lee Institute & Shanghai JiaoTong University, FAN YANG, School of Physics, Beijing Institute of Technology — Recent observations of diminishing supefluid phase stiffness in overdoped cuprate high-temperature superconductors challenges the conventional picture of superconductivity. Here, through analytic estimation and verified via variational Monte Carlo calculation of an emergent Bose liquid, we point out that Mottness of the underlying doped holes dictates a strong phase fluctuation of the supefluid at moderate carrier density. This effect turns the expected doping-increased phase stiffness into a dome shape, in good agreement with the recent observation. Specifically, the effective mass divergence due to "jamming" of the low-energy bosons reproduces the observed nonlinear relation between phase stiffness and transition temperature. Our results suggest a new paradigm, in which the high-temperature superconductivity in the cuprates is dominated by physics of Bose-Einstein condensation, as opposed to pairing-strength limited Cooper pairing.

8:24AM W48.00003: Ground state properties of the Emery model in the underdoped regime*  ADAM CHICIAK (Presenter), William & Mary College, ETTORE VITALI, California State University, Fresno, SHIWEI ZHANG, Flatiron Institute — We perform extensive Auxiliary-Field Quantum Monte Carlo (AFQMC) calculations for the three-band Hubbard (Emery) model in the underdoped regime, in order to study the ground-state properties of Copper-Oxygen planes in the cuprates. Interfacing generalized Hartree-Fock calculations with cutting-edge AFQMC techniques in a self-consistent scheme, we are able to resolve small energy scales, which is crucial for determining the complex candidate orders in such a system. We explore the charge order, spin order, and localization properties as a function of charge-transfer energy.

A dynamical cluster approximation study of \( T_c \) in a composite superconducting-metallic two-component model.  

PHILIP DEE (Presenter), Department of Physics and Astronomy, The University of Tennessee, Knoxville, THOMAS MAIER, Computational Sciences and Engineering Division and Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Can we realize enhanced \( T_c \) in a low superfluid density superconductor by coupling it to a metal? This idea, which was postulated in [1] and shown perturbatively in [2], suggests that coupling a layer with a large pairing scale \( \Delta_0 \) but small phase stiffness to a non-interacting metallic layer can raise \( T_c \) to its mean-field value \( T_{MF} = \Delta_0 / 2 \). We studied this system nonperturbatively using the dynamical cluster approximation for a 2D attractive Hubbard model coupled to a noninteracting metallic layer via interlayer hopping. In contrast to prior work, our results for \( T_c \) appear only to decrease with increasing interlayer coupling.

Effect of non-phonon modes on the isotope effect and Hall resistivity in cuprates  
DA WANG (Presenter), Nanjing Univ — Non-phonon boson modes are widely observed in cuprates. Their existence may cause many interesting phenomena. In this work, we investigate their effects on the \( T_c \) isotope coefficient and Hall resistivity. (1) The coexistence of phonon and non-phonon modes leads to anomalous isotope effect. In special, if one of the boson modes (either phonon or non-phonon) is pair-breaking, large isotope coefficient \( \alpha > 0.5 \) can be obtained and a scaling of \( \alpha \sim \ln^2(T_c) \) as \( T_c \to 0 \) is predicted. This study indicates that \( \alpha > 0.5 \) may be caused by pair-breaking phonon. (2) If the non-phonon boson mode is stabilized by the magnetic field, the Hall coefficient shows a strong field dependence, in special near a van Hove filling. This may challenge the current understanding of the \( \text{``Hall number''}: p \to 1+p \) or \( p \to \infty \)?

9:00AM W48.00006: Magnetic impurities as hosts of odd-frequency superconductivity*
DUSHKO KUZMANOVSKI (Presenter), ALEXANDER BALATSKY, NORDITA, Stockholm University — Odd-frequency (odd-$\omega$) superconductivity is an example of unconventional dynamical order, where the Cooper pair correlations are both non-local and odd in relative time. Historically, the most important role regarding proximity-induced odd-$\omega$ pairing was played by superconductor-ferromagnet heterostructures. Shrinking the magnetic domain of this setup to the extreme, we demonstrate that all the necessary ingredients for generating odd-$\omega$ pairing are present in the vicinity of a paramagnetic impurity embedded in a conventional single-band bulk spin-singlet s-wave superconductor. We investigate the appearance of all possible pair amplitudes in accordance with the Berezinskii SPOT = -1 rule, which in our single-orbital case, trivially has O = +1. We study the spatial and frequency dependence of components classified by spatial parity, their evolution with impurity strength, and identify a reciprocity between different symmetries related through impurity scattering. We present calculations of physically measurable observables, such as spin-polarized local density of states, local spin susceptibility that carry signatures of odd-$\omega$ in some of their features.

9:12AM W48.00007: Harmonic Fingerprint of Unconventional Superconductivity*
MICHAEL KLETT (Presenter), XIANXIN WU, TILMAN SCHWEMMER, MARIO FINK, WERNER R HANKE, RONNY THOMALE, Institute for Theoretical Physics, University of Wuerzburg — The structure of superconducting pairing is determined by microscopic details such as the interaction profile and Fermiology beyond the spatial symmetry classification along irreducible point group representations of the underlying lattice. The pairing wave function unfolds in its orbital-resolved Fourier profile which we call the harmonic fingerprint (HFP), allowing us to formulate a concise connection between microscopic parameter changes and their impact on superconductivity. We present an analysis - based on random phase approximation calculations - of twisted bilayer graphene (TBG) involving d+id, s±, and f-wave order. Including nonlocal interactions - which unavoidably enter the low-energy electronic description of TBG - increases the weight of higher lattice harmonics and furthermore has a significant effect on the orbital structure of the paring states.

*The work in Wuerzburg is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) through Project-ID 258499086 - SFB 1170 and through the Wuerzburg-Dresden Cluster of Excellence on Complexity and Topology in Quantum Matter –ct.qmat Project-ID 39085490 - EXC 2147.
In heavy fermion system, multipole degree of freedom induce interesting phenomena, such as unconventional superconductivity (SC) and Anomalous Hall Effect (AHE). Recent experiments have revealed that unconventional s-wave SC state without any sigh-reversal emerges near the AFM phase in heavy fermion compound CeCu$_2$Si$_2$. However, this fact cannot be explained by conventional Migdal-Eliashberg (ME) theory. To overcome this difficulty, we study the microscopic SC paring mechanism in the presence of strong spin-orbit interaction (SOI) and higher-order many body effects ignored in ME theory. As a result, we find that unconventional s-wave state is realized near the AFM phase against the strong magnetic fluctuations. Moreover, obtained s-wave SC originates from interference between electric and magnetic multipole fluctuations due to the mode coupling effects given by many body effects. In addition, we propose large AHE will be induced due to the multi-orbital nature and strong SOI in the present system. [1] R. Tazai and H. kontani, J. Phys, Soc. Jpn. 88, 063701 (2019).

We study the effect of spin-orbit coupling (SOC) on the Hund's coupling induced orbital-singlet spin-triplet superconductivity in the three-orbital Hubbard model with rotationally-invariant slave-boson (RISB) mean-field theory. In the absence of SOC, RISB reproduces the phase diagram similar to the one obtained from dynamical mean-field theory, where the superconducting state emerges from the Hund's metal crossover regime. In the presence of SOC, the intrinsic particle-hole asymmetry in atomic levels, introduced by SOC, leads to different superconducting behaviors for above and below half-filling; the SOC suppresses the superconductivity in these two regimes with distinct manners. We analyze how these behaviors are connected to the spin and charge fluctuations and the atomic multiplets statistics. Our results provide insight into the pairing mechanism in Sr$_2$RuO$_4$ and iron-based superconductors.
9:48AM W48.00010: Influence of the Rutgers Relation on underdoped cuprate properties*

PATRICIA SALAS CASALES (Presenter), M. A. SOLÍS, Instituto de Física, UNAM — Within the extended Layered Boson-Fermion Model of Superconductivity [1,2] the Rutgers Relation, which relates the difference between the normal and the superconducting isobaric specific heats with the thermodynamic critical field, is combined with the first-principles relation of the critical field derivative as well as with the penetration and coherence lengths to get a novel expression for the penetration length $\lambda(T)$, which is more suitable for high temperature superconductors, as we have seen after applying it to underdoped cuprate superconductors $YBa_2Cu_3O_{6+x}$.

We compare our current results for the penetration length and the normalized superfluid density as functions of temperature as well as of doping $x$, with experiments and our previously reported results, obtaining a substantial improvement.

10:00AM W48.00011: DMRG and weak coupling studies of the two-leg Hubbard ladder*

YUVAL GANNOT (Presenter), YI-FAN JIANG, STEVEN KIVELSON, Stanford Univ — The Hubbard model is of paradigmatic significance in the study of highly correlated electron systems. Hubbard ladders are particularly interesting as they exhibit a subtle interplay between multiple phases even at weak coupling. Here, we reexamine the ground state phase diagram of the two-leg ladder in the limit of asymptotically weak coupling, an approach pioneered by Balents and Fisher (BF).

Among other things we find that the presence of a dangerously irrelevant operator leads to an instability of a previously predicted partially gapped phase. The result is a Luther-Emery (LE) liquid - the 1D analogue of a superconductor - characterized by a hierarchy of energy scales: the principle gap depends exponentially on $1/U$ in the asymptotic $U \to 0^+$ limit, as found by BA, while the additional gaps are smaller still by factors of $U^{1/2}$ compared to the dominant gap. Using DMRG to study the same ladder for intermediate values of $U$ (as small as $U = 4t$), we find qualitative behavior (LE phase and the existence of two distinct gap scales) similar to that predicted by the weak coupling theory.

*This work was supported in part by the Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-76SF00515.
10:12AM W48.00012: Beyond s- and d-waves: $d + d$ intra- and inter-band pairing in multiband superconductors* QIMIAO SI (Presenter), Department of Physics and Astronomy, Rice University, EMILIAN NICA, Department of Physics, Arizona State Univ — Recent experiments in multiband Fe-based and heavy-fermion superconductors have challenged the long-standing dichotomy between standard s- and d-waves. We discuss an alternative in the form of a gapped $d + d$ intra- and inter-band pairing which provides a natural interpolation between standard s and d-waves. We illustrate that this is equivalent to an $s\tau_3$ pairing initially proposed in the context of Fe-based superconductors [1]. We demonstrate that similar candidates are possible outside of the Fe-based family by constructing an analog for the heavy-fermion superconductor CeCu$_2$Si$_2$. We compare and contrast $d + d$ with similar pairings which occur in $^3$He.

Session W49 DCMP: Superconductivity and Competing phases Mile High Ballroom 1B - David Tanner, University of Florida

8:00AM W49.00001: Signatures of a pair density wave in striped cuprates at high magnetic fields ($H$)* PAUL BAITY (Presenter), ZHENZHONG SHI, JASMINKA TERZIC, DRAGANA POPOVIC, Dept. of Phys. & Natl. High Magnetic Field Lab., Florida State Univ., TAKAO SASAGAWA, Tokyo Inst. of Tech. — In underdoped cuprates, a putative pair density wave (PDW) state has been suggested to be responsible for the pseudogap regime, but the evidence for a PDW remains inconclusive. To test the interlayer frustration, the crucial component of the PDW picture, we performed transport measurements on La$_{1.7}$Eu$_{0.2}$Sr$_{0.1}$CuO$_4$ and La$_{1.48}$Nd$_{0.4}$Sr$_{0.12}$CuO$_4$ with “striped” spin and charge orders in perpendicular magnetic fields $H_{\text{perp}}$, and we also applied an additional field parallel to CuO$_2$ layers ($H_{\text{para}}$). We detected several phenomena predicted to arise from the existence of a PDW, including an enhancement of interlayer superconducting (SC) phase coherence with increasing $H_{\text{para}}$. Our results are consistent with the presence of local, PDW pairing correlations that compete with the uniform SC order at temperatures $T^0_c < T < (2-6)T^0_c$, where $T^0_c$ is the zero-field SC transition temperature, and become dominant at high enough $H_{\text{perp}}$ as $T \rightarrow 0$.

8:12AM W49.00002: Re-investigating the pseudogap phase of cuprates.  PAOLO ABRAMI (Presenter), SVEN BADOUX, ANTONY CARRINGTON, Physics, University of Bristol — The nature of the pseudogap state and the role it plays in the rich phase diagram of cuprate superconductors is yet to be fully understood. It is still an open question whether the transition to this state is a true phase transition or a slow crossover. A further question is whether the phase transition terminates at a zero temperature quantum critical point and what influence this has on the superconductivity. Recently, measurements of in-plane magnetic torque have suggested an abrupt transition close to the estimated edge of the pseudogap phase; suggesting a thermodynamic transition to an electronically nematic state. Here we further investigate these effects in different high Tc cuprates and how extrinsic effects can influence the signals seen.

8:24AM W49.00003: Diffuse Scattering Studies of Local Correlations in ErBa$_2$Cu$_3$O$_{6+x}$* BISHAM POUDEL (Presenter), BOGDAN M DABROWSKI, Physics, Northern Illinois University, DANIEL PHELAN, MATTHEW KROGSTAD, RAYMOND OSBORN, STEPHAN ROSENKRANZ, OMAR CHMAISSEM, Materials Science Division, Argonne National Lab — The origin of unconventional superconductivity in cuprate superconductors remains a great challenge. Early observations of stripe correlations in La$_{2-x-y}$Nd$_x$Sr$_y$CuO$_4$ confirmed the existence of spin and charge density wave orders near a “magical” p = 1/8 hole-doping where superconductivity disappears. At about the same time, ARPES measurements observed a pseudogap at temperatures much higher than T$_C$. The observation of CDW and pseudogap states appearing together and vanishing near optimal doping led to the speculation that these parameters are correlated and have a common origin. However, with the detection of weak charge density waves in YBCO near optimal doping (away from p = 1/8), these claims need to be re-evaluated. In that regard, rare-earth crystal field spectroscopy, used as a probe of the local structural and electronic environment in ErBa$_2$Cu$_3$O$_{6+x}$, provided evidence for charge-transfer between the copper chains and planes and the formation of clusters with three distinct states. In this talk, I will discuss recent single crystal diffuse scattering work to elucidate the nature of local short-range order and its correlation with CDW and the pseudogap states.

*Work at Argonne (data collection and analysis) was supported by the U.S. DOE, Office of Science, BES, DMSE
Spatially Inhomogeneous Competition between Superconductivity and the Charge Density Wave in YBa$_2$Cu$_3$O$_{6.67}$

JAEWON CHOI (Presenter), Physik-Institut, University of Zurich, OLEH IVASHKO, Deutsches Elektronen-Synchrotron DESY, ELIZABETH BLACKBURN, Department of Physics, Lund University, RUIXING LIANG, DOUGLAS ANDREW BONN, WALTER N HARDY, Department of Physics & Astronomy, University of British Columbia, ALEXANDER HOLMES, European Spallation Source, NIELS BECH CHRISTENSEN, Department of Physics, Technical University of Denmark, MARKUS HUECKER, Department of Condensed Matter Physics, Weizmann Institute of Science, SIMON GERBER, Laboratory for Micro and Nanotechnology, Paul Scherrer Institut, OLOF GUTOWSKI, UTARUETT, MARTIN VON ZIMMERMANN, Deutsches Elektronen-Synchrotron DESY, EDWARD M. FORGAN, Department of Physics & Astronomy, University of Birmingham, STEPHEN HAYDEN, H. H. Wills Physics Laboratory, University of Bristol, JOHAN CHANG, Physik-Institut, University of Zurich — Application of magnetic field induces new charge density wave (CDW) order in the high-temperature superconductor YBa$_2$Cu$_3$O$_{7-x}$ (YBCO), which is defined here as ferro-coupled CDW (F-CDW). It can be differentiated from the conventional antiferro-coupled CDW (or AF-CDW) by their c-axis correlations. This discovery has provoked a number of questions such as how does superconductivity compete with two CDW orders? and are either of these orders responsible for the electronic reconstruction? High-energy x-ray diffraction experiments were carried out to find a clue to those questions. The intensity of F-CDW order in YBa$_2$Cu$_3$O$_{6.67}$ was investigated as a function of magnetic field and temperature. We found that F-CDW order exists from low-field range B ~ 5 T, and regions of the sample with F-CDW order suppress superconductivity stronger than those with AF-CDW order. It implies that the superconducting state in some regions is more fragile than that in the other regions. In addition, F-CDW order has sufficiently long correlation length to explain the reconstruction of the electronic state. Our study sheds a light on the role of F-CDW order in superconducting and normal state properties of underdoped YBCO.
8:48AM W49.00005: No pseudogap magnetism detected in optimally to heavily overdoped

**Bi$_{2+x}$Sr$_2-x$CaCu$_2$O$_{8+d}$** single crystals by $\mu$SR*  

SHAYAN GHEIDI (Presenter), ANDRE M CÔTÉ, Simon Fraser Univ, SARAH DUNSIGER, CMMS, TRIUMF, KOLAWOLE ABAYOMI AKINTOLA, ALEX FANG, SHYAM SUNDAR, Simon Fraser Univ, GENDA GU, Brookhaven National Laboratory, JEFF SONIER, Simon Fraser Univ — Weak, temperature-dependent, quasi-static magnetism has been detected within the pseudogap (PG) phase of optimally-doped ($T_c = 91$ K) and overdoped ($T_c = 80$ K) Bi$_{2+x}$Sr$_2-x$CaCu$_2$O$_{8+d}$ (Bi2212) single crystals by zero-field (ZF) muon spin relaxation (mSR) [A. Pal et al., Phys. Rev. B 97, 060502(R) (2018)]. However, in this study it was not possible to determine whether the magnetism onsets at the PG temperature ($T^*$) due to the occurrence of muon diffusion above $T \sim 150$ K. To address this issue, we performed a similar ZF-mSR investigation of overdoped single crystals ($T_c = 70$ K and 55 K) in which $T^*$ lies below the muon diffusion temperature. The results are similar to that obtained for the lower doped samples, indicating that the anomalous magnetism is independent of hole-doping concentration and thus apparently not associated with the PG. We have carried out additional ZF-mSR measurements on these samples using an ultra-low background spectrometer. The new measurements verify the source of the magnetism comes from the Bi2212 samples. Potential origins of the anomalous magnetism will be discussed.

*Acknowledged support from Natural Sciences and Engineering Research Council of Canada (NSERC).

9:00AM W49.00006: Nematic Cooper-pair mass renormalization in copper oxide superconductors  

JONATHAN WARDH (Presenter), MATS GRANATH, Goteborg Univ, JIE WU, IVAN BOZOVIĆ, Brookhaven National Laboratory — We show that the observation of rotational symmetry breaking from transverse resistivity measurements in the normal state of LaSrCuO by Wu et al.$^1$ can be accounted for by the thermal fluctuations of a 2D superconductor with significant in-plane phase stiffness anisotropy. The conductivity tensor is modeled by distinct normal state and paraconducting components, with different effective mass tensors corresponding in general to non-aligned nematic directors and different mass anisotropies. The model is supported by new experimental data showing the rotation of the measured nematic director in the presence of a magnetic field that suppresses superconductivity. The pair mass/phase stiffness anisotropy grows dramatically with underdoping, pointing to an exotic pseudogap state with quasi-one-dimensional pair fluctuations, despite a relatively weak single-particle anisotropy.

9:12AM W49.00007: Magnetic-field-tuned superconducting quantum phase transition in underdoped Bi$_{2}$Sr$_{2-x}$La$_x$CuO$_{6+\delta}$* 

JASMINKA TERZIC (Presenter), BAL POKHAREL, PAUL BAITY, LILY STANLEY, DRAGANA POPOVIC, Department of Physics and National High Magnetic Field Lab, Florida State University, SHIMPEI ONO, Central Research Institute of Electric Power, Japan — In underdoped cuprates, the value of the upper critical magnetic field ($B_{c2}$) has been under debate. However, recent studies on the La-214 family have firmly established vortex phase diagrams that include an intermediate, viscous vortex liquid regime, regardless of the presence of charge order. We perform similar studies in underdoped Bi$_{2}$Sr$_{2-x}$La$_x$CuO$_{6+\delta}$ (La-Bi2201), which exhibits short-range charge order, by measuring linear transport, voltage-current characteristics and Hall effect in $B$ up to 45 T and temperatures ($T$) down to 0.017 K. Our data reveal an insulatinglike high-field normal state and a qualitatively the same vortex phase diagram as in underdoped La-214 cuprates, thus supporting the universality of the vortex phase diagram with an intermediate phase, i.e. the importance of quantum phase fluctuations as $T \rightarrow 0$, in underdoped cuprates. The properties of the apparent two-stage superconductor-insulator transition are discussed and compared to that in highly underdoped La$_{2-x}$Sr$_x$CuO$_4$.

9:24AM W49.00008: Incommensurability of the dynamic spin modulations in La$_{2-x}$Sr$_x$CuO$_4$ ($x=0.12$)*

WEI HE (Presenter), Department of Materials Science and Engineering, Stanford University, JIAJIA WEN, Department of Applied Physics, Stanford University, K. M. SUZUKI, SHUN ASANO, Institute for Materials Research, Tohoku University, WEI TIAN, Neutron Scattering Division, Oak Ridge National Laboratory, MASAKI FUJITA, Institute for Materials Research, Tohoku University, YOUNG SANG LEE, Department of Applied Physics, Stanford University — The high-temperature superconducting cuprates display intriguing physical phenomena due to the presence of competing or intertwined phases. One of the remarkable observations in both Sr-doped La$_{2-x}$Sr$_x$CuO$_4$ (LSCO) system and O-doped La$_2$CuO$_{4+y}$ is the so-called Y-shift, which refers to a small shift of both spin density wave (SDW) and charge density wave (CDW) peak positions from the high-symmetry Cu-Cu bond direction. However, the ordering temperatures for the SDW and CDW are different. Above the superconducting transition temperature ($T_c$), there is only incipient spin fluctuation coexisting with the CDW order. In this talk, I will present our recent high-resolution inelastic neutron scattering experiment which characterized the Y-shift in the spin fluctuation regime in LSCO ($x=0.12$). The implication of the result will be discussed. Our study provides important information on the nature of the spin fluctuation in this system.

Emergence of superconductivity in two transition metal chalcogenides

NIKOLAOS BINISKOS, SAJNA HAMEED, DAMJAN PELC (Presenter), School of Physics and Astronomy, University of Minnesota, YUAN LI, International Center for Quantum Materials, School of Physics, Peking University, XIANGDE ZHU, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota — Superconducting (SC) and charge-density-wave (CDW) states are pair condensates of electrons and of electrons and holes, respectively. In many quantum materials, these two states are found to coexist or compete. Transition-metal chalcogenides such as TaSe$_{2-x}$S$_x$[1] and ZrTe$_{3-x}$Se$_x$[2] exhibit both SC and CDW phases and may be viewed as model systems to study the interplay between these two types of order. In both systems, substitutional disorder enhances SC order and suppresses CDW order [1,2]. We use AC nonlinear magnetic response, a probe that was recently shown to be highly sensitive to SC fluctuations [3], to correlate the diamagnetic response above the superconducting transition temperature with the substitutional disorder. Our results indicate rather narrow SC fluctuation regimes, yet with unconventional temperature dependences of the diamagnetic signal. We discuss these findings in the context of recent work on oxide superconductors [3].

Direct observation of an incommensurate charge density wave in the superconductor Ta$_4$Pd$_3$Te$_{16}$

ZHENZHONG SHI (Presenter), STEPHEN J KUHN, Department of Physics, Duke University, FELIX FLICKER, Rudolph Peierls Centre for Theoretical Physics, Department of Physics, Clarendon Laboratory, University of Oxford, WILLIAM STEINHARDT, SACHITH DISSANAYAKE, Department of Physics, Duke University, TONI HELM, Max Planck Institute for Chemical Physics of Solids, JOOSEOP LEE, JACOB RUFF, Cornell High Energy Synchrotron Source, Cornell University, GILBERTO F L FABBRI, Advanced Photon Source, Argonne National Laboratory, DAVID E GRAF, National High Magnetic Field Laboratory, Florida State University, JOERG STREMPFER, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, SARA HARAVIFARD, Department of Physics, Department of Mechanical Engineering & Materials Science, Duke University — The various electronic instabilities such as superconductivity (SC) and charge density wave (CDW) in low dimensions often conspire to determine some novel ground states in strongly correlated systems. In this talk we present our experimental and theoretical results. We report the observation of a highly unusual incommensurate charge density wave (CDW) in the superconductor Ta$_4$Pd$_3$Te$_{16}$, using synchrotron X-ray diffraction. Additionally, our de Haas-van Alphen (dHvA) quantum oscillation measurements detect no evidence of Fermi surface reconstruction across the CDW transition. The temperature-pressure phase diagram was also determined, and the SC dome is found to be centered at the pressure where the CDW vanishes.
10:00AM W49.00011: Nematic order and Charge order in $\text{Ba}_{0.6}\text{Sr}_{0.4}\text{Ni}_{2}\text{As}_{2}$  PRARTHUM SARAF
(Presenter), CHRIS ECKBERG, University of Maryland, College Park, SANGJUN LEE, Department of Physics, Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, JOHN COLLINI, University of Maryland, College Park, STELLA SUN, Department of Physics, Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, DANIEL J CAMPBELL, University of Maryland, College Park, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, PETER MICHAEL ABBAMONTE, Department of Physics, Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Studies in the Cuprates and the Fe-based superconductors have hinted at a relationship between charge order order and superconductivity. The recent study on $\text{Ba}_{1-x}\text{Sr}_{x}\text{Ni}_{2}\text{As}_{2}$ shows strong nematic susceptibility for the B1G symmetry with increasing Sr doping corresponding to an enhancement in $T_c$. $\text{Ba}_{0.6}\text{Sr}_{0.4}\text{Ni}_{2}\text{As}_{2}$ is at the border of lattice driven nematic order and electronically driven nematic order. We report on X-ray and Neutron measurements on $\text{Ba}_{0.6}\text{Sr}_{0.40}\text{Ni}_{2}\text{As}_{2}$ that show the existence of three charge density waves. An incommensurate CDW in the tetragonal phase with $q=(0.27,0,0)$ and two commensurate CDWs in the triclinic phase with $q=(0.33,0,0)$ and $(0.5,0,0)$ are observed. The commensurate CDWs in the triclinic phase exist down to base temperature. We will discuss these results as well as elastoresistance measurements in $\text{Ba}_{0.6}\text{Sr}_{0.4}\text{Ni}_{2}\text{As}_{2}$.

10:12AM W49.00012: Charge Order in Tunable Electronic Nematic Superconductor $\text{Ba}_{1-x}\text{Sr}_x\text{Ni}_2\text{As}_2$  JOHN COLLINI (Presenter), University of Maryland, College Park, SANGJUN LEE, STELLA SUN, University of Illinois, Urbana Champaign, CHRIS ECKBERG, University of Maryland, College Park, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, PETER ABBAMONTE, University of Illinois, Urbana Champaign, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Recent discoveries of charge order in the cuprates and electron nematic order in the iron-based superconductors has pointed towards the possibilities of both orderings being tied to mechanisms of high $T_c$ superconductivity. The $\text{Ba}(1-x)\text{Sr}(x)\text{Ni}_2\text{As}_2$ system, closely related to the $\text{BaFe}_2\text{As}_2$ system, has recently been shown to exhibit both types of ordering without the presence of any magnetic order. We report single crystal X-ray diffraction observations that show a unidirectional charge order with wavevector $(0.27,0,0)$ in $\text{BaNi}_2\text{As}_2$ decays and vanishes by $x=0.65$. We also show that the $(0.33,0,0)$ CDW in the triclinic phase evolves into a $(0.5,0,0)$ CDW by $x=0.65$. The evolution of the charge order in this system correlates well with the reported evolution of nematicity and superconductivity, suggesting a strong link between the three phases.
**10:24AM W49.00013: Interstitial Oxygen Dopant Dynamics in La$_2$CuO$_{4+y}$ Probed by Coherent X-rays**  
MINGDE JIANG (Presenter), WEI HE, JIAJIA WEN, Stanford Univ, ANDREI FLUERASU, YUGANG ZHANG, LUTZ WIEGART, NSLS-II, Brookhaven National Lab, YOUNG SANG LEE, Stanford Univ — Oxygen doping La$_2$CuO$_4$ (LCO) yields the superconductor La$_2$CuO$_{4+y}$ with the highest $T_c$ in the LCO family. The interstitial oxygen dopants are mobile and can be annealed to form an ordered lattice, manifested as a satellite Bragg peak in x-ray diffraction. We present x-ray photon correlation spectroscopy (XPCS) data, measuring the dynamic timescale of the corresponding oxygen ordering diffraction peaks in order to infer the interstitial oxygen dopant mobility and its temperature dependence.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under contract No. DE-AC02-76SF00515. **10:36AM W49.00014: An evidence of the three-dimensional superconductivity evolution through apical oxygen in YBCO**  
HAI HUANG (Presenter), SANG JUN LEE, SLAC - Natl Accelerator Lab, MASAKI FUJITA, Institute for Materials Research, Tohoku University, TERUKAZU NISHIZAKI, Department of Electrical Engineering, Kyushu Sangyo University, CHI-CHANG KAO, JUN-SIK LEE, SLAC - Natl Accelerator Lab — Superconductivity in the high-$T_c$ cuprates originates from transport phenomena in their universal structural CuO$_2$ plane. Meanwhile, the role of the apical oxygen which locates between CuO$_2$ planes has brought significant attention. This is because the superconducting temperature ($T_c$) varies based on cuprates, even though they have the same CuO$_2$ structure and doping. Here, we investigated the oxygen order at the Cu-O chain layer in YBa$_2$Cu$_3$O$_{6.73}$ (YBCO), which is connected with CuO$_2$ plane through the apical oxygen. For this purpose, we performed resonant soft x-ray scattering measurement around the Cu $L_3$-edge. We found that the evolution of the three-dimensional (3D) superconductivity in YBCO is strongly correlated with the oxygen order. More details will be introduced in the presentation.

*All soft x-ray experiments were carried out at the SSRL (beamline 13-3), SLAC National Accelerator Laboratory, supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Contract No. DE-AC02-76SF00515.*
10:48AM W49.00015: Fast moving superconducting vortices and determination of the critical current in high pulsed magnetic fields* BORIS MAIOROV (Presenter), MAXIME LEROUX, IVAN NEKRASHEVICH, Los Alamos National Laboratory, MASASHI MIURA, Seikei University, FEDOR BALAKIREV, LEONARDO CIVALE, Los Alamos National Laboratory — Expanding non-linear transport (I-V) studies to magnetic fields above those accessible by DC magnets can bring valuable information about systems such as superconductors, charge-density waves and topological semi-metals. All-superconducting very-high field magnets also make it technologically relevant to study vortex matter in this regime. However, pulsed magnetic fields reaching 100T in milliseconds impose technical and fundamental challenges that have prevented the realization of these studies. Here, we present a fast I-V DC technique that enables determination of the superconducting critical current in pulsed magnetic fields, beyond the reach of DC magnets. We demonstrate this technique on Cu- and Fe-based superconductors on single-crystalline and metallic substrates with excellent agreement with DC field measurements. The I-V characteristics change with the magnetic field rate (dH/dt). We capture this unexplored vortex physics through a model based on the broken symmetry of the vortex velocity profile produced by the applied current

Friday, March 6, 2020 8:00 AM - 10:48 AM

Session W50 DCMP: Correlated Chains and 1D Models Mile High Ballroom 1C -

Daniel Agterberg, University of Wisconsin - Milwaukee

8:00AM W50.00001: Spin chains with long range RKKY interaction* LUHANG YANG (Presenter), ADRIAN FEIGUIN, Physics, Northeastern University — Spin-chains are not well ordered antiferromagnets: their correlations decay algebraically and they do not develop true long-range order. Higher dimensional magnets may develop long-range order and, in such a case, the excitations are gapless magnons with well-defined Goldstone modes. To reconcile these two pictures we interpret magnons as bound states of spinons. The introduction of antiferromagnetic long-range RKKY interactions effectively increases the dimensionality of the chains and allow them to develop long range AFM order without violating Mermin-Wagner's theorem. We study the transition from gapless disordered to gapless ordered phases through the spin dynamical structure factor with the DMRG method. We identify signatures of bound states leaking out from the spinon continuum and the formation of coherent Goldstone modes. We also consider the effects of easy-axis anisotropy and we compare to predictions from spin-wave theory.

*We thank the NSF for support through Grant No. DMR-1807814
8:12AM W50.00002: Dynamics of a tunable spin chain with three-body interactions
KHAGENDRA ADHIKARI (Presenter), KEVIN STUART DAVID BEACH, Univ of Mississippi — We formulate a projective Monte Carlo scheme for a spin-half chain with tunable 3-body interactions that encompass the Fredkin model and its t-deformed extension. Dynamical correlation functions are measured directly in various regions of the phase diagram. We report a high-quality numerical estimate of the large dynamical exponent at the Fredkin point.

8:24AM W50.00003: Universality and Quantum Criticality in Quasiperiodic Spin Chains*
UTKARSH AGRAWAL (Presenter), ROMAIN VASSEUR, Univ of Mass - Amherst, SARANG GOPALAKRISHNAN, CUNY College of Staten Island, Staten Island — Quasiperiodic systems are aperiodic but deterministic, so their critical behavior differs from that of clean systems as well as disordered ones. Quasiperiodic criticality was previously understood only in the special limit where the couplings follow discrete quasiperiodic sequences. Here we consider generic quasiperiodic modulations; we find, remarkably, that for a wide class of spin chains, generic quasiperiodic modulations flow to discrete sequences under a real-space renormalization group transformation. These discrete sequences are therefore fixed points of a functional renormalization group. This observation allows for an asymptotically exact treatment of the critical points. We use this approach to analyze the quasiperiodic Heisenberg, Ising, and Potts spin chains, as well as a phenomenological model for the quasiperiodic many-body localization transition.

*This work was supported by the US Department of Energy, Office of Science, Basic Energy Sciences, under Early Career Award No. de-sc0019168 (Utkarsh Agrawal and Romain Vasseur), the Sloan Foundation through a Sloan Research Fellowship (Romain Vasseur), and by NSF Grant No. DMR-1653271 (Sarang Gopalakrishnan).

8:36AM W50.00004: Universal Spin Dynamics in Infinite-Temperature One-Dimensional Quantum Magnets*
MAXIME DUPONT, JOEL MOORE (Presenter), University of California, Berkeley — We address the nature of spin dynamics in various integrable and non-integrable, isotropic and anisotropic quantum spin-S chains, beyond the paradigmatic S=1/2 Heisenberg model. In particular, we investigate the algebraic long-time decay \( \sim t^{-1/z} \) of the spin-spin correlation function at infinite temperature, using state-of-the-art simulations based on tensor network methods. We identify three universal regimes for the spin transport, independent of the exact microscopic model: (i) superdiffusive with \( z=3/2 \), as in the Kardar-Parisi-Zhang universality class, when the model is integrable with extra symmetries such as spin isotropy that drive the Drude weight to zero, (ii) ballistic with \( z=1 \) when the model is integrable with a finite Drude weight, and (iii) diffusive with \( z=2 \) with easy-axis anisotropy or without integrability, at variance with previous observations.

*This work was funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05-CH11231 through the Scientific Discovery through Advanced Computing (SciDAC) program (KC23DAC Topological and Correlated Matter via Tensor Networks and Quantum Monte Carlo).
8:48AM W50.00005: Excitations of critical quantum spin chains from non-equilibrium classical dynamics  
STÉPHANE VINET (Presenter), GABRIEL LONGPRÉ, WILLIAM WITCZAK-KREMPA, Université de Montreal — We study critical quantum spin chains with spin 1/2 that are dual to the non-equilibrium dynamics of a classical spin chain coupled to a bath. One example is the Kawasaki dynamics of an Ising chain. We give the exact groundstates, and single magnon excitations. Solutions for the two-magnon spectra are derived via the Bethe Ansatz. We discuss the corresponding dynamical critical exponents, which suggest that these chains host multiple dynamics at low energy. We also discuss a generalization to higher dimensions.

9:00AM W50.00006: Critical quantum spin chains from non-equilibrium classical dynamics: level statistics and entanglement entropy*  
GABRIEL LONGPRÉ (Presenter), STÉPHANE VINET, WILLIAM WITCZAK-KREMPA, Université de Montreal — A critical quantum spin 1/2 chain dual to the non-equilibrium Kawasaki dynamics of an Ising chain coupled to a bath is presented. Its level spacing distributions are analysed in the context of random matrix theory. The implications on the integrability of the system are discussed. Scaling of the entanglement entropy of exact states is studied against the eigenstate thermalization hypothesis.

*This research was partly funded by the Alexander Graham Bell Canada Graduate Scholarship from the Natural Sciences and Engineering Research Council of Canada.

9:12AM W50.00007: 1D spin chain with topologically constrained dynamics  
ZHEHAO DAI (Presenter), Massachusetts Institute of Technology MIT, ADAM NAHUM, Physics, Oxford University — We discuss a new type of quantum critical point in 1+1D realizing topologically constrained dynamics different from blastic or diffusive transport. We discuss the scaling structure and intuitive understandings of the operator contents.
9:24AM W50.00008: Dynamical properties of a driven dissipative dimerized $S = 1/2$ chain

BRUCE NORMAND (Presenter), Neutrons and Muons Research Division, Paul Scherrer Institute, MOHSEN YARMOHammadi, Lehrstuhl für Theoretische Physik I, Technische Universität Dortmund, CONSTANTIN MEYER, Institut für Theoretische Physik, Georg-August-Universität Göttingen, BENEDIKT FAUSEWEH, Los Alamos National Laboratory, GOETZ S UHRIG, Lehrstuhl für Theoretische Physik I, Technische Universität Dortmund — We consider the dynamical properties of a gapped quantum spin system coupled to the electric field of a laser, which drives the resonant excitation of specific phonon modes that modulate the magnetic interactions. We deduce the quantum master equations governing the time-evolution of both the lattice and spin sectors, by developing a Lindblad formalism with bath operators providing an explicit description of their respective phonon-mediated damping terms. We investigate the non-equilibrium steady states (NESS) of the spin system established by a continuous driving, delineating parameter regimes in driving frequency, damping, and spin-phonon coupling for the establishment of non-trivial properties. We characterize these NESS by their frequency and wave-vector content, explore the timescales for transient and relaxation behavior, and discuss the critical role of the type of bath adopted. Our study lays a foundation for the quantitative modelling of experiments currently being designed to control coherent many-body spin states in quantum magnetic materials.

*We thank the Swiss National Science Foundation (SNF) and the German Research Foundation (DFG).

9:36AM W50.00009: Generalization of the Haldane conjecture to SU(n) chains

KYLE WAMER (Presenter), Physics and Astronomy, University of British Columbia, MIKLÓS LAJKÓ, FREDERIC MILA, Institute of Physics, Ecole Polytechnique Federale de Lausanne, IAN AFFLECK, Physics and Astronomy, University of British Columbia — Recently, SU(3) chains in the symmetric and self-conjugate representations have been studied using field theory techniques. For certain representations, namely rank-p symmetric ones with p not a multiple of 3, it was argued that the the ground state exhibits gapless excitations. For the remaining representations considered, a finite energy gap exists above the ground state. In this paper, we extend these results to SU(n) chains in the symmetric representation. For a rank-p symmetric representation with n and p coprime, we predict gapless excitations above the ground state. If p is a multiple of n, we predict a unique ground state with a finite energy gap. Finally, if p and n have a greatest common divisor 1<q<n, we predict a ground state degeneracy of n/q, with a finite energy gap. To arrive at these results, we derive a non-Lorentz invariant flag manifold sigma model description of the SU(n) chains, and use the renormalization group to show that Lorentz invariance is restored at low energies. We then make use of recently developed anomaly matching conditions for these Lorentz-invariant models. We also review the Lieb-Shultz-Mattis-Affleck theorem, and extend it to SU(n) models with longer range interactions.
9:48AM W50.00010: Constructing Low-Energy Effective Models for the Hydrogen Chain using sb-DMRG* RANDY SAWAYA (Presenter), STEVEN ROBERT WHITE, University of California, Irvine — Sliced-basis DMRG(sb-DMRG) is used to simulate a chain of hydrogen atoms which is then transformed to an effective low-energy model. The downfolding procedure involves a change of basis from the real-space grid of the hydrogen chain to a set of atom-centered Wannier functions. Instead of conventional Wannier functions constructed from mean-field bands, we construct them directly from the exact DMRG one particle density matrix. We consider two versions of this. In the first, we use only the ground state to construct the density matrix. This more conventional approach produces a model which poorly reproduces spin and charge gaps. We obtain much better models using Wannier functions constructed from an average density matrix over a small set of low lying DMRG eigenstates.

*We are thankful for support from the Simons Foundation.

10:00AM W50.00011: Fractons from confinement in one dimension* SHRIYA PAI, MICHAEL PRETKO (Presenter), University of Colorado, Boulder — Recent work has shown that two seemingly different physical mechanisms, namely fracton behavior and confinement, can give rise to non-ergodicity in one-dimensional quantum many-body systems. We demonstrate an intrinsic link between these two mechanisms by studying the dynamics of 1d confining theories, such as lattice gauge theories. We show that, within certain parameter regimes, these models exhibit effective fracton dynamics, characterized by immobility of stable single-particle excitations and free motion of dipolar bound states. By perturbatively integrating out the linearly confining field, we obtain an effective fracton Hamiltonian for the confined charges which exhibits conservation of dipole moment. We discuss an intuitive understanding of these results in terms of the motion of the confining strings, leading to potential extensions to higher dimensions. We thereby interpret recent observations of nonthermal eigenstates and glassy dynamics in confining theories in terms of corresponding results in the fracton literature.

10:12AM W50.00012: Emptiness Formation Probability in 1D Bose Liquids. HSIU-CHUNG YEH (Presenter), ALEX KAMENEV, University of Minnesota — We study emptiness formation probability (EFP) in interacting 1D Bose liquids. That is the probability that a snapshot of its ground state reveals exactly zero number of particles within the interval $|x| < R$. For a weakly interacting liquid there is parametrically wide regime $1/n < R < \xi$ (here $n$ is the average density and $\xi$ is the healing length), where EFP exhibits a non-trivial crossover from the Poisson to the Gaussian behavior. We employ the instanton technique [A. Abanov, 2004] to study quantitative details of these regime and compare it with previously reported limited cases.

This work was supported by NSF grant DMR-1608238.
10:24AM W50.00013: One-dimensional repulsive Hubbard model with mass imbalance
YUCHI HE (Presenter), Carnegie Mellon University, DAVID PEKKER, ROGER MONG, University of Pittsburgh — We investigate the phase diagram of the one-dimensional repulsive Hubbard model with mass imbalance away from half-filling. Using DMRG we show that this model has a triplet paired phase at generic fillings, consistent with previous theoretical analyses. We argue that this phase is a topological critical phase, based on our observation of a long-range string order and the absence of an odd-even effect. We also find, using DMRG, that at $1/3$ filling, commensurate effects lead to two additional phases: a crystal phase and a trion phase. Finally, we demonstrate how all of these phases descend from Tomonaga-Luttinger liquid theory.

10:36AM W50.00014: Dielectric breakdown of strongly correlated insulators in one dimension: Universal formula from non-Hermitian sine-Gordon theory
KAZUAKI TAKASAN (Presenter), University of California, Berkeley, MASAYA NAKAGAWA, Department of Physics, University of Tokyo, NORIO KAWAKAMI, Department of Physics, Kyoto University — Application of sufficiently strong electric fields to insulators induces finite currents and then the insulators become metallic. This phenomenon is called dielectric breakdown. In this talk, we present our recent study about the dielectric breakdown of generic strongly correlated insulators in one dimension [1]. Combining bosonization techniques with a theory of quantum tunneling, we develop an effective field-theoretical description of dielectric breakdown with a non-Hermitian sine-Gordon theory. Then, we derive an analytic formula of the threshold field which is a many-body generalization of the Landau-Zener formula. Importantly, we point out that the threshold field contains a previously overlooked factor originating from charges of elementary excitations, which should be significant when a system has fractionalized excitations. We apply our results to integrable lattice models and confirm that our formula is valid in a broad range including the weak coupling regime, indicating its wide and potential applicability. Our results unveil universal aspects in nonlinear and nonequilibrium transport phenomena for various strongly correlated insulators.

**W50.00015: Deconfined quantum criticality in a spin chain with long-range interactions**

SIBIN YANG (Presenter), Boston Univ, DAO-XIN YAO, Physics, Sun Yat-Sen University, ANDERS W SANDVIK, Boston Univ — We study a 1D spin-1/2 model with long-range power-law decaying unfrustrated (bipartite) Heisenberg exchange interactions \( J_r \propto r^{-\alpha} \) (for odd distances \( r \)) and a competing multi-spin interaction \( Q \) favoring a dimerized (valence-bond solid, VBS) ground state. Employing quantum Monte Carlo techniques and Lanczos exact diagonalization, we analyze order parameters and excited-state level crossings to characterize quantum phase transitions between the different ground states hosted by the model in the \((\alpha, Q)\) plane. For \( 1 < \alpha < 1.3 \), we find a direct continuous quantum phase transition between a long-range ordered antiferromagnetic state and a VBS state, providing an analogy to the two-dimensional deconfined quantum-critical point. Unlike previous 1D analogies of deconfined quantum criticality, where the two ordered phases both have fractional excitations, in our model the excitations fractionalize at the critical point, changing from anomalous, sublinearly dispersing spin waves in the antiferromagnetic phase to deconfined spinons in the VBS phase. We extract critical exponents and also use order-parameter histograms to study possible emergent symmetries.

**Friday, March 6, 2020 8:00 AM - 10:24 AM**

**Session W51 DCMP: Graphene: Valleytronics, Plasmonics, and Excitonics** Mile High Ballroom 1D - Aubrey Hanbicki

**8:00AM W51.00001: Strain-induced valley polarization in monolayer graphene**

DUXING HAO (Presenter), CHEN-CHIH HSU, MARCUS L TEAGUE, JIAQING WANG, NAI-CHANG YEH, Caltech — We use nearly strain-free PECVD-grown graphene [1] to induce controllable strain and pseudo-magnetic fields by nanoscale strain engineering [2]. By placing strain-free monolayer graphene and monolayer h-BN on architected silicon nanostructures fabricated by electron-beam lithography, we demonstrate broken global inversion symmetry and provide experimental evidences for strain-induced giant pseudo-magnetic fields and valley polarization by scanning tunneling spectroscopic studies at room temperature. Here we report transport properties of monolayer graphene devices using both DC and low-frequency lock-in techniques. Non-local resistance and non-local magnetoresistance are measured on both strained and unstrained graphene devices to confirm the strain-induced valley Hall effect. We further use different circularly-polarized light to enhance or suppress the valley Hall effect via selectively exciting electrons in the corresponding valley. Our approach thus paves a new way to realize scalable graphene-based valleytronics.

*This work is jointly supported by ARO under the MURI program (Award #W911NF-16-1-0472) and NSF under the Physics Frontier Centers program at Caltech (Award #1733907).
Plasmonic Doppler Effect in Graphene

YINAN DONG (Presenter), LIN XIONG, Columbia University, ISABELLE PHINNEY, Massachusetts Institute of Technology, RAN JING, ZHIYUAN SUN, ALEXANDER MCLEOD, SHUAI ZHANG, Columbia University, MICHAEL M FOGLER, University of California San Diego, PABLO JARILLO-HERRERO, LEONID LEVITOV, DENIS BANDURIN, Massachusetts Institute of Technology, DMITRI BASOV, Columbia University — High mobility two-dimensional electron gases reveal an intriguing phenomenon of the plasmonic Doppler shift. The plasmonic response is altered when direct current (DC) is applied provided the drift velocity of electrons reaches a substantial fraction of the Fermi velocity. When plasmons are coupled with light, surface plasmon polaritons (SPP) are predicted to acquire a quasi-relativistic Doppler effect [D.S. Borgnia and L.Levitov, arXiv: 1512.09044]. Here we utilize cryogenic nano-imaging technique to search for the current-induced Doppler effect in the SPP dynamics in graphene. Directional carrier flow breaks time-reversal symmetry and causes non-reciprocal plasmonic responses in infrared frequencies. Changes of SPP wavelength in real space are attributable to the Doppler effect. SPP imaging data inform us of the behavior of hybrid quasiparticles under current flow.

Plasmonic Nonreciprocity and Doppler Effect: The Role of Electron-Electron Interactions

HAOYANG GAO, ZHIYU DONG (Presenter), EGOR KISELEV, LEONID LEVITOV, Physics, Massachusetts Institute of Technology — Plasmonic modes propagating in the presence of an electrical DC current offer an appealing tool for achieving optical nonreciprocity at the nanoscale. This talk will discuss an approach relying on the DC-current-induced plasmonic Doppler effect, wherein downstream (upstream) propagation results in a blue (red) frequency shift of plasmon resonance, respectively. The carrier drift velocity in modern high-mobility two-dimensional electron systems can reach a substantial fraction of the Fermi velocity, leading to a strong Doppler effect. Since time reversal symmetry is broken in the presence of a flow, neither nonlinear coupling nor pumping, conventionally used to achieve nonreciprocity, are required in this case. We find that electron-electron interactions impact the magnitude of the effect, enhancing the Doppler shift substantially relative to the free-particle base value. Estimates of this effect based on Landau Fermi-liquid theory will be discussed and compared with the results of a microscopic approach.
8:36AM W51.00004: Valley polarization braiding in strained graphene*  
DAIARA FARIA  
(Presenter), Instituto Politécnico, Universidade do Estado do Rio de Janeiro, CARLOS LEÓN, Instituto de Física, Universidade Federal Fluminense, LEANDRO R. F. LIMA, Departamento de Física, Universidade Federal Rural do Rio de Janeiro, ANDREA LATGÉ, Instituto de Física, Universidade Federal Fluminense, NANCY SANDLER, Department of Physics and Astronomy, Ohio University — Previous works on deformed graphene predict the existence of valley-polarized states, however, optimal conditions for their detection remain challenging. We show that in the quantum Hall regime, edge-like states in strained regions can be isolated in energy within Landau gaps. We identify precise conditions for new conducting edges-like states to be valley polarized, with the flexibility of positioning them at chosen locations in the system. A map of local density of states as a function of energy and position reveals a unique braid pattern that serves as a fingerprint to identify valley polarization[1].

8:48AM W51.00005: Interacting Valley Chern Insulator in Moiré Systems*  
XIAOCHUAN WU  
(Presenter), YICHEN XU, University of California, Santa Barbara, CHAO-MING JIAN, Kavli Institute of Theoretical Physics, Santa Barbara, CENKE XU, University of California, Santa Barbara — One salient feature of systems with Moiré superlattice is that the Chern number of “minibands” originating from each valley of the original graphene Brillouin zone becomes a well-defined quantized number because the miniband from each valley can be isolated from the rest of the spectrum due to the Moiré potential. Then a Moiré system with a well-defined valley Chern number can become a nonchiral topological insulator with U(1) × Z_3 symmetry and a Z classification at the free fermion level. Here we demonstrate that the strongly interacting nature of the Moiré system reduces the classification of the valley Chern insulator from Z to Z_3, which is very different from the previously known examples of interaction reduced classification of topological insulators. We also show that an interacting valley Chern insulator is topologically equivalent to a bosonic symmetry protected topological state made of local boson operators. The effect of this interaction influenced classification is estimated in experimental systems.

Twisted Bilayer Graphene: Atomic Crystal Structure, Electronic Structure and Plasmonic Interactions* ZHONGWEI DAI (Presenter), Center for Functional Nanomaterials, Brookhaven National Laboratory, ZHAOLI GAO, Department of Physics and Astronomy, University of Pennsylvania, CALLEY EADS, SAMUEL TENNEY, Center for Functional Nanomaterials, Brookhaven National Laboratory, ALAN T JOHNSON, Department of Physics and Astronomy, University of Pennsylvania, JERZY T. SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory — Recent discovery of unconventional superconductivity in twisted bilayer graphene (tBLG) has triggered intensive discussions about the importance of interlayer coupling effects in commensurate tBLG, which was overlooked previously. Much of its macroscale properties, such as conducting electron behavior and light matter interactions in the commensurate tBLG systems remain unknown. Here we present study of the interlayer coupling effects in the twisted 30° bilayer graphene system using surface sensitive low energy electron microscopy (LEEM), Raman scattering and infra-red scattering near-field optical microscopy (IR-sSNOM). Strong crystal structure coupling between two graphene sheets was revealed by a sharp 12-fold symmetrical LEED diffraction pattern. Enhancement of interlayer light scattering was also observed by Raman spectroscopy. Most surprisingly, the plasmonic interaction was observed to be sharply quenched on 30° twisted bilayer graphene in contrast with enhanced plasmonic interaction on non-twisted, bilayer graphene.

Filling-factor-dependence of the magnetoplasmon spectrum in graphene JORDAN PACK (Presenter), JORDAN RUSSELL, YASHIKA KAPOOR, JESSE BALGLEY, JEFF AHLERS, Washington University, St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ERIK HENRIKSEN, Washington University, St. Louis — We present cyclotron resonance measurements of a graphite-gated, hexagonal boron nitride-encapsulated monolayer graphene device. We observe a remarkable progression of the CR lineshape as a function of the Landau level filling factor, \( \nu \), from a single peak at \( \nu=0 \) to four peaks at \( \nu=1 \) to two peaks for \( \nu>2 \), giving an unprecedented spectroscopic view of the evolution of the magnetoplasmon spectrum arising from the broken spin and valley symmetries in the \( N=0 \) Landau level. By comparing to many-particle theories of graphene CR, we extract precise values for the renormalized Fermi velocity and a Dirac mass due to sublattice-symmetry breaking by the hBN. A simple model of LL shifts due to interactions allows extraction of the effective \( g \) values for Zeeman gaps in the \( N=0 \) Landau level both at and below the Fermi energy. Additionally we find evidence for a small yet clear electron-hole asymmetry.
9:24AM W51.00008: Band Structures and Localized Graphene Surface Plasmons with Periodic Charge Doping*  MICHAEL SAMMON (Presenter), University of Minnesota, DIEGO RABELO DA COSTA, Physics, Universidade Federal do Ceará, TONY LOW, University of Minnesota — We present recent band structure calculations of artificial plasmonic crystals created by periodic doping. We focus on the Lieb and Kagome lattice, two lattices known to exhibit topological features. We show that within the Drude approximation of the conductivity and for neutral doping with alternating charges, the Kagome lattice exhibits both a flat band and a band gap with a large local density of states. Additionally, for doping of alternating, both lattices exhibit strong localization of the plasmon electric field intensity near the region of vanishing charge density. We discuss the effect of interband transitions on these properties.

*This work was supported by the National Science Foundation NSF/EFRI grant (#EFRI-1741660)

9:36AM W51.00009: Isotopic Effect of Carrier Relaxation in Graphene-hBN Heterostructures*  ALEXANDRA BRASINGTON (Presenter), Physics, University of Arizona, JAMES H. EDGAR, Chemical Engineering, Kansas State University, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, ARVINDER S SANDHU, BRIAN J LEROY, Physics, University of Arizona — In atomically thin systems, the choice of substrate plays an important role in the relaxation of photo-excited carriers. In previous work, hexagonal boron nitride (hBN) substrates have been shown to improve the thermal relaxation rates of carriers in graphene as compared to silicon oxide substrates. Naturally occurring boron contains a mixture of two isotopes with atomic masses 10 and 11 with abundances of 20% and 80% respectively. Theoretical studies have predicted a higher thermal conductivity with higher isotopic purity of hBN, due to reduced phonon scattering from isotopic defects. We utilize femtosecond pump-probe spectroscopy to observe the time dynamics of photo-excited carriers in graphene-hBN heterostructures for both natural and isotopically pure hBN.

*The work at the University of Arizona was supported by the U.S. Army Research Laboratory and the U.S. Army Research Office under Contract/Grant No. W911NF-14-1-0653.

9:48AM W51.00010: Evidence for excitonic solid states in double layer graphene  YIHANG ZENG (Presenter), QIANHUI SHI, ANNA OKOUNKOVA, Columbia Univ, KENJI WATANABE, TAKASHI TANIGUCHI, nims, JIA LI, physics, Brown Univ., CORY DEAN, Columbia Univ — Spatially indirect excitons can form when electron-doped and hole-doped 2D quantum wells are brought into close proximity. In the condition that interlayer separation is sufficiently large to suppress recombination and small enough that interlayer coulomb interactions are strong, the system can spontaneously condense into a superfluid-like macroscopically coherent state, termed an exciton condensate. In a double layer graphene system in the presence of magnetic field, upon decreasing the exciton density, we observe a sharp transition from an exciton superfluid to an exciton insulator, which shows insulating behavior in both charge transport and exciton transport measurement. At elevated temperature, the excitonic insulating state exhibits perfect coulomb drag, which is the signature of an exciton superfluid. Our data suggests a phase diagram consisting of a pinned excitonic Wigner crystal at lower exciton density, which transitions to a superfluid-like state at elevated temperature.
QIAOXIA XING (Presenter), Fudan Univ — Graphene plasmonics, allowing strong light-matter interactions, subwavelength light confinement and in situ tunability, has gained much attention due to the potential to develop new optoelectronic and photonic devices. Here, we experimentally demonstrate graphene split ring resonators with deep subwavelength confined magnetic dipole, quadrupole and electric dipole responses in terahertz regime. All modes can be tuned via chemical doping or stacking multiple graphene layers. Finite-element frequency domain simulations nicely reproduce experimental results. Our study demonstrates an example of tunable multiple resonances based on graphene, and shed new light on its application in tunable high-frequency magnetic metasurfaces.

DEEPAN KISHORE KUMAR (Presenter), NAI-CHANG YEH, Caltech — We have previously shown that our PECVD-grown, quasi-1D GNSPs exhibited perfect purity, high mobility [1] and strong broadband absorption [2]. Here we report broadband photoluminescence (PL) and ultra-long carrier lifetimes in GNSPs from time-resolved PL (TRPL) studies. GNSPs were deposited on quartz substrates to form uniform films with thicknesses of 5, 10, 20, 40 and 50 μm for the TRPL measurements. We used Nd:YAG laser at 355 nm with 10 ps pulse width and 0.1 mJ pulse energy under a repetition rate of 10Hz to carry out TRPL studies at temperatures from 15 K to 290 K. Detailed analysis of the TRPL data revealed two carrier lifetimes of $\tau_1 (~ 1 \text{ ns})$ and $\tau_2 (~ 10 \text{ ns})$, both were independent of either temperature or thickness, and the values were $\sim 10^3$ times longer than any lifetimes reported to date for graphene-based materials. We attribute the ultra-long lifetimes to the nanoscale quasi-1D nature of GNSPs, which breaks the global inversion symmetry so that photo-excited hot electrons and holes are rapidly separated due to their large differences in mobility, *a.k.a.* the photo Dember effect.

*This work is jointly supported by United Advanced Material and Army Research Office.

ZHIMING PAN (Presenter), RYUICHI SHINDOU, Peking Univ — Graphite in the quantum limit shows unconventional in-plane and out-of-plane transport behavior. To uncover its microscopic origin, we construct an interacting electron model with a pair of electron band and hole band with the valley degree of freedom. We use a fermionic renormalization group (RG) method and study a parquet RG equation of the model with screened Coulomb interaction. We found that, for strong screening region, the one-loop RG indicates a dominant instability of valley charge density wave (VCDW) with a finite pairing between the two valleys. We further construct an effective mean-field theory and clarify the in-plane transport behavior of the VCDW phase.
**W51.00014: Generation and Detection of Valley Current in Single and Double Layered Graphene through the Electron-Phonon Interaction**

ANKANG LIU (Presenter), ALEXANDER FINKELSTEIN, Department of Physics and Astronomy, Texas A&M University — We report a possible method to generate and detect the valley current carried by quasi-particles in both single and double layered graphene. We observe that the term in the collision integral originated from mixing the scalar and vector gauge-field-like vertices in the electron-phonon interaction turns current carriers of two different valleys in opposite directions. As a result, the electron-phonon collision produces a valley current. Finally, we show that the valley current carried by quasi-particles could be not only generated but also detected in a non-local resistance measurement through the inverse version of this mechanism. Our study proposes a new approach to manipulate the valley degrees of freedom in a pristine graphene or bilayer graphene sample without breaking the spatial inversion symmetry. The effect increases with temperature owing to a higher rate of collisions with phonons at higher temperatures.

**Session W52 DCMP: Thin Film Coatings and Applications** Mile High Ballroom 1E - Daniel Dougherty, North Carolina State University

**8:00AM W52.00001: Growth of Conformal Thin Film Si Coatings on Terraced Substrates Using Subsequent Oblique Incidence Xe⁺ Ion Bombardment**

EMMETT RANDEL (Presenter), CARMEN SUSANA MENONI, RICHARD M BRADLEY, Colorado State University — Using a Si surface pre-patterned with a 500 nm pitch sinusoidal profile, it is demonstrated that ordered terraced topographies with sub-nanometer scale roughness on the facets develop under oblique incidence 1500 eV Xe⁺ broad beam ion bombardment. Bi-layers of SiO₂/Si were then deposited onto the terraced substrate using ion beam sputtering. Following the deposition of each Si layer, the oblique incidence Xe⁺ bombardment was repeated to restore the terraced structure. This work was performed in tandem with theory in an effort to refine models, showing agreement in selection of terraced slopes and the development of transverse roughness along the facets.

*Work supported by NSF Grant No. 1508745*
Amorphous oxides to improve the coatings of future gravitational wave detectors*  

GABRIELE VAJENTE (Presenter), Caltech, MARIANA FAZIO, Department of Electrical and Computer Engineering, Colorado State University Fort Collins, LE YANG, Department of Chemistry, Colorado State University Fort Collins, ALENA ANANYEVA, GARILYNN BILLINGSLEY, Caltech, ASHOT MARKOSYAN, RICCARDO BASSIRI, MARTIN M. FEJER, Edward L. Ginzton Laboratory, Stanford University, CARMEN SUSANA MENONI, Department of Electrical and Computer Engineering, Colorado State University Fort Collins — Amorphous oxides like tantala and titania-doped-tantala have been used as high index material for high reflectivity coatings in many applications, including the mirrors of current gravitational wave detectors. The sensitivity of those detectors is currently limited by coating Brownian noise, which is related to elastic energy loss in the coatings, as shown by the Fluctuation-Dissipation Theorem. This motivates a wide range search of an alternative amorphous material with lower mechanical loss, that could provide a substitute for the high refractive index currently used, namely titania-doped-tantala.

We characterized the optical and elastic properties of several oxides: yttria, hafnia, niobia, alumina, zirconia, zinc oxide, germania and doped germania. We also measured the mechanical loss at room temperature of all materials. Additionally, we performed several heat cycles and measured the changes induced in the mechanical loss.

We found interesting results for germania and doped germania: they exhibit room-temperature loss angles much lower than all oxides other than silica, making them a promising candidate for the high reflectivity coatings of future gravitational wave detectors.

*This work is supported by the National Science Foundation through grants No. 1708010 and 1710957.
8:24AM W52.00003: Wide survey of Ta$_2$O$_5$-based mixed oxide coatings for gravitational wave detectors* MARIANA FAZIO (Presenter), Department of Electrical and Computer Engineering, Colorado State University, LE YANG, Department of Chemistry, Colorado State University, GABRIELE VAJENTE, ALENA ANANYEVA, GARILYNN BILLINGSLEY, LIGO Laboratory, California Institute of Technology, ASHOT MARKOSYAN, RICCARDO BASSIRI, MARTIN M. FEJER, Department of Applied Physics, Ginzton Laboratory, Stanford University, CARMEN SUSANA MENONI, Department of Electrical and Computer Engineering, Department of Chemistry, Colorado State University — Thermal noise is a fundamental limitation in optical interferometry experiments as thermally driven fluctuations cause variations in the optical path. The sensitivity of gravitational wave detectors, such as Advanced LIGO and Advanced Virgo, is affected by the thermal noise in the high-reflectivity mirrors of the end masses. These mirrors are multilayer stacks of alternating layers of TiO$_2$:Ta$_2$O$_5$ and SiO$_2$, with the main source of thermal noise being the mechanical loss of TiO$_2$:Ta$_2$O$_5$. Towards the goal of identifying other potential dopants that can further decrease the thermal noise, we carried out an extensive study of Ta$_2$O$_5$ doped with different oxides: Al$_2$O$_3$, HfO$_2$, Nb$_2$O$_5$, Sc$_2$O$_3$, SiO$_2$, TiO$_2$, Y$_2$O$_3$, ZnO, and ZrO$_2$. Films were grown by reactive sputtering with a 20% dopant cation concentration. The influence of the dopant on the structure, optical properties, crystallization temperature and mechanical loss was evaluated. We found that oxides with the lowest Gibbs free energy of formation, such as Sc$_2$O$_3$, inhibit the complete oxidation of the Ta$_2$O$_5$ phase. We identify dopants for which the material crystallizes as a ternary compound, such as TiO$_2$ and ZnO, which can induce atomic mixing and reduce mechanical loss.

8:36AM W52.00004: Dielectrowetting of nematic liquid crystal films* ENSELA MEMA (Presenter), US Military Academy, LINDA CUMMINGS, LOU KONDIC, New Jersey Institute of Technology — We consider a mathematical model that describes the flow of a Nematic Liquid Crystal (NLC) film placed on a surface that contains interlaced electrodes (which generate an electric field that varies in the plane of the substrate). We assume that the NLC film is thin relative to the inter-electrode spacing. Under the usual long-wave scaling, a partial differential equation that describes the time evolution of the thin film is obtained. Due to the dielectric nature of NLC molecules, this equation is coupled to a boundary value problem that describes the interaction between the nematic director and the electric field potential. After validating our fully nonlinear simulations by linear stability analysis, we discuss the influence of an applied electric field on the stability of the NLC film.

*This work was supported in part by NSF Grant No. DMS-1815613
8:48AM W52.00005: Sound velocity study in multilayer ultrathin films using wavelet transform*  SAEED YOUSEFI SARRAF (Presenter), ROBBYN TRAPPEN, NAVID MOTTAGHI, ALAN BRISTOW, MIKEL HOLCOMB, West Virginia University — Ultrafast spectroscopy of thin films reveals mechanisms responsible for relaxation of charge carriers’ energy to lower energy states. In the case of a strong enough excitation pump pulse, a shock wave will travel with the sound velocity, longitudinally in the thin film. Due to the interference effect, the shock wave superimposes a sinusoidal wave on the transient reflectivity, which can be used to calculate the sound velocity. In lower thicknesses, this sinusoidal behavior is not analyzable by Fourier transforms. Wavelet transforms, which use scalable wavelets localized in time and space, are perfect tools to analyze these fast-vanishing oscillations. Wavelet analysis has been applied to the residual sinusoidal TR to extract information related to different oscillatory modes, in multilayer ultrathin films. This approach can isolate the location of various oscillatory modes with close energy ranges, at the surface, interface and in the bulk of the heterostructures. As a result, implementation of wavelet transforms provided information regarding the sound velocity and acoustic phonons in multilayer thin films.

*We acknowledge funding support from ACS (PRF #56642-ND10) for students, NSF (DMR-1608656) for growth, and DOE (DE-SC0016176) for optics supplies.

9:00AM W52.00006: Mixture and nanolamine – a pathway to understand coating mechanical loss* LE YANG (Presenter), MARIANA FAZIO, Colorado State University, GABRIELE VAJENTE, ALENA ANANYEVA, GARILYNN BILLINGSLEY, California Institute of Technology, ASHOT MARKOSYAN, RICCARDO BASSIRI, MARTIN M. FEJER, Stanford University, CARMEN SUSANA MENONI, Colorado State University — Composite oxides in the form of mixture and nanolamine are extensively used in optical coatings and as dielectric materials. Tunable properties accessible through mixing and nanolayering have drawn great attention to these composite thin films. TiO2-Ta2O5 mixture coating has been shown to reduce the mechanical loss compared to pure Ta2O5 coating thereby improving the sensitivity of the Advanced LIGO gravitational wave detector. In this work, reactive biased target ion beam deposition was used to grow mixture and nanolamine coatings of SiO2-Ta2O5 and TiO2-Ta2O5. Different mechanisms of mechanical loss reduction through heat treatment are observed. Ta2O5-SiO2 mixtures annealed at 750°C show diffraction only from the crystallized orthorhombic Ta2O5 phase, indicating an immiscibility of SiO2 in Ta2O5. Additionally, Ta2O5-SiO2 nanolayers remained separate by sharp interface after annealing. On the contrary, mixing identified by blurring of interfaces is observed in Ta2O5-TiO2 nanolamine after annealing at 650°C. This behavior resembles the mixture coating. This work brings out new understanding of the physical mechanism of coating mechanical loss reduction at room temperature.

*This work is supported by the National Science Foundation LIGO program through grant No. 1708010
Monitoring structural changes in steel thin films in electrolyte *in situ* by X-ray standing waves

DEBI GARAI (Presenter), Diamond Light Source Ltd, Amity Univ., ILARIA CARLOMAGNO, ELETTRA, AXEL WILSON, Diamond Light Source Ltd, CARLO MENEGHINI, Univ. Roma TRE, VLADYSLAV SOLOKHA, Diamond Light Source Ltd, JKU Linz, CHRISTIAN MORAWE, ESRF, AJAY GUPTA, Amity Univ., JORG ZEGENHAGEN, Diamond Light Source Ltd — Ultra-thin stainless steel films were deposited on Ru/B4C multilayers using DC magnetron sputtering and characterised by synchrotron X-rays. The X-ray standing wave (XSW) technique revealed the metal distribution with depth. Typical for stainless steel [1], the near surface region was free of nickel. The oxidation states of Cr, Ni and Fe were determined by X-ray near edge absorption structure (XANES) under XSW condition. Nickel was found to be largely metallic whereas Fe and Cr were oxidized in the surface region, forming an about 2 nm passive layer. Exposure to 0.1M KCl at cathodic potential of -0.6 V vs Ag/AgCl resulted in expansion of the steel film due to in-diffusion of hydrogen. Using XSW/XANES, structural and chemical changes of the steel film were further traced *in situ* as a function of electrode potential up to +0.8 V. Results will be presented in the talk.

Deformation profile and interface-mediated defect interaction in Cu/CuZr nanolaminates: An effective-temperature description

MICHAEL TONG (Presenter), University of Michigan-Ann Arbor, CHARLES LIEOU, Los Alamos National Laboratory, IRENE BEYERLEIN, University of California, Santa Barbara — Both simulations and experiments have suggested that Cu/CuZr nanolaminates are stronger and more ductile than their individual constituents due to interface-mediated interactions between plasticity carriers. We use the effective-temperature theories of dislocation and amorphous shear-transformation-zone (STZ) plasticity to study amorphous-crystalline interface (ACI)-mediated plasticity in Cu/CuZr nanolaminates under mechanical straining. The model is shown to capture reasonably well the measured deformation response when strained either in tension parallel to or in compression normal to the amorphous-crystalline interface. Our analysis indicates that increasing CuZr or decreasing Cu layer thickness increases the maximum flow stress for both perpendicular and parallel loading cases. In all slip strain analyses, maximum slip strain occurs at the ACI, thus indicating that plasticity carriers accumulate at the interface and are absorbed there. These findings indicate a significant anisotropy in strength with greater sensitivity to layer thickness for the case of tensile loading parallel to the ACI. Further findings signify that slip strain is more sensitive when the nanolaminate is compressed perpendicular to the ACI.
The next major upgrade to gravitational wave detector LIGO, called Advanced LIGO+ or A+, is planned to operate at room temperature and requires 4 times improvement in coating mechanical loss to meet its design sensitivity. The coatings are made up of alternating layers of high and low refractive index materials to make the mirrors highly reflective. The current coatings have amorphous silica as the low index layer and titania-doped tantala as the high index layer. The mechanical loss of high index layer dominates the coating loss and the thermal noise requirement for A+ could be met by finding a high index layer with low enough mechanical loss. In this talk, I will describe the research efforts aimed at finding such a coating. In particular, I will talk about how the atomic structure measurements and modeling of amorphous oxides are being used to guide the coating development process. I will highlight some interesting correlations in the structure and loss measurements and draw some empirical conclusions. Finally, I will discuss the thermally activated relaxation processes (TARP) in amorphous oxides based on atomic simulations of two-level systems (TLSs). TARP is believed to be the source of mechanical loss in amorphous materials.
9:48AM W52.00010: Addressing the Achilles’ Heels of Amorphous Carbon Overcoats with Doping: Mechanisms of Thermal and Oxidative Degradation  FILIPPO MANGOLINI (Presenter), University of Texas at Austin, BRANDON KRICK, Department of Mechanical Engineering and Mechanics, Lehigh University, TEVIS D.B. JACOBS, SUBARNA R. KHANAL, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, FRANK STRELLER, J. BRANDON MCCLIMON, Department of Materials Science and Engineering, University of Pennsylvania, JAMES HILBERT, Department of Mechanical Engineering and Applied Mechanics, University of Pennsylvania, SOMURI V. PRASAD, Sandia National Laboratories, THOMAS SCHARF, Department of Materials Science and Engineering, University of North Texas, JAMES OHLHAUSEN, Sandia National Laboratories, JENNIFER R. LUKES, Department of Mechanical Engineering and Applied Mechanics, University of Pennsylvania, W. GREGORY SAWYER, Department of Mechanical and Aerospace Engineering, University of Florida, ROBERT W CARPICK, Department of Mechanical Engineering and Applied Mechanics, University of Pennsylvania — Harsh environments pose materials durability challenges across different sectors. While amorphous carbon materials have been used as coatings in environmentally-demanding applications owing to their unique properties, their limited thermal stability and high reactivity in oxidizing environments have inhibited their use in many technologies. Silicon- and oxygen-containing hydrogenated amorphous carbon (a-C:H:Si:O) films are promising for several applications because of their higher thermal stability and lower residual stress compared to hydrogenated amorphous carbon (a-C:H). However, an understanding of their superior thermo-oxidative stability compared to a-C:H is lacking.

Here, we performed X-ray photoelectron/absorption spectroscopy experiments and molecular dynamics simulations to show how the introduction of silicon and oxygen in a-C:H enhances: 1) the stability at elevated temperatures in both vacuum and oxidizing environments; and 2) the resistance to degradation upon exposure to the harsh conditions of low Earth orbit (LEO) aboard the International Space Station. These findings provide a novel physically-based understanding of the superior stability of a-C:H:Si:O in harsh environments compared to a-C:H.

10:00AM W52.00011: capillarity-enhanced thin-film mineral coating in 3D-printed porous micromodel  HONGXIA LI (Presenter), AIKIFA RAZA, TIEJUN ZHANG, Mechanical Department, Khalifa University — In subsurface-related applications such as hydrocarbon recovery, carbon sequestration and water filtration, 3D-printed porous media, usually polymer-based material, are quite different from natural rocks. It is highly desireable to functionalize 3D-printed models in mimicking the surface chemistry of natural rocks. Here, we propose a surface-coating approach by seeding calcite nanoparticles (CalNPs) followed by in-situ growth of calcite crystals along the inner surfaces of as-printed 3D micromodels. Notably, surface coating inside porous media is quite challenging compared to the flat surfaces due to the capillary effect in the irregular pores/throats. To guarantee the coating uniformity, we tuned the properties of coating solutions for a lower surface tension, lower viscosity and higher volatility. In this way, we promote the formation of an ultra-thin liquid film in confined space of porous media. The stability of the coating layer, specifically the CalNPs, was also investigated using water-flush experiments. The capillary-rise enhanced nanoparticle stability is revealed from atomic force microscope (AFM) analysis. Through this work, we provide guidance on thin-film coating in porous media, where the effect of capillarity is a critical issue and requires careful attention.
10:12AM W52.00012: Effects of substrate bias on current for varying argon intensity in a low-pressure hydrogen/argon plasma in chemical vapor deposition. BHAVESH RAMKORUN (Presenter), KALLOL CHAKRABARTY, SUMNER B HARRIS, SHANE A CATLEDGE, Univ of Alabama - Birmingham — Studies have shown that in CVD, low substrate temperature often favors amorphous materials growth over crystalline. In a hydrogen/argon plasma acting on a negatively DC-biased silicon substrate, hydrogen alpha and bias current due to ion bombardment were monitored for temperature <1000°C. The temperature was controlled through microwave power of 0.6kW, and pressure of 10 – 30 torr. The flow rate of argon was varied between 0 sccm and 500 sccm, and hydrogen's was 500 sccm. Optical Emission Spectroscopy (OES) of hydrogen line was found to be influenced by argon flow rate. Current was recorded for several values of the applied bias voltage from 100V to 340V. A decrease in current with decreasing hydrogen emission for glow discharge systems has been reported in the literature. Our results substantiate these results, and further show a peak in current at 10 and 20 torr. OES data was used to estimate the plasma electron temperature to be constant at approximately 0.5 eV. This suggests that the observed peak in current may be due to variation in plasma density as Ar flow changes between 0 sccm and 500 sccm. These results may be used to correlate plasma emission characteristics with substrate bias conditions in order to better predict and control MPCVD grown materials.

10:24AM W52.00013: Measuring Local Electric Fields and Local Charge Densities at Electrode Surfaces using Graphene-enhanced Raman Spectroscopy (GERS)-based Stark-shifts* HAOTIAN SHI (Presenter), BOFAN ZHAO, STEVE CRONIN, Univ of Southern California — We report spectroscopic measurements of the local electric fields and charge densities at electrode surfaces using graphene-enhanced Raman spectroscopy (GERS) based on the Stark-shifts of surface-bound molecules (CuPc) and the G band frequency shift in graphene. The shifts in vibrational frequencies of the graphene G band and CuPc are obtained simultaneously and correlated. The 1531 cm⁻¹ peak exhibits Stark-shifts and can, thus, be used to report the local electric field strength at the electrode surface under electrochemical working conditions. Computational simulations using density functional theory (DFT) predict similar Stark shifts and provide a detailed atomistic picture of the electric field-induced perturbations to the surface-bound CuPc molecules.

National Science Foundation Grant CHE-1707657 (L.J.) and NRT-1449785. (M.B.)
10:36AM W52.00014: Ferroelectric polarization rotation through He irradiation induced uniaxial strain* ANDREAS HERKLOTZ (Presenter), ROBERT ROTH, KATHRIN DORR, NIRANJAN RAMAKRISHNEGOWDA, University of Halle-Wittenberg, YOGESH SHARMA, ALESSANDRO MAZZA, THOMAS ZAC WARD, Oak Ridge National Laboratory — The physical properties of ferroic thin films are typically dominated by their domain configurations and their responses to external fields. A central prerequisite to domain engineering and harnessing functionalities of ferroelectric thin films is thus the control of the polarization orientation. Historically, the direction of ferroelectric polarization in thin films has been mainly tailored by heteroepitaxial in-plane strain or a variation of growth conditions inducing defects.

Here, we deploy low-energy He implantation as an alternative approach. Ion implantation induces uniaxial out-of-plane strain, while the in-plane strain remains fixed due to coherent growth on the substrate. We show that this kind of uniaxial strain engineering effectively leads to polarization rotation from in-plane towards out-of-plane as the uniaxial strain is increasing. We find that this polarization rotation can be achieved via two different mechanisms: (i) via a sequence of phase transitions related to changes of crystal symmetries and (ii) via a continuous shift of the ferroelectric domain ratio towards out-of-plane oriented domains.

Session W53 DMP: 2D Photonics and Optoelectronics Mile High Ballroom 1F -

Stephen Wu, University of Rochester - Tag(s): Focus
Two-dimensional ReS$_2$ for nonlinear photonics

BENJAMIN SMITH
(Presenter), Centre for Nanoscience and Nanotechnology, Department of Physics, University of Bath, KRISTINA RUSIMOVA, ANDRIY GORBACH, Centre for Photonics and Photonic Materials, Department of Physics, University of Bath, JUEJUN HU, SKYLAR DECKOFF-JONES, Department of Materials Science & Engineering, Massachusetts Institute of Technology, DANIEL WOLVERSON, Centre for Nanoscience and Nanotechnology, Department of Physics, University of Bath — The layered transition metal dichalcogenides (TMDs) have been the focus of increasing research in photonics, in part due to their large nonlinear optical (NLO) susceptibilities. Amongst the TMD family, the semiconducting rhenium dichalcogenides (ReX$_2$, where X = S or Se) are unusual due to their highly-anisotropic in-plane crystal structure. A Peierls distortion of the crystal lattice results in the formation of chains of Re atoms along one of the crystallographic directions. This structure leads to anisotropic optical, electrical and mechanical properties. Here, we demonstrate that this anisotropic crystal structure is highly useful for incorporating such 2D flakes within waveguides. It is shown that ReS$_2$ flakes preferentially cleave along the $a$ axis, producing flakes with long and narrow dimensions. This allows for waveguide integration with a long interaction length between the propagating light and the NLO material. ReS$_2$ flakes were exfoliated and characterised using Raman and atomic force microscopy (AFM). Waveguide devices incorporating these flakes were fabricated.

THz Photoconductive Antennas Using Thin Black Phosphorus

M. HASAN DOHA (Presenter), AHMAD F. RAWWAGAH, JOSH P. THOMPSON, ARASH FEREIDOUNI, Physics, University of Arkansas, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, MIAOQING HUANG, Computer Science and Computer Engineering, University of Arkansas, MAGDA O. EL-SHENAWEE, Electrical Engineering, University of Arkansas, HUGH CHURCHILL, Physics, University of Arkansas — We report the fabrication and characterization of THz photoconductive antennas using thin (~50 nm) black phosphorus (BP) as the photoconductor and hexagonal boron nitride (hBN) as a capping layer to prevent oxidation of BP and enhance absorption. Dipole antennas were fabricated on oxidized high-resistivity silicon substrates, and BP and hBN flakes were picked up and transferred onto the antennas inside a nitrogen glovebox. BP flakes were aligned with the armchair axis along the anode-cathode gap of the antenna, with crystal orientation measured using reflection anisotropy. The transfer matrix technique was used to optimize the thickness of BP and hBN for maximum absorption. Photocurrent imaging under illumination with ~100 fs pulses at 1550 nm showed a bias-dependent maximum photocurrent near the anode side of the antenna gap with a responsivity at 50 kHz of about 0.2 mA/W at a source-drain bias of -100 mV. We will also report ongoing measurements to compare THz output power of these antennas with reference devices in which silicon is used as the photoconductor.
Defect and interface engineering for high-performance 2D photodetectors

ZHENHUA NI (Presenter), Southeast University — The performance of photodetectors based on two-dimensional (2D) materials is strongly influenced by defects and the interface [1]. The de-trap time of carriers from a deep trap could be prolonged by several orders of magnitude as compared to shallow trap, resulting in additional decay time of the device. We demonstrate that the trap states in 2D ReS$_2$ could be efficiently modulated by defect engineering through molecule decoration, and the both the response time and responsivity of the device is greatly improved [2]. We further elaborate that plasmon-induced hot electron transfer (HET) from tungsten suboxide nanocrystals to graphene is a sufficient fast process (<150 fs) to prevent carrier cooling and trapping processes. A fast near infrared (NIR) detector empowered by HET is demonstrated, and the response time is three-orders of magnitude faster than that based on common band-edge electron transfer [3]. Our results indicate that defect and interface engineering is a new strategy for implementation of efficient and high-speed photoelectric devices.

Lithographic bandgap engineering of graphene on the 10 nm scale: the role of edges

LENÉ GAMMELGAARD, BJARKE SØRENSEN JESSEN, JOSE MANUAL CARIDAD, DTU Physics, Technical University of Denmark, MORTEN RISHØJ THOMSEN, Department of Physics, Ålborg University, TIMOTHY JOHN BOOTH, DTU Physics, Technical University of Denmark, TAKASHI TANIGUCHI, KENJI WATANABE, Research Center for Functional Materials, NIMS, JOACHIM DAHL THOMSEN, Materials Science and Engineering, Massachusetts Institute of Technology, DAVID MACKENZIE, Department of Electronics and Nanoengineering, Aalto University, THOMAS G PEDERSEN, Department of Physics, Ålborg University, MADS BRANDBYGE, ANTTI-PEKKA JAUHO, PETER BØGGILD (Presenter), DTU Physics, Technical University of Denmark — In the light of graphene's rich electronic properties and potentially high performance in applications, one of the most obnoxious roadblocks have been to pattern graphene on a small scale. Early theoretical work predicted that the bandstructure of graphene could be engineered by nanopatterning, such as nanoribbons and antidot lattices. Unfortunately, edge disorder and contamination associated with typical lithographic processes have strong detrimental effects on the transport properties. This has held back efforts to utilize quantum confinement in practical graphene devices as well as downscaling graphene components to a scale comparable to mainstream silicon electronics. The key is to control the chemistry and roughness of the edges, which has a striking impact on charge distribution and scattering in graphene, as illustrated by breakdown of the Quantum Hall Effect and ferroelectric behavior in graphene devices. By careful patterning through the hexagonal boron nitride encapsulation layer, we fabricated graphene devices with 35 nm pitch hole arrays and nm-scale edge roughness, yet exceptionally high carrier mobility. The distinct magnetotransport features are in quantitative agreement with zero-parameter tight-binding calculations and analytical models, including a ca. 150 meV bandgap. In addition we find that the subtle moiré-superlattice signatures associated with a small finite twist angle between the graphene and hexagonal boron nitride survives the aggressive lithographic patterning, suggesting that nanoscale circuits and components that exploit the novel properties of twisted 2D layers are feasible.

Graphene Double-Layer Heterostructure Photodetectors with Broadband, High and Fast Responsivity at Room Temperature*

HO VINH (Presenter), YIFEI WANG, ZACHARY HENSCHEL, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech, MICHAEL P. COONEY, NASA Langley Research Center, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — The hybrid semiconductor/graphene photodetectors have been intensively investigating due to their applications ranging from imaging, sensing to communications in the infrared region. Integration of colloidal semiconductor quantum dots with graphene can increase the responsivity of such photodetectors. However, the response time is in millisecond to second scale, caused by optical traps at interfaces between semiconductor quantum dots and graphene. Another limitation is that the operation bandwidth still has not expanded beyond near-infrared region due to the bandgap of semiconductor quantum dots. Here, we report photodetectors based on two graphene single-layers separated by a 5-nm Ti$_2$O$_3$ thin-film engineered by the e-beam evaporation method. The Ti$_2$O$_3$ barrier is utilized as a tunneling charge transport channel between two graphene layers to reduce the charge recombination, and also as a mean for light absorber. Our devices show a high responsivity together with a fast response time in the nano-second scale, and a broadband spectral response at room temperature.

Mismatch-free tunnel spin contacts by photo-induced molecular functionalization of single layer graphene*

NOEL NATERA CORDERO (Presenter), JESUS TOSCANO-FIGUEROA, VICTOR GUAROCHICO, DENIS BANDURIN, CHRISTOPHER ROBERT ANDERSON, IRINA GRIGORIEVA, IVAN JESUS VERA MARUN, Univ of Manchester — A major issue preventing efficient spin injection in graphene is the mismatch between the contact and the spin impedance of the channel. This is of particular relevance for ultra-thin (0.6 nm) alumina tunnel barriers. We overcame this problem by growing the alumina barriers on graphene functionalized with phenyl radicals. The functionalization is achieved by using a laser beam to catalyse a photochemical reaction in benzoyl peroxide. The sub-micron spatial resolution enabled by the focused laser beam allows a direct comparison of different functionalization levels within a single graphene flake. Raman spectroscopy and Atomic Force Microscopy showed a dependence of the roughness of the tunnel barrier on the level of functionalization with the roughness of the barrier on functionalized graphene, reduced to half of that on pristine graphene. This functionalization mitigates the impedance mismatch problem, leading to an order of magnitude increase in the spin valve response.

High-performance WSe$_2$ lateral pn-homojunction achieved with oxygen plasma-treatment for broadband photodetector applications*  

SEKHAR BABU MITTA (Presenter), FIDA ALI, YANG ZHENG, WON JONG YOO, Sungkyunkwan Univ — 2D transition metal dichalcogenides have shown significant potential for developing future nanoscale optoelectronic devices, among them, bulk tungsten diselenide (WSe$_2$) with an indirect bandgap (1.2 eV) is a promising material for optoelectronic applications due to its tunable energy bands, fast charge transfer, and strong optical absorption. Here, we demonstrate the fabrication of WSe$_2$ lateral pn-homojunction via oxygen (O$_2$) plasma-doping for high-performance broadband photodetector applications. The WSe$_2$ pn-homojunction photodetectors display higher photoresponsivities of 250 mA/W and 2000 mA/W, EQE of 97 % and 420 %, and detectivity of 7.7 × 10$^9$ Jones and 7.2 × 10$^{10}$ Jones for visible (520 nm) and near IR (852 nm) laser illuminations, respectively at $V_g = 0$V and $V_d = 1$V. The O$_2$ plasma-doping enables an effective charge generation and separations at the junctions upon the laser illuminations and resulting in superior optoelectronic properties which aid us in the development of lateral pn-homojunction as promising broadband photodetectors.

Stamping of Naked and Suspended 2D Materials to Engineer Light Absorption  

ISRAEL REBOLLO (Presenter), FERNANDA CRISTINA RODRIGUES MACHADO, GARETH J MELIN, ALEXANDRE CHAMPAGNE, Department of Physics, Concordia University, Montreal, Canada — We present a nitrocellulose-based method to manipulate naked and suspended 2DM one by one. We make optical measurements on several heterostructures to demonstrate the ability to tune graphene light absorption by a factor of 20. We show spatially-deterministic micron-scale positioning of graphene, boron nitride, and MoS$_2$ naked crystals. Raman spectroscopy confirms the low defect density introduced upon transfer. We detail micro-Raman measurements on a suspended graphene heterostructure of about 12 µm$^2$ to test the validity of an exclusive absorption model based on first-principles calculations [1]. We build several other graphene heterostructures with 2 distinct geometries to engineer the exclusive graphene light absorption. Future applications include optical transducers where a small gate voltage moves a suspended 2DM to vastly enhance or suppress its exclusive light absorption. 

**9:48AM W53.00009: Novel Plasmonic Waveguides from Coulomb Engineered Two-Dimensional Materials**  ZHIHAO JIANG (Presenter), STEPHAN WOLFGANG HAAS, Univ of Southern California, MALTE ROESNER, Institute for Molecules and Materials, Radboud University — Plasmonic excitations in two-dimensional (2D) materials are strongly affected by the screening environment, which allows us to control them by the dielectric properties of the substrate. Here we present how these plasmonic excitations can be spatially confined within a homogeneous 2D material with the help of structured heterogeneous dielectric substrates. By using this environmentally-imprinted plasmonic confinement to spatially guide the propagating surface plasmons within the 2D material we can construct fundamentally new plasmonic waveguides. Our quantum mechanical random phase approximation calculations show that this plasmonic confinement can be induced in areas of in- or decreased substrate permittivities, depending on the excitation frequency. We study in detail how the spatial extend of the environmental dielectric pattern affects these novel plasmonic waveguides and find that sub nm plasmonic confinement can be achieved. Our proposal renders dielectric engineering a truly non-invasive way of imprinting plasmonic waveguide channels into otherwise homogeneous 2D materials with promising potential for quantum optics.

**10:00AM W53.00010: Enhanced resonant Raman spectrum of multilayer WS2 with thin film plasmonic cavity**  CHUN YUAN WANG (Presenter), Physics, University of Texas at Austin, MENG HSIEN LIN, HUNG YING CHEN, 2. Meta-SERS co. ltd, Taiwan, JIAMIN QUAN, JUNHO CHOI, XIAOQIN (ELAINE) LI, Physics, University of Texas at Austin, SHANGJR GWO, Physics, National Tsing Hua University, CHIH-KANG SHIH, Physics, University of Texas at Austin — Interactions of tightly bound electron-hole pairs (excitons) and the lattice vibration modes (photon) in two-dimension (2D) transition metal dichalcogenide (TMD) crystal is a subject of considerable current interest. Here, we report investigations of exciton resonance Raman spectroscopy assisted by plasmonic thin film cavity from single monolayer to tens of monolayers in WS2. Without the plasmonic cavity and under A exciton resonant excitation condition, the Raman response indeed shows strong enhancement relative to the no-resonance condition, as reported by others previously [1]. With plasmonic cavity, the Raman signal is enhanced further as anticipated [2]. However, we find the enhancement factor show dramatic dependence on the TMD layer thickness with an optimal thickness in the range of few nanometer. More specifically, we find that at this range of thickness, the Raman enhancement is more than 2 orders of magnitude higher than that for the monolayer case. Possible mechanisms will be discussed.

10:12AM W53.00011: Optical temperature determination during laser annealing of graphite oxide*  
SHASHANK RAM NANDYALA (Presenter), JOSEPH R MURPHY, MICHAEL A SEAS, VIVEK JAIN, SUBASH KATTEL, JON M PIKAL, PATRICK A JOHNSON, JOHN ACKERMAN, WILLIAM RICE, Univ of Wyoming — Highly conductive, graphene-like, reduced graphite oxide (rGO) can be synthesized from graphite oxide (GO) via photochemical methods, solution chemistry, and high-temperature treatments. In order to develop intricate circuitry and conductive patterns out of rGO, controlled laser-based annealing of GO has been extensively developed. Here, we show that this laser-based technique creates a localized, optically induced thermal reaction in GO. We determine the local temperature at the irradiation spot by comparing the Stokes and anti-Stokes scattering intensities giving us a simultaneous measure of temperature during annealing. Using this technique, we compare the optically induced GO-to-rGO transition with standard induction furnace annealing. The optically created rGO patterns, which we show can be produced in air, argon, and vacuum environments, are characterized using electrical conductivity and Raman scattering. Our ability to generate conductive circuits using optical annealing of GO creates new opportunities for economical carbon-based electronics.

10:24AM W53.00012: Optical probe of the low doping regime in graphene: Comparison of Raman spectroscopy and transport measurements*  
ZHUOFA CHEN (Presenter), MOUNIKA VUTUKURU, ANNA K SWAN, Boston Univ — Identifying charge density fluctuations and impurities in graphene is vital for high-quality graphene-based devices. Here, we developed an optical probe to evaluate the doping level and charge fluctuation in the range from $10^{10}$ cm$^{-2}$ to $10^{12}$ cm$^{-2}$ by using the Raman 2D peak. We compare charge density estimated from Raman measurements with electrical transport measurement, the benchmark method for evaluating charge density fluctuations and other scattering mechanism. At low doping level(< $10^{12}$ cm$^{-2}$), the 2D Raman peak becomes asymmetric and can be fitted by two peaks, and the 2D peak-split(in cm$^{-1}$) correlates with charge density with high precision ($2\times10^{10}$ cm$^{-2}$ per 2D peak-split wavenumber). Our work provides a simple and non-invasive optical method to quantify the doping levels of graphene from $10^{10}$ cm$^{-2}$ to $10^{12}$ cm$^{-2}$, two orders of magnitude higher precision than previously reported optical methods [1]. The 2D peak-split method provides a platform for evaluating the quality of graphene before building high-quality graphene devices.

10:36 AM W53.00013: Probing strong light-matter interaction in the optically thin limit  
ERIC YUE MA (Presenter), TONY F HEINZ, Stanford Univ — Sharp and isolated resonances in condensed-matter systems yield pronounced signatures in dielectric function, which, in turn, are manifest in the reflectance and transmittance spectra. A canonical example is the Reststrahlen band, extended spectral bands with near-unity reflectance, known to occur in ionic crystals near their optical phonon frequencies in the mid-infrared. Although Reststrahlen bands in bulk materials have been extensively studied, their behavior in the optically thin limit has not been examined systematically. With the advent of 2D van der Waals materials, it has become possible to probe materials with precise thicknesses across several orders of magnitudes, with essentially no change to the dielectric function down to the few- or monolayer limit. Here we present a systematic study of Reststrahlen-like reflection bands when the material transitions from optically thick to optically thin. We describe, experimentally and theoretically, the evolution of the reflectance spectra and their relation to radiative and nonradiative rates.

Session W54 DCMP: Topological Devices and Nanostructures Mile High Ballroom 2A

8:00 AM W54.00001: Robust axion insulator and Chern insulator phases in a two-dimensional antiferromagnetic topological insulator*  
CHANG LIU (Presenter), YONGCHAO WANG, HAO LI, YANG WU, YAOXIN LI, JIAHENG LI, KE HE, YONG XU, JINSONG ZHANG, YAYU WANG, Tsinghua University — Topology, magnetism, and two-dimensional materials are among the most actively-pursued fields in physics and material science. Here, we investigate the quantum transport behaviors of exfoliated MnBi$_2$Te$_4$, an antiferromagnetic topological insulator that hosts all three properties simultaneously. In the six septuple-layer crystal, we observe robust axion insulator state in zero magnetic field, over a wide field range, and at relatively high temperatures. A moderate magnetic field drives it into the Chern insulator state through a topological quantum phase transition. These results pave the road for realizing the topological magnetoelectric effect and axion electrodynamics in condensed matter systems.

8:12AM W54.00002: Gate field effects on the topological insulator BiSbTeSe2 interface

SHUANGLONG LIU, University of Florida, YANG XU, Purdue University, YUN-PENG WANG, University of Florida, YONG CHEN, Purdue University, JAMES NATHAN FRY, HAI-PING CHENG (Presenter), University of Florida — Inspired by experimental efforts, we study interfacial processes between two slabs of BiSbTeSe2 (BSTS) via first principles calculations. Topological surface states are absent for the BSTS interface at its equilibrium separation, but our calculations show that they appear if the inter-slab distance is greater than 6 Å. More importantly, we find that topological interface states can be preserved by inserting two or more layers of hexagonal boron nitride between the two BSTS slabs. Using a first-principles based method that allows us to simulate a back gate, we observe that at low bias the extra charge induced by a gate voltage resides on the surface that is closest to the gate electrode, leaving the interface almost undoped. This explains the origin of the observed insensitivity of transport properties to back voltage at low bias. Our study resolves a few questions raised in experiment, which does not yet offer a clear correlation between microscopic physics and transport data.

8:24AM W54.00003: Controlling Strain Gradients in Weyl Semimetals

CARSTEN PUTZKE (Presenter), JONAS DIAZ-GOMEZ, Ecole Polytechnique Federale de Lausanne, RONI ILAN, Tel-Aviv University, DMITRY I. PIKULIN, Microsoft Station Q, University of California, ADOLFO G GRUSHIN, University Grenoble Alpes, NITYAN NAIR, University of California, Berkeley, CHANDRA SHEKAR, HORST BORRMANN, CLAUDIA FELSER, MPI-CPfS Dresden, JAMES ANALYTIS, University of California, Berkeley, PHILIP MOLL, Ecole Polytechnique Federale de Lausanne — Exposing Weyl semimetals to an external magnetic field leads to the quasiparticle chirality, which has attracted much attention over the past years. The magnetic field causes a shift in the node position and opens a new transport channel. The application of strong magnetic fields for future technological use of this phenomenon is technically impractical. An alternative path has been proposed theoretically. By using strain gradients in Weyl semi-metals it is possible to tune the position of the nodes in a spatially inhomogeneous manner, causing a similar effect as the application of a magnetic field, hence termed pseudo-magnetic field. In the Dirac semimetal Cd$_3$As$_2$ the application of the magnetic field leads to splitting into Weyl nodes with Fermi arcs only pointing along $k_z$, making this a good test candidate. We will show how the new concept of pseudo-magnetic fields is applied to Cd$_3$As$_2$. Using focused ion beam micro structuring we have been able to fabricate samples of Cd$_3$As$_2$ that can be deformed elastically by bending. Studying the coherent electron path composed of two Fermi arcs on opposing surfaces has allowed us to test the proposed pseudo-magnetic fields and to give an upper limit for its strength.

**8:36AM W54.00004: Spinful quantum dot coupled to the edge states of a topological insulator**

PARAMESHWAR PASNOORI (Presenter), NATAN ANDREI, Rutgers University, New Brunswick, COLIN RYLANDS, physics, university of maryland — Coupling a local quantum impurity to an interacting one dimensional system leads to striking strongly correlated effects. Here we study a spinful quantum dot coupled to the edge states of a topological insulator modeled by an interacting helical Luttinger liquid. We solve the model exactly using Bethe Ansatz and study the ground state properties of the system including the occupation number of the impurity and its density of states. Explicit expressions for the impurity magnetic susceptibility is derived at zero temperature.

**8:48AM W54.00005: Current-driven dynamics of spin textures on a surface of topological insulators**

DAICHI KUREBAYASHI (Presenter), NAOTO NAGAOSA, RIKEN CEMS — The application of topological properties has attracted research interest to more efficiently manipulate magnetization. For instance, at the interface of the topological insulator and the ferromagnetic insulator, the electrical control of magnetic textures, magnetization switching induced by electric current, and spin-charge conversion have been intensely studied theoretically and experimentally.

In this talk, we present analytical expressions of the spin-transfer torques on a surface of the magnetic topological insulator by including the higher-order contributions of momentum, k²-term and the hexagonal warping. We obtain six different types of the spin-transfer torque including both the field-like and the damping-like torques; the four of them appear only when the higher-order momentum contributions are included. In addition, we discuss the dynamics of magnetic skyrmions driven by the spin-transfer torques on the surface of the topological insulator. Unlike the skyrmion dynamics in conventional metals, we find that the dynamics significantly depends on the internal structure of magnetic textures.

9:00AM W54.00006: Nontrivial topology in ultrathin bismuth nanowires: An electronic transport study.*  
TITO HUBER (Presenter), Howard University, ALBINA NIKOLAEVA, Lises.Academy Sciences Moldova, LEONID KONOPKO, Academy of Sciences of Moldova — In the past, bismuth was considered to be topologically trivial on the basis of theoretical study of band inversions and angle resolved photoemission spectroscopy. However, the topological properties of bismuth are the subject of renewed study because of the observations of high mobility exhibited by Bi nanowires (suggesting topological protection) as well as the proposal of higher-order topology. We studied the magnetoresistance (MR) in samples of ultrathin nanowires of bismuth, diameter ~50 nm, that exhibit high mobility (Huber et al, Scientific Reports 7,15569 (2017)). The MR exhibits peaks for a sequence of orientations of the magnetic field B, including a coherence peak for B//(111), that can be interpreted in terms of Yamaji magic angles. Magic angles are observed in layered conductors with an open, corrugated, Fermi surface. In contrast, bulk bismuth does not display magic angles since the Fermi surface consist of small ellipsoids and is closed. We will discuss our interpretation of the observations in terms of inter-Bi bilayer coupling and hinge states.

9:12AM W54.00007: Non-local Fermi level tuning of topological insulator Bi$_{2-x}$Sb$_x$Se$_3$ nanoplate devices*

YASEN HOU (Presenter), RUI XIAO, LUKE MCCLINTOCK, HENRY TRAVAGLINI, DONG YU, University of California, Davis — The spin-polarized topological surface states of a topological insulators (TIs) are attractive because of their potential applications in spintronics. A critical challenge of accessing the surface states is to reliably tune the chemical potential with respect to the bulk bands and Dirac point. Here we report non-local Fermi level tuning in Bi$_{2-x}$Sb$_x$Se$_3$ nanoplate devices. We found that applying a local electric field on a Bi$_{2-x}$Sb$_x$Se$_3$ nanoplate device induces a Fermi level shift hundreds of microns away. As temperature decreases to 77K, such a Fermi level shift is frozen, and the device stay in a different electronic state. Magnitude and direction of the Fermi level shift can be controlled by the applied electric field, which then tune the device conductance, field effect behavior and photo-generated carrier transport distance. The non-local Fermi level shift follows very well with a diffusion model and predicts a diffusion coefficient of $2 \times 10^{-6}$ cm$^2$/S at room temperature. Potential candidates for the diffusing carriers include vacancies of selenium and charge traps.

9:24AM W54.00008: Quantum spin Hall quantum point contacts  CHRISTOPH FLECKENSTEIN (Presenter), University of Wurzburg — Quantum spin Hall insulators (QSHIs) provide helical, time reversal protected edge modes. When strongly localized and thus considerably one-dimensional, these edge states may be described in terms of helical Luttinger liquids. In that respect, especially the formation of interaction induced gaps is particularly exciting. Although the formation of the underlying scattering terms might be demanding for isolated helical edges, the situation shifts when both edges of the QSHI are brought in proximity to each other. Then, the increased number of channels enables a variety of scattering terms, all of which relevant even for weak repulsive Coulomb interactions. Indeed, very recent transport experiments on QSHI quantum point contacts not only imply the existence of interactions at the helical edge, but also indicate the presence of two-particle scattering terms. This is especially interesting, since these terms, among proximity induced superconductivity, constitute one brick for the construction of parafermionic excitations in the same system.

9:36AM W54.00009: Giant and gate-tunable spin-galvanic effect in graphene-topological insulator van der Waals heterostructures at room temperature  DMITRII KHOKHRIAKOV (Presenter), MD ANAMUL HOQUE, BOGDAN KARPIAK, SAROJ DASH, Chalmers Univ of Tech — Unique electronic spin textures in topological states of matter are promising for emerging spin-orbit driven memory and logic technologies. However, there are several challenges related to the enhancement of their performance, electrical gate-tunability, interference from trivial bulk states, and heterostructure interfaces. We address these challenges by integrating graphene [1] with a 3D topological insulator (TI) in a van der Waals heterostructure [2] to take advantage of their remarkable spintronic properties and engineer strong proximity-induced spin-charge conversion phenomena. In these heterostructures, we experimentally demonstrate a giant spin-galvanic effect at room temperature due to an efficient conversion of a nonequilibrium spin polarization into a transverse charge current [3]. Importantly, we show a strong gate-tunability of the spin-galvanic signal, tracing its origin to the proximity-induced Rashba-Edelstein effect. These findings open interesting opportunities for exploring exotic physical phenomena and new device functionalities governed by topological proximity effects.

9:48AM W54.00010: Topological Sliding Moiré Heterostructure*  SHIZENG LIN (Presenter), YING SU, Los Alamos Natl Lab — We investigate the effect of sliding motion of layers in Moiré heterostructures on the electronic state. We show that the sliding Moiré heterostructure can generate nontrivial topology characterized by the first and second Chern number in the high dimensional manifold spanned by the physical dimensions and synthetic dimensions associated with the sliding displacement. The nontrivial topology implies a topological charge pumping caused by the sliding motion. We demonstrate the nontrivial topology and charge pumping explicitly in a one dimensional bi-chain model and the small-angle twisted bilayer graphene. Contrary to the conventional belief that the interlayer sliding in incommensurate Moiré Heterostructures does not affect the electronic structure, our results reveal that the sliding motion can generate nontrivial topology dynamically and hence cannot be neglected in the dynamical process.

Session W55 DCMP: Non-Hermitian Topological Phases Mile High Ballroom 2B

8:00AM W55.00001: Homotopical classification of non-Hermitian band structures  ZHI LI (Presenter), ROGER MONG, Univ of Pittsburgh — We proposed a framework towards the topological classification of non-Hermitian band structures. Different from previous K-theoretical approaches, our approach is homotopical, which enables us to see more topological invariants. Specifically, we considered the classification of non-Hermitian systems with separable band structures. We found that the whole classification set is decomposed into several sectors, based on the braiding of energy levels. Each sector can be further classified based on the topology of eigenstates (wave functions). Due to the interplay between energy level braiding and eigenstates topology, we found some torsion invariants, which only appear in the non-Hermitian world. We further proved that these new topological invariants are unstable, in the sense that adding more bands will trivialize these invariants.
8:12 AM W55.00002: Doubling theorem for Fermi points, degenerate points, and exceptional points in 2D non-Hermitian systems
CHING-KAI CHIU (Presenter), Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, ZHESEN YANG, Institute of Physics, Chinese Academy of Sciences, ANDREAS P SCHNYDER, Max-Planck Institute for Solid State Physics — Fermion doubling theorem, which is known as Nielsen-Ninomiya theorem, states that once a Weyl node with a non-zero topological charge is present in the 3D Brillouin zone, the node must be accompanied by at least one Weyl node to neutralize the total topological charge in the entire Brillouin zone. In 2D non-Hermitian systems, Fermi points, degeneracy points, and exceptional points can be protected by non-zero topological invariants in the absence of symmetries. We show that these three types of protected points obey the doubling theorem in the 2D Brillouin Zone in this talk.

8:24 AM W55.00003: Non-Hermitian exceptional Landau quantization in electric circuits*
XIAO-XIAO ZHANG (Presenter), MARCEL FRANZ, University of British Columbia — Alternating current RLC electric circuits form an accessible and highly tunable platform simulating Hermitian as well as non-Hermitian quantum systems. We propose here a realization of a time-reversal invariant pseudo-magnetic field, enabling the exploration of non-Hermitian physics under external magnetic field. Based on circuit realizations of non-Hermitian Dirac and Weyl systems under magnetic field, we identify the low-energy physics with a generic real energy spectrum from the non-Hermitian relativistic Landau quantization of exceptional points and rings, avoiding the non-Hermitian skin effect and providing a physical example of quasiparticles moving in the complex plane. Realistic detection schemes are designed that can be used to probe the flat energy bands, sublattice polarization, edge states protected by a non-Hermitian sublattice symmetry, and a characteristic nodeless probability distribution.

8:36 AM W55.00004: Topological invariants for non-Hermitian chiral-symmetric systems*
TIMO HYART (Presenter), WOJCIECH BRZEZICKI, Institute of Physics, Polish Academy of Sciences — We show that the topology of one-dimensional chiral-symmetric non-Hermitian systems is determined by a hidden Chern number described by an effective 2D Hermitian Hamiltonian $H_{\text{eff}}(k, \eta)$, where $k$ is the momentum and $\eta$ is the imaginary part of the energy [1]. This Chern number manifests itself as topologically protected in-gap end states at zero real part of the energy. We show that the bulk-boundary correspondence coming from the hidden Chern number is robust and immune to non-Hermitian skin effect. We introduce a minimal model Hamiltonian supporting topologically nontrivial phases in this symmetry class, derive its topological phase diagram and calculate the end states originating from the hidden Chern number. We discuss various generalizations and realizations of this model, and the corresponding topological invariants.

8:48AM W55.00005: Non-Hermitian band theory of directional amplification  WENTAN XUE (Presenter), MING-RUI LI, FEI SONG, YU-MIN HU, ZHONG WANG, Tsinghua University — Owing to its open-system nature, amplification of electromagnetic and other signals is naturally described in terms of non-Hermitian operators. Recently, it has been shown that the non-Hermitian band theory is dramatically shaped by the non-Hermitian skin effect (NHSE), namely the exponential accumulation of eigenstates to the boundary of the system. In view of the NHSE, non-Bloch band theory based on the generalized Brillouin zone has been formulated to predict the topological edge modes. Here, we show that the non-Bloch band theory provides a natural framework for the intriguing phenomenon of directional amplification (or nonreciprocal amplification) that is useful in many applications. The magnitude of directional amplification is expressed in terms of the quantities of the generalized Brillouin zone. Our results provide a natural and quantitative theoretical formulation for the directional amplification.

9:00AM W55.00006: Non-Hermitian skin effect and chiral damping in open quantum systems* FEI SONG (Presenter), SHUNYU YAO, ZHONG WANG, Tsinghua University — One of the unique features of non-Hermitian Hamiltonians is the non-Hermitian skin effect, namely, that the eigenstates are exponentially localized at the boundary of the system. The non-Hermitian skin effect plays a crucial role in the non-Hermitian topology and bulk-boundary correspondence. For open quantum systems, a short-time evolution can often be well described by the effective non-Hermitian Hamiltonians, while long-time dynamics calls for the Lindblad master equations, in which the Liouvillian superoperators generate time evolution. In this Letter, we find that Liouvillian superoperators can exhibit the non-Hermitian skin effect, and uncover its unexpected physical consequences. It is shown that the non-Hermitian skin effect dramatically shapes the long-time dynamics, such that the damping in a class of open quantum systems is algebraic under periodic boundary conditions but exponential under open boundary conditions. Moreover, the non-Hermitian skin effect and non-Bloch bands cause a chiral damping with a sharp wave front.

**9:12AM W55.00007: Observation of non-Hermitian topology and its bulk-edge correspondence***  
ANANYA GHATAK (Presenter), MARTIN BRANDENBOURGER, JASPER VAN WEZEL, CORENTIN COULAIS, Univ of Amsterdam — Topological edge modes and the bulk-edge correspondence has enabled the creation of robust electronic, electromagnetic and mechanical transport properties across a wide range of systems, from cold atoms to metamaterials, active matter and geophysical flows. Recently, in the advent of non-Hermitian topological systems novel topological phases have been introduced. However, whether such phases can be experimentally observed, and what their properties are, have remained open questions. Here, we discover and observe a novel form of bulk-edge correspondence for non-Hermitian topological phases. We find that a change in the bulk non-Hermitian topological invariant corresponds to a change of localization of the topological edge mode. Using a quantum-to-classical analogy, we create a mechanical metamaterial with non-reciprocal interactions, in which we observe experimentally the predicted bulk-edge correspondence, demonstrating its robustness. Our results have a major impact on the field of non-Hermitian topology and boost metamaterials by opening new avenues to manipulate waves in unprecedented fashions.

**9:24AM W55.00008: Symmetry and Topology in Non-Hermitian Physics**  
KOHEI KAWABATA (Presenter), Department of Physics, University of Tokyo, KEN SHIOZAKI, Yukawa Institute for Theoretical Physics, Kyoto University, MASAHITO UEDA, Department of Physics, University of Tokyo, MASATOSHI SATO, Yukawa Institute for Theoretical Physics, Kyoto University — Non-Hermiticity enriches topological phases beyond the existing framework for Hermitian topological phases. Here, we develop a general theory of symmetry and topology in non-Hermitian physics. We demonstrate that non-Hermiticity ramifies and unifies the celebrated Altland-Zirnbauer symmetry for insulators and superconductors, leading to 38-fold symmetry instead of the 10-fold one. Moreover, we reveal that two types of energy gaps are relevant for non-Hermitian systems because of the complex-valued nature of energy spectra, both of which constitute non-Hermitian topology. Based on these fundamental insights in non-Hermitian physics, we completely classify topological phases of non-Hermitian insulators and superconductors, as well as semimetals that support exceptional points. Our work paves the way toward unique phenomena and functionalities due to the interplay of non-Hermiticity and topology, such as symmetry-protected topological lasers and dissipative topological quantum computation.

Classification of Exceptional Points and Non-Hermitian Topological Semimetals

TAKUMI BESSHO (Presenter), Yukawa Institute for Theoretical Physics, Kyoto University, KOHEI KAWABATA, Department of Physics, University of Tokyo, MASATOSHI SATO, Yukawa Institute for Theoretical Physics, Kyoto University — Exceptional points are universal level degeneracies induced by non-Hermiticity. Whereas the past decades witnessed their new physics, the unified understanding has yet to be obtained. Here we present the complete classification of generic topologically stable exceptional points according to fundamental symmetries of charge conjugation, parity, and time reversal. This classification reveals unique non-Hermitian gapless structures with no Hermitian analogs and systematically predicts unknown non-Hermitian semimetals and nodal superconductors; a topological dumbbell of exceptional points in three dimensions is constructed as an illustration. Our work paves the way towards richer phenomena and functionalities of exceptional points and non-Hermitian topological semimetals.

Non-Hermitian physical aspects in disordered Weyl/Dirac semimetals

TAIKI MATSUSHITA (Presenter), Osaka Univ, YUKI NAGAI, JAEA, SATOSHI FUJIMOTO, Osaka Univ — Recently, the platform of non-Hermitian physics is extended to many-body or disordered systems where quasiparticles possess a finite lifetime. The realization of non-Hermitian topological defects in equilibrium systems attracts great interests because non-Hermitian nature makes topological classification very rich. For example, non-Hermitian perturbations in Weyl Hamiltonian lead to the realization of Weyl exceptional rings and flat bands.

Here, we show the non-Hermitian physics in disordered Weyl semimetals. In this presentation, we propose a general scheme for the generation of disorder-induced Weyl exceptional rings, a spectral collapse of Landau levels. Our scheme for a generation Weyl exceptional ring is applicable to almost all Weyl materials. Thus, Weyl exceptional rings in disordered Weyl semimetals are detectable by using photoemission or quasiparticle interference experiments. In addition, we propose that a new type of non-Hermitian effects in Weyl semimetals, the spectral collapse of Landau levels. We show that non-Hermitian perturbation leads to the collapse of Landau quantization which corresponds to non-Hermitian topological phase transition.

Non-Hermitian fractional quantum Hall states with 1/3 filling

YOSHIDA TSUNEYA (Presenter), KOJI KUDO, YASUHIRO HATSUGAI, Univ of Tsukuba — We elucidate the emergence of non-Hermitian fractional quantum Hall states (nHFQH) with 1/3 filling for cold atoms with two-body loss. We characterize the nHFQH states with the topological degeneracy under the periodic boundary condition and the total Chern number C_{tot}=1 for the ground state triplet. Furthermore, we point out that nHFQH states emerge even when the interaction is purely dissipative.

This work is partly supported by JSPS KAKENHI Grants No.JP16K13845, No.JP17H06138, and No.JP18H05842. A part of numerical calculations were performed on the supercomputer at the ISSP in the University of Tokyo.
10:12AM W55.00012: Appearance of a topological semimetal phase in 1D non-Hermitian systems
KAZUKI YOKOMIZO (Presenter), SHUICHI MURAKAMI, Tokyo Institute of Technology —
In our previous work, we establish a non-Bloch band theory in one-dimensional (1D) tight-binding non-Hermitian systems [1]. We show how to determine the generalized Brillouin zone \( C_\beta \) for the complex Bloch wave number \( \beta = e^{ik} \), \( k \in \mathbb{C} \). In contrast to Hermitian cases, where \( C_\beta \) is always a unit circle, in non-Hermitian systems \( C_\beta \) is a closed curve, not necessarily a unit circle. Furthermore, we find that \( C_\beta \) can have cusps, and its shape depends on system parameters. A byproduct of our theory is that one can prove the bulk-edge correspondence between the winding number defined from \( C_\beta \) and existence of topological edge states.

From the non-Bloch band theory, we show that in 1D non-Hermitian systems with both sublattice symmetry and time-reversal symmetry, a topological semimetal phase with exceptional points is stabilized, and this phase extends over a finite region on the phase diagram. This stems from unique features of the generalized Brillouin zone \( C_\beta \); as a system parameter changes, \( C_\beta \) also changes so as to keep the system gapless. Furthermore, we also find that the motion of the exceptional points within the topological semimetal phase is related to the change of the value of the winding number. [1] K. Yokomizo and S. Murakami, Phys. Rev. Lett. 123, 066404 (2019)

Session W56 DCMP: Density Waves in Materials Mile High Ballroom 2C - Emma Cating-Subramanian

8:00AM W56.00001: Novel photoinduced charge density wave state and periodic lattice distortion in 17-TaSe\(_2\)
YINGCHAO ZHANG (Presenter), XUN SHI, WENJING YOU, ZHENSHEUNG TAO, YIGUI ZHONG, Department of Physics and JILA, University of Colorado, Boulder, PETER OPPENEER, Department of Physics and Astronomy, Uppsala University, MICHAEL BAUER, KAI ROSSNAGEL, Institute of Experimental and Applied Physics, Kiel University, HENRY KAPTEYN, MARGARET MURNANE, Department of Physics and JILA, University of Colorado, Boulder —

The amplitude mode in a charge density wave (CDW) material is the collective modulation of the relevant periodic lattice distortion (PLD). Here we use a femtosecond laser pulse to displacively excite the coherent amplitude mode in the CDW material 17-TaSe\(_2\). We then use time- and angle-resolved photoemission to track the dynamic evolution of the amplitude mode and electronic band structure – and in particular, the position and the width of the Ta 5\(d\) band. At sufficiently high fluences, and within a half-cycle of the amplitude mode oscillation, the PLD of 17-TaSe\(_2\) first relaxes to the position of the normal state, before overshooting to form an inverted CDW transient state. Moreover, the band width is maximum for the normal state, while it is reduced for both the ground CDW state and the inverted CDW state. Another important observation is that this inverted CDW state has larger density of states at the Fermi level than the normal state. Our observations are consistent with both density functional theory (DFT) and tight binding calculations. Our results show the possibility of using light to generate unique lattice distortions and electron correlations via ultrafast coherent phonon excitation.
8:12AM W56.00002: Suppression of charge density wave transitions in La(\textit{Ag}_{1-x}\textit{Au}_x)\textit{Sb}_2 (0 \leq x \leq 1) by pressure.\footnote{This work was supported by the Department of Energy, Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-07CH11358.} SERGEY L. BUD'KO (Presenter), LI XIANG, Ames Laboratory and Iowa State University, DOMINIC H RYAN, Department of Physics and Centre for the Physics of Materials, McGill University, PAUL C CANFIELD, Ames Laboratory and Iowa State University — LaAgSb$_2$ exhibits two CDW transitions at ambient pressure: at $T_1 \sim 207$ K a lattice modulation along the $a$-axis develops and upon further cooling, at $T_2 \sim 186$ K, an additional CDW ordering along the $c$-direction appears.\cite{1} Here, we report resistivity measurements on La(\textit{Ag}_{1-x}\textit{Au}_x)\textit{Sb}_2 (0 \leq x \leq 1) samples at ambient and high pressure that reveal suppression of both CDW transitions by pressure and Au substitution. By introducing simple pressure scale shifts for different $x$-values, the $T(P)$ data fall onto universal $T_1(P^*)$ and $T_2(P^*)$ curves. Results will be compared with and contrasted to the literature data on (La$_{1-x}$\textit{R}_x)AgSb$_2$ ($R$ = Ce, Nd).\cite{2}

8:24AM W56.00003: Emergence of charge density wave domain walls network in Pt doped TiSe$_2$\footnote{acknowledge support from DMREF 1629068} DAVIDE IAIA (Presenter), University of Illinois at Urbana-Champaign, KYUNGMIN LEE, Physics, The Ohio State University, JESSE CHOE, Physics, Rice University, JUNJING ZHAO, JUQIANG LI, Physics, University of Virginia, MING SHI, JUNZHANG MA, MENGYU YAO, Swiss Light Source, Paul Scherrer Institute, ZHENYU WANG, University of Illinois at Urbana-Champaign, MASAYUKI OCHI, Physics, Osaka University, RYOTARO ARITA, Applied Physics, University of Tokyo, UTPAL CHATTERJEE, Physics, University of Virginia, EMILIA MOROSAN, Physics, Rice University, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign, NANDINI TRIVEDI, Physics, The Ohio State University — Charge density wave (CDW) incommensuration in the TiSe$_2$ family proceeds through the formation of domain walls (DWs). Previous scanning tunneling microscopy (STM) studies on Cu intercalated TiSe$_2$ have shown that DWs host an extra population of electrons and might play an important role in the emergence of superconductivity. Here we report a low temperature STM study of Pt-doped TiSe$_2$. A network of nanometer-thick DWs is observed and STM spectra reveal local inhomogeneity of the electronic properties which results in the emergence of pseudogaps of different size. In contrast to Cu intercalation, Pt substitution creates a network of 1D channels of low energy transport which subtract electrons from the bulk enhancing correlation effects. The interplay between electron correlation and disorder induced by DWs might be fundamental for the metal to insulator transition reported by previous transport measurements.
8:36AM W56.00004: Scanning Tunneling Microscopy of the Nearly-Commensurate and Incommensurate Charge Density Wave Phases of 1T-TaS$_2$*  MICHAEL BOYER (Presenter), MANOJ K SINGH, BISHNU SHARMA, BONING YU, Clark University — 1T-TaS$_2$ is an intensely-studied charge density wave (CDW) compound which hosts a wealth of interesting and diverse physics. At low temperatures, 1T-TaS$_2$ is in a Mott insulating, commensurate CDW state. At higher temperatures, the material can enter into triclinic, nearly-commensurate, and incommensurate CDW states. Studies across all four CDW states using multiple experimental techniques have been conducted, but considerable emphasis has been on the low-temperature commensurate CDW state. Here we present our scanning tunneling microscopy measurements on the higher-temperature nearly-commensurate and incommensurate CDW phases with a focus on domains, domain walls, and their changes with temperature.

*We acknowledge support from NSF Grant number DMR-1904918.

8:48AM W56.00005: Charge density wave (CDW) and magnetism in RNiC$_2$ family (R = rare earth metal)*  MARTA ROMAN (Presenter), KAMIL K. KOLINCIO, TOMASZ KLIMCZUK, Faculty of Applied Physics and Mathematics, Gdansk University of Technology — The ternary rare-earth nickel dicarbides RNiC$_2$ (R - rare earth metal) with a non-centrosymmetric, orthorhombic crystal structure offer a unique opportunity to tune the ground state with varying R atom. The charge density wave (CDW) has been found for most of the members of the RNiC$_2$ family (R = Pr – Lu) with the Peierls temperature scaling linearly with the unit-cell volume. LaNiC$_2$ compound is an unconventional superconductor, SmNiC$_2$ undergoes a ferromagnetic transition and the rest of the compounds (apart from nonmagnetic YNiC$_2$ and LuNiC$_2$ exhibiting large positive magnetoresistance and PrNiC$_2$ where only a weak magnetic anomaly is observed) order antiferromagnetically below 25 K.

In this presentation, the large diversity of physical phenomena occurring in the RNiC$_2$ family will be discussed in terms of relations between various types of ordering on the basis of magnetic, transport and galvanomagnetic measurements. The main emphasis will be put on the CDW mutually interacting with magnetism in the polycrystalline RNiC$_2$ and their solid solutions.

*The project was financially supported by the National Science Centre (Poland), Grant UMO-2015/19/B/ST3/03127.
9:00AM W56.00006: Core-level and Resonant Photoemission across the Charge Density Wave Transition in 1T-TiSe₂
ASHISH CHAINANI (Presenter), CHIEN-WEN CHUANG, Condensed Matter Physics, Natl Synchrotron Rad Res Ctr, Taiwan, YOSHIKAZU TANAKA, MASAKI OURA, RIKEN SPring-8 Center, Hyogo, Japan, KAI ROSSNAGEL, Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — We study the electronic structure of the charge density wave (CDW; \( T_{CDW} = 200 \) K) material 1T-TiSe₂, using core-level photoemission and valence band resonant photoemission spectroscopy (RESPES) across the Ti L-edge threshold. While 1T-TiSe₂ was extensively studied using various techniques including angle-resolved photoemission spectroscopy (ARPES)[1], time-resolved ARPES[2] and resonant inelastic X-ray scattering[3], the Ti L-edge RESPES has not been reported. The Ti 2p and Se 3d spectra show clear shifts across the CDW transition associated with band structure changes in the CDW phase. The Ti L-edge RESPES shows a clear resonance of Ti 3d character states and a Ti LVV Auger correlation satellite. Applying the Cini-Sawatzky method provides an estimate of the effective on-site Coulomb correlation energy between two holes, \( U_{dd} = -1.5 \) eV. The results are consistent with core level Auger spectra of 1T-TiSe₂[4], suggesting the effective attractive Coulomb correlation energy would favour a band Jahn-Teller based model for describing the CDW transition in 1T-TiSe₂.

9:12AM W56.00007: High-temperature charge density wave in rare-earth tetratelluride
BAIQING LYU (Presenter), ALFRED ZONG, Massachusetts Institute of Technology MIT, DONG WU, International Center for Quantum Materials, Peking University, MAKOTO HASHIMOTO, DONGHUI LU, SLAC National Accelerator Laboratory, Stanford Synchrotron Radiation Lightsource, SU-DI CHEN, Stanford University, MAN LI, YA BOO HUANG, Shanghai Synchrotron Radiation Facility, NUH GEDIK, Massachusetts Institute of Technology MIT — Charge density waves (CDWs) are broken-symmetry ground states that are driven by the electron-phonon interaction in quasi one-dimensional (1D) or two-dimensional (2D) metals. The subject has generated considerable interest as it offers important insights into electron-phonon physics, its competition or coexistence with other ground states, as well as its potential role in the phase diagram of high-Tc cuprates. Recently, a CDW state was found in a newly synthesized quasi-2D compound, rare-earth tetratelluride. Here, by high-resolution angle-resolved photoemission spectroscopy, we demonstrate that in the CDW state, the Fermi surface is fully gapped but the gap size is momentum-dependent. Surprisingly, the CDW persists to above 400 K, providing a remarkable system for the room-temperature study of 2D semiconductors with collective electronic states.
**9:24AM W56.00008: Charge Density Wave Order in the Organic Metal α-(ET)$_2$ KHg(SCN)$_4$**

RAJU GHIMIRE (Presenter), BRET LARAMEE, OWEN GANTER, Clark University, ZAHIRUL ISLAM, ULRICH WELP, Argonne National Laboratory, JENNIFER NEU, National High Magnetic Field Laboratory, CHARLES C AGOSTA, Clark University — The family of crystalline organic metals α-(ET)$_2$ XHg(SCN)$_4$, with X=K, NH$_4$, Ti, or Rb are of interest because three of the compounds have a coexisting charge density wave (CDW) and metallic phase at low temperatures, while one (X = NH$_4$) has a superconducting ground state. They are all triclinic crystals and have a quarter filled conduction band. To find the nature of the density wave state we studied α-(ET)$_2$ KHg(SCN)$_4$ using elastic x-ray scattering at the Advanced Photon Source at Argonne National Laboratory. We will present preliminary scattering data at 4 K to search for incommensurate CDW, below the thermodynamic phase transition at 8K, and contrast it with data at 104 K. We encountered serious challenges of radiation damage to these organic materials and employed a mitigation scheme by using 18 keV x-rays with reduced incident flux for extended period of time. There seems to be a weak broadening of Bragg peaks below 8 K, which would indicate some structural anomaly at this temperature.

*We acknowledge funding from NSF, DMR-1905950.
Work at Materials Science Division of Argonne National Laboratory was supported by the US Department of Energy (DOE).This research used resources of the APS, User Facility operated by Argonne National Laboratory under Contract DE AC02-06CH11357.

JAN-HENDRIK PÖHLS (Presenter), MARGARETHA SANDOR, MARTIN OTTO, LAURENT RENÉ DE COTRET, MARK SUTTON, BRADLEY SIWICK, McGill Univ — Investigations of structural dynamics on the sub-picosecond timescale can provide a detailed fundamental understanding of the non-equilibrium properties of materials. While structural transformations are related to intensity changes in Bragg peaks, thermal diffuse scattering can reveal complete information on the underlying phonon modes. Because thermal diffuse scattering intensities are many order of magnitude lower than Bragg intensities, very sensitive measurements are required.

In this talk, I will present ultrafast electron diffuse scattering to directly observe electron-phonon interactions in charge-density wave (CDW) materials with a time resolution of ~100 fs. It was found that CDW materials and high-temperature superconductors (HTS) have a similar origin and hence, gaining deep insights in CDW materials is expected to enhance our understanding of HTS. Using a combination of density functional theory and experimental studies, the rich electron-phonon interactions of two CDW materials (*i.e.*, niobium diselenide and tantalum disulfide) were investigated. Measurements suggest photoexcitation significantly stiffens/softens acoustic modes only at certain wave-vectors, a phenomenon we have also investigated computationally.

*I would like to acknowledge the FRQNET PBEEE fellowship.*
**3D-ΔPDF analysis of three-dimensional CDW compound \((\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\)**

PUSPA UPRETI (Presenter), Physics (NIU) and Material Science Division (ANL), Northern Illinois University and Argonne National Lab, LEKHANATH POUDEL, NIST Center for Neutron Research, MATTHEW KROGSTAD, STEPHAN ROSENKRANZ, Material Science Division, Argonne National Laboratory, OMAR CHMAISSEM, Physics (NIU) and Material Science Division (ANL), Northern Illinois University and Argonne National Lab, RAYMOND OSBORN, Material Science Division, Argonne National Laboratory — A three-dimensional compound series \((\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\) has been identified as a promising system to understand the interplay between the charge-density-waves (CDW) and the superconductivity. The second order CDW transition temperature \(T^*\) in this family can be fully suppressed with the substitution of Ca for Sr, giving rise to a Quantum Critical Point at \(x\approx0.9\) at ambient pressure. For a comprehensive understanding of the lattice instability connected to this CDW transition and superconductivity, diffuse scattering measurements were performed on a single crystal doping series in \((\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\) with \((x=0, 0.1, 0.5, 0.6, 0.65, 0.7, 0.9)\) using x-ray diffraction. A 3D-ΔPDF analysis shows that there is an order-disorder transition at \(T^*\), with local distortions still present at higher temperature.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.*

**Optical Thermal Diffusivity Measurements in PdxErTe3**

ERIK KOUNTZ (Presenter), JOSHUA A STRAQUADINE, JIECHENG ZHANG, AHARON KAPITULNIK, IAN FISHER, Stanford Univ — PdxErTe3 is a quasi-2D metal with two stripe ordered charge density wave (CDW) orders with of Pd intercalated between the ErTe3 layers [1]. Increasing Pd intercalation increases disorder and suppresses the CDW transitions [1,2]. We use a photo-thermal microscope for high resolution thermal diffusivity and optical reflectivity measurements by measuring phase delay in local reflectivity. This is supplemented with resistivity and thermopower measurements. Our primary observation is a decrease of thermal diffusivity and the onset of anisotropy in all transport channels below the higher temperature CDW transition. We will further discuss the relation between thermal and charge transport, and the applicability of Wiedemann-Franz law through the two CDW transitions.

Density Wave Order in Superconducting Nb-Bi$_2$Se$_3$

Yanan Li (Presenter), Christian A Parsons, University of Wisconsin - Milwaukee, Sanath Ramakrishna, William Nelson, Ryan Baumbach, Arneil P Reyes, National High Magnetic Field Laboratory/Florida State University, Prasenjit Guptasarma, University of Wisconsin - Milwaukee

Topological Insulators such as Bi$_2$Se$_3$ and Bi$_2$Te$_3$, observed to have hexagonally deformed Fermi surfaces and strong nesting, have been proposed as potential candidates for the existence of density wave order. The presence of such order becomes particularly interesting in the context of superconductivity appearing in systems such as Cu-Bi$_2$Se$_3$ and Nb-Bi$_2$Se$_3$, and of possible intercalation-induced spontaneous symmetry breaking. So far, from experiments, we have some hints of density wave order, such as from electron diffraction and angle-resolved photoemission spectroscopy in Cu-Bi$_2$Se$_3$, and the observation of multiple Fermi surfaces in torque-magnetometry based quantum oscillations in Nb-Bi$_2$Se$_3$. However, there are no direct reports of Charge Density Wave order from resistivity. Here we report, for the first time, evidence for the coexistence of superconductivity with CDW order from transport measurements on single crystals of Nb$_x$-Bi$_2$Se$_3$ (0 < x < 0.25). We also report our studies of specific heat, magnetization, and $^{209}$Bi NMR. Based on our results, we argue that the Nb d orbital might not be responsible for the observation of multiple Fermi surfaces, and that such order could simply be induced by intercalants (Bi or Nb, or both). Further work is needed in this area.

Electronic Raman scattering spectra of various types of BEDT-TTF compounds

We measured Raman scattering spectra of various types of BEDT-TTF compounds such as a charge ordered material $\alpha$-(BEDT-TTF)$_2$I$_3$, a dimer-square lattice material $\beta$-(BEDT-TTF)$_2$I$_3$ and a quantum spin-liquid material $\kappa$-(BEDT-TTF)$_2$Ag$_2$(CN)$_3$. These three compounds show the broad Raman structures, which can be ascribed to the electronic Raman scattering. These structures correspond to charge excitation and magnetic excitation. Comparing these electronic Raman signals, we will discuss the electronic states of these compounds. For example, $\alpha$-(BEDT-TTF)$_2$I$_3$ shows a phase transition from charge ordered state to Dirac electron state. For clarification of the electronic state of $\alpha$-(BEDT-TTF)$_2$I$_3$, we focus on the charge excitation in the reflectivity and Raman spectra.
Alkali-metal-TCNQ salt, K-TCNQ, is a quasi-one-dimensional organic charge-transfer complex with segregated columns of alkali cations and TCNQ anion. The compound undergoes structural transition at Tc ~ 395 K as a result of strong electron-lattice interaction inherent in quasi-one-dimensional systems. Below Tc, an electric-induced transition from insulating to metallic phase is observed and contains two threshold behaviors in current-voltage characteristics, akin to charge density wave (CDW) systems. In CDW systems, the lower threshold is attributed to Coulomb blockade for soliton nucleation and the upper one is the depinning field. The upper threshold field follows an exponential temperature-dependence like in CDW systems implying collective charge dynamics near the transition. Low-frequency conductance noise spectroscopy is employed to understand charge carrier dynamics across both the thresholds. The power spectral density (PSD) of the measured current fluctuation increases by almost three orders around the lower threshold implying possible nucleation of phase solitons and on approaching the upper threshold field possible indications of CDW sliding are seen in the behavior of PSD. The existence and dynamics of CDW in these organic charge-transfer systems will be presented.
8:00AM W57.00001: Anomalous phonon vibrations of monolayer MoS$_2$ revealed by polarization degree of freedom of light* TENG-DE HUANG, KRISTAN BRYAN SIMBULAN, YANNWEN LAN, TING-HUA LU (Presenter), Department of Physics, National Taiwan Normal University — Light of linear and circular polarization is broadly used to explore interesting light-matter interaction in layered two-dimensional transition metal dichalcogenides (TMDs) such through Raman scattering and photoluminescence. Little attention has been given to the interaction of TMD materials and light with the elliptical polarization state. We applied elliptically polarized light in micro-Raman spectroscopy to observe variations in the relative intensity of the two most dominant Raman peaks of MoS$_2$. This provides an additional degree of freedom affecting the relationship between the two orthogonal components of the material's in-plane lattice vibrations. Different magnitudes of the in-plane lattice vibrations along two orthogonal directions were induced by varying the light from circularly polarized to elliptically polarized states. Besides, with changing the incident linear polarization angle, the out-of-plane $A_{1g}$ phonon mode red shifts, while the in-plane $E_{2g}$ phonon mode blue shifts. The anomalous lattice vibrations of monolayer MoS2 originate from the built-in strain introduced by the SiO$_2$/Si substrate. This work investigates the material's unexplored fundamental phonon property which may enlighten past and future studies.

*MOST 108-2112-M-003-009

8:12AM W57.00002: A first-principles study of the thermodynamic and vibrational properties of ReS$_2$ under pressure* NATALYA SHEREMETYEVA (Presenter), DAMIEN TRISTANT, ANTHONY YOSHIMURA, JASON GRAY, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, LIANGBO LIANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute — Two-dimensional layered materials (2DMs) are promising candidates for novel devices due to their tunable properties. The properties can be tuned by e.g. controlling the number of layers or applying external pressure on the structures. In order to control the (tuned) properties exactly, precise characterization of 2DMs' is needed. Here, the effect of hydrostatic pressure on the structural, energetic, electronic, and vibrational properties of layered bulk ReS$_2$ was studied using density functional theory. The electronic band gap of the 1T phase is shown to undergo a nearly-direct to indirect transition at about 9 GPa, while the 1T' phase is found to remain a robust nearly-direct band gap material under pressure. The computational analysis of the vibrational properties of both ReS$_2$ phases reproduced existing experimental Raman spectroscopy data for $\omega$ vs. $P$ trends and provided a path towards an accurate phase discrimination using infrared spectroscopy, inelastic neutron, and X-ray scattering.

8:24AM W57.00003: Van der Waals and Electron Stimulated Covalent Hydrogenation of Borophene  SHAOWEI LI (Presenter), University of California, Berkeley, MATTHEW S RAHN, QIUCHENG LI, MARK C HERSAM, Northwestern University — The recent experimental realization of atomically thin, crystalline boron sheets has opened a new direction in the study of synthetic 2D materials. Chemical modification of borophene could further enable fine-tuning of its band structure for nanoelectronic applications. Here, we present the first experimental study of both the non-covalent and covalent hydrogenation of borophene. Adsorbed hydrogen molecules are observed to form a triangular lattice on both $v_{1/6}$ and $v_{1/5}$ borophene polymorphs. The rotational excitation of H$_2$ is detected at 36 meV, indicating the adsorption of hydrogen is dominated by its van der Waals interaction with borophene. The formation of this H$_2$-borophene vertical heterostructure increases the work function of borophene. Moreover, covalent modification of borophene is achieved by inducing a hydrogen-borophene reaction at elevated tip bias voltage. This reaction significantly modifies the electronic structure of borophene and further increases its work function. Overall, this work illustrates the sensitivity of the electronic properties of borophene to chemical modification, which is expected to stimulate further exploration of boron-based chemistry in the two-dimensional limit.

8:36AM W57.00004: Native point defects and impurities in WSe$_2$*  DARSHANA WICKRAMARATNE (Presenter), United States Naval Research Laboratory — Tungsten diselenide (WSe$_2$) is being actively pursued for two-dimensional electronics and as a host for single-photon emitters. We have studied the properties of native defects and impurities in WSe$_2$ using density functional theory with a hybrid functional. We find that all native defects give rise to levels that are deep in the band gap, and thus will not contribute to conductivity. The defect chemistry of WSe$_2$ is likely dominated by common background impurities. In particular, substitutional oxygen, carbon, and transition metal impurities such as vanadium, are low energy defects. Our results allow us to comment on the origin of the frequently observed $p$-type conductivity and sub-band gap emission lines in as-grown WSe$_2$.

8:48AM W57.00005: Discontinuous Evolution of the Structure of Stretching Polycrystalline Graphene.  FEDERICO D'AMBROSIO (Presenter), Univ of Utrecht, VLADIMIR JURIČIĆ, NORDITA, GERARD T. BARKEMA, Univ of Utrecht — Polycrystalline graphene has an inherent tendency to buckle, i.e. develop out-of-plane, three-dimensional structure, yielding a rich landscape of configurations. A force applied to stretch a piece of polycrystalline graphene influences the out-of-plane structure. In this talk, we show that if the graphene sheet is well-relaxed, as long as is not completely crystalline, this happens in non-linear fashion: occasionally, a tiny increase in stretching force induces a significant displacement, an avalanche-like event in which ridges and vertices are created and annihilated around the defects, which in turn can create vibrations in the surrounding medium [1]. We establish this effect in computer simulations: by continuously changing the strain, we follow the non-affine displacements of the atoms that turn out to exhibit a discontinuous evolution. Furthermore, the displacements exhibit a hysteretic behavior upon the change from low to high stress and back. Our results motivate further studies of dynamical elasticity of polycrystalline quasi-two-dimensional systems, and in particular the implications on their mechanical and thermal properties.

9:00AM W57.00006: Control of thermoelectric properties in MoSe$_2$ thin films by using He$^+$ irradiation  HYUK JIN KIM (Presenter), University of Seoul, VAN QUANG NGUYEN, THI HUONG NGUYEN, University of Ulsan, YANGJIN LEE, Yonsei University, SERA KIM, MAENG-JE SEONG, Chung-Ang University, KWANPYO KIM, Yonsei University, SUNGLAE CHO, University of Ulsan, YOUNG JUN CHANG, University of Seoul — Defect engineering have been widely used via chemical doping and ion irradiation techniques for modifying electrical and thermal properties. For increasing figure of merit, ZT=$\alpha^2 \sigma T/\kappa$ in thermoelectric materials, tuning of electrical and thermal characteristics plays an important role, where $\alpha$ is the Seebeck coefficient, $\sigma$ is the electrical conductivity, and $\kappa$ is the thermal conductivity. Here, we present our experimental control of both electrical conductivity and Seebeck coefficient of MoSe$_2$ thin films by irradiating high-energy He$^+$ ion beams. From different doses, we observed enhancement of electrical conductivity despite small decrease of Seebeck coefficient, which results in improvement of thermoelectric performance, i.e. power factor ($\alpha^2 \sigma$), for temperature range of 300K – 420K. To understand the irradiation-induced defects, we discuss complementary experimental analysis, such as X-ray diffraction, transmission electron microscopy and Raman spectroscopy.
9:12AM W57.00007: Shape - Composition - Defect Interplay in 2D Transition Metal Dichalcogenides* [Invited]  DAVID SROLOVITZ (Presenter), Materials Science and Engineering, City Univ of Hong Kong, JOEL M BERRY, Lawrence Livermore National Laboratory, SIMEON RISTIC, Materials Science and Engineering, University of Pennsylvania — We focus on the interplay of the 2D sheet shape via local variations in composition and/or variations in topological defect density through a combination of strain engineering and shape programming. This includes patterning composition and defect profiles via growth on non-flat substrates and patterning profiles via composition patterning. We implement these ideas theoretically and within phase field and finite element method computations. We then explore applications of these ideas to create a diverse set of composition, defect, and shape patterns and programming bilayer twist. We then exploit Janus structures to program bilayer twist and to actuate dynamic shape change.

9:48AM W57.00008: Study of the Shape Single Crystal Graphene Growth by Chemical Vapor Deposition on Copper Foil*  THARANGA NANAYAKKARA (Presenter), SAJITH WITHANAGE, U. KUSHAN WIJEWARDENA, ANNIKA KRIISA, RASANGA L SAMARaweera, RAMESH MANI, Georgia State University — The chemical vapor deposition (CVD) growth of single-crystal graphene on polycrystalline copper foils is a complex process affected by thermodynamics, kinetic, and growth parameters. Moreover, these factors lead to the diversity of island shapes of single-crystal graphene, including hexagons, flowers, squares, stars, dendrites, butterflies, hourglass, and lobes. Here, we present experimental observations of the different shapes of the micrometer-sized single-crystal graphene on copper foil obtained by the CVD technique. We applied Atomic Force Microscopy (AFM) and optical microscopy techniques to examine the diverse growth morphologies of the graphene shapes in different copper domains with various crystal orientations and the evolution of the nuclei shapes over the time.

10:00AM W57.00009: Coupling of Quantum Valley Hall Edge States between CVD Bilayer Graphene Layer Stacking Domain Walls

QICHENG ZHANG (Presenter), University of Pennsylvania, SHENG WANG, University of California at Berkeley, ZHAOLI GAO, SEBASTIAN HURTADO PARRA, PAUL MASIH DAS, JOEL M BERRY, ZACHARIAH M ADDISON, WILLIAM PARKIN, MARIJA DRNDIC, JAMES MAKATO KIKKAWA, EUGENE JOHN MELE, University of Pennsylvania, FENG WANG, University of California at Berkeley, ZHENTANG LUO, Hong Kong University of Science and Technology, ALAN T JOHNSON, University of Pennsylvania — Quantum valley Hall (QVH) edge states are topologically protected in the absence of valley mixing. In addition to the long mean free path from the protection, their inter-wall coupling enables novel properties such as current partition and valley filtering, when arranged in specific configurations. Stacking order alternation across a boundary in Bernal stacking bilayer graphene creates a layer stacking wall (LSW) where QVH edge states are bound. However, the uncontrollable strain of LSWs upon their creation places a big challenge to study their inter-wall coupling. Here we use different strain mechanisms during chemical vapor deposition (CVD) and subsequent transfer processes to create well-separated LSWs and close packing LSW bundles, and report inter-wall coupling of QVH edge states in the latter case through electron transport measurements.

10:12AM W57.00010: Preferential hole formation in WSe$_2$ by electron beam irradiation

DONGHAN SHIN (Presenter), ANDREW O'HARA, Department of Physics and Astronomy, Vanderbilt Univ, JUNHAO LIN, Department of Physics, Southern University of Science and Technology, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt Univ — In recent years, the trigonal-prismatic transition-metal dichalcogenides (TMDs) have been extensively studied due to a wide range of physical properties and applications. Scanning transmission electron microscopy (STEM) is a powerful tool for the investigation of material systems at the atomic level and the imaging of defect configurations. Moreover, STEM can be used to induce and modify defects. We will show that, using STEM, round multivacancy holes of various diameters and densities can be easily formed and stabilized in WSe$_2$, but not in other TMDs like WS$_2$. We report density-functional-theory (DFT) calculations to investigate the structure and stability of the observed defects in WSe$_2$. We construct a comprehensive model to explain how the observed stable defects form and grow in different TMDs by calculating formation energies, displacement thresholds, and electronic structures. The demonstrated control of high-density uniform multivacancies has potential for applications relating to molecular translocation.

*This work was supported by Department of Energy Grant DE-FG-02-09ER46554 and used resources of the National Energy Research Scientific Computing Center (NERSC), a U.S. Department of Energy Office of Science User Facility operated under Contract No. DE-AC02-05CH11231.
**10:24AM W57.00011: Structural Evolution of Many-Layer Epitaxial Graphene on 4H-SiC During Low-Energy Ion Implantation**  
*PAUL MICELI (Presenter), ALESSANDRO MAZZA, Univ of Missouri - Columbia, ANNA L MIETTINEN, Georgia Inst Tech, TIMOTHY R CHARLTON, THOMAS ZAC WARD, Oak Ridge National Laboratory, XIAOQING HE, ALEX A DAYKIN, SUCHISMITA GUHA, GUANG BIAN, Univ of Missouri - Columbia, EDWARD CONRAD, Georgia Inst Tech — The ability to modify graphene with defects and chemisorption is of interest for its potential to tailor graphene's physical properties, including induced p-orbital magnetism that could be useful for spintronics. As a pathway towards these goals, we have investigated the behavior of multilayer epitaxial graphene implanted by low-energy ions (360-2000 eV) of H, D and He. In situ x-ray scattering reveals that the ions expand the spacing between graphene layers, which depends on the type of ion, the fluence, as well as whether the range of the ion distribution resides at the buried interface or within the graphene. Neutron reflectivity measurements show that H remains chemisorbed in the graphene. We show that the apparently different behavior among the ions and their distributions can be understood by a single concept and by the appropriate scaling of the data.

**10:36AM W57.00012: Controlling Nanoscale Thermal Expansion of Monolayer Transition Metal Dichalcogenides by Alloy Engineering**  
*XUAN HU, ZAHRA HEMMAT, LEILY MAJIDI, Univ of Illinois - Chicago, JOHN CAVIN, Department of Physics, Washington University in St. Louis, ROHAN MISHRA, Washington University in St. Louis, SERDAR OGUT, AMIN SALEHI-KHOJIN, ROBERT KLIE (Presenter), Univ of Illinois - Chicago — Two dimensional materials, such as transition metal dichalcogenides (TMDs), graphene, boron nitride (BN) are seen as promising materials for future high power/high frequency electronics. However, the large difference in the thermal expansion coefficient (TEC) between many of these 2D materials could impose a serious challenge for the design of monolayer-materials-based nano-devices. To address this challenge, alloy engineering of TMDs is used to tailor their TECs. Here, in-situ heating experiments in a scanning transmission electron microscope are combined with electron energy-loss spectroscopy and first-principles modeling of monolayer Mo$_{1-x}$W$_x$S$_2$ with different alloying concentrations to determine the TEC. Significant changes in the TEC are seen as a function of chemical composition in Mo$_{1-x}$W$_x$S$_2$, with the smallest TEC being reported for a configuration with the highest entropy. This study provides key insights into understanding of nanoscale phenomena that control TEC values of 2D materials.

10:48AM W57.00013: Superelasticity and anomalous mechanical response of two-dimensional SiO2 under tensile and bending deformations*  RICARDO NUNES (Presenter), NESTOR REINA, HELIO CHACHAM, Physics, UFMG — Silica displays a rich phenomenology of mechanical response to deformations in its 3D form. It recrystallizes by dislocation creep and shows non-linear elastic behavior under large strains. In this study, we discuss results from first-principles calculations, that indicate that the recently synthetized 2D form of silica (2D-SiO2) displays as rich a response to mechanical deformations as its 3D counterpart. Under tensile uniaxial strain of up to 30% in both armchair (AC) and zigzag (ZZ) directions, 2D-SiO2 shows a non-linear elastic response, and the stress-strain curves do not display the plastic deformation platoo. At larger than 30% strains, the response is highly anisotropic: while in the AC direction the lattice breaks, in the ZZ direction it recovers the broken bonds and undergoes a process akin to a 15° rotation of the lattice. For even larger strains another effective rotation (by 30°) of the lattice takes place. The effective rotation is shown to occur also in the presence of vacancies in the SiO2 layer. Moreover, 2D-SiO2 shows an intrinsic non-linear response to bending deformations even for small deformations. We identify a metastable structure of a 2D-SiO2 layer that is connected with the anomalous bending response of 2D silica.

Session W58 DCMP: Exotic Features of Superconductors  Mile High Ballroom 3B

8:00AM W58.00001: Aharonov-Casher effect with vortices in an amorphous superconductor  ARNAB ROY (Presenter), AVIAD FRYDMAN, Bar Ilan Univ — A trajectory of a magnetic moment in an electric field results in the acquisition of a topological phase called the Aharonov-Casher (A-C) phase, analogous to the A-B phase acquired by a charged particle in a magnetic field. In condensed matter, experiments demonstrating the A-C effect are relatively few, the earliest being for superconducting vortices traversing a fabricated Josephson-junction array. In that regular geometry, a periodic response to induced charge was observed. In an irregular geometry, in analogy with universal conductance fluctuations, a complex quasi-periodic respinse may be expected.

An amorphous superconductor close to a superconductor-insulator transition (SIT) provides such a complex multiply connected region for superconducting vortices to interfere, as indicated by recent studies. In this study with amorphous indium oxide close to a disorder driven SIT, we introduce vortices in the system by applying a perpendicular magnetic field. The motion of these vortices around superconducting islands generates a complex interference pattern in the form of a spontaneous voltage that is tunable with both gate voltage and magnetic field. This effect is a demonstration of the quantum behavior of Josephson vortices which are present in the system close to the SIT.
8:12AM W58.00002: IDEAL DIAMAGNETIC RESPONSE OF A PRISTINE GRAPHENE-n-HEPTANE-PERMALLOY SYSTEM* SERAFIM TEKNOWIJOYO, Chapman Univ, YASUSHI KAWASHIMA, Tokai University, RAJENDRA DULAL, SARA CHAHID, ARMEN GULIAN (Presenter), Chapman Univ — We explored magnetic screening of milligauss fields in a system comprised of a single-layer graphene (on various substrates) wetted by n-heptane in the presence of a thin Fe-Ni foil parallel to the graphene layer. Our initial task was to confirm the results and find the origins of ideal diamagnetic screening reported previously in [Y. Kawashima, arXiv:cond-mat/1801.09376]. Indeed, we obtained ideal diamagnetic response. Also, in some cases “paramagnetic Meissner effect” has been obtained which in case of superconducting origin of observed facts can be associated with Wohlleben effect. At the same time, a crucial dependence of humidity and possibly other atmospheric factors on results has been observed which can be explained by chemisorption described in e.g. [T.L. Burnett et.al., arXiv:1204.3323]. These factors completely inhibit both normal and negative diamagnetism. To minimize this effect experiments were performed in Ar atmosphere. This may or may not be a footprint of superconductivity at room temperature. In both cases understanding the signal under different conditions may spread a light on a yet unknown phenomenon in condensed matter physics.

*This work was supported in part by the ONR Grants N00014-16-2269, N00014-17-1-2972, N00014-18-1-2636 and N00014-1901-2265.

8:24AM W58.00003: Odd Frequency Pairing in Superconducting Systems Using Renormalization Group Approach HENOC EJIGU (Presenter), University of California, Riverside — We investigate odd frequency pairing of electron-electron interaction on superconducting systems using the renormalization group method. Several experimental results induced by proximity effect have shown the feasibility of odd frequency pairing. Efforts have been made in the theoretical arena, since its first conception by Berezinskii, to understand this phenomenon, but many questions still remain unanswered. In our work, by considering a two-dimensional rotationally invariant Fermi surface and spinless system within the framework of renormalization group, we present a brief elucidation on the microscopic mechanism for odd frequency pairing, and show a self-contained derivation of the exact flow equation for the vertex functions and self energy that depend on the gradual evolution of the microscopic model action to the final effective action as a function of a continuously decreasing energy scale.
Local structure of the cuprate superconductors

ZACHARY ANDERSON (Presenter), DAMJAN PELC, University of Minnesota, MATTHEW KROGSTAD, Argonne National Lab, NIKOLAOS BINISKOS, BIQIONG YU, LIAM THOMPSON, JACK ZWETTLER, RICHARD SPIEKER, NINA G BIELINSKI, University of Minnesota, STEPHAN ROSENKRANZ, RAYMOND OSBORN, Argonne National Lab, MARTIN GREVEN, University of Minnesota — The cuprate superconductors have long been known to be electronically inhomogeneous at the nanoscale, although the nature and role of the inhomogeneity remain debated. Recent studies of superconducting fluctuations in cuprates have uncovered a universal inhomogeneity-driven regime in multiple compounds [1], and similar findings for other perovskite-derived superconductors point to universal underlying structural inhomogeneity [2]. Here we present complementary X-ray and neutron diffuse scattering studies of several cuprates, with the real-space local structure determined by the 3D ΔPDF method [3]. The experiments reveal intricate short-range correlated structural distortions, even in HgBa$_2$CuO$_{4+δ}$, which features a simple tetragonal average structure. We discuss the doping dependence of the local structure and correlations with the superconducting $T_C$.

*This work was funded by the DOE through the University of Minnesota Center for Quantum Materials under DE-SC-0016371.

Plasticity and stress engineering of cuprate superconductors

DAMJAN PELC (Presenter), ZACHARY ANDERSON, LIAM THOMPSON, School of Physics and Astronomy, University of Minnesota, MATTHEW KROGSTAD, Argonne National Laboratory, NIKOLAOS BINISKOS, BIQIONG YU, JACK ZWETTLER, RICHARD SPIEKER, NINA G BIELINSKI, School of Physics and Astronomy, University of Minnesota, STEPHAN ROSENKRANZ, RAYMOND OSBORN, Argonne National Laboratory, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota — Ceramic materials, including the cuprate high-temperature superconductors, are generally thought to be brittle at low temperatures due to their rigid ionic and covalent bonding. We present here the surprising discovery of room-temperature plasticity in the cuprates, observed with compressive stress perpendicular to the copper-oxygen planes. We further show that the electronic properties, in particular superconductivity, can be manipulated via plastic deformation. We discuss the origin of these effects and correlate them with structural changes as investigated by neutron and X-ray diffuse scattering measurements.

*This work was funded by the DOE through the University of Minnesota Center for Quantum Materials under DE-SC-0016371.
9:00AM W58.00006: Thermodynamic Evidence for a Multi-component superconducting order parameter in Sr$_2$RuO$_4$*

SAYAK GHOSH (Presenter), Cornell University, ARKADY SHEKHTER, National High Magnetic Field Laboratory, FABIAN JERZEMBECK, NAOKI KIKUGAWA, DMITRY SOKOLOV, ANDREW MACKENZIE, CLIFFORD W. HICKS, Max Planck Institute for Chemical Physics of Solids, BRAD J RAMSHAW, Cornell University — The unconventional superconductivity of Sr$_2$RuO$_4$ has remained a mystery for over 25 years, even though its normal metallic state is quite well-understood. Reaching a consensus on the bulk order parameter symmetry has been difficult primarily due to the contradictions that exist between several major experimental findings. We performed resonant ultrasound spectroscopy (RUS) measurements on Sr$_2$RuO$_4$, to measure its entire symmetry-resolved elastic tensor through T$_C$ ($\sim$1.43 K). Since different superconducting order parameters couple differently to shear and compressional sound modes, measurement of all elastic moduli places strong constraints on the order parameter symmetry, independent of microscopics. We observe a thermodynamic discontinuity in one of the shear moduli ($c_{66}$) at T$_C$, which requires a two-component superconducting order parameter ($E$ representation of $D_{4h}$). We discuss leading $E$-symmetry order parameters, and suggest that it may be necessary to go beyond the conventional "singlet/triplet" paradigm to finally resolve the mystery that is Sr$_2$RuO$_4$. We also measure an anomalous attenuation peak in compressional sound below T$_C$, possibly arising due to sound absorption into order parameter collective modes.

*Supported by the National Science Foundation under Grant No. DMR-1752784.

9:12AM W58.00007: Manipulating superconductivity in Sr$_2$RuO$_4$ thin films through epitaxial strain

HARI NAIR (Presenter), NATHANIEL SCHREIBER, JACOB RUF, LUDI MIAO, YAWEN FANG, YONGHUN LEE, Cornell University, MARIO BRÜTZAM, CHRISTO GUGUSCHEV, Leibniz-Institut für Kristallzüchtung, BRAD J RAMSHAW, KYLE M SHEN, DARRELL SCHLOM, Cornell University — Pushing the van Hove singularity in the $\gamma$ band of Sr$_2$RuO$_4$ towards the Fermi level can potentially raise the transition temperature, $T_c$, of this unconventional superconductor. To test this concept, we explore the effect of biaxial strains from –0.9% to +1.0% imposed by commensurate epitaxy on (NdAlO$_3$)$_{0.39}$–(SrAl$_{1/2}$Ta$_{1/2}$O$_3$)$_{0.61}$ (NSAT), NdGaO$_3$, (LaAlO$_3$)$_{0.29}$–(SrAl$_{1/2}$Ta$_{1/2}$O$_3$)$_{0.71}$ (LSAT), LaGaO$_3$, and SrTiO$_3$ substrates on the superconducting $T_c$ and upper critical field $H_{c2}$ of Sr$_2$RuO$_4$ thin films. These biaxial strain studies are distinct from and compliment the existing uniaxial strain studies on Sr$_2$RuO$_4$ single crystals. Mean free paths up to 144 nm are observed in Shubnikov-de Haas oscillation measurements on these thin films and $T_c$s range from 1 K to 1.8 K for films with similar residual resistivities. The measured mean free paths in combination with the coherence lengths, determined from upper critical field measurements, established that all films are superconducting in the clean limit.
9:24AM W58.00008: Spectroscopic study of doped strontium ruthenates compositions

RAJENDRA DULAL (Presenter), VAHAN NIKOGHOSSYAN, Chapman Univ, BORIS GORSHUNOV, ELENA ZHUKOVA, Moscow Physical-Technical University, YURI ALESCHENKO, ANDREY MURATOV, Moscow P.N. Lebedev Physical Institute, SERAFIM TEKNOWJJOYO, SARA CHAHID, ARMEN GULIAN, Chapman Univ — Extraordinary properties of Sr$_2$RuO$_4$ have attracted much attention since the discovery of superconductivity in this material in [Y. Maeno et.al., Nature 372, 532 (1994)]. This material are isostructural to the high T$_c$ cuprate superconductors which motivated extensive search of physically and chemically modified ruthenates [Gulian, et.al., Quantum Stud. Math. Found., 5, 161 (2018)]. One of the compositions Sr$_2$Ru$_{1-x}$Re$_x$O$_3$Se, revealed feature, which most naturally fitted into the pattern of presence of a small fraction of superconducting phase in a multiphase sample with the dominant ferromagnetic phase, almost masking out this superconductivity at ~30 K. We present compositional, morphological, structural, magnetotransport, heat capacity, magnetic susceptibility, Raman and terahertz spectroscopy data to facilitate theoretical analysis of metamagnetism vs. superconductivity in this material.

*This work was supported in part by the ONR Grants N00014-16-2269, N00014-17-1-2972, N00014-18-1-2636, and N00014-1901-2265.

9:36AM W58.00009: μSR study on the antiperovskite oxide supercondctor Sr$_{3-x}$SnO

ATSUTOSHI IKEDA (Presenter), Department of Physics, Kyoto University, ZURAB GUGUCHIA, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, SHUN KOIBUCHI, Department of Physics, Kyoto University, MOHAMED OUDAH, Stewart Blusson Quantum Matter Institute, University of British Columbia, SHINGO YONEZAWA, Department of Physics, Kyoto University, HUBERTUS LUETKENS, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, YOSHITERU MAENO, Department of Physics, Kyoto University — Antiperovskite (inverse perovskite) oxides are the materials crystallizing in the same structure as the ordinary perovskite oxides but with the inverted positions of the metal element and oxygen. Some of these materials are theoretically suggested to be topological crystalline insulators based on the first-principles calculations [1, 2]. We discovered the first superconductivity among this group of oxides in Sr$_{3-x}$SnO [3]. Reflecting the topology of the electronic band structure in the normal state, a topological superconductivity is theoretically proposed in this compound [3, 4]. In order to investigate the nature of the superconducting state, we performed the muon spin rotation (μSR) experiment. Under small magnetic fields, we successfully observed increase of the relaxation rate of μ$^+$ below the transition temperature and confirmed the bulk superconductivity. The ratio between the relaxation rate and transition temperature $\sigma/T_c$ is much smaller than those of the conventional superconductors and close to the values known for unconventional ones.

Friday, March 6, 2020 8:00 AM - 10:48 AM
**8:00AM W59.00001: Topological Surface States of Cadmium Arsenide Thin Films**  
LUCA GALLETTI (Presenter), DAVID KEALHOFER, TIMO SCHUMANN, MANIK GOYAL, SALVA SALMANI REZAIE, SUSANNE STEMMER, University of California, Santa Barbara — Thin films of the topological semimetal cadmium arsenide (Cd$_3$As$_2$) can host different types of topological surface states, depending on their crystallographic orientation$^1$. Here we elucidate the nature of these surface states by comparing films grown in (112) and (001) orientations, respectively. For (112) thin films Weyl orbits$^2$, involving Fermi arcs on opposite surfaces, have been predicted, which should exhibit a thickness-dependent phase in quantum oscillations. We compare quantum transport in films of varying thickness at apparently identical gate-tuned carrier concentrations and find no clear dependence of the relative phase of the quantum oscillations on the sample thickness$^3$. Small variations in carrier densities, difficult to detect in low-field Hall measurements, lead to shifts in quantum oscillations that are commensurate with previously reported phase shifts. By contrast, measurements of the quantum Hall effect in (001)-oriented thin films show evidence of topological insulator-like states at bottom and top interfaces. Quantum oscillation measurements in different geometries are used to determine interactions between the surfaces.

**8:12AM W59.00002: Large Thermal Hall effect observed in Bi$_{89}$Sb$_{11}$ topological insulator and Weyl Semimetal**  
DUNG VU (Presenter), Department of Mechanical Engineering, Ohio State Univ - Columbus, NANDINI TRIVEDI, Department of Physics, Ohio State Univ - Columbus, JOSEPH P C HEREMANS, Department of Mechanical Engineering, Ohio State Univ - Columbus — Bi$_{89}$Sb$_{11}$ alloy, a topological insulator, becomes a Weyl semimetal in a magnetic field above a critical value $H_C$ applied along the trigonal direction (001). We measured a Bi$_{89}$Sb$_{11}$ single crystal sample along the trigonal axis in a longitudinal magnetic field $H>H_C$. We observed large field-induced increases in the longitudinal electronic thermal conductivity along (001), which is mostly linear in field and maximal for $35K<T<200K$, attributed to the thermal chiral anomaly [1]. We report a large thermal Hall effect in the sample for the same temperature range: magnetic field applied along (001), heat flux along (010); transverse temperature gradient measured along (100), longitudinal gradient along (010). peaks at 0.07 in the temperature range $160K<T<200K$. We will present the field dependence of the sample's transport properties including thermopower, Nernst thermopower, Hall and electrical resistivity, and thermal conductivity, and discuss possible connections of this large thermal Hall effect to conveyor-belt entropy transport mediated by topologically protected Fermi arc surface states in Weyl semimetals [2].

*Funding: Center for Emergent Materials, NSF-DMR-1420451.
8:24AM W59.00003: Spin Zero Effect in Dirac Semimetal ZrTe$_5$*  JINGYUE WANG (Presenter), JINGJING NIU, BAOMING YAN, XINQI LI, RAN BI, Peking Univ, YUAN YAO, Institute of Physics CAS, DAPENG YU, South University of Science and Technology of China, XIAOSONG WU, Peking Univ — One of the characteristics of topological materials is their non-trivial Berry phase. Experimental determination of this phase largely relies on a phase analysis of quantum oscillations. We study the angular dependence of the oscillations in a Dirac material ZrTe$_5$ and observe a striking spin zero effect, i.e., vanishing oscillations accompanied with a phase inversion. This indicates that the Berry phase in ZrTe$_5$ remains non-trivial for arbitrary field direction, in contrast with previous reports. The Zeeman splitting is found to be proportional to the magnetic field based on the condition for the spin zero effect in a Dirac band. Moreover, it is suggested that the Dirac band in ZrTe$_5$ is likely transformed into a line-node other than Weyl points for the field directions at which the spin zero occurs. The results underline a largely overlooked spin factor when determining the Berry phase from quantum oscillations.

8:36AM W59.00004: Electric modulation of the Fermi arc spin polarization of a Dirac semimetal nanowire*  BENCHUAN LIN (Presenter), SHUO WANG, Southern University of Science and Technology, ANQI WANG, Peking Univ, KE XIA, DAPENG YU, Southern University of Science and Technology, ZHI-MIN LIAO, Peking Univ — The spin polarization of the exotic topological surface states of Dirac/Weyl semimetals, namely Fermi arcs, were predicted to exist but never accessed in a simple transport structure. Here we report the direct access of the Fermi arc spin polarization through the electromagnetic transport experiment. The net spin polarization was manifested as a voltage of the ferromagnetic contact, which was induced by applying a charge current via spin momentum locking property of the Fermi arc in the Cd$_3$As$_2$ nanowire. Moreover, a gate voltage controlled topological phase transition of the surface states is demonstrated to be able to switch on/off the spin signals. Thus a topological field-effect transistor is proposed.

Large in-plane Hall/Nernst effect generated by Berry curvature in Weyl semimetallic phase of indium doped $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  

CHENGLONG ZHANG, TIAN LIANG (Presenter), YOSHINORI TOKURA, RIKEN — The Hall/Nernst effects have led to interesting phenomena in modern physics such as Berry curvature. The conventional Hall/Nernst signals appear only when the magnetic field is applied perpendicular to the sample because the conventional Lorentz force vanishes when the magnetic field is applied in the plane.

Interestingly, in the Weyl semimetallic phase of indium doped $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$, large in-plane Hall/Nernst signals are observed. This suggests the existence of large Berry curvature coming from the Weyl nodes. When no magnetic field is applied, the time reversal symmetry requires the Weyl nodes to distribute such that Hall/Nernst signals vanish completely. As the magnetic field is turned on, the Weyl nodes move in the momentum space and generate the finite value of Hall/Nernst signals, even when the magnetic field is applied in the plane. The implication of the experimental data will be discussed.

Magnetic electron lensing in the 3D Dirac semi-metal $\text{Cd}_3\text{As}_2^*$

XIANGWEI HUANG, CARSTEN PUTZKE, CHUNYU GUO, JONAS DIAZ, Ecole Polytechnique Federale de Lausanne, MARKUS KOENIG, HORST BORRMANN, Max-Planck-Institute for Chemical Physics of Solids, NITYAN NAIR, JAMES ANALYTIS, University of California, Berkeley, PHILIP MOLL (Presenter), Ecole Polytechnique Federale de Lausanne — While electrons moving perpendicular to a magnetic field are confined to cyclotron orbits, they can move freely parallel to the field. This simple fact leads to complex current flow in clean, low carrier density semi-metals, such as current jets along the magnetic field when currents pass through point-like constrictions. Occurring accidentally at imperfect current injection contacts, “current jetting” plagues the research of longitudinal magnetoresistance. We demonstrate the controlled generation of tightly focused electron beams in a new class of microdevices machined from crystals of the Dirac semi-metal $\text{Cd}_3\text{As}_2$. The current beams can be guided by tilting an in-plane magnetic field and their range tuned by the field strength. Finite element simulations quantitatively capture the voltage induced at faraway contacts when the beams are steered towards them, supporting the picture of controlled electron jets. These experiments demonstrate the first direct control over the highly non-local signal propagation unique to 3D semi-metals in the current jetting regime.

Higher harmonics of quantum oscillations uncover Dirac Fermions in LaRhIn$_5$

ARIS ALEXANDRADINATA (Presenter), University of Illinois at Urbana-Champaign, CHUNYU GUO, CARSTEN PUTZKE, Institute of Material Science and Engineering, Ecole Polytechnique Federale de Lausanne, FENGREN FAN, Max Planck Institute for Chemical Physics of Solids, SHENGNAN ZHANG, QUANSHENG WU, OLEG V. YAZYEV, Institute of Material Science and Engineering, Ecole Polytechnique Federale de Lausanne, KENT SHIRER, MAJA BACHMANN, Max Planck Institute for Chemical Physics of Solids, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, CLAUDIA FELSER, YAN SUN, Max Planck Institute for Chemical Physics of Solids, PHILIP MOLL, Institute of Material Science and Engineering, Ecole Polytechnique Federale de Lausanne — Quantum oscillations are commonly used to experimentally diagnose the band topology of a semimetal. When the cyclotron orbit encloses a topological defect, it is often presumed that the nontrivial Berry phase results in a $\pi$-phase shift of the fundamental harmonic. However, this presumption neglects how spin-orbit coupling renders the Berry phase a continuously varying quantity, and ignores the Zeeman interaction with the spin-orbit-induced magnetic moment. Here, we overcome these shortcomings and demonstrate how to rigorously identify three-dimensional Dirac fermions from the higher harmonics of quantum oscillations. Applying this method to the intermetallic LaRhIn$_5$, we unambiguously identify the nontrivial Berry phase of a topological Fermi pocket with a small frequency $\approx 7T$, despite the presence of large, trivial Fermi pockets which dominate transport by orders of magnitude. Our analysis identifies LaRhIn$_5$ as a 3D Dirac-point metal, revising a previous proposal of LaRhIn$_5$ as a nodal-line semimetal by Mikitik et. al. [Phys. Rev. Lett. 93, 106403 (2004)]. The electronic similarity of LaRhIn$_5$ to the prototypical heavy-fermion superconductors Ce(Co,Rh,Ir)In$_5$ further suggests them as prime candidates for strongly-correlated Dirac systems.

α-Sn Magnetotransport Devices

OWEN VAIL (Presenter), US Army Rsch Lab - Adelphi, YU HAO CHANG, SEAN HARRINGTON, Materials Department, University of California, Santa Barbara, PATRICK AUBREY FOLKES, PATRICK TAYLOR, BARBARA NICHOLS, GEORGE J DE COSTER, US Army Rsch Lab - Adelphi, CHRIS J PALMSTROM, Materials Department, University of California, Santa Barbara — α-Sn, the diamond-cubic phase of tin, is of significant scientific interest due to its topological band structure and single-element nature. Consistent high-quality growth on insulating CdTe opens the doors to unconventional electronics using a widely available material. After verifying epitaxial growth of our films, we perform transport measurements to characterize the electronic carriers in the material. We identify two-channel transport and attribute the n-type transport to a semimetallic channel that tentatively suggests Dirac behavior, while the p-type component corresponds to growth impurities resulting from the CdTe substrate. We apply a field effect gate voltage in order to map out the charge neutrality point and modulate the channel between majority n-type and majority p-type carriers. Careful preparation of the CdTe surface before growth is considered crucial to attain a low dopant density and accessible topological states on an insulating substrate. This work readily lends itself to the development of topologically enabled devices for fieldable applications such as low power electronics in order to achieve a high level of computation at the edge.

*Office of the Under Secretary of Defense for Research and Engineering: Laboratory University Collaboration Initiative
Cadmium arsenide ($\text{Cd}_3\text{As}_2$) is a three-dimensional Dirac semimetal that also hosts exotic surface states connecting the projections of the Dirac nodes. Probing the electronic properties of thin films of $\text{Cd}_3\text{As}_2$ requires tuning of the Fermi level close to the Dirac nodes. Conventional gate dielectrics, such as $\text{Al}_2\text{O}_3$, must be deposited at low temperatures that do not exceed the stability limit of $\text{Cd}_3\text{As}_2$, which introduces a high density of (near) interface trap states that limit the modulation of carrier densities that can be achieved [1]. To address this problem, here we report on the use of hexagonal boron nitride (hBN) towards high-quality $\text{Cd}_3\text{As}_2$ devices. In addition to protecting the $\text{Cd}_3\text{As}_2$ channel from photoresist, the high breakdown voltage of hBN also allows us to tune the carrier density up to a larger range allowing us to explore new quantum states.

MoTe$_2^*$ [Invited] JOHN SCHNEELOCH (Presenter), YU TAO, Univ of Virginia, CHUNRUO DUAN, Physics, Rice University, JUNJIE YANG, Physics, New Jersey Institute of Technology, SACHITH DISSANAYAKE, Physics, Duke University, FENG YE, ADAM ACZEL, JAIME A. FERNANDEZ-BACA, Neutron Scattering Division, Oak Ridge National Laboratory, GUANGYONG XU, Neutron-Condensed Matter Science Group, National Institute of Standards and Technology, MASAKI MATSUDA, Neutron Scattering Division, Oak Ridge National Laboratory, DESPINA LOUCA, Univ of Virginia — Neutron scattering has a proud history of elucidating certain kinds of structural phase transitions, but sliding layer transitions such as those in MoTe$_2$ have been relatively neglected. On cooling, the monoclinic 1T'-MoTe$_2$ transitions into the orthorhombic T$_d$-MoTe$_2$, which has received much attention since it was reported to be a Weyl semimetal and to exhibit extreme magnetoresistance. MoTe$_2$ structures can, to a good approximation, be built from sequences of two symmetry-equivalent stacking operations, with transitions occurring via layer sliding between different stackings. Thus, a wide variety of nearly-degenerate structures are conceivable, and our elastic neutron scattering studies show that changes in stacking with temperature in MoTe$_2$ are, indeed, complex. Both order-to-order and order-to-disorder transitions exist along the T$_d$-1T' thermal hysteresis loop. A pseudo-orthorhombic T$_d^*$ phase with a four-layer unit cell appears only on warming. T$_d^*$ is centrosymmetric, and the order-to-order transitions between T$_d$ and T$_d^*$ may make a more convenient topological switch than the disordered transitions to and from 1T'. The kink in resistivity vs. temperature on warming is primarily due to the onset of T$_d^*$, and the residual hysteresis in the resistivity toward the temperature extremes is likely related to changes in the presence of 1T'- or T$_d$-phase twin domain boundaries. Changes in stacking have a subtle effect on low-energy shear phonon modes, as seen from inelastic neutron scattering. A multitude of ways of influencing these transitions are known; we will discuss how both W-substitution and pressure drive the transition toward a simpler phase coexistence behavior, though with opposite effects on transition temperature or the 1T' $\beta$ angle. We will discuss changes in band structure with pressure and strain. Finally, we will discuss open questions concerning the cause of the transition.

10:36AM W59.00012: Quantitative analysis of chiral anomaly induced negative magnetoresistance in nodal-line semimetal SrAs$_3$
MINHAO ZHAO (Presenter), FAXIAN XIU, Fudan Univ — Recently, three-dimensional topological nodal-line semimetals has been reported frequently as a new class of quantum materials. In nodal-line semimetals, the conduction and the valence bands contact with each other. The band crossing points around the Fermi level form a closed loop. Chiral anomaly is one of the property of nodal-line semimetal. The phenomenon of chiral anomaly in transport measurement is negative magnetoresistance (NMR) when current is parallel with magnetic field. The electronic conductivity induced by chiral anomaly is:
$$\sigma_{zz}=\frac{e^2}{4\pi^2 \hbar c} \nu c \left((eB)^2 \nu^2/\mu^2 \tau\right)$$
[1]. The $\nu$ is fermi velocity; $\mu$ is chemistry potential and $\tau$ is scattering time. The $\tau$ depends on the magnetic field and temperature. When the magnetic is higher than the quantum limit, the $\tau$, the NMR will saturate.

Among the predicted nodal-line semimetals[2], SrAs$_3$ has high mobility and low fermi energy, which makes this material an ideal platform to research the behavior of NMR with magnetic field and temperature. Under 31.5 T, we observed the process from NMR appeared to saturated. And analyzed the behavior of NMR quantitatively. Combined with the result from PPMS, we also got the temperature dependence of $\tau$.

W59.00013: Observation of a Thermoelectric Hall Plateau in the Extreme Quantum Limit*
WENJIE ZHANG (Presenter), Peking Univ, PEIPEI WANG, Southern University of Science and Technology of China, BRIAN SKINNER, Ohio State University, RAN BI, Peking Univ, VLADYSLAV KOZII, Massachusetts Institute of Technology, CHANG-WOO CHO, Southern University of Science and Technology of China, RUIDAN ZHONG, JOHN SCHNEELOCH, Brookhaven National Laboratory, DAPENG YU, Southern University of Science and Technology of China, GENDA GU, Brookhaven National Laboratory, LIANG FU, Massachusetts Institute of Technology, XIAOSONG WU, Peking Univ, LIYUAN ZHANG, Southern University of Science and Technology of China — The thermoelectric Hall effect is the generation of a transverse heat current upon applying an electric field in the presence of a magnetic field. Here we demonstrate that the thermoelectric Hall conductivity $\alpha_{xy}$ in the three-dimensional Dirac semimetal ZrTe$_5$ acquires a robust plateau in the extreme quantum limit of magnetic field. The plateau value is independent of the field strength, disorder strength, carrier concentration, or carrier sign. We explain this plateau theoretically and show that it is a unique signature of three-dimensional Dirac or Weyl electrons in the extreme quantum limit. We further find that other thermoelectric coefficients, such as the thermopower and Nernst coefficient, are greatly enhanced over their zero-field values even at relatively low fields.

Friday, March 6, 2020 8:00 AM - 10:36 AM
8:00AM W60.00001: Planar Hall effect in thin films of the 3D Dirac semimetal Cd$_3$As$_2$

MANIK GOYAL (Presenter), TIMO SCHUMANN, DAVID KEALHOFER, SUSANNE STEMMER, University of California, Santa Barbara — Cd$_3$As$_2$ is a 3D Dirac semimetal with doubly degenerate band crossings at isolated points in the bulk Brillouin zone. It can also host gapless surface states. In Dirac and Weyl semimetals, a giant planar Hall effect (PHE) has been predicted to be associated with the chiral anomaly. In this talk, we will discuss our measurements of the PHE in (001) and (112) oriented epitaxial thin films of Cd$_3$As$_2$ having a wide range of film thicknesses. We show that the PHE depends sensitively on the Fermi level. Studies of films of different thickness allow us to distinguish the contributions of bulk and surface states. We will discuss the different mechanisms that give rise to the PHE in these films.

8:12AM W60.00002: NMR Investigation of Field-Induced Energy Gap in Topological Node-Line Semimetal ZrGeSe

GUOQING WU (Presenter), SHENGTANG WAN, RONGXING CAO, JIAN HU, XIANGHUA ZENG, YAFANG XU, JINBO ZHANG, Yangzhou Univ, LIN WANG, Beijing High Pressure Science Center, QIULIANG WANG, Chinese Academy of Science, LEI GUO, Southeast University, RENKUI ZHENG, Chinese Academy of Science, BING WU, fayetteville state university — The discovery of topological semimetals provides opportunities to explore the exotic properties of relativistic fermions in condensed matter. Among those materials, the nodal-line semimetal represents a new type of topological quantum state which displays Dirac cones along a one-dimensional line or a closed circle protected by combined symmetry of inversion and time-reversal, in contrast with the Dirac or Weyl semimetals with discrete Dirac or Weyl cones. Here we report NMR investigation of field-induced energy gap in topological nodal-line semimetals of ZrGeSe single crystals, with high magnetic field up to 16 T and high hydrostatic pressure up to 50 GPa. We found that the opening of the energy gap is driven by the magnetic field-induced anti-ferromagnetic (AFM) order, and the gap opening is highly restricted under high pressure.

8:24AM W60.00003: Violation of Ohm`s law in a Weyl metal

DONGWOO SHIN (Presenter), JEEHOON KIM, Pohang Univ of Sci & Tech — Weyl metal is one of the topological non-trivial materials holding Weyl fermions which are massless and have a chirality. The Weyl metal has been described in terms of axion electromagnetism rather than in Maxwell electromagnetism, and has peculiar properties such as chiral anomaly, the presence of magnetic monopole in the reciprocal lattice space and negative longitudinal magneto resistance. In this presentation, by transportation experiment besides negative longitudinal magneto resistance, we observed ohm’s law was broken in the Weyl metal and carried experimental and theoretical analysis of the violation of ohm`s law [1].

8:36AM W60.00004: Interplay of Dirac Nodes and Volkov-Pankratov Surface States in Compressively Strained HgTe  
DAVID MAHLER (Presenter), JULIAN-BENEDIKT MAYER, PHILIPP LEUBNER, LUKAS LUNCZER, DOMENICO DI SANTE, GIORGIO SANGIOVANNI, RONNY THOMALE, EWELINA M HANKIEWICZ, HARTMUT BUHMANN, CHARLES GOULD, LAURENS W MOLENKAMP, University of Wurzburg — With the advent of topological materials, the Weyl fermion, a massless particle once proposed to describe neutrinos, can now be investigated in condensed matter systems as Weyl semi-metals, and their close cousins Dirac semi-metals. The HgTe material system, as a prototypical topological insulator for transport studies, is ideally suited, as the tunability of the details of its band structure through strain engineering, and its Fermi level by gating provide unparalleled control for the investigation of Weyl/Dirac semi-metals [1].
We can clearly disentangle surface and bulk contributions by using gate voltage to tune the Fermi energy precisely to the Weyl/Dirac nodes and thus convincingly identify the chiral anomaly. We find no evidence for Fermi-arcs, but topological surface states, that are responsible for the transport in the electron regime. These states are created by the same band inversion leading to the formation of the Dirac/Weyl nodes, and therefore must always be present. Additionally, in the hole regime surface states induced by the electric field, so called massive Volkov-Pankratov states [2, 3], are observed.

8:48AM W60.00005: Exploring broken time-reversal symmetry in Cd$_3$As$_2$/(Ga,Mn)Sb Dirac semimetal/ferromagnetic semiconductor heterostructures*  
ARPITA MITRA (Presenter), RUN XIAO, NITIN SAMARTH, Pennsylvania State University — Cd$_3$As$_2$ has attracted attention as a canonical Dirac semimetal. In this study, we aim to break time reversal symmetry (TRS) in Cd$_3$As$_2$ by interfacing with a ferromagnetic semiconductor, (Ga,Mn)Sb. We have grown epitaxial Cd$_3$As$_2$/(Ga,Mn)Sb bilayers using molecular beam epitaxy on GaSb (111) buffer layers deposited on GaAs (111)B substrates. High-resolution x-ray diffraction shows good crystalline quality of GaSb and Cd$_3$As$_2$ layers with full width half maximum of rocking curves, 0.04° and 0.11°, respectively. Atomic force microscopy shows smooth surfaces of (Ga,Mn)Sb and Cd$_3$As$_2$ with root mean square roughness ~ 1.3 nm. SQUID magnetometry reveals that (Ga,Mn)Sb films are ferromagnetic, while low temperature magnetoresistance data show that they are highly resistive for the Mn composition used. We report the temperature dependent magneto-transport properties in these Cd$_3$As$_2$/(Ga,Mn)Sb heterostructures and investigate the magnetic proximity effect by varying the thickness of the Cd$_3$As$_2$ layer. We are also exploring interfacing Cd$_3$As$_2$ with other ferromagnetic semiconductors in order to find an efficient material for breaking TRS in Cd$_3$As$_2$.

9:00AM W60.00006: Negative longitudinal magnetoresistance, anisotropic magnetoresistance, and planar Hall effect in epitaxial thin films of elemental Bismuth*

EUGENE ARK (Presenter), DESHUN HONG, TERENCE BRETZ-SULLIVAN, CHANGJIANG LIU, SHULEI ZHANG, Materials Science Division, Argonne National Laboratory, LEENA AGGARWAL, VIDYA MADHAVAN, Physics, University of Illinois at Urbana-Champaign, ANAND BHATTACHARYA, Materials Science Division, Argonne National Laboratory — Observations of negative longitudinal magnetoresistance (NLMR), anisotropic magnetoresistance (AMR), and the planar Hall effect (PHE) under an in-plane magnetic field are often used as indications of non-trivial topology in non-magnetic material systems. We show NLMR, AMR, and PHE in crystalline epitaxial thin films (< 50 nm) of elemental Bismuth (111) grown by molecular beam epitaxy on intrinsic GaAs (111) substrates. Films were characterized in-situ using scanning tunneling microscopy to confirm topography and density of states. Furthermore, the thickness and temperature dependence of these phenomena are investigated, demonstrating a high degree of tunability. We posit that these observations may be due to the Rashba effect in the surface states of Bi (111), rather than any non-trivial topological effects.

9:12AM W60.00007: Quantum Hall effect due to surface states in (001)-plane cadmium arsenide thin films

DAVID KEALHOFER (Presenter), Physics, UC Santa Barbara, LUCA GALLETTI, TIMO SCHUMANN, Materials, UC Santa Barbara, ALEXEY SUSLOV, National High Magnetic Field Laboratory, SUSANNE STEMMER, Materials, UC Santa Barbara — We report transport studies of gated Hall bar structures fabricated from (001)-oriented epitaxial thin films of cadmium arsenide, a three-dimensional Dirac semimetal, in magnetic fields up to 45 T. This orientation does not host Fermi arc-type surface states because the Dirac nodes project onto the same point in the surface Brillouin zone. Recent developments in the growth of these layers have resulted in films with quantum mobilities exceeding 4,000 cm²/Vs. We explain the quantum Hall effect, which prominently features plateaus at even and odd filling factors across a range of carrier density, in terms of a surface state different from the Fermi arc-type states thought to exist on other surfaces, underlining differences between these measurements and those in the more widely studied (112)-plane films.
9:24AM W60.00008: Anomalous Hall Effect induced by extremely low field in ultra pure ZrTe$_5$  
JOSHUA MUTC (Presenter), PAUL MALINOWSKI, QIANNI JIANG, ZHAOYU LIU, University of Washington,  
DI XIAO, Physics, Carnegie Mellon University, JIUN-HAW CHU, University of Washington —  
ZrTe$_5$ has gathered interest in recent years due to its non-trivial topology. In monolayer form, it is  
predicted to be a quantum spin hall insulator. In bulk, it is predicted to reside extremely close to  
a phase transition between a strong and weak topological insulator, with a 3D Dirac semimetal  
state at the boundary between these two phases. We report detailed measurements of the  
anomalous hall effect (AHE) in ultra-pure, high mobility bulk ZrTe$_5$. We find the hall resistance  
saturates at an extremely low magnetic field (B $\ll$ 1T), and remains at the saturation value for  
fields up to 32T. This AHE is present despite no evidence of magnetism in ZrTe$_5$. We investigate  
the AHE effect in ZrTe5 as a function of temperature, magnetic field angle, strain, and doping,  
and discuss the origins of this effect.

9:36AM W60.00009: Epitaxial Growth and in-situ magneto-transport of Na$_3$Bi – a 3D Dirac semimetal  
DANA PEIRCE (Presenter), IGOR PINCHUK, RYAN MUZZIO, SIMRANJEET SINGH, JYOTI KATOCH, Carnegie Mellon Univ —  
3D topological Dirac semimetals (TDS) such as Na$_3$Bi and Cd$_3$As$_2$ possess Dirac nodes located outside the time-reversal invariant momentum points in the Brillouin zone. Recent theoretical and experimental work shows that quantum confinement of 3D TDS can open a tunable bulk bandgap and give rise to thickness-dependent alternate transitions between trivial and quantum spin Hall insulator states. In this talk, we will present our results on ultra-thin growth of Na$_3$Bi films on insulating substrates using molecular beam epitaxy (MBE). We will also discuss our efforts towards angle-dependent high-field in-situ magnetotransport measurements on back-gated thin films of Na$_3$Bi.
9:48AM W60.00010: Evolution of the electronic structure of the Weyl semimetal TaAs under pressure  ZUZANA MEDVECKA (Presenter), MARCEL NAUMANN, MARCUS P. SCHMIDT, VICKY SÜSS, HELGE ROSNER, MICHAEL NICKLAS, ELENA HASSINGER, Max Planck Institute for Chemical Physics of Solids — Weyl semimetals provide ideal condensed matter platform to study Weyl fermions. When current and magnetic field are parallel in such systems, the chiral anomaly is expected to induce a negative longitudinal magnetoresistance. To observe this special feature the Fermi level must be close to the band crossing points (Weyl nodes) where quasiparticles behave like Weyl fermions [1].

We studied whether hydrostatic pressure can tune the Weyl node energy in TaAs closer to the Fermi level by the Shubnikov-de Haas effect at pressures up to 2.5 GPa. Analysis of the quantum oscillations (QO) showed that the big electron and hole Fermi surface pockets in TaAs are shrinking in size by 40% while the small electron pocket does not. Therefore some of the Weyl nodes are moving closer to the Fermi level with pressure.

Two-band model fits of the magnetoconductivity reveal that the electron and hole densities and mobilities in TaAs do not show a significant evolution with pressure. This seeming disagreement with QO can be explained by the smaller electron pocket being probably the main contributor to the magnetoresistance in TaAs. Our experimental data are further supplemented by theoretical calculations.

10:00AM W60.00011: The chiral qubit: quantum computing with chiral anomaly* [Invited]
QIANG LI (Presenter), Brookhaven National Laboratory — The quantum chiral anomaly enables a nearly non-dissipative current in the presence of chirality imbalance. We propose to utilize the chiral anomaly for the designs of qubits potentially capable of operating at THz frequency and at room temperature with a coherence time to gate time ratio of about $10^4$. The proposed “Chiral Qubit” is a micron-scale ring made of a Weyl or Dirac semimetal, with the $|0\rangle$ and $|1\rangle$ states corresponding to the symmetric and antisymmetric superpositions of chiral currents circulating along the ring clockwise and counter-clockwise. A fractional magnetic flux through the ring induces a quantum superposition of the $|0\rangle$ and $|1\rangle$ quantum states. The entanglement of qubits can be implemented through the near-field THz frequency electromagnetic fields (EMF). We show that the Hamiltonian of the chiral qubit is similar to that of the superconducting qubit. This means that quantum gates can be implemented in a traditional way, and the algorithms developed for superconducting quantum processors will apply. Light-driven (THz) ultrafast topology switching, demonstrated experimentally in Dirac/Weyl semimetal recently, will be discussed.

The author is grateful for collaborations with Dmitri Kharzeev and Jigang Wang.

**8:00AM W61.00001: Electronic structure and ferroelectricity of multiferroic Lu\(_{0.5}\)Sc\(_{0.5}\)FeO\(_3\)**

JEONG KYU KIM (Presenter), Pohang Univ of Sci & Tech, BONGJAE KIM, Department of Physics, Kunsan National University, Gunsan 54150, Korea, DONGHWAN KIM, KYOO KIM, Pohang Univ of Sci & Tech, YOUNGHAK KIM, Pohang Accelerator Laboratory, Pohang 37673, Korea, YAZHONG WANG, SANG-WOOK CHEONG, R-CEM & Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, JAE-HOON PARK, KYUNG-TAE KO, Pohang Univ of Sci & Tech — We investigated the electronic structure of a multiferroic Lu\(_{0.5}\)Sc\(_{0.5}\)FeO\(_3\) single crystal using x-ray absorption spectroscopy, cluster model calculation, and ab initio analysis. X-ray linear dichroism measurement reveals that the A-site ion hybridizes strongly with O ions, where the hybridization strength of Lu is nearly twice larger than that of Sc. In addition, the anisotropic hybridization of Lu is larger, that results in the wider splitting of \(a_{1g}\) states from \(e_g\pi\) states. The difference affects the energetic landscape of ferroelectric transition which is captured in ab initio calculation. Interestingly, the Born effective charge of planar O ions exhibits small deviation from a nominal valence instead of the anisotropic bonding, while that of apical O ion shows large value. Our observation suggest that the electronic contribution of \(e_g\pi\) and \(e_g\sigma\) bonds to six apical O ions in AO\(_8\) cage should be counted in to describe a ferroelectric instability in h-A(Mn,Fe)O\(_3\)

**8:12AM W61.00002: Competing magnetic orders and anisotropic transport in quantum critical Sr\(_3\)Ru\(_2\)O\(_7\)**

ADITYA PUTATUNDA (Presenter), GUANHUA QIN, Univ of Missouri - Columbia, WEI REN, Dept of Physics, Univ of Shanghai, DAVID SINGH, Univ of Missouri - Columbia — We investigated Sr\(_3\)Ru\(_2\)O\(_7\), the classic example of a quantum critical metal known to show a metamagnetic quantum phase transition as well as electronic nematicity, through first-principles calculations. The density functional calculations predict a ferromagnetic ground state in contrast to its experimentally observed paramagnetic character. This raises the question whether there exists competing magnetic orders that suppresses its ferromagnetism and if so, then what are those? We performed a thorough search to identify such low energy antiferromagnetically ordered metastable states. We indeed obtain such an (almost) doubly degenerate state with a striped order and calculated its associated transport properties within Boltzmann transport theory. Our results indicate significant transport anisotropy which have been discussed in context of strong spin fluctuations present in this material.

Dynamical simulation of spin-orbit insulator and application to bilayer iridate

HIDEMARO SUWA (Presenter), Department of Physics, University of Tokyo, GIA-WEI CHERN, Department of Physics, University of Virginia, KIPTON BARROS, Theoretical Division and CNLS, Los Alamos National Laboratory, CRISTIAN BATISTA, Department of Physics and Astronomy, The University of Tennessee — Spin-orbit insulators emerge in 5d electron systems with strong spin-orbit interaction, which can be described by a Hubbard model in the intermediate coupling regime of intra-atomic Coulomb repulsion (U) comparable to the dominant hopping amplitude (t). A reliable calculation in this regime is theoretically challenging because of the lack of a small parameter. We have developed a new numerical approach that enables large-scale numerical simulations (on finite lattices of more than 10,000 sites) of dynamical correlation functions at finite temperatures in a broad range of U/t values. The simulation of the self-consistent density matrix dynamics is combined with sampling from the Boltzmann distribution. As a relevant application of the newly developed method, we have calculated the dynamical spin structure factor of the bilayer iridate Sr$_3$Ir$_2$O$_7$. Our approach gives an excellent account of the experimental observations. The present method can be applied not only to iridates but also to various systems without any restrictions on the hopping amplitudes, lattice geometry, or electron filling fraction.

Infrared Spectroscopic Study on Doping Evolution of the Electronic Response of Sr$_3$(Ir$_{1-x}$Ru$_x$)$_2$O$_7$

GIHYEON AHN (Presenter), Hanyang Univ, JULIAN L SCHMEHR, STEPHEN WILSON, Materials Department, University of California, Santa Barbara, SOONJAE MOON, Hanyang Univ — We investigate the electronic response of the spin-orbit-coupled Sr$_3$(Ir$_{1-x}$Ru$_x$)$_2$O$_7$ system over a wide doping range by using infrared spectroscopy. Our data show that the electronic ground state evolves from the effective total angular momentum $J_{\text{eff}} = 1/2$ Mott state to a correlated metallic state with Ru doping. We observe that the Ru-doping-driven insulator-metal transition occurs only above a critical Ru concentration of $x_c \approx 0.35$. The low-energy optical response of the compound located at the insulator-metal transition boundary shows a peculiar behavior that might be associated with the spin-lattice coupling. Our data also suggest that the effect of the spin-orbit coupling in the electronic response may persist even in the metallic compounds with high Ru concentration. We will discuss the changes in the electronic structure associated with the insulator-metal transition.
Temperautre dependence of the low-energy electronic structure of Ca$_3$Ru$_2$O$_7$ IGOR MARKOVIC (Presenter), Univ of St Andrews, MATTHEW D. WATSON, Diamond Light Source, OLIVER J CLARK, FEDERICO MAZZOLA, Univ of St Andrews, EDGAR ABARCA MORALES, DMITRY SOKOLOV, ANDREW P. MACKENZIE, Max Planck Institute for Chemical Physics of Solids, PHIL KING, Univ of St Andrews — We use angular-resolved photoemission spectroscopy (ARPES) and ab initio calculations to study the low-energy electronic band structure of a bilayer ruthenate system, Ca$_3$Ru$_2$O$_7$, across a wide temperature range. Ca$_3$Ru$_2$O$_7$ is a bad metal which undergoes two magnetic transitions [1]: a Néel ordering at 56 K and a spin-reorientation with a coupled structural transition at 48 K. At low temperatures we find it to be a compensated semimetal, in general agreement with previous ARPES [2] and de Haas-van Alphen [3] experiments. Our measurements across the 48 K transition, however, reveal dramatic changes in the low-energy electronic structure in terms of the shape and size of the Fermi surface. This is accompanied by a significant increase in the scattering rate, and our temperature-dependent ARPES suggests new insights into the unusual transport properties of this system in its “bad metal” phase. We further explore the role of crystal structure, magnetism, and spin-orbit coupling in the evolution of the electronic structure across the 48 K phase transition.

Hydrodynamic electron flow in PdCoO$_2$: in-plane microwave spectroscopy JAMES DAY (Presenter), GRAHAM BAKER, University of British Columbia, SEUNGHYUN KHIM, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids, DOUGLAS ANDREW BONN, University of British Columbia — Hydrodynamic electron flow—in which electronic viscosity affects transport properties—has been observed in the DC resistance of PdCoO$_2$ [1]. Predictions that hydrodynamic effects also influence the AC electromagnetic response of a metal exist [2, 3], but confirming experimental evidence is lacking. In these proposals, the electronic viscosity affects the gradient of the induced current density, thereby influencing the diffusion of electromagnetic fields into the sample. Here we report results of microwave spectroscopy measurements of PdCoO$_2$ aimed at testing these predictions.

In the measurements reported here, a microwave magnetic field was applied parallel to the $ab$ plane. The induced response has two components. First, flow along a high-mobility ($a/b$) direction, with a velocity gradient along the low-mobility $c$ direction. Second, flow along the low-mobility $c$ direction, with a velocity gradient along a high-mobility ($a/b$) direction. The latter is favorable to observing nonlocal electrodynamics. We see the onset of the anomalous skin effect.

Graham Baker (Presenter), James Day, University of British Columbia, Seunghyun Khim, Andrew Mackenzie, Max Planck Institute for Chemical Physics of Solids, Douglas Andrew Bonn, University of British Columbia — Hydrodynamic electron flow—in which electronic viscosity affects transport properties—has been observed in the DC resistance of PdCoO$_2$ [1]. Predictions that hydrodynamic effects also influence the AC electromagnetic response of a metal exist [2,3], but confirming experimental evidence is lacking. In these proposals, the electronic viscosity affects the gradient of the induced current density, thereby influencing the diffusion of electromagnetic fields into the sample. Here we report results of microwave spectroscopy measurements of PdCoO$_2$ aimed at testing these predictions.

In the measurements reported here, a microwave magnetic field was applied parallel to the $c$ axis. The induced flow is always along a high-mobility ($a/b$) direction, with a velocity gradient along the other high-mobility ($b/a$) direction. This geometry is favorable to observing the effect of viscosity. The results appear to be inconsistent with existing predictions.

9:24AM W61.00008: Suppression of ferromagnetic spin correlation in the filled skutterudite superconductor SrOs$_4$As$_{12}$ revealed by $^{75}$As NQR-NMR*  
Yuji Furukawa (Presenter), Qing Ping Ding, Iowa State University, K Nishine, Jun-Ichi Hayashi, Yukihiro Kawamura, Chihiro Sekine, Muroran Institute of Technology — Recently new filled-skutterudite compounds Sr$_T$$^4$As$_{12}$ ($T$ = Fe, Ru, Os) have been synthesized, which provides a new opportunity of systematic studies of the effects of different $d$ electron of 3$d$, 4$d$ and 5$d$ in the systems [1]. Motivated by the recent observation of ferromagnetic spin correlations in the 3$d$ compound SrFe$_4$As$_{12}$ [2], we have carried out nuclear quadrupole resonance (NQR) and nuclear magnetic resonance (NMR) measurements to investigate the role of magnetic fluctuations in the newly discovered superconductor 5$d$-compound SrOs$_4$As$_{12}$ which exhibits a superconducting transition at $T_c$ = 4.8 K [3]. From the temperature dependence of Knight shift $K$ and nuclear spin lattice relaxation time $T_1$, we found that no obvious ferromagnetic spin correlations in SrOs$_4$As$_{12}$. Furthermore, the temperature dependence of $1/T_1$ in the superconducting state evidences a conventional $s$-wave superconductivity in SrOs$_4$As$_{12}$.

9:36AM W61.00009: First Principles Studies of Fe-intercalated NbS₂*  SOPHIE WEBER
(Presenter), University of California, Berkeley, JEFFREY B NEATON, Kavli Energy Nanoscience Institute at Berkeley — Layered transition metal dichalcogenides (TMDs) can allow for the intercalation of magnetic ions, resulting in novel magnetic and electronic properties which can be tuned by altering intercalant species and concentration. Recent experiments on Fe₁/₃NbS₂, a bulk antiferromagnet with a Néel temperature of 42K, have shown that an applied current can reversibly switch the magnetic order, which is read out in the resistivity*. It is hypothesized that the magnetoelectric response to the current is due to a redistribution of magnetic domains**. To shed light on these findings, we examine the ground state structure and magnetic properties of Fe₁/₃NbS₂ using density functional theory calculations. We compute energetics of different experimentally proposed magnetic orderings, and the corresponding band structures and Fermi surfaces. Implications of our calculations for the reported switching behavior and resistivity response are discussed.

9:48AM W61.00010: Theory of magneto-elastoresistance and application to WTe₂: exploring electronic structure and extremely large magnetoresistance under strain*  PETER ORTH
(Presenter), NA HYUN JO, Iowa State University, LIN-LIN WANG, Ames Laboratory, SERGEY L. BUD'KO, PAUL C CANFIELD, Iowa State University — The application of uniaxial stress to is a promising route to probe and control the properties of quantum materials. One crucial step is to quantify the effects of strain on the electronic band structure, carrier density and mobility. Here, we demonstrate that much information can be obtained by exploring a novel experimental observable: magneto-elastoresistance (MER), which refers to magnetic field-driven changes of the elastoresistance. We apply this powerful approach to study the combined effect of strain and magnetic fields on the semi-metallic transition metal dichalcogenide WTe₂, and discover a large and temperature non-monotonic elastoresistance (ER) that can be tuned by magnetic field. We report on our theoretical analysis of these observations based on semi-classical Boltzmann transport theory combined with input from first-principles calculations. We highlight how MER can generally yield new insights beyond the zero field ER. For WTe₂ specifically we derive an effective low-energy three-band model that can account for the salient experimental features.

10:36AM W61.00012: Nonequilibrium Orbital Transitions via Applied Electrical Current in Calcium Ruthenate

BING HU (Presenter), HENGDI ZHAO, University of Colorado, Boulder, FENG YE, CHRISTINA HOFFMANN, Neutron Scattering Division, Oak Ridge National Laboratory, ITAMAR KIMCHI, GANG CAO, University of Colorado, Boulder — Simultaneous control of structural and physical properties via applied electrical current poses a key, new research topic and technological significance. Studying the spin-orbit-coupled antiferromagnet Ca$_2$RuO$_4$, and its derivative with 3% Mn doping to alleviate the violent first-order transition for more robust measurements, we find that a small applied electrical current couples to the lattice by significantly reducing its orthorhombicity and octahedral rotations, concurrently diminishing the 125K antiferromagnetic transition and inducing a new orbital order below 80K. The phase diagram reveals a critical regime near a current density of 0.15A/cm$^2$ that separates the vanishing antiferromagnetic order and the new orbital order. Further increasing current density (> 1A/cm$^2$) enhances competitions between relevant interactions in a metastable manner, leading to a peculiar glassy behavior above 80K. The coupling between the lattice and nonequilibrium driven current is interpreted theoretically in terms of $t_{2g}$ orbital occupancies. The current-controlled lattice is the driving force of the observed novel phenomena. Finally, we note that current-induced diamagnetism is not discerned in pure and slightly doped Ca$_2$RuO$_4$.

10:48AM W61.00013: Quantum liquid from strange frustration in the trimer magnet Ba$_4$Ir$_3$O$_{10}$

HAO ZHENG (Presenter), HENGDI ZHAO, YIFEI NI, CHRISTOPHER POCS, YU ZHANG, University of Colorado, Boulder, FENG YE, CHRISTINA HOFFMANN, XIAOPING WANG, Neutron Scattering Division, Oak Ridge National Laboratory, MINHYEA LEE, MICHAEL A HERMELE, ITAMAR KIMCHI, GANG CAO, University of Colorado, Boulder — We present the experimental observation of a new kind of frustrated quantum liquid arising in an unlikely place: the magnetic insulator Ba$_4$Ir$_3$O$_{10}$ where Ir$_3$O$_{12}$ trimers form an unfrustrated square lattice. Experimentally we find a quantum liquid state persisting down to 0.2 K that is stabilized by strong antiferromagnetic interaction with Curie-Weiss temperature -766 K. The astonishing frustration parameter of 3800 is beyond any known iridate thus far. Heat capacity and thermal conductivity are both linear at low temperatures, a familiar feature in metals but here in an insulator pointing to an exotic quantum liquid state; a mere 2% Sr substitution for Ba produces long-range order at 130 K and destroys the linear-T features. Although the Ir$^{4+}$(5d$^5$) ions in Ba$_4$Ir$_3$O$_{10}$ appear to form Ir$_3$O$_{12}$ trimers of face-sharing IrO$_6$ octahedra, we propose that intra-trimer exchange is reduced and the lattice recombines into an array of coupled 1D chains with additional spins. An extreme limit of decoupled 1D chains can explain most but not all of the striking experimental observations, indicating that the inter-chain coupling plays an important role in the novel frustration mechanism leading to this quantum liquid.

8:00AM W62.00001: Exciton Transport in the Electron-hole System $\text{Ta}_2\text{NiSe}_5$  

AKITOSHI NAKANO (Presenter), Physics, Nagoya University, TAKAYUKI NAGAI, Materials Research Center for Element Strategy, Tokyo Institute of Technology, NAOYUKI KATAYAMA, HIROSHI SAWA, Applied Physics, Nagoya University, HIROKI TANIGUCHI, ICHIRO TERASAKI, Physics, Nagoya University — A ternary transition metal chalcogenide, $\text{Ta}_2\text{NiSe}_5$ has been recently proposed as a candidate of the Excitonic insulator (EI). An extremely flattened band dispersion in a single particle excitation spectrum observed by an angle resolved photoemission spectroscopy is regarded as evidence of the EI phase in this compound[1]. However, macroscopic physical property to evidence the spontaneously generated electron-hole pairs in $\text{Ta}_2\text{NiSe}_5$ have not been found yet. 

In this time we focus on the dielectric constant and thermopower of single crystals of $\text{Ta}_2\text{NiSe}_5$. The dielectric constant characterizes the charge response upon an ac field that rocks an electron-hole pair. In particular, when the electron-hole pairs are tightly bound, they can behave as permanent electric dipoles and should exhibit a peculiar ac response. Similarly a temperature gradient couples to excitons. 

The dielectric constant below 50 K shows relaxor-like relaxation, implying the existence of randomly distributed electric dipoles. Furthermore, a large thermopower of 600 $\mu$V/K at 100 K suddenly drops toward zero down to 50 K. We ascribe these highly unconventional transport properties in $\text{Ta}_2\text{NiSe}_5$ at low temperatures to exciton transport.

Time-resolved ARPES signatures of pump driven normal-to-excitonic insulator transition

* ENRICO PERFETTO (Presenter), Physics Department, Univ of Roma, DAVIDE SANGALLI, ANDREA MARINI, ISM, CNR, GIANLUCA STEFANUCCI, Physics Department, Univ of Roma — We consider a ground-state band insulator turning into a nonequilibrium excitonic insulator (EI) when pumping it at sub-gap frequencies slightly larger than the excitonic energy. The macroscopic polarization in the non-equilibrium EI phase is characterized by self-sustained oscillations with a frequency depending on the absorbed energy. We show that during the pump-driving the excitonic ARPES structure undergoes a convex-to-concave shape transition and concomitantly the system goes through a BEC-BCS crossover. Furthermore attosecond pulses shone after the pump-driving at different times \( t_{\text{delay}} \) generate a photocurrent which oscillates in \( t_{\text{delay}} \). This phenomenon is related to the AC response of an exotic Josephson junction.

Dynamics of an order parameter coupled phonon in an excitonic insulator

HONGLIE NING (Presenter), OMAR MEHIO, MICHAEL BUCHHOLD, Institute for Quantum Information and Matter, California Institute of Technology, TAKASHI KURUMAJI, JOSEPH G CHECKELSKY, Department of Physics, Massachusetts Institute of Technology, GIL REFAEL, DAVID HSIEH, Institute for Quantum Information and Matter, California Institute of Technology — An impulsively stimulated Raman active phonon can be suppressed or amplified using two optical pulses tailored to be period-matched with this certain mode. \( \text{Ta}_2\text{NiSe}_5 \) is an excitonic insulator candidate which exhibits multiple coherent phonons in transient reflectivity. We conducted double-pump coherent phonon spectroscopy measurements on \( \text{Ta}_2\text{NiSe}_5 \) to understand the interaction between the phonon and the excitonic order parameter. We further developed theoretical methods to simulate the dynamics of the order parameter coupled phonon.
8:36AM W62.00004: Imaging and Spectroscopy of an Exciton Condensate* SUBHRADEEP MISRA (Presenter), Department of Condensed Matter Physics, Weizmann Institute of Science, MICHAEL STERN, Physics Department and Institute of Nanotechnology and Advanced Materials, Bar-Ilan University, VLADIMIR UMANSKY, ISRAEL BAR-JOSEPH, Department of Condensed Matter Physics, Weizmann Institute of Science — We study the spatial and spectral properties of the photoluminescence of an exciton liquid at low temperatures and show that it evolves from a disordered liquid to a homogenous Bose-Einstein condensate, extending over a few hundred microns and covering the entire area of the mesa. The appearance of the condensate is marked by the emergence of a narrow PL peak, which gains strength as the temperature is reduced, and as the power is increased. We suggest that this peak is a result of the dark condensate formation and its interaction with the bright thermal exciton population.

*This work is funded by the Israeli Science Foundation (ISF).

8:48AM W62.00005: Bardasis-Schrieffer polaritons in excitonic insulators* ZHIYUAN SUN (Presenter), ANDREW MILLIS, Columbia Univ — Bardasis-Schrieffer (BS) modes in superconductors are fluctuations of order parameters corresponding to subdominant pairing channels, e.g., d-wave fluctuations in a s-wave superconductor. We generalize the notion of BS mode to excitonic insulators and show that in s-wave excitonic insulators, a p-wave BS mode exists at energies below the gap energy, has a non-vanishing optical matrix element with light and moreover hybridizes strongly with photons to form Bardiasis-Schreiffer polaritons, which are observable in both far-field and near-field optical experiments. We also show that strong driving of the BS mode by an intense light pulse can convert an s-wave excitonic insulator to a p-wave insulator and trap it there.

*This work is supported by the DOE under Grant DE-SC0019443.
9:00AM W62.00006: Discrete breaking of symmetry in the excitonic phase of Ta$_2$NiSe$_5$

GIACOMO MAZZA (Presenter), College de France, MALTE ROESNER, Radboud University, LUKAS WINDGAETTER, SIMONE LATINI, ANGEL RUBIO, Max Planck Institute for Structure and Dynamics of Matter, ANTOINE GEORGES, College de France — Ta$_2$NiSe$_5$ (TNS) is an excitonic insulator candidate material. Condensation of excitons is supposed to originate from particle-hole pairs formed across valence and conduction bands which weakly overlap at the Fermi level. Yet clear cut signatures of such a phase together with its possible origins remain open questions. Here we report on the understanding of the symmetry principles underlying an instability of the excitonic type in TNS.

By means of ab-initio calculation we uncover a set of discrete symmetries in the high-temperature phase of TNS with significant effect to its low-energy band structure. We derive a minimal electronic model consistent with these symmetries and present evidence of an electronic phase transition related to a spontaneous breaking of these symmetries. The breaking of such discrete symmetries is intrinsically coupled to a lattice instability, which drives the high-temperature orthorhombic structure to the low-temperature triclinic one. Our results open new perspectives on the interpretation of a phase characterized by the condensation of excitons hosted by this material.

9:12AM W62.00007: Cluster mean-field analysis of the finite-temperature properties of the one-dimensional extended Falicov-Kimball model*

MASAHIRO KADOSAWA (Presenter), Physics, Chiba Univ, SATOSHI NISHIMOTO, Institute for Theoretical Solid State Physics, IFW-Dresden, KOUDAI SUGIMOTO, Physics, Keio Univ, YUKINORI OHTA, Physics, Chiba Univ — Motivated by a recent finding that Ta2NiSe5 is in a strong-coupling excitonic insulator state [1], we study finite-temperature properties of the one-dimensional extended Falicov-Kimball model (EFKM), the simplest lattice model for the excitonic insulator state. Here, we use the cluster mean-field method with a sine-square deformation and calculate the finite-temperature phase diagrams of the model, which are compared with the results of a previous study at zero temperature [2]. Moreover, we calculate the optical conductivity spectra of the model at finite temperatures and find that the temperature dependence of the spectral features observed in experiment [3] are well reproduced by our calculations.

*This work was supported in part by SFB 1143 of the Deutsche Forschungsgemeinschaft, by Grants-in-Aid for Scientific Research from JSPS (Projects No. JP17K05530 and No. JP19K14644), and by Keio University Academic Development Funds for Individual Research.
9:24AM W62.00008: Global Spin Current in Excitonic Phases of the Two-Band Hubbard Model* \textsc{Shunsuke Yamamoto} (Presenter), \textsc{Hisao Nishida}, Physics, Chiba University, \textsc{Koudai Sugimoto}, Physics, Keio University, \textsc{Yukinori Ohta}, Physics, Chiba University — It has recently been pointed out that the k-space spin texture may emerge in the doped excitonic phase of a two-orbital Hubbard model containing the cross-hopping terms with certain symmetry [1-3]. Thanks to the spontaneous breaking of the inversion symmetry by the excitonic phase transition, the global spin current perpendicular to the applied electric field is induced by the spin-dependent off-diagonal component of the Drude weight. The mechanism is quite different from the conventional one originated from the spin Hall effect where a spin-orbit coupling plays an essential role, and thus our result gives a new route to generate a spin current.

*This work was supported in part by Grants-in-Aid for Scientific Research from JSPS (Projects No. JP17K05530 and No. JP19K14644) and by Keio University Academic Development Funds for Individual Research.

9:36AM W62.00009: Sign-Free Determinant Quantum Monte Carlo Study of the Bilayer Hubbard and Two-Orbital Hubbard-Kanamori Models \textsc{Xuxin Huang} (Presenter), Applied Physics, Stanford University, \textsc{Martin Claassen}, Center for Computational Quantum Physics, The Flatiron Institute, \textsc{Brian Moritz}, SLAC National Accelerator Laboratory and Stanford University, SSRL Materials Science Division, \textsc{Thomas Devereaux}, Materials Science and Engineering, Stanford University — Two-band Hubbard models, as prototypes for various strongly correlated systems, have attracted intense research interest over the past few decades. Determinant Quantum Monte Carlo (DQMC), an unbiased finite-temperature numerical technique well suited to study such models, generically suffers from the fermion sign problem. However, for some variations, e.g. the bilayer Hubbard model with symmetric electron-hole doping and the half-filled two-orbital Hubbard-Kanamori model, particle-hole symmetry can be utilized to perform sign-problem-free studies. Here, using DQMC we show that the bilayer Hubbard model possesses a Berezinskii–Kosterlitz–Thouless (BKT) transition to an inter-layer biexciton condensate at intermediate coupling and finite electron-hole doping. For the Hubbard-Kanamori model, we treat the full rotationally invariant interaction, including the Hubbard and Hund's coupling terms, using a decoupling scheme which involves a 12-state auxiliary field per site, and present the magnetic correlation and phase transition results obtained from DQMC.
**9:48AM W62.00010: Novel states of charge-imbalanced polariton condensates**  
ARTEM STRASHKO (Presenter), Center for Computational Quantum Physics, Flatiron Institute, Simons Foundation, FRANCESCA MARCHETTI, Departamento de Fisica Teorica de la Materia Condensada & Condensed Matter Physics Center (IFIMAC), Universidad Autonoma de Madrid, ALLAN MACDONALD, Department of Physics, The University of Texas at Austin, JONATHAN KEELING, SUPA, School of Physics and Astronomy, University of St Andrews — Polariton condensation is a well-established phenomenon featuring all the signatures of an ordinary condensate. However, in the context of polariton condensation, almost exclusively balanced systems, with equal densities of electrons and holes, have been studied. This misses a whole class of potential exotic imbalanced condensed states like an FFLO or a breached-pair state.

Inspired by pioneering works on imbalanced electron-hole systems in TMDC monolayers strongly coupled to a cavity photon, using variational mean-field theory, we explore whether a combination of strong matter-light coupling and electric field biasing promotes novel condensed states, which do not exist otherwise.

On top of a balanced polariton and a dark imbalanced FFLO condensates, we find novel imbalanced polaritonic states with coexisting polariton condensate and unpaired electrons with either isotropic or anisotropic Fermi surface depending on applied bias voltage. These states arise due to combination of strong matter-light coupling and long-range Coulomb potential.

**10:00AM W62.00011: π-ton contributions to optical conductivity in correlated electron systems**  
ANNA KAUCH (Presenter), PETRA PUDLEINER, KATHARINA ASTLEITHNER, PAUL WORM, CLEMENS WATZENBÖCK, Vienna Univ of Technology, PATRIK THUNSTRÖM, Uppsala University, TIN RIBIC, KARSTEN HELD, Vienna Univ of Technology — The interaction of light with solids gives rise to new bosonic quasiparticles, with the exciton being the most famous of these polaritons. While excitons are the generic polaritons of semiconductors, we show that for strongly correlated systems another polariton is prevalent [1] -- originating from the dominant antiferromagnetic or charge density wave fluctuations in these systems. As these are usually associated with a wave vector \((\pi, \pi, \ldots)\) or close to it, we call the derived polaritons \(\pi\)-tons.

These \(\pi\)-tons yield the leading vertex correction to the optical conductivity in all correlated models studied:

- the Hubbard
- the extended Hubbard model
- the Falicov-Kimball
- the Pariser-Parr-Pople model

both in the insulating and in the metallic phase.

10:12AM W62.00012: Quantum nematicity in EuB$_6$  
GABRIELLE BEAUDIN (Presenter), ANDREA BIANCHI, WILLIAM WITCZAK-KREMPA, Universite de Montreal — Our experimental discovery of a quantum nematic phase in the colossal magneto resistive material EuB$_6$ constitutes a breakthrough in quantum material research. Unlike the quantum nematics in the cuprate and arsenide superconductors, there is no nearby lattice instability complicating the interpretation, making EuB$_6$ a clean model system for studying electronic nematicity. Interestingly, the nematic appears in the same region of the temperature-magnetic field phase diagram where experiments indicate magnetic polarons. This not only indicates a new understanding of nematicity but also paves the way for obtaining novel magneto resistive transistor action in spintronic devices.

10:24AM W62.00013: Strong polaron–spin fluctuations drive the insulator–semimetal transition in low-density electron gases  
ANDREA BIANCHI (Presenter), GABRIELLE BEAUDIN, ALEXANDRE DÉSILETS-BENOIT, Universite de Montreal, STAVROS SAMOTHRAKITIS, KILIAN STENNING, School of Metallurgy and Materials, University of Birmingham, MICHAEL NICKLAS, MPI-CPFS, SIMON GERBER, NIKOLA EGETENMEYER, JORGE GAVILANO, MICHEL KENZELMANN, LNS, PSI, ROBERT CUBITT, CHARLES DEWHURST, Institut Laue Langevin, MARK LAVER, Physics, University of Warwick — One of the outstanding questions in physics is the formation of magnetic moments in metallic systems of low carrier density. For the design of materials for spintronic applications, we need to understand the physics in a regime where mobile charge carriers couple strongly to the magnetic moments. One way to realise such a strong interaction is to work with materials with a low carrier density where two competing electronic ground states are close in energy. Switching between these different electronic ground states then leads to large effects in the electronic transport. What makes the physics in these colossal magnetoresistance (CMR) materials fascinating is that the CMR effects stem from an electronic phase separation at the nanometre scale, despite the fact that these materials are chemically homogeneous. "Magnetic polarons" are thought to be responsible for the CMR effects in some materials. Here we present results of a small angle neutron scattering (SANS) study showing the dramatic influence of magnetic polarons on ferromagnetic fluctuations in EuB$_6$, giving clear evidence for their involvement in the insulator-to-metal transition as the result of large scale magnetic fluctuations.

Friday, March 6, 2020 8:00 AM - 11:00 AM

Session W63 DCMP: STM on twisted 2D heterostructures  
Mile High Ballroom 4D - Jairo Velasco Jr., University of California, Santa Cruz
Recent experiments on magic-angle twisted bilayer graphene (MATBG) have shown various intriguing low-temperature electronic phases induced by filling of the moiré flat bands [1][2]. These phases, including correlated insulator and superconducting phases, are derived from a high-temperature “parent phase,” which is currently not well understood. Previously, there have been scanning tunneling microscopy and spectroscopy (STM/STS) measurements of this parent phase that have shown signatures of strong electronic correlations [3]. In this talk, we report on new, higher resolution STM/STS studies of this phase. Our experimental results reveal new distinct filling-dependent spectroscopic features that reflect key information on the nature of many-body correlations in MATBG. We have found that these features can be compared to a model of strongly interacting electrons in the flat bands allowing us to determine the microscopic origin of these features as well as extract an estimate of the strength of electronic correlation in MATBG.

*This work has been supported by the Moore Foundation and the DOE.
Magic-angle twisted bilayer graphene (MATBG) has a complex gate-accessible electronic phase diagram characterized by a variety of exotic insulating, superconducting, and topological phases. Using a homebuilt dilution-fridge scanning tunneling microscope (STM), we probe the spectroscopic properties of MATBG to gain insight into the underlying mechanisms of its phases. At partial filling of the flat bands, consistent with previous studies, our measurements at high temperatures (< 12K) show significant deviations from the single-particle density of states (DOS), indicating the presence of strong electronic interactions [1]. We extend these STM measurements to millikelvin temperatures, where we explore how the “parent phase” develops into correlated insulating and superconducting phases. Our measurements have uncovered a series of gate-dependent energy gaps in the DOS at the Fermi level corresponding to electron fillings at which electrical transport measurements reveal these phases. These spectra, along with their magnetic field and spatial dependencies, provide key information about the microscopic origin of each energy gap and their connection to the various electronic phases in MATBG.

*This work is supported by the Moore Foundation and the DOE.
Spectroscopy with scanning tunneling microscopy (STM) in a high magnetic field can be used to probe the quantization of the density of states into Landau levels (LL), which provides important information on electronic properties such as the relevance of broken symmetries and the presence or absence of Dirac cones. We apply this technique to study gated magic-angle twisted bilayer graphene (MATBG) devices, for which recent magnetotransport studies have reported transitions in the LL fan diagrams as a function of the filling of electrons in MATBG’s flat bands [1-3]. These reported changes correlate with the appearance of various correlated insulating, magnetic, and superconducting phases. Our STM measurements are carried out in a dilution-fridge system allowing us to resolve the energy of the LL with high resolution and to probe MATBG devices as a function of filling of its flat band. We will describe these measurements, their connection to the magnetotransport studies, and their interpretations in terms of microscopic properties of MATBG as a function of electron density.

8:36AM W63.00004: Atomic-scale structure and electronic properties of twisted double bilayer graphene  

CARMEN RUBIO VERDÚ (Presenter), SIMON ELI TURKEL, LARRY SONG, Physics Department, Columbia University, DANTE KENNES, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, LEDE XIAN, Max Planck Institute for the Structure and Dynamics of Matter, HECTOR OCHOA, Physics Department, Columbia University, ANGEL RUBIO, Center for Computational Quantum Physics (CCQ), The Flatiron Institute, ABHAY PASUPATHY, Physics Department, Columbia University — The fundamental properties of 2D materials are dramatically modified when they are brought next to each other to form a vertical heterostructure. The electronic characteristics of such van der Waals materials can be further controlled by the twist angle degree of freedom, inducing electronic flat bands that lead to emergent phases such as correlated insulating (CI) and superconducting (SC) states in twisted bilayer graphene. Such phenomenology is expected in higher order heterostructures where the vertical stacking order plays a major role. Recent works showed that double bilayer graphene (tDBG) at a twist angle of ~1.3° hosts displacement field tunable CI and SC states, as well as ferromagnetic order. We show real-space imaging of tDBG moiré superstructure by means of Scanning Tunneling Microscopy/Spectroscopy (STM/STS). STS reveals the presence of van Hove singularities whose spatial distribution within the moiré unit cell is determined by the inequivalent stacking sites. Tuning carrier density and displacement field reveals long-range broken symmetries that emerge when the Fermi level is brought in the vicinity of such flat bands. Our results shed light into the underlying mechanisms behind electron-electron correlations in tDBG and the emergent ferromagnetic order.

8:48AM W63.00005: Identifying the effect of hBN alignment on twisted bilayer graphene using scanning tunneling microscopy*  

CHENG-LI CHIU (Presenter), XIAOMENG LIU, YONGLONG XIE, BERTHOLD JAECK, Princeton University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ALI YAZDANI, Princeton University — When two graphene layers are stacked with a small twist angle, a moiré superlattice arises that modifies the electronic band structure. Specifically, at the magic angle (~1.1deg), the bands become flat. In these flat bands, various correlated electronic states emerge. In some samples, correlated insulating behaviors are observed at integer fillings, accompanied by superconducting states upon doping. In other samples, the quantum anomalous Hall effect replaces the correlated insulator at ¾ filling while superconductivity is absent. Despite the lack of direct experimental evidence, it has been suggested that the latter phase is produced by the alignment between graphene and the hBN substrate. Using a scanning tunneling microscope (STM), we extract the hBN alignment information from graphene-hBN moire lattice superimposed on the graphene-graphene moire lattice. Comparing spectra from different samples, we explore the effect of hBN alignment on the electronic properties of twisted bilayer graphene.

**9:00AM W63.00006: Imaging moiré superlattices in twisted bilayers of 2D materials**

LEO MCGILLY (Presenter), ALEXANDER KERELSKY, NATE FINNEY, Columbia University, KOSTANTIN SHAPOVALOV, Institute of Materials Science of Barcelona, AUGUSTO GHIOTTO, EN-MIN SHIH, YIHANG ZENG, SAMUEL MOORE, WENJING WU, YUSONG BAI, Columbia University, LIN ZHOU, Nanjing University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JAMES C HONE, XIAOYANG ZHU, DMITRI BASOV, CORY DEAN, CYRUS DREYER, ABHAY PASUPATHY, Columbia University — Two-dimensional materials stacked into van der Waals (vdW) heterostructures form moiré superlattices as a result of a relative rotational misalignment between layers as well as a lattice mismatch between two dissimilar materials. The resulting physics of the vdW heterostructures can be dominated by the large scale periodicity of the moiré superlattice which is generally substantially larger than the atomic scale lattice. In this work we outline a method to visualize the real-space moiré superlattices in a variety of twisted vdW heterostructures utilizing piezoresponse force microscopy which locally measures an electromechanical sample surface deformation. Its origin is suggested to arise due to the flexoelectric effect wherein electric polarization is induced through strain gradients present within moiré superlattices.

**9:12AM W63.00007: Flat bands in small angle twisted bilayer WSe$_2$**

ZHIMING ZHANG (Presenter), Physics Department, University of Arizona, YIMENG WANG, Department of Electrical and Computer Engineering, The University of Texas at Austin, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, KEIJI UENO, Department of Chemistry, Saitama University, EMANUEL TUTUC, Department of Electrical and Computer Engineering, The University of Texas at Austin, BRIAN J LEROY, Physics Department, University of Arizona — The discovery of superconductivity in magic angle twisted bilayer graphene has ignited great interest in exploring flat bands in two-dimensional van der Waals heterostructures. We demonstrate for the first time the existence of flat bands in the electronic structure of a 3° twisted bilayer WSe2 sample using low temperature scanning tunneling microscopy and spectroscopy. Using variable height spectroscopy, we observe sharp peaks in the density of states near the valence band edge related to the flat bands. By decay constant measurements, we assign various peaks in the density of states to different locations in the Brillouin zone. By direct spatial mapping of the wavefunctions at the flat band energy, we have found that the flat band is localized in the form of a hexagonal network, which is in excellent agreement with first-principle density functional theory calculations.

Effect of Spin-orbit Coupling in Twisted Bilayer and Double Bilayer Transition Metal Dichalcogenides

SUDIPTA KUNDU, MIT NAIK, MANISH JAIN (Presenter), Center for Condensed Matter Physics, Department of Physics, Indian Institute of Science — Since the discovery of flat bands at magic angles in twisted bilayer graphene, the formation of flat bands has been predicted for several other twisted bilayers, especially twisted transition metal dichalcogenides (TMDs). The effect of spin-orbit coupling is quite prominent in TMDs such as WSe$_2$. Using a multiscale approach, based on classical force-fields for structural relaxation and density functional theory calculations for electronic structure, we investigate the influence of spin-orbit coupling on the flat bands in twisted TMD systems. Owing to spin-valley coupling, spin-orbit interaction affects the flat bands of the twisted bilayer TMDs with twist angle close to 0$^\circ$ differently than those near 60$^\circ$. The spin-orbit splitting of bands near valence band edge decreases with smaller twist angle. We study wavefunction localization near valence and conduction band edges in these bilayers and extend our studies to twisted double bilayer TMDs as well.

Tunable Moiré Superlattice of Artificially Twisted Monolayers

YI-CHENG CHIANG (Presenter), PO YEN CHEN, XIN-QUAN ZHANG, YING-YU LAI, CHUN-AN CHEN, ERH-CHEN LIN, Materials Science and Engineering, National Tsing Hua University, SYU YOU GUAN, Physics, Academia Sinica, SHANGJR GWO, Physics, National Tsing Hua University, CHIA-SENG CHANG, Physics, Academia Sinica, LIH JUANN CHEN, YI-HSIEN LEE, Materials Science and Engineering, National Tsing Hua University — Twisting between two stacked monolayers modulates periodic potentials and forms the Moiré electronic superlattices, which offers an additional degree of freedom to alter material property. Considerable unique observations, including unconventional superconductivity and quantized interlayer excitons are correlated to the electronic superlattices but further study requires reliable routes to study the Moiré in real space. Scanning tunneling microscopy (STM) is ideal to precisely probe the Moiré superlattice and correlate coupled parameters among local electronic structures, strains, defects, and band alignment at atomic scale. Here, a clean route is developed to construct twisted lattices using synthesized monolayers for fundamental studies. Diverse electronic superlattices are experimentally confirmed with STM at room temperature.
9:48AM W63.00010: Unsupervised learning of nematic order from scanning tunneling spectroscopy on twisted bilayer graphene* SAMUEL LEDERER (Presenter), Cornell University, YOUNGJOON CHOI, Caltech, PAVEL ISMAILOV, Cornell University, ANDREW WILSON, NYU, STEVAN NADJ-PERGE, Caltech, EUN-AH KIM, Cornell University — Moiré materials such as magic angle twisted bilayer graphene (TBG) provide an exciting platform for the study of novel states of matter, but their large unit cells present significant difficulties for atomic resolution probes such as scanning tunneling microscopy (STM). We therefore develop an automated method to extract salient physical quantities from STM data on moiré materials, and apply it to measurements on TBG that visually suggest the breaking of rotational symmetry (i.e. nematic order). We apply the machine learning technique of Gaussian mixture modeling to this data to classify the STM images at different bias voltages into several categories in an unbiased fashion. This classification yields evidence for a nematic order that manifests itself in a manner strongly dependent on bias voltage. In addition to providing evidence for spatial symmetry breaking in TBG, our techniques can be applied in the future to overcome the intrinsic challenges of exploiting STM in the burgeoning field of moiré materials.

10:00AM W63.00011: Moiré superlattice of a charge transfer Kondo monolayer and its interplay with superconductivity* SHUANGZAN LU, Wuhan University, HYEONGDO NAM, PENGHAO XIAO, University of Texas at Austin, YANPING GUO, Wuhan University, MENGKE LIU, University of Texas at Austin, YUSONG BAI, Wuhan University, ZHENGBO CHEN, University of Texas at Austin, HAITAO ZHOU, Chinese Academy of Sciences, GRAEME HENKELMAN, University of Texas at Austin, GREGORY A FIETE, Northeastern University, H.-J. GAO, Chinese Academy of Sciences, ALLAN MACDONALD, University of Texas at Austin, CHENDONG ZHANG (Presenter), Wuhan University, CHIH-KANG SHIH, University of Texas at Austin — Moiré pattern formation has emerged as a powerful tool to create controllable two-dimensional electronic superlattices. Moiré superlattices can exhibit remarkable properties such as unconventional superconductivity and Mott insulators in twisted graphene bilayers, and moiré exciton bands in transition metal dichalcogenide heterobilayers. Here, we report on the observation of a moiré superlattice formed between an organic monolayer and a s-wave superconductor. Although the organic molecule does not contain magnetic atoms, the interlayer charge transfer from the superconductor to the p-orbitals creates a local moment leading to the co-existence of Kondo screening and Cooper pair formation, and to an interplay between superconductivity and the Kondo effect. More specifically, the moiré pattern leads to a strong modulation of the “local” Kondo temperature by a factor of three. In addition, the interplay of Kondo screening and Cooper pair formation leads to a modulation of the pairing gap by about 30%. We show that the periodicity of these superlattices is tunable by the twist angle, making it possible to tailor the properties of this heterostructure.

10:12AM W63.00012: Scanning tunneling microscopy and spectroscopy of graphene on in-plane anisotropic rhenium disulfide*  RYAN PLUMADORE (Presenter), JUSTIN BODDISON-CHOUINARD, SAMANTHA SCARFE, ADINA A LUICAN-MAYER, Univ of Ottawa — Van der Waals heterostructures made of graphene placed on top of other 2D materials have been shown to affect the band structure of graphene and lead to proximity-induced novel phenomena. In this talk, we focus on a system that has graphene placed on top of the in-plane anisotropic semiconductor ReS$_2$. Using scanning tunneling microscopy and spectroscopy, we characterized the changes at the atomic scale in the structure and electronic properties of Dirac electrons placed in the longitudinal periodic potential of ReS$_2$.

*The authors acknowledge funding from the National Sciences and Engineering Research Council (NSERC) Discovery Grant RGPIN-2016-06717. We also acknowledge the support of the National Sciences and Engineering Research Council of Canada (NSERC) through Strategic Project STPGP 521420.

10:24AM W63.00013: Transition Metal Adatoms on Graphyne: Electronic Structure and Thermoelectric Properties*  ANDREA LATGE (Presenter), PEDRO VENEZUELA, DEBORA RODRIGUES, Instituto de Física, Niterói, RJ Brazil, Universidade Federal Fluminense — Thermoelectricity is the advantageous property of some materials to convert waste thermal energy into electricity. The research interest of achieving high thermoelectric efficiency increased in the recent years, specially promoted by the demand for eco-friendly energy harvesting technology. It is known that 2D systems provide much higher thermoelectric conversion than bulk materials, due to enhancement of Seebeck coefficient and reduction of phonon thermal conductivity. Therefore, graphene nanostructures and other 2D sp-sp2 carbon allotropes such as graphynes and graphdiynes are promising candidates to thermoelectric applications and spin caloritronics, an emerging technology combining spintronics and thermoelectronics.

Here we investigated structural and electronic properties of Mn and Fe adatoms adsorbed on Graphyne (Gy) using density functional theory. We verified that the band structure of Gy sheets, strongly depends on the adatom distance to the plane. To explore the effects of quantum confinement, we also discuss the functionalization of Gy nanoribbons. Finally, we focus on the electronic transport and thermoelectric quantities with the perspective of spin caloritronics nanodevices.

10:36AM W63.00014: Electronic structure of carbon nanotubes on graphene substrates
BENEDETTA FLEBUS (Presenter), ALLAN MACDONALD, University of Texas at Austin — Allotropes of carbon, including one-dimensional carbon nanotubes and two-dimensional graphene sheets, continue to draw attention as promising platforms for probing the physics of electrons in lower dimensions. Recent research has shown that the electronic properties of graphene multilayers are exquisitely sensitive to the relative orientation between sheets, and in the bilayer case exhibit strong electronic correlations when close to a magic twist angle. Here, we investigate the electronic properties of a carbon nanotube deposited on a graphene sheet by deriving a low-energy theory that accounts both for rotations and rigid displacements of the nanotube with respect to the underlying graphene layer. We show that this heterostructure is described by a translationally invariant, a periodic or a quasi-periodic Hamiltonian, depending on the orientation and the chirality of the nanotube. Furthermore, we find that, even for a vanishing twist angle, rigid displacements of a nanotube with respect to a graphene substrate can alter its electronic structure qualitatively. Our results identify a promising new direction for strong correlation physics in low dimensions.

10:48AM W63.00015: Q-Valley Quasiparticle Interference in Few-Layer Transition Metal Dichalcogenides*
PATRICK CHEUNG (Presenter), YAN-FENG ZHOU, FAN ZHANG, University of Texas at Dallas — Quantum transport experiments have provided compelling evidence for the threefold flavors of the Q-valley electrons in few-layer transition metal dichalcogenides (TMD). We study the quasiparticle interference (QPI) due to Q-valley electrons scattering off localized impurities, which modifies the local density of states. In the quantum Hall regime, all the TMD odd-layers thicker than bilayer exhibit Landau level triplets. When a Landau level triplet is one-third filled or empty, the flavor SU(3) symmetry is broken in the ferroelectric nematic ground states tunable by an in-plane electric field and an out-of-plane magnetic field. We show the QPI patterns of such flavor states, which can be probed by scanning tunneling spectroscopy.

Session W65 DCMP: Superlattices and Nanostructures IV: Polaritons and Plasmons Mile High Ballroom 4F - GuangXin Ni, Columbia Univ
8:00AM W65.00001: Calibration of long-lifetime polariton structures* JONATHAN BEAUMARIAGE (Presenter), ZHENG SUN, Physics and Astronomy, University of Pittsburgh, MARK STEGER, National Renewable Energy Laboratory, DAVID M MYERS, Polytechnique Montreal, SHOUVIK MUKHERJEE, DAVID WAYNE SNOKE, Physics and Astronomy, University of Pittsburgh, LOREN PFEIFFER, KENNETH WEST, Electrical Engineering, Princeton University — In short-lifetime polariton samples both the upper and lower polariton branches can be resolved through white light reflectivity. However, in long-lifetime polariton samples the linewidths are so narrow that they can not be resolved through typical spectroscopy. Additionally, photoluminescence from the upper polaritons can often not be seen at relevant detunings, as the upper polaritons quickly drop down to lower polariton states. As such, the calibration of long-lifetime polariton samples is uniquely challenging compared to short-lifetime polariton samples. In this work, we will show various measurements which demonstrate the cavity lifetime is 100 ps or more, and use this collective set of information to create an accurate calibration of the long-lifetime polariton samples.

8:12AM W65.00002: Dynamics of an Exciton-Polariton Condensate in a Tilted Ring Microcavity* SHOUVIK MUKHERJEE (Presenter), Univ of Pittsburgh, VALERII K. KOZIN, ANTON V. NALITOV, IVAN A. SHELYKH, University of Iceland, ZHENG SUN, Univ of Pittsburgh, DAVID M MYERS, Engineering Physics, Polytechnique Montreal, BURCU OZDEN, Penn State Abington, JONATHAN BEAUMARIAGE, Univ of Pittsburgh, LOREN PFEIFFER, KENNETH WEST, Princeton University, ANDREW DALEY, University of Strathclyde, DAVID WAYNE SNOKE, Univ of Pittsburgh — We have created polariton condensates in a semiconductor microcavity with a lifetime greater than the equilibration time scale for the system at cryogenic temperature (below 10 K). By etching the microcavity into ring micro-channels of width 15 μm we confined the condensate to flow in a circular trap. We have directly imaged the motion of the condensate in the ring using time-resolved optical microscopy techniques. We study both the dynamical and the steady-state regime and present quantitative bounds on the strength of the interactions between polaritons in this system. We also measure the spatial coherence of the condensate in these micro-channels leading to important implications for scaling such networks of micro-channels for simulating NP-hard problems.

8:24AM W65.00003: Pushing Photons with Electrons: Observation of the Polariton Drag Effect*  QI YAO (Presenter), Univ of Pittsburgh, DAVID M MYERS, Polytechnique Montreal, BURCU OZDEN, Pennsylvania State University, JONATHAN BEAUMARIAGE, Univ of Pittsburgh, LOREN PFEIFFER, KENNETH WEST, Princeton University, DAVID WAYNE SNOKE, Univ of Pittsburgh — Exciton-polaritons are quasiparticles that are a superpositions of excitons and photons. In a microcavity, exciton-polaritons have an effective mass and can form a Bose-Einstein condensate (BEC). Experimentally, this condensate can be generated by pumping light into a microcavity structure with quantum wells at the antinodes of the light field, and then we can measure the the energy, real-space and momentum-space distributions of the polaritons using the light they emit, using conventional optical methods.

In our experiment, we observed a change in the angle of emission of the photons when injecting electrons to the system, which indicates that the interaction of electrons with the polaritons changes the momentum of the polariton condensate. The condensate flow was accelerated when electrons flow with the same direction, while the condensate was slowed down when electrons flow in the opposite direction. Because the experiment is a photon-in, photon-out system, this is equivalent to steering photons using a DC electrical current.

8:36AM W65.00004: Observation of the amplitude mode in a microcavity polariton condensate driven by quantum fluctuations*  MARK STEGER (Presenter), National Renewable Energy Laboratory, RYO HANAI, ALEXANDER EDELMAN, PETER B LITTLEWOOD, James Franck Institute and Department of Physics, University of Chicago, DAVID WAYNE SNOKE, JONATHAN BEAUMARIAGE, Physics and Astronomy, University of Pittsburgh, BRIAN FLUEGEL, National Renewable Energy Laboratory, KENNETH WEST, LOREN PFEIFFER, Electrical Engineering, Princeton University, ANGELO J MASCARENHAS, National Renewable Energy Laboratory — We directly observe emission into the amplitude mode from an exciton-polariton condensate: the signature of this mode being the ghost-branch photoluminescence at energies below the condensate. This amplitude mode, the number-fluctuation variant of the Goldstone mode, appears in many forms of condensed matter; however, the polariton system gives a unique way to passively monitor this mode in the steady-state system without driving the population far out of equilibrium. This mode is predicted to manifest as an excitation of condensed particles into the upper-polariton state. Here we present experimental results in agreement with our theoretical analysis. Additionally, we present a family of ghost-branch modes that require an expanded theory to capture.

**8:48AM W65.00005: Hyperbolic phonon polaritons in calcite for nanoscale infrared confinement**  
VANESSA BRESLIN (Presenter), National Research Council, United States Naval Research Laboratory, DANIEL RATCHFORD, ALEXANDER GILES, ADAM DUNKELBERGER, JEFFREY OWRUTSKY, United States Naval Research Laboratory — Phonon-polaritons are collective oscillations resulting from the coupling of photons with optical phonons in polar materials and are supported within a material-specific spectral region called the Reststrahlen band, which is bounded by the transverse and longitudinal optical phonons. In this region, the material behaves optically like a metal due to the negative real part of the permittivity, resulting in the incident light being strongly reflected. When polar materials are nanostructured, phonon-polaritons can enable a variety of near-field optical effects such as sub-diffraction light confinement. Interestingly, a polar material which supports phonon-polaritons can also have anisotropic optical properties, such that different components of its permittivity tensor have opposite signs. These materials are referred to as hyperbolic as they behave optically like a dielectric in one direction and like a metal in the other. Here, we report on the observation of hyperbolic phonon-polaritons (HPhPs) in calcite nanopillar arrays, demonstrate the aspect ratio dependence of the HPhP resonance frequencies, and verify our results through comparison to an analytical model. Calcite is an ideal low-loss material for studying HPhPs that could find applications in mid-IR nanophotonic devices.

**9:00AM W65.00006: Creation of partially rotating vortex of polariton condensate by non-resonant Laguerre-Gaussian optical excitation in semiconductor microcavity**  
DAEGWANG CHOI, MIN PARK, BYOUNG YONG OH, MIN-SIK KWON, Department of Physics, KAIST, SUK IN PARK, HANG KYU KANG, SOOSEOK KANG, JIN DONG SONG, Center for Opto-Electronic Convergence Systems, KIST, HYOU NGSOON CHO, YONG-HOON CHO (Presenter), Department of Physics, KAIST — An exciton-polariton is a bosonic quasi-particle formed by a strong coupling between a quantum well exciton and a cavity photon in a semiconductor microcavity. Its bosonic nature offers the ground state condensation and superfluidity that hosts quantized vortices generated by various optical excitation methods. Here, we observed a new method for creating quantized vortices in the polariton superfluid whose vorticity is determine by the orbital angular momentum of a non-resonant Laguerre-Gaussian optical excitation.[1] Moreover, the polariton condensate is found to be in two different energy states, a vortex carrying excited state and the irrotational ground state, which is confirmed by the tomographic interferometer.[2] As a result, only a part of superfluid is found to be rotating with a vortex core and the fraction of the rotating superfluid can be controlled by changing the excitation beam size or the pumping power. This striking observation will be helpful for improving our understanding of relaxation process and non-equilibrium physics in semiconductor and non-equilibrium superfluid.

Topological Surface-plasmon-polariton Modes on Biharmonic Metal-dielectric Gratings

THOMAS SMITH (Presenter), ALESSANDRO PRINCIPI, Physics and Astronomy, University of Manchester — The area of topological plasmonics is a relatively new and rather unploughed field. The majority of progress thus far has been in constructing crystal structures whose atomic sites take the form of an array of metallic nanoparticles. Such nanoparticles are capable of hosting localised plasmon-polariton modes, which form the basis upon which a tight-binding model may be generated. Through this model, the topological character of the lattice may be probed. A similar result may be arrived at by considering surface-plasmon-polariton resonances on biharmonic metal-dielectric gratings. In such a case, provided that the surface is smooth and has a parabolic profile, the amplitude of the SPP mode may be described by an emergent 1D Schrödinger equation. This equation may then be made to mimic the SSH model through a suitable manipulation of the physical parameters of the system. Then topological states may be observed within the basic scattering formalism, whose existence and character are then confirmed through a tight-binding model.

*This work was made possible through the support of the EPSRC with the Ph.D. studentship grant EP/N509565/1 and the Royal Society International Exchange grant IES\R3\170252.

Photonic crystal for graphene plasmons

LIN XIONG (Presenter), CARLOS FORSYTHE, Columbia Univ, MINWOO JUNG, Cornell University, ALEXANDER MCLEOD, YUTAO LI, SHUAI ZHANG, YINAN DONG, SONG LIU, Columbia Univ, MICHAEL M FOGLER, University of California San Diego, JAMES H. EDGAR, Kansas state university, GENNADY SHVETS, Cornell University, CORY DEAN, DIMITRI BASOV, Columbia Univ — Graphene surface plasmon polaritons (SPPs) are hybrid excitations of electrons and photons which can be controlled by the optical properties of graphene. Periodically varying the optical properties results in a photonic crystal for graphene SPPs. Here we utilize cryogenic near-field optical microscopy to study the band structure induced by a graphene photonic crystal consisting of a high-mobility graphene atop a patterned SiO₂ dielectric layer [Xiong, Nat. Commun. 10: 4780 (2019)]. Gating through the dielectric provides a periodic field effect that spatially modulates local carrier densities [Forsythe, Nat. Nanotech. 13, 566–571 (2018)] and the propagation of plasmon polaritons through the graphene. A full plasmonic bandgap and characteristic SPP propagation properties are revealed. Selective engineering of domain wall in the middle of the photonic crystal produces localized SPP modes propagating strictly along the domain wall. These findings signify a new route towards designer-engineered band-structures to route and manipulate highly confined plasmons within high mobility graphene devices.
9:36AM W65.00009: Plasmon resonance shift and near electric field of silver nanoparticles: Theoretical analysis of size, shape, and aggregation effects. MASAFUYU MATSUI (Presenter), HISAO NAKAMURA, AIST — We develop theoretical method to analyze optical response of nanoparticles by combining with discrete dipole approximation. To clarify microscopic level mechanism of plasmon resonance and near field effect, the induced dipole is decomposed into contributions from the electric field by incident light (an incident light term) and that by the induced dipole oscillations (a dipole-dipole interaction term). We examine our theoretical approach to silver nanoparticles and analyze size, shape-dependence of optical response as well as effect of aggregation. The analysis quantitatively reveals that the incident light term dominates the plasmon resonance along the direction of the small diameter whereas the dipole-dipole interaction term is dominant in that of the large diameter. To show effect of aggregation to optical response, we calculate total optical response of interacting two nanospheres. The plasmon resonance along the direction, on which two spheres are aligned, is caused by an interparticle interaction, resulting in the similar behavior to the prolate nanospheroid. These results indicate usefulness of modeling of the optical response of multi-nanoparticles by that of a shape-anisotropic nanoparticle.

9:48AM W65.00010: Size tunable passive cloaking platform using self-assembled plasmonic nanostructures. Imran Khan,1 Arnold Kim,2 and Sayantani Ghosh1 1Department of Physics, University of California, Merced, CA 95343 USA 2Department of Applied Mathematics, Univ* IMRAN KHAN (Presenter), Physics, University of California, Merced, ARNOLD D.KIM, Applied Mathematics, Univ of California - Merced, SAYANTANI GHOSH, Physics, University of California, Merced — Plasmonic cloaking works by suppressing dominant scattering harmonics radiated from the cloaked object. A shell made of plasmonic nanoparticles (NPs), in combination with the cloaked object as a core, creates the complete plasmonic cloaking structure. In this study, we present the design and fabrication of spherical nano- to micron-scale shell structures via molecular self-assembly of gold NPs, with the goal of reduced scattering and therefore, cloaking, in the VIS-NIR spectral range. Scattering suppression range is varied by tuning the critical parameters of the effective medium, such as core to shell radius ratio and the filling fraction of the NPs in the shell wall. In addition to experimental work, we have also developed a multiscale simulation platform that explicitly models multiple scattering by the gold NPs and their multiple interactions with the core. Simulation results shows that the nano-assembled spheres yield suppressed visibility in the desired spectral range.

Session W66 DCMP: Quantum Many-Body Scars Four Seasons 1 - Nicolas Regnault, Ecole Normale Superieure - Tag(s): Invited
Quantum many-body scars: a new form of weak ergodicity breaking in constrained quantum systems* [Invited] ZLATKO PAPIC (Presenter), Univ of Leeds — Recent experiments on large chains of Rydberg atoms [1] have demonstrated the possibility of realising one-dimensional, kinetically constrained quantum systems. It was found that such systems exhibit surprising signatures of non-ergodic dynamics, such as robust periodic revivals in global quenches from certain initial states. This weak form of ergodicity breaking has been interpreted as a manifestation of "quantum many-body scars" [2], i.e., the many-body analogue of unstable classical periodic orbits of a single particle in a chaotic stadium billiard. Scarred many-body eigenstates have been shown to exhibit a range of unusual properties which violate the Eigenstate Thermalisation Hypothesis, such as equidistant energy separation, anomalous expectation values of local observables and subthermal entanglement entropy. I will demonstrate that these properties can be understood using a tractable model based on a single particle hopping on the Hilbert space graph, which formally captures the idea that scarred eigenstates form a representation of a large SU(2) spin that is embedded in a thermalising many-body system. I will show that this picture allows to construct a more general family of scarred models where the fundamental degree of freedom is a quantum clock [3]. These results suggest that scarred many-body bands give rise to a new universality class of constrained quantum dynamics, which opens up opportunities for creating and manipulating novel states with long-lived coherence in systems that are now amenable to experimental study.

Quantum many-body scars: connections to integrability and stability* [Invited] ANUSHYA CHANDRAN (Presenter), Boston Univ, VEDIKA KHEMANI, Stanford University, CHRISTOPHER LAUMANN, Boston Univ, CHENG-JU LIN, Perimeter Institute for Theoretical Physics, OLEXEI I MOTRUNICH, Caltech — Quantum many-body scar states are exceptional finite energy density eigenstates in an otherwise thermalizing system that do not satisfy the eigenstate thermalization hypothesis. Recent atomic array experiments in the Rydberg blockaded regime suggests that the simplest blockaded Hamiltonian, the PXP Hamiltonian, has such scars in its spectrum. In this talk, I will discuss the connections between integrability and quantum scars by identifying a proximate integrable point at which the non-thermal signatures of the scar states become more pronounced. I will further discuss the stability of quantum scars to generic perturbations. Although the scar states hybridize with the other states in the spectrum upon perturbation, their nonthermal properties survive for a parametrically long time in quench experiments.

*This work was supported by National Science Foundation (NSF) through Grants No. DMR-1619696, PHY-1656234 and DMR-1752759. The work was also supported by the Sloan Foundation through the Sloan Research Fellowship and by the Perimeter Institute for Theoretical Physics.
We study the spin-1 XY model on a hypercubic lattice in d dimensions and show that this well-known nonintegrable model hosts an extensive set of anomalous finite-energy-density eigenstates with remarkable properties. Namely, they exhibit subextensive entanglement entropy and spatiotemporal long-range order, both believed to be impossible in typical highly excited eigenstates of nonintegrable quantum many-body systems. While generic initial states are expected to thermalize, we show analytically that the eigenstates we construct lead to weak ergodicity breaking in the form of persistent oscillations of local observables following certain quantum quenches—in other words, these eigenstates provide an archetypal example of so-called quantum many-body scars. This work opens the door to the analytical study of the microscopic origin, dynamical signatures, and stability of such phenomena.
9:48AM W66.00004: Phenomenology and mechanisms of Quantum many-body scarring*

[Invited] WEN WEI HO (Presenter), Harvard University, SOONWON CHOI, University of California, Berkeley, CHRISTOPHER J TURNER, University of Leeds, HANNES PICHLER, Harvard University, ALEXIOS MICHAELIDIS, IST Austria, SAMBUDDHA CHATTOPADHYAY, Harvard University, ZLATKO PAPIC, University of Leeds, MAKSYM SERBYN, IST Austria, DMITRY ABANIN, University of Geneva, MIKHAIL LUKIN, Harvard University — A central postulate of statistical mechanics is ergodicity -- a generic interacting, quantum many-body system initialized out of equilibrium is expected to explore its allowed phase phase and eventually thermalize. Known exceptions to this behavior include strongly disordered, many-body localized (MBL) systems, and finely-tuned integrable systems. In this talk, I will discuss a different mechanism pertaining to a weak form of ergodicity breaking: Quantum many-body scarring (QMBS) [1]. Motivated by recent quench experiments with Rydberg atom arrays [2] which observed surprisingly slow thermalizing dynamics from certain simple initial states, QMBS is tied to the presence of special, eigenstate thermalization hypothesis(ETH)-violating eigenstates in the many-body spectrum. I will first discuss how a variational description of the many-body dynamics seen in the experiments, using the time-dependent variational principle (TDVP) over a manifold of entangled matrix-product states, can capture this non-thermalizing dynamics and furthermore provide some insight into the connection to the similarly named phenomenon of quantum scars in single-particle chaos in terms of isolated, unstable, periodic orbits [3]. I will also discuss a complementary approach in which the scarred states can be understood as arising from an embedded su(2) symmetric subspace [4]. More generally, I will discuss physical mechanisms giving rise to QMBS in other settings that can be analytically understood, such as from the idea of embedded Hamiltonians [5] and from the dynamics of virtual entangled pairs [6].

10:24AM W66.00005: Integrability, Thermalization, and Quantum Scars in a Constrained Hamiltonian [Invited] SANKHYA MOUDGALYA (Presenter), Physics, Princeton University, ABHINAV PREM, Princeton Center for Theoretical Sciences, Princeton University, RAHUL NANDKISHORE, Physics, University of Colorado, Boulder, NICOLAS REGNAULT, Ecole Normale Superieure, ANDREI BERNEVIG, Physics, Princeton University — We study the quantum dynamics of a simple translation invariant, center-of-mass preserving model of interacting fermions in one dimension, which arises in multiple experimentally realizable contexts. We show that this model exhibits a Hilbert space that fractures into exponentially many dynamically disconnected Krylov subspaces. Each of the exponentially large Krylov subspaces can either be integrable or non-integrable. We analytically find examples of several integrable subspaces, and show evidence for the validity of Eigenstate Thermalization Hypothesis (ETH) restricted to each non-integrable subspace. This model thus exhibits phenomenology associated with quantum scars, i.e. the fate of an initial product state under time-evolution depends on the properties of the Krylov subspaces it has weights in. In addition, some of the non-integrable Krylov subspaces show conventional quantum scars, which manifest as revivals and slow thermalization of certain charge density wave configurations.

Session W67 DCMP: Strange Metal Physics

8:00AM W67.00001: Theories of Planckian dissipation in strongly correlated systems [Invited] AAVISHKAR PATEL (Presenter), Physics, University of California, Berkeley, SUBIR SACHDEV, Physics, Harvard University — The apparently universal value, $2\pi k_B T/h$, of the transport scattering rate observed experimentally in a wide variety of non-Fermi liquid metals with $T$-linear resistivity has been a longstanding mystery in condensed matter physics; this phenomenon is called 'Planckian dissipation'. We present a lattice model of fermions with $N$ flavors and random interactions that describes a non-Fermi liquid metal at low temperatures $T \to 0$, in the solvable limit of large $N$. We begin with quasiparticles around a Fermi surface with effective mass $m^*$, and then include random interactions that lead to fermion spectral functions with frequency scaling with $2\pi k_B T/h$. The resistivity $\rho$ obeys the Drude formula $\rho = m^*/(ne^2\tau_{tr})$, where $n$ is the density of fermions, and the transport scattering rate is $1/\tau_{tr} = f 2\pi k_B T/h$; we find $f$ to be of order unity and essentially independent of the strength and form of the interactions, hence 'universal'. The random interactions are a generalization of the Sachdev-Ye-Kitaev models; it is assumed that processes nonresonant in the bare quasiparticle energies only renormalize $m^*$, while resonant processes are shown to produce Planckian dissipation. We point out some predictions of this theory that are, in principle, testable in photoemission experiments. We further present some other large $N$ models that can also give rise to Planckian dissipation under certain conditions.

*This research was supported by the U.S. Department of Energy under Award No. DE-SC0019030, and by the Miller Institute for Basic Research in Science.
The perfectly linear temperature dependence of the resistivity observed as $T \rightarrow 0$ in a variety of metals close to a quantum critical point (QCP) is a major puzzle of condensed matter physics. I will present resistivity measurements supporting that $T$-linear resistivity as $T \rightarrow 0$ is a generic property of cuprates, associated with a universal scattering rate [1]. We measured the low-$T$ resistivity of the bi-layer cuprate Bi2212 just above its pseudogap critical point $p^*$ and found that it exhibits a $T$-linear dependence with the same slope as in the single-layer cuprate Nd-LSCO close to its own $p^*$, despite their very different Fermi surfaces and structural, superconducting and magnetic properties. We then showed that the $T$-linear coefficient (per CuO$_2$ plane), noted $A$, for various cuprates presenting this phenomenon, is given by a universal relation implying a specific scattering rate for charge carriers in all these samples: $1/\tau = h/2\pi k_B T$, where $h$ is the Planck constant and $k_B$ is the Boltzmann constant. This specific scattering rate corresponds to what is called the Planckian limit, and works not only for hole-doped cuprates but also for electron-doped cuprates, despite the different nature of their QCP and strength of their electron correlations.

9:12AM W67.00003: Strange Metals and Anomalous Dimensions for Conserved Currents

[Invited] PHILIP PHILLIPS (Presenter), University of Illinois at Urbana-Champaign — The unsaturating resistivity exceeding the Ioffe-Regel-Mott bound in the strange metal phase of the cuprates implies that electrons are not the propagating degrees of freedom. The search for new degrees of freedom has led some to conclude that not only does the relevant gauge field that describes the interactions with electromagnetic radiation have an anomalous dimension but so does the current. This conclusion flies in the face of the well known result in quantum field theory that conserved quantities do not acquire anomalous dimensions under any amount of renormalization. My talk will focus on demistifying the claim of anomalous dimensions of conserved quantities. I will show that Nother’s Second Theorem[1,2] actually allows for electromagnetisms in which the conserved current and gauge field can actually have arbitrary dimensions. Specific models are constructed which exhibit such anomalies[1,2]. I will show that the resulting Aharonov-Bohm effect deviates strongly from the standard result and hence can be used a sharp test of anomalous dimensions in the strange metal phase of the cuprates.

*We thank DMR19-19143 for partial funding.

10:24AM W67.00005: Strange metallicity in the doped Hubbard model [Invited] THOMAS DEVEREAUX (Presenter), Stanford Univ — Strange or bad metallic transport, defined by its incompatibility with conventional quasiparticle pictures, is a theme common to strongly correlated materials and ubiquitous in high temperature superconductors. The Hubbard model represents a minimal starting point for modeling strongly correlated systems. Here we demonstrate strange metallic transport in the doped two-dimensional Hubbard model using determinantal quantum Monte Carlo calculations. Over a wide range of doping, we observe resistivities exceeding the Mott-Ioffe-Regel limit with linear temperature dependence. The temperatures of our calculations extend to as low as 1/40 the non-interacting bandwidth, placing our findings in the degenerate regime relevant to experimental observations of strange metallicity. Our results provide a foundation for connecting theories of strange metals to models of strongly correlated materials.
Organic electrochemical transistors (OECTs) have gained considerable interest for applications in bioelectronics, power electronics, circuits and neuromorphic computing. Their defining characteristic is the bulk-modulation of channel conductance owing to the facile penetration of ions into the (semi)conducting polymeric channel. For this reason, their device scaling relies on film thickness, and often relaxes the stringent demands of clean and controlled interfaces required in traditional FETs. Despite recent progress and a rapidly expanding library of new materials, the understanding of stability and transport/coupling of ionic and electronic carriers remain largely unexplored. We highlight recent synthetic and processing approaches used to tailor device properties and stability, as well as new opportunities enabled by such advances. Our understanding of critical processes in electrochemical devices further requires us to study these materials in device-relevant conditions, considering the effects of ions and solvent on microstructure and transport. To this end, we report on recent efforts using ex situ as well as operando scattering and spectroscopy to build a more device-relevant picture of structure-transport relations.
Visualizing charge transfer across length scales in printable, conductive polymer electrodes* [Invited] ERIN RATCLIFF (Presenter), Univ of Arizona — Organic electrochemical transistors leverage the unique hybrid electrical/ionic conduction mechanism of conductive polymers when interfaced with mobile electrolyte species. Understanding the underlying structure-function properties of charge transport and transfer is critical to new technological development. Specifically, semicrystalline conductive polymers exhibit a heterogeneous spatial landscape of sub-populations of different electronic and physical properties at nanometer length scales. Each of these sub-populations is expected to have different potential-dependent electrical and ionic charge transport properties, but these behaviors are difficult to resolve at nanometer length scales. This talk will cover a tool suite of spectroelectrochemical methodologies that enables resolution of sub-population behaviors in conductive polymer electrodes, including measurement of potential-dependent ion diffusion coefficients. New nanoscale characterization approaches to measure localized charge transfer rates and structures will also be discussed.

Monitoring plant physiology with organic electrochemical transistors

ELENI STAVRINIDOU (Presenter), Linkoping University — Plants are the basis of food, providers of oxygens and regulators of the ecosystem. Plants convert solar energy into chemical energy with the process of photosynthesis where carbon dioxide is converted to sugar molecules. Sugars are not only the energy source in plants but also important signalling molecules, involved in regulation of physiology including stress responses. Currently there are no methods that allow real time monitoring of sugar transport in plants. Sugar detection is based on enzymatic assays, chromatography and/or mass spectrometry; all of these methods require sample collection and preparation. Organic electrochemical transistors (OECTs) are ideal tools for interfacing with organisms, since they can translate complex biological input to an electronic readout signal. OECT sensors can operate in complex media and they can directly detect products from the biological unit. In my group we are developing sugars sensors based on the organic electrochemical transistor for monitoring plant processes in-vitro and in-vivo. In a first example we measure the export of glucose in real time, from isolated chloroplasts, with a temporal resolution of 1min. The OECT based platform is able to distinguish the metabolic phase of the chloroplast prior isolation from the plant. In another example we are developing implantable OECT-based sugar sensors for in-vivo, real time monitoring of sugar transport in trees. The OECTs sensors show high device to device reproducibility, stability during the operation in the in-vivo environment and most importantly they do not cause a significant wound response from the plant. The sensors reveal kinetics of sugars transport that were not observed before. Our work benchmarks the OECT-based sensors as powerful tools for monitoring processes in plants, in real time both, in-in vivo and in-vitro systems.

Electrolyte-Gated Transistors for Fundamental Physics and Applications

C. DANIEL FRISBIE (Presenter), University of Minnesota — Electrolyte-gated transistors (EGTs) constitute a general class of devices in which an electrolyte is employed as the gate insulator; the very large capacitance of the electrolyte results in low voltage operation, high gate-induced carrier densities, and consequently high transconductance. These devices are divided into two broad categories, either the electric double layer transistor (EDLT) or the electrochemical transistor (ECT), depending on the mechanism of operation. This talk will begin with a general description of EGTs using a solid state electrolyte or ion gel, including typical fabrication methods, principles of operation (i.e., electrochemical vs double-layer charging), and quasi-static and dynamic performance. Applications of EGTs in printed electronics and biosensing will be briefly described, and then the discussion will move to use of EGTs to explore transport physics in novel materials at high carrier density. Specific examples include double layer gating of organic semiconductor single crystals such as rubrene and C60, and 2D materials, such as tellurene. In the case of tellurene, we are able to access the insulator-to-metal transition.

Adapting organic electronics to biology (and not vice versa)!*

RÓISÍN OWENS (Presenter), Chemical Engineering and Biotechnology, University of Cambridge — In vitro models of biological systems are essential for our understanding of biological systems. In many cases where animal models have failed to translate to useful data for human diseases, physiologically relevant in vitro models can bridge the gap. Many difficulties exist in interfacing complex, 3D models with technology adapted for monitoring function. Polymeric electroactive materials and devices can bridge the gap between hard inflexible materials used for physical transducers and soft, compliant biological tissues. An additional advantage of these electronic materials is their flexibility for processing and fabrication in a wide range of formats. In this presentation, I will discuss our recent progress in adapting conducting polymer devices, specifically the Organic Electrochemical Transistor (OECT), to integrate with 3D cell models. We go further, by generating 3D electroactive scaffolds capable of hosting and monitoring cells. I will also highlight recent research using biomimetic models of cell membranes interfaced with organic electronic electrodes and transistors for drug discovery.

Session X01 DAMOP: Dissipative and Far-From-Equilibrium Quantum Dynamics in AMO Systems 103
11:15AM X01.00001: Theory of non-Hermitian fermionic superfluidity subject to inelastic collisions in ultracold atoms  KAZUKI YAMAMOTO (Presenter), Department of Physics, Kyoto University, MASAYA NAKAGAWA, Department of Physics, University of Tokyo, KYOSUKE ADACHI, BDR, RIKEN, KAZUAKI TAKASAN, Department of Physics, UC Barkeley, MASAHITO UEDA, Department of Physics, University of Tokyo, NORIO KAWAKAMI, Department of Physics, Kyoto University — In recent years, non-Hermitian (NH) quantum systems have been actively studied [1,2]. However, since most of the previous studies dealt with single-particle physics, understanding of many-body physics in NH systems is yet in its infancy.

Motivated by recent experimental advances in ultracold fermionic atoms, we analyze a non-Hermitian (NH) BCS Hamiltonian with complex-valued interactions arising from inelastic scattering between fermions [3]. We develop a mean-field theory to obtain a NH gap equation for order parameters, which are similar to but different from the standard BCS ones because of the inequivalence of left and right eigenstates in the NH physics. We find unconventional phase transitions unique to NH systems: the superfluidity breaks down and reappears with increasing dissipation, featuring exceptional points for weak attractive interactions. As for strong attractive interactions, the superfluid gap never collapses but is enhanced by dissipation due to an interplay between the BCS-BEC crossover and the quantum Zeno effect.

11:27AM X01.00002: The Threefold Way in Non-Hermitian Random Matrices*  RYUSUKE HAMAZAKI (Presenter), KOHEI KAWABATA, NAOTO KURA, MASAHITO UEDA, Physics, University of Tokyo — Non-Hermitian random matrices have been utilized in diverse scientific fields such as dissipative and stochastic processes, nuclear physics, and neural networks. However, the only known universal level-spacing statistics are those of the Ginibre ensemble characterized by complex-conjugation symmetry. In this talk, we report our discovery of two distinct universality classes characterized by transposition symmetry [1]. We find that transposition symmetry alters repulsive interactions between two neighboring eigenvalues and deforms their spacing distribution, which is not possible with other symmetries including Ginibre's complex-conjugation symmetry which can affect only nonlocal correlations. Our results complete the non-Hermitian counterpart of Dyson's threefold classification of Hermitian random matrices and serve as a basis for characterizing nonintegrability and delocalization in open quantum systems with symmetry [1,2].

*R. H. was supported by the Japan Society for the Promotion of Science through Program for Leading Graduate Schools (ALPS) and JSPS fellowship (JSPS KAKENHI Grant No. JP17J03189).
The effective non-hermitian Hamiltonian (ENH) in strongly-correlated electron systems (SCES), which is introduced by H. Shen and L. Fu (PhysRevLett.120.146402), is derived by the spectral function, and the non-hermitian physics is now studied eagerly.

However, the essential questions, "Is this ENH the same one as the ENH in the context of open quantum system?" and "Why is the post selection not necessary to derive the ENH in SCES?", still remain. In this paper, we prove that the ENH in each context, OQS and SCES, corresponds to each other and clarify why the post selection is not necessary in SCES by treating the model in SCES as in OQS. Moreover, we propose the method to detect the non-hermitian properties in OQS without post selection, which is the great obstacle to experimental detection.

The Lindblad equation is a well-known quantum master equation that describes the evolution of open quantum systems. In general, the Lindblad equation is more challenging to analyze than the Schrödinger equation for closed systems, as one has to deal with the space of operators rather than the Hilbert space. One approach to this difficulty is to construct exactly solvable models. However, very few exact results are available for open many-body systems, although many such examples are known in closed many-body systems.

In this talk, we construct a solvable example of a quantum Ising model with bulk dissipation [1]. By vectorizing the density matrix, its Liouvillian is mapped to a non-Hermitian analog of the Ashkin-Teller model, further reducing to the staggered XXZ chain with pure-imaginary anisotropy parameters. Using this mapping, we show that the steady states are doubly degenerate and these two are unique. Moreover, we obtain the exact formula for the Liouvillian gap, the inverse relaxation time, for a particular set of parameters corresponding to a uniform XXZ chain. The result implies a kind of phase transition for the first decay mode.

*JSPS KAKENHI Grant No. 18K03445 and Institute for Physics of Intelligence
12:03PM X01.00005: Effects of dipole-dipole interaction in atomic vapors probed by two-dimensional coherent spectroscopy*  DANFU LIANG (Presenter), Department of Physics, Florida International University, SHAOGANG YU, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, YIFU ZHU, Department of Physics, Florida International University, XIAOJUN LIU, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, HEBIN LI, Department of Physics, Florida International University — Neutral atoms without permanent dipole moments can interact due to transition-induced dipole moments. Dipole-dipole interactions (DDIs) can lead to an energy shift of the atomic energy level and a change in the dephasing rate. The DDIs are usually detected by measuring the energy shift which might be difficult for weak DDIs, while the dephasing rate change has been largely overlooked. Optical two-dimensional coherent spectroscopy (2DCS) is extremely sensitive to DDIs and able to reveal the dephasing rate change due to DDIs. We implemented photon-echo, 1Q-2Q and double-quantum optical 2DCS to probe the effect of DDIs in the rubidium atomic vapor. From these spectra, we retrieved the decay rate change due to DDIs for the hyperfine levels of $^87\text{Rb}$ or $^85\text{Rb}$'s D2 lines. The results show that the change in dephasing rate is the primary effect, compared to the energy shift, of DDIs in dilute atomic vapors. This technique allows us to detect weak DDIs and measure the effects in both energy shift and dephasing rate due to DDIs.

*This research is based on work supported by the National Science Foundation (PHY-1707364)

12:15PM X01.00006: Effects of a dissipative coupling to the momentum of a particle in a double well potential*  DOMINIK MAILE (Presenter), Department of Physics, University of Konstanz, SABINE ANDERGASSEN, Department of Theoretical Physics, University of Tübingen, GIANLUCA RASTELLI, Department of Physics, University of Konstanz — Double well potentials offer the possibility of coherent state preparation and therefore constitute important building blocks in the analysis of quantum information and quantum engineering devices. Here we present a study of the coherent tunneling in a parabolic double well potential in presence of different dissipative interactions. Specifically, we investigate the effects of an environmental coupling to the momentum and/or to the position of a particle in the potential. Using the semiclassical approximation to calculate instanton paths in Euclidean time, we find that momentum dissipation greatly enhances the coherent tunnel splitting. In presence of both types of dissipation, the momentum dissipation shifts the critical coupling strength of the dissipative phase transition induced by the position dissipation.

Symmetry Breaking and Phase Transition in a Driven-Dissipative Kerr Oscillator

X. H. H. ZHANG (Presenter), HAROLD U BARANGER, Duke University — We show that quantum many-body effects can appear in a single non-linear oscillator that is driven by an external field in the presence of dissipation. This simple system is a paradigmatic example of open quantum many-body systems in which there has been great interest recently due to recent experimental advances such as quantum simulation. Here, weak non-linearity plays the role of the thermodynamic limit. Using both analytical and numerical methods, we demonstrate $\mathbb{Z}_2$ symmetry breaking and the corresponding phase transition.

Open quantum systems approach to Bose polaron problems with applications

MIGUEL GARCIA-MARCH (Presenter), Univ Politecnica de Valencia, MOHAMMAD MEHBOUDI, CHRISTOS CHARALAMBOUS, ICFO - The Institute of Photonics Sciences, ANIELLO LAMPO, Internet Interdisciplinary Institute (IN3), LUIS A. CORREA, University of Exeter, MACIEJ A LEWENSTEIN, ICFO - The Institute of Photonics Sciences — We discuss the dynamics of one and two quantum impurities immersed in a homogeneous or trapped Bose-Einstein condensate (BEC) in the framework of the quantum Brownian motion model [1-4]. When the impurities are untrapped, we show that the long-time behavior is superdiffusive. For the trapped impurities, we discuss the realistic conditions for the final state to be squeezed or to present entanglement in the two impurities case. We discuss two applications: i) for quantum non-demolition thermometry in a BEC [5]; and ii) to construct a system that permits a heat current between two BECs, and evaluate this system as a thermal diode [6].

12:51PM X01.00009: Universality in the decay and revival of Loschmidt Echoes  MYUNG-JOONG HWANG (Presenter), Division of Natural Sciences, Duke Kunshan University, BO-BO WEI, Physics department, The Chinese University of Hong Kong, Shenzhen, SUSANA HUELGA, MARTIN PLENIO, Institute of Theoretical Physics, Ulm university — Understanding non-equilibrium quench dynamics through a quantum phase transition is an important theoretical task. It has long been observed that a sudden quench dynamics near a quantum phase transition characterised by the Loschmidt echo exhibits a critically enhanced decay. In this contribution, we present the dynamical scaling laws that govern the decay and revival of the Loschmidt echo completely characterised by equilibrium critical exponents of a critical point. We reveal such dynamical scaling laws by analyzing relevant perturbations to the Loschmidt echo cast in a scaling invariant form. We will show the validity and the generality of the predicted dynamical scaling laws using numerical calculation of a diverse range of critical models such as Ising spin models with a short and long range interaction, a finite-component system phase transition, and a topological phase transition. Our finding promotes the Loschmidt echo to a quantitative non-equilibrium probe of criticality and allows for quantitative predictions on the role of criticality on various physical scenarios where the Loschmidt echo is central to describing non-equilibrium dynamics.

1:03PM X01.00010: Analytical Study of Decoherence in Rydberg Atom Qubits  ANANT KALE (Presenter), MANUEL ENDRES, Caltech — Individually trapped neutral atoms are a promising candidate for use in quantum computing and simulation applications. Entanglement can be generated between these atoms via strong dipole-dipole interactions by driving them to highly excited Rydberg states (n>20). However, the fidelity of single qubit operations as well as 2 qubit entangling gates is limited by several decoherence channels of which the dominant ones are finite temperature effects, laser frequency noise and intensity noise. Here we present an analytical (perturbative) expression for the effect of these noise sources on the rabi oscillations of a single atom and a pair of atoms in the Rydberg blockade regime. We derive this result in terms of the power spectral density (PSD) of the noise sources and use it to predict the maximum achievable single qubit and 2-qubit gate fidelities. Using this analytical result, we can appropriately adjust the driving laser’s locking parameters in experiments to modify its PSD and increase coherence time as well as gate fidelities. This work provides crucial insight for upcoming experiments aiming to entangle two alkaline-earth atoms for the first time.

1:15PM X01.00011: Non-Hermitian topological light steering  HAN ZHAO, XINGDU QIAO, TIANWEI WU (Presenter), BIKASHKALI MIDYA, University of Pennsylvania, STEFANO LONGHI, Dipartimento di Fisica, Politecnico di Milano, LIANG FENG, University of Pennsylvania — Photonic topological insulators provide a route for disorder-immune light transport, which holds promise for practical applications. Flexible reconfiguration of topological light pathways can enable high-density photonics routing, thus sustaining the growing demand for data capacity. By strategically interfacing non-Hermitian and topological physics, we demonstrate arbitrary, robust light steering in reconfigurable non-Hermitian junctions, in which chiral topological states can propagate at an interface of the gain and loss domains. Our non-Hermitian–controlled topological state can enable the dynamic control of robust transmission links of light inside the bulk, fully using the entire footprint of a photonic topological insulator.
**1:27PM X01.00012: Quantum Quenches in Coupled Luttinger Liquids: Truncated Spectrum Approach vs Semi-Classics**

ROBERT KONIK (Presenter), CMPMSD, Brookhaven National Laboratory, ANDREW JAMES, Physics, Open University, ANDREW HALLAM, Physics, University of Ghent — We consider a quantum quench of multiple Luttinger liquids. Here we initialize the system by supposing the Luttinger liquids are in their ground state. At t=0 we turn on a tunnel coupling between the liquids. We then study the subsequent time evolution of quantities such as the mode occupation numbers. We show that there are discrepancies between the results as determined by the truncated spectrum approach and a semi-classical treatment. We argue that this difference is real through unitary perturbation theory which is exact at short times. We comment on the relevance of these results for experimental quantum quenches on two coupled Luttinger liquids.

*We acknowledge support by the Office of Basic Energy Sciences, Material Sciences and Engineering Division, US Department of Energy (DOE) under Contract No. DE-SC0012704.

**1:39PM X01.00013: Non-equilibrium dynamics of the Pokrovsky-Talapov model**

VALENTIN KASPER (Presenter), ICFO, JAMIR MARINO, University of Mainz, SICONG JI, JOERG SCHMIEDMAYER, TU Vienna, EUGENE DEMLER, Harvard University — The unprecedented control in AMO systems allows us to study paradigmatic models of solid-state and high-energy physics. In particular AMO systems give us the unique opportunity to study the non-equilibrium physics of systems of closed quantum systems which is difficult or impossible in a solid state or high energy context. In this work we study the non-equilibrium physics of the Pokrovsky-Talapov model which is effectively realized by two Raman tunnel-coupled one-dimensional Bose gases. In particular, we study two quench protocols: a quench from the commensurate to incommensurate phase and vice versa. In particular, we compute the short and medium time dynamics of density and phase fluctuations and comment on the dynamics of emergent defects in this system.

**1:51PM X01.00014: New exact eigenstates in the Lesanovsky model, proximity to integrability and the PXP model, and approximate scar states**

DANIEL MARK (Presenter), Department of Physics, Caltech, CHENG-JU LIN, Perimeter Institute for Theoretical Physics, OLEXEI I MOTRUNICH, Department of Physics, Caltech — Cold Rydberg atoms have received significant recent attention. We study a model of Rydberg atoms in a nearest-neighbor Rydberg blockaded regime, introduced by Lesanovsky in Phys. Rev. Lett. 108, 105301 (2012). This many-body model (which has one parameter $z$) has an exactly known gapped, liquid ground state, and two exactly known low-lying excitations. We discover two new exact low-lying eigenstates. We also discuss behavior of the model at small parameter $z$ and its proximity to an integrable model. Lastly, we discuss connections between the PXP and Lesanovsky models at intermediate $z$. The PXP model describes a recent experiment that observed unusual revivals from a charge density wave initial state, which are attributed to a set of many-body "scar states" which do not obey the eigenstate thermalization hypothesis. We discuss the possibility of scar states in the Lesanovsky model.

Friday, March 6, 2020 11:15 AM - 1:39 PM
11:15AM X02.00001: Modeling and experimental studies of neat and metal-doped stishovite, coesite, and quartz under high pressure.*  ISKANDER BATYREV (Presenter),
MICHAEL C GOLT, ROSARIO C SAUSA, CCDC Army Research Laboratory —
The results of a comparative study of neat and doped silicon dioxide polymorphs (Fe, Ni or Cu) obtained by density functional theory (DFT) at 0 K and at ambient pressure, 10 GPa, and 20 GPa are presented. The metal atoms are introduced at substitutional and octahedral interstitial sites of the crystal, and the relaxed structures are analyzed and ranked according to total energy. Changes in the enthalpy of the neat and doped crystals are estimated at selected temperatures using quantum mechanics molecular dynamics (DFT-MD). We report the modeled enthalpy of the neat and doped crystals, as well as the dependency of the unit-cell parameters, band gaps, and Raman-active modes on pressure, and compare some of these results to those obtained experimentally using a diamond anvil cell. In addition, we present our search results of the high-pressure phases of silicon dioxide using DFT-based evolutionary simulations and report on the stability of the silica phases, as evaluated by convex-hull construction.

11:27AM X02.00002: Dynamics of the High-Pressure Phase Transition in 2,4,6-triamino-1,3,5-trinitrobenzene (TATB)*  BRAD STEELE (Presenter), MATTHEW KROONBLAWD, I-FENG W KUO, Lawrence Livermore Natl Lab — Understanding the sensitivity and performance of energetic materials (EMs) requires information on how they respond under extreme conditions. TATB is an insensitive crystalline EM with graphitic-like layers and a resilient 2D intermolecular hydrogen bonded network. Recent static compression diamond anvil cell experiments combined with first-principles calculations found evidence it undergoes a high-pressure phase transition that involves sliding of its graphitic layers. Layer sliding alters the stacking motif and leads to a transition from a triclinic to monoclinic unit cell. In this work, the dynamics of the phase transition under pressure are investigated using density functional theory and a classical force field. Assessments of the thermodynamic drivers and kinetic barriers for the transition are discussed.

*This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344. Thanks to the Laboratory Directed Research and Development Program at LLNL for supporting this study under 18-SI-004.
11:39AM X02.00003: Pseudopotentials for simulations of materials at extreme conditions*

D HAMANN (Presenter), Physics and Astronomy, Rutgers University, Piscataway, NJ and Mat-Sin Research LLC, Murray Hill, NJ, JOHN PASK, Physics Division, Lawrence Livermore Nat. Lab., Livermore, CA — The ONCVPSP approach [1] has been extended to permit deep core electrons to be active and to accurately reproduce atomic scattering properties to high energies. The basic principles of generalized norm conservation and systematic convergence optimization have been preserved. The original algorithms have been revised to permit consistent optimization of multiple pseudo wave functions for each angular momentum. Ground-state benchmark performance with active deep levels is comparable to that for the original 1 and 2 projector valence plus shallow-core potentials. A confined-atom model has been developed to compare pseudo and all-electron atoms at extreme temperatures and pressures, and verifies the accuracy of the extended potentials up to temperatures which ionize deep core electrons. The open-source oncvpsp-4.0.1 code incorporating these advances for scalar- and fully-relativistic treatments is now available.

*This work was performed in part under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

11:51AM X02.00004: Chemical Potential of Nitrogen at High Pressure and High Temperature: Application to Phase Diagram Calculations of Nitrogen-Rich Compounds*

HANOF ALKHALDI (Presenter), PETER KROLL, University of Texas at Arlington — High-pressure research of nitrogen-rich compounds is driven by a quest for hard materials and compounds with high energy density, but also has implications for planetary science. To predict the formation of nitrogen-rich compounds at high pressure and high temperature, knowledge of the chemical potential of nitrogen at extreme conditions is an indispensible ingredient. Here, we provide models together with intelligible data for the chemical potential of molecular nitrogen at temperature and pressure conditions relevant for experiments in the diamond anvil cell. In combination with first-principles calculations, we derive pressure−temperature phase diagrams readily accessible to guide experimental efforts. We demonstrate the validity of our approach for characteristic systems, including pure nitrogen and nitrogen-rich metal nitrogen phases that have already been discovered at pressures above 50 GPa. We then provide predictions for new metal-nitrogen compounds awaiting their synthesis at high pressure and high temperature.

Finite-Temperature Dynamics of Elemental Electrides Under Extreme Conditions

REETAM PAUL (Presenter), SUXING HU, VALENTIN KARASIEV, Laboratory for Laser Energetics, University of Rochester, NY, STANIMIR BONEV, Lawrence Livermore National Laboratory, CA — Crystalline alkali metals generally exhibit near free-electron behavior at ambient conditions. For sodium at high pressures of above 200GPa, a deviation from such a metallic behavior was found in the insulator hP4 electride phase[1]. We investigated the temperature-induced changes in such systems using density functional theory. For the solid phase, the closure of the band gap with increasing temperature was explored through a comparison between the time scales for electron–phonon and phonon–phonon interactions. However, the more-intriguing aspect has been the observation of a metallic state, upon melting of Na-hP4, with coalescent dynamic electron bubbles rather than a conventional uniform electron gas. In essence, the emphasis of this work is to highlight the differences between the dynamics of the electride phases of pure elements, e.g., Na-hP4, vis-à-vis non-electride phases, e.g. Na-tI19, under thermal effects.

This material is based upon work supported by the Department of Energy National Nuclear Security Administration under Award Number DE-NA0003856.

A first-principles study on the phase stability of Mg$_{1-x}$Fe$_x$N alloys: the unconventional rock-salt occurrence under high pressure

MARIBEL NUNEZ VALDEZ (Presenter), Goethe University Frankfurt, JOHANNES WAGNER, Helmholtz-Zentrum Potsdam (GFZ) — Due to the large atomic radius difference of Mg and Fe, alloys between them cannot be synthesized at ambient pressure. However, using a combination of high pressure and nitrogen incorporation, Serghiou et al [1] reported a rock-salt (RS) solid solution formation between MgN and FeN. The potential of these materials for applications in spintronics and their structural analog condition to Mg$_{1-x}$Fe$_x$O, one of the most abundant phases of the Earth's interior, require knowledge of their properties. Therefore, we employ ab initio electronic structure calculations based on density functional theory (DFT) to investigate the field stability, structural and magnetic properties of bulk Mg$_{1-x}$Fe$_x$N. Our results provide insights to understand the interplay between pressure and composition to stabilize the RS structure and the rise/suppression of magnetism in the solid solution.

M. Núñez Valdez is also at the Helmholtz-Zentrum Potsdam (GFZ).

**Local Hydrodynamic Pressure for Strongly Inhomogeneous States**

JAMES DUFTY (Presenter), JEFFREY WRIGHTON, Physics, University of Florida, KAI LUO, Geophysical Laboratory, Carnegie Institution for Science —

Continuum descriptions of complex systems, both classical and quantum, are increasingly adopted as alternatives first principles many-body analyses. The macroscopic momentum balance equation has its origin in the underlying exact conservation law, with a precisely defined operator for the associated momentum flux. Its average in a local equilibrium ensemble provides the basis for a hydrodynamic description. In particular, a local pressure is defined in terms of the trace of the average momentum flux. Other definitions for a local pressure are possible, such as a local virial pressure or a thermodynamic pressure obtained from the grand potential for local equilibrium. It is shown that all three local pressures have the same global pressure but differ locally, except for weakly inhomogeneous states. For uniform temperature, the trace of the momentum flux agrees with the local thermodynamic pressure even for strong density inhomogeneity.

This provides an important connection to density functional methods for hydrodynamic applications. For non-uniform temperatures and strong inhomogeneities there is no simple relationship among the different definitions of the local pressure, so the proper choice is that from the average momentum flux.

**32 Ages of the universe in just 2 weeks: High-speed Shock-waves in DFT**

JACOB WILKINS (Presenter), Oxford e-Research Centre, University of Oxford, MATT I. J. PROBERT, Department of Physics, University of York — To date, the ab initio exploration of materials in extreme conditions has focused on equilibrium studies. However, this fails to capture the dynamic effects commonly seen in the shock-waves used to reach extreme conditions experimentally. In order to more accurately reproduce these mechanisms, we have developed a partially fire-and-forget approach to induce a series of independent shocks into the medium, to determine the shock response of the material.

We have also used optimisations of the Hugoniostat[1] approach tailored to ab initio calculation, so that we can use DFT-based methods to accurately calculate a complete Hugoniot in a single calculation. Using the series of isolated shocks and a predictor algorithm to approach the target pressure in uniform steps. From this, we can extract an ideal coupling parameter, reducing the calculation time, even for extreme compressions.

These two distinct improvements make it feasible to perform ab initio shock studies with high accuracy in DFT. We demonstrate these capabilities with simulations of shocks in quartz.

12:51PM X02.00009: Study of compaction, preheating and strength in shock compressed porous silica  JASON KOSKI (Presenter), KEITH A JONES, TRACY JOHN VOGLER, J MATTHEW D LANE, Sandia National Laboratories — The shock response of porous silica is investigated using molecular dynamics. We develop Hugoniot curves of amorphous SiO$_2$ as a function of initial preheat temperature for $T = 300K$ to $T = 600K$ and a range of porous states ranging from full density (2.2 g/cc) down to aerogel densities (0.22 g/cc). We focus on relatively low shock pressures (under 6.0 GPa) where the compaction state changes significantly in this regime. We show peak and residual shear stress plots as a function of pressure for this system. We find that the overall strength is dependent on the compaction state of the material, which is a function of both the initial temperature and initial porosity.

1:03PM X02.00010: Accelerating the characterization of energy landscapes with swarm intelligence and machine learning*  LI ZHU (Presenter), RONALD COHEN, TIMOTHY A STROBEL, Carnegie Inst of Washington — The prediction of reaction pathways for solid-solid transformations remains a key challenge. Here, we develop a pathway sampling method via swarm intelligence and graph theory and demonstrate that our PALLAS method is an effective tool to help understand phase transformations in solid-state systems. The method is capable of finding low-energy transition pathways between two minima without having to specify any details of the transition mechanism a priori. We benchmarked our PALLAS method against known phase transitions in cadmium selenide (CdSe) and silicon (Si). PALLAS readily identifies previously-reported, low-energy phase transition pathways for the wurtzite to rock-salt transition in CdSe and reveals a novel lower-energy pathway that has not yet been observed. In addition, PALLAS provides detailed information that explains the complex phase transition sequence observed during the decompression of Si from high pressure. We also introduce a computationally efficient approach based on machine learning techniques, allowing us to map the energy landscapes efficiently. The PALLAS methodology represents a promising tool for materials by design with valuable insights for novel synthesis.

1:15PM X02.00011: Anomalies in thermal properties of ferromagnesite \((\text{Mg}_{1-x}\text{Fe}_x)\text{CO}_3\) across the spin transition*

HAN HSU (Presenter), CHRISTIAN CRISOSTOMO, National Central University, Taiwan, WENZHONG WANG, ZHONGQING WU, University of Science and Technology of China — Ferromagneiste \((\text{Mg,Fe})\text{CO}_3\) is considered as a major carbon carrier in the Earth’s lower mantle. Thorough knowledge of this mineral at high pressure \((P)\) and temperature \((T)\) can thus provide valuable insights to the Earth's deep carbon cycle. With \(\text{Fe}^{2+}\) substituting \(\text{Mg}^{2+}\) in the octahedral site, \((\text{Mg,Fe})\text{CO}_3\) undergoes a spin transition from the high-spin \((\text{HS}, S = 2)\) to the low-spin \((\text{LS}, S = 0)\) state at 45–50 GPa. Previous static calculations [1] adopting the local density approximation + self-consistent Hubbard \(U\) (LDA+U_\text{sc}) method have successfully explained the spin transition and accompanying volume/elastic anomalies observed in room-temperature experiments. Here, by combining LDA+U_\text{sc} with lattice dynamics, we compute the thermal properties of \((\text{Mg,Fe})\text{CO}_3\) at high-\((P,T)\) conditions. Our results indicate that nearly all thermal properties, including thermal expansion, Grüneisen parameter, heat capacity, and thus thermal conductivity, are significantly changed by spin transition. Geophysical and geochemical consequence of spin transition in \((\text{Mg,Fe})\text{CO}_3\) can thus be expected.

*The work is primarily supported by the Ministry of Science and Technology of Taiwan under Grants No. MOST 107-2112-M-008-022-MY3 and 107-2119-M-009-009-MY3.

1:27PM X02.00012: Shock compression of dry Air*

NILANJAN MITRA, SUBHADEEP PAL (Presenter), Indian Institute of Technology Kharagpur — A molecular dynamics based shock compression study is presented for dry air. Dry air is modeled to consist of 78.08% of Nitrogen, 20.95% of Oxygen and 0.97% of Carbon-dioxide. Shock Hugoniot curves are developed for air under various initial temperature and pressure conditions simulating air at various mean-sea-level altitudes. Reactive potentials have been used for the simulations and possibilities of dissociation and ionization of the gaseous molecules along with chemical reactions between the gasses have been investigated. Equation of state parameters are also derived from the MD simulations for use in continuum simulations.

Session X08 DQI: Qubit Coherence and Noise Characterization 104 - Kevin Young, Sandia National Laboratories
11:15AM X08.00001: Anomalous Charge Noise in Superconducting Qubits  CHRIS WILEN (Presenter), BRADLEY CHRISTENSEN, ALEXANDER M OPREMCKA, AMEYA RISWADKAR, LARA FAORO, LEV B IOFFE, ROBERT F MCDERMOTT, University of Wisconsin - Madison — We describe experiments to probe fluctuations in offset charge in weakly charge-sensitive superconducting qubits that depart from the transmon regime. We explore a range of device geometries to elucidate the surprising scale dependence of charge noise in these qubits, and we describe experiments to investigate possible spatial correlation in charge fluctuations in neighboring devices. Since quantum error correction schemes such as the two-dimensional surface code rely on the assumption of uncorrelated noise, these studies could have implications for scale-up towards fault-tolerant superconducting qubit arrays.

11:27AM X08.00002: Phonon traps reduce the quasiparticle density in superconducting circuits  FRANCESCO VALENTI (Presenter), FABIO HENRIQUES, THIBAULT CHARPENTIER, MARC LAGOIN, CLEMENT GOURIOU, Karlsruhe Institute of Technology, MARIA MARTÍNEZ, Universidad de Zaragoza, LAURA CARDANI, MARCO VIGNATI, INFN-Sezione di Roma, LUKAS GRUENHAUPT, DARIO GUSENKOVA, JULIAN FERRERO, SEBASTIAN T. SKACEL, WOLFGANG WERNSDORFER, ALEXEY V. USTINOVI, Karlsruhe Institute of Technology, GIANLUIGI CATELANI, Forschungzentrum Jülich, OLIVER SANDER, IOAN-MIHAI POP, Karlsruhe Institute of Technology — Out of equilibrium quasiparticles (QPs) are a main source of decoherence in high impedance superconducting quantum circuits. Despite significant progress in the understanding of QP dynamics, pinpointing their origin and decreasing their density remain outstanding tasks. The cyclic process of recombination and generation of QPs implies the exchange of phonons between the superconducting film and the underlying substrate. Reducing the number of substrate phonons with frequencies above the spectral gap of the superconductor should result in a reduction of QPs [1]. Indeed, we demonstrate that surrounding high impedance resonators made of granular aluminum (grAl) with lower gapped thin film aluminum islands increases the internal quality factors of the resonators in the single photon regime, suppresses the noise, and reduces the rate of observed QP bursts [2]. The aluminum islands are positioned far enough from the resonators to be electromagnetically decoupled, thus not changing the resonator frequency, nor the loading. We therefore attribute the improvements observed in grAl resonators to phonon trapping at frequencies close to the spectral gap of aluminum, well below the grAl gap.

11:39AM X08.00003: Photon-assisted charge-parity switches in superconducting qubits*
KYLE SERNIAK (Presenter), Yale University, MANUEL HOUZET, Univ. Grenoble Alpes, CEA, INAC-Phelips, Grenoble, France, GIANLUIGI CATELANI, JARA Institute for Quantum Information (PGI-11), Forschungszentrum Jülich, Germany, SPENCER DIAMOND, MAX HAYS, VALLA FATEMI, MICHEL H. DEVORET, LEONID GLAZMAN, Yale University — Here we identify a mechanism by which stray photons, with energy large enough to break Cooper pairs, can cause decoherence in superconducting qubits. Similar to decoherence induced by steady-state nonequilibrium quasiparticles, these photon-assisted tunneling (PAT) processes are associated with a change in the charge parity of the qubit. This enables the separation of these quasiparticle-related processes from other contributions to decoherence. Our theory predicts similar rates of PAT-induced relaxation and excitation of the qubit, in agreement with recent experiments. This talk will detail the similarities and differences between PAT processes and decoherence induced by nonequilibrium quasiparticle tunneling.

*Work supported by: ARO, NSF, ANR, and AFOSR

11:51AM X08.00004: Microscopic charging and in-gap states in superconducting granular aluminum*
FANG YANG, Institute for Nanoelectronic Devices and Quantum Computing, Fudan University Shanghai, TIM STORBECK, THOMAS GOZLINSKI, LUKAS GRUENHAUPT (Presenter), IOAN-MIHAI POP, WULF WULFHEKEL, Physikalisches Institut, Karlsruhe Institute of Technology — Granular aluminum (grAl) is a viable material for high-impedance quantum circuits [1], thanks to its high kinetic inductance, low microwave frequency losses [2], and fabrication by deposition of pure aluminum in an oxygen atmosphere. The material’s microstructure – pure aluminum grains in non stoichiometric aluminum-oxide – can be modeled as a Josephson junction array [3], in which the oxide thickness is controlled by the oxygen partial pressure during deposition. Here we present scanning tunneling microscope measurements of the local electronic structure of superconducting grAl and we confirm an increased superconducting gap in the grains of films with $\rho \approx 300 \, \mu\Omega\text{cm}$ and $\rho \approx 2000 \, \mu\Omega\text{cm}$. In the high resistivity film, we find Coulomb charging effects, a first indication for grain decoupling, and in-gap states on individual grains, which could contribute to flux noise and dielectric loss not only in devices employing grAl, but also in pure aluminum circuits, where such states could form in Josephson junctions or in oxidized aluminum surfaces.

**12:03PM X08.00005: Probing non-equilibrium quasiparticle populations in superconducting quantum circuits.**

JAMES FARMER (Presenter), DARIAN HARTSELL, HAIMENG ZHANG, EVANGELOS VLACHOS, ELI M LEVENSON-FALK, Univ of Southern California — Non-equilibrium quasiparticle (QP) populations in superconducting quantum circuits are a limiting source of decoherence. When properly phase biased, nanobridge Josephson junctions provide sub-gap bound states for QPs and so function as QP traps [1]. The occupation of a trap state by a QP alters the inductive contribution of the junction to its host circuit. Thus, the population of QPs trapped in the junction can be directly measured by probing the resonance of a capacitively shunted nanobridge with standard superconducting qubit hardware. By measuring QP trapping in real time and performing statistical analyses, one can infer information about the QP generation, annihilation, and trapping mechanisms. We discuss these single-shot fidelity measurements of QPs trapping in the junctions of a nanobridge SQUID embedded in a superconducting resonator. We further discuss the use of our device as a tool for measuring QP properties and for testing methods of QP mitigation. [1] E. M. Levenson-Falk, F. Kos, R. Vijay, L. Glazman, and I. Siddiqi, Phys. Rev. Lett. 112, 047002 (2014).

**12:15PM X08.00006: Improved material loss measurement using cryogenic resonator testbed**

HAOZHI WANG (Presenter), COREY RAE MCRAE, KEEGAN MULLINS, University of Colorado, Boulder, JOSH MUTUS, DAVID FORK, Google, DAVID PAPPAS, NIST Boulder — Loss measurements are critical for the superconducting qubit community as the coherence of quantum systems are limited by loss through energy relaxation. The standard procedure for measuring loss is to design and fabricate resonators that incorporate the material-under-test and measure the temperature, power, and geometry dependence. By analyzing the transmission $S_{21}$ data on complex plane, it is possible to extract the internal quality factor, $Q_i$, i.e. the inverse of the loss tangent of the material. However, there are several variations of experimental set-up, measurement and fitting algorithms used in the field. This results in uncertainty when comparing $Q_i$ values between research groups. In this talk, we will compare the results of different measurement configurations, especially for input and output line filtering and isolation, and quantify the accuracy of loss measurement in order to identify best practices for resonator measurement and setup procedures.

**12:27PM X08.00007: Detection of non-equilibrium quasiparticles in charge sensitive transmons**

CIHAN KURTER (Presenter), MARTIN O SANDBERG, VIVEKANANDA ADIGA, ZLATKO MINEV, AARON FINCK, IBM Tj Watson Research Center, ANDREW EDDINS, ROBERT M SHELBY, IBM Almaden Research Center, MARKUS BRINK, JERRY M. CHOW, IBM Tj Watson Research Center — Non-equilibrium quasiparticles are considered possible sources causing decoherence in superconducting qubits. Thus, exploring the dynamics of quasiparticles is crucial to understand their mechanism and how to minimize their presence in superconductors. Here, we study charge parity fluctuations in 2D transmon qubits with sufficiently strong coupling and low $E_J/E_C$ ratio. We will show measurements of density of quasiparticles on various qubits to discuss impact on coherence.
12:39PM X08.00008: Experimental study of flux noise in nanowire transmons subject to an applied magnetic field*  
THIJS STAVENGA (Presenter), Delft University of Technology, FLORIAN LUTHI, Intel Corporation, ELMORE VAAL, OLUWATUMININU ALUKO, Delft University of Technology, PETER KROGSTRUP, Niels Bohr Institute, University of Copenhagen, LEONARDO DICARLO, Delft University of Technology — Flux noise is generally the dominant dephasing mechanism in transmon qubits using SQUID loops as a tunable inductive element. Continuing experimental research ambitions to elucidate the microscopic origin and mitigation of flux noise. In this work, we experimentally investigate flux noise using an unconventional knob for circuit QED: an applied magnetic field. We first present various changes introduced to our circuit QED system to further extend the field compatibility of resonators and nanowire transmons beyond 70 mT. Next, we use standard coherence measurements and sensitivity analysis on and off flux sweetspots to investigate the dependence of flux noise on field applied along the axis of the two constituent nanowire junctions.

*Research funded by the ERC Synergy Grant QC-lab, Microsoft Corporation, and the Danish National Research Foundation.

12:51PM X08.00009: Surface spin induced 1/f flux noise dependent on SQUID geometry (1)*  
LEON DING (Presenter), JOCHEN BRAUMUELLER, ANTTI VEPSALAINEN, YOUNGKYU SUNG, MORTEN KJAERGAARD, Research Laboratory of Electronics, Massachusetts Institute of Technology, TIM MENKE, Harvard University; Research Laboratory of Electronics, Massachusetts Institute of Technology, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, BETHANY NIEDZIELSKI, ALEXANDER MELVILLE, JONILYN YODER, CYRUS F. HIRJIBEHEDIN, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM OLIVER, Department of Electrical Engineering and Computer Science, Department of Physics, Massachusetts Institute of Technology; MIT Lincoln Laboratory — Magnetic flux noise is the dominant source of dephasing in tunable superconducting qubits. While the mechanism behind this 1/f flux noise is poorly understood, it has been proposed that it originates from random fluctuations of spin impurities located on the surface of SQUIDs. A previously proposed microscopic model predicts that flux noise increases with the perimeter and decreases with the wire width of the SQUID loop. Here, we demonstrate the validity of this model by measuring the flux noise amplitudes of about 50 capacitively shunted flux qubits over a wide range of geometric SQUID parameters. Our results show good agreement with the proposed model assuming independent spins, and may therefore serve as a guide on how to improve SQUID designs to minimize 1/f flux noise.

*This research was funded in part by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), and the Department of Defense (DoD) via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002. Surface spin induced 1/f flux noise dependent on SQUID geometry (2)*
JOCHEN BRAUMUELLER (Presenter), LEON DING, ANTTI VEPSALAINEN, YOUNGKYU SUNG, MORTEN KJAERGAARD, TIM MENKE, RONI WINIK, Massachusetts Institute of Technology MIT, DAVID K KIM, BETHANY NIEDZIELSKI, ALEXANDER MELVILLE, JONILYN YODER, CYRUS F. HIRJIBEHEIDIN, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM OLIVER, Massachusetts Institute of Technology MIT — The dominant source of decoherence in frequency tunable superconducting qubits is 1/f flux noise, presumably originating from local magnetic spin impurities located at the surface of their SQUID loops. Here, we measure the flux noise amplitudes of capacitively shunted flux qubits and study their dependence on geometric parameters of their SQUID loops. Our data show good agreement with a previously presented microscopic model for independent spin impurities which has so far eluded experimental verification. We discuss limitations of the proposed model for superconducting films of finite thickness and provide numerical simulations of the current distribution in our SQUIDs, which can refine the considered model. Finally, we apply and confirm our results by observing consistently low flux noise amplitudes in samples with optimized SQUID parameters – small perimeters and large wire widths.

*This research was funded in part by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), and the Department of Defense (DoD) via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002. Characterizing non-classical non-Gaussian noise: photon shot noise fluctuations*
YUXIN WANG (Presenter), AASHISH CLERK, University of Chicago — Understanding how to accurately describe environmental noise is of crucial importance for designing control protocols that enable high-fidelity quantum operations. While standard approaches often assume classical Gaussian noise, going beyond these assumptions is important in many settings. Here, we consider both the non-classical and non-Gaussian nature of photon number fluctuations in a driven dissipative quantum resonator; such fluctuations can be a significant limitation on the performance of superconducting qubits. We extend the Keldysh approach for characterizing this quantum noise [1,2] to calculate its frequency-resolved third cumulant, the so-called bispectrum. We discuss how the quantum noise bispectrum directly reveals features of non-classicality and non-equilibrium bath dynamics. We also show how this quantum bispectrum could be measured using standard experimental tools in circuit QED.

*This work was supported as part of the Center for Novel Pathways to Quantum Coherence in Materials, an EFRC funded by the US DOE, Office of Basic Energy Sciences.
1:27PM X08.00012: Identifying Noise Sources via Multi-level Quantum Noise Spectroscopy*
YOUNGKYU SUNG (Presenter), ANTTI VEPSALAINEN, JOCHEN BRAUMÜLLER, FEI YAN, JOEL WANG, MORTEN KJAERGAARD, RONI WINIK, PHILIP KRANTZ, ANDREAS BENGTTSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology MIT, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, MOLLIE SCHWARTZ, JONILYN YODER, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology MIT — Identifying dominant sources of noise and mitigating or eliminating them is crucial for engineering robust quantum devices. Although existing quantum noise spectroscopy (QNS) protocols provide insight into noise sources by measuring the noise power spectral density, they do not directly identify the physical origin of the noise process. Here, we develop and experimentally validate a multi-level QNS protocol using a superconducting transmon qubit as a spectrometer. This technique has two notable implications: First, it expands the applicability and spectral range of a qubit spectrometer beyond the two-level approximation. Second, it can be applied to higher excited levels, which enables us to extract and identify the noise contributions from multiple noise sources.

*This research was funded by the ARO grant No. W911NF-14-1-0682; and by the Department of Defense via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of the U.S. Government.

1:39PM X08.00013: Measuring effective temperatures of qubits using correlations
ANATOLY KULIKOV (Presenter), ROHIT NAVARATHNA, ARKADY FEDOROV, The University of Queensland — Initialization of a qubit in a pure state is a prerequisite for quantum computer operation. Qubits are commonly initialized by cooling to their ground states through passive thermalization or by using active reset protocols [1, 2]. To accurately quantify quality of the initialization and to shed light on origin of spurious excitation one requires an accurate tool to measure the excited state population [3]. We propose a new technique of finding the excited state population of a qubit using measurement correlations in time. We experimentally implement the proposed method using a circuit QED platform and compare its performance with previously developed techniques [4]. The method does not rely on having high-fidelity measurement or the higher energy levels. We measure the spurious qubit population with accuracy of up to ≈0.01% and discuss its possible sources.

Photon Shot Noise Limited Charge Sensitivity in a Hybrid Quantum System

SISIRA KANHIRATHINGAL (Presenter), MILES BLENCOWE, BENJAMIN BROCK, ALEXANDER J RIMBERG, Dartmouth Coll — Hybrid mesoscopic quantum systems serve as essential building blocks for quantum information and metrology devices. One such system that displays a rich variety of behavior in the quantum-classical regime is a Cooper pair transistor embedded in a quarter wave cavity (cCPT). As one application, this device can act as a highly sensitive charge detector, and form the basis for an optomechanical system in the single photon strong coupling regime. We present a theoretical analysis of the photon shot noise limited charge sensitivity of the device, assuming a low average photon number drive. This lower bound is difficult to achieve using conventional detection approaches, owing mainly to the low frequency noise caused by the coupling of thermally activated two-level-fluctuators to the cCPT. The effects of this interaction are observed as 1/f noise in the microwave cavity fundamental resonance frequency. Using careful calibration of a feedback mechanism called Pound-Drever-Hall (PDH) locking, we should be able to observe this noise near the low photon limit. Moreover, a modified PDH scheme may possibly suppress this noise, and achieve charge sensitivity close to our theoretical, minimum shot noise prediction.

*This work was supported by the NSF under Grant Nos. DMR-1807785, DMR-1507400.

Characterization of noise correlations in superconducting quantum circuits

TENGHUI WANG (Presenter), FENG WU, JINGWEI ZHOU, HAO DENG, GENGYAN ZHANG, XUN JIANG, WENLONG YU, HSIANG-SHENG KU, CHUNQING DENG, Alibaba Quantum Laboratory, Alibaba Group — Superconducting quantum circuits have been an important platform to realize a scalable quantum computing system. Qubit decoherence, which is caused by the fluctuations of its environment, remains a main obstacle to realize fault-tolerant quantum computing. To reduce decoherence, it is important to identify the source of fluctuations by precisely characterizing its correlations. Prevalent methods only consider the second order correlation under the Gaussian approximation. However, environment with higher order correlations is not uncommon in mesoscopic quantum systems. Based on a weak measurement scheme [1], we present an experiment to detect high-order correlations in a superconducting circuit. We verified the scheme by reconstructing the noise power spectral density and compared the results with that obtained from dynamical decoupling. We also demonstrated the characterization of higher-order correlation of the environment.

Session X16 DQI: Superconducting Qubits: 3D Integration and Cryogenic Packaging 201 - Josh Mutus, Google Inc.
11:15AM X16.00001: Scalable packaging for superconducting qubits with vertical wiring*
SHUHEI TAMATE (Presenter), YUTAKA TABUCHI, Research Center for Advanced Science and Technology, The University of Tokyo, LASZLO SZIKSZAI, KOICHI KUSUYAMA, KUN ZUO, Center for Emergent Matter Science, RIKEN, YUJI HISHIDA, WEI QIU, HIROTAKA TERAI, National Institute of Information and Communications Technology, MASAHIRO UKIBE, GO FUJII, KAZUMASA MAKE, NAOYA WATANABE, KATSUYA KIKUCHI, National Institute of Advanced Industrial Science and Technology, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — Superconducting quantum circuits are one of the most promising platforms for realizing a large-scale quantum computer. To implement realistic quantum error correction codes, such as surface codes, we aim at integrating a two-dimensional array of superconducting qubits in a scalable way. Therefore, a natural strategy for the chip packaging is to use the third dimension for the wiring. Here we demonstrate a packaging scheme for a qubit chip, where coaxial cables for the control and readout of qubits are vertically connected to the backside of the chip. The electrical contacts between the superconducting circuits and coaxial cables are provided by spring probes and superconducting through-silicon via. We will present the design and performance of the chip and package.

CHAN U LEI (Presenter), LEV KRAYZMAN, SUHAS GANJAM, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Superconducting quantum circuits provide a promising platform for quantum information processing. Resonant modes found in superconducting enclosures can be engineered to offer superior coherence and a better electromagnetic environment than their planar analogs. Here, we will discuss the Multilayer Microwave Integrated Quantum Circuit (MMIQC). This platform combines the high coherence of 3D superconducting enclosures with the lithographic precision and versatility of existing MMIC (Monolithic Microwave Integrated Circuit) technology to realize quantum modules that are both scalable and highly coherent. In this talk, we will present an overview of the MMIQC architecture and the ability to realize modular quantum networks.

*US Army Research Office grant W911NF-18-1-0212.
Multilayer Microwave Integrated Quantum Circuits: Part 2*

LEV KRAYZMAN (Presenter), CHAN U LEI, SUHAS GANJAM, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Superconducting quantum circuits provide a promising platform for quantum information processing. Resonant modes found in superconducting enclosures can be engineered to offer superior coherence and a better electromagnetic environment than their planar analogues. Here, we will discuss the Multilayer Microwave Integrated Quantum Circuit (MMIQC). A crucial component of the MMIQC is the realization of a high quality superconducting enclosure. The ability to make such a component necessitates the production of a high quality superconducting seam. In this talk, we will present an indium bump-bonding approach to produce superconducting seams with RF conductance exceeding $10^{10}/\Omega m$.

*US Army Research Office grant W911NF-18-1-0212

Multilayer Microwave Integrated Quantum Circuits: Part 3*

SUHAS GANJAM (Presenter), CHAN U LEI, LEV KRAYZMAN, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Superconducting quantum circuits provide a promising platform for quantum information processing. Resonant modes found in superconducting enclosures can be engineered to offer superior coherence and a better electromagnetic environment than their planar analogs. Here, we will discuss the Multilayer Microwave Integrated Quantum Circuit (MMIQC). A crucial component of the MMIQC is the realization of a high quality superconducting enclosure. In this talk, we will demonstrate on-chip microwave resonant cavities with low-power quality factors exceeding 300 million. In addition, we will describe their power and temperature dependence. Finally, we will discuss factors that may limit the performance of these cavities by placing bounds on intrinsic loss mechanisms.

*US Army Research Office grant W911NF-18-1-0212
Superconducting qubits are amongst the most promising platforms towards building near term, practical quantum information processors. As the number of qubits per device increases, package design becomes an increasingly important aspect enabling efficient qubit control. Multiple, often interrelated factors such as spurious modes, conduction losses, and crosstalk impose challenges that require a comprehensive approach to package design. Here, we provide an overview of our recent work aimed at addressing these challenges, including chip-to-board interconnect design, interposer design, and material choices. We present results from simulations of these elements and corresponding physical measurements on a newly designed package.

12:15PM X16.00006: 3D Integration with Protected Qubits*  ANJALI PREMKUMAR (Presenter), ANDRAS GYENIS, PRANAV MUNDADA, ANDREW HOUCK, Princeton University — Large-scale quantum computation will require 3D integrated architectures to achieve all-to-all connectivity, individual qubit addressability, and protection against crosstalk and decoherence channels. A central challenge in 3D quantum hardware is ensuring that additional materials and structures (such as dielectrics) do not suppress qubit lifetimes. Thus far, 3D integration schemes have typically involved a vacuum region between the qubit and other structures to avoid dielectric loss [1,2,3]. In this talk, we propose to use intrinsically protected qubits for 3D integration: resistance to dielectric loss allows for simple layered structures similar to classical 3D architectures. We show that disjoint support in fluxonium qubits leads to relaxation times \(\sim 10\text{ms}\), even when low-quality-factor SiN is deposited on top. We demonstrate a two-layer fluxonium device fabricated with techniques common in single-layer processing. The ideas explored here will allow for simple, repeatable fabrication processes for 3D quantum processors based on protected qubits.

12:27PM X16.00007: Quantifying the impact of a caps and vias architecture for superconducting qubits  KEITH JACKSON (Presenter), ANDREW BESTWICK, SHANE A CALDWELL, MATTHEW J REAGOR, Rigetti Quantum Computing — Scaling high-fidelity superconducting quantum processors to hundreds of qubits requires low on-chip crosstalk at both DC and microwave frequencies, control of the microwave environment seen by each qubit, and accurate coupling strengths between specific modes. To enable this, we describe a chip architecture that combines superconducting caps with recessed cavities bump bonded to a quantum IC with superconducting vias. We describe measurements showing the impact of both caps and vias across a 16+ qubits, including data that enable us to separate out the effects of caps, vias, and the placement of the cap indium bumps on device crosstalk.

12:39PM X16.00008: Design Considerations for Near-term Quantum Processors  ANNA STOCKKLAUSER (Presenter), Rigetti Quantum Computing — Progress in the development of quantum computing systems based on superconducting qubits brings more and more near-term applications within reach. Accelerating this progress requires improvements in the reliability and manufacturability of quantum chips and other specialized components as quantum processors approach 100+ qubits. This talk will address challenges and solutions in the design and fabrication of superconducting qubit-based quantum processors related to scaling, 3D integration, and device operation. We will discuss how these improvements support progress towards demonstrating practical near-term applications with variational algorithms on hybrid quantum-classical machines.

The presented work is the result of a cross-team effort at Rigetti Computing.
Cryogenic Thermalization Measurements of Microwave Attenuators*
ANIKET MAITI (Presenter), VIJAY JAIN, LUIGI FRUNZIO, ROBERT SCHOELKOPF, Yale University — Dephasing due to residual thermal photons in readout cavities is a leading factor in limiting the coherence of superconducting qubits. This thermal noise originates from strong cavity drives and poor thermalization of microwave attenuators. It has been shown that cold attenuators could allow one to approach the qubit decoherence limits imposed by $T_1$ [1]. We thus study the thermalization of cryo-attenuators by using a coaxial stub cavity over-coupled to a microwave input line for absolute temperature measurement. In particular, we look at the power dependence and the time constant for the temperature of a few attenuator designs, and discuss strategies for improvement.

*We acknowledge support from the U.S. Army Research Office Grant Nr. W911NF-18-1-0212

Dilution-equivalent solid-state chip refrigeration* ALBERTO RONZANI (Presenter), JANNE LEHTINEN, EMMA MYKKANEN, ANTTI KEMPPINEN, LEIF GRÖNBERG, ANTTI MANNINEN, MIKA PRUNNILA, VTT Micro & Nanoelectronics — Cooling below 100 mK is an operative prerequisite in several quantum technology applications. It is typically achieved in expensive He3/He4 dilution refrigerators, where massive thermal payloads are cooled to very low temperatures over the course of tens of hours. Yet, in several quantum devices, only few miniaturized active elements are required to reach such low temperature levels.

Here we present a multi-stage thermionic cooler, targeting the 1.5K to 100 mK range. Its core concept consists in suspending silicon substrates with semiconductor-superconductor tunnel junctions, providing both phonon isolation and efficient electron cooling of chip-level payloads.

Compared to dilution refrigeration, our approach reduces sub-kelvin cooldown times to few seconds and benefits from intrinsically maintenance-free operation. Furthermore, the negligible system mass and footprint are optimally suited to compact turnkey systems and are especially ideal for space-borne applications.

1:15PM X16.00011: Hot electron measurements below 100 mK for quantum devices*

ZACHARY STEFFEN (Presenter), SUDEEP DUTTA, RUI ZHANG, YIZHOU HUANG, KUNGANG LI, FREDERICK C WELLSTOOD, BENJAMIN PALMER, University of Maryland, College Park — Recently, the electron-phonon coupling constant of the resistive alloy material nichrome (NiCr) was estimated as $\Sigma_{\text{NiCr}} = (5 \times 10^8) \text{ Wm}^{-3}\text{K}^{-5}$ from measurements of the dephasing rate of a superconducting transmon qubit coupled to a NiCr attenuator [1]. In this talk, we will discuss ongoing measurements to more directly measure the electron temperature and find the electron-phonon coupling constant of NiCr. In particular, we have fabricated NIS junctions consisting of NiCr/AlOx/Al structures and measured the current voltage characteristics at temperatures down to 20 mK. These measurements will be used to extract the electron temperature of the NiCr material which can be compared to the previously reported value, allowing for more accurate thermal modeling of future NiCr devices.

1:27PM X16.00012: Extending Superconducting Qubits Out of Plane (Part 1): Qubits with Air Bridge Crossovers in Multi-Tier Stacks*

JONILYN YODER (Presenter), JUSTIN MALLEK, DAVID K KIM, DONNA-RUTH YOST, GREG CALUSINE, RABINDRA DAS, ALEXANDRA DAY, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, DANNA ROSENBERG, MIT Lincoln Laboratory, GABRIEL ORR SAMACH, MIT Lincoln Laboratory, Massachusetts Institute of Technology, MOLLIE SCHWARTZ, STEVEN WEBER, MIT Lincoln Laboratory, WILLIAM OLIVER, MIT Lincoln Laboratory, Massachusetts Institute of Technology — Out-of-plane connectivity within superconducting quantum circuits enables increased complexity and wiring density. We are developing heterogeneous 3D integration of a qubit tier combined with an interposer with high-aspect-ratio superconducting through-silicon vias and a superconducting multi-chip module. In part 1 of this talk, we will focus on circuit complexity within the superconducting qubit tier, including implementation of air bridge crossovers (1) to increase mutual inductance by directly embedding them within qubit and coupler loops, (2) to improve connectivity of the ground plane, and (3) as a method for routing wires and circuit elements past each other.

*This research is funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) under Air Force Contract No. FA8721-05-C-0002. 1:39PM X16.00013: Extending Superconducting Qubits Out of Plane (Part 2): Through-Silicon Vias*  JUSTIN MALLEK (Presenter), JONILYN YODER, DONNA-RUTH YOST, RABINDRA DAS, ALEXANDRA DAY, DANNA ROSENBERG, GREG CALUSINE, MATTHEW COOK, EVAN GOLDEN, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, MOLLIE SCHWARTZ, COREY STULL, SERGEY TOLPYGO, WAYNE WOODS, WILLIAM OLIVER, MIT Lincoln Laboratory — Addressing complex arrays of high coherence qubits is a necessary capability for the construction of a quantum processor. To enable high connectivity of superconducting qubits we are utilizing heterogeneous 3D integration of a qubit tier, an interposer with high-aspect-ratio superconducting through-silicon vias (TSVs), and a superconducting multi-chip module. In part 2 of this talk we will focus on the fabrication of TSVs within the interposer tier and their implementation within multi-tier stacks.

*This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. The views and conclusions contained herein are those of the authors and should not be interpreted as necessarily representing the official policies or endorsements, either expressed or implied, of ODNI, IARPA, or the US Government.

1:51PM X16.00014: Quantifying Losses in Transmon Qubits*  GREG CALUSINE (Presenter), WAYNE WOODS, ALEXANDER MELVILLE, KYLE SERNIAK, DAVID K KIM, JONILYN YODER, WILLIAM OLIVER, MIT Lincoln Lab — Reducing losses in superconducting qubit circuits is critical for enabling the development of large-scale quantum computing architectures. This task is especially challenging in the face of variability resulting from device-to-device differences and fluctuating device properties. We apply statistical characterization of sets of superconducting resonators and transmon qubits to overcome variability and quantify loss contributions from a variety of sources such as surface and bulk dielectrics, packaging, and nonequilibrium quasiparticles. As part of this approach, we develop the fabrication processes and EM modeling techniques necessary for accurately modeling dielectric losses. Through this study, we seek to develop a model of qubit losses that allows for iterative improvement in device coherences and consistency.

*This material is based upon work supported by the Department of Defense under Air Force Contract No. FA8721-05-C-0002. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the Department of Defense.
Effects of surface treatments and packaging on transmon qubits
MATTHIAS MERGENTHALER (Presenter), CLEMENS MÜLLER, MARC GANZHORN, STEPHAN PAREDES, PETER MÜLLER, STEFAN FILIPP, ANDREAS FUHRER, IBM Research - Zurich — The last two decades have seen significant advances in the coherence times of superconducting qubits. However, further progress in transmon coherence times seems to require substantial effort in understanding the remaining limitations due to material interfaces and imperfections, which give rise to two level fluctuators [1-3]. Often, ion milling is an integral part of Josephson junction fabrication and possibly damages the material surface, but its impact on qubit coherence is not well understood and needs experimental investigation.
Here, we present our work towards understanding decoherence mechanisms in flux-tunable transmon qubits. We study the effects of qubit packaging under UHV and controlled atmospheres on the qubit coherence. In addition, we analyze the impact of surface treatments, such as UV light exposure and ion milling, on the qubit parameters. For further insight, qubit coherence and parameter fluctuations are investigated by tracking the coherence times and transition frequencies of multiple qubits over several hours. The resulting noise spectra for different packaging and treatment methods are then compared.

Session X17 DQI: Fabrication of Silicon Qubits 203 - Eleanor Crane, London Center Nanotechnology

State-of-the-art Quantum Dot devices from a full 300mm process line: towards scalable spin qubit devices
HUBERT C GEORGE (Presenter), STEPHANIE BOJARSKI, RAVI PILLARISETTY, BRENNEN MUELLER, LESTER LAMPERT, THOMAS WATSON, FLORIAN LUTHI, ROMAN CAUDILLO, DAVID J MICHALAK, ERIC HENRY, OTTO ZIETZ, JEANETTE MARIE ROBERTS, Components Research, Intel Corporation, ANNE-MARIJE ZWERVER, TOBIAS KRÄHENMANN, GERTJAN EENINK, GIORDANO SCAPPUCCI, MENNO VELDHORST, LIEVEN M VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, JIM CLARKE, Components Research, Intel Corporation — Intel continues with its efforts towards the fabrication of spin qubit devices in a full 300mm process line. Significant progress has been achieved on the fin-based process flow that yields QD devices with performance comparable to academic's state-of-the-art devices. Among other important milestones of this work is the implementation of fin-to-fin charge sensing which is needed to operate in the single electron regime. We will also present updates on wide linear array devices as well as the current status of spin qubit device fabrication; both are key to the long-term implementation of scalable spin qubit devices in silicon for quantum computing technology.
11:27AM X17.00002: The impact of using palladium gates for silicon quantum dot fabrication: defect densities and strain  RYAN STEIN (Presenter), ZAC BARCIKOWSKI, University of Maryland, College Park, JOSHUA POMEROY, MICHAEL DAVID STEWART, National Institutue of Standards and Technology —
Quantum dots (QD) in the silicon MOS system benefit from the use of palladium or platinum for gate materials because the small grain size of these metals compared to aluminum aids in shrinking the gate and dot dimensions. However, it is not clear what differences arise with respect to process-induced defect density and homogeneous strain. Here, we present measurements of oxide defect densities (fixed charge and interface trap density) as a function of forming gas anneal temperature for three different gate metals: Al, Ti/Pd, and Ti/Pt. We also investigate the concomitant effect of these anneals on the mechanical properties of the gate material, such as the intrinsic film stress, coefficient of thermal expansion, and bi-axial modulus. Our initial results indicate that Ti/Pd and Ti/Pt result in much higher fixed charge density and higher, though comparable, interface trap densities when compared to Al. These results provide guidance on adjusting QD fabrication for these gate materials.

11:39AM X17.00003: Revising the point-charge model for dopants in Si and applications to atomic-scale system simulations  KEYI LIU (Presenter), University of Maryland, College Park, PIOTR T. ROZANSKI, MICHAL ZIELINSKI, Institute of Physics, Nicholaus Copernicus University, GARNETT BRYANT, Nanoscale Device Characterization Division, National Institute of Standards and Technology —
Dopants in silicon are strong candidates for qubits in scalable solid-state quantum systems. Tight-binding (TB) theory has been used to provide a good atomic-scale model with reasonable precision when a central cell correction is adjusted to fit to experimental binding energies for one choice of the bulk Si TB parameters. However, this simple model fails to predict the correct dopant level energy degeneracies for many other well-established bulk Si TB models. We argue that the point-charge dopant model with a simple central cell correction is missing vital contributions from the dopant potential that must be included to encapsulate the underlying physics. We have developed a dopant model that includes several new corrections that are obtained explicitly using atomic orbitals to evaluate the appropriate dopant matrix elements rather than by fitting to experiment. We find that these new corrections play a critical role in defining the dopant physics, as all bulk Si TB parameters predict the correct ordering of dopant levels in our new model. Results are discussed to show the effect on interdopant exchange coupling and the level structure of dopant clusters. Finally, we discuss how these models can be utilized to effectively simulate many-body physics in atom chains and arrays.
11:51AM X17.00004: Low-frequency electron spin-qubit detuning noise in highly purified $^{28}\text{Si}/^{28}\text{SiGe}$

TOM STRUCK, ARNE HOLLMANN, RWTH Aachen University, FLOYD SCHAUER, ANDREAS SCHMIDBAUER, Universität Regensburg, VEIT LANGROCK, Forschungszentrum Jülich, OLESIY FEDORETS, RWTH Aachen University, KENTAROU SAWANO, Tokyo City University, HELGE RIEMANN, NIKOLAY V ABROSIMOV, Leibniz-Institut für Kristallzüchtung, LUKASZ CYWINSKI, Polish Academy of Sciences, DOMINIQUE BOUGARD, Universität Regensburg, LARS SCHREIBER (Presenter), RWTH Aachen University — The manipulation fidelity of a single-electron spin qubit gate-confined in a $^{28}\text{Si}/^{28}\text{SiGe}$ quantum dot has recently been drastically improved by nuclear isotope purification [1]. Here, we characterize a $^{28}\text{Si}/^{28}\text{SiGe}$ device with an embedded nanomagnet, a large valley splitting (> 0.2 meV [2]), and a remaining $^{29}\text{Si}$ concentration of only 60 ppm in the strained silicon quantum well layer, which is grown by molecular beam epitaxy. We identify the combination of charge noise and gradient magnetic field as the dominant source of low frequency qubit detuning noise. The power spectral density (PSD) of the charge noise explains the frequency-dependence of the detuning noise PSD, as well as the observation of a decreasing time-ensemble spin dephasing time with increasing measurement time over several hours [3]. We also comment on the role of the remaining nuclear spins in the SiGe barrier on the qubit dephasing and the origin of the observed large valley splitting.

*DFG projects BO 3140/4-1, 289786932; BMBF Contract No. FKZ: 13N14778; QuantERA ERA-NET Cofund in Quantum Technologies implemented within the European Union’s Horizon 2020 Programme.

12:03PM X17.00005: Single-electron control in a foundry-fabricated 2D array of silicon quantum dots

FABIO ANSALONI (Presenter), ANASUA CHATTERJEE, HEORHII BOHUSLAVSKYI, FERDINAND KUEMMETH, Univ of Copenhagen — Two-dimensional quantum dot arrays constitute a useful platform for spin-qubit processors and condensed matter simulations. With the advent of foundry-fabricated silicon qubits [1], larger CMOS quantum dot arrays become increasingly promising for implementing multi-qubit devices. We use a 2x2 array of quantum dots, fabricated fully at CEA-LETI using industrial silicon-on-insulator technology, to reconfigure the array as single, double, triple, or quadruple dots, and use dispersive charge sensing to deplete all dots down to the last electron. Combining high-frequency reflectometry with pulsed-gate techniques, we tune tunneling rates and demonstrate the shuttling of individual electrons within the two-dimensional array.

*We thank Louis Hutin, Silvano De Franceschi and Maud Vinet for providing the LETI FDSOI samples, funded by European Union's Horizon 2020 research and innovation programme under grant agreement No. 688539.
Spin Qubits Confined to a Silicon Nano-Ridge

JAN KLOS (Presenter), BIN SUN, JACOB BEYER, SEBASTIAN KINDEL, LENA HELLMICH, JOACHIM KNOCH, LARS SCHREIBER, RWTH - Aachen — Electrostatically defined quantum dots (QDs) in silicon are an attractive platform for quantum computation based on electron spin qubits. Si qubit devices have been demonstrated by the modification of industrial FinFETs [1]. We propose a scalable qubit device fabricated by industry-compatible processes such as damascene and spacer processes [2]. The device consists of a double array of QDs formed along a silicon nano-ridge. We implement TiN side-gates, a global back-gate and a dense metallic top-gate array for controlling the QDs potentials. In order to minimize potential fluctuations caused by interface roughness and charged defects at the Si/SiO₂ interface, the nano-ridge is anisotropically etched and exhibits atomically flat {111} facets. We characterized its interface roughness and the defect density of the Si/SiO₂ interface. The most relevant process modules are experimentally demonstrated including local oxidation of the silicon nano-ridge, side-gate formation and top-gate fabrication using a low-pitch self-aligned spacer process.

Silicon spin qubit development in a 300 mm integrated process

NARD DUMOULIN STUYCK (Presenter), KU Leuven, imec, ROY LI, STEFAN KUBICEK, FAHD A MOHIYADDIN, BOGDAN GOVOREANU, IMEC, ASSER ELSAYED, MOHAMED SHEHATA, KU Leuven, imec, JULIEN JUSSOT, BT CHAN, IULIANA RADU, IMEC, MARC HEYNS, KU Leuven, imec — Semiconductor spin qubits are developing at a rapid pace with increasing qubit coherence times and quantum gate-fidelities over the last years [1]. This progress has resulted in multiple proposals for large-scale spin qubit-arrays [2-4]. However, scaling up existing qubit prototypes to several qubit arrays require advanced fabrication techniques.

We address this challenge by employing a state-of-the-art 300mm fabrication process [5-6]. In this talk, we present the integration of Si-MOS spin qubit devices in an hybrid integration scheme, which combines e-beam and optical lithography. This enables fast turn-around times while still offering the necessary qubit design flexibility. Furthermore, industrial-scale characterization allows for the room temperature statistical extraction of key device and material parameters. This data and its correlation to low temperature device performance will be discussed, along with the main challenges for further development.

*N. D.S. acknowledges FWO-Vlaanderen for a SB research grant*
12:39PM X17.00008: Industrial quantum dot arrays for spin-qubit quantum computation by all-optical 300mm lithography  TOBIAS KRÄHENMANN (Presenter), ANNE-MARIJE ZWERVER, QuTech and Kavli Institute of Nanoscience, TU Delft, The Netherlands, STEPHANIE BOJARSKI, HUBERT C GEORGE, BRENNEN MUELLER, JIM CLARKE, Components Research, Intel Corporation, Hillsboro, OR, USA, LIEVEN M VANDERSYPEN, QuTech and Kavli Institute of Nanoscience, TU Delft, The Netherlands — Using quantum dot arrays fabricated in a 300mm process line, we demonstrate well-controlled single and double quantum dots formed in an isotopically enriched $^{28}$Si-MOS substrate. These devices are fully fabricated with optical lithography, plasma etching, and chemical-mechanical polishing techniques for patterning, compatible with state of the art industrial fabrication. In the many-electron regime independent tunnel-barrier control is shown, a prerequisite for high-fidelity two-qubit control. Data driven process improvements of the quantum dots have led to a significant increase in charge-sensing sensitivity capable of single shot read-out. Using state of the art charge detection methods, we are able to observe single-electron occupation of these quantum dot arrays. The few-electron regime shows stable device behavior, with dots forming both under the plunger and barrier gates. The occurrence of spurious dots is analyzed. Here, we will show our latest results on utilizing these quantum dot arrays as spin-qubits.

12:51PM X17.00009: Pauli spin blockade for holes in a hot silicon FinFET* SIMON GEYER (Presenter), LEON CAMENZIND, RICHARD J. WARBURTON, DOMINIK ZUMBUHL, ANDREAS V. KUHLMANN, Department of Physics, University of Basel — Quantum information can be encoded in the spin state of a single electron or hole confined to a semiconductor quantum dot (QD) (Loss and DiVincenzo, PRA57, 120 (1998)). Silicon is a particularly promising platform for scalable spin-based quantum computing due to its fully developed, industrial manufacturing processes. Furthermore, a nearly nuclear-spin-free environment can be engineered by means of isotopic purification. Holes in silicon are of particular interest, since they are subject to a strong spin-orbit-interaction, allowing for fast, all-electrical spin manipulation (Maurand et al., Nature Comm. 7, 13575 (2016)). We define single and double QDs in a FinFET-like device architecture. A second gate layer, which is fabricated in a self-aligned process, allows for in-situ adjustments of the tunnel couplings and makes these devices highly tunable. In addition, conventional impurity-doped source and drain contacts are replaced in an overlapping-gate structure by a metallic silicide. We observe Coulomb blockade and, furthermore, Pauli spin blockade for both electrons and holes. The large singlet-triplet splitting allows spin blockade for holes to be observed at temperatures as high as 10 K, paving the way for a hot spin-qubit. 

*Supported by SNSF, SNF, EMP and G H Endress Foundation
Crossbar architecture with individually addressable single electron transistors* PETER BAVDAZ (Presenter), GERTJAN EENINK, JOB VAN STAVEREN, CARMINA ALMUDEVER, FABIO SEBASTIANO, MENNO VELDHORST, GIORDANO SCAPPUCCI, Delft University of Technology — Achieving sublinear scaling of interconnects between room temperature equipment and cryogenic hardware is essential in engineering a practical spin based quantum computer. This requirement is equally present in high throughput characterization for the device fabrication-measurement cycle. In addition to cryogenic multiplexing, the lines into the cryostat can be further reduced at the qubit plane. Here, a sparse crossbar architecture of single electron transistors (SETs) is presented, allowing for the formation of a quadratic number of unique SETs with linearly increasing control lines. We show experimental effort toward realizing crossbars which are operated using a CMOS multiplexer consisting of commercial components at 50 mK capable of supporting up to 648 SETs. These structures provide insight into shared control, enable statistical characterization of substrate uniformity and serve as a platform for device design optimization. Furthermore, by evolving the unit cell, such structures can act as stepping-stones towards proposed fully-coupled crossbar qubit architectures and integration of cryogenic electronics.

*This work is part of the research programme OTP with project number 16278, which is (partly) financed by NWO. M.V. acknowledges support from the NWO Vidi Program.

Silicon quantum dot fabrication with subtractive processing THOMAS MCJUNKIN (Presenter), EVAN R MACQUARRIE, MARK ALAN ERIKSSON, University of Wisconsin - Madison — The overlapping aluminum gate design for silicon quantum dot qubits has shown success in the formation of one and two qubit systems. However, charge noise and device consistency are still major points of concern for silicon quantum systems. Here, we present an alternative approach to silicon quantum dot fabrication, utilizing negative-tone e-beam lithography and subtractive processing to replicate the typical three-layer aluminum gate structure with two layers of palladium gates. Using high-precision HSQ e-beam resist, all plunger, barrier/tunnel, and accumulation gates can be fabricated as a single layer. This eliminates overlay issues and ensures barrier gates, typically written as the third layer, have large action on the dots. The self-oxidation of the three aluminum gate layers is replaced with a single layer of deposited dielectric. Progress towards the realization of a well-controlled, lower noise quantum dot system using etched palladium gates will be presented.
Charge and Hybrid Qubits in 22nm FDSOI process  

ELENA BLOKHINA (Presenter), PANAGIOTIS GIOUNANLIS, School of Electrical and Electronic Engineering, UCD, DIRK R LEIPOLD, IMRAN BASHIR, MIKE ASKER, Equal1 Labs, ALI ESMAILIYAN, HONGYING WANG, TEERACHOT SIRIBURANON, ANDRII SOKOLOV, R. BOGDAN STASZEWSKI, School of Electrical and Electronic Engineering, UCD — A number of recent studies report the achievements of silicon-based qubits. Furthermore, the benefits of nanometer-scale CMOS technologies boost the potential of miniaturization, scalability and full system integration for quantum computers. This abstract presents the recent development of a quantum system-on-a-chip utilizing quantum structures fabricated in 22nm FDSOI. The main challenge of achieving deep cryogenic operation for the mixed-signal classic circuit controlling the quantum core was surpassed by using programmable local heating DACs that slightly boost the local temperature of the die, which needs to be maintained around 4 K. A staged multi-phase operation was adopted for the digital core in order to minimize the quantum decoherence originated in digital noise injection.

We show that the fabricated quantum structures can be used to realize charge and/or hybrid qubits. The theoretical analysis and modeling of qubits are based on a Hubbard model in the tight-binding limit. Different types of qubits (for instance, spin, charge or hybrid) have been examined. Various topologies of interacting qubits are investigated exhibiting maximally entangled states. Preliminary experimental results are also presented.

Improving Gate Dielectrics for Reducing Charge Noise in Si/SiGe Quantum Dots  

NATHAN HOLMAN (Presenter), JOHN DODSON, EVAN MACQUARRIE, University of Wisconsin - Madison, LISA F EDGE, HRL, ROBERT F MCDERMOTT, SUSAN NAN COPPERSMITH, MARK G FRIESEN, MARK ALAN ERIKSSON, University of Wisconsin - Madison — We report on the materials development of a novel low temperature SiO$_2$ gate dielectric for use in Si/SiGe quantum dot devices. X-ray Photoemission Spectroscopy (XPS) measurements show nitric acid oxidation of silicon (NAOS) or silicon-germanium alloys produces a more stoichiometric and thicker silicon oxide over other low temperature techniques [1]. Using this approach, we create a ~1.7 nm SiO$_2$ gate dielectric over the active region of a Si/SiGe quantum dot device coupled to a Nb microwave resonator for charge state readout. By measuring the current noise in a quantum dot we observe a 1/f power spectral density of chemical potential noise with an amplitude of 0.203 μeV$^2$/Hz at 1 Hz which compares favorably to similar devices using ALD Al$_2$O$_3$ and native SiO$_2$ [2]. Further, we demonstrate low frequency Landau-Zener spectroscopy of a double dot charge qubit and discuss cavity-charge coupling experiments [3,4].

References:
Electron spins in silicon have long coherence times and are a promising qubit platform. However, electric field noise in semiconductors poses a challenge for most single- and multi-qubit operations in quantum-dot spin qubits. Here, we investigate the dependence of low-frequency charge noise spectra on temperature and aluminum-oxide gate dielectric thickness in Si/SiGe quantum dots with overlapping gates. We find that charge noise increases with aluminum oxide thickness. Additionally, we observe strong dot-to-dot variations in the temperature dependence of the noise magnitude and spectrum. These findings suggest that each quantum dot experiences noise caused by a distinct ensemble of two-level systems, each of which has a non-uniform distribution of thermal activation energies. Taken together, our results suggest that charge noise in Si/SiGe quantum dots originates at least in part from a non-uniform distribution of two-level systems near the surface of the semiconductor.

Session X18 GSNP: The Statistical Physics of Real-world Networks II
11:15AM X18.00001: The statistical physics of real-world networks: standing on Jaynes’ shoulders* [Invited]  FABIO SARACCO (Presenter), Networks Unit, IMT School For Advanced Studies Lucca —

In 1957 Jaynes proposed an Information Theory approach to derive the statistical ensembles of Statistical Mechanics: the maximisation of the Shannon entropy, after constraining the energy of the system, returns exactly the probability distributions of the canonical ensemble. Otherwise stated, Jaynes’ approach consists in fixing some crucial information regarding the description of the system (i.e. the energy) and then maximising the “ignorance” about the unconstrained degrees of freedom.

Recently, the same approach was extended to the study of complex networks. Analogously, the constraints represent some - local or global - informative quantities for the description of the real system, while all other observables are left completely random. This approach provides a reliable benchmark for the analysis of complex networks, to reconstruct a network from a limited information or to highlight the role of local constraints in the ensemble non equivalence. In the present seminar I will review the definition and the evolution of such framework and introduce some of its last applications in different fields, as online social networks, economic and financial systems, biological networks.

* I acknowledge support from the EU project SoBigData (Grant No. 654024) and from the Italian “Programma di Attivita’ Integrata” (PAI), project “TOol for Fighting FakEs” (TOFFEe) funded by IMT School for Advanced Studies Lucca.

11:51AM X18.00002: Complex networks with complex nodes* [Invited]  RAISSA D'SOUZA (Presenter), University of California, Davis — The statistical physics perspective has provided a wealth of understanding about the structure and function of massive networks including phase transition behaviors, non-trivial network structures such as modularity and heterogeneous degree distributions, and the analysis of the dynamics unfolding on networks. It reveals the massive implications that network structure has on network function and resilience. Yet, complementary to this perspective of complex networks, simple networks of nonlinear nodes have been studied extensively in fields of dynamical systems and control theory. Real world networks -- from brain networks to social networks to critical infrastructure networks -- lie at the interface of both, with nonlinear nodes and highly non-trivial network structures. We are at a point in time when there is opportunity for these fields to come together. This talk will survey results of a recent project at three different scales on the complex node versus complex network spectrum, from synchronization in nanoscale oscillations to hierarchy and stability in multilayered social systems of macaque monkeys.

* The speaker gratefully acknowledges support from the US Army Research Office MURI Award No. W911NF-13-1-0340 and DARPA Award No. W911NF-17-1-0077.
12:27PM X18.00003: Percolation in real interdependent networks* [Invited] FILIPPO RADICCHI (Presenter), Indiana Univ - Bloomington — The function of a real network depends not only on the reliability of its own components, but is affected also by the simultaneous operation of other real networks coupled with it. Robustness of systems composed of interdependent network layers is generally framed and characterized in terms of percolation models. In this talk, I will consider three different percolation models that provide different insights on the robustness of real-world interdependent networks. I will first consider the ordinary percolation model and illustrate a theoretical approach consisting in a system of heuristic equations able to approximate the phase diagram for arbitrary networks. Second, I will introduce and characterize the redundant percolation model, a genuine model for interdependent networks where the addition of new layers boosts system robustness by creating redundant interdependencies among network layers. Third, I will generalize the problem of optimal percolation from single-layer to multi-layer networks, and present several algorithms for finding approximate solutions to the problem.

1:03PM X18.00004: Structure, phase transitions, and message passing in sparse networks [Invited] MARK NEWMAN (Presenter), Univ of Michigan - Ann Arbor — Most networks and graphs encountered in empirical studies, including the Internet and the World Wide Web, social networks, and biological and ecological networks, are very sparse. Standard spectral and linear algebra methods perform poorly when applied to such networks. Message passing methods, such as belief propagation, offer an alternative that can deliver better performance as well as new analytic insights. This talk will introduce the message passing method through a progressive series of examples and illustrate how the method can be used for a wide range of calculations of network structure and function. Among other things, the talk will touch upon the calculation of percolation thresholds, graph spectra, and community structure, the deep connections between message-passing fixed points and structural phase transitions in networks, and a new solution to the long-standing problem of message passing on networks with a high density of short loops.

1:39PM X18.00005: A Networks View on Functional Brain Dynamics: timeseries, behavior and beyond [Invited] TOMMASO GILI (Presenter), Networks Unit, IMT School for Advanced Studies Lucca — Most of what we know about brain functioning comes from the time dependent investigation of its activity through the registration of specific proxies. Neurovascular and electrophysiological timeseries have been vastly used to associate the brain functional segregation with specific behavioral outcomes. In this presentation I will show the networks perspective of brain functioning by highlighting the state-of-the-art of graph embedding in human neuroscience and the fundamental role of functional topology in supporting human behavior in healthy subjects and in neuropsychiatric patients.

Friday, March 6, 2020 11:15 AM - 2:15 PM
Session X19 DBIO: Frontiers in Actomyosin Stress Sensing and the Dynamics of the Cytoskeleton 207 - John Crocker, University of Pennsylvania - Tag(s): Invited

11:15AM X19.00001: Elementary contractile unit and collective motor behavior [Invited]  
JACQUES PROST (Presenter), Curie Institute Paris and MechanoBiology Singapore, CNRS/NUS — After introducing the main features characterizing an elementary contractile unit in cells as studied in M Sheetz lab in Singapore and Columbia New-York, I will recall theoretical results concerning motor collections obtained over the years. In particular I will show how a symmetry breaking transition, emergent feature of a large number of molecular motor collection, underpins a number of biological functions such as muscle oscillations. I will then show how a simple modification of the theoretical framework allows to understand all experimental observations including force build-up followed by a relaxation and the existence of half integer steps in the contraction/relaxation curve, which is a resurgence of a nanoscopic scale in a mesoscopic system.

Myosin filaments reversibly generate large forces in cells  

11:51AM X19.00002: Julie Theriot Invited Talk [Invited] —

12:27PM X19.00003: Dissecting fat-tailed fluctuations in the cytoskeleton with active micropost arrays* [Invited]  
DANIEL REICH (Presenter), Johns Hopkins University — The actomyosin cytoskeleton is critical to a wide range of cellular mechanobiology and mechanotransduction. However, the understanding of the connections between molecular-scale processes and cell-scale mechanical phenomena is not complete. Using active micropost array detectors containing magnetic actuators, we have characterized the mechanics and fluctuations of cells’ actomyosin cortex and stress fiber networks in detail. Both structures show consistent power law viscoelastic behavior and highly intermittent fluctuations with fat-tailed amplitude distributions. In the cortex, the dynamics are dominated by occasional large events, similar to what is seen in earthquakes or systems with avalanches. We have observed this behavior across multiple cell types and substrate stiffnesses, and the regular arrays of microposts enable measurement of the largest events’ symmetry and extent (up to several micrometers), revealing spatiotemporal dynamics resembling that seen in plastic solids. These results suggest that actomyosin components may self-organize into marginally stable plastic networks that give cells their unique biomechanical properties.

*Supported in part by NIH grant HL-127087.
1:03PM X19.00004: How immune cells respond to physical cues – the role of cytoskeletal dynamics* [Invited] ARPITA UPADHYAYA (Presenter), University of Maryland, College Park — The activation of lymphocytes, an essential step in the adaptive immune response, involves the binding of specialized receptors with antigens. This results in large-scale dynamics and re-structuring of the cytoskeleton, and movement of receptors into sub-micron clusters, which are critical for immune cell activation. Antigen presenting surfaces possess a wide variety of physical attributes, which influence cytoskeletal organization and receptor mobility, but how cells respond to these physical cues is not well understood. I will summarize our recent studies that examine how immune cells respond to physical cues such as surface mobility and topography. Regulation of membrane receptor mobility is important in tuning cellular response to external signals, such as during B cell signaling following the binding of B cell receptors (BCR) to antigen. We have used single molecule imaging to examine BCR movement and machine learning techniques to relate receptor trajectories to their signaling states. We find that the dynamic actin network fine-tunes receptor mobility and receptor-ligand interactions, thereby modulating B cell signaling. In vivo, B cells encounter surfaces of antigen presenting cells that are highly convoluted with a wide range of curvatures. We have used nanotopographic surfaces that allow systematic variation of geometric parameters to show that surface features on a subcellular scale influence B cell signaling and actin dynamics. Nanotopography-induced actin dynamics requires BCR signaling, actin polymerization, and myosin contractility. The topography of the stimulatory surface also modulates the distribution of BCR clusters and calcium signaling in activated B cells. Active cytoskeletal control of receptor diffusion may be a general feature that directs how diverse cell types respond to physical stimuli and transduce external signals into internal chemical signals.

1:39PM X19.00005: Cells in microgels: 3D printed microtissues and three-dimensional cell migration [Invited] TAPOMOY BHATTACHARJEE (Presenter), Princeton University, THOMAS ANGELINI, University of Florida — In most natural settings, cells thrive in 3D complex environments. The demand of studying cells in 3D has led to the development of many 3D growth media and various bio-printing techniques. Most 3D growth media use bio-degradable polymer networks; during 3D bio-printing cell-loaded polymeric filaments are spatially arranged that solidify during the printing process to preserve the shape. However, the spatial variation in network structure and the transience of degradable gels make quantitative cell behavior studies in these materials extremely challenging. Moreover, the general approaches of 3D bio-printing rely on intimate interactions between cells and specialized materials. Instead, we have developed a 3D growth medium from the jammed system of granular polyelectrolyte microgels that allows for 3D culture of cells. We find that single cell motility can be altered by varying inter-microgel pore spacing in 3D growth media. The self-healing nature of this growth media allows creation of highly precise tissue like structures by direct injection of cells inside the sacrificial 3D media. Finally, we have characterized the macroscopic rheological behaviors of this 3D medium and related them to the classic polyelectrolyte physics scaling laws that control single-microgel elasticity This work provides a revised approach of 3D cell culture and bio-printing and yields principles for predicting cellular migration and creating complex structures of cells with direct implications for tissue-engineering.
11:15AM X20.00001: Statistical Physics of Noninteracting Bacterial Populations* [Invited]
FARSHID JAFARPOUR (Presenter), University of Pennsylvania — Genetically identical bacterial cells in identical environments display significant variability in their phenotypic behavior; they grow at different rates, divide at different sizes, and have different generation times. With recent advances in single-cell technologies, now we can measure not only the distributions of these quantities but also the subtle correlations between these variables both within and across generations. These statistical descriptions have paved the way for the phenomenological models of cellular growth and division. In this talk, I will take these phenomenological models as the microscopic dynamics of individual cells to quantitatively predict the macroscopic properties of populations both in batch and chemostat settings. In particular, I derive the growth rate of the population, the rate at which a population approaches its steady state, and the rate of neutral genetic drift from the single-cell variables.

*This material is based upon work supported by the National Science Foundation under Grant No. NSF-DMR-1506625.

11:51AM X20.00002: Optimal segregation of key proteins in microbes
JISEON MIN (Presenter), ARIEL AMIR, Harvard University — Asymmetric segregation of key proteins at cell division has been observed in various unicellular organisms, including E. coli and budding yeast. It is often assumed to enhance the fitness of the population. We study the population growth in the presence of asymmetric segregation and find, generically, a phase transition occurring between a regime where asymmetry is beneficial to one where it is detrimental. We investigate the nature of this phase transition in the presence of asymmetry in cell division, stochasticity and multiple key proteins, each of which can be beneficial or deleterious, segregating in different proportions.
Understanding Cell Size Homeostasis and Phenotypic Switching Dynamics during Bacterial Filamentation

YANYAN CHEN (Presenter), JAVIER BUCETA FERNANDEZ, Lehigh University — Colonies of bacteria undergoing filamentation present a noticeable phenotypic diversity in terms of their size and yet homeostasis is achieved. While the mechanism for achieving size homeostasis at a normal size scale is clear, the following questions remain in the context of filamentation. How do filamentous strains achieve size homeostasis? What is the dynamics underlying phenotypic switching? To answer these questions, we have modeled the bacterial growth and division processes during filamentation and performed analyses of experimental phenotypic lineage trees. Our model reveals how making compatible the observed adder-like correlations at the collective level and sizer properties at the individual cell level. We further show that size homeostasis is independent on the division pattern (i.e. what septa are eventually selected for cell cleavage in filamentous cells). Also, our analyses of lineage trees combined with mathematical models suggest that changes in the phenotypic composition of colonies mainly derive from a switch of the growth/division mode. Altogether, our work sheds light on the dynamics of filamentation and helps to understand the transition from a regular to a filamentous phenotype.

Effect of non-genetic inheritance dynamics on the variation in cellular traits [Invited]

HARSH VASHISTHA, MARYAM KOHRAM, HANNA SALMAN (Presenter), Univ of Pittsburgh — Isogenic cell populations exhibit large phenotypic heterogeneity even when experiencing homogenous environmental conditions. The evolution of this heterogeneity is limited in part by the inheritance of cellular traits from one generation to the next. In this talk, we will introduce a new experimental technique based on trapping sister bacterial cells in microfluidic channels immediately after they separate from a single mother. Our new setup allows us to follow the sister cells growth and gene expression dynamics for up to ~100 generations while both cells experience identical environmental conditions. This in turn, provides a quantitative measurement of how identical cells become different over time, which reflects the non-genetic inheritance effects, and reveals their contribution to restraining the variability of cellular traits. Our results show that the inheritance dynamics vary significantly among different cellular traits, and its effects, can extend up to ~10 generations.
12:51PM X20.00005: A large deviation principle linking lineage statistics to fitness
ETHAN LEVIEN (Presenter), SEAS, Harvard University, TREVOR GRANDPRE, Physics department, UC Berkeley, JANE KONDEV, Physics department, Brandeis University, ARIEL AMIR, SEAS, Harvard University — In exponentially proliferating populations of bacteria, a population may double at a rate greater than or less than the average doubling time of a single-cell, depending on the variability and heritability of generation times at the single-cell level. Previous studies have shown that the distribution of generation times obtained from an isolated lineage is, in general, insufficient to determine the population’s doubling time or growth rate, both of which are proxies for fitness. This poses a fundamental challenge for experimentalists who wish to probe the fitness effects of physiological perturbations using single-cell tracking data. Using a large deviation approach, we present a procedure for inferring a population’s fitness from lineage statistics that is independent of the model specifics. Interestingly, the Large deviation structure underlying the population dynamics imposes a fundamental constraint on the accuracy to which one can infer a population’s fitness from finite lineage data.

1:03PM X20.00006: A Sensitivity Analysis of Growth Rate to Perturbations in Essential Gene Expression
PAOLA BARDETTI (Presenter), ENRIQUE ROJAS, New York Univ NYU — Cell growth is one of the most fundamental physiological processes that bacteria perform, yet the mechanisms by which cells achieve specific growth rates are unknown. To elucidate the genetic basis for cell growth, we performed an essential genome-wide stability analysis of single-cell growth rate upon CRISPRi-mediated perturbation in gene expression. We used mechanistic mathematical modeling to interpret our data. We found that acute transcriptional inhibition of expression of a ribosomal subunit resulted in a growth rate decay that could be predicted by the linear correlation between ribosome concentration and growth rate previously reported. While this confirms that ribosome concentration is rate-limiting with respect to growth, transcriptional inhibition of several other genes involved in various processes resulted in much more rapid growth decay. Overall, decay times were heterogeneous even among genes in the same metabolic pathway. Genes whose inhibition yields fast growth-rate decay times represent key regulators of cellular growth rate. We found that the proteolysis of these proteins is critical for their ability to efficiently mediate growth-rate kinetics in response to nutrient shifts.
CHUNG YIN LEUNG (Presenter), ROGELIO RODRIGUEZ-GONZALEZ, GUANLIN LI, YORAI WARDI, JOSHUA WEITZ, Georgia Inst of Tech — The spread of antibiotic-resistant pathogens is a global threat to public health. As such, there is growing interest in alternative antimicrobials including phage, or viruses that only infect bacteria. However, phage therapy has shown inconsistent efficacy in clinical trials, possibly due to heterogeneity in the host immune response. By combining nonlinear population models and animal experiments, we have shown that host immunity can work synergistically with phage to cure an acute respiratory infection. Nonetheless, phage therapy could still fail when phage resistance is high. In such cases, we consider two strategies proposed to enhance the robustness of phage therapy: combining phage with antibiotics and combining different strains of phage (phage cocktail). Our model predicts that host immunity is also required for the efficacy of phage-antibiotic combinations. Finally, we discuss applications of optimal control theory to optimize the dosing and composition of single phage and phage cocktail therapy, and opportunities to extend findings to application of phage therapy to complex spatial environments.

SUCKJOON JUN (Presenter), University of California, San Diego — Bacterial physiology is a branch of biology that aims to understand overarching principles of cellular reproduction. Many important issues in bacterial physiology are inherently quantitative, and the field is currently enjoying its second Renaissance due to physicists. In this talk, I will focus on cell-size control and homeostasis, a fundamental problem that has been rapidly transforming just in the past few years. I will introduce some of the long-standing questions, and explain the answers that experimentalists and theorists have provided so far. Collectively, the emerging picture is likely to answer a general class of problems in biology beyond bacteria, i.e., how individual cells can converge to their average state without invoking any apparent feedback mechanisms.

11:15AM X21.00001: Reactive Modeling of Silica Synthesis*  ROLAND FALLER (Presenter), Chemical Engineering, University of California, Davis — Reactive Molecular Dynamics can describe complex problems where quantum approaches are too slow and do not properly take into account environmental effects and on the other hand classical molecular dynamics is not capable of describing reactions. ReaxFF is a good model for such systems but it needs to be properly trained for the system at hand. In this study we train a ReaxFF model for silica synthesis as an industrially important question is to characterize silica gels and organo-silicon surface coatings. These are formed by reactive condensation of organo-silicon precursors. The morphologies of silica gels obtained from alkoxy silanes can then be determined using our newly trained models and improved simulation techniques. It is found that the gels obtained from trialkoxysilanes are more loosely bonded, and that the chemistry of the headgroup is important to the gel morphology. We furthermore can describe the chemisorption of alkoxy silanes with organic headgroups to hydroxylated silica surfaces. This approach can also be applied to zeolite synthesis.

11:27AM X21.00002: Evolution of Amorphous Calcium Sulfate Nanoparticles into Crystalline Phases and Development of Short Range Order  CAIYUN JIA (Presenter), Zhejiang University, JAMES J DE YOREO, Pacific Northwest National Lab, BAOHONG GUAN, Zhejiang University — The involvement of amorphous precursors in crystal nucleation remains an important but poorly understood phenomenon in materials science. In particular, the mechanisms by which amorphous precursor evolves to crystalline phase is typically unclear. By maintaining calcium sulfate at a low supersaturation to slow the nucleation rate, we captured amorphous calcium sulfate (ACS) nanoparticles of distinct sizes and shapes, and observed several stages of its evolution. The ACS nanoparticles grow by fusion accompanied by internal structural evolution and gradually develop a layered morphology. Aggregation of the growing ACS particles gives birth to bulk ACS material exhibiting a more compact structure within which crystalline domains form and develop into the gypsum structure. Structural characterization reveals the ACS nanoparticles have a proto-gypsum property ranging from short-range order to medium-range order and that the ACS nanoparticles are hydrous within which elimination of H2O molecules from the first to the second coordination shell of Ca facilitates ions transport and therefore formation of nanocrystalline domains within the amorphous precursors. This finding provides new insights into the evolution of amorphous precursors and their role in multi-stage crystallization.
11:39AM X21.00003: Using neutral atoms to study in situ damage on organic materials
GEORGIOS STRATIS (Presenter), JORDAN D. ZESCH, Physics, The University of Texas at Austin, HENRY PAN, LAUREN J. WEBB, Chemistry, The University of Texas at Austin, MARK G RAIZEN, Physics, The University of Texas at Austin — We use helium atoms excited in a metastable state to characterize in real-time damage induced on organic materials due to electron impact. More specifically, we used a self-assembled monolayer of 11-bromo-1-undecanethiol on gold-coated silicon exposed to 30 eV electron beam. After each electron beam exposure, we probed the sample using helium atoms in $^3S_1$ state that is 19.8 eV above the ground state. Once the helium atoms encounter the sample's surface, they de-excite and the excess energy causes electron emission from the surface. By measuring the kinetic energies of the emitted electrons we can determine chemical changes that occurred between each electron beam exposure. Due to the fact that metastable helium atoms barely damage our sample while being probed, this technique ensures that any chemical changes we observe are solely due to the electron beam impact. This project is part of a broader effort to develop a neutral atom microscope.

11:51AM X21.00004: Quantitatively Accurate Theory to Predict Adsorbed Configurations of Surfactants on Metal Surfaces
SUMIT SHARMA (Presenter), XUEYING KO, ohio univ — We have developed a theoretical model to predict adsorbed configurations of linear surfactant molecules on metal surfaces. Our coarse-grained simulations of adsorption of surfactants show that our theoretical model is quantitatively accurate in predicting adsorbed configurations. We show that depending on the relative interaction strengths of the polar group and the alkyl tails with the metal surface, the linear surfactant molecules either adsorb by lying parallel to the surface to form stripes or adsorb perpendicular to the surface to form a monolayer. In the case of monolayer formation, our theory predicts that adsorbed surfactant molecules will undergo an orientational transition. This orientational transition is seen in simulations and have also been reported in experiments.

*NSF CBET # 1705817

12:03PM X21.00005: Prospects for polarized neutron scattering from substrate molecules prepared via Signal Amplification by Reversible Exchange
GEORGE THURSTON (Presenter), MICHAEL KOTLARCHYK, Rochester Institute of Technology — We calculate and simulate absolute polarized neutron scattering cross sections for prototypical substrate molecules that have been proven to acquire nuclear spin hyperpolarization via Signal Amplification by Reversible Exchange (SABRE), such as pyridine. Because of the dramatic spin-dependence of polarized neutron scattering, combined with degrees of hyperpolarization that can be orders of magnitude in excess of thermal polarizations, such molecules will exhibit scattering cross sections that provide for potentially useful probes of molecular conformation and solution structure. We examine cross-sections for the neutron spin-flip and no-spin-flip cases. Experiments that combine these cross-sections can yield useful partial structure factors, including direct measurements of distances between chosen nuclei. We explore protocols that yield potentially useful signals proportional both to the first and second powers of the degree of nuclear spin hyperpolarization, and address considerations needed for practical implementation.
12:15PM X21.00006: Development of Angle-Dependent Phase Field Crystal Model for Vapor-Liquid-Solid Transitions

ZI-LE WANG (Presenter), State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, ZHI-RONG LIU, College of Chemistry and Molecular Engineering, Peking University, ZHI FENG HUANG, Department of Physics and Astronomy, Wayne State University, DUAN WENHUI, State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University — As an efficient and fast-developing continuum modeling approach, the phase field crystal (PFC) method is able to resolve systems on atomic length and diffusive timescales. It can well describe system elasticity, plasticity and other important properties by introducing a free energy functional of a conserved atomic density field. However, what is lacking in majority of PFC models is the interaction or coexistence between vapor and condensed phases, an important factor for many physicochemical processes. Here we present a new PFC model based on the angle-adjustable density field formulation we developed before, which incorporates bond-angle dependence of anisotropic interparticle interactions. The relative stability of vapor, liquid and solid phases, the coexistence and transitions between them, and the corresponding interfacial dynamics can be well described by the model. The pressure-temperature phase diagram for pure substance has been obtained, with results consistent with those of some real material systems. Our new PFC model could serve as an effective tool to model realistic experimental processes such as chemical vapor deposition and vapor-liquid-solid growth.

12:27PM X21.00007: Combining Optical Tweezers and Laser Induced Nucleation to Get Liquid Phase Separation and Polymorphically Selective Crystals*

OMAR GOWAYED (Presenter), TASFIA TASNIM, JANICE ABER, BRUCE ALLEN GARETZ, JOSÉ FUENTES-RIVERA, NYU Tandon Sch of Engr — A laser-induced phase-separated (LIPS) solution droplet formed by tightly focusing a continuous-wave, near-infrared laser beam at the glass/solution interface of a mm-thick layer of glycine in D$_2$O was irradiated with a single unfocused ns near-IR laser pulse in order to study the effect of nonphotochemical laser-induced nucleation (NPLIN) on the droplet, as well as to help characterize the behavior of the LIPS droplet. This revealed that NPLIN could nucleate crystals within a LIPS droplet and that the LIPS droplet was observed to be more labile to spontaneous nucleation than the control for the first 40 min of relaxation. The resulting crystals were analyzed using powder X-ray diffraction, and 100% of crystals formed within the LIPS droplet induced by NPLIN and by spontaneous nucleation were α-glycine. The results indicate that the LIPS droplet and the surrounding solution are not equilibrium phases of aqueous glycine, but phases in which gradient optical forces have induced a partitioning of large and small solute clusters.

Separation of Carbon Dioxide from Mixed Vapors by Blockage of Methane in Graphene Nanoribbons* SILVINA GATICA (Presenter), HIND H ALJADDANI, Howard University —
We study numerically the adsorption of a mixture of CO2 and CH4 on a graphite substrate covered by graphene nanoribbons (NRs). The NRs are flat and parallel to the graphite surface, at a variable distance ranging from 0.6 nm to 1.4 nm. We show that the NRs-graphite substrate acts as an effective filter for CO2. Our study is based on Molecular Dynamics (MD) simulations. Methane is considered a spherical molecule and carbon dioxide is represented as a linear rigid body. Graphite is modeled as a continuous material, while the NRs are approached atomistically. We observe that when the NRs are placed 0.6 nm above the graphite surface, methane is blocked out, while CO2 molecules can diffuse and be collected in between the NRs and the graphite surface. Consequently, the selectivity of CO2 is extremely high. We also observe that the initial rate of adsorption of CO2 is much higher than CH4. Overall we show that the filter can be optimized by controlling the gap between NRs and the NRs-graphite separation.

*This work used the Extreme Science and Engineering Discovery Environment (XSEDE) through allocation TG-DMR180036.

On-surface synthesis of graphene nanostructures on non-metallic substrates* MAREK KOLMER (Presenter), Oak Ridge National Laboratory, ANN-KRISTIN STEINER, Friedrich Alexander University Erlangen-Nuremberg, RAFAL ZUZAK, LUKASZ ZAJAC, Jagiellonian University in Krakow, MADS ENGELUND, Espeem S.A.R.L, SZYMON GODLEWSKI, Jagiellonian University in Krakow, WONHEE KO, MIGUEL ANGEL FUENTES-CABRERA, JINGSONG HUANG, AN-PING LI, Oak Ridge National Laboratory, MAREK SZYMONSKI, Jagiellonian University in Krakow, KONSTANTIN AMSHAROV, Friedrich Alexander University Erlangen-Nuremberg — On-surface synthesis of atomically precise carbon-based nanostructures has generated enormous expectations about their potential applications. However, so far selected noble metals have been mostly used as substrates catalyzing the on-surface reactions strongly limiting this perspective.

Here, we will present a method to tackle this long-standing challenge of on-surface synthesis of predesigned carbon nanostructures directly on non-metallic substrates [1]. We will show that thermally triggered intra-molecular C-C coupling is effectively realized on a model transition metal oxide substrate via selective activation of C-F bonds and corresponding cyclodehydrofluorination reactions. Our low temperature STM, XPS and mass spectroscopy experiments prove that flexible oligophenylene chains can be transformed into predesigned nanographene molecules. Finally, we will discuss a strategy to combine C-F bond activation with previous reports on the inter-molecular C-C bond formation [2,3].

1:03PM X21.00010: Anisotropic Ti ionic diffusion giving the anisotropic photo-reactivity in rutile TiO$_2$: A Diffusion Monte Carlo Study  TOM ICHIBHA (Presenter), Materials Science and Technology division, Oak Ridge National Laboratory, ANOUAR BENALI, Computational Science Division, Argonne National Laboratory, KEN'TA HONGO, Research Center for Advanced Computing Infrastructure, JAIST, RYO MAEZONO, School of Information Science, JAIST — Self-diffusion of Ti interstitials is essential for TiO$_2$ photo-catalysts, because it works for maintaining the surface stoichometry and keeping the photo-reactivity. We revisited ab initio evaluations of the barrier energies along the possible diffusion paths of Ti interstitials in rutile TiO$_2$ bulk using diffusion Monte Carlo method. Our calculation predicted that Ti interstitials diffuse faster in parallel to c-axis, reasonably explaining why rutile TiO$_2$ has a superior photo-activity on (001) surface to (110). Our prediction does not support the previous GGA-DFT works, and this discrepancy can be explained by the poor cancellation of the self-interactions in GGA-DFT.

1:15PM X21.00011: Unraveling the mechanism of catalytic water oxidation via de novo synthesis of reactive intermediate*  ALIREZA KARBAKHSH RAVARI (Presenter), Department of Physics and Astronomy, Purdue University — Artificial photosynthesis has the potential to provide carbon-free fuel. The current systems are limited by the lack of understanding of multi-electron water oxidation catalysts (WOC). Trial and error is the only way that new catalysts are being discovered. A thorough spectroscopic analysis of the prototypical [(tpy)(bpy)Ru(H$_2$O)]$^{2+}$ -which is the parent complex in the largest family of WOCs- is presented in this study and will give us a clear understanding of dynamics of this catalyst family. This understanding would help to design a catalyst rationally. De novo synthesis of the reactive intermediate with 2,2'-bipyridine-N-oxide, resulted in a hundredfold catalytic activity compare to the parent compound. In situ Raman spectroscopy along with electrolysis of parent and enriched intermediate shed light on the mechanism of the catalysts. Finally, the redox potential of the ligand was shown to be correlated with the rate of O$_2$production.

Controlling robot dynamics via environmental deformations

HUSSAIN GYNAI (Presenter), SHENGKAI LI, YASEMIN OZKAN-AYDIN, Georgia Inst of Tech, CAMILA DOMINGUEZ, Central Florida University, ENES AYDIN, PABLO LAGUNA, DANIEL I GOLDMAN, Georgia Inst of Tech — In an effort to construct a robophysical analog gravity system, we previously studied the dynamics of a 200-gram differential wheeled robot driving on a deformable spandex membrane (d=2.4m) with a static central depression (Li et al., 2019). The system displays rich dynamics, including precessing orbits reminiscent of those in general relativity. Remarkably, the vehicle-membrane system can be mapped to the dynamics of a test particle in a fiducial spacetime. To take the next step and study how the vehicle dynamics can be manipulated via dynamic non-local changes in membrane curvature, we developed an automated gantry system that can control the position of a spherical object which creates a local deformation on the membrane. From experiments implementing a closed, circular object trajectory, the translating depression can capture the locomoting car from specific initial conditions, depending on initial orientation and position of the car and object trajectories. We explore how feedback from internally based measurements of the vehicle’s tilt and acceleration can enhance capture rates.

Modeling and simulation of complex dynamic musculoskeletal architectures

XIAOTIAN ZHANG (Presenter), FAN KIAT CHAN, TEJASWIN PARTHASARATHY, MATTIA GAZZOLA, University of Illinois at Urbana-Champaign — Natural creatures, from fish and cephalopods to snakes and birds, combine neural control, sensory feedback and compliant mechanics to effectively operate across dynamic, uncertain environments. In order to facilitate the understanding of the biophysical mechanisms at play and to streamline their potential use in engineering applications, we present here a versatile and robust numerical approach to the simulation of musculoskeletal architectures. It relies on the assembly of heterogeneous, active and passive Cosserat rods into dynamic structures that model bones, tendons, ligaments, fibers and muscle connectivity. We demonstrate its utility in a range of problems involving biological and soft robotic scenarios across scales and environments: from the engineering of millimeter-long bio-hybrid robots to the synthesis and detailed reconstruction of complex musculoskeletal systems. The versatility of our methodology offers a powerful framework to aid forward and inverse bioengineering designs as well as fundamental discovery in the functioning of living organisms.

11:39AM X22.00003: Chrono: A multi-physics engine for simulation of robophysical systems

MILAD RAKHSHA (Presenter), RADU SERBAN, DAN NEGRUT, Mechanical Engineering, University of Wisconsin-Madison — Early-stage computer analysis of robophysical systems informs critical design decisions, where systematic study of the design-space via experiment can be challenging and expensive. We present the latest capabilities of a multi-physics platform, called Chrono, that allows for computer modeling and simulation of such systems. The term multi-physics is used herein as a broad umbrella for rigid body dynamics with frictional-contact, flexible body dynamics, fluid dynamics, and fluid-solid interaction. This paradigm is critical in many robophysical systems since locomotion of rigid/flexible robots in conjunction with rigid, granular, and fluid substrates is ubiquitous. The simulation platform supports applications that range from locomotion of robotic agents over non-trivial geometries and on gravel, to underwater robotics. Furthermore, we describe how these simulations can be used as episodes of deep reinforcement learning models for training smart agents who can learn efficient locomotion pathways through machine learning. This is important because (i) fine-tuning the optimum design parameters can be laborious, and (ii) training agents in a virtual environment instead of the real world reduces the time and risks of the operation.

ASHER ELMQUIST (Presenter), RADU SERBAN, DAN NEGRUT, University of Wisconsin - Madison — We present here a simulation infrastructure designed to allow for safe, low-cost, and rapid development, testing, and evaluation of robot control strategies particularly in scenarios that are difficult or impossible to test in reality. The software platform provides (a) simulated dynamics to support interaction between the robots and the environment, (b) simulated sensing to provide the robots with a realistic perspective of the environment, (c) simulated communication to support inter-robot communication used for collaboration and coordination. Support of dynamics allows the exploration of physics-limited scenarios such as slip, collisions, non-linear flexibility, or interaction with fluid. Combining the dynamic simulation with virtual sensing allows us to enhance the capability of the control strategies by exploring sensing limited scenarios such as low light or inclement weather. In addition to dynamics and sensing, simulated communication in the virtual environment allows for coordination that may be used in multi-robot scenarios. These complex scenarios that include dynamics, sensing, and communication are parallelized in this simulation framework such that hundreds of variations can be performed to probe difficult or impossible to test edge-cases.
12:03PM X22.00005: Learning to locomote in the presence of symmetry  SCOTT KELLY (Presenter), Univ of North Carolina - Charlotte — Deep reinforcement learning algorithms provide a paradigm whereby a biomorphic robot can refine a strategy for efficient locomotion based on judicious trial and error, exploiting a biologically inspired architecture for the storage of experiential knowledge. An important feature of this paradigm is its applicability to systems for which accurate mathematical models are unavailable, so that behavioral policies must be constructed directly from sensor feedback. It's commonly the case that even when a mathematical model is unavailable for a system's dynamics, fundamental considerations ensure that symmetries underlie these dynamics. Practical reinforcement learning in a physical setting requires a parsimonious approach to data collection and representation. This talk will discuss the use of symmetry to improve the economy with which a physical robot can learn to locomotive efficiently.

12:15PM X22.00006: Nonlinear distance and velocity estimation from optic flow  FLORIS VAN BREUGEL (Presenter), University of Nevada, Reno — Vision is widely used by animals and robots for position and velocity estimation. Robots typically use stereopsis or feature recognition to extract distance from image data. Stereopsis, however, requires 2 calibrated cameras positioned at a sufficiently large distance, and feature based methods require computationally expensive image processing. These limitations preclude small animals and robots from estimating distance in this manner. What alternative solutions exist? I will review a nonlinear estimation method for separating distance and velocity information from optic flow generated by a single dynamically moving camera. Unfortunately, this approach requires calculating the time derivative of optic flow, a notoriously noisy signal. To overcome this limitation, we use a new neural network optic flow estimator, flownet2, and total variation regularization methods to estimate smooth derivatives. These steps allow us to independently measure distance and velocity from a single dynamically moving camera. We propose that this approach to integrating multiple sensory modalities during dynamic motion, which we refer to as idiokinemetry, is likely a general feature of how animals perceive the world, and may inspire the development of smaller and more robust robotic systems.
Raising head facilitates antenna cleaning in a honey bee*  WEI ZHANG (Presenter), JIANING WU, ZHIGANG WU, School of Aeronautics and Astronautics, Sun Yat-Sen University — Antennae are arguably of significance for honey bees to engage in olfaction, foraging, flying and other physiological behaviors. Contamination on the hairy antennae by dust and pollen is an ineluctable problem. Honey bees have a special structure, namely the antenna cleaner on their forelegs, to clean their antennae with. The antenna cleaner is composed of a deep notch on the ventral surface of the proximal end of the basitarsus and a large spur, which is movable, inserted at the inner angle of the distal end of the tibia. To maintain cleanliness, a honey bee grooms antennae frequently by swinging forelegs with the elaborate antenna cleaner. By high-speed imaging, we find that the honey bee raises its head while grooming antennae by forelegs. By theoretical and experimental combined study, we demonstrate that the head-raising behavior accelerates relative speed by 310% and increases friction force by 70%, which facilitates a swift and efficient grooming stroke. This behavior may inspire next-generation cleaning devices applied in microelectromechanical systems.

Large scale quantitative phenotyping of aversive behaviour and habituation in C. elegans*  LUIGI FERIANI (Presenter), IDA BARLOW, ADAM MCDERMOTT-ROUSE, ANDRE BROWN, Imperial College London — The nematode C. elegans has been influential in the development of the physics of behaviour, especially in methods for representing and analysing postural dynamics. To apply these methods in the context of genetic and drug screens, we need to be able to record behaviour with high resolution and throughput. We have combined robotic liquid handling, multi-camera imaging systems, and tracking software in a high-throughput pipeline that can record from about 500 samples simultaneously. Quantitative analysis of the spontaneous locomotion of C. elegans already yields a multidimensional phenotype that allows us to detect even subtle drug treatment-induced changes in its behaviour. We have added a wide-area, intense blue LED illumination to our recording system to increase the dimensionality of the explored phenotype space by both analysing the response elicited by a single stimulus, and studying simple of forms of learning such as habituation to repeated stimulations.

Using robotics and physics to understand the evolution of novel functional morphologies

BROOKE FLAMMANG (Presenter), Biology, New Jersey Institute of Technology, KAELYN GAMEL, AUSTIN GARNER, University of Akron — Remoras are fishes that attach to other swimming organisms via an adhesive disc evolved from dorsal fin elements. However, the factors driving the evolution of remora disc morphology are poorly understood. Fortunately, the fundamental physics of suction and friction are mechanically conserved through time. Using a morphologically relevant bioinspired remora disc, we experimentally investigated the performance of hypothetical evolutionary intermediates. Herein, we translated fundamental biological principles into engineering design rules and show that a passive model system can autonomously achieve adhesive forces measured in live remoras in any environment. Our experimental results show that an increase in lamellar number resulted in an increase in shear adhesive performance, supporting the phylogenetic trend observed in extant remoras. The greatest pull-off forces measured for our model were on surface roughness on the order of shark skin and exceeded those measured for live remoras attached to shark skin by almost 60%. Overall, relative to fossil remoras and their closest ancestor, extant remoras exhibit a morphology indicative of selection for enhanced shear adhesive performance.

Electrically Programmable Micro-Scale Shape Memory Devices*

QINGKUN LIU (Presenter), WEI WANG, MICHAEL REYNOLDS, MARC MISKIN, MICHAEL CAO, DAVID MULLER, PAUL L MCEUEN, ITAI COHEN, Cornell University — We demonstrate microscale shape memory devices capable of achieving micrometer bending radius with a holding time of several tens of hours. The core of these devices consists of a nanometer-thin platinum layer capped on one side by titanium. Under application of potentials in the range of 1 volt, ions oxidize the platinum, create a differential in stress between the two sides, and cause the structure to bend. Using thick panels we can localize the bending and readily create 3D shapes and patterns that can be reversibly erased and rewritten by short electrical pulses. This electrical programmability can be harnessed to make sequential and bidirectional folding. We demonstrate several reconfigurable 3D patterns, kirigami, and origami motifs. As such these micro-scaled shape memory devices enable a variety of applications in fields ranging from mechanical memory storage to microscopic robots.

1:15PM X22.00011: The radical pair mechanism can provide a sensitive and robust magnetic compass for birds. SHAWN STRAUSSER (Presenter), THORSTEN RITZ, University of California, Irvine — Many adult birds can travel 5,000km or more with a precision of centimeters. Earth's magnetic field provides an omnipresent source of information that aides in this navigation. The mechanism by which animals sense the Earth's magnetic field remains one of the most important problems in sensory biology. The radical pair mechanism (RPM) proposes that the Earth’s magnetic field influences a chemical pathway via electron spins in a radical pair. Recently it has been shown that a so called “quantum needle” radical pair model can be extraordinarily sensitive to directional changes, thus potentially providing the basis for a highly sensitive magnetic. However, it has also been shown that many compass systems are fragile, i.e. that even small, naturally occurring, variations in parameters can abolish effects that are observed in models without considering such noise. Here, we ask what effects noise has on a quantum needle compass system. Rather than reducing the quantum needle, noise is found to either leave the needle intact or even enhance it in some systems. This suggest that a quantum needle based compass may not only be distinguished by a high sensitivity, but also by being unusually robust to noise, making it a highly optimized system for magnetoreception.

1:27PM X22.00012: Breathing from Underground: Diurnal Variability in the Ventilation Mechanism of Termite Mounds SAURABH SAXENA (Presenter), NEDA YAGHOOBIAN, Florida State Univ — Termites are social insects that build massive porous mounds for creating a habitable environment for their colony. These structures exhibit intricate architectures that can effectively harness natural wind, solar energy, and colony’s metabolic heat to produce controlled microclimates in termite nests. Based on experimental studies, several mechanisms have been proposed to explain the ventilation and gas exchange process in termite mounds, such as, metabolism-driven convection, the impact of external wind, and formation of thermal gradients due to diurnal variation of the mound surface temperature. This study investigates the underlying physics of the ventilation mechanisms in termite mounds. Computational fluid dynamics (CFD) modeling is used to simulate flow past and through the porous bodies of termite mounds. For this purpose, the Navier–Stokes equations are modified in a Direct Numerical Simulation using the Darcy-Brinkman-Forchheimer model to represent the porosity. The effect of the diurnally variable surface temperatures is considered through the dynamic coupling of the CFD model with an energy balance-based model that simulates the spatiotemporally variable surface temperatures in high resolution.
1:39PM X22.00013: Specialisation and plasticity in a primitive social insect  
SOLENN PATALANO, BSRC Alexander Fleming, ADOLFO ALSINA, Max Planck Institute for the Physics of Complex Systems, WOLF REIK, The Babraham Institute, STEFFEN RULANDS (Presenter), Max Planck Institute for the Physics of Complex Systems — Biological systems rely on an influx of energy from the environment to build and maintain complex spatio-temporal structures in noisy environments. It has recently become evident that they also have the remarkable capacity to break up and rebuild such structures, exemplified by the capability of differentiated cells to reprogram after injury. Here we use primitive societies of *Polistes* wasps as a model system where we experimentally perturb the nest and follow the re-establishment of the social steady state. We combine a unique experimental strategy correlating measurements across vastly different spatial scales with a theoretical approach to show that *Polistes* integrates antagonistic processes on different scales to simultaneously achieve plasticity and robust specialisation. We show that stability of the nest relies on epigenetic DNA modifications that suppress transcriptional noise. Such dynamics provide a general principle of how both specialization and plasticity can be achieved in biological systems.

1:51PM X22.00014: Hydrodynamics of sheep herds  
RAPHAEL SARFATI (Presenter), University of Colorado, Boulder, MARINE DE MARCKEN, University of Washington, ORIT PELEG, University of Colorado, Boulder — The collective motion of living entities, from cells to wildebeests, is a fascinating and aesthetic phenomenon which continues to intrigue physicists as well as any curious observer. Over the past decade, many compelling findings have come out of the rigorous study of systems such as bird flocks and mosquito swarms, where individuals are scattered and interact remotely. In parallel, slowly-moving aggregates of grasping individuals, such as ants and bees, have been successfully investigated from a material perspective. A third category of interest is now surfacing, in which individuals move collectively while remaining in a near-jamming state. This includes for example crowds of humans, or herds of sheep, which are the focus of this presentation. By employing optical flow methods to measure the velocity field of dense sheep herds, we construct a hydrodynamics framework to study the collective motion of living systems flowing like liquids. The proposed methods are versatile and can be adapted to other flocking systems, such as flamingoes, penguins, etc.

2:03PM X22.00015: The decision-making and mechanics of honey bee swarm formation  
GARY NAVE (Presenter), ORIT PELEG, University of Colorado, Boulder — In late spring and early summer, honey bee colonies may begin the process of swarming, in which the colony will send two-thirds of its population, including the mother queen, to form a new hive. The bees assemble themselves into a temporary hanging cluster for anywhere from a few hours to several days, protecting the queen and young bees while scouts identify a new nest location. While the house-hunting process has been studied, the process of formation has remained overlooked. In this work, we present both experimental results and computational modeling on the process of swarm formation to address questions of decision-making as bees join the swarm and the mechanical properties of bees within the swarm. Using agent-based modeling methods, we identify local decision-making rules that reproduce the experimentally observed behaviors in swarm formation. Understanding the behavior of honey bees during swarming lays the groundwork for improved control strategies for multi-agent robotic systems.
11:15AM X23.00001: The role of physical forces in cortical morphogenesis* [Invited] MARIA HOLLAND (Presenter), University of Notre Dame — Between individuals and across species, brain morphology is strikingly consistent in some significant ways. One example is a characteristic pattern of cortical thickness in gyrencephalic, or folded, brains - thick outer folds, or gyri, and thin inner folds, or sulci. This raises the question: which factors (genetic, biochemical, physical, and/or others) lead to this morphological consistency? In a recent combined theoretical, numerical, and experimental study, we found that the physical forces generated by buckling instabilities were sufficient to generate physiological gyral-sulcal thickness ratios. We now consider the more complex, fully three-dimensional pattern of cortical thickness in the brain, and investigate the role of physical forces in its evolution, consistency, and variability.

*NSF CRII grant: IIS-1850102

11:51AM X23.00002: New directions for the animal shape analysis VASYL ALBA (Presenter), JAMIE CARTHEW, MADHAV MANI, RICHARD CARTHEW, Northwestern University — We used a new precise tool to address a question of quantitative description of the morphological traits in biological systems. We found that directions of natural variation are related to the directions of well-known mutations. We studied a population of fruit flies that were under developmental pressure as well as different species. We found some conserved features in the ensemble variability and identified features that are associated with environmental conditions and with genetic variation.
Surface Stresses Drive Morphological Changes in Three-Dimensional Microtissues

ERIK MAILAND (Presenter), Institute of Mechanical Engineering and Bioengineering, Ecole Polytechnique Federale de Lausanne, BIN LI, Department of Mechanical and Aerospace Engineering, Cornell University, JEROEN EYCKMANS, Department of Biomedical Engineering, Boston University, NIKOLAOS BOUKLAS, Department of Mechanical and Aerospace Engineering, Cornell University, MAHMUT SELMAN SAKAR, Institute of Mechanical Engineering and Bioengineering, Ecole Polytechnique Federale de Lausanne

The formation and maintenance of tissue boundaries is vital for morphogenesis and homeostasis as groups of cells with distinct functions must often be kept physically separated. Cells organize into sheets on the tissue surfaces by forming intercellular mechanical connections directly or through the ECM. The collective dynamics of boundary regulation have been extensively studied with micropatterned epithelial monolayers, whose behavior has been captured using physical models based on nematic liquid crystals. However, less is known about surface effects in 3D fibrous tissues and their contribution to tissue architecture. We developed a high-throughput biomimetic platform for the study of morphogenesis in multilayered 3D microtissues. We performed local mechanical perturbations using a robotic microsurgery system and selective optochemical manipulations using a programmable projector. We show both experimentally and by using computer simulations that cells at the tissue boundary develop surface stresses and, together with contractile cells residing in the core, drive macroscale deformation. We demonstrate that targeted elimination of cells at the tissue surface induces a local stress gradient that leads to tissue morphogenesis.

Mechanoregulation of Valvular Morphogenesis

JONATHAN BUTCHER (Presenter), Cornell University

Defective heart valve morphogenesis is a major cause of preterm fetal death and premature postnatal tissue failure. While much has been learned over the past 30 years regarding the genetic and molecular agents engaged in valve morphogenesis, much less is known about how these networks contribute to cellular and tissue level responses essential for sculpting initially amorphous globular cushions into elongated, thin, and striated leaflets that are competent for long term biomechanical function. Recent studies from our group and others have highlighted that the local mechanical environment within the fetal heart are essential mediators of proper, and when perturbed defective, valvular growth and maturation. We here clarify the embryonic and fetal mechanical environment and elaborate how these mechanical signals coordinate and integrate both canonical valvulogenic signaling programs and previously understudied cellular migration and traction generating programs towards maturation. As this field deepens in its understanding, new opportunities to engineer molecular therapies to harness mechanotransduction and/or mechanosensation could help rebalance disturbed valvulogenic programming, improve anatomical outcomes at birth, and ultimately extend valve performance.

Organ Size Coordination by Chemical Signaling

OJAN K DAMAVANDI

Presenter, Syracuse University, DAVID LUBENSKY, University of Michigan — A profound open question in biology is how animals ensure that their body parts have the correct relative proportions given that development is often noisy. For instance, wings of the same fruit fly do not differ in size by more than about 1% in normal conditions. More interestingly, knocking out a single gene (dilp8) responsible for a hormone secreted by the organs in fly larvae leads to increased size asymmetry of 2-3% between left and right wings. Inspired by this example, we model noisy growth of bilaterally symmetric organs and investigate different mechanisms of organ size coordination using a single coordination signal secreted by the organs. We find that generally feedback can help coordinate organs during growth, thus suppressing variability and speeding development, but that no mechanism with a single signal can robustly coordinate final organ sizes. Finally, we show that a particularly appealing mechanism is proportional feedback on growth rate, which best matches the available data on the biological signatures of dilp8 in flies. Our work suggests that while inter-organ feedback is beneficial to development, organs must additionally employ autonomous size specification mechanisms to ensure low asymmetry at the end of growth.

NSF DMR-1056456; NSF GRFP DGE-1256260.

Generating Cell Fate Patterns via Mechanical Stress in Stem Cell Colonies

HAYDEN NUNLEY (Presenter), XUFENG XUE, JIANPING FU, DAVID LUBENSKY, Univ of Michigan - Ann Arbor — Embryonic development depends on fate specification events in which a field of initially equivalent cells differentiates in a spatially controlled manner. A key example is neural induction in which a strip of cells differentiates into the neural plate, flanked by the neural plate border (NPB). Classic studies of neural induction have confirmed the role of diffusible chemical signals from neighboring tissues; the role of mechanical signals in fate patterning events like neural induction remains poorly understood.

Recent experiments in stem cell colonies on micropatterned substrates demonstrated that neural induction can be recapitulated without exogenous morphogen gradients [1]. We propose a mechanical model for neural induction in which cell fate determines active contractility and in which mechanical stress biases cell fate. This model reproduces a key experimental observation, that the concentric width of the NPB domain is approximately independent of colony size. The model also predicts a non-monotonic dependence of the NPB domain width on substrate stiffness. Preliminary experimental results are consistent with model predictions.

NSF DGE 1256260, NSF CMMI 1917304, NSF-Simons Center for Quantitative Biology Pilot Grant
1:15PM X23.00007: How can proteins take derivatives? MANON WIGBERS (Presenter), Ludwig Maximilian University of Munich, TZER HAN TAN, MIT, FRIDTJOF BRAUNS, TOBIAS HERMANN, Ludwig Maximilian University of Munich — Many cellular processes, such as cell division and cell motility, rely crucially on the dynamic localization of proteins in space and time. These localization patterns emerge collectively from local molecular interactions of proteins. To analyze how the interplay of diffusion and protein interactions on a nanometer scale influence the protein patterns on the cellular scale, the framework of reaction-diffusion models has proven useful. The study of such systems goes back to Turing, who showed how patterns can emerge from a homogenous steady state when two reactive components have different diffusivities. However, in nature, systems typically develop in a heterogeneous and temporally evolving environment and from one pattern into another, rather than from a homogeneous steady state into a pattern.

Here, we study how protein localization patterns arise in heterogeneous systems. We show how localization patterns of upstream regulators dynamically control pattern formation. In particular, we identify concrete mechanisms through which downstream systems can effectively take spatial or temporal “derivatives” of the upstream protein concentration profile. Such mechanisms allow the cell to precisely and robustly control spatial protein organization.

1:27PM X23.00008: Hierarchical “buckling without bending” and brain shape* JENNIFER SCHWARZ (Presenter), MAHESH CHANDRASEKHAR GANDIKOTA, Syracuse University, TYLER ENGSTROM, Physics, William and Hobart Smith College, TENG ZHANG, Syracuse University — While studies of brain shape development have focused on the cerebrum, the cerebellum, otherwise known as the little brain, typically houses more neurons than the cerebrum and has a distinct morphology with 8-10 primary lobes that subsequently branch into smaller lobes. A recent “buckling without bending” model quantifies the onset of shape change in the developing cerebellum. It consists of an inner incompressible core of cells and an outer fluid-like cortical layer of dividing cells encased by a basement membrane. Additionally, there are two types of fibrous cells—ones spanning the cerebellum and ones spanning the cortical layer. The onset of shape change is a consequence of mechanical constraints on the outer fluid-like cortical layer as it proliferates. This model is now generalized beyond the onset of shape change to predict shape development at later stages. In particular, a hierarchical version of the model is implemented to predict subsequent branching of the smaller lobes. Predictions are compared with various mammalian cerebella exhibiting varied counts of branching generations. We also explore how some aspects of “buckling without bending” may lead to a new level of detail for characterizing shape change in the developing cerebrum.

*NSF-DMR-1832002
1:39PM X23.00009: Mechanomorphogenesis of bacterial biofilms*  JING YAN (Presenter), Yale University — Surface-attached bacterial communities called biofilms display a diversity of morphologies. Although structural and regulatory components required for biofilm formation are known, it is not understood how these essential constituents promote biofilm surface morphology. Here, using *Vibrio cholerae* as our model system, we combine mechanical measurements, theory and simulation, quantitative image analyses, surface energy characterizations, and mutagenesis to show that mechanical instabilities, including wrinkling and delamination, underlie the morphogenesis program of growing biofilms. We also identify interfacial energy as a key driving force for mechanomorphogenesis because it dictates the generation of new and the annihilation of existing interfaces. Finally, we discover feedback between mechanomorphogenesis and biofilm expansion, which shapes the overall biofilm contour. The morphogenesis principles that we discover in bacterial biofilms, which rely on mechanical instabilities and interfacial energies, should be generally applicable to morphogenesis processes in tissues in higher organisms.

1:51PM X23.00010: Quantifying mechanochemical coupling in the actomyosin cortex during early development in vivo  MELIS TEKANT (Presenter), ALEXANDRU BACANU, YOON JUNG, JORN DUNKEL, NIKTA FAKHRI, Massachusetts Institute of Technology MIT — Spatiotemporal symmetry-breaking transitions in biochemical patterns are essential in triggering morphological changes during the development of all life forms, both at the unicellular and multicellular level. The realization of cell and tissue-scale deformations is achieved through intra-cellular force networks that translate localized biochemical signals into effective mechanical stresses that determine the global shape dynamics. However, the mechanochemical coupling between the biochemical patterns, force network activity and the resulting stresses is not well understood. Here, we quantify the local coupling between membrane-bound Rho-GTP and the mechanical deformations of the actomyosin cortex in the starfish oocytes during meiosis. We generate various Rho-GTP dynamic patterns and map the resulting stress patterns via tracking endogenous tracer particles embedded in the cell cortex. This method provides a novel approach to probe the local coupling between biochemistry and mechanics and the resulting morphological changes.
2:03PM X23.00011: The role of environment, material, and function in the morphological diversity of termite mounds  TADEU FAGUNDES (Presenter), JUAN ORDONEZ, NEDA YAGHOOBIAN, Florida State Univ — Several species of termites across the globe construct mound architectures that are of several orders of magnitude larger than themselves. These superstructures exhibit distinctive structural designs that range widely in size and shape. There are several studies exploring the function of termite mound structures, but only a few works explore reasons behind the morphological variety observed in them. To explain this diversity, the present work introduces a computational model that couples the mound’s environment, material, and thermal function to its shape. Using the fundamentals of heat transfer, the model captures the main features observed in termite mounds, such as the mound orientation and spire tilt. The influence of each environmental agent over the mound structure is analyzed, revealing a strong correlation between the mound structure and the combined effects of the environmental forces. The proposed methodology can be used in the prediction of the effect of environmental forces on the thermal performance and architecture of any natural structure for which structural and environmental information can be obtained. As such, this framework provides a broader view of the factors that are effective in the form and function of naturally made structures.

Session X25 GSNP: Pattern Formation, Chaos, Nonlinear Dynamics III

402 - Thomas Witten, University of Chicago

11:15AM X25.00001: Operator scrambling, hypersensitivity, and quantum Lyapunov spectrum*  BIN YAN (Presenter), NIKOLAI SINITSYN, WOJCIECH HUBERT ZUREK, Los Alamos National Laboratory — This work presents a model study of the quantum inverted harmonic oscillator (IHO), an archetype example for quantum chaotic systems. It is shown that the IHO exhibits hypersensitivity to perturbations, i.e., the Loschmidt echo decays as a double exponential. A quantum Lyapunov spectrum has been introduced to detect the exponential operator growth in chaotic systems. The IHO is demonstrated to possess a quantum Lyapunov spectrum that is identical to the classical one.

11:27AM X25.00002: Non-equilibrium Renormalization Group Fixed-Points of the Quantum Potts Chain*  YANTAO WU (Presenter), Princeton University — We devise a renormalization group recursion relation of the Loschmidt amplitude of the quantum Potts chain. The non-equilibrium fixed-points of the renormalization procedure determine the dynamical phases of the system, giving rising to a dynamical quantum phase transition. We will also discuss how there fixed-points affect the dynamical phase transition of the disordered Potts chain and the Loschmidt amplitude of the excited states.

*DOE Award DE-SC0017865

11:39AM X25.00003: Laminar Chaos in a Mackey-Glass feedback circuit with Variable Time-Delay*  DAVID JIN (Presenter), Grinnell College, JUAN PABLO SPEER, University of Alabama, Birmingham, JOSEPH HART, YANNE CHEMBO, THOMAS E. MURPHY, RAJARSHI ROY, Institute for Research in Electronics and Applied Physics, University of Maryland, College Park — Laminar chaos is a newly discovered chaotic behavior theoretically predicted in 2018 [1], which can be characterized by steady-state phases separated by short and irregular burst-like transitions. It has been observed experimentally in an optoelectronic variable time-delay feedback system implemented with a field-programmable gate array (FPGA) [2]. The Mackey-Glass model, developed to simulate the physiological mechanism of red blood cells, is a common time-delay system that can yield a wide range of periodic and chaotic dynamics. We report here the observation of laminar chaos in an electronic Mackey-Glass feedback circuit, the first observation of its kind, implemented with an Arduino board to produce variable time delays. This unique system implementation allows us to easily create audio signals from laminar chaos that contrast with signals generated by a system with a constant time delay.

Theory of gating in recurrent neural networks

KAMESH KRISHNAMURTHY (Presenter), Dept. of Physics and Princeton Neuroscience Institute, Princeton University, TANKUT CAN, Initiative for the Theoretical Sciences, The Graduate Center, CUNY, DAVID SCHWAB, Initiative for the Theoretical Sciences, The Graduate Center, CUNY and Facebook AI Research —

Understanding the emergent dynamics of networks of neurons is a central challenge in theoretical neuroscience. Most of the work in understanding the dynamics of these networks has focused on models with `additive interactions', where the input to a neuron is a weighted sum of the output of the rest of the network. However, there is ample evidence from neurophysiology that neurons can have gating or multiplicative interactions, where e.g. one neuron can dynamically decide whether another neuron is influenced by the rest of the network. Such gating interactions lead to qualitatively different behavior of single neurons, and are likely to have even more dramatic effects on the collective behavior of a network. Furthermore, researchers in machine learning have found that gating interactions facilitate training of model neural networks. Thus, gating can have significant implications for information processing. We leverage tools from the field theory of disordered systems to develop a theory of gating in a canonical neural network model. Our theory allows us to elucidate the dynamical aspects of gating which are important for the network's information processing capabilities.

Short-term forecasting of hyperchaotic time series by noisy echo state network

TAKAYA MIYANO (Presenter), AREN SHINOZAKI, Ritsumeikan Univ, YOSHIHIKO HORIO, Research Institute of Electrical Communication, Tohoku University — We have applied a noisy echo state network, wherein pseudorandom numbers subject to uniform distribution are input to the reservoir nodes, to the short-term forecasting of a hyperchaotic time series generated by a star network of nonidentical Lorenz subsystems. The chaotic dynamics have five positive Lyapunov exponents with a Lyapunov dimension exceeding 12. Although the predictive model incurs a large prediction error, it is capable of reproducing the geometric structure of the hyperchaotic attractor with sufficient fidelity. We discuss these results in terms of Ueda's view of chaos, wherein chaotic dynamical behavior is recognized as a piecewise deterministic process with intervening stochastic processes such as numerical round-off errors and perturbations caused by experimental measurements.

12:15PM X25.00006: Critical branching processes in digital memcomputing machines

SEAN BEARDEN (Presenter), FORREST C SHELDON, MASSIMILIANO DI VENTRA, University of California, San Diego — Memcomputing is a novel computing paradigm that employs time non-locality (memory) to solve combinatorial optimization problems. It can be realized in practice by means of non-linear dynamical systems whose point attractors represent the solutions of the original problem. It has been previously shown that during the solution search digital memcomputing machines go through a transient phase of avalanches (instantons) that promote dynamical long-range order. By employing mean-field arguments we predict that the distribution of the avalanche sizes follows a Borel distribution typical of critical branching processes with exponent $\tau=3/2$. We corroborate this analysis by solving various random 3-SAT instances of the Boolean satisfiability problem. The numerical results indicate a power-law distribution with exponent $\tau=1.51\pm0.02$, in very good agreement with the mean-field analysis. This indicates that memcomputing machines self-tune to a critical state in which avalanches are characterized by a branching process, and that this state persists across the majority of their evolution. [1]

12:27PM X25.00007: Connecting Dynamics and Trainability in Recurrent Neural Networks

TANKUT CAN (Presenter), Initiative for the Theoretical Sciences, The Graduate Center, CUNY, KAMESH KRISHNAMURTHY, Dept. of Physics and Princeton Neuroscience Institute, Princeton University, DAVID SCHWAB, Initiative for the Theoretical Sciences, The Graduate Center, CUNY and Facebook AI Research — Recurrent neural networks (RNNs) are well-suited for complex sequential learning tasks, but are notoriously difficult to train due to the problem of exploding or vanishing gradients (E VG) of the cost function. Local switch-like multiplicative “gates” were introduced to address this issue by modulating inter-neuron interactions and selectively updating the state of the network, promoting longer time scales. As such, these "gated" RNNs seem to mitigate the EVG, making training tractable. However, the specific role of each gate type on dynamics and training remains unclear. We take a dynamical systems perspective to study these questions for two popular gated RNN architectures: the Gated Recurrent Unit (GRU) and Long Short-Term Memory (LSTM). Using random matrix theory, we elucidate how gating enriches the repertoire of dynamical behavior expressed by these networks. Our approach furthermore sheds light on how gating is able to overcome the EVG by shaping asymptotic stability. Finally, we connect the intrinsic dynamics upon random parameter initialization to the subsequent ease of training GRUs and LSTMs.

12:39PM X25.00008: Misalignment-induced frequency locking in lasers  
NIKETH NAIR (Presenter), YEHUDA BRAIMAN, Oak Ridge National Lab — We study arrays of heterogeneous single-mode semiconductor lasers coupled through an external cavity with facet misalignments. This system can be modeled mathematically as a set of coupled nonlinear delay-differential equations. The heterogeneity, in the form of frequency detuning, is represented as parametric disorder between the oscillators, and the facet misalignments is represented by a small disordering of the time-delays in the coupling terms. In this system, we show that the introduction of time-delay disorder induces perfect frequency locking in a system that otherwise is unable to frequency-lock due to heterogeneous natural frequencies, as well as chaotic behavior.

12:51PM X25.00009: Self-beating*  
KUAN-REN CHEN (Presenter), JIAN-SHIUNG HONG, Department of Physics, National Cheng Kung University, ALEXANDER CHEN, School of Electrical Engineering and Computer Science, The Pennsylvania State University — There are two kinds of nonlinear mechanism. Beat is typical for the kind involving two or more frequencies. The other kind involves only one frequency due to large wave amplitude or weak media. Considering only linear materials and processes, we discover a new mechanism of self-beating to produce a wave function that does not appear to be linear. During a pulsed light being transmitted through a plasmonic slit, a portion of the light pulse transmits as a sub-pulse, while the rest is reflected at the exit interface, propagates a round-trip, and then reaches the exit again. These linear processes repeat. The superposition of transmitted sub-pulses with a phase delay in-between produces a periodic light that beats its original light frequency. Together with the plasma effects of non-uniform dispersion and sub-pulse spreading, self-beating can explain intrigue phenomena observed. The analytical model explains the complicated simulation results.

1:03PM X25.00010: Chaotic Dynamics Enhance the Sensitivity of Inner Ear Hair Cells  
JUSTIN FABER (Presenter), DOLORES BOZOVIC, University of California, Los Angeles — Hair cells of the auditory and vestibular systems can detect sounds that induce sub-nanometer vibrations of the hair bundle, below the stochastic noise levels of the surrounding fluid. Hair cells of certain species are known to oscillate without external stimulation. These spontaneous oscillations are believed to be a manifestation of an underlying active mechanism and may play a role in signal detection. We previously demonstrated experimentally that the spontaneous oscillations exhibit chaotic dynamics. We propose that the instabilities giving rise to chaotic dynamics are responsible for the extreme sensitivity of hair cells. We will present experimental measurements of spontaneous and driven hair bundle oscillations. By varying the conditions of the surrounding fluid, we were able to modulate the degree of chaos observed in the hair cell dynamics. We found that the hair bundle is most sensitive to small-amplitude stimulus when it is poised in the weakly chaotic regime. Further, we found that the response time to a force step decreases as the level of chaos is increased. These results agree well with our numerical simulations of a chaotic Hopf oscillator and suggest that chaos may be responsible for the extreme sensitivity and temporal resolution of hair cells.
1:15PM X25.00011: Nonlinear Coherent Perfect Absorbers*  YAQIAN TANG (Presenter), DO HYEOK JEON, TSAMPIKOS KOTTOS, Physics, Wesleyan University — Coherent perfect absorber (CPA) is a resonant mechanism in which a cavity with a minimal amount of losses can completely absorb incident radiation with an appropriately tailored waveform. The cavity acts as an interferometric trap that confines the incident light for long times and thus amplifies the net absorption. Although in current studies, it was assumed that the medium inside the cavity is linear, there are realistic scenarios where nonlinear mechanisms are engaged.

Here we develop the theoretical framework for the design of CPA waveforms under nonlinear conditions. As an example, we use a photonic circuit consisting of an array of coupled resonators with a nonlinear target embedded in the array. A general solution for the design of the incoming waveform is proposed, and a plethora of CPA frequencies that depend on the intensity of the incident radiation is found—a feature that was not present in linear CPAs. Furthermore, we have demonstrated that under appropriate conditions one can realize a CPA degeneracy, which resembles an exceptional point singularity.

1:27PM X25.00012: Recent advances on non-normalizable Boltzmann-Gibbs statistics and infinite-ergodic theory  EREZ AGHION (Presenter), Max Planck inst. for physics of complex systems, DAVID A KESSLER, ELI BARKAI, Bar Ilan Univ — The equilibrium state of a thermal system, in the presence of a strongly confining potential, is given by the famous Boltzmann-Gibbs distribution. This, along with the ergodic hypothesis, are hallmarks of statistical physics. If the potential is weakly confining, the Boltzmann factor is non-normalizable and the particle packet is constantly expanding. This gives rise to many questions. Among them: can we still infer the shape of the potential landscape, by observing the spatial distribution of the diffusing particles? How do we obtain ensemble and time-averaged observables in this case? And what is the entropy-energy relation in this system?

We show that the non-normalizable Boltzmann state is obtained from an entropy maximization principle, in the spirit of the canonical ensemble from standard thermodynamics, as well as from the ground state of the effective Hamiltonian of the system. The ergodic properties of important physical observables, like energy and occupation times in the system, are given by the Aaronson-Darlin-Kac theorem, and a generalized virial theorem is derived. Thus, our work extends the standard thermodynamic theory to a new class of potentials, and provides further strong evidence to the physical significance of infinite-ergodic theory.
Experimental Observation of a Non-Normalizable Boltzmann State

CARSTEN DIETVORST (Presenter), DIEGO KRAPF, Colorado State University — The probability density function of a particle in equilibrium suspended in a fluid follows a Boltzmann distribution, \( P(x) = \exp(-V(x)/k_BT)/Z \), where \( V \) is the potential energy, \( k_BT \) is thermal energy, and \( Z \) is the normalizing partition function. However, there are cases where the Boltzmann distribution is not normalizable and the system cannot reach thermodynamic equilibrium. It has recently been shown theoretically and via simulations that, in many instances, a particle coupled to a heat bath approaches in the long time a non-normalizable Boltzmann state, such that \( P_t(x) = \exp(-V(x)/k_BT-x^2/4Dt)/Z_t \), where \( D \) is the diffusion coefficient and \( Z_t \sim t^{-\alpha} \) [1]. These systems violate the ergodic hypothesis, i.e. the time average of an observable does not converge to the ensemble average in the long time limit. Here, we test these predictions using functionalized polystyrene beads near a charged surface in liquid. The electrostatic potential \( V(x) \sim \exp(-x/\lambda_D) \), with Debye length \( \lambda_D \), yields a non-normalizable Boltzmann distribution. We track charged particles in 3D near surfaces bearing different surface charge densities. Our experiments reveal a non-normalizable Boltzmann state and ergodicity breaking in agreement with theoretical predictions.

Experimental Search for Supradegeneracy*

DANIEL SHEEHAN (Presenter), Univ of San Diego — Recently a new statistical mechanical phenomenon has been formally identified that turns some thermodynamic intuitions on their heads: supradegeneracy [1]. Normally, population inversion (as in lasers) requires nonequilibrium conditions, but supradegenerate systems are predicted to exhibit inversion at equilibrium. If realized, this phenomenon might help lead to improved photovoltaics and to new types of thermophotovoltaics and batteries [2]. Although supradegenerate systems do not appear in Nature, it seems likely that manmade ones can be realized. This talk reviews the current laboratory search for supradegeneracy in condensed matter systems, specifically, in semiconductors and concentration-graded ionomer membranes.

Lacunarity exponents in chaotic systems

MARC PRADAS (Presenter), MICHAEL WILKINSON, School of Mathematics and Statistics, The Open University, UK, GREG HUBER, Chan Zuckerberg Biohub, ALAIN JACK PUMIR, Physics, ENS-Lyon — Many physical processes result in very uneven, apparently random, distributions of matter, characterised by fluctuations of the local density varying over orders of magnitude. Examples include the distribution of stars within galaxies, distribution of debris floating on fluids, distribution of human population, and the distribution of small inertial particles in a turbulent flow. Many of these systems can be described by chaotic dynamical systems and the existence of a power-law describing the high-density regions is consistent with the notion that chaotic systems can have fractal invariant measures. However, the distribution of density in the sparse regions can also have a power-law distribution, with an exponent that we refer to as lacunarity exponent, and which is not related to the fractal properties of the system. Here, we discuss a robust mechanism that explains the wide occurrence of these power laws and gives analytical expressions for the lacunarity exponent in some cases of interest, including simple chaotic models and the problem of particles advected by fluid flow.

Session X27 DBIO: Physics of Neural Systems

Unifying criticality and the neutral theory of neural avalanches

SAKIB MATIN (Presenter), THOMAS TENZIN, W. KLEIN, Boston Univ — The interest in the question of criticality in the brain has been prompted by experiments which show that the collective firing of neurons (neural avalanches) follow power-law distributions. Three proposed explanations of this emergent scale-free behavior are criticality, neutral theory, and self-organized criticality. We study a model of the brain for which the dynamics are governed by neutral theory and find that the scale-free behavior is controlled by the proximity to a critical point. Our results unify the neutral theory of neural avalanches with criticality, which requires fine tuning of control parameters, and rule out self-organized criticality. We use tools from percolation theory to characterize the critical properties of the neural avalanches and identify the tuning parameters, which are consistent with experiments. The scaling hypothesis provides a unified explanation of the power laws which characterize the neural avalanches. We discuss how our results can motivate future empirical studies of criticality in the brain.
11:27AM X27.00002: Spontaneous spatial symmetry breaking in excitatory neuronal networks and its effects in sparsely connected networks. MIHAI BIBIREATA (Presenter), VALENTIN SLEPUKHIN, ALEX LEVINE, University of California, Los Angeles — We explore the dynamics of the preBötzinger complex, the mammalian central pattern generator with N \sim 10^3 neurons, which produces a collective metronomic signal that times the inspiration. Our analysis is based on a simple firing-rate model of excitatory neurons with dendritic adaptation (the Feldman Del Negro model [Nat. Rev. Neurosci. 7, 232 (2006), Phys. Rev. E 82, 051911 (2010)]) interacting on a fixed, directed Erdős–Rényi graph. In the all-to-all coupled variant of the model, there is a type of spontaneous symmetry breaking in which some fraction of the neurons become stuck in a high firing-rate state, while others become quiescent. This separation into firing and non-firing clusters persists into more sparsely connected networks, but is now determined by k-cores in the directed graphs. It produces a number of features of the dynamical phase diagram that violate the predictions of mean-field analysis. In particular, we observe in the simulated networks that stable oscillations do not persist in the large-N limit, in contradiction to the predictions of mean-field theory. Moreover, we observe that the oscillations in these sparse networks are remarkably robust in response to killing neurons, surviving until \sim 20% of the network remains. This is consistent with experiment.

11:39AM X27.00003: A model for oscillatory gating of information flow between neural circuits as a function of local recurrence MIKAIL KHONA (Presenter), ILA R FIETE, Massachusetts Institute of Technology MIT — Physical connections between neurons are hardwired on the timescale of seconds, but information and signals must be routed flexibly for computation on the same timescales. Many species exhibit circuit-level oscillations with systematic phase relationships between spikes and the regional oscillation. We present a mechanistic neural model of communication, regulated by oscillations. If one or more networks (the “transmitters”) drives a second (the “receiver”) and both network states are periodically modulated, what relationships in their oscillations will allow the transmitter to optimally drive the receiver? As the receiver network moved parametrically from a ‘sensory’ regime to a ‘memory’ regime, we show that the optimal phase offset depends on its operating mode. A sensory network responds optimally when cells are maximally depolarized, or when the transmitter-receiver pair have zero phase offset, while a network with strong recurrent weights, external inputs are drowned out by local contributions when cells are maximally depolarized, and a phase offset of 90 degrees is optimal. Our results generalize to networks with global inhibition, asynchronous inputs and to networks with discrete fixed points in the strong coupling regime.
11:51AM X27.00004: Quasicriticality or Criticality in the brain?* LEANDRO FOSQUE (Presenter), JOHN BEGGS, GERARDO ORTIZ, Indiana Univ - Bloomington, RASHID WILLIAMS-GARCIA, Mathematics, University of Pittsburgh —
Recent experimental studies (Fontenele et. al. 2019) show that critical exponents for size and duration distributions of avalanches in cortical activity are scattered across, clustering around a dynamical critical scaling relation line. Had one assumed these samples were in critical states and all brains, across species, belong to the same universality class, then we should have only observed one point on that scaling line. So, why do experiments show a spread of points along the scaling line, even within the same species? The quasicriticality hypothesis (Williams-Garcia et al. 2014) states that the brain operates in a quasicritical state, which allows optimal information processing, given external stimulus. We conjecture that those experimental results are consistent with quasicriticality. We further show evidence, by performing numerical simulations of our cortical branching model (CBM), of quasicriticality. Thus, the quasicriticality hypothesis is consistent with the observed scattered data along the dynamical critical scaling relation line.

12:03PM X27.00005: Compression as a path to simpler models of collective neural activity* LUISA RAMIREZ (Presenter), Univ Fed de Minas Gerais, WILLIAM S BIALEK, princeton university —
Experiments now make it possible to observe, simultaneously, the electrical activity of hundreds or even thousands of neurons in a small region of the brain. But making models that capture the behavior of these real neural networks easily leads to a combinatorial explosion of complexity and we need explicit strategies for simplification. In many condensed matter systems, interactions are local, but this is not an effective guide for neurons. More abstractly, interactions may be compressible, so that the influence of the whole system on each degree of freedom can be represented by just a few bits of information. We test this idea, analyzing experiments from the vertebrate retina and the mouse hippocampus. Data sets are large enough to provide reliable sampling of activity patterns in subgroups of neurons, and within these groups we find, for example, that the influence of eight neurons on one neuron can be captured almost completely with just ten states, much less than the 256 possible states. This compression can be iterated, providing a path to describing the influence of the whole network on each neuron with a much reduced number of parameters.

*Travel grant support.
12:15PM X27.00006: Effects of local excitations on large-scale brain network dynamics: Insights from coupled Wilson-Cowan oscillators under perturbative stimulation
EVANGELIA PAPADOPOULOS (Presenter), CHRISTOPHER LYNN, University of Pennsylvania, DEMIAN BATTAGLIA, Aix-Marseille University, DANIELLE BASSETT, University of Pennsylvania — Composed of many coupled dynamical units, the brain is a canonical example of a complex network. At the macroscale, it consists of large neuronal populations that generate time-varying activity and that interconnect via a web of anatomical links. However, despite recent progress, we still lack a mechanistic understanding of how large-scale brain networks shape system-wide dynamics, and specifically, how local changes in neural activity affect functional interactions across the brain as a whole. Motivated by a vast literature suggesting that synchronization of activity underlies the coordination of distinct brain areas, we combine structural connectivity data and biophysical modeling to study how regional excitations of activity modulate network-wide synchrony. By employing computational modeling, we examine how the impacts of excitations depend on the location of the perturbation, and, crucially, on the baseline state of the system. Furthermore, we uncover state-specific relationships between brain network properties and the effects of local excitations on the coherence of network dynamics. As a whole, this work provides insight into how local changes in neural activity can propagate via structural links to cause distributed alterations to inter-regional communication patterns.

12:27PM X27.00007: Robust simplicity in the multimodal sensory control of insect flight.
SIMON SPONBERG (Presenter), VARUN SHARMA, Georgia Inst of Tech — Animal movement combines many physiological and physical systems to enable agility and robust behavior. Frequently the behavior that’s manifest can be described, at least in specific experimental contexts, by relatively low order, and often linear, dynamical systems. How does this simplicity arise from the component systems and are the emergent dynamics preserved in the face of changes of context? Insect flight is a challenging task with unstable mechanics and control requirements on the order of a single wingstroke. Using an agile hawk moth, Manduca sexta, tracking a robotic flower during foraging behavior we have shown that the underlying frequency response is linear, time invariant on the scale of 10’s of seconds, and relies on the linear superposition of vision and touch (via the moth’s long proboscis). However, as light levels drop the dynamics of the visual system adjusts, producing slower responses and reduced visual-motor gains. Does the simple emergence remain? We show that the mechanical, touch response to the flower also adjust correspondingly to produce a robust linear superposition of the two cues across contexts. In high and low light cases the two sensory system partition the frequency domain and this partition shifts as light levels dim.
12:39PM X27.00008: Scalable maximally informative dimensions analysis of deep neural networks  JIMMY KIM (Presenter), Northwestern University, DAVID J. SCHWAB, Institute for Theoretical Science, CUNY Graduate Center — Maximally informative dimensions (MID) is a technique in neuroscience used to analyze neural responses to natural stimuli. It assumes that neurons are only sensitive to a low-dimensional subspace within the high-dimensional stimulus space and extracts those relevant dimensions by maximizing the mutual information between the neural response and stimulus projections. Despite its advantages, MID suffers from scalability issues of the optimization. As such, in practice, no more than a handful of dimensions can be found. Here, we present a method based on variational lower bounds of mutual information that allows for the efficient extraction of large number of informative dimensions. We demonstrate this method by studying a deep neural network trained on CIFAR-10, and suggest possible applications towards the information-theoretic view of deep learning as well as a new, principled method of visualizing multiple different facets of a neuron.

12:51PM X27.00009: Inferring structure-function relationships in neural networks from geometric features of their error landscapes*  JAMES FITZGERALD (Presenter), TIRTHABIR BISWAS, Janelia Research Campus — Neural computation in biological and artificial networks relies on nonlinear synaptic integration. The synaptic connectivity between neurons in these networks is a critical determinant of overall network function. However, what features in connectivity are specifically required to generate measurable network-level computations are largely unknown. Here we introduce a geometric framework for calculating and analyzing connectivity constraints in nonlinear recurrent neural networks of rectified linear units. We focus on network-level functions defined by steady-state responses to a finite set of input conditions. By analytically determining how well any network approximates the responses, we show that error landscapes typically have degenerate global minima with several flat and semi-flat dimensions. The latter emerges from the rectifying nonlinearities. Further, at increasing noise or error levels, topological transitions occur where the space of admissible solutions changes suddenly and drastically. This is reminiscent of sudden changes associated with phase transitions in physical systems. These results allow us to develop a formalism for extracting rigorous insights into neural network structure and function from the geometries and topological transitions of error surfaces.

*HHMI
1:03PM X27.00010: An olfactory pattern generator for functional neural circuit analysis in *Drosophila larva*  
GUANGWEI SI (Presenter), JACOB BARON, YU FENG, ARAVINTHAN SAMUEL,  
Harvard University — For physical stimuli, it is straightforward to engineer patterns to stimulate the sensory circuits and probe the functional properties. However, this framework is generally not applicable to olfaction, since olfactory stimuli lack a well-defined space. The typical olfactory stimuli, fixed odor panels of pure chemicals, natural scents or mixtures, lack the capability to systematic sample the olfactory sensory periphery. Here, we present a stimuli method that project activity pattern directly onto the olfactory receptor neurons. This method is based on the flexible and precise mixing of an optimized set of primary odors using microfluidics. The primary odors were derived for the *Drosophila larva* to separately target each free variable in the olfactory code, the activity of an individual olfactory receptor neuron type. Our device allows us to program and deliver any mixture of primary odors from all combinatorial possibilities during an experiment, allowing selection of any receptor neuron activity combination on demand. We combine this stimulus method with imaging the olfactory representations in the *Drosophila larva* from receptor neurons to interneurons of the antennal lobe and Kenyon Cells of the mushroom body.

*This work was supported by an NSF grant (NSF-IOS-1556388).

1:15PM X27.00011: Sequential and efficient neural-population coding of complex task information  
SUE ANN KOAY (Presenter), Princeton Neuroscience Institute, Princeton University, STEPHAN Y THIBERGE, Bezos Center for Neural Dynamics, Princeton University, CARLOS BRODY, DAVID TANK, Princeton Neuroscience Institute, Princeton University — A crucial component of cortical computation is context: variables that indicate the external state of the world, and the internal state of the animal. However, the need to simultaneously represent many pieces of information in neural activity can also pose computational challenges for neural systems to overcome. We recorded from large neural populations in posterior cortices as mice performed a complex, dynamic task involving multiple interrelated variables. How are these variables represented together without crosstalk, and what of their time-dependent relationships to each other? We found that the neural encoding implied that correlated task variables were represented by uncorrelated modes in an information-coding subspace, which can in theory enable optimal decoding directions to be insensitive to neural noise levels. Across posterior cortex, principles of efficient coding thus applied to task-specific information, with neural-population modes as the encoding unit. Remarkably, this encoding function was multiplexed with rapidly changing, sequential neural dynamics, yet reliably followed slow changes in task-variable correlations through time. We can explain this as due to a mathematical property of high-dimensional spaces that the brain might exploit as a temporal scaffold.
Heterogeneity of timescales in random networks with bistable units

NICOLAE ISTRATE (Presenter), Department of Physics, Institute of Neuroscience, University of Oregon, MERAV STERN, Department of Applied Mathematics, University of Washington, LUCA MAZZUCATO, Departments of Biology and Mathematics, Institute of Neuroscience, University of Oregon — Recent experiments reveal that neural circuits operate in a regime with simultaneous presence of multiple timescales. Such heterogeneity of timescales was observed not only across different brain areas (Murray JD et al 2014) but also across neurons within the same circuit (Cavanagh SE et al 2016) during periods of ongoing activity, suggesting that it may be an intrinsic dynamical property of recurrent circuits. Here we investigate which neural mechanisms may support this heterogeneous distribution of timescales. We show that random neural networks with bistable units (Stern M et al 2014) naturally exhibit large heterogeneity of timescales across neurons in the presence of a distribution of self-couplings. We provide a biophysical interpretation for the bistable units in our rate network in terms of Hebbian assemblies. We show that, in recurrent spiking networks where excitatory and inhibitory neurons are arranged in assemblies, one can achieve a heterogeneous distribution of timescales when assembly sizes are unequal. We thus interpret the rate network self-couplings as potentiated synaptic couplings between neurons within the same assembly. Our results establish a novel theoretical framework to investigate the observed heterogeneity of intrinsic neuronal timescales.

Recurrence Neural Networks Learn Simple Computations on Complex Time Series through Examples*

JASON KIM (Presenter), ZHIXIN LU, DANIELLE BASSETT, University of Pennsylvania — A hallmark of artificial and biological neural networks is their ability to represent and generalize complex information. Artificial neural networks generate novel images of cats after seeing many pictures of cats. Conference attendees generate creative new future research directions after carefully listening to a talk. How do neural networks represent, manipulate, and extrapolate complex information given only examples? Previous methods such as FORCE learning have demonstrated the ability of a neural network to replicate complex, and even chaotic, patterns of observed outputs in response to specific patterns of driving inputs. Here, we explain how a neural network further learns the underlying computations performed on the observed outputs. Specifically, we demonstrate that a neural network trained to output slightly translated or rotated chaotic manifolds in response to small driving inputs can extrapolate this output to generate largely translated or rotated chaotic manifolds in response to large driving inputs. We conclude with an analytic understanding of how this extrapolation occurs, yielding design principles for creating neural networks that can generalize knowledge.

1:51PM X27.00014: Universal scaling laws of interaction time distribution in honeybee and human social networks*  
SANG HYUN CHOI (Presenter), VIKYATH D RAO, TIM GERNAT, ADAM HAMILTON, GENE ROBINSON, NIGEL GOLDENFELD, University of Illinois at Urbana-Champaign — Compared to the heavy-tailed inter-event time distribution which reflects collective emergent properties, the duration of interaction events has received less attention but may reflect the variability in the interaction behavior. Here we report measurements of trophallaxis and face-to-face event durations of honeybees show that its distribution is heavy-tailed as in human face-to-face interactions. We derive the power-law form by viewing the termination of an interaction as a particle escaping over an energy barrier. The variability within the population is represented by the distribution of barrier heights determined by extreme value theory. We find a universal scaling law connecting the exponent in the interaction time distribution to that in the barrier height distribution, which is verified by both honeybee and human data. Although less prominent than in humans, individual differences in honeybee interactivity, which are usually overlooked, are confirmed. Our work shows how individual differences can lead to universal patterns of behavior that transcend species and specific mechanisms of social interactions.

2:03PM X27.00015: Social inhibition maintains adaptivity and consensus of honey bees foraging in dynamic environments  
SUBEKSHYA BIDARI (Presenter), ZACHARY KILPATRICK, ORIT PELEG, University of Colorado, Boulder — To effectively forage in natural environments, organisms must adapt to changes in the quality and yield of food sources across multiple timescales. How do individuals foraging in groups use private observations and the opinions of their neighbors in changing environments? We address this problem in the context of honey bee colonies whose inhibitory social interactions promote adaptivity and consensus needed for effective foraging. Individual and social interactions within a mathematical model of collective decisions shape the nutrition yield of a group foraging from feeders with temporally switching quality. Social interactions improve foraging from a single feeder if temporal switching is fast or feeder quality is low. When the colony chooses from multiple feeders, the most effective form of social interaction is direct switching, whereby bees flip the opinion of nestmates foraging at lower yielding feeders. Model linearization shows that effective social interactions increase the fraction of the colony at the correct feeder and the rate at which bees reach that feeder. Our mathematical framework allows us to compare a suite of social inhibition mechanisms, suggesting experimental protocols for revealing effective colony foraging strategies in dynamic environments.

Session X28 DCMP: Quantum Nanomechanics  
405-407 - Mark Dykman, Michigan State Univ - Tag(s): Invited
Superconducting qubits are an excellent system for building quantum computing systems, due to their good individual qubit performance metrics, the availability of a high fidelity two-qubit entangling gate, and their easy lithographic scaling to large qubit numbers. In addition, these qubits provide unique opportunities as testbed systems for quantum communication as well as developing hybrid quantum systems. One compelling opportunity is provided by the ability to use superconducting qubits to control and measure acoustically-active structures, structures that can potentially serve to link these qubits to other two-level systems or to e.g. optical signals. I will describe our recent progress in coupling superconducting qubits to surface acoustic waves. In one experiment we have demonstrated the quantum control of a single microwave-frequency mechanical mode in a surface acoustic wave (SAW) resonator [1]. In a second experiment [2], we have launched and received itinerant phonons in a 2 mm long acoustic Fabry-Perot resonator, and generated a phonon-mediated entanglement between two qubits.

Quantum acoustics: creation and control of multi-phonon Fock states

ROBERT SCHOELKOPF (Presenter), Yale University — Quantum states of mechanical motion can be important resources for quantum information, metrology, and studies of fundamental physics. There have recently been several new demonstrations that advance our ability to generate, control, and measure individual quanta of motion. In our approach, we combine a superconducting qubit with a piezoelectric transducer, which can couple to high quality factor bulk acoustic resonators [1]. In analogy with cavity QED, this system allows for strong coupling between the electrical excitations of the qubit and single Gigahertz phonons trapped in a single-crystal substrate, opening new capabilities for manipulation of mechanical degrees of freedom in the quantum domain. First, we show that a single excitation can be controllably swapped back and forth between the qubit and the acoustic resonator. Next, by employing a flip-chip geometry and a phononic “supercavity” made by curving one side of the substrate, we observe increased phonon lifetimes approaching 100 microseconds, comparable to state-of-the-art qubit coherence times. Using this system, we can then carry out a protocol to climb the phonon ladder, creating multi-photon Fock states or superpositions of Fock states, and measuring the Wigner function of the results using the qubit. I will talk about the prospects of using these mechanical degrees of freedom as multi-mode memories and as probes of the fundamental mechanisms of decoherence in quantum systems.

This work performed in collaboration with Yiwen Chu, Peter Rakich, Taekwan Yoon, Vijay Jain, and Prashanta Kharel.

Mechanical resonators based on carbon nanotubes feature a series of truly exceptional properties. Carbon nanotubes are the lightest resonators fabricated thus far. The mechanical vibrations are enormously sensitive to the electrons flowing through the nanotube, and vice versa. Taking advantage of this coupling, we developed a novel detection method that allows us to measure the mechanical vibrations of nanotube resonators with an unprecedented sensitivity [1]. In this talk, I will discuss our efforts to cool the amplitude of the thermal vibrations to a few quanta [2]. Cooling is achieved using a simple yet powerful method, which consists in applying a constant (DC) current of electrons through the suspended nanotube in a dilution fridge. I will also present results where we strongly couple mechanical vibrations to the two electron states involved in single-electron tunnelling (SET). It effectively creates a highly nonlinear potential for mechanical vibrations despite the relatively low quanta population (about 80 quanta). This enables us to demonstrate the polaronic nature of charge transport through a nanoelectromechanical device.

Nitroxide Radical Polymer-Solvent Interactions and Solubility Parameter Determination  

ALEXANDRA EASLEY (Presenter), Materials Science and Engineering, Texas A&M University, LILLIAN VUKIN, DYLAN HOWARD, JOSE L PENA, Artie McFerrin Department of Chemical Engineering, Texas A&M University, JODIE LUTKENHAUS, Artie McFerrin Department of Chemical Engineering and Materials Science and Engineering, Texas A&M University — Nitroxide radical polymers such as poly(2,2,6,6-tetramethylpiperidinyloxy-4-ylmethacrylate) (PTMA) are electrode materials of interest for organic batteries. They exhibit a reversible capacity (111 mAh/g theoretical), high redox potential (3.6 V vs Li/Li⁺), and rapid charging. One major consideration for the design and processing of organic batteries is the interaction between the polymer and solvent, such as the electrolyte. For example, linear PTMA may dissolve in the electrolyte solution, which leads to capacity fade during long-term cycling. To predict these polymer-solvent interactions, the Flory-Huggins interaction parameter, the Hildebrand and Hansen solubility parameters of PTMA are determined using group contribution calculations and experimental methods. Using calculated and measured solubility parameters, the Flory-Huggins interaction parameter for PTMA is estimated for common battery electrolyte systems. Membrane osmometry is used to confirm the PTMA Flory-Huggins interaction parameter. Once confirmed, the PTMA Flory-Huggins interaction equation is used to recommend new electrolyte solvents to improve battery performance.

Shape Engineering of Monodispersed Cone-Shaped Particles by Tuning Blend Structure of AB Diblock Copolymer and C-Type Copolymer within Emulsion  

EUN JI KIM (Presenter), JAE MAN SHIN, KANG HEE KU, YONGJOO KIM, HONGSEOK YUN, BUMJOON KIM, KAIST — Precise control of the shape and nanostructure of block copolymer (BCP) particles are of great interest for their shape-dependent physical properties. Here, we exploit the blend of poly(styrene-block-1,4-butadiene) (PS-b-PB) BCP and poly(methylmethacrylate-statistical-(4-acryloylbenzophenone)) (P(MMA-stat-4ABP)) sCP within the colloidal confinements to develop a series of particles with different symmetry. The key strategy for tuning the particle shape is to systematically control the incompatibility between the BCP and sCP by varying the mole fraction of 4ABP in sCPs (Φ₄ABP) and the volumetric ratio of sCPs in total blend (fₛCP). The particles were produced by membrane emulsification method to have monodisperse particle size and shape, and the particle shape can be tuned sequentially from striped ellipsoid to Janus-sphere, to cone-shaped with the increase of Φ₄ABP and fₛCP. In particular, the shape-anisotropy of cone-shaped particles was systematically controlled by varying the size and Janusity, which is supported by quantitative calculation from the modified theoretical model. Furthermore, the importance of the shape control of monodispersed cone-shaped particles was demonstrated by investigating the colloidal coating property of these particles.
11:51AM X32.00004: Aqueous Solution Behavior of Poly(ethylene oxide) in Presence of Complex Ions*  DAVID HOAGLAND (Presenter), SATYAM SRIVASTAVA, ZACHARY FINK, Univ of Mass - Amherst, ELIZABETH BURNS, GCP Applied Technologies — Poly(ethylene oxide) (PEO) in aqueous solutions has often been studied by experiment and modeling, but despite widespread use, questions about solution properties remain. Motivated by PEO's potential to reduce CO2 emissions as a strength-building concrete additive, chain conformation was examined in solutions containing complex ions present during concrete curing. Ion-induced changes for linear 100,000 g/mol PEO were mostly unremarkable and consistent with past reports, the hydrodynamic radius by dynamic light scattering or intrinsic viscosity depressed slightly as ion concentration grows. Trends for aluminum-containing ions [at neutral and basic pH monovalent anion Al(OH)4 predominates] were different, with radius by dynamic light scattering approximately 50% larger than by intrinsic viscosity. We hypothesize weak ion-mediated coupling between hydroxyl end groups disruptable by shearing. In support, hydrodynamic radius by dynamic light scattering fell to the value by intrinsic viscosity when hydroxyl end groups were converted to methoxy end groups. The chemistry of the ion-induced chain association remains unclear.

12:03PM X32.00005: Quantitatively Determining of Population Ratios in Bimodal Polymeric Solutions by Neutron Scattering*  GUAN-RONG HUANG (Presenter), KUNLUN HONG, CHI-HUAN TUNG, DONGSOOK CHANG, CHRISTOPHER N LAM, CHANGWOO DO, YUYA SHINOHARA, Oak Ridge National Lab, SHOU-YI CHANG, National Tsing Hua University, YANGYANG WANG, WEI-REN CHEN, Oak Ridge National Lab — Association of amphiphilic polymers in aqueous solutions is of fundamental importance. The coexistence of unimers and aggregates over a broad range of phase regions has been widely reported. Although scattering technique has been employed to identify the structure of micellar aggregates and free unimers as well as its time-evolution processes, the determination of their relative population of unimer and aggregate itself is still challenging. Here, using small angle neutron scattering, we present a comprehensive SANS study of n-dodecyl-PNIPAm. By adjusting the deuterium/hydrogen ratio of water, the intra-micellar polymer and water distributions are obtained. The micellar aggregation number and number density are further determined. Most importantly, the distributions of unimers and micellar aggregations at different temperatures are obtained quantitatively for the first time.

*SANS experiment was carried out on EQ-SANS at SNS and polymer synthesis and characterization was performed at CNMS; both are DOE Office of Science User Facilities. part of the research (data analysis) was supported by the Laboratory Directed Research and Development Program at ORNL.
12:15PM X32.00006: Role of Miscibility in the Shape Memory Properties of Polymer Blends
SURBHI KHEWLE (Presenter), PRATYUSH DAYAL, Chemical Engineering, Indian Inst of Tech Gandhinagar — Shape Memory Polymers (SMPs) are smart materials capable of transforming back to their intended shape and therefore, are used to replicate biomimetic functionalities in artificial materials. Here, we demonstrate that unlike chemical synthesis, polymer blending can be used as an effective technique to design SMPs. In our work, we consider partially miscible crystalline and amorphous polymer blends, to represent the hard and soft segments of SMPs, respectively. To determine the miscibility of blend we construct equilibrium phase diagram by combining Flory-Huggins and phase-field theories that account for both, amorphous-amorphous and crystal-amorphous interactions. We incorporate the effect of these interactions into standard viscoelastic model and determine thermo-mechanical behaviour of SMP blend, using composition dependent viscoelastic properties calculated from Equivalent Box Model. Finally, via simulations, we determine shape fixity and recovery ratios and demonstrate that our calculations are in excellent agreement with the experimental results for PCL-SBS blends. We believe that our findings can not only be utilized to design SMP blends with tailored properties but also be used to establish their structure-property relationships.

*The authors thank IIT Gandhinagar for funding.

12:27PM X32.00007: Dynamic interfacial trapping of Janus nanorod aggregates in polymer blends
FELIPE LEIS PAIVA, MICHAEL HORE, Department of Macromolecular Science ad Engineering, Case Western Reserve University, ARGIMIRO SECCHI, COPPE Graduate Program in Chemical Engineering, Universidade Federal do Rio de Janeiro, VERONICA CALADO, School of Chemistry, Universidade Federal do Rio de Janeiro, JOAO M MAIA (Presenter), SHAGHAYEGH KHANI, Department of Macromolecular Science ad Engineering, Case Western Reserve University — Taking advantage of both shape and chemical anisotropy on the same nanoparticle offers rich plasmonic and self-assembly possibilities for nanotechnology. Combining Dissipative Particle Dynamics and Discrete Dipole Approximation calculations, the directed assembly of Janus nanorod aggregates in polymer blends has been assessed, along with the optical properties resulting thereof. Janus rods become kinetically-trapped and exhibit either parallel or antiparallel alignment with respect to their long axis. This depends on several factors that can be precisely tuned. Ultimately, two different aggregate structures result from rod tumbling that are not observed under quiescent conditions: monolayer-like aggregates exhibiting trapped rods with antiparallel configuration; and stacked nanorod arrays similar to superlattice sheets. Hence, the present study offers fundamental insight into relevant parameters governing the directed assembly of Janus nanoparticles at an interfacial level as well as an assessment of the potentially novel optical applications deriving from the resulting aggregate structures, such as peculiar displays and sensors.

Tuning Diblock Copolymer Micelles by Cosolvent Effects: A Simulation Study

DONG MENG (Presenter), JING ZONG, Mississippi State Univ — A powerful method to manipulate the micellar structures formed by amphiphilic diblock copolymers (DBC) in a selective solvent is by addition of a cosolvent. Unlike the single-solvent case, few simulation studies on DBC micellization in solvent mixtures have been reported due to high computational cost associated with the necessity of treating solvents explicitly. Here, the Field-Accelerated Monte Carlo simulation is employed for the task under the expanded grand canonical ensemble. We investigate the effects of introducing a cosolvent on the critical micelle concentration, micellar morphology, and aggregation number. Specifically, we consider two types of solvent pair: interacting-solvent and cononsolvent pairs. It is found that the interacting-solvent pair promotes morphology transition from micelles to vesicles. In the case of cononsolvent pair with respect to the corona block, aggregation number of micelles increases significantly as the result of maximizing contact between polymers and the minor amount of cosolvent. Our study reveals the competing and cooperative interplays of solvent pairs in determining the DBC micellar structures, pointing out the necessity of considering solvent explicitly in simulations as oppose to the conventional "effective-single-solvent" approach.

Efficient sampling of polymer conformations using Brownian Bridges

VIVEK NARSIMHAN (Presenter), SHIYAN WANG, DORAISWAMI RAMKRISHNA, Purdue Univ — In this talk, we introduce a mathematical concept known as a stochastic bridge, and describe how it can be utilized in many areas of polymer physics. A stochastic bridge is a random process whose start and end regions in phase space are specified. Such processes naturally find utility in situations when one wants to sample polymer conformations with a given topology and/or energy. In the first part of the talk, we expand upon our previous work and discuss how one can systematically generate bridge processes for continuous polymer chains described by a stochastic differential equation. We will then discuss how to use such ideas to generate polymer conformations of a given topology (e.g., rings, polymers with fixed winding or twist, etc.). We will then study a canonical problem – a polymer under an external field – and show how a bridge formulation allows one to exactly sample polymer conformations in a given range of total energy. This methodology thus allows one to sample rare events (i.e., high energy) efficiently, or conversely most probable configurations (i.e., low energy). We will conclude on how to scale these ideas to larger dimensional systems, and discuss some advantages and disadvantages of using bridge processes compared to other biased sampling strategies.
1:03PM X32.00010: Investigation of polymer diffusion in confined geometries using differential dynamic microscopy techniques  EMMANUEL HITIMANA (Presenter), SVETA MOROZOVA, Macromolecular Science and Engineering, Case Western Reserve University — The fundamental understanding of polymer diffusion in confined geometries is important for industrial as well as broader applications such as transport in cell-like environments, improved drug delivery, and filtration. However, the study of polymer diffusion in such environments is often challenging due to the nanometer size scales of polymers and to the inhomogeneous geometry of the landscape. We have developed differential dynamic microscopy (DDM) techniques to investigate the dynamics of fluorescein tagged poly-l-lysine chains in confined environments in any arbitrary direction along textured surfaces. Using a curved surface, we can control the local confinement. The role of polymer molecular weight, concentration, confinement, and local geometry on polymers dynamics will be discussed.

1:15PM X32.00011: Direct visualization of branched polymer dynamics using single molecule studies*  SHIVANI PATEL (Presenter), CHARLES M SCHROEDER, University of Illinois at Urbana-Champaign — We study the dynamics of single branched polymers in dilute and non-dilute solutions using single-molecule fluorescence microscopy. In particular, we use a hybrid enzymatic-synthetic approach to synthesize DNA-based branched polymers such as comb polymers that contain a long backbone with multiple side branches grafted at various positions. Following synthesis, we directly study the dynamics of single branched polymers, particularly in non-dilute solutions in extensional flow, and compare them to the dynamics of linear polymers. We further study the effects of background concentration and polymer topology on branched polymer dynamics in order to elucidate the non-equilibrium behavior of topologically complex polymers. For instance, our work on comb polymer dynamics has shown that contrary to dilute solutions and melts, the addition of branches on to a linear backbone speeds up the relaxation of comb polymers compared to their linear analogs in semi-dilute solutions. Overall, our work shows that single polymer dynamics can be used to provide a direct link between polymer microstructure and bulk rheological properties.

1:27PM X32.00012: Additive Driven Morphological Transition of Block Copolymer Particles: Elongation, Transformation and Disassembly of Single Domain  
SEONGHAN LEE (Presenter), JAE MAN SHIN, KANG HEE KU, BUMJOON KIM, KAIST — Particles with controllable shape and internal morphology received great attention as a promising colloidal material. Here we report co-assembly of polystyrene-\(b\)-poly(2-vinylpyridine) (PS-\(b\)-P2VP) diblock copolymer (BCP) and bromoalkyl based small molecule additives confined in evaporative emulsion droplet. The presence of additives with varying volume fraction (\(\varphi\)) resulted in (1) significant increase of aspect ratio of prolate particles from 2.4 to 4.5 (\(\varphi<0.40\)), (2) unique transformation of domain structure from conventional lamellar stacks into spherical shaped, multi-layered lamellar (\(0.40<\varphi<0.45\)), and (3) disassembly of single lamellar domains into micellar spheres (\(0.45<\varphi\)). Investigation on the morphological evolution of particle demonstrated that the favorable interaction with P2VP and bromine-containing additives allows quaternization and significant swelling of P2VP domains, which is further assisted with the presence of external aqueous phase. This additive induced morphological transformation was further systematically controlled by incorporation various types of additives to achieve control over the degree of P2VP domain swelling.

1:39PM X32.00013: Single molecule visualization of single ring polymers in the flow-gradient plane of shear flow*  
MICHAEL TU (Presenter), Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign, RAE M ROBERTSON-ANDERSON, Department of Physics, University of San Diego, CHARLES M SCHROEDER, Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — The lack of free ends on ring polymers yields a unique topology that has fascinated polymer physicists and chemists for decades. Despite recent progress, we still lack a clear understanding of the molecular-level dynamics of ring polymers. Here, we use single-molecule imaging to directly visualize individual ring polymers in shear flow. We have built a custom shear flow apparatus to be used in conjunction with single-molecule fluorescence microscopy to study the dynamics of individual ring polymers in the flow-gradient shear flow. Using this device, we are able to characterize the fractional extension and orientation angle of ring polymers under steady shear, and compare the responses to their linear counterparts. We report the steady-shear fractional extension, orientation angle, and temporal-averaged spatial conformations of ring polymers in shear flow as a function of the applied dimensionless flow strength (\(Wi\), Weissenberg number), and compare the results to their linear polymer counterparts. We also report observations of tumbling and tank-treading-like behavior of ring polymers in shear flow. Overall, these results provide new molecular-level insights into the dynamics of ring polymers in flow.

*NSF CBET-1604038
Phase behavior of diblock copolymer-homopolymer ternary blends containing an asymmetric diblock copolymer*  

BO ZHANG (Presenter), SHUYI XIE, FRANK S BATES, TIMOTHY LODGE, University of Minnesota — Lifshitz points (LPs) are predicted to exist in symmetric A/B/A-B ternary blends in the mean-field limit, where A and B are homopolymers and A-B is the corresponding diblock copolymer. At finite molecular weights, the LP is replaced by a channel of bicontinuous microemulsion (BμE) due to fluctuation effects. A recent study of symmetric ternary blends, where A is poly(cyclohexylethylene) (PCHE) and B is poly(ethylene) (PE), demonstrated that the BμE is bracketed by a line of congruent lamellar-disorder transitions and a Scott line of critical points, at homopolymer content near the predicted LP value. In this work, we investigated the phase behavior of a similar PCHE/PE/PCHE-PE ternary blend but with a compositionally asymmetric diblock copolymer. The phase behavior, which was determined using small angle X-ray and neutron scattering and optical transmittance measurements, revealed that the line of congruent transitions is decoupled in composition from the line of critical points. Additionally, a wide range of phase space between the compositions associated with the congruent condition and Scott line was identified as containing the BμE morphology.

Interactions between Colloidal Particles Mediated by Nonadsorbing Polymers: Casimir and Anti-Casimir Effects  
PENGFEI ZHANG, Center for Advanced Low-Dimension Materials, State Key Laboratory for Modification of Chemical Fibers and Polymer Materials, Donghua University, QIANG WANG (Presenter), Colorado State University — Using a lattice self-consistent field (SCF) theory and the corresponding lattice Monte Carlo (MC) simulations combined with our recently proposed Z method (Zhang, P.; Wang, Q. Soft Matter, 2015, 11, 862), we examined homopolymer solutions confined between two parallel and nonabsorbing surfaces and in equilibrium with a bulk solution, and accurately calculated the effective interaction between the two surfaces. Close to the critical point of the bulk solution, we found for the first time the Casimir effect with long-range attractive intersurface potential $W<0$ extending to $D/R_e \approx 10$, where $D$ denotes the intersurface separation and $R_e$ the root-mean-square chain end-to-end distance in the bulk solution. On the other hand, by directly comparing our MC results with SCF predictions based on the same model system, we were able to quantitatively and unambiguously distinguish the mean-field and the fluctuation contributions to $W$, and found for the first time the fluctuation-induced repulsion $W>0$ between the two surfaces at intermediate $D=R_e$ (i.e., the anti-Casimir effect) predicted by Semenov and Obukhov (Obukhov, S. P.; Semenov, A. N. Phys. Rev. Lett. 2005, 95, 038305), which is about one order of magnitude stronger than that due solely to the finite chain length given by the SCF theory.

Friday, March 6, 2020 11:15 AM - 2:15 PM

Session X33 DPOLY DSOFT DMP: Polymer Crystals and Crystallization II  
505 - Toshikazu Miyoshi, Univ of Akron - Tag(s): Focus
11:15AM X33.00001: Controlling the Mechanical Behavior of Hydrogenated Polynorbornene*  
JARED KLEIN (Presenter), RICHARD REGISTER, Princeton University —  
Hydrogenated polynorbornene (hPN) synthesized via ring-opening metathesis polymerization is a semi-crystalline polymer even while atactic, as it is able to accommodate stereodefects within the crystal. We have previously shown control over phase behavior in hPN via epimerization of the cyclopentylene ring in the backbone structure. The polymorphic transition temperature into a rotationally-disordered state, \( T_{cc} \), is strongly affected by epimerization, while epimerization has only a minor effect on the melting temperature, \( T_m \), and no appreciable effect on the total crystallinity (J. P. Klein and R. A. Register, J. Polym. Sci. B, 57, 1188 (2019)). In this talk, the effect of epimerization on both the stress-strain behavior and dynamic mechanical thermal properties are discussed. Epimerization causes a decrease in both the Young's modulus and the yield strength of the polymer, and it also reduces the breadth of the modulus-vs.-T plateau region (above \( T_g \)) significantly, in line with the decrease in \( T_{cc} \). hPN-based polymers with a pyrene endgroup show a strong fluorescence sensitivity to melting/crystallization, and work is underway to evaluate their utility in probing other hPN transitions.

*NSF Polymers Program (DMR 1402180) and NSF MRSEC Program through PCCM (DMR 1420541)

11:27AM X33.00002: What happens upon annealing of pre-drawn semicrystalline polymers?  
TRAVIS SMITH (Presenter), SHIQING WANG, Univ of Akron — As part of efforts to understand mechanical behavior semicrystalline polymers under large deformation, we investigate what happens to predrawn semicrystalline polymers upon annealing at elevated temperatures. For instance, LLDPE drawn at room temperature will neck to its characteristic draw ratio around 5.5 and will shrink by 10% when unloaded but will remain in this highly stretched state for many years. Such predrawn PE samples will either exhibit various levels of retractive stress when held at a fixed length or shrink by different amounts, depending on the annealing temperature. The physical meaning of this characteristic will be explored experimentally, first mechanically and eventually by in situ WAXS and SAXS measurements. Specifically we will search for evidence to support our concept that there is partial melting upon annealing due to the chain tension produced by the pre-cold-drawing, at temperatures well below the melting temperature. The universality of the phenomenology and its molecular interpretation is explored by making a similar investigation of a second semicrystalline polymer, poly(ethylene terephthalate), drawn above its glass transition temperature \( T = 70 \) Celsius.

Entanglement Effect on Chain-Folding Structure in Semicrystalline Polymer Blends

FAN JIN (Presenter), TOSHIKAZU MIYOSHI, Univ of Akron — Entanglement effect on chain-folding structure of semicrystalline polymers is not clearly understood over the past decades. Very recently, we demonstrated that Poly(Lactic Acids) chains with three different molecular weights of 46K, 90K, and 320K g/mol do not change adjacent re-entry structure under different supercoolings. It was suggested that entanglement of polymer chains limit adjacent re-entry number in the melt-grown crystals. In this study, we isothermally crystallize polymer blend samples consisting of long and short Poly(Lactic acid) chains from the melt state. Only long polymer chains are labeled by $^{13}$C. $^{13}$C-$^{13}$C double quantum (DQ) spectroscopy is applying to study local chain-folding structure of PLLA as a function of blending ratio and as a function of molecular weight of short PLLA chains.

Flow-Induced Crystallization of Polymers during Multi-Axial Deformation

LIANGBIN LI (Presenter), University of Science and Technology of China — Flow- or stretch-induced crystallization (FIC/SIC) is believed to be mainly responsible for the excellent mechanical properties of polymers during real processing. The development of synchrotron radiation (SR) X-ray scattering techniques with high time resolution has been a mainstream research tool to study the structural evolution of polymers under complex external fields. The FIC behaviors of polymers during multi-axial deformation like biaxial stretching, film blowing and service of sounding balloon has been systematically studied with the combination of in-situ SR X-ray scattering and the custom-built devices. Considering the phenomenon of frustrating SIC for natural rubber during biaxial stretching, we proposed a new model for SIC based on the results of theoretical calculation and the in-situ X-ray scattering, which decoupled the free energy contributions of chain orientation from that of conformational entropy reduction. This model is also suitable for the crystallization of polymers under other flow fields.

Homogeneous crystal nucleation – Nucleation kinetics and thermal stability of nuclei*  
CHRISTOPH SCHICK (Presenter), RUSLAN ADRIANOV, TIMUR MUKHAMEZTYANOVA, Butlerov Institute of Chemistry, Kazan Federal University, RENE ANDROSCH, Interdisciplinary Center for Transfer-oriented Research in Natural Sciences, Martin Luther University Halle-Wittenberg — Crystal nucleation in polymer melts at common laboratory cooling rates (< 10 K/s) is typically heterogeneous. Studying homogeneous crystal nucleation in bulk samples requires bypassing the low-supercooling temperature range of pre-dominant heterogeneous nucleation. This became possible with the availability of fast scanning chip calorimetry. The strategy for studying homogeneous nucleation kinetics by fast scanning calorimetry will be introduced [1]. We will discuss the temperature dependency of the rate of homogeneous nucleation and its relation to the glass transition. We describe a method allowing to investigate the ability of nuclei to stabilize/grow on heating to the crystallization temperature [2] and, finally, to determine the thermal stability of homogeneous nuclei in polymers.

Are Spherulites Spherical? 3D Visualization of Semicrystalline Polymer Morphology Using Optical Tomography*  
SHU-GUI YANG, ZHEN-ZHEN WEI, Univ of Sheffield, GORAN UNGAR (Presenter), School of Materials Science and Engineering, Xian Jiaotong University, PANTEA KAZEMI, Univ of Sheffield, HUI-JIE XIE, Physics Department, Zhejiang Sci-Tech University, LILIANA CSEH, School of Materials Science and Engineering, Xian Jiaotong University, HINA SABA, Physics Department, Zhejiang Sci-Tech University — Spherulites, shish-kebab, cylindrites and other morphological features of bulk semicrystalline polymers have been studied for decades using methods such as polarized optical microscopy, TEM or AFM. For these studies either thin films or thin sections were used, giving 2D but not 3D pictures. The organization in the 3rd dimension has been implied rather than directly observed. Attempts at 3D imaging have been made with varying success using approaches, notably electron tomography (TEM) and some other methods. Most studies focussed on polymer blends and block copolymers, relying on contrast produced by the chemically different components, although some remarkable images of crystal lamellae were obtained by TEM. However 3D images of microstructure on the crucial 10-1000 micron scale, especially of single-component polymers or their nanocomposites, are still missing. Here we present first such images obtained by confocal microscopy using appropriate sample preparation and image processing. Already rather unsuspected features of 3D morphology are emerging, previously being hidden by the limitations of the conventional techniques.

12:51PM X33.00007: Advanced Polymeric Particles Templated by Polymer Crystallization at Curved Liquid/Liquid Interface  
MARK STAUB (Presenter), CHRISTOPHER LI, Drexel Univ —  
Polymeric micro/nanoparticles have attracted significant interest in the past few decades due to their relevance in a number of fields. The methods commonly employed tend to provide particles that have simple morphology of spheres or cylinders that are inherently fluidic and dynamic due to the long chain nature of macromolecules. As more complex particles, in function and structure, are emerging as solutions to a variety of problems, simple and versatile methods to obtain them are a necessity. Towards this aim, our group has developed a miniemulsion crystallization process where polymer single crystal-like growth is confined to a dynamic liquid/liquid interface. This process produces unique hollow polymer capsules termed “crystalsomes” that have excellent mechanical properties compared to their amorphous counterpart the polymersome. This talk will focus upon using blends of amphiphilic block co-polymers in the miniemulsion process to template hierarchically structured crystalsomes. The block co-polymers serve as macromolecular surfactant along with the hydrophobic segment acting as the crystalline motif. It will be shown by altering the hydrophobic monomeric unit, its degree of polymerization, and the particle size a variety of crystalsomes with tunable porosity can be obtained.

1:03PM X33.00008: Phenomenological Theory of Prefreezing at the Solid-Melt Interface  
OLEKSANDR DOLYNCHUK (Presenter), MUHAMMAD TARIQ, THOMAS THURN-ALBRECHT, Experimental Polymer Physics, Institute of Physics, Martin Luther University Halle-Wittenberg —  
Crystallization of liquids is usually initiated at the interface to a solid. The underlying process can be either heterogeneous nucleation or the recently observed process of prefreezing. The latter is the reversible and abrupt formation of a crystalline layer at the interface melt-solid at temperatures higher than the bulk melting point. We present a phenomenological theory of prefreezing and derive such equilibrium properties as the temperature dependent thickness of the prefrozen layer, the prefreezing temperature $T_{\text{max}}$, and the mesoscopic jump of thickness at $T_{\text{max}}$. The theory provides a clear thermodynamic explanation of the abrupt formation of a crystalline layer as a result of the interplay of the interfacial energies $\gamma_{\text{sub,cry}}$, $\gamma_{\text{cry,melt}}$, and $\gamma_{\text{sub,melt}}$. The prefreezing temperature $T_{\text{max}}$ was found to depend on all three interfacial energies and bulk parameters. However, we show that the difference of the interfacial energies $\Delta \gamma = \gamma_{\text{sub,melt}} - (\gamma_{\text{sub,cry}} + \gamma_{\text{cry,melt}})$ acts as a driving force for prefreezing, as $T_{\text{max}}$ tends to increase with increasing $\Delta \gamma$. The analytical outcomes are in accordance with recent experimental results for polyethylene and poly(ε-caprolactone) crystallized on graphite and MoS$_2$ via prefreezing.

1:15PM X33.00009: Role of flow-induced nematic order in polyethylene nucleation*
WENLIN ZHANG (Presenter), RONALD LARSON, Univ of Michigan - Ann Arbor — We employ united-atom molecular dynamics (MD) simulations to quantify the role of nematic order in polyethylene (PE) nucleation. In our simulations, stretched periodic PE chains are blended with free PE chains of the length of 500 and 1000 backbone carbons (C500 and C1000). These bidisperse systems are the simplest realizations of real polymer samples, in which only polymers with long branches or high molecular weights are stretched by flows. By simulating isothermal nucleation and performing mean-first-passage time analysis for the growth of the largest nucleus in our simulations, we show that the nucleation rate of PE increases exponentially with increasing average nematic order of monomers. We also validate the predicted quiescent nucleation rates by computing the crystallization half-time at various temperatures using the crystal growth velocity, sampled from simulations of isothermal crystallization of chains near crystalline slabs, and the Avrami equation. The predicted crystallization half-times agree with experiments, suggesting our predicted nucleation rates are reasonable.

*We are grateful for the funding of this work by Dow under a University Partnership grant and the computational resources provided by the Extreme Science and Engineering Discovery Environment (XSEDE).

1:27PM X33.00010: Crystallization and liquid crystallinity in heptadecanylcarbazole-dithienylbenzothiadiazole (PCDTBT) conjugated polymers*
RYAN FAIR (Presenter), Materials Science and Engineering, Pennsylvania State University, ENRIQUE GOMEZ, Chemical Engineering, Pennsylvania State University — Conjugated polymers exhibit rich phase behavior including liquid crystalline and crystalline phases. Conflicting reports of one such polymer, poly[N-9'-heptadecanyl-2,7-carbazole-alt-5,5-(4',7'-di-2-thienyl-2',1',3'-benzothiadiazole)] (PCDTBT), have claimed the material to be amorphous or semicrystalline. We use oscillatory shear rheology to demonstrate that PCDTBT exhibits liquid crystallinity by identifying the nematic to isotropic temperature. We also find a crystalline phase when annealed at high temperatures, which is likely due to the high $T_g$, near 120 °C, that is identified also through rheology. We corroborate the phase behavior using X-ray diffraction, differential scanning calorimetry, and polarized optical microscopy. High resolution transmission electron microscopy reveals the consequences of annealing in the amorphous or liquid crystalline phase prior to crystallization, and yields images of the crystalline morphology that are produced under these different conditions.

1:39PM X33.00011: Analyzing morphological and optical properties of poly(3-hexylthiophene) (P3HT) via emitted light's polarization  
HUAN NGUYEN (Presenter), PAULO TARAUJO, Univ of Alabama - Tuscaloosa — With the improvement in synthetic methodologies, polythiophenes and specifically poly(3-hexylthiophene) (P3HT) have become forerunners in the field of conjugated polymers. We study P3HT's morphological and optical properties via measurements of absorption and polarization-resolved photoluminescence via Stokes spectroscopy. Our recent results show that P3HT's aggregation behaviors change drastically when using chloroform stabilized and non-stabilized by amylene. Specifically, P3HT drop-cast films made from stabilized chloroform presented H-aggregates, while similar samples using non-stabilized chloroform exhibited J-aggregates. Here, we hypothesize that the amylene from stabilized chloroform induces a higher probability for the stacked coupling of isolated chains via weak van-der-Waals force leading to the formation of H-aggregates. To rule the influence of amylene out, we are currently performing a set of analyses and experiments consisting of temperature-dependent measurements, thermal annealing, various P3HT chain sizes, and blended MeOH@Chloroform solvents.

1:51PM X33.00012: Computational Model for End-On LCEs*  
JAMES WATERS (Presenter), ANNA BALAZS, Univ of Pittsburgh —  
In main-chain liquid crystalline elastomers (LCE’s), and in side-chain LCE’s where mesogens are attached to the polymer backbone at their midpoint, the polymer chains comprising the elastomer align with the mesogens when they are in the nematic state. For the case of side-chain mesogens attached at one end, though, ordering of the mesogens can induce alignment of the polymer backbone either parallel or orthogonal to the nematic director. We incorporate a theory of side-chain LCE’s into a constitutive model for elastomers to describe these competing effects. We compare simulation results against experiment, and show how an end-on attachment scheme can create elastomers with bidirectional responses, meaning as temperature is varied, a single structure can be made to bend or twist in different directions. We anticipate that this can dramatically increase the possibilities for soft robotic systems.

Session X34 DPOLY: Organic Electronics III: Electrochemical Transistors and Doping  
506 - Dean DeLongchamp, National Institute of Standards and Technology
11:15AM X34.00001: Charge and Ion Transport in Radical Polymer-based Organic Electrochemical Transistors  BRYAN BOUDOURIS (Presenter), HO JOONG KIM, Davidson School of Chemical Engineering, Purdue Univ — Radical polymers are composed of a non-conjugated macromolecular backbone with open-shell sites that are present on the side chains of each repeat unit. Previously, we have demonstrated that this macromolecular design motif alters the route by which charge is transported in solid-state electronic devices when compared with the more common conjugated polymers utilized in organic electronics. Here, we report on the application of a specific high-performance radical polymer, poly(4-glycidyloxy-2,2,6,6-tetramethylpiperidine-1-oxyl) (PTEO), as the active layer component in an electrolyte-gated organic electrochemical transistor (OECT) device structure. Specifically, we establish the differences in charge and ion transport (i.e., mixed conduction) in these inherently glassy radical polymer systems relative to many oft-used OECT semicrystalline macromolecular materials. Moreover, we highlight the unique synergies that exist between mixed conduction that exist in non-conjugated radical polymer systems. Finally, we manipulate the degree of crosslinking within the radical polymer thin films after casting of the film (i.e., through the use of photoinitiated crosslinking) in order to demonstrate a mechanically-stable, solvent-robust OECT that achieves high device performance as well.

11:27AM X34.00002: Quantifying the Energetics of Ion Injection into Mixed Ionic/Electronic Conductors*  LUCAS FLAGG (Presenter), CONNOR BISCHAK, RAMSESS JAVIER, DAVID S GINGER, Chemistry, University of Washington — Organic electrochemical transistors (OECTs) rely on the electrochemical doping of an organic semiconductor to modulate the conductivity of the channel. This doping process requires electronic charge injection into the polymer from the metal contacts, as well as charge compensation by an ion provided by the electrolyte. Numerous factors have been shown to affect the ease and speed of ion injection including polymer side chain, polymer crystallinity, ion type, pH, solvent, etc. Here we use kinetics derived from temperature dependent spectroelectrochemistry measurements to extract the activation energy of ion injection into a polymer semiconductor. We compare the energetics of injection in a variety of different polymers, salts, and solvents to quantify the contribution of each of the factors controlling ion injection. A deeper understanding of the relative importance of each factor will help with future design of mixed ionic/electronic conductors.

11:39AM X34.00003: Counter-ion exchange as a tool to modulate polaron delocalization and temperature stability of doped polymeric semiconductors* ELAYNE THOMAS (Presenter), KELLY A PETERSON, DAKOTA RAWLINGS, RACHEL A SEGALMAN, MICHAEL L. CHABINYC, University of California, Santa Barbara — The design of high-performance doped semiconductors requires an understanding of the coupling between ionic and electronic carriers. We utilize a method of counter-ion exchange using the polymeric semiconductor PBTTT-C_{14} to deconvolute the effects of ionic/polaronic interactions with the electrical properties of doped semiconducting polymers. Here, the dopant NOPF_{6} is used followed by the exchange of counter-ions ranging from 5 to 11 Å in diameter. The long-range order of the polymeric crystallites is not affected with this exchange process while effectively modifying the counter-ion distance to the charge carrier. Doped films achieve electrical conductivity of 320 S/cm and is not sensitive to an increased ion-polaron distance. We posit that other factors dominate the electrical properties at a device scale, such as the morphology and presence of domain boundaries. Interestingly, the temperature stability of the doped film can be drastically improved with the use of counter-ions containing less labile bonds. This platform serves as a unique way to retain the morphology of polymeric thin films while studying charge interactions at the local scale.

11:51AM X34.00004: The role of counter ion structure on the spatial distribution and molecular configuration of charge carriers in solid state electrochemically doped conjugated polymers DAKOTA RAWLINGS (Presenter), RACHEL A SEGALMAN, MICHAEL L. CHABINYC, University of California, Santa Barbara — In a chemically doped or electrochemically doped conjugated polymer, electronic charge carriers are inherently associated with a countercharge in the form of a molecular or atomic counterion. It is expected that the structure of the counter ion will affect its distribution in the polymer film along with that of associated electronic charge carriers. Furthermore, the effect of counter ion structure on the charge storage configuration (i.e. polaron vs. bipolaron) is unknown. Here, we quantify the charge configuration and the distribution of charge carriers between aggregated and amorphous domains as a function of the counter ion structure in semicrystalline conjugated polymer films. We employ an organic electrochemical transistor with a cation tethered polymeric ionic liquid (PIL) as the gate dielectric, where the size and structure of the mobile anionic counterion in the PIL can be varied to modulate the counterion that is associated to charge carriers in the semiconductor. Operando electron paramagnetic resonance and in situ device measurements reveal the polaron to bipolaron ratio as a function of the gate bias for a range of counter ions. This is paired with in situ optical spectroscopy to determine the distribution of charge carriers between amorphous and aggregated domains.
12:03PM X34.00005: Understanding the Working Mechanism of Organic Electrochemical Transistors* VIKASH KAPHLE, PUSHPA PAUDEL, BJORN LUSSEM (Presenter), Kent State Univ - Kent — The organic electrochemical transistor (OECT) is a key element for the field of organic bioelectronics [Nat. Rev. Mat. 3, 17086, 2018]. OECTs are versatile and can be functionalized for a wide range of analytes, including various metabolites, hormones, or neurotransmitters.

Operation of OECTs is often described by a 1D model based on standard TFT theory [Adv. Func. Mat. 17, 3538, 2007]. Still, although the model is successful in explaining general trends of device operation, a quantitative analysis is still challenging.

In this presentation, limits of current OECT device models are discussed. It is argued that the current model implicitly neglects lateral ion migration inside the transistor channel, which leads to non-equilibrium solution. To address this problem, a 2D numerical simulation is presented that solves the continuity equation of holes and cations consistently. It is argued that cations accumulate at the drain electrode, which leads to an additional potential drop at the contacts. This potential drop can be explained by an additional contact resistance, which increases with applied gate potential. The model predictions are confirmed experimentally by measuring the channel potential and the contact resistance of OECTs.

*Funding from the NSF (EECS #1750011) is acknowledged.

12:15PM X34.00006: Bio-Sensors Based on Organic Electrochemical Transistors* PUSHPA PAUDEL (Presenter), VIKASH KAPHLE, DRONA DAHAL, RAJ KISHEN RADHA KRISHNAN, BJORN LUSSEM, Kent State Univ - Kent — Organic Electrochemical Transistors (OECTs) are capable of sensing a wide variety of biomolecules such as Glutamate, Acetylcholine [1], Lactic acids [2], or Glucose [3]. However, despite this success, the precise sensing mechanisms is still under discussion. This lack of understanding precludes a targeted design of OECT applications and currently limits the sensitivity of these devices. Here, we study the working mechanism of OECT based neurotransmitter (Acetylcholine and Glutamate) and Glucose sensors. We discuss the selectivity of these sensors, and study the influence of channel dimensions on their sensitivity. Finally, approaches to increase the spatial and temporal resolution of these transistors are presented.

A flexible complementary logic circuit built from two identical organic electrochemical transistors. LORENZO TRAVAGLINI, ADAM P MICOLICH, CLAUDIO CAZORLA, ERICA ZEGLIO, School of Materials Science and Engineering, Univ of New South Wales, ANTONIO LAUTO, School of Science, Western Sydney University, DAMIA MAWAD (Presenter), School of Materials Science and Engineering, Univ of New South Wales — Organic electrochemical transistor (OECT) with a conjugated polymer as the electrically active channel is the basic unit in organic bioelectronic devices. Increased functionalities can be further achieved by building complementary logic circuits combining more than one OECT in different architectures. The simplest circuit can be built by connecting one p-type and one n-type organic semiconductors in series. In this study, we build a complementary logic circuit on a flexible substrate with two OECTs having one material as the active channel. We demonstrate its DC operation with a gain of ~ 7 and its AC response within a frequency range suitable for physiological applications. Our approach to use one single material as an active channel in both OECTs simplifies the manufacturing process and eliminates the need to source different materials with similar electrical performances.

Humidity-Dependent Mixed Ionic-Electronic Conduction in Polythiophene-Derived Polyelectrolytes. GARRETT GROCKE (Presenter), BAN DONG, SHRAYESH PATEL, University of Chicago — Conjugated polyelectrolytes that can conduct both ionically and electronically are attractive candidates for next-generation electrochemical devices. Importantly, the ability to transport both electronic and ionic charge carriers is intimately linked to processing conditions and morphology. This work reports the influence of humidity on the structure and conduction of a series of poly[3-(potassium-n-alkanoate) thiophene]s in the thin film regime. These materials were found to be highly resistive under anhydrous conditions but exhibited mixed ion-electron conduction as a function of increasing relative humidity. UV-Vis-NIR measurements provide evidence for water-assisted formation of alkanoate-stabilized polythiophene polaron states and thus generation of charge carriers for electronic conduction, wherein dissociation of potassium-alkanoate bonds leads to the enhanced ionic conductivity. Additionally, in-situ humidified synchrotron X-ray scattering experiments reveal the resiliency of the underling semicrystalline morphology to increasing relative humidity, which balances the extent of both electronic and ionic conductivity. Our results show the strong influence of humidity on mixed ion-electron conduction characteristics of conjugated polyelectrolytes in self-doped conditions.
12:51PM X34.00009: Charge Transport, Morphological Properties and Cooling Performance of Functionally Graded Semiconducting Polymer Thin Films as Organic Thermoelectrics
TENGZHOU MA (Presenter), BAN DONG, University of Chicago, JOSEPH WALTER STRZALKA, Argonne National Laboratory, SHRAYESH PATEL, University of Chicago — Molecularly doped semiconducting polymers have demonstrated great potential in organic thermoelectrics (TEs) for thermal energy management. While functionally graded materials (FGMs) where transport properties are spatially controlled have been proven to improve TE device performance, experimentally fabricating FGMs has been a challenging task. In this work, we utilize the facile processability to modulate electronic properties through molecular doping of conjugated polymers to fabricate and characterize FG thin films. We leverage sequential vapor doping of poly[2,5-bis(3-tetradecylthiophen-2-yl)thieno[3,2-b]thiophene] (PBTTT) with 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F₄TCNQ) to fabricate one form of FGMs: continuously graded thin films. We observe the presence of a 5mm gradient across which doping level and transport properties vary continuously. We predict TE cooling performance based on our experimental results where cold side temperature ($T_c$) and coefficient of performance are calculated through linear constitutive relations coupled with conservation of charge and energy. The results demonstrate that $T_c$ of graded samples are significantly improved compared to that of uniform profile. This study provides guidelines to further development on more complex FGMs.

1:03PM X34.00010: Modulating Spin Concentrations in Self-Doped Organic Molecules
DANIEL POWELL (Presenter), LUISA WHITTAKER-BROOKS, University of Utah — N-type doping methods in organic systems typically combine small ionizable species with a semiconductor scaffold in solution before casting the pair into films. How dopants distribute within the cast semiconductor is unpredictable. The distribution of dopants, which vary from small to very large in their relative sizes, may affect semiconductor continuity, grain boundaries, morphology and packing of the semiconductor, electronic state distribution near the Fermi-energy, and yield topological variations in the electronic structure. Direct comparisons between different doping concentrations can therefore be rather nebulous, making the selection of the proper dopant for a given organic semiconductor highly convoluted. These challenges may be mitigated using self-dopants, where the electron source is covalently attached to the semiconductor. We have investigated the effects of steric hindrance, counterions, and dopant/semiconductor proximity on the efficiency of self-doping in a variety of perylene diimides. We believe our findings offer design considerations for the fabrication of effective self-dopants in n-type organic semiconductors.
1:15PM X34.00011: Bio-sourced Eumelanin Pigments: Charge Transport Properties and Beyond

MANUEL REALI (Presenter), ABDELAZIZ GOUDA, CLARA SANTATO, Ecole Polytechnique de Montreal — Green electronics recently opened new research avenues to use bio-sourced, biocompatible materials to limit the environmental footprint of electronics\textsuperscript{1-3}. Within bio-sourced carbon-based materials, eumelanin, a black-brown conjugated biopigment, emerged as an excellent candidate for green electronics.

Eumelanin features fascinating properties (e.g. broadband optical absorption\textsuperscript{4,5}, metal-ion chelation\textsuperscript{6}, mixed ionic/electronic conductivity\textsuperscript{7-9}) and biocompatibility\textsuperscript{1,10}. Its conjugated sp\textsuperscript{2} backbone suggests that it would be a naturally occurring semiconductor. The amorphous semiconductor model (ASM) for eumelanin, proposed in the 70s after the observation of an electrical resistive switching of wet melanin pellets\textsuperscript{11}, has been recently questioned by proposing mixed electronic/protonic and proton membrane models\textsuperscript{8,9,12}.

Herein, we report for the first time the electrical resistive switching response of dry eumelanin pellets, as opposed to previous studies indicating dry eumelanin as an insulating material\textsuperscript{11,13}. Wet pellets show a reversible and reproducible resistive switching, in agreement with McGinness et al\textsuperscript{11}. These findings rather suggest that dry pellets would be predominant electronic conductors.

1:27PM X34.00012: Evaluation of environmental effects on the performance of 2,8-difluoro 5,11-bis(triethylsilylethynyl) anthradithiophene thin-film transistors*

ZAFRULLAH JAGOO (Presenter), Univ of NC - Chapel Hill, ZACHARY LAMPORT, OANA D. JURCHESCU, Wake Forest University, LAURIE MCNEIL, Univ of NC - Chapel Hill — The electrical performance of organic transistors has been known to suffer from exposure to high moisture and oxygen levels. Reduction of the carrier mobility, threshold voltage shifting to more negative gate voltages and appearance of a hysteresis loop when scanning the gate voltage in the forward direction and then backwards are all manifestations of transistor deterioration. The worst possible outcome would be that the transistor is not longer functional after prolonged exposure to air. The study was conducted using a bottom-gate bottom-contact transistor with 2,8-difluoro 5,11-bis(triethylsilylethynyl) anthradithiophene (diF-TES ADT) as the active layer. The top surface of the semiconductor was uncovered and the device characteristics were measured at different oxygen and humidity levels. We found out that the organic thin-film transistor performed better electrically in the absence of water vapor and oxygen. Moreover, the degradation was reversible if the source of water vapor and oxygen was removed. This demonstrate the importance of encapsulation in organic semiconductor devices.

*NSF Award NSFDMR-1708379
1:39PM X34.00013: Bio-sourced, potentially biodegradable materials for fast response moisture sensors  
ABDELAZIZ GOUDA (Presenter), MANUEL REALI, CLARA SANTATO, Ecole Polytechnique de Montreal — Humidity is a very important physical parameter that plays an imperative role in technology and human activity. Researchers are paying more attention to develop moisture-responsive materials with outstanding characteristics such as high sensitivity, wide humidity detection range, fast response and short recovery times to keep pace with the ongoing development in technology. Abundant, bio-sourced and biodegradable organic materials, such as melanin, are needed to enable the development of eco-designed technologies that alleviate the environmental footprint of the electronics sector. Melanin is a ubiquitous biomacromolecule with diverse functions including hydration dependent electrical response [1], photoresponse [2], antioxidant [3], metal chelation [4], and free radical scavenging [5]. Melanin originates from the oxidative polymerization of (5,6)-dihydroxindole (DHI) and (5,6)-dihydroxindole 2-carboxyl acid (DHICA) building blocks [6]. DHI-melanin features ordered, conjugated structure with better electrical conductivity with respect to DHICA-melanin [5]. Herein, we investigate DHI-melanin and DHI-DHICA melanin thin films, spin coated and polymerized on technologically relevant and potentially biodegradable substrates, as active layers for fast response moisture sensors.

1:51PM X34.00014: Effects of Molecular Weight and Annealing on Charge Carrier Concentration in Thin PANI-CSA Films  
ARUN KUMAR AGARWAL (Presenter), SIDDHARTHA PANDA, Materials Science Programme, Indian Institute of Technology Kanpur, Kanpur, Uttar Pradesh, India — PANI-CSA thin films have shown promising results like higher temperature sensitivities (Ahmad et al, J. Appl. Polym. Sci. 2013) and overcoming limitations of Wiedemann-Franz law (Jin et al, J. Phys. D: Appl. Phys. 2010) hence, can be used in flexible wearable sensors, thermoelectric devices. However, charge transport in PANI-CSA thin films is not very well understood. Effect of doping on electrical conductivity ($\sigma$) in PANI-CSA, effect of molecular weight ($M_W$) on mobility ($\mu$) in RR-P3HT (Zhang et al, Jour. of Amer. Chem. Soc. 2006) and change in grain size on annealing in P3HT:PCBM (Beal et al, Macromolecules 2010) have been reported. However, there is no study on effect of $M_W$ on charge carrier concentration ($n$) in annealed PANI-CSA thin films. PANI-CSA thin films (~50-70nm) were fabricated with different $M_W$ of PANI-EB. Their $\sigma$ was checked before and after annealing which showed a strong dependence on $M_W$. Annealing decreased $\sigma$ for all films but effect was more prominent at lower $M_W$. AFM was done to map morphological changes with $M_W$ and annealing. DC Hall measurements were done to measure $\mu$ but were inconclusive due to low $\mu$ (Yamada et al, Synth. Met. 2019) hence, AC Hall measurements were done which indicated that the change in $\sigma$ has two contributors; change in $\mu$ and change in $n$. 
Effects of concentration and local structure on charge trapping in polymer electrets with amine-based substituents.* EVAN PLUNKETT (Presenter), QINGYANG ZHANG, CHEN CHI, HOWARD EDAN KATZ, DANIEL REICH, Johns Hopkins University — Thin film polymer dielectrics with controllable electronic properties are of considerable interest for applications in organo-electronic systems. We use amine-based moieties in thin film polystyrene dielectrics to modify electron and hole trap states and densities. When chemically bound to polymers and also when introduced as free additives, these moieties induce changes in static potential differences that modify the behavior of adjacent electronic materials. For example, N,N'-diphenyl-N,N'-di-p-tolybenzene-1,4-diamine in polystyrene exhibited threshold voltage shifts up to \( \Delta V_{th} = O(50V) \) after application of static electric fields as measured in pentacene-based OFETs. Films with free additive concentration in the range of 1-3% showed a strongly concentration dependent stability in \( V_{th} \), in contrast to polystyrene systems with tethered amines. Stability is higher at lower amine concentrations suggesting clustering of additives is an important effect in these systems.

Session X35 DPOLY DSOFT: Kinetics and Aggregation of Polymers in Complex Fluids and Geometries 507 - Jeffrey Ethier, Illinois Institute of Technology

Network Centrality of Heterogeneous Elastomers for Describing Mechanical Property  YOSHIFUMI AMAMOTO (Presenter), KEN KOJIO, ATSUSHI TAKAHARA, Kyushu Univ, YUICHI MASUBUCHI, Nagoya University, TAKAAKI OHNISHI, The University of Tokyo — There have been a lot of attempts to describe structure-property relationships of heterogeneous elastomers. However, it is hard to evaluate the heterogeneity quantitatively. In this presentation, we report the network structure of the elastomers in terms of connectivity was evaluated based on centrality, one of indicators utilized in complex network science, and its effect for the mechanical property was investigated. A construction and a uniaxial elongation of elastomers were performed with coarse-grained molecular dynamics simulation. End-to-end distance of partial chains, which strongly affect stress in entropy elasticity was evaluated. We found that the end-to-end distance increased with increasing the network centrality. Furthermore, network centrality incorporating initial end-to-end distance could be a unified indicator for the mechanical property of the heterogeneous elastomers. We think the complex network could be one of the suitable approaches to reveal structure-property relationships of materials.
11:27AM X35.00002: Understanding aggregation and growth in a cross-linked polymer film*

TINE CURK (Presenter), ERIK LUIJTEN, Northwestern University — Oil paints, used by celebrated artists such as Rembrandt, Picasso, Dalí and others, are composite materials consisting of pigment nanoparticles and polymerized drying oil. Dissociation of the pigment results in metal ions that react with the oil, yielding an insoluble metal soap. Over time scales of decades to centuries, these metal soaps aggregate, forming visible clusters and thus tainting the original work of art.

Lack of understanding of the aggregation and growth processes that occur in a cross-linked film hinders the conservation efforts aimed at preserving traditional works of art. To understand this degradation process, we propose a theoretical model combining existing models of nucleation and growth, as well as Ostwald ripening, with the elasticity and creep behavior of cross-linked polymers. Our model predicts the growth rates of clusters spanning nanoscopic to macroscopic length scales. The analytical results are supported by Monte Carlo simulations.

*This research was supported in part by the Andrew W. Mellon Foundation via the Center for Scientific studies in the Arts at Northwestern University.

CARLOS LOPEZ (Presenter), ANDREA SCOTTI, MONIA BRUGNONI, STEFFEN BOCHENEK, JEROME CRASSOUS, WALTER RICHTERING, Physical Chemistry, RWTH Aachen University — Soft, adaptive microgels are potential building blocks for smart materials with precisely controlled viscoelastic properties that are highly responsive to environmental conditions. We compare the flow properties of different PNIPAM microgels: regularly crosslinked and ultra-low crosslinked (ULC) microgels. We show that the flow properties of ULC microgels reveal a colloid-to-polymer transition with increasing solution concentration. At low concentrations, the viscoelastic properties and phase behaviour of ULC microgels are identical to those of regularly crosslinked microgels. With increasing concentration, the viscosity and plateau modulus display a much weaker increase for ULC relative to regularly cross-linked systems. Oscillatory rheology in the linear viscoelastic region reveals that for regularly crosslinked microgels in concentrated solution, the flow properties are determined by the highly cross-linked core, while for ULC microgels the brush-like interaction is dominant.

11:51AM X35.00004: Electrostatics and Rheology of Unentangled Semidilute Polyelectrolyte Solutions  GUANG CHEN (Presenter), ANTONIO PERAZZO, HOWARD A STONE, Princeton University — Polyelectrolytes (PE) are charged polymers in polar solvents. Classical scaling theory suggests that the viscosity $\eta$ for salt-free semidilute unentangled PE solutions in $\Theta$ solvents obeys the empirical Fuoss law $\eta \sim c^{1/2}$ in the higher polymer concentration ($c$) regime, and $\eta \sim c^{5/4}$ in the lower $c$ regime. However, recent experiments have also reported $\eta \sim c^{0.68}$ and $\eta \sim c^{0.91}$, which are at odds with the classical scaling theory. To rationalize the four distinct scaling laws, we probe the electrostatic energy per monomer under the influence of salt and their contributions to the viscosity of PE solutions. We identify four consecutive regimes dependent on the magnitude of the ratio of the polymer concentration over the salt concentration, which capture the unexplained observations and classical PE solution theories, and provide physical insights for the effects of salt contamination and added salt on the properties of both weakly and strongly charged semidilute unentangled PE solutions.

12:03PM X35.00005: Patterned fluorescence photobleaching recovery on multicomponent sodium polystyrene sulfonate solutions to investigate temporal aggregate formation.*  PAUL BALDING (Presenter), PAUL RUSSO, RACHEL BORRELLI, Georgia Institute of Technology — Patterned fluorescence photobleaching recovery was used to investigate multicomponent mixtures of sodium polystyrene sulfonate (NaPSS) to further understand translational diffusion and formation of temporal aggregates observed in dynamic light scattering (DLS) of charged macromolecules. Mixtures consisted of fluorescein isothiocyanate labeled NaPSS probe and an unlabeled NaPSS matrix in salt concentrations that exceeded $C_p/C_s = 5.7$. In an effort to entrain single polymers into temporal aggregates, the matrix concentration was increased for several molecular weight probe polymers. If dilute probes enter matrix polymer aggregates then probe diffusion would be dictated by the aggregate, independent of probe molecular weight. But measured self-diffusion depended on probe molecular weight, evidence against probe aggregate inclusion. Further, probe diffusion depended on matrix molecular weight, at least above the entanglement concentration, suggesting that probes do not become entrained in the temporal aggregates, but respond to the presence of matrix polymer. Diffusion in unimodal NaPSS systems obeyed theoretical scaling laws of $D \sim C^{-0.5}$ but did not exhibit bi-exponential decay behavior as would be expected for diffusers in and outside temporary aggregates.

12:15PM X35.00006: Simulating Surface-Grafted Polymers in Solvent Mixtures: Effects of Cononsolvency  JING ZONG (Presenter), DONG MENG, Chemical engineering, Mississippi State Univ — One puzzling phenomenon about polymer conformations in a mixture of solvents is the cononsolvency effect -- polymers in a good solvent undergo reentrant coil-to-globule-to-coil transition upon addition of a good cosolvent. Recent studies have suggested the generic nature of the cononsolvency effect independent of chemically specific details of the polymer and solvents. In this study, we first reinforce such claim by showing that a coarse-grained soft model frequently used in studying polymers is able to reproduce the reentrant transition at the single-chain level, provided that solvents are treated explicitly. In our Monte Carlo simulations, the coil-to-globule-to-coil transition occurs as the chemical potential of polymers in solution decreases upon increasing the cosolvent fraction, ruling out increasingly worse solvent quality as the cause of collapse. To further our microscopic understanding, we apply the soft model to studying conformational responses of surface-grafted polymers under the cononsolvency effect. By analyzing the inter-polymer density correlations, we illustrate the highly correlated nature of polymer clustering mediated by the cosolvents. Conformational responses of high grafting density brushes will also be discussed in the context of smart sensor surfaces.

12:27PM X35.00007: Humidity- and surfactant-accelerated aging in poly(vinyl alcohol)-based thin films*  KATARZYNA MAJERCZAK (Presenter), ZHENYU JASON ZHANG, Univ of Birmingham — This work aims to understand how relative humidity (RH) and chemical composition influence the diffusion of guest molecules in formulated polymer films replicating packaging materials for detergent products. Surface morphology of thin poly(vinyl alcohol) films containing glycerol and surfactants of various headgroup chemistry was examined using Atomic Force Microscopy under controlled RH conditions (15% – 55% RH). Diffusion was found to be controlled by both surfactant “blooming” from the polymer matrix and RH, leading to changes in film morphology. Anionic surfactants bloomed in the films at low concentration (1 wt%) above a threshold of 35% RH. Higher concentrations (above 3 wt%) were required for blooming of cationic surfactant, while nonionic surfactants showed no changes in film morphology regardless of concentration or RH. It is likely that chemical compatibility and charge-pairing effects are the main driving forces for these changes. Increased RH and presence of glycerol could enhance the free volume within the polymer matrix, accelerating diffusion and therefore achieving equilibrium (surfactant blooming), as confirmed by Dynamic Vapour Sorption measurements.

Simulations of symmetric diblock copolymer melts have shown that the order-disorder transition (ODT) is given by \((\chiN)_{ODT} = 10.495 + 41\tilde{N}^{-1/3} + 123\tilde{N}^{-0.56}\), where \(\tilde{N}\) is the invariant polymerization index. This result, however, is specific to monodisperse molecules, whereas there is always some degree of polydispersity in experiments even when the molecules are synthesized by anionic polymerization. Using simulations, the polydispersity correction to the ODT is evaluated for the small degrees of polydispersity characteristic of anionic polymerization. We find that polydispersity reduces \((\chiN)_{ODT}\) for large \(\tilde{N}\), but increases \((\chiN)_{ODT}\) for small \(\tilde{N}\). These corrections should allow experimentalists to estimate the Flory-Huggins \(\chi\) parameter with greater accuracy.

*This work was supported by NSERC of Canada and Compute Canada

The thermodynamics of the binding of a charged dendrimer [poly(amidoamine)] to an uncharged graphene sheet is investigated through simulations and a mean-field theory. A non-monotonicity that is observed in the degree of binding of the dendrimer as a function of pH is explained through potential of mean force (PMF) calculations and the Flory-Huggins-Debye-Huckle type mean field theory, by analyzing the electrostatic and non-electrostatic interactions between the pairs of dendrimer, graphene, and water molecules and ions. The simulation trends are satisfactorily reproduced by the theoretical results. In addition to the van der Waals interactions between the dendrimer and the graphene sheet, it is found that the presence of the solvent ions and counterions too has a major influence on these trends.

1:03PM X35.00010: Complex Viscosity of Helical and Doubly Helical Polymeric Liquids from General Rigid Bead-Rod Theory  JOURDAIN PIETTE, A. JEFFREY GIACOMIN (Presenter), MONA KANSO, Queen's University — With general rigid bead-rod modelling, we recreate shapes of complex macromolecular structures with beads, by rigidly fixing bead positions relative to one another. General rigid-bead rod theory attributes the elasticity of polymeric liquids to the orientation that their macromolecules develop during flow. For oscillatory shear flow, the frequency dependencies of both parts of the complex viscosity are predicted correctly. In this paper, we use general rigid-bead rod theory for the most complex macromolecular architectures to date. We thus explore the role of helix geometry on the complex viscosity of a helical polymeric liquid. Specifically, we investigate the effects of helix radius, flight length, helix length and the number of beads per flight on the complex viscosity function, the fluid relaxation time, the zero-shear values of the steady shear viscosity and of the first normal stress coefficient. As a worked example, we examine specifically deoxyribonucleic acid (DNA). Using general rigid bead-rod theory, we dissect the DNA to see how the first helix, second helix, and then the base pairs, each contribute to the complex viscosity. We next explore the rheological implications of gene replication to find that the unzipping of DNA into a pair of single strands is viscostatic.

1:15PM X35.00011: The tail free discotic liquid crystal 1,2,3,4,7-pentafluorotriphenylene: a study in structural variations*  MITCH POWERS (Presenter), BRETT ELLMAN, JOHN PORTMAN, Physics, Kent State University, ZHE LI, Advenchen Laboratories, KUNLUN WANG, PARIKSHIT GURAGAIN, ROBERT J TWIEG, SCOTT BUNGE, Chemistry, Kent State University, LEWIS L SHARPNACK, DENA MAE AGRA-KOOIJMAN, Physics, Kent State University, SATYENDRA KUMAR, SUNY-Albany — Discotic liquid crystals are disc shaped molecules that self assemble into long columns of cofacial molecules while still maintaining some liquid-like properties. They are typically formed by rigid aromatic molecular cores surrounded by a number of flexible tails. The tails play an important role, as they separate the columns and provide a source of entropy which inhibit crystallization. In this contribution, we describe a tail free discotic liquid crystal 1,2,3,4,7-pentafluorotriphenylene (7F-TFT). We will explore the nature of this tail free mesophase by comparing this compound with a number of closely related compounds based on tetrafluorotriphenylene. By varying the position and chemical species of the fifth substituent, we will see the effects that molecular structure have on this unusual mesogen.

1:27PM X35.00012: Effects of Boundary Conditions and Alignment Methods on Liquid Crystal Performance in Microwave Devices  JASON NOBLES (Presenter), OLHA MELNYK, ANATOLIY GLUSHCHENKO, ROBERT CAMLEY, ZBIGNIEW J CELINSKI, University of Colorado, Colorado Springs — Microwave devices are ubiquitous in our daily lives; cell phones, satellite communications, automobile safety radars all depend on microwaves. We are working on a technology, a merger of microwave science with liquid crystal physics, that has the potential to revolutionize microwave technology by reducing the size and cost of these devices by a factor of 100. As part of this effort, we are investigating a variety of the techniques used to control the initial state of the liquid crystal in a device to determine the optimum method to use with this emerging microwave technology. From our work, we see that a treated thin film of polyimide provides the best results. However, our work also demonstrates that, if a specialized liquid crystal known as dual frequency liquid crystal is used, the initial state of the liquid crystal does not significantly impact the performance of the device. This discovery reduces the number of steps necessary to manufacture microwave devices, saves on chemical and treatment costs, and eliminates several manufacturing challenges unique to liquid crystal based microwave devices. These benefits add up to a significant savings in time and cost during the design and manufacture of microwave components based on liquid crystal technology.

1:39PM X35.00013: Fast Water Transport in Polyelectrolyte Brush Functionalized Nanochannels*  VISHAL SANKAR SIVASANKAR (Presenter), SAI ANKIT ETHA, HARNOOR SINGH SACHAR, SIDHARTHDA SACHAR, Mechanical Engineering, University of Maryland, College Park — The need for enhanced transport and enhanced separation in nanochannels is prevalent across disciplines of fluid mechanics, material science, bio-medicine, nanotechnology, etc. In this study, we show that the functionalization of nanochannel with pH-responsive polyelectrolyte (PE) brushes, which we model using newly formulated augmented Strong Stretching theory, can lead to fast electroosmotic (EOS) transport of water. We observe that the presence of PE brushes results in enhanced flux when compared to brush free nanochannel. This is because of the localization of the EDL charge density away from the flow retarding wall. The enhanced flux obtained in brush functionalized nanochannels tends to be comparable to graphene-based state-of-the-art nanostructures which indicate that such a system could be used for fast transport of water. Moreover, we also witness a large gradient in the flow profiles, for certain conditions of the solvent, which suggests that these brush functionalized nanochannels could also be useful in size-based separation of particles.

Mechanisms of Surfactant Adsorption and Interfacial Tension Lowering for Enhanced Oil Recovery (EOR) Applications

JAEYUB CHUNG (Presenter), BRYAN BOUDOURIS, ELIAS I FRANSES, Chemical Engineering, Purdue Univ — The robust evaluation of aqueous surfactant formulations depend on their ability to lower the interfacial tensions (IFTs) of oil/water interfaces for mobilizing oil. For a formulation to be most effective, the IFT of an oil/water interface should be ultralow (<0.01 mN/m). We have discovered that there are two types of relevant equilibrium IFTs (EIFTs). The un-pre-equilibrated EIFT (EIFT$_{up}$) is established when primarily the surfactants have equilibrated across the interface, and applies to the early stages of the EOR process. The pre-equilibrated EIFT (EIFT$_{p}$) is established when the oil and aqueous components are also equilibrated, and is applied to the later stages. The two EIFTs can be different due to the preferential partitioning of the various surfactant components usually present in commercial surfactants. Such partitioning can change drastically the chemical potentials and the partition coefficients of these surfactant components, and causes an IFT shift to a more stable value as the oil and aqueous phases components equilibrate also at longer times. The results have significant implications for understanding the effect of the surfactant concentration and composition on the EIFT.

Session X36 DPOLY: Fantastic Polyelectrolytes and How They Behave in Coacervates

601/603 - Michael Rubinstein, University of North Carolina at Chapel Hill - Tag(s): Invited
**11:15AM X36.00001: Structure and Dynamics of Polyelectrolyte Solutions and Coacervates**

[Invited] RALPH COLBY (Presenter), Pennsylvania State University — The shear rate dependence of viscosity is used to evaluate the concentration dependences of specific viscosity, relaxation time and terminal modulus for several polyelectrolytes in three solvents: deionized water, ethylene glycol and glycerol. Small-angle X-ray scattering determines the correlation length of these polyelectrolyte solutions from a peak in their scattering function, which changes as expected with solvent dielectric constant. In semidilute unentangled solutions, dynamics are described by the Rouse model and combined with the correlation length in different ways to determine the number density of chains, which allows calculation of the number-average molecular weight using a robust method that is insensitive to the presence of salt. The high viscosity glycerol solvent allows characterization of the viscoelastic response of high molecular weight polyelectrolytes over a wide range of frequency, showing Rouse character in unentangled solutions and a clear rubbery plateau in strongly entangled solutions.

A simple way to make a polyampholyte gel is to mix oppositely charged polyelectrolytes, which precipitate to form a sediment that is termed a coacervate. Hydrophilic coacervates (with roughly 70 % water in them) are reversible gels with labile ionic interactions and their dynamics are described by a sticky Rouse model. In both examples, while not everything is understood for these complicated forms of condensed matter, polymer physics can be used to gain important insights.

*This work was supported by the NSF Chemistry Division.

**11:51AM X36.00002: Phase Behavior and Viscoelasticity of Polyelectrolyte Coacervates at High Salt Concentrations**

[Invited] JENNIFER LAASER (Presenter), FRANCES J MORIN, MARISSA PUPPO, LEXI KNIGHT, Chemistry, University of Pittsburgh — Separating the salt and polymer volume fraction-dependent dynamics of complex coacervates is challenging because changing the salt concentration of the sample typically also changes the polymer concentration in the polymer-rich phase. Here, we describe a way to address this challenge using a “salt-addition” method for preparation of complex coacervates that allows us to increase the salt concentration of the coacervate without significantly changing the polymer volume fraction. Using this method, we investigate the rheology of polystyrenesulfonate (PSS)/poly(diallyldimethylammonium chloride) (PDADMAC) coacervates at salt concentrations near and above the critical salt concentration. We find that the dependence of the relaxation times on salt concentration is similar to that observed in previous studies, but that the relaxation times scale significantly more strongly with polymer volume fraction than previously assumed. Additionally, we identify a second critical salt concentration above which the coacervates separate at high salt concentrations, and use thermogravimetric analysis to characterize the phase behavior of these materials in the high-salt regime. These results demonstrate that the salt addition method is a powerful approach for exploring and identifying new behaviors of coacervates in the high salt limit.

12:27PM X36.00003: Fantastic Entanglements between Polyelectrolytes in Solutions [Invited]
CARLOS LOPEZ (Presenter), Physical Chemistry, RWTH Aachen University — We study the entanglement properties of flexible and semiflexible polyelectrolytes sodium polystyrene sulfonate and sodium carboxymethyl cellulose. In dilute salt-free and excess-salt solutions these polymers adopt rod-like and expanded coil conformations respectively. The solvent’s ionic strength has a large impact on the conformation of polyelectrolytes, and the number of binary interchain contacts, quantified through the intrinsic viscosity and osmotic pressure respectively. While adding salt leads to a large decrease in polymer size, it does not affect their entanglement density and entanglement crossover. This contradicts packing models of polymer entanglement and suggests that the density of binary contacts in solution is not affected by the solvent quality. Based on this observation, we work out the reptation dynamics of polyelectrolytes in salt-free solution, which differ appreciably from earlier models.

1:03PM X36.00004: Structure and rheology of polyelectrolyte complex coacervates [Invited]
AMANDA MARCIEL (Presenter), Rice Univ, SAMANVAYA SRIVASTAVA, University of California, Los Angeles, MATTHEW TIRRELL, The University of Chicago — Polyelectrolyte complexes are highly tunable materials that span from low-viscosity liquids (coacervates) to high-modulus solids with high water content, making them attractive as surface coating, membrane purification and bioadhesive materials. However, most of their properties and their effects with salt, pH, polymer ratio and temperature have only been qualitatively described. Here, we present an investigation of the structure and chain conformations, and rheological properties of polyelectrolyte complex (PEC) coacervates comprising biomimetic model polyelectrolytes. Systematic studies using small-angle X-ray scattering (SAXS) of the structure and chain behavior in liquid PEC coacervates revealed a physical description of these materials as strongly screened semidilute solutions of polyelectrolytes comprising oppositely charged chains. At the same time, solid PECs were found to be composed of hydrogen-bonding driven stiff ladder-like structures with large correlation lengths. While the liquid complexes behaved akin to semidilute polyelectrolyte solutions upon addition of salt, the solids were largely unaffected by it. Terminal relaxations of the chains in PEC coacervates were explored by rheology measurements. Excellent superposition of the dynamic moduli data was achieved by a time-salt superposition.

1:39PM X36.00005: Fantastic Saloplastic* [Invited] JOSEPH SCHLENOFF (Presenter), MO YANG, ZACH DIGBY, KHALIL AKKAOUI, Florida State Univ — Oppositely-charged polymers spontaneously assemble into amorphous complexes or coacervates, driven mainly by the release of counterions. Macromolecules within these polyelectrolyte complex/coacervates, PECs, are well blended due to pairing of oppositely-charged repeat units Pol⁺ and Pol⁻. These charge pairs can be quickly and reversibly broken by the addition of salt to the solution in which PECs are immersed, reducing their bulk modulus. This reversible doping by salt, termed saloplasticity, controls all of the physical and mechanical properties of PECs. This talk will illustrate the concept and origin of saloplasticity and show how a “stick association” theory of polymers can be extended to PECs to predict their dynamics as a function of salt doping.

11:15AM X37.00001: Finite speed of quantum scrambling with long range interactions
[Invited] ANDREW LUCAS (Presenter), University of Colorado, Boulder — In a locally interacting many-body system, two isolated qubits, separated by a large distance r, become correlated and entangled with each other at a time $t \geq r/v$. This finite speed v of quantum information scrambling limits quantum information processing, thermalization and even equilibrium correlations. Yet most experimental systems contain long range power law interactions -- qubits separated by r have potential energy $V(r) \propto r^{-\alpha}$. Examples include the long range Coulomb interactions in plasma ($\alpha=1$) and dipolar interactions between spins ($\alpha=3$). In one spatial dimension, we prove that the speed of quantum scrambling remains finite for sufficiently large $\alpha$. This result parametrically improves previous bounds, compares favorably with recent numerical simulations, and can be realized in quantum simulators with dipolar interactions. Our new mathematical methods lead to improved algorithms for classically simulating quantum systems, and improve bounds on environmental decoherence in experimental quantum information processors.

11:51AM X37.00002: Emergent locality in systems with power-law interactions*
[Invited] YEVGENY BAR LEV (Presenter), Ben-Gurion University of the Negev — In generic systems with local interactions transport is diffusive and information propagates inside a quasicausal "light-cone" parametrized by a constant velocity known as the Lieb-Robinson velocity. Introducing long-range interactions, should intuitively enhance transport by long-range hops, and deform the linear "light-cones," into a superballistic form. Using two numerically exact techniques I will show that this is not the case for a number of generic one-dimensional systems. All studied systems, for sufficiently short-range interactions, show universal behaviour of asymptotically emergent locality and a unique composite transport comprised of diffusive and superdiffusive features.

12:27PM X37.00003: Locality and Digital Quantum Simulation of Power-Law Interactions
[Invited] MINH CONG TRAN (Presenter), University of Maryland, College Park — The propagation of information in non-relativistic quantum systems obeys a speed limit known as a Lieb-Robinson bound. We show that Lieb-Robinson bounds provide tighter estimates for the gate count in quantum algorithms for simulating power-law interacting Hamiltonians. In addition, we prove new Lieb-Robinson bounds using techniques from quantum simulation algorithms. This brings the analysis full circle, revealing a deep connection between Lieb-Robinson bounds and digital quantum simulation.

1:03PM X37.00004: Dominic Else Invited Talk [Invited] —
1:39PM X37.00005: Signaling and scrambling for strongly long-range interacting quantum systems [Invited]  ZHEXUAN GONG (Presenter), Colorado School of Mines, ANDREW GUO, MINH C TRAN, ANDREW CHILDS, University of Maryland, ALEXEY V GORSHKOV, National Institute of Standard and Technology — Strongly long-range interacting quantum systems—those with interactions decaying as a power-law $1/r^\alpha$ in the distance $r$ on a D-dimensional lattice for $\alpha \leq D$—have received significant interest in recent years. They are present in leading experimental platforms for quantum computation and simulation, as well as in theoretical models of quantum information scrambling and fast entanglement creation. Since no notion of locality is expected in such systems, a general understanding of their dynamics is lacking. As a first step towards rectifying this problem, we prove two new Lieb-Robinson-type bounds that constrain the time for signaling and scrambling in strongly long-range interacting systems, for which no tight bounds were previously known. Our first bound applies to systems mappable to free-particle Hamiltonians with long-range hopping, and is saturable for $\alpha \leq D/2$. Our second bound pertains to generic long-range interacting spin Hamiltonians, and leads to a tight lower bound for the signaling time to extensive subsets of the system for all $\alpha < D$. This result also lower-bounds the scrambling time, and suggests a path towards achieving a tight scrambling bound that can prove the long-standing fast scrambling conjecture.

Session X38 DQI: Superconducting Qubits: Circuit Theory, Hamiltonian Analysis and Design Tools 607 - Arne Grimsmo, Univ of Sydney

11:15AM X38.00001: QuCAT: superconducting quantum circuit analyzer tool in Python*
MARIO GELY (Presenter), GARY STEELE, Delft University of Technology — Quantum circuits constructed from Josephson junctions and superconducting electronics are key to many quantum computing and quantum optics applications. Designing these circuits involves calculating the Hamiltonian describing their quantum behavior. In this talk, we present QuCAT, or "Quantum Circuit Analyzer Tool", an open-source framework to help in this task. This open-source Python library features an intuitive graphical or programmatical interface to create circuits, the ability to compute their Hamiltonian, and a set of complimentary functionalities such as calculating dissipation rates or visualizing current flow in the circuit.

MATTHEW WEIPPERT (Presenter), KRISTINA COLLADAY, DAVID FERGUSON, RYAN J EPSTEIN, Northrop Grumman - Mission Systems — We report on efficient quantum simulation of large superconducting circuits using matrix product states (MPS) and the density matrix renormalization group (DMRG) technique. We analyze a circuit containing a chain of Josephson junctions, forming a superinductor, with a flux-tunable compound center junction. Kuzmin et al. explored similar circuits experimentally, achieving super strong coupling in circuit electrodynamics [1]. We obtain the lowest-lying eigenstates and energies for a chain length of 40 Josephson junctions with derived error bounds. Using these tensor network techniques we investigate the offset charge sensitivity of the circuit as a function of compound junction flux, which is not amenable to classical analysis and is intractable via exact diagonalization.

This research was supported by the Army Research Office under contract W911NF-17-C-0024.

AGUSTIN DI PAOLO (Presenter), THOMAS BAKER, ALEXANDRE FOLEY, DAVID SENECHAL, ALEXANDRE BLAIS, Institut quantique and Departement de Physique, Universite de Sherbrooke — We introduce a tensor-network method tailored to the simulation of large-scale superconducting quantum circuits. We leverage information unavailable to other state-of-the-art numerical techniques to produce first-principles coherence-time estimates for the fluxonium qubit. In particular, we study the charge dispersion of this qubit due to coherent quantum phase slip processes. Taking advantage of this novel approach, we present direct numerical evidence of the validity of the effective theory introduced in [V. E. Manucharyan et. al, PRB 85, 024521 (2012)].

This work was undertaken thanks in part to funding from NSERC and the Canada First Research Excellence Fund.

DAVID FERGUSON (Presenter), DAVID J. CLARKE, RYAN J EPSTEIN, MOE S KHALIL, Northrop Grumman - Mission Systems, DANIEL WEISS, JENS KOCH, Northwestern University — Many superconducting qubits, such as transmons, are naturally described in terms of Cooper-pair charges hopping on and off of the nodes of the superconducting circuit. Others, such as flux qubits, are naturally described via superconducting vortices hopping in and out of the loops of the superconducting circuit. This talk describes a method to transform the Hamiltonian of a superconducting circuit from the Cooper-pair number basis to the dual vortex-number basis. In contrast to other methods that also accomplish this transformation, our method is non-perturbative and isospectral. It provides a useful framework to compare and evaluate the novel properties of qubits of the flux-qubit type such as nonstoquasticity and decreased sensitivity to environmental noise.

This research was supported by the Army Research Office under contract W911NF-17-C-0024.
12:03PM X38.00005: Designing Better Superconducting Qubits using First-Principles Calculations and Theory  
SINEAD GRIFFIN (Presenter), Lawrence Berkeley National Laboratory — Superconducting qubits have emerged as one of the leading candidates for scalable quantum computing, despite suboptimal coherence times and resonantor quality factors. In this work, we combine first-principles calculations and effective models to describe key performance losses in niobium-based superconducting qubits. We find that defects play a decisive role in their operational efficiency, and that careful control of stoichiometry can significantly improve their performance. We compare our theoretical predictions with recent experiments confirming the importance for defects for understanding decoherence pathways in qubits and quantum materials.

12:15PM X38.00006: Design and Analysis of Multi-Qubit Superconducting Chips for Extensible Surface Coding*  
NADIA HAIDER (Presenter), QuTech and TNO, The Netherlands, ALESSANDRO BRUNO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, MARC BEEKMAN, PIOTR KAMINSKI, QuTech and TNO, The Netherlands, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands — We present an effective numerical method to analyze qubit-qubit avoided crossings and two-qubit gate times in a superconducting multi-qubit chip. Our hybrid simulation approach, combining finite element and circuit simulation, is a convenient tool to investigate complex chip layouts with limited computational resources. The simulation method has been applied to design and investigate a new multi-qubit chip layout. This new chip design and improved fabrication process have allowed us to also reduce mode hybridization between qubits and resonators and to increase qubit coherence time.

*Research funded by Intel Corporation.

12:27PM X38.00007: Design and quantization of superconducting circuits*  
ZLATKO MINEV (Presenter), THOMAS G MCCONKEY, FIRAT SOLGUN, JERRY M. CHOW, JAY M GAMBETTA, DAVID MCKAY, IBM TJ Watson Research Center — Quantum information processing using superconducting circuits has steadily developed into a large and diverse field. The success of building larger devices emphasizes the need to more efficiently and accurately design and quantize the distributed microwave structures, including non-linear elements, such as Josephson tunnel junctions, which comprise these devices. In this talk, we review some recent results on the comparison between several of the commonly used quantization and design approaches.

*IBM Research
12:39PM X38.00008: Derivation of the Hamiltonian of a flux qubit-LC oscillator circuit using the circuit variables*  FUMIKI YOSHIHARA (Presenter), National Institute of Information and Communications Technology, SAHELI ASHHAB, Qatar Environment and Energy Research Institute, TOMOKO FUSE, KOUICHI SEMBA, National Institute of Information and Communications Technology — We derive the Hamiltonian of a single-Josephson-junction flux qubit-LC oscillator circuit using the standard quantization procedure [1]. The derived Hamiltonian consists of terms related to the LC oscillator, the flux qubit (and its higher energy levels), and the product of the two flux variables. This Hamiltonian is similar to that of the quantum Rabi model, where a two-level atom and a harmonic oscillator are coupled by a dipole-dipole interaction. Therefore, it is not surprising that the observed transmission spectra of a flux qubit-LC oscillator circuits can be well fitted by the quantum Rabi Hamiltonian [2]. We also find that the simple picture that models the coupling using a common inductor shared by the LC oscillator and the flux qubit needs only a minor modification. We thank Michel Devoret and Motoaki Bamba for stimulating discussions.

*This work was supported by Japan Society for the Promotion of Science Grant-in-Aid for Scientific Research (Grant No. JP19H01831), and Japan Science and Technology Agency Core Research For Evolutionary Science and Technology (Grant No. JPMJCR1775)

12:51PM X38.00009: Efficient Hamiltonian Parameter Estimation with Sequential Monte Carlo Technique*  JÉRÉMY BÉJANIN (Presenter), CAROLYN EARNEST, MATTEO MARIANTONI, Department of Physics and Astronomy and Institute for Quantum Computing, University of Waterloo, YUVAL R SANDERS, Department of Physics and Astronomy and ARC Centre of Excellence for Engineered Quantum Systems, Macquarie University — As quantum computers grow in size the task of calibrating them becomes more complex. There are many parameters to optimize for and the resulting performance of the qubits depends strongly on how well various quantities are measured. For example, knowledge of the coupling to neighboring qubits or resonators is necessary for two-qubit gates. In addition, it is preferable if qubits are located far away in frequency from harmful systems like Two-Level State defects.

By utilizing a frequency tunable qubit as a probe, we can measure the parameters of a resonance, namely the frequency and coupling strength, and use this information to calibrate gates or improve coherence times. Because these parameters fluctuate over time, this calibration should be repeated regularly. It is therefore important that it runs quickly. Using tunable transmon superconducting qubits, we demonstrate a method to efficiently measure the parameters of these resonant couplings. Initially, these parameters are estimated from a state of zero knowledge with a method based on Hamiltonian dynamics. Subsequently, a Sequential Monte Carlo technique can quickly refine and improve the accuracy of that estimate.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund (CFREF).
ANDREY KLOTS (Presenter), University of Wisconsin - Madison, LEV B IOFFE, Google.; University of Wisconsin - Madison, ROBERT F MCDERMOTT, University of Wisconsin - Madison — We propose a mathematical formalism and software that allow to express Hamiltonian of any superconducting circuit in a standardized way. The process allows for efficient/quick diagonalization of Hamiltonians of complex circuits. With vastly increasing number of various complicated qubit designs (0-pi qubits, gmoms,...) it becomes necessary to be able to describe various LCJ circuits analytically and model them numerically. Normally, this requires thorough study of different degrees of freedom in the circuit in order to decide which variables are essential to understanding the properties of a circuit and which are secondary. Proposed formalism automatically classifies different degrees of freedom of a circuit based on their essential properties (charge quantization, mode frequencies) and role in the circuit. Hamiltonian of any qubit circuit can be automatically obtained and the generalized coordinates can be quantized in a most natural way: through charge number operators for charge islands and photon number operators for oscillatory circuit modes. This, in turn allows us to automatically and efficiently find eigenstates of various quantum qubit circuits. We show how the formalism is used for advancing practical qubit applications.

*We thank ARO HiPS W911NF-18-1-0106
Quantum landscape engineering of superconducting circuit ground states for higher-order coupler design* TIM MENKE (Presenter), Harvard Department of Physics, MIT Research Laboratory of Electronics, MIT Department of Physics, Harvard University, Massachusetts Institute of Technology, CYRUS F. HIRJIBEHEDIN, STEVEN WEBER, MIT Lincoln Laboratory, JOCHEN BRAUMÜLLER, ANTTI VEPSALAINEN, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, GABRIEL ORR SAMACH, MIT Research Laboratory of Electronics, MIT Department of Electrical Engineering and Computer Science, MIT Lincoln Laboratory, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, BETHANY NIEDZIELSKI, DANNA ROSENBERG, MOLLIE SCHWARTZ, JONILYN YODER, MIT Lincoln Laboratory, ALAN ASPURU-GUZIK, Department of Chemistry and Department of Computer Science, Vector Institute for Artificial Intelligence, CIFAR Senior Fellow, University of Toronto, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, ANDREW JAMES KERMAN, MIT Lincoln Laboratory, WILLIAM OLIVER, Research Laboratory of Electronics, Department of Electrical Engineering and Computer Science, Department of Physics, MIT Lincoln Laboratory, Massachusetts Institute of Techn — The response of the ground state energy of a superconducting circuit to external magnetic flux can be shaped by design to engineer quantum devices including artificial spin couplers. We propose a methodology for adding higher-order polynomial terms into the ground state energy versus flux by strongly coupling a series of rf SQUIDs. The fundamental instance of two rf SQUIDs generating a ground state with 4th-order terms is implemented experimentally. Probing this circuit with a sensor flux qubit, the qubit’s transition frequency maps the derivative of the quartic ground state in accordance with simulation. Modest levels of qubit coherence are maintained despite the relatively strong inductive coupling. These results demonstrate the viability of this design for use as a 4-local coupler and show promise for extending to higher polynomial order.

*This research is funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002.
The Hodgkin-Huxley model describes the conduction of the nervous impulse through the axon, whose membrane’s electric response can be described by multiple connected electric circuits containing capacitors, voltage sources, and conductances. These conductances depend on previous depolarizing membrane voltages, which can be identified with a memory resistive element called memristor. Inspired by the recent quantization of the memristor, the Hodgkin-Huxley model has been studied in the quantum regime. The circuit obtained in this model is proposed as the building block for the construction of quantum neurons networks which can process quantum information. Hence, we study two such circuits connected in series, coupled to a quantized source. Since the main quantum contribution on these systems comes from the second moment of the voltage, we study correlations such as degree of coherence, between voltage and conductance in both circuits, proving they are quantum variables. This study paves the way for advances in hardware-based neuromorphic quantum computing, as well as quantum machine learning, which might be more efficient resource-wise.

The manipulation and the measurement of any system made of superconducting qubits rely on the use of often strong microwave drives. Current experiments show that the standard Lindblad Master Equation commonly used to describe these driven systems breaks down even for moderate drive strength. We developed a corrected numerical implementation of the Floquet-Markov Master Equation that exactly takes into account the effects of drives and apply it to study more accurately the dissipative dynamics of superconducting qubits.

1:51PM X38.00014: Lifetime renormalization of driven transmon qubits and the classification of mechanisms for drive-induced energy relaxation*  
HAKAN TURECI  
(Presenter), Princeton University, ALEXANDRU PETRESCU, Département de Physique, Université de Sherbrooke, MOHAMMAD MOEIN MALEKAKHLAGH, IBM Thomas J. Watson Research Center — Recent experiments in superconducting qubit systems have shown an unexpectedly strong dependence of the qubit relaxation rate on the readout drive power. This phenomenon limits the maximum measurement strength and thus the achievable readout speed and fidelity. In two recent papers [1,2] we have shown that the leading mechanism responsible for the enhancement of energy relaxation times of weakly anharmonic qubits is the presence of number non-conserving terms in the Josephson potential, which activate additional multi-photon and qubit-cavity correlated relaxation channels in the presence of drives. We address here a realistic experimental setup and account for the joint effects of radiative (Purcell) decay at finite temperature and dephasing.

Session X41 GMAG DMP: Novel Magnetic Materials 707 - Christopher Safranski, IBM TJ Watson Research Center
Crystal growth and characterization of the magnetic properties of intercalated transition metal dichalcogenides

KANNAN LU (Presenter), University of Illinois at Urbana-Champaign, DEEPAK SAPKOTA, The University of Tennesse, Knoxville, ADAM ACZEL, LISA DEBEER-SCHMITT, YAN WU, Oak Ridge National Lab, DAVID MANDRUS, The University of Tennesse, Knoxville, GREG MACDOUGALL, University of Illinois at Urbana-Champaign

The intercalated transition metal dichalcogenide (TMDC) Cr$_{1/3}$NbS$_2$ has attracted significant interest in recent years due to reports of a magnetic soliton lattice in this material in finite fields. This novel topological state of matter is understood to result from competing Zeeman, Dzyaloshinskii-Moriya and ferromagnetic exchange terms in the spin Hamiltonian. Despite this theoretical understanding, there are few other experimental realizations of soliton lattice materials beyond the singular compound Cr$_{1/3}$NbS$_2$. With this motivation in mind, we have undertaken a concerted effort at Illinois to grow large single crystals of additional intercalated TMDCs, and characterize them with a series of techniques, including magnetization, heat capacity, x-ray and neutron scattering. In this talk, I will report on these data and their implications for the magnetic ground states for each of the materials studied. In particular, I will report on our use of powder x-ray diffraction and magnetization to infer information about the centrosymmetry of the structure in these materials, and thus the potential for DM interactions. I will supplement with neutron diffraction from single crystals to comment on ordered ground states, and their potential to contain soliton phases in finite fields.

Vestigial Potts nematicity in a triangular lattice magnet

JÖRN VENDERBOS (Presenter), Drexel Univ, RAFAEL FERNANDES, Physics, University of Minnesota

Motivated by recent experimental evidence for spontaneous rotational symmetry breaking in the hexagonal antiferromagnet Fe$_{1/3}$NbS$_2$, this talk discusses the general theory of nematic order in magnetic system with hexagonal symmetry, focusing in particular on the possibility of a vestigial nematic phase. In stark contrast to tetragonal systems, such as the iron-pnictides, nematic order in hexagonal systems is described by the 3-state Potts model. We develop the general theory of (single-q) magnetic order at degenerate symmetry-related wave vectors, and show that distinct magnetic phases can be elegantly captured by composite order parameters: bilinears of the primary magnetic order parameters which transform irreducibly under the symmetry group. Singling out the composite nematic order parameter, we extend the Landau-type mean field theory with magnetic fluctuations and show that a vestigial nematic phase, i.e., a non-magnetic phase with broken rotation symmetry, can exist. We discuss experimental signatures and interpret our results in light of the reported measurements on Fe$_{1/3}$NbS$_2$. 
Effect of Confinement on Magnetism and Skyrmionic Properties of CoSi Nanoparticles

RABINDRA PAHARI (Presenter), BALAMURUGAN BALASUBRAMANIAN, AHSAN ULLAH, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, ROHIT PATHAK, ARTI KASHYAP, School of Basic Sciences, Indian Institute of Technology Mandi, RALPH SKOMSKI, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, GEORGE C HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, DAVID SELLMYER, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska — Quantum-confinement and surface effects often result in unusual magnetic ordering, modified ordering temperatures, and different spin structures in nanoparticles as compared to the corresponding bulk alloys [1, 2]. In sharp contrast to non-magnetic bulk equiatomic CoSi, we show a magnetic ordering at room temperature with a net magnetic moment \( m = 0.11 \mu_B/Co \) for CoSi nanoparticles. The nanoparticles have an average size of 11.6 nm, and crystallize in the cubic B20 structure, which supports spin spirals and skyrmions with broken helicity caused by non-zero Dzyaloshinskii-Moriya (DM) interactions [3]. DC susceptibility and anomalous Hall resistivity measurements are used to discuss the effect of confinement within the small diameter of CoSi nanoparticles on the room-temperature skyrmionic properties, which are essential for exploiting these complex spin structures for practical applications.

New magnetic orderings in elemental Neodymium

HASITHA SURIYA ARACHCHIGE (Presenter), Department of Physics & Astronomy, University of Tennessee, Knoxville, LISA DEBEER-SCHMITT, Neutron Scattering Science Division, Oak Ridge National Laboratory, DAVID PARKER, ANDREW MAY, Materials Science & Technology Division, Oak Ridge National Laboratory, MARKUS BLEUEL, Center for Neutron Research, National Institute of Standards and Technology, GANESH POKHAREL, Department of Physics & Astronomy, University of Tennessee, Knoxville, WEI TIAN, Neutron Scattering Science Division, Oak Ridge National Laboratory, CRISTIAN BATISTA, Neutron Scattering Division and Shull-Wollan Center, Oak Ridge National Laboratory, DAVID MANDRUS, Department of Materials Science & Engineering, University of Tennessee, Knoxville, ANDREW D CHRISTIANSON, Materials Science & Technology Division, Oak Ridge National Laboratory — The element neodymium is one of the most magnetically complex elements. Previous reports find a myriad of magnetic phases as a function of temperature and field below the antiferromagnetic transition temperature of 19.9 K [1-3]. Here we present a small angle neutron scattering (SANS) study of neodymium to probe whether the complex magnetic interactions on the double hexagonal closed packed (DHCP) crystal structure of neodymium can host novel spin textures. The SANS measurements reveal several new features. Firstly, the measurements establish regions in the HT phase diagram where scattering patterns characteristic of a skyrmion lattice are present. Additionally, we find new low field phase boundaries and pockets that bear some semblance to existing phase diagrams of skyrmion materials.

12:03PM X41.00005: Magnetic textures in single crystals of Ni$_{1-x}$Fe$_x$Br$_2$* BINOD RAI (Presenter), Materials Science and Technology Division, Oak Ridge National Laboratory, HASITHA SURIYA ARACHCHIGE, GANESH POKHAREL, Physics and Astronomy, The University of Tennessee, YAOHUA LIU, Neutron Scattering Division, Oak Ridge National Laboratory, SHIZENG LIN, Theoretical Division, Los Alamos National Laboratory, CRISTIAN BATISTA, Physics and Astronomy, The University of Tennessee, DAVID MANDRUS, Materials Science and Engineering, The University of Tennessee, ANDREW D CHRISTIANSON, ANDREW MAY, Materials Science and Technology Division, Oak Ridge National Laboratory — Recently, frustrated systems with finite easy axis anisotropy have been proposed as a route to realize topological spin textures. In this context, Ni$_{1-x}$Fe$_x$Br$_2$ has been predicted to host a field-induced skyrmion phase. This presentation will discuss the magnetic properties of Ni$_{1-x}$Fe$_x$Br$_2$ single crystals and the magnetic field-temperature phase diagram. NiBr$_2$ crystallizes in the centrosymmetric CdCl$_2$ structure type. It exhibits a commensurate antiferromagnetic phase below $T_N = 48$ K and an incommensurate helimagnetic phase below $T_{IC} = 22$ K, both with easy plane anisotropy. The helimagnetic structure of Ni$_{1-x}$Fe$_x$Br$_2$ is tuned as a function of composition and applied magnetic field, as demonstrated using bulk measurements and neutron scattering. A change in magnetic anisotropy from easy plane to easy axis is observed around $x = 0.07$, which is expected as a key feature to realize a skyrmion phase in this system.

12:15PM X41.00006: Imaging skyrmions in B20 epitaxial thin films grown on Si substrates using variable temperature Magnetic Force Microscopy (MFM) CAMELIA SELCU (Presenter), TAO LIU, DENIS PELEKHOV, ROLAND BENNETT, BINBIN WANG, NURIA BAGUES SALGUERO, JACOB REPICKY, JOSEPH P CORBETT, BRENDAN MCCULLIAN, Ohio State Univ - Columbus, YUNQIU (KELLY) LUO, Laboratory of Atomic and Solid State Physics (LASSP), Cornell University, SHUYU CHEN, ADAM S AHMED, P CHRIS HAMMEL, MOHIT RANDERIA, JAY A GUPTA, DAVID W. MCCOMB, ROLAND KAWAKAMI, Ohio State Univ - Columbus — In the search for the next-generation magnetic storage, tuning the size of the skyrmions with high Curie temperatures ($T_C$) promotes the possibility to use them for such application. We have successfully grown Fe-rich Fe$_{1.2}$Ge thin films using Molecular Beam Epitaxy (MBE) with a $T_C$ higher than the room temperature. Furthermore, we have observed skyrmions in the Fe-rich Fe$_{1.2}$Ge thin films at room temperature. Here, we report the first time imaging of the skyrmions in FeGe and Fe rich Fe$_{1.2}$Ge epitaxial thin films grown on Si substrates using Magnetic Force Microscopy (MFM). Based on the MFM images, skyrmions were observed in temperatures and magnetic fields consistent with the topological Hall measurements for the FeGe thin films. Additionally, the topological Hall resistance scales down with the density of skyrmions at lower temperatures in these films. Also, we observed skyrmion motion and annihilation which might be driven by the stray field of the MFM tip probably due to the defects in the FeGe films.
Skyrmions are a topologically protected magnetic texture that attracts attention both for its interesting physics, and for potential spintronics applications. Central to the realization of applications is the requirement to have small skyrmions. Recently, skyrmions have been reported to exist in two new materials, Gd$_2$PdSi$_3$ [1] and Gd$_3$Ru$_4$Al$_{12}$ [2]. The skyrmions in these materials are reportedly extremely small (2.3 – 3 nm compared to 20 – 60 nm in other materials), and, in contrast to most known skyrmion materials, are thought to be stabilized by frustration, rather than by the antisymmetric Dzyaloshinskii-Moriya interaction.

In this talk, we will present measurements of resonant X-ray scattering on Gd$_2$PdSi$_3$ and muon spin rotation on Gd$_2$PdSi$_3$ and Gd$_3$Ru$_4$Al$_{12}$. These measurements reveal interesting new features about the magnetic structures in these materials, as well as the dynamics surrounding these magnetic states.

Lattice dynamics of antiperovskite manganese nitrides exhibiting large negative and positive thermal expansion*  
SHEENA PATEL (Presenter), STJEPAN B HRKAC, JEFFREY BROCK, NELSON HUA, University of California, San Diego, HAIDAN WEN, Argonne National Laboratory, OLEG SHPYRKO, ERIC FULLERTON, University of California, San Diego — Antiperovskite manganese nitrides Mn$_3$AN (where A is a metal or semiconducting element) have strong charge-spin-lattice interactions resulting in magnetovolume effects such as large positive (PTE) and negative thermal expansion (NTE) over transitions between their ferrimagnetic, antiferromagnetic, and paramagnetic phases [1]. We grow films of Mn$_3$Cu$_{1-x}$Ge$_x$N with x = 0.1 to 0.5, which exhibit tunable NTE coefficients over a 50 K region, occurring anywhere from around 100 K to around 400 K depending on x. We also grow films of Mn$_3$Cu$_{1-x}$Ni$_x$N with x = 0.09 to 0.10, which have a first order hysteretic PTE of 1-1.5% near 100 K and exhibit NTE for a total lattice contraction of roughly 0.5% over a 25 K range around 175 K. These regions are linked to transitions in magnetic phases. To probe the coupling of the structure and magnetism, we have measured the X-ray diffraction following photoexcitation within and through the interesting regions at the Advanced Photon Source. We present the complex lattice dynamics and discuss the spin-lattice coupling driving their response.

Non-periodic magnetic structure in chiral helimagnet Mn$_{1/3}$NbS$_2$*  
SUNIL KARNA (Presenter), Department of Physics and Astronomy, Louisiana State University, Baton Rouge, MICHALIS CHARILAOU, Department of Physics, University of Louisiana at Lafayette, ANDRAS KOVÁCS, Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, LISA DEBEER-SCHMITT, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, DAVID P YOUNG, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge — We have investigated the magnetic state of Mn$_{1/3}$NbS$_2$ through $ac$-magnetic susceptibility, Small-angle Neutron Scattering (SANS), Lorentz Transmission Electron Microscopy (LTEM) and micromagnetic simulations. The $ac$ susceptibility displays temperature, field, and frequency dependencies which define a complex phase diagram below the critical temperature for magnetic ordering, $T_C = 45$ K. SANS reveals a streak of magnetic scattering along the c-axis near $Q = 0$ appearing below $T_C$, demonstrating a disordered ferromagnetic (FM) or helical spin ordering in this system. The width of this streak shortens and becomes more intense near $T_C$ and is gradually suppressed by the application of $H$ along the beam. Micromagnetic simulations of thin lamella are in agreement with LTEM images of Mn$_{1/3}$NbS$_2$ where extended FM regions result from a shape anisotropy in thin samples that are separated by the chiral domain walls.

*This material is based upon the work supported by the U.S. Department of Energy under EPSCoR Grant No. DE-SC0012432 with additional support from the Louisiana Board of Regents.
1:03PM X41.00010: Local structural distortions and magnetism in lacunar spinel compounds* JULIA ZUO (Presenter), EMILY C SCHUELLER, RAM SESHADRI, STEPHEN WILSON, University of California, Santa Barbara — Lacunar spinels $AB_4Q_8$ ($A=$Al, Ga, Ge; $B=$V, Nb, Mo, Ta; $Q=$S, Se) display a variety of novel phenomena including skyrmion lattices and pressure-induced insulator-metal transitions and superconductivity. The high temperature structure features unique tetrahedral transition-metal clusters with $S=1/2$ moments on an FCC lattice. Low temperature distortions of these clusters are crucial to the properties of lacunar spinels. In skyrmion hosts GaV$_4$S$_8$ and GaV$_4$Se$_8$, a low temperature rhombohedral distortion allows for polar and magnetic order. In GaNb$_4$Se$_8$ and GaTa$_4$Se$_8$, antiferromagnetic interactions lead to geometric frustration and a magnetic transition associated with a tetragonal distortion. We present results of local structural characterization on lacunar spinels in connection to their magnetic properties.

1:15PM X41.00011: Magnetic texture evolution within uniaxial kagome ferromagnets immediately below Curie temperature AKIRA SUGAWARA (Presenter), TETSUYA AKASHI, Center for Exploratory Research, Hitachi Ltd, MOHAMED A KASSEM, Department of Physics, Assiut University, YOSHIKAZU TABATA, TAKESHI WAKI, HIROYUKI NAKAMURA, Department of Materials Science and Engineering, Kyoto University — Magnetic textures such like skyrmion and skrmionic bubbles attracts attention in connection with topology of electronic structures. Such texture formation usually occurred slightly below Curie temperature ($T_C$) due to competition of micromagnetic parameters that change rapidly with approaching $T_C$. We examined magnetic texture within two uniaxial kagome ferromagnets: Co$_3$Sn$_2$S$_2$ ($T_C=176$ K) studied extensively as a Weyl-semimetal and Fe$_3$Sn$_2$ ($T_C= 657$ K) interested for its massive Dirac fermions. In-situ Lorentz microscopy was performed during cooling across $T_C$ under zero field. In Co$_3$Sn$_2$S$_2$, nucleation of bubble domains followed by their spontaneous reorganization occurred in narrow temperature range immediately below $T_C$, whereas the domain wall motion was mostly frozen below 160 K. The morphology of the domains also depended on cooling rate through domain wall creep associated with thermal depinning. The magnetic phase diagram is influenced by slow spin dynamics also, hence is not determined uniquely as a function of field and temperature. In contrast such creep motion did not occur in Fe$_3$Sn$_2$ immediately below $T_C$, whereas domain wall motion occurred continuously in wide temperature range down toward room temperature.
Hexagonal ferrites such as PbFe$_{12}$O$_{19}$, SrFe$_{12}$O$_{19}$, BaFe$_{12}$O$_{19}$ show interesting magnetic and ferroelectric properties at low temperatures. The magnetic ordering temperature of these compounds can be tuned by random site dilution replacing Fe ions by Ga ions, for example in PbFe$_{12-x}$Ga$_x$O$_{19}$. According to recent experiments, the critical temperature of these compounds varies as $T_c \propto (1 - x/x_c)^{2/3}$, where $x_c$ is very close to the percolation threshold of the lattice [1]. Motivated by these results, we re-examine the shape of the magnetic phase boundary over the entire $x$ range from 0 to $x_c$. We perform large scale Monte-Carlo simulation of diluted XY and Heisenberg models for both cubic lattices and lattices representing the crystal structure of the hexaferrites. In particular, we study the critical behavior of the percolation transition and width of the critical region.

References:

We report the observation of a chemical-substitution driven phase transition from a gapped quantum paramagnetic phase to one with long range order in Cs$_{1-x}$Rb$_x$FeCl$_3$. The $x = 0$ compound in this series of triangular-lattice antiferromagnets has a spin-singlet ground state due to strong easy-plane magnetic anisotropy. In contrast, the $x = 1$ material orders magnetically in a 120° structure [1]. Calorimetric and magnetic experiments performed on a series of samples with $0 \leq x \leq 1$ reveal that in the low-temperature limit magnetic order appears at $x \sim 0.35$. Inelastic neutron scattering experiments show that this coincides with the closure of the gap in the spin excitation spectrum. It appears that disorder effects in this material are more pronounced than those in the only other known phase transition of this type, namely in DTNX [2].

Intrinsic stability of magnetic anti-skyrmions in the tetragonal inverse Heusler compound Mn$_{1.4}$Pt$_{0.9}$Pd$_{0.1}$Sn

RANA SAHA, ABHAY KANT SRIVASTAVA, TIANPING MA (Presenter), JAGANNATH JENA, PETER WERNER, Nano-Systems from ions, spins and electrons, Max Planck Institute of Microstructure Physics, VIVEK KUMAR, CLAUDIA FELSER, Solid State Chemistry, Max Planck Institute for Chemical Physics of Solids, STUART PARKIN, Nano-Systems from ions, spins and electrons, Max Planck Institute of Microstructure Physics — Magnetic anti-skyrmions [1] are one of several chiral spin textures that are of great current interest both for their topological characteristics and potential spintronic applications. Anti-skyrmions were recently observed in the inverse tetragonal Heusler material Mn$_{1.4}$Pt$_{0.9}$Pd$_{0.1}$Sn. Here we show, using Lorentz transmission electron microscopy, that anti-skyrmions are found over a wide range of temperature and magnetic field in wedged lamellae formed from single crystals of Mn$_{1.4}$Pt$_{0.9}$Pd$_{0.1}$Sn for thicknesses ranging up to ~250 nm [2]. The temperature-field stability window of the anti-skyrmions varies little with thickness. Using micromagnetic simulations we show that this intrinsic stability of anti-skyrmions can be accounted for by the symmetry of the crystal lattice which is imposed on that of the Dzyaloshinskii-Moriya exchange interaction. These distinctive behaviors of anti-skyrmions makes them particularly attractive for spintronic applications.

Friday, March 6, 2020 11:15 AM - 2:15 PM

Session X42 GMAG: Structured Materials

Vacancies in artificial spin ice*

PABLO DÍAZ (Presenter), FELIPE BREVIS, EUGENIO VOGEL, Univ de La Frontera — We study artificial spin-ice systems (in the form of square arrays of islands of magnetic materials) from the numerical point of view. Typical Permalloy elongated and anisotropic islands [1] occupy the positions completely filling a layer L×L, with variable L; several equivalent layers are then piled up. We focus on the vertices (that are the convergence points of islands) as the internal layers are diluted upon introducing vacancies (lack of islands). This is both a random and controlled process for a single internal layer; the uppermost and lower-most layers remain without vacancies. The introduction of vacancies generated several new types of vertices that can be characterized according to their distribution depending of vacancy concentration. We found that a small amount of vacancies has strong influence on the vertex distributions. Moreover, we considered a code based format for the different vertices and found that is possible to write on each layer complete and robust messages. The propagation of information in a transverse way (from top to lower layer) is also explored.

11:27AM X42.00002: Field-tunable correlations in perpendicular artificial spin ice arrays
SUSAN KEMPINGER (Presenter), North Central College, YU-SHENG HUANG, PAUL EDWARD LAMMERT, Penn State University, MICHAEL VOGEL, JOHN PEARSON, Argonne National Lab, AXEL HOFFMANN, University of Illinois, VINCENT CRESPI, Penn State University, PETER E SCHIFFER, Yale University, NITIN SAMARTH, Penn State University — Artificial spin ice (ASI) provides an effective platform for the study of custom designed frustration and its relationship with geometry, interaction, and stochasticity. Perpendicular ASI is particularly useful in this context, as the state of each element in a lattice is readily accessed using Kerr microscopy and the microstate of the entire lattice can be characterized through an applied field protocol. Unfortunately, studies of perpendicular ASI have been limited by weak interactions between elements. We have overcome this limitation by fabricating perpendicular ASI systems from Pt/Co islands on a soft-magnetic Ni_{80}Fe_{20}(Py) underlayer to increase interactions. In the simplest case, the Py is saturated and serves to break the lateral symmetry in the arrays. We show that this configuration leads to a highly tunable system with unusual properties such as directionally-tunable interactions, preferred next-nearest neighbor coupling, and in situ adjustable coordination number. This project was funded by the US Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division under Grant No. DE-SC0010778

11:39AM X42.00003: Competition between topological order and long range order in Santa Fe spin ice
AYHAN DUZGUN (Presenter), CRISTIANO NISOLI, Los Alamos National Laboratory — Artificial spin ices are two-dimensional arrays of interacting single-domain ferromagnetic nano-islands [1,2]. Santa Fe Ice is a newly proposed and recently realized artificial spin ice lattice whose vertex-frustrated [3,4] spin ensemble can be described by strings of topologically protected excitations. We have investigated numerically Santa Fe Ice in and out of equilibrium. Depending on structural parameters, its ground state can either be a disordered topological phase [5,6] or an ordered, anti-ferromagnetic state. In the latter case, however, the topological phase is still present and can trap the system, delaying or preventing the relaxation to the ordered state either after quenches or even after a slow annealing when in the neighborhood of the structural transition.

11:51AM X42.00004: Shape transformations of flexible ferromagnetic ribbons

KOSTIANTYN YERSHOV (Presenter), Leibniz Institute for Solid State and Materials Research, IFW Dresden, D-01171 Dresden, Germany, VOLODYMYR P. KRAVCHUK, Karlsruhe Institute of Technology, D-76131 Karlsruhe, Germany, DENIS D. SHEKA, Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine, JEROEN VAN DEN BRINK, Leibniz Institute for Solid State and Materials Research, IFW Dresden, D-01171 Dresden, Germany, YURI GAIDIDEI, Bogolyubov Institute for Theoretical Physics of National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine — We propose a minimal extension of the anisotropic 2D Heisenberg model in order to describe flexible magnetic systems with coupled magnetic and mechanical subsystems[1,2]. The coupling between the magnetic and mechanical subsystems is driven by uniaxial anisotropy with the easy-axis normal or tangential to the magnetic film and by the Dzyaloshinskii--Moriya interaction (DMI). We show that the presence of DMI results in a spontaneous deformation of a flexible magnetic ribbon. The final state is characterized by the geometrical chirality whose sign is determined by the sign of the DMI constant. Depending on the mechanical, magnetic, and geometric parameters of the system one can obtain two different states: a twisted-state with zero curvature of the central line is typical for small DMI constants and narrow ribbons, while a DNA-like state with nonzero curvature of its central line is preferable for large DMI constants and wider ribbons. All these states can be efficiently controlled by magnetic fields opening new possibilities in the development of nanorobots in the context of organicelectronics and spintronics.

12:03PM X42.00005: A New Approach of Constructing Shape-controlled Nanowire Arrays

FEI CHEN (Presenter), RUWEN PENG, MU WANG, Nanjing Univ — Magnetic nanowires with controlled morphology and crystallinity are enabling devices with novel functionalities. The fabrication of the nanowires with specific shapes such as standing U-shaped nanowires and helical nanowires is still challenging, especially on a rough and bumpy surface. Here we demonstrate a unique way to fabricate cobalt nanowire arrays on an arbitrarily-shaped surface by electrodeposition. When the pH of the electrolyte is around 2.3, the deposit shows monocrystalline hcp structure with the c-axis perpendicular to the long-axis of the nanowire arrays. On the other hand, when the pH is around 4.5, the deposit shows polycrystalline hcp structure. Counter intuitively, here the growth direction of nanowire is perpendicular to its longitudinal axis, and the specific geometry of nanowires can be achieved by introducing specially designed shaped substrate. The spatial separation and the width of the nanowires can be tuned by voltage, electrolyte concentration and temperature in electrodeposition. By taking cobalt nanowire array as an example, we show that head-to-head and tail-to-tail magnetic domain walls can be easily introduced and modulated in the nanowire arrays, which is enlightening to construct new devices such as domain wall racetrack memory.
We experimentally observe both U- and S-shaped zero-field magnetic configurations in single square permalloy dots, with a dot's configurational state dependent on field history and temperature. Magnetization of 170 nm x 170 nm x 7 nm dots is probed using 4-terminal anisotropic magnetoresistance (AMR) measurements. Room temperature field sweeps parallel to the dot edge yield AMR curves characteristic of both a U-shaped state [1], and of a previously unreported S-shape, for identical field sweep parameters. The S-shape sweep pattern is not observed at low T, implying the state is thermally activated, a result confirmed by micromagnetic simulations. The S-state also occurs when sweeping the field off-axis by several degrees, consistent with minimizing Zeeman interaction energy. The existence of multiple zero-field configurations precludes use of the Stoner-Wolfarth model typically used at this scale, instead necessitating a more complicated configurational picture as dot size decreases.

This work supported in part by NSF Grant No. DMR 1609782. Portions of this work conducted in the Minnesota Nano Center, which is supported by the NSF through the National Nano Coordinated Infrastructure Network, Award Number NNCI -1542202.
In-tissue embedded magnetic nanoparticle (MNPs) detection is one of the most interesting cases for biomedical applications. Biological (especially tumor) tissues present a variety of morphologies. Ferrogels (FG) are magnetic composites that are widely used in the area of biomedical engineering and biosensing. We propose to substitute biological samples and use synthetic ferrogel to mimic main properties of the living systems at the stage of the development of magnetic biosensor prototypes. Natural tissue requires tight protocol of storage/testing but synthetic hydrogels are less demanding to test conditions. In order to make FG widely available there is a need in the development of synthesis techniques with enhanced size of a batch. Electrophysical techniques of electric explosion of the wire or laser target evaporation (LTE) are suitable for this objective. We have developed magnetic biosensor prototype for the detection of mesoscopic distributions of magnetic nanoparticles using magnetoimpedance phenomenon. Prototypes with FeNi/Ti or FeNi/Cu multilayered elements were designed and the stray fields of embedded LTE MNPs were measured. A model for MI response based on a solution of Maxwell equations was developed. We discuss the possibility of creation of a new generation of drug delivery systems for magnetic field assisted delivery, positioning and biosensing.

**1:03PM X42.00008: Tunability of magnetism in Heusler Mn$_3$Ga: Crossover between cubic and tetragonal phase upon Co-substitution**

THI QUYNH ANH NGUYEN (Presenter), HUYNH THI HO, SOON CHEOL HONG, SONNY H. RHIM, Univ of Ulsan — Structural and magnetic properties of Co substituted Mn$_{3-x}$Co$_x$Ga ($x = 0$-$1$) is investigated using *ab initio* calculations. Ferrimagnetic Mn$_3$Ga possesses two inequivalent Mn sites, octahedral Mn-I and tetrahedral Mn-II, where Co prefers Mn-II site, which leads to intriguing physics. Notably, structural transition, from tetragonal to cubic phase, occurs around $x=0.6$. Unlike other Co compounds, local moment of Co nearly vanishes in tetragonal phase, which results in decreasing total moment with Co concentration. In contrast, in cubic phase Co retains usual moment: Magnetic moment increases linearly with $x$ obeying Slater-Pauling rule of cubic Heusler, $M = N_V - 24$, where $M$ is the magnetization, $N_V$ is numbers of valance electrons. In particular, the integral $M$, a signature of half-metallicity, emerges in cubic phase for $x=0.5$ and $1.0$. Furthermore, the vanishing moment of Co for tetragonal phase is analyzed phenomenologically using Heisenberg model, where the exchange coefficients of two Mn sites tends to compensate.

**1:15PM X42.00009: Deconvoluting Magnetic contributions in BiFeO$_3$ NPs using First Order Reversal Curves**

ALEXANDER CARDONA RODRÍGUEZ (Presenter), EDWIN ER RAMOS, NICOLÁS VERGARA, DIEGO CARRANZA, ANDREAS REIBER, JUAN RAMÍREZ, University of the Andes — BiFeO$_3$ (BFO) in bulk is ferroelectric (FE) and antiferromagnetic (AF) at room temperature. Additional it also possesses a Dzyaloshinski-Moria (DM) anisotropy that produces a 62 nm wavelength spin spiral. Therefore, in nanostructured BFO systems, a complex ferromagnetism-like behavior appears that depends on the balance between size and magnetic length scales. Furthermore, it is known that the physical properties in perovskites in general, and BFO in particular, are very sensitive to changes in their crystal structure. Hence, one can exploit such effects to control their degrees of freedom. Here we present first-order reversal curves (FORC) as a reliable method to deconvolute the BFO magnetic contributions that appear when nanostructured in the form of nanoparticles with sizes below and above the wavelength spin spiral. We use FORC to obtain coercivity distributions for different nanoparticles sizes. Our results suggest two main contributions to BFO magnetism that can be related to an intrinsic core-shell structure that forms due to strain relaxation.

Magnetorheological elastomers (MREs) are polymers with embedded micron or submicron ferromagnets. MREs are a promising platform for studying cell responses to dynamic mechanical changes in their environment, as the shear modulus is tunable via an applied magnetic field [1]. MREs deform under applied magnetic fields, including visible twisting. In this work, we used a multi-scale approach to model the magnetic reversal and field-dependent deformations. Ferromagnetic particles in the polymer interact via dipolar coupling, but are also permitted to move; the balance of dipole, elastic energies, and Zeeman energy dictates the deformations of MREs. A point-dipole based model was used to study the behavior of a collection of particles in an elastomer matrix, and micromagnetic simulation results for a ferromagnetic sphere provided the susceptibilities used as input parameters. Volume-preserving in- and out-of-plane deformations were incorporated in the model, as well as, twisting of the matrix as observed in experiments. Modelling results will be presented and compared to experimental hysteresis measurements.

Ferromagnetic Liquid Droplets

Ferrofluids are dispersions of ferromagnetic or superparamagnetic nanoparticles in carrier fluids and are paramagnetic liquids that become magnetized in the presence of an external magnetic field but completely lose the magnetization at remanence when the field is removed. We have found a route to reversibly transform these paramagnetic droplets into ferromagnetic droplets by the formation, assembly and jamming of a magnetic nanoparticle-surfactants at the interface of the droplet with a surrounding immiscible fluid that encapsulates the magnetic nanoparticle dispersion. These liquid droplets have a coercivity and remanent magnetization at room temperature. They couple features of liquids, including versatile and reversible control of shape, and translational and rotational degrees of freedom, but preserve a magnetic moment, enabling remote manipulation by an external magnetic field. The droplets were shaped into cylinders, made buoyant in the surrounding liquid, and, in response to a rotating permanent magnet, rotated at an increasing angular velocity that reached a size-dependent maximum velocity. Assemblies of multiple liquid magnets form switchable, dynamic self-organized patterns, similar to those of Mayer's floating magnets. The ability to shape and manipulate the ferromagnetic liquid droplets opens possibilities for magnetically actuated sensors, all-liquid magnetic storage medium and magnetically driven 3D-printed robotic systems. These findings represent a new concept where soft matter, nanotechnology and magnetism meet, establishing a platform for a new generation of all-liquid devices. In collaboration with N. Kent, A. Ceballos, R. Streubel, Y. Jiang, Y. Chai, J. Forth, S. Shi, D. Wang, B. A. Helms, P. D. Ashby, P. Fischer and T. P. Russell.

Session X43 DCOMP DMP: Computational design and discovery of novel materials VII: Machine learning and high throughput computing

702 - Feng Zhang, Ames Lab
11:15AM X43.00001: Density Functional Theory Calculations on Surface Oxygen Vacancy Formation in Metal Oxides  
YOYO HINUMA (Presenter), Chiba Univ, TAKASHI TOYAO, Hokkaido University, TAKASHI KAMACHI, Fukuoka Institute of Technology, ZEN MAENO, SATORU TAKAKUSAGI, SHINYA FURUKAWA, Hokkaido University, ICHIGAKU TAKIGAWA, RIKEN, KEN-ICHI SHIMIZU, Hokkaido University — Properties of materials may be significantly changed from intrinsic ones by making small physical and chemical changes in the form of defects. As a result, various point and extended defects are intentionally introduced to govern their chemical reactivity, catalytic, electrical, optical, and mechanical properties. One mechanism important in catalysis is the Mars-Van Krevelen mechanism that is frequently encountered. An example is where O vacancy sites on a metal oxide catalyst surface acts as the reaction site.

Accurate calculation of the surface vacancy formation energy based on first principles calculations require calculation of a surface model and is much more computationally expensive than a bulk calculation. Catalysts typically require a certain physical quantity to be within a certain range, hence rapid judgement of whether a candidate material is viable or not based on quantities (descriptors) that are easy to calculate can significantly accelerate the screening process. We report on correlations between descriptors that can be calculated at low cost and the O vacancy formation energy of various insulating binary oxide materials [Hinuma et al., J. Phys. Chem. C 2018, 122, 29435] as well as spinel oxides containing zinc.

11:27AM X43.00002: Genarris 2.0: A Random Structure Generator for Molecular Crystals  
RITHWIK TOM (Presenter), TIM C ROSE, IMANUEL BIER, HARRIET O’BRIEN, Carnegie Mellon University, ALVARO VAZQUEZ-MAYAGOITIA, Argonne National Lab, NOA MAROM, Carnegie Mellon University — Genarris 2.0 is an open-source Python code, parallilized with mpi4py, that performs configuration space screening of molecular crystals by random structure generation. It may be used for generating initial populations to seed other structure search algorithms (such as genetic algorithms) or for generating datasets to train machine learning models. The target unit cell volume is estimated from the single molecule structure by a machine-learned model trained on data from the Cambridge Structural Database (CSD). Crystal structures are then generated in all space groups compatible with the requested number of molecules per cell (Z) with one molecule in the asymmetric unit (Z’=1), including those with special Wyckoff positions. To avoid unphysically close intermolecular distances, structures undergo a cascade of three increasingly rigorous checks. Special settings are applied for strong hydrogen bonds, which are automatically detected. Once an initial dataset of several thousand structures is generated, a smaller dataset may be selected based on quality and diversity criteria via user-defined workflows. For clustering Genarris uses the affinity propagation machine learning algorithm with a relative coordinate descriptor (RCD) or a radial symmetry function (RSF) representation.
Exploring the quantum chemical space of small molecules: QM7-X database

JOHANNES HOJA, LEONARDO MEDRANO SANDONAS, Physics and Materials Science Research Unit, University of Luxembourg, BRIAN ERNST, Department of Chemistry and Chemical Biology, Cornell University, ALVARO VAZQUEZ-MAYAGOITIA (Presenter), Argonne Leadership Computing Facility, Argonne National Laboratory, ROBERT DISTASIO, Department of Chemistry and Chemical Biology, Cornell University, ALEXANDRE TKATCHENKO, Physics and Materials Science Research Unit, University of Luxembourg — Robust and extensive databases of molecular properties are required to enable rational exploration of chemical space. Most databases created so far either include only equilibrium structures of molecules or do not use sufficiently high level of quantum mechanics. Here, we introduce the QM7-X database created with the goal of sampling the vast chemical space for small organic molecules. As basis for QM7-X, we used all molecules within the GDB7 database. All possible enantiomers and diastereomers were also added. Then, to have a sufficient sampling of the potential energy surface, we have considered 100 non-equilibrium conformations around every conformer of a molecule, producing a database of approximately 4.2 million structures in total. Several physicochemical properties were subsequently computed by performing quantum mechanics calculations using FHI-AIMS code at the PBE0-MBD level of theory. As a first attempt for predicting molecular properties, we have applied neural networks in the form of the SchNet package. We also demonstrate that the exploration of the QM7-X chemical space breaks traditional textbook notions of chemical correlations and enables building robust and transferable machine learning models for molecular property prediction.

Matching Crystal Structures Atom-to-Atom: Applications to Phase Transitions and Interface Structures*

FELIX THERRIEN (Presenter), Colorado School of Mines, PETER GRAF, National Renewable Energy Laboratory, VLADAN STEVANOVIC, Colorado School of Mines — Finding an optimal match between two different crystal structures underpins many important materials science problems including describing solid-solid phase transitions, developing models for interface and grain boundary structures, finding suitable substrates and their orientation, etc. We designed and implemented an algorithm that tackles this problem by finding the atom-to-atom map and alignment that minimizes a chosen distance function. We demonstrate its capacity to describe transformation pathways of several solid-solid transformations. In particular we show its ability to seamlessly predict important experimentally observed characteristics of the martensitic transformation of steel. Next, we study several interfaces and show our method's relevance in predicting interfacial planes and their orientation relationships. Finally, from our findings, we define a rigorous metric for measuring distances between crystal structures and use it as a tool to screen the Inorganic Crystal Structure Database.

12:03PM X43.00005: Predicting h-BCN Geometric Structures Using Clustering and Regression Methods* 
SONALI JOSHI (Presenter), DAVE AUSTIN, DUY LE, TALAT S. RAHMAN, Univ of Central Florida — Despite the fact that hexagonal graphene-like boron–carbon–nitrogen (h-BCN) monolayer, a synthesized material that has received a great deal of attention thanks to its intriguing properties and its potential application, there is no consensus on its geometric structure. We report here results of our machine learning approach that utilizes clustering and neural networks to find the lowest energy structure of h-BCN. Our dataset consists of 300 randomly generated h-BCN structures, optimized using density functional theory based calculations. To characterize the atomic environment of the atoms, a pattern recognition scheme based on neighbors was developed. We found that our model accurately predicts the total energy of h-BCN structure with a R-squared score as high as 0.85, depending on the number of k-means clusters used. We will also discuss the improvement of our predictions using a deep neural network.

*Work supported in part by DOE grant DE-FG02-07ER15842

12:15PM X43.00006: Towards a Crystalline Organic Superconductor Database* 
OWEN GANTER (Presenter), CHARLES C AGOSTA, Clark University — A database of layered organic crystalline materials containing structural information, experimentally determined properties, and electronic band structure is proposed. Layered organic crystals have a rich electronic phase diagram and exhibit numerous electronic ground states including traditional and unconventional superconductivity, charge and spin density waves, Dirac points, and spin liquid states. The proposed database will be a versatile tool for scientists studying quantum materials and will pave the way towards new discoveries and materials via machine learning methods. We will present a computer algorithm for analyzing the crystal structure of layered organic crystals and storing the extracted structure parameters in the database. The algorithm analyzes molecular conformation, dimerization, packing types, and intermolecular interactions of cations that form the conductive layer of these materials. We will discuss the challenges of inputting experimentally determined material properties from scientific articles into the database, and the best methods to do it. We will also show a Python based system for automatically initializing, executing, and analyzing WIEN2k DFT calculations for materials in the database.

*We acknowledge the support Grant# DMR-1905950 from the NSF
12:27PM X43.00007: Accelerated enumeration of derivative structures using zero-suppressed binary decision diagram  KOHEI SHINOHARA (Presenter), ATSUTO SEKO, Kyoto Univ, TAKASHI HORIZIYAMA, Hokkaido Univ, MASAKAZU ISHIHATA, NTT Communication Science Laboratories, JUNYA HONDA, The Univ of Tokyo, ISAO TANAKA, Kyoto Univ — The enumeration of “derivative structures” [1], which are unique substitutional atomic configurations derived from a given parent lattice, plays an essential role in searching for the ground states in multi-component systems. The possible size of supercells to enumerate the derivative structures, however, is limited because the number of the derivative structures increases exponentially as the number of sites in a substitutional lattice increases. In the present study, we apply a compressed data structure of the zero-suppressed binary decision diagram (ZDD) [2] to enumerate the derivative structures much more efficiently. We also employ an efficient procedure [3] to build the ZDD representing the derivative structures without listing all substitutional structures. The present study shows simple applications of the procedure to enumerate the derivative structures for the face-centered cubic and hexagonal close-packed parent lattices in binary, ternary, and quaternary systems. The present procedure with the ZDD should significantly contribute to computational approaches based on the derivative structures.

12:39PM X43.00008: Multifidelity Learning and Statistical Analysis of Material Properties*
ABHIJITH GOPAKUMAR (Presenter), MOHAN LIU, Northwestern University, RAMAMURTHY RAMPRASAD, Georgia Institute of Technology, CHRISTOPHER MARK WOLVERTON, Northwestern University — There are many examples of materials data where the coexistence of two types of datasets occur: a smaller, higher-fidelity (higher accuracy) dataset, and a larger, lower-fidelity dataset. Here, we investigate a statistical modeling approach for materials properties in these cases of varying fidelity. Kriging based multi-fidelity learning is an approach suited to these cases, and we demonstrate its usefulness by applying it to model and predict the chemical properties of compounds in the Open Quantum Materials Database (OQMD). Specifically, we focus datasets of DFT-calculated bandgaps, and consider a case of high-fidelity data from computationally expensive hybrid HSE calculations and low-fidelity PBE GGA calculations. The multifidelity model is trained on a database containing 1100 HSE bandgaps and combined with results from the OQMD which contains a much larger set of PBE bandgaps. We demonstrate the utility of this multifidelity approach in predicting HSE bandgaps for all materials in OQMD, analyze the predicted results for various material classes, and compare the multifidelity approach with multiple single-fidelity machine learning models trained on the same dataset.

*Toyota Research Institute (TRI) Accelerated Materials Design and Discovery program
12:51PM X43.00009: Symbolic Regression in Materials Science* YIQUN WANG (Presenter), JAMES RONDINELLI, Northwestern University — One of the fundamental research objectives of materials science is to design new materials with optimal performance. Typical machine learning models could be powerful predictors but not ideal in terms of interpretability. Here we present on an alternative to machine-learning models: symbolic regression (SR), which simultaneously searches for the optimal form of a function and set of parameters to the given problem, and is a powerful regression technique when little if any a-priori knowledge of the data distribution is available. We present how SR can learn the Landau free energy expansion describing the structural phase transition in LaNiO$_3$ using existing computational data [1]. Our model is able to capture the coupling of the temperature and order parameter, and we successfully predicted the structural phase transition at high temperature. We encourage materials scientists to utilize SR to open challenges in materials research, which could potentially unearth hidden governing laws in materials science from a data-driven approach.

1:03PM X43.00010: DFT-45B---a fertile soil (data) for your seeds (machine learning algorithms)* CHANDRAMOULI NYSHADHAM (Presenter), CHRISTOPH KREISBECK, Kebotix, Inc., Cambridge, MA 02139, USA., GUS HART, Brigham Young Univ - Provo — Machine-learning (ML) models have become the new paradigm in computational materials science for predicting properties of materials with the accuracy of quantum mechanics at a fraction of the cost. Accurate data (fertile soil) is crucial and helps us to build better ML models (healthier plants) using any ML algorithms (seeds). The inconsistencies in the materials data extracted from existing material repositories---less than a few hundred calculations for each alloy system, varied sizes of prototypes, and varying k-point density for different cell sizes---make it challenging to develop effective ML models. We created a DFT-based materials dataset (DFT-45B) consisting of 45 binary alloys (all binary combinations of 10 different elements---Ag, Al, Co, Cu, Fe, Mg, Nb, Ni, Ti, and V) with over 71775 calculations free of such inconsistencies. Each alloy system includes all possible enumerated crystal structures until 8 atoms for fcc, bcc and hcp crystal types. As the data encompasses the space of 10 elements and all their binary combinations, it is helpful to understand the similarity between various elements and alloys. In this talk, we present the methodology and heuristics of the dataset.

1:15PM X43.00011: Bayesian Machine Learning in Metamaterial Design: Fragile Becomes Supercompressible  
MIGUEL BESSA (Presenter), PIOTR GLOWACKI, MICHAEL HOULDER, Delft University of Technology — Designing future-proof materials goes beyond a quest for the best. The next generation of materials needs to be adaptive, multipurpose, and tunable. This is not possible by following the traditional experimentally guided trial-and-error process, as this limits the search for untapped regions of the solution space. Here, a computational data-driven approach is followed for exploring a new metamaterial concept and adapting it to different target properties, choice of base materials, length scales, and manufacturing processes. Guided by Bayesian machine learning, two designs are fabricated at different length scales that transform brittle polymers into lightweight, recoverable, and supercompressible metamaterials. The macroscale design is tuned for maximum compressibility, achieving strains beyond 94% and recoverable strengths around 0.1 kPa, while the microscale design reaches recoverable strengths beyond 100 kPa and strains around 80%. The data-driven code is available to facilitate future design and analysis of metamaterials and structures (https://github.com/mabessa/F3DAS).

1:27PM X43.00012: A roadmap for machine learning in alloy modeling*  
GUS HART (Presenter), Brigham Young Univ - Provo, TIM MUELLER, John Hopkins University, CORMAC TOHER, STEFANO CURTAROLO, Duke University — Years before the data science craze, ideas of modern machine learning played an essential role in alloy modeling. Genetic algorithms (for both searching materials space and model construction), statistical learning methods based on Bayesian ideas, dimensionality reduction approaches (cluster expansion, compressive sensing, interatomic potentials, etc.) have contributed to a rich heritage of innovation in the field. Recent developments in data science, and the affordability of generating unprecedented volumes of high-quality training data, open up further avenues. New materials informatics approaches, machine-learned interatomic potentials (GAP, SNAP, MTP, genetic programs, atomic cluster expansion, and others), new thermodynamic approaches such as nested sampling, etc., provide unrivaled opportunities in computational alloy modeling and discovery. We highlight past successes and spotlight promising new approaches.

*Office of Naval Research (MURI N00014-13-1-0635)
Leveraging machine learning to determine nanoscale structures from theory and experiments* VENKATA SURYA CHAITANYA KOLLURU, SPENCER HILLS, ERIC SCHWENKER, NOBUYA WATANABE, FATIH G SEN, ARUN KUMAR MANNODI KANAKKITHODI, MICHAEL STERNBERG, MARIA CHAN (Presenter), Argonne Natl Lab — Determining the atomistic details of nanoscale structures is a fundamental problem. Although there are both experimental and computational methods to determine these nanoscale structures, they both possess limitations. We develop the FANTASTX code (Fully Automated Nanoscale To Atomistic Structure from Theory and eXperiment) to overcome the limitations of either by combining both experimental and computational data using machine learning techniques. We demonstrate the effectiveness of FANTASTX by determining the structures of nanoparticles and solid interfaces from x-ray and electron microscopy data combined with atomistic and first principles energies, using multi-objective optimization and a variety of canonical and grand canonical sampling algorithms.

*We acknowledge funding from the USDOE: Center for Electrochemical Energy Science EFRC, Argonne National Laboratory LDRD program, and the Center for Nanoscale Materials under Contract No. DE-AC02-06CH11357; computational resources of the National Energy Research Scientific Computing Center under Contract No. DE-AC02-05CH11231.

Machine learning for novel and improved inorganic scintillators ANJANA TALAPATRA (Presenter), CHRISTOPHER STANEK, BLAS PEDRO UBERUAGA, GHANSHYAM PILANIA, Los Alamos National Laboratory — Scintillators are detector materials with a wide range of applications, from medical imaging to radiation detection. These materials convert a fraction of the energy deposited by high energy radiation into visible or ultraviolet photons. An ideal scintillator may have high light output, fast response time, and emission at suitable wavelengths. However, no single scintillator is ideal for all uses; there is a need to design custom scintillators optimized for each application. Currently, the discovery and design of new scintillators relies on a laborious, time-intensive approach, yielding little physical insight and leaving a vast space of potentially revolutionary materials unexplored. To accelerate the discovery of optimal scintillator materials, we are developing a closed loop machine learning driven adaptive design framework based on literature data, experiments and calculations. This talk presents an overview of this framework, focusing on the screening of complex chemistries with high band-gaps to identify promising materials amenable to band-gap/band-edge engineering to yield custom scintillation properties. The framework is general and is expected to prove useful for applications beyond scintillator discovery such as photovoltaic and semi-conductor materials.
2:03PM X43.00015: Exploring Information Density in Crystalline and Amorphous Configurations using Deep Neural Networks  SHYAM DWARAKNATH (Presenter), Lawrence Berkeley National Laboratory, WISSAM A SAIDI, Mechanical Engineering & Materials Science, University of Pittsburgh — Predicting the properties of amorphous systems is one of the grand challenges for computational material science. Deep neural network potentials (DNP) promise to recreate the chemical fidelity of DFT while scaling to much larger systems, enabling more realistic simulations of amorphous materials. DNPs also provide a tool to analyze large quantities of DFT data by selective training and evaluation. We trained a DNP on the crystalline polymorphs for SiO2 from the Materials Project. This DNP successively predicted the total energies of several DFT computed quasi-amorphous configurations suggesting that the local atomic environments encoded in amorphous compounds are also present in the potential energy space covered by polymorphism. More importantly, a DNP trained on just the amorphous configurations was able to predict the energies of polymorphs, including the ground state configuration over 100 meV/atom below the lowest included amorphous configuration. This suggests that DNPs trained on quasi-amorphous configurations may be an effective means of identifying ground state configurations as well as polymorphism in never before explored systems.

Friday, March 6, 2020 11:15 AM - 1:51 PM

Session X45 GMAG: Magnetic Anisotropy: Hard and Soft Materials 706 - Scooter Johnson, U.S. Naval Research Laboratory - Tag(s): Focus
11:15AM X45.00001: First-principles calculations on the surfaces and interfaces of SmFe$_{12}$*
TOMOHARU SHIOZAWA (Presenter), YUTA AINAI, Department of Materials Science and Engineering, Tokyo Institute of Technology, YASUTOMI TATETSU, University Center for Liberal Arts Education, Meio University, YOSHIHIRO GOHDA, Department of Materials Science and Engineering, Tokyo Institute of Technology — Nd-Fe-B sintered magnets are currently used in a wide range in industry. However, it is seriously problematic that the coercivity of Nd-Fe-B sintered magnets significantly decreases at high temperatures. In contrast, a new magnetic compound SmFe$_{12}$ has a higher magnetic anisotropy than Nd$_2$Fe$_{14}$B which is the main phase of Nd-Fe-B sintered magnets. Therefore, SmFe$_{12}$-based magnets can be expected as a preferable alternative of existent magnets. The performance of magnets is strongly influenced by microstructural interfaces. However, there are few studies about interfaces including SmFe$_{12}$.

We performed first-principles calculations on the surfaces and interfaces of Nd$_2$Fe$_{14}$B and SmFe$_{12}$, and analyzed the structural stability and magnetic properties. The surface energies of SmFe$_{12}$ and Nd$_2$Fe$_{14}$B are examined to find the most stable surfaces. Then, the interface of SmFe$_{12}$ with a subphase is constructed using the most stable surface structures. For stable interface structures, the magnetic properties are examined, where the magnetic moment of Fe is enhanced around the interface of SmFe$_{12}$/SmCu. We will also present the results on the magnetic anisotropy and the magnetic coupling at SmFe$_{12}$-based interfaces.

*This work was partially supported by ESICMM funded by MEXT (Grant No. 12016013).

11:27AM X45.00002: Additive manufacturing of PPS bonded NdFeB magnets to design a Halbach array for polarized neutron reflectivity experiments*
TEJ LAMICHHANE (Presenter), Oak Ridge National Lab — Additive manufacturing (AM) is a layer by layer material printing technology which is found to be very useful in permanent magnet (PM) manufacturing. In bonded PM, the mechanical strength and the loading volume fraction of magnetic materials can be increased by mechanical extrusion of optimally magnetic particle loaded polymer composites. AM process reduces the price of magnet production by reducing the waste of magnetic materials via net-shaped printing and avoiding the cost of expensive complex molding tools needed for small scale industrial production. AM printed isotropic polyphenylene sulfide (PPS) bonded Nd-Fe-B magnets were used to design a cylindrical Halbach array for polarized neutron reflectivity measurements. We will discuss in detail about the challenges associated in developing the prototype Halbach ring magnet and validate the concept of variable magnetic contrast in neutron measurements.

*This research was supported by the Laboratory Directed Research and Development (LDRD) program of Oak Ridge National Laboratory and Critical Materials Institute, an Energy Innovation Hub funded by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Advanced Manufacturing Office.
11:39AM X45.00003: First-principles Study on Crystalline Nd-Fe alloys as Candidate Structures for Grain-Boundaries in Nd-Fe-B Sintered Magnets*  
YUTA AINAI (Presenter), Department of Materials Science and Engineering, Tokyo Institute of Technology, YASUTOMI TATETSU, University Center for Liberal Arts Education, Meio University, ASAKO TERASAWA, YOSHIHIRO GOHDA, Department of Materials Science and Engineering, Tokyo Institute of Technology — Due to technological progress in industry, the coercivity enhancement of Nd-Fe-B sintered magnets at high temperatures is highly demanded. It has been identified that the grain-boundaries (GBs) are known as Nd-Fe alloys with fcc diffraction patterns. However, the detailed atomic arrangement on the atomic scale is still unclear. Therefore, in this study, we investigated Nd-rich alloys with Fe as a candidate structures for GBs. 
First, we performed first-principles calculations for cuprite, fluorite, half-Heusler, and sphalerite Nd-Fe alloys in a wide range of the Fe composition ratio in order to determine the most stable fcc Nd-Fe alloy. We found that only the fluorite Nd-Fe alloy keeps the high crystallinity in a range of around 65 to 100 at.%. In contrast, cuprite, half-Heusler, and sphalerite alloys become amorphous-like structures after optimizing structures. 
Second, we added metallic elements such as Al, Co, Cu, and Ga into the fluorite Nd-Fe alloys and optimized the structures in order to check the stability. Only the formation energies of the fluorite Nd-Fe-Ga alloys show the negative values. These results indicate that Ga promotes the stabilization of Nd-Fe alloys more than any other metallic elements.

*This work was support in part by MEXT as the ESICMM (Grant No. 12016013).

11:51AM X45.00004: Low-Dimensional Hard Magnetic Materials [Invited]  
J LIU (Presenter), University of Texas at Arlington — Ferromagnetism is a size-dependent physical phenomenon. Although the size dependence has been studied in theory for decades, nanoscale ferromagnetic materials especially hard magnetic nanostructures and materials with controllable size and shape are not available till recently. We have worked at bottom-up approaches to preparation of low-dimensional hard magnetic materials including nanoparticles and nanowires/nanorods. By adopting newly developed “salt-matrix annealing”, “surfactant-assisted milling” and improved chemical solution techniques, we have successfully synthesized monodisperse hard magnetic FePt and SmCo nanoparticles as well as FeCo, CoNi, CoCx and Co based nanowires/nanorods. These first-ever-available nanoscale ferromagnets display various hard and soft magnetic properties at room temperature which are found to be strongly size and shape dependent. A systematic study on size dependent Curie temperature of the L1₀ structured FePt ferromagnetic nanoparticles with size from 2 to 15 nanometers reveals the finite size effect in the tiny ferromagnets. In case of the Co nanowires with controlled diameter and length, coercivity up to the theoretical limit has been achieved that renewed our understanding of the Brown’s Paradox. The ferromagnetic nanocrystals can be used as building blocks for advanced bulk and thin film magnets, and can be also applied in biomedicine and ferrofluid technologies.
12:27PM X45.00005: High-throughput search for rare-earth free permanent magnets*
ALENA VISHINA (Presenter), OLGA VEKILOVA, HEIKE HERPER, OLLE ERIKSSON, Uppsala Univ — High performance permanent magnets are needed for a large number of applications, such as electric motors, wind mills. At the same time most high performance magnets contain rare-earth (RE) materials which makes them expensive.
We propose to apply a high-throughput approach to the search of RE free permanent magnets. Going through a large number of known structures from ICSD [1], and using a full-potential LMTO method with relativistic formulation as implemented in the RSPt code [2] to calculate magnetic anisotropy and Tc, we are looking for the materials with magnetization >1 T, uniaxial anisotropy >1 MJ/m³, and Tc>300 K to identify the suitable replacement for rare-earth containing materials. Starting with the materials containing 3d+5d+1 extra elements of the periodic table to test the method, we have found several candidates that have characteristics suitable for a good permanent magnet, such as Pt₂FeCu, Pt₂FeNi, W₂FeB₂, etc. Based on the search result we have also proposed two new materials, not existing in ICSD - Pt₂FeCo and Pt₂CoNi [3].

*We acknowledge financial support of the SSF and SNIC for the computation resources.

12:39PM X45.00006: Development of magnetic hardness in melt-spun Mn₅₀Bi₅₀₋ₓMₓ alloys (M = Mg, In, Sn, Sb, Bi) subjected to magnetic-field annealing* ALEXANDER GABAY, GEORGE C HADJIPANAYIS (Presenter), Univ of Delaware — The theoretical maximum energy product (BH)ₘ of the MnBi compound, 20 MGOe, perfectly fits the "gap" between the inexpensive hard ferrites and the supply-critical rare-earth magnets. Decades of R&D efforts focused on consolidation of fine MnBi single crystals could only produce MnBi magnets exhibiting (BH)ₘ of 5–8 MGOe. A different approach relying on a melt-spinning, followed by compaction and magnetic-field annealing avoids the highly reactive single crystals, but it does not develop coercivity Hₐ in the binary MnBi alloys. Here, we report how alloying with M = Mg, In, Sn and Sb affects the phases, the texture and the hard magnetic properties of field-annealed magnets prepared from the melt-spun Mn₅₀Bi₅₀₋ₓMₓ alloys. Sn delays the formation of the MnBi phase while further decreases the already low Hₐ. 1.5 at.% In decreases the solidus temperature and slightly increases the Hₐ. In melt-spun alloys modified with 1.5 at.% Sb, a transient metastable phase ensures a submicron size of MnBi grains and leads to a Hₐ > 7 kOe, but suppression of the texture limits the (BH)ₘ to 5.4 MGOe. Alloing with Mg increases the Hₐ without undermining the texture; a breakthrough (BH)ₘ of 9.8 MGOe was realized in the Mn₅₀Bi₄₇Mg₃ magnet.

*Work supported by DOE through DE-FG02-90ER45413 and EE0007794.
Tuning of spin reorientation temperature of SmFeO$_3$: Role of exchange interaction between 4f & 3d electrons

AZAM KHAN ( Presenter), ANJU AHLAWAT, SRINIBAS SATAPATHY, AK KARNAL, Raja Ramanna Centre for Advanced Technology — Emergent technologies based on spintronics demand the unprecedented control on magnetic anisotropy. Here we present the control on magnetic anisotropy of SmFeO$_3$ by the means of Tm$^{3+}$ doping at Sm$^{3+}$ site.

A series of nano particles of Sm$_{1-x}$Tm$_x$FeO$_3$ (X=0, 0.3, 0.5, 0.7, 1) orthoferrite have been synthesized by sol-gel auto-combustion method and phase purity was confirmed by the X-ray diffraction pattern. The crystallographic information obtained from Rietveld refinement and Raman spectroscopy confirmed the changes in oxygen octahedra with the change in doping percentage of Tm$^{3+}$ ion in SmFeO$_3$. Temperature dependent dc magnetization measurement implies the tuning of spin reorientation temperature from 480 K to 80 K as a function of Tm$^{3+}$ ion doping concentration. The room temperature magnetic isotherm confirms the canted antiferromagnetic character of nano particles. Sm$_{0.7}$Tm$_{0.3}$FeO$_3$ shows the spin reorientation at room temperature which might be used in room temperature spintronics devices.

Self-biased nanocrystalline barium hexaferrite thick films formed by aerosol deposition for microwave devices

Scooter Johnson (Presenter), United States Naval Research Laboratory, Dong-Soo Park, Korean Institute of Material Science, Sanghoon Shin, Syed B Qadri, United States Naval Research Laboratory, Pavel Kabos, Kevin Coakley, National Institute of Standards and Technology, Edward P Gorzkowski, United States Naval Research Laboratory — High-frequency devices utilizing magnetic materials such as barium hexaferrite (BaFe$_{12}$O$_{19}$, BaM) are critical for many electronics. One promising route to forming these materials is aerosol deposition (AD), a process that creates thick 95% dense films by room-temperature impact consolidation*. AD utilizes high-velocity impact to fracture and mechanically and chemically bonds solid particles together.

We use AD to deposit BaM in a non-magnetically biased (NMB) and in a 4 kOe bias field (MB). We report results of these films as-deposited and sintered from 700C to 1000C.

The best films were deposited under MB and annealed at 1000C and show a clear OOP orientation (23 % improvement compared to NMB). Properties include, magnetic saturation: 62 emu/g (72 emu/g bulk) and remanence: 43 emu/g. FMR results give an anisotropy field of 15 kOe (16 kOe bulk), linewidth of 1.8 kOe, and damping factor of 4x10$^{-4}$. Films deposited under NMB show comparably poorer values. XRD results suggest good crystallinity and phase uniformity overall. Sintering increases the crystallite size from about 10 nm to 25 nm.

The overall results suggest that depositing the films with AD under MB significantly increases the magnetic orientation of the film.

Investigation of fabrication method of $L1_0$-FeCo multilayer film

HISAAKI ITO (Presenter), TAKUYA MIYASHITA, TAKUYA KUMAGAI, Sci Univ of Tokyo, TOSHIO MIYAMACHI, FUMIO KOMORI, The Univ of Tokyo, TOMOYUKI KOGANEZAWA, TAKUO OHKOCHI, JASRI, MASATO KOTSUGI, Sci Univ of Tokyo — The $L1_0$-type FeCo ordered phase exhibits large magnetic anisotropy, large magnetic moment, and high Curie temperature. Since $L1_0$-FeCo does not contain rare-earth elements, it is a potential candidate as a high-performance magnetic material [1]. On the other hand, the $L1_0$-FeCo system is at a non-equilibrium state, and its fabrication has been a challenge so far [2]. To overcome the problem, we inserted periodic buffer layers between the FeCo layers to maintain the $L1_0$ (fcc) structure [3]. For establishing the fabrication method of $L1_0$-FeCo, we here investigated the growth temperature ($T_s$) dependence of (7 ML-FeCo/3 ML-Ni buffer)$_3$ films fabricated by pulsed laser deposition.

The formation of the stable B2 (bcc) structure was suppressed at $T_s = 450°C$ or lower. Although the formation of the fcc structure was confirmed, the $L1_0$-ordering was not recognized. Unfortunately, the spontaneous easy axis of magnetization in all the specimens was still the in-plane direction. However, the in-plane magnetization decreased at $T_s = 300$ and 450°C, and the magnetocrystalline anisotropy showed the maximum value for $T_s = 300°C$.

Influence of W thickness on Perpendicular Magneto-crystalline Anisotropy of Pt/Co/W(111) Superlattices

HUYNH THI HO (Presenter), SANGHOON KIM, SONNY H. RHIM, SOON CHEOL HONG, Univ of Ulsan — Tri-layer superlattice with reflection asymmetry in the spirit of Rashba effect has been explored in spintronics. Pt/Co/W (111) superlattice is investigated by employing first-principles calculations to clarify experimental results, where perpendicular magnetocrystalline anisotropy (PMA) depends on W thickness. Moreover, the enhancement of PMA with respect to Pt/Co due to non-magnetic W is examined. Our calculation results show that the thickness dependence of PMA is evident, whose maximum occurs when W is three monolayers, where the orbital hybridization at interfaces with W is responsible for PMA. Surprisingly, W contributes to PMA with appreciable orbital magnetic anisotropy, which follows the so-called Bruno relation, $E_{PMA} \sim m_{orb}^+ - m_{orb}^-$. To clarify the physics origin, PMA is analyzed in the framework of second-order perturbation theory, where $\langle m=-2 | L_z | m=+2 \rangle$ dominates. In addition, $k$-resolved PMA demonstrates that contribution is from the $\Gamma$ with $d$ orbitals of $m = \pm 2$, where $m$ is the magnetic quantum number.

1:39PM X45.00011: An efficient model for modelling Barkhausen noise in PMA thin films
AUDUN SKAUGEN (Presenter), LASSE LAURSON, Computational Physics Laboratory, Tampere University
and Helsinki Institute of Physics — The motion of domain walls in thin films with perpendicular
magnetic anisotropy (PMA) is of great interest due to their technological applications in spintronic devices, as well as the critical phenomenon of Barkhausen noise due to the domain wall pinning to quenched disorder. However, current numerical studies of domain walls, using micromagnetic discretized solvers on the entire system, are limited to small system sizes by the expensive computation of the far-field forces between every pair of spins. As a result, the statistical signature of Barkhausen noise has strong finite size effects in such studies.

We present an efficient, principled numerical model which reduces the description of the PMA thin film to a single one-dimensional domain wall, by integrating over the coordinate perpendicular to the domain wall. The full nonlocal demagnetizing field is included in the computation, but formulated as an integral over the remaining dimension along the wall. This allows for numerical studies of Barkhausen noise in large systems, while still including physical effects such as Walker breakdown and nonlocal interactions.

Session X46 GMAG DMP: 3D Frustrated Magnets: Other Geometries 708 -
Jeremy Carlo, Villanova Univ - Tag(s): Focus
11:15AM X46.00001: Frustrated Magnetism in Mott Insulating V$_2$O$_3$ [Invited] HARALD JESCHKE
(Presenter), Okayama University — The phase diagram of V$_2$O$_3$ as function of transition metal
doping and temperature is famous for showing transitions between metallic and insulating and
between paramagnetic and antiferromagnetic phases. In particular, the Mott metal-insulator
transition which is induced by a few percent of chromium doping has been studied intensively.
Using a combination of density functional theory calculations and inelastic neutron scattering
experiments, we study the magnetic interactions in the chromium-stabilized antiferromagnetic
and paramagnetic insulating phases as function of temperature [1]. The calculations based on an
energy mapping technique [2] are performed for low temperature monoclinic and high
temperature rhombohedral structures. Both calculations and INS cross sections reveal significant
magnetic frustration and degeneracy of the paramagnetic insulating phase which is relieved by
the rhombohedral-to-monoclinic transition at $T_N$=185 K. Magnetic frustration can be shown to be
present in rhombohedral (V$_{1-x}$Cr$_x$)$_2$O$_3$ for a large range of dopings. This suggests that magnetic
frustration plays an important role in suppressing the magnetic long-range-ordering temperature
and thereby exposing a large phase space for the paramagnetic Mott metal-insulator transition.

11:51AM X46.00002: Magnetic Field Induced Phase Transition in Spinel GeNi$_2$O$_4$*
TATHAMAY BASU (Presenter), TAO ZOU, Z DUN, Michigan State Univ, CLARINA RELOJ DELA CRUZ,
TAO HONG, HUIBO CAO, Oak Ridge National Laboratory, MENGZE ZHU, Michigan State Univ,
HAIDONG ZHOU, University of Tennessee, XIANGLIN KE, Michigan State Univ — Cubic spinel GeNi$_2$O$_4$
exhibits intriguing magnetic properties with two successive antiferromagnetic phase transitions
(~12 and 11 K) in the absence of structural distortion. By means of heat capacity and magnetic
susceptibility measurements, we have revealed a new magnetic phase in presence of magnetic
field field ($\geq$ 4 T) along the [111] direction, which is not observed when the magnetic field is
applied along the [100] and [110] directions. Neutron powder diffraction measurements confirm
such a field-induced phase transition and suggest it be ascribed to a spin reorientation in
presence of magnetic field. We will discuss the potential mechanisms regarding such a peculiar
magnetic anisotropy in this cubic system.

Sciences, Materials Sciences and Engineering Division, under Award No. DE-SC0019259.
12:03PM X46.00003: Characterization of the crystal field scheme of a new family of geometrically frustrated rare earth spinels.* DALMAU REIG-I-PLESSIS (Presenter), GREG MACDOUGALL, University of Illinois, ADAM ACZEL, Oak Ridge National Lab, ALEXANDRA COTE, SEAN VAN GELDERN, University of Illinois — The pyrochlore lattice is known for having a large variety of exotic, frustration-driven phases, the specifics of which are determined by the symmetry of the local moments and their interactions. Here we present on a new family of compounds MgRE$_2$Se$_4$ (RE = Ho, Tm, Er, and Yb), which form in the spinel structure, were the rare earth atoms are a pyrochlore sublattice. In this presentation we will show inelastic neutron scattering measurements of the crystal electric field (CEF) excitations. We fit this neutron data to find the most likely CEF Hamiltonian for each compound in the family and comment on the possible consequences of the result. We show that MgTm$_2$Se$_4$ has a spin singlet ground ground state with a low lying signlet excited state, similar to an Ising moment in a transverse field. MgHo$_2$Se$_4$ has an Ising ground state with several additional thermally accessible levels. MgEr$_2$Se$_4$ is shown to have Ising moments and is a spin ice compound. MgYb$_2$Se$_4$ is shown to be an effective spin 1/2 system with strong spin anisotropy.

*I acknowledge support from National Science Foundation, under grant number DMR-1455264-CAR, as well as from U.S. D.O.E., Office of Science, Office of Workforce Development for Teachers and Scientists, Office of Science Graduate Student Research (SCGSR) program.

12:15PM X46.00004: Update on the Magnetic and Structural Properties of the Solid Solutions CuAl$_{2(1-x)}$Ga$_{2x}$O$_4$* THOMAS BULLARD (Presenter), MICHAEL SUSNER, UES, Inc., KEITH TADDEI, Oak Ridge National Lab, JACILYNN BRANT, Nature Communications, TIMOTHY HAUGAN, RQQM, Air Force Research Lab — Magnetic frustration continues to be an area of interest due to its association with the emergence of novel magnetic ground states such as spin glasses. Two systems that have been identified as spin glasses are the spin ½ antiferromagnetic spinels CuAl$_2$O$_4$ and CuGa$_2$O$_4$. In this research we examine the solid solution between these two end members, CuAl$_{2(1-x)}$Ga$_{2x}$O$_4$. The solution displays magnetic glassy properties such as bifurcation in the FC - ZFC DC susceptibility, a frequency dependence of the freezing temperature, memory effects, and slow relaxation. Whether the system is better classified as a cluster glass or insulator spin glass will be discussed. Further, we observe an increase in the magnetic frustration as Ga$^{3+}$ is replaced with Al$^{3+}$. We have examined the atomic occupancy of the even members of the solid solution via neutron and synchrotron diffraction. As Ga$^{3+}$ is replaced with Al$^{3+}$ we find an increase in frustration as the magnetic Cu$^{2+}$ ion shifts from the octahedral to the tetrahedral sublattice.

Mean field theory for cooperative magnetism in non-Kramers garnets

BRUNO TOMASELLO (Presenter), Institut Laue - Langevin, RAFAŁ WAWRZYNIAK, Max Planck Institute for Chemical Physics of Solids, GÖRAN NILSEN, ISIS neutron source, STFC, TOM FENNELL, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institut, TIM ZIMAN, Institut Laue - Langevin — Kramers’ theorem entails a fundamental symmetry valid only for odd-electron systems, i.e. any eigenstate and its time-reversed counterpart belong to the same spectrum. Notwithstanding, the magnetic states of non-Kramers ions, which have even number of electrons, can be constrained because of time-reversal symmetry. Indeed, if the low-lying singlets of a crystal of such ions are well gapped from the eigenstates at higher energies, then the magnetic moments at low-temperatures can only be axially anisotropic and only magnetostriction can account for low energy fluctuations. Rare-earth garnets are a suitable playground for studying the competition of magnetic frustration, magneto-elasticity, induced magnetic ordering, and the role of nuclear moments. This talk presents our current theoretical understanding of the non-Kramers garnet Tb$_3$Ga$_5$O$_{12}$, benefitting from state of the art neutron scattering experiments for the crystal-field and magnetic structure – PRB, 100, 094442(2019). The discussion highlights the mean-field theory proposed in the 70s by Hammann & Manneville for the induced magnetic ordering found in both Tb$_3$Ga$_5$O$_{12}$ and Ho$_3$Ga$_5$O$_{12}$. We contrast our study to the work of Paddison et al. on the magnetic ordering and excitations of the non-Kramers Ho$_3$Ga$_5$O$_{12}$ – arXiv:1908.03530(2019).

Absence of long-range magnetic ordering in the S=1/2 frustrated system Ca$_3$Cu$_2$GeV$_2$O$_{12}$

CHRISTOPHER WIEBE (Presenter), Univ of Edinburgh, JOEY A. LUSSIER, Dept. of Chemistry, University Of Winnipeg, BROOKE RICHTIK, COLE D MAUWS, Dept. of Chemistry, University of Manitoba, JEFFREY LYNN, NIST — Quantum spin liquids can be found in materials with a combination of geometric frustration along with low spin. Due to its spin of S=1/2, the copper (II) ion is often present in the discussion of new spin liquid candidates. The solid state compound Ca$_3$Cu$_2$GeV$_2$O$_{12}$ is a material that crystallizes in the garnet structure (space group #230, Ia-3d), where 3-dimensional frustration from competing exchange interactions is known to occur. Heat capacity measurements have shown a lack of sharp ordering transitions in this compound down to 0.35 K, which is confirmed with a lack of long-range magnetic order via neutron diffraction measurements to 0.07 K. This system displays a Weiss temperature of -0.93(1) K indicating net antiferromagnetic interactions and significant $J_1$-$J_2$ competition causing frustration. Using both neutron and X-ray diffraction along with heat capacity and magnetometry, the work presented here shows that Ca$_3$Cu$_2$GeV$_2$O$_{12}$ has potential as a new spin liquid candidate.

*We are grateful for funding of this project through NSERC (Discovery Grant and Canada Research Chair program), the CFI, and the Leverhulme Trust.
Magnetic order and single-ion anisotropy in Tb$_3$Ga$_5$O$_{12}$ rare-earth garnet. RAFAL WAWRZYNCZAK (Presenter), BRUNO TOMASELLO, Institut Laue-Langevin, PASCAL MANUEL, DMITRY KHALYAVIN, DUC LE, TATIANA GUIDI, ISIS Facility, Rutherford Appleton Laboratory-STFC, ANTONIO CERVELLINO, Paul Scherrer Institut, TIM ZIMAN, MARTIN BOEHM, Institut Laue-Langevin, GÖRAN NILSEN, ISIS Facility, Rutherford Appleton Laboratory-STFC, TOM FENNELL, Paul Scherrer Institut — Terbium gallium garnet (TGG), Tb$_3$Ga$_5$O$_{12}$ exhibits complex low-temperature magnetism, that involves frustration, single-ion anisotropy and induced-moment type ordering. Tb$^{3+}$ magnetic ions form two interpenetrating half-garnet lattices – three-dimensional arrangements of corner-sharing triangles. The low-symmetry local environment of Tb$^{3+}$ sites provides a complete lifting of the degeneracy within the lowest crystal electric field (CEF) manifold. The resulting ground-state observed with inelastic neutron scattering is a quasidoublet comprised of two closely-lying singlets. The spectroscopic data allowed for refinement of the CEF Hamiltonian parameters and retrieval of its eigenstates. Despite the singlet ground-state TGG orders magnetically at $T_N=0.25$ K, much lower than $|\theta_{CW}|=8$ K given by the bulk susceptibility. Neutron powder diffraction has shown the ordered structure to be of a multiaxial antiferromagnet type with strong single ion anisotropy. The results of powder magnetization measurements are in good agreement with values based on the CEF model down to 20 K, where the onset of magnetic correlations is seen. Also, a strong temperature-dependence of the quasidoublet ground-state is found. These observations suggest existence of a correlated paramagnet regime of unknown nature.

Field dependence of magnetic order in frustrated diamond-like antiferromagnet LiYbO$_2$* MITCHELL BORDELON (Presenter), LORENZO J POSTHUMA, University of California, Santa Barbara, ERIC M KENNEY, Physics, Boston College, NICHOLAS BUTCH, CRAIG BROWN, NIST Center for Neutron Research, ARNAB BANERJEE, Neutron Scattering Division, Oak Ridge National Laboratory, MICHAEL JOHN GRAF, Physics, Boston College, STEPHEN WILSON, University of California, Santa Barbara — Frustrated magnetism is a hotbed for searching for new electronic phases of matter. This can theoretically lead to states such as the spiral spin liquid where coplanar degenerate spiral states contain coherently fluctuating spins. One proposed venue for this state has been in the cubic diamond lattice arising from frustration in a J$_1$-J$_2$ Hamiltonian. Here we propose a new materials system where spiral spin liquids may potentially be observed based upon a tetragonally-elongated diamond lattice. This is exemplified by effective J = 1/2 moments within LiYbO$_2$ via a combination of low-energy inelastic neutron scattering, crystalline electric field analysis, and linear spin wave theory. Magnetic order and its evolution under magnetic field will be discussed.

A breathing pyrochlore lattice has alternating tetrahedra of different sizes, in which there exist different interactions. The competition of these interactions could lead to some interesting phenomena, for example, magnetic frustration and magnetoelastic coupling [1]. The breathing pyrochlore material LiGaCr$_4$S$_8$ has been measured to have a negative thermal expansion from 10 K to 110 K [1]. We performed THz transmission spectroscopy measurements in this temperature range on a polycrystal sample. An absorption at around 0.3 THz was found, which is possibly an excitation of the Cr$^{3+}$ ion. We also observed a strong absorption above 0.6 THz likely due to lattice vibrations.

*This research is supported by the Center for Emergent Materials, an NSF MRSEC under award number DMR-1420451. GP, DM, ADC are supported by the Gordon and Betty Moore Foundation's EPIQS Initiative and U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.
1:27PM X46.00010: Single Crystal Growth and Magnetic-Thermal Characterization of a Rare-Earth Based Breathing Pyrochlore Family  

RABINDRANATH BAG (Presenter), LALIT YADAV, ZHENZHONG SHI, SACHITH DISSANAYAKE, Department of Physics, Duke University, Durham, North Carolina, USA, DAVID E GRAF, EUN SANG CHOI, Department of Physics, National High Magnetic Field Laboratory, Florida State University, Florida, USA, FRANZ LANG, Department of Physics, University of Oxford, Oxford, UK, CATALINA SALAZAR MEJIA, ELIZABETH GREEN, Department of Physics, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, STEPHEN BLUNDELL, Department of Physics, University of Oxford, Oxford, UK, SARA HARAVIFARD, Department of Physics and Department of Mechanical Engineering & Materials Science, Duke University, North Carolina, USA — The Breathing Pyrochlore (BP) lattice, which consists of three dimensionally corner sharing tetrahedra with alternating sizes, has recently attracted much attention due to presence of frustrated or competing interactions. BP system has also been proposed to host of many intriguing phenomena such as Quantum Spin Liquid, Quantum Spin Ice and Weyl magnons, due to anisotropic spin-spin interactions [1-3]. Large and high quality single crystals of BP compounds are highly needed, in order to advance these hypotheses experimentally. We have successfully grown single crystals of a rare-earth BP family, using the uniquely modified travelling solvent floating zone techniques. Additionally, we have performed specific heat, thermal conductivity, AC/DC magnetic susceptibility, magnetization, magneto-dielectric, μSR and X-ray diffraction measurements to probe the physical properties of these new compounds. In this talk I will present the results of our single crystal growth and characterization efforts.

Breathing pyrochlore systems are composed of corner-sharing tetrahedra of different sizes pointing in opposing directions, leading to different intra- and inter-tetrahedra exchange interactions and the emergence of the Dzyaloshinskii-Moriya interaction due to loss of inversion symmetry. They are predicted to host exotic physics including quantum spin ice, quantum spin liquid, and field-tunable Weyl magnons. In this talk we will present single-crystal field-dependent unpolarized and polarized inelastic neutron scattering measurements on Yb-based breathing pyrochlore system, as well as a theoretical model that can effectively describe some of our experimental findings.

1:51PM X46.00012: Neutron Scattering Studies of Rare-Earth Based Breathing Pyrochlore System.

LALIT YADAV (Presenter), RABINDRANATH BAG, SACHITH DISSANAYAKE, ZHENZHONG SHI, Department of Physics, Duke University, GUANGYONG XU, HUI WU, CRAIG BROWN, NICHOLAS BUTCH, Center of Neutron Research, National Institute of Standards and Technology, FRANZ LANG, STEPHEN BLUNDELL, Department of Physics, University of Oxford, SARA HARAVIFARD, Department of Physics and Department of Mechanical Engineering & Materials Science, Duke University

Breathing Pyrochlore materials have emerged as a promising candidate to study frustrated magnetism and topological phenomena, such as Weyl and Dirac magnons. We have initiated design and synthesize of rare-earth based Breathing Pyrochlore compounds. Further, we have been using neutron diffraction and inelastic scattering techniques to probe the static and dynamic properties of these compounds. In this talk, we are going to present our latest experimental results.

Session X47 GMAG DMP DCOMP: Multiferroics and Magnetoelectricity in Complex Oxides

Natalia Perkins, University of Minnesota - Tag(s): Focus
THz spectroscopy of BiFeO$_3$ in the magnetic-field-induced canted AFM state. * JOHAN VIIROK (Presenter), LAUR PEEDU, URMAS NAGEL, TOOMAS ROOM, National Institute of Chemical Physics and Biophysics, DÁVID SZALLER, Institute of Solid State Physics, Vienna University of Technology, Austria, VILMOS KOCSIS, SANDOR BORDACS, Department of Physics, Budapest University of Technology and Economics, Hungary, ISTVAN KEZSMARKI, Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, HANS ENGELKAMP, DIMA KAMENSKY, High Field Magnet Laboratory, Radboud University, The Netherlands, KOMALAVALLI THIRUNAVUKKARASU, MYKHAYLO OZEROV, DMITRY SMIRNOV, JUREK KRZYSTEK, National High Magnetic Field Laboratory, Tallahassee, FL, YUKIHIRO OZAKI, TOSHIMITSU ITO, YASUHIDE TOMIOKA, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, TRINANJAN DATTA, Department of Chemistry and Physics, Augusta University, Augusta, GA, RANDY FISHMAN, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN — BiFeO$_3$ is a well-known room temperature multiferroic material where the cycloidal magnetic order induces electric polarization in addition to existing polarization. The cycloidal order is transformed by strong magnetic fields into a canted antiferromagnetic (AFM) order above B=18T and the cycloidal modes are replaced by excitations of the canted AFM structure [U. Nagel et al., Phys. Rev. Lett., 110:257201, (2013)].

Here we present the THz spectroscopy results for three different magnetic field orientation, parallel to hexagonal c axis, perpendicular and parallel to a axis, measured on the single FE domain crystals grown by the laser-diode heating floating-zone method [T. Ito et al., Cryst. Growth Des. 11 (2011) 5139]. The dependence of mode frequencies as a function of magnetic field were studied up to 35T at liquid He temperatures. In light of these experimental results, a microscopic model is proposed for the canted AF phase.

*Part of the research was supported by the by the Estonian Ministry of Education and Research Grant IUT23-3 and by the European Regional Development Fund project TK134.
11:27AM X47.00002: Magnetoelectric spectroscopy of spin excitations in LiCoPO$_4$*  
TOOMAS ROOM (Presenter), JOHAN VIROK, LAUR PEEDU, URMAS NAGEL, National Institute of Chemical Physics and Biophysics, Estonia, SANDOR BORDACS, Department of Physics, Budapest University of Technology and Economics and MTA-BME, Hungary, ISTVAN KEZSMARKI, Experimental Physics 5, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, Germany, VILMOS KOCSIS, YUSUKE TOKUNAGA, YASUJIRO TAGUCHI, YOSHINORI TOKURA, Center for Emergent Matter Science (CEMS), RIKEN, Japan — In this work [V. Kocsis et al., PRB 100, 155124 (2019)] we study optical magnetoelectric (ME) effect using optical directional anisotropy as measured by the THz absorption spectroscopy of spin resonances in LiCoPO$_4$. The antiferromagnetic domains are selected by ME poling and their population is measured by directional anisotropy [V. Kocsis et al., PRL 121, 057601 (2018)]. Here we demonstrate that the directional anisotropy can also be used to investigate the form and the spectral dependence of the ME susceptibility tensor and hence to identify different spin-multipolar orders responsible for the ME effect. From the spectrum of the directional anisotropy one can determine the static ME coupling via the ME susceptibility sum rule. We conclude, for the poling magnetic field direction along the local electric polarization, the observed ME spin resonances are responsible for the static ME effect and the symmetric part of the ME tensor with zero diagonal elements dominates over the antisymmetric components.

*Part of the work was supported by The Estonian Ministry of Education and Research under Grant No. IUT23-03, and the European Regional Development Fund project TK134.

11:39AM X47.00003: Model for the Spin Dynamics of the Multiferroic (NH$_4$)$_2$FeCl$_5$ (H$_2$O)*
RANDY FISHMAN (Presenter), WEI TIAN, JAIME FERNANDEZ-BACA, Oak Ridge National Lab, JANICE L MUSFELDT, University of Tennessee, JUN HEE LEE, MINSEONG LEE, Ulsan National Institute of Science and Technology, JOHN SINGLETON, National High Magnetic Field Lab, Los Alamos — The multiferroic behavior of any material sensitively depends on the microscopic interactions between the spins. We evaluate the magnetic interactions in the multiferroic erythrodsiderite (NH$_4$)$_2$FeCl$_5$ (H$_2$O) by comparing inelastic neutron scattering spectra of a single crystal sample with a simple Heisenberg model containing five exchange interactions and an easy-plane anisotropy. The cycloidal spin state in every bc plane is produced by two competing exchange interactions. Using the observed wavevector of this cycloidal spin state is used as a constraint, excellent agreement is found between the observed and predicted spectra. The resulting exchange and anisotropy parameters are compared with the predictions of first-principle calculations.

OMAR CHMAISSEM (Presenter), KAMAL CHAPAGAIN, Physics, Northern Illinois University, BIANCA HABERL, Neutron Scattering Division, Oak Ridge National Lab, JEFFREY LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, SAUL LAPI DUS, X-ray Science Division, Advanced Photon Source, Argonne National Lab, CURTIS KENNEY-BENSON, HPCAT, X-ray Science Division, Advanced Photon Source, Argonne National Lab, BOGDAN M DABROWSKI, Institute of Physics, Polish Academy of Sciences, STEPHAN ROSENKRANZ, Materials Science Division, Argonne National Lab — Multiferroic oxides have recently emerged as key materials with the potential to tackle the exploding demand for systems that enable efficient energy usage and enhance the functionality of spintronic devices. In this talk, I will discuss the recent development of single-site manganese-based multiferroic perovskite materials, Sr$_{1-x}$Ba$_x$Mn$_{1-y}$Ti$_y$O$_3$, with ferroelectric transition temperatures boosted to ~430 K. Using a series of temperature-dependent scattering experiments at various pressures, we demonstrate the tunable character of coupling between the magnetic and ferroelectric order parameters and show that ferroelectricity could be easily manipulated through the application of either external or chemical pressures. Measurements of the magnetic and structural properties under pressure allowed the construction of a detailed P-T phase diagram in which the diverse phases are delineated. Impressive spontaneous polarization values of ~30 $\mu$C/cm$^2$, in agreement with Ti-free Sr$_{1-x}$Ba$_x$MnO$_3$, are calculated using an empirical c/a-based equation or derived from a point charge model with bond-lengths and angles determined by neutron diffraction.

*Work at MSD at ANL (scattering and analysis) was supported by the U.S. DOE, Office of Science, Materials Sciences and Engineering Division.*
12:03PM X47.00005: Insights into the coupled phenomena in molecular multiferroic (ND$_4$)$_2$[FeCl$_5$(D$_2$O)] via inelastic neutron scattering studies*  WEI TIAN (Presenter), RANDY FISHMAN, HUIBO CAO, GABRIELE SALA, DANIEL M. PAJEROWSKI, TAO HONG, LUKE L. DAEMEN, YONGQIANG CHENG, JAIME A. FERNANDEZ-BACA, Oak Ridge National Lab — (ND$_4$)$_2$[FeCl$_5$(D$_2$O)] is a rare molecular magnet exhibiting direct coupling between magnetism and electric polarization as well as a very rich magnetic field versus temperature phase diagram[1-3]. In order to gain a deep understanding of the emergent coupled phenomena, we performed inelastic neutron scattering experiments to investigate the dynamics in this material. Our data analysis shows the spin dynamics can be described by a Heisenberg Hamiltonian model with an easy-plane anisotropy that captures the key observations. Our inelastic neutron scattering results also reveal the role the ion played in the intriguing properties observed in (NH$_4$)$_2$[FeCl$_5$(H$_2$O)].

12:15PM X47.00006: Magnetization reversal by electric field in Co substituted bismuth ferrite thin film  MASAKI AZUMA (Presenter), Tokyo Institute of Technology and Kanagawa Institute of Industrial Science and Technology, KEISUKE SHIMIZU, Tokyo Institute of Technology, KEI SHIGEMATSU, Tokyo Institute of Technology and Kanagawa Institute of Industrial Science and Technology, HAJIME HOJO, Kyushu University — Electric field manipulation of magnetization is intensively investigated because of potential application in low-power-consumption non-volatile magnetic memory devises. Ferroelectric BiFeO$_3$ has a cycloidal space-modulated spin structure with a periodicity of 62 nm superimposed on the G-type antiferromagnetic structure. The presence of cycloidal ordering prohibits the appearance of net ferromagnetic magnetization due to spin canting and a linear magnetoelectric effect. We have observed a spin structure transition from low-temperature cycloidal one to high-temperature collinear one at ~200 K using Mössbauer spectroscopy in rhombohedral BiFe$_{0.1}$Co$_{0.9}$O$_3$ thin films fabricated by PLD on SrTiO$_3$ (STO) (111) substrate. Spontaneous magnetization of 0.03 u$_B$/f.u. confined in a magnetic easy plane perpendicular to the electric polarization is generated by Dzyaloshinskii-Moriya interaction. Films fabricated on GdScO$_3$ (110) substrate has out-of-plane component of magnetization which can be observed by MFM. It is demonstrated that the out-of-plane magnetization can be reversed by electric polarization reversal using PFM at room temperature.
12:27PM X47.00007: Spin-liquid-like state in ferroelectric TbInO$_3$ with a nearly triangular lattice* [Invited] VALERY KIRYUKHIN (Presenter), Rutgers University — Quantum spin liquids (QSL) have been continuously attracting attention since Anderson’s seminal work in 1970’s. As most visionary ideas, QSLs have been found to be relevant to many diverse branches of physics, ranging from superconductivity to quantum computing applications. Known QSL candidate compounds are typically based on geometrically frustrated magnetic lattices, such as the kagome and triangular (TL) lattices. After decades of activity, their properties are still enigmatic, and the number of strong QSL candidates is limited. We describe a recently-discovered QSL candidate TbInO$_3$, containing nearly-triangular layers of non-Kramers Tb$^{3+}$ ions. No signs of static magnetic order are found down to the temperatures two orders of magnitude smaller than the effective interaction energy, by a variety of complementary techniques. Inelastic neutron scattering studies reveal a broad continuum of magnetic excitations located at the TL Brillouin zone boundary that can be described in the framework of the uncorrelated nearest-neighbor valence bonds model. TbInO$_3$ is also ferroelectric, containing atomically-sharp domain boundaries that could host exotic states. These observations make TbInO$_3$ a rather unique QSL candidate, in which fluctuating quantum magnetic state is combined with ferroelectricity.

1:03PM X47.00008: An annealing study of CaMn$_2$O$_4$-d, a possible multiferroic candidate* MELISSA GOOCH (Presenter), Texas Center for Superconductivity, Univ of Houston, HUNG-CHENG WU, Physics, National Sun Yat-sen University, LIANGZI DENG, Texas Center for Superconductivity, Univ of Houston, HUNG-DUEN YANG, Physics, National Sun Yat-sen University, PAUL C. W. CHU, Texas Center for Superconductivity, Univ of Houston — Manganese oxides have experienced a considerable increase in research interest due to their rich and complex phase diagrams. Ca-Mn-O is an excellent example, whose rich phase diagram contains phases that have been theoretically predicted to be multiferroic and CaMn$_2$O$_4$ to date is still not well understood and a hopeful candidate. Polycrystalline samples were synthesized and annealed with two different growth environments to further investigate the effect of oxygen deficiencies. Therefore, argon as well as oxygen gas flows were utilized. From initial dc magnetization and $C_p$ measurements, the previously report $T_N$ ~ 220 K was observed for both samples. However, a spontaneous polarization ($P_S$) was observed at ~ 253 K for the oxygen annealed sample with no applied field while no $P_S$ was observed up to 7 T and temperatures down to 2 K for the argon annealed sample. Anomalies above 260 K were detected in both samples, which were not only time-, but also field-dependent. Measurements are ongoing to gain greater insight into this complex system.

1:15PM X47.00009: Pressure effect on multiferroics investigation with neutron scattering*
YAN WU, WEI TIAN, HUIBO CAO (Presenter), Oak Ridge National Lab — Multiferroics have attracted tremendous research interests with their rich physics and potential in constructing next-generation multifunctional devices. The type-II multiferroics have magnetic phase related ferroelectricity. In a system where the magnetic phase is closely correlated with crystal lattice, compressing the unit cell with high pressure would lead to distinct magnetic phase transitions and then tune the ferroelectricity. We studied systems mainly with neutron scattering techniques in identifying their magnetic phase transitions under pressures to provide understanding for change of the ferroelectric properties in the system.

1:27PM X47.00010: Magnetostructural domain wall patterning in ferrimagnetic spinels*
LAZAR KISH (Presenter), University of Illinois at Urbana-Champaign, ADAM ACZEL, LISA DEBEER-SCHMITT, ALEXANDER N. THALER, Oak Ridge National Laboratory, DALMAU REIG-I-PLESSIS, University of British Columbia, ALEXANDER ZAKRZEWSKI, GREG MACDOUGALL, University of Illinois at Urbana-Champaign —
The ferrimagnetic spinels Mn3O4 and MnV2O4 are known for their anomalous magnetoresponsive behavior, including strong magnetoelastic and magnetodielectric couplings. Mechanically strained samples of these materials show a real-space separation of the volume into stripe-like regions of alternating magnetization on the nanometer lengthscale. I will show small angle neutron scattering data associating these features with known first order magnetic transitions in these materials, and their control via applied magnetic field. I will then draw a direct connection to bulk magnetic measurements, and demonstrate how these domains can lead to anomalous magnetization behaviors.

*Research was supported by National Science Foundation under NSF DMR 1455264

1:39PM X47.00011: Large and highly anisotropic magnetocaloric effects in disordered-perovskite RCr0.5Fe0.5O3 single crystals (R = Gd, Er) HYUNJUN SHIN (Presenter), JONGHYUK KIM, DONGGUN OH, YOUNG JAI CHOI, NARA LEE, Yonsei University — We have successfully synthesized the disordered-perovskite RCr0.5Fe0.5O3 (R=Gd, Er) single crystals which crystallize in an orthorhombic Pbmn structure, and investigated anisotropic magnetic and magnetocaloric properties. In GdCr0.5Fe0.5O3, the isotropic nature of large Gd3+ moments leads to a tremendously large entropy change of ~50 J/kg K for both ab and c axes. On the other hand, ErCr0.5Fe0.5O3 exhibits a highly anisotropic magnetocaloric effect which results in a rotational entropy variation of ~21 J/kg K at the ordering temperature of Er3+ moments, TEr = 6 K. Our findings suggest the important roles of magnetic anisotropy of rare-earth magnetic ions and enrich fundamental and applied research on magnetic materials in view of distinct magnetic characteristics in disordered perovskites.
An ab initio Study of Oxygen Vacancies in Ba$_2$CuO$_4$ and Sr$_2$CuO$_4$

MATTHEW MATZELLE (Presenter), CHRISTOPHER LANE, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University — Oxygen vacancies play a key role in providing a fertile environment for superconductivity to emerge in the Ba$_2$CuO$_4$ and Sr$_2$CuO$_4$ family of novel superconductors. However, there is considerable debate as to whether or not the vacancies reside in the CuO$_2$ plane or at the apical sites. Using state-of-the-art ab initio techniques, we systematically examine the energy landscape and electronic structure of oxygen vacancies in Ba$_2$CuO$_4$ and Sr$_2$CuO$_4$. A number of different configurations involving single and multiple vacancies are considered. Planar vacancies are found to yield lower energies, and materials with apical vacancies display exotic band structures. Finally, we will briefly connect our results to recent experiments.

THz spectroscopy of spin excitations in magnetoelectric LiCoPO$_4$ in high magnetic fields

Laur Peedu (Presenter), Toomas Room, Johan Viirok, Urmas Nagel, National Institute of Chemical Physics and Biophysics, Sandor Bordacs, Budapest University of Technology and Economics, Vilmos Kocsis, Yusuke Tokunaga, Yasujiro Taguchi, Yoshinori Tokura, Riken, Hans Engelkamp, Uli Zeitler, High Field Magnet Laboratory, Radboud University, Istvan Kezsmarki, University of Augsburg — LiCoPO$_4$ belongs to the family of magnetoelectric lithium-orthophosphates. In these compounds the cross-coupling between magnetization and electric polarization leads to variety of spin excitations that have entangled dynamic electric and magnetic properties. In this work THz spectroscopy was used to measure absorption spectra of spin excitations in LiCoPO$_4$ single crystal below antiferromagnetic ordering temperature and in magnetic field up to 32 T. Three spin flop transitions for the magnetic field parallel to the magnetic easy axis were identified from the magnetic field dependence of spin excitations and from the magnetic field dependence of magnetization. Using polarized light and ME poling to create a single ME domain [V. Kocsis et al. PRL121, 057601 (2018), PRB100, 155124 (2019)], the selection rules of spin excitations were determined. Several magnetic-, electric-dipole active and magnetoelectric resonances were found.

Disorder Effects on Superconducting Island Arrays Proximity-Coupled to Graphene*  
RITA GARRIDO MENACHO (Presenter), VINCENT HUMBERT, NADYA MASON,  
University of Illinois at Urbana-Champaign — Two-dimensional superconductors have been extensively studied due to the presence of quantum phase transitions (QPT) in these systems at millikelvin temperatures. One of the most investigated QPT is the Superconductor-(Metal)-Insulator Transition (SMIT). However, in the presence of disorder, the nature of transport across the SMIT is not well understood, largely because disorder is difficult to controllably tune in 2D superconducting films. To overcome this difficulty, we have developed arrays of superconducting Sn islands proximity-coupled to graphene with controllable island point disorder and graphene disorder. We studied the SMIT in these devices as a function of magnetic field and analyzed the transport signatures using scaling. Depending on the amount of point disorder, graphene disorder, and device geometry, we observed an evolution in the critical exponents from diffusive to percolative transport. We additionally performed Hall measurements, in which we observed peaks in the transverse resistance corresponding to pinning and depinning of magnetic field-induced vortices. These transport signatures suggest unusual behavior as a function of disorder near the Quantum Critical Point (QCP).

The effects of charge carriers, organic solvents and magnetic ions on the superconductivity of doped 1T-SnSe₂  
HANLIN WU (Presenter), SHENG LI, DANIEL PEIRANO PETIT, BING LV, Physics, University of Texas at Dallas — We reported bulk superconductivity up to 7.6 K through careful manipulation of the charge carrier density and basal spacing \(d\) in the chemically intercalated two dimensional CdI₂-type 1T-SnSe₂ phase. We found out the very unusual scaling behaviour of \(T_C\) with the basal spacing distance caused by different organic co-intercalation, meanwhile the \(T_C\) appears to be almost independent with the alkali metal concentration. In this presentation, we focus on more chemical doping studies that close to the insulator-superconducting transition regime, more precisely-controlled doping level and various organic molecules have been tested through soft chemical methods. In addition, intercalation of the magnetic molecules are also carried out to study the interplay of superconductivity, magnetism, and possible charge density wave transition in these intercalated system. The details of the results will be presented with their physics origins being further elaborated.
**11:39AM X48.00003: Uniaxial strain effect on superconductivity in 1D and 2D LaAlO$_3$/SrTiO$_3$ channels**

XINYI WU (Presenter), MEGAN BRIGGEMAN, JOSEPH ALBRO, JIANAN LI, Univ of Pittsburgh, JUNG-WOO LEE, HYUNGWOOD LEE, CHANG-BEOM EOM, Univ of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Univ of Pittsburgh — We investigate the effects of uniaxial strain on superconductivity of nanowires in LaAlO$_3$/SrTiO$_3$. The interface of LaAlO$_3$ and SrTiO$_3$ has a high-mobility 2D electron gas which can be superconducting at sub-Kelvin temperatures. We are able to create 1D conducting channels at the interface using conductive atomic force microscope lithography [1]. Superconductivity in the system is associated with ferroelastic domain boundaries [2] and therefore is in 1D regimes. Application of an external uniaxial stress is expected to displace the ferroelastic domain boundaries. Our experiments indicate that uniaxial stretching of the nanowire in the parallel direction completely suppress the superconducting state, while reversal of the applied strain restores superconductivity. We will discuss implications of possible electron-pairing mechanism in the 1D superconductor.

**11:51AM X48.00004: Effect of quantum fluctuations on the critical supercurrent through a mesoscopic normal-metal island**

VLADIMIR BUBANJA (Presenter), Callaghan Innovation — We consider the transport properties of a single-electron transistor consisting of a diffusive normal-metal island and superconducting electrodes. We show that the interplay of a dissipative impedance of the gate electrode, a weak magnetic field, and a charging energy of the island causes a suppression of the critical supercurrent of the transistor. When the device is voltage biased, pumping of single electrons can be achieved by a periodic modulation of the gate voltage [1-3]. We derive the analytic expressions for the error rates and show that they are suppressed by the applied magnetic field [4].

**12:03PM X48.00005: Low Temperature Terahertz Nano-Imaging of BSCCO High Temperature Superconductor**  
RAN JING (Presenter), ROCCO VITALONE, MICHAEL BERKOWITZ, GUANGXIN NI, Columbia University, The Department of Physics, BRIAN S Y KIM, Columbia University, The Department of Mechanical Engineering, DMITRI BASOV, Columbia University, The Department of Physics — Terahertz (THz) near-field imaging and nano-spectroscopy is a capable tool to research nano-scale low energy electromagnetic phenomena. Of particular interest are high-temperature superconductors (HTSC) whose characteristic energy scale exists in the THz regime. We discuss our recent development of a cryogenic, scanning near-field microscope suitable for nano-scale imaging and spectroscopy throughout the THz frequency range. We report THz near-field measurements of optimally doped and over-doped BSCCO-2212 thin film devices above and below their superconducting transition temperatures. Near-field can measure the c-axis Josephson plasma resonance (JPR) spectroscopically. Further, the large anisotropy between the in and out of plane plasma frequency caused by JPR also contributes to a hyperbolic polariton modes in the bulk of a thin film which can be detected by near-field imaging [1][2].

**12:15PM X48.00006: Electric Field Effects in Mesoscopic Metal Superconductors**  
LOREN ALEGRIA (Presenter), CHARLOTTE BOETTCHER, AMIR YACOBY, Harvard University — The superconducting state of metals is typically thought to be negligibly affected by the presence of externally applied electric fields, given sub-nanometer screening lengths. But recent studies of mesoscopic metallic superconducting channels at millikelvin temperatures observe a reduction of the superconducting critical current under applied gate voltage [1]. We extend these measurements of Ti and Al nanowires and find revealing effects, including voltage tuned oscillations in the critical current as a function of magnetic field. We present possible explanations and experiments underway to evince the origin of the effect.

*This research was supported by an appointment to the Intelligence Community Postdoctoral Research Fellowship Program at Harvard University, administered by Oak Ridge Institute for Science and Education through an interagency agreement between the U.S. Department of Energy and the Office of the Director of National Intelligence.*
**12:27PM X48.00007: Quasiparticle Poisoning of a Superconducting Island by Nonequilibrium Phonons**

ELSA T MANNILA (Presenter), OLIVIER MAILLET, Aalto University, VILLE F MAISI, Lund University, JUKKA P PEKOLA, Aalto University — Quasiparticle excitations are detrimental to the operation of various superconducting devices. The density of quasiparticles should be exponentially suppressed at low temperatures, but commonly a quasiparticle density many orders of magnitude larger than the thermal expectation is observed. Phonons with energy greater than twice the superconducting gap can break Cooper pairs to form quasiparticles, and conversely two quasiparticles recombining to form a Cooper pair will emit such phonons. In our experiment, we demonstrate how the superconducting island of a single-electron transistor is poisoned with quasiparticles and the parity effect is consequently destroyed, when another heated superconducting island is used as an emitter of nonequilibrium phonons, while a thermal phonon emitter, a similarly heated normal metal island, creates much fewer quasiparticles.

**12:39PM X48.00008: InAs nanowire Josephson junctions with in-situ grown full shell Al**

IJU CHEN (Presenter), MARTIN BJERGFELT, THOMAS KANNE NORDQVIST, DAMON JAMES CARRAD, THOMAS SAND JESPERSEN, KASPER GROVE-RASMUSSEN, JESPER NYGÅRD, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen — Superconductor-semiconductor hybrid nanowires are ideal material systems for studying various quantum transport phenomena such as Andreev and Majorana bound states. For quantum information technologies based on these quantum phenomena, it is highly desirable to develop hybrid nanowires with high-quality superconductor-semiconductor interfaces and ballistic transport in the semiconductor. In this study, we use shadow mask structures on the growth substrate to grow full shell Al-InAs-Al Josephson junction nanowires in situ. The in-situ grown junction can be free from surface damage and over-etching associated with the Al etching process. Electrical characterization of the Josephson junctions shows a hard superconducting gap. We observe multiple Andreev reflections in the open-channel regime and sub-gap states in the tunnel coupled regime. Furthermore, as a result of fluxoid quantization in the Al shell, the superconductivity is modulated by the magnetic flux and its effect on the Josephson junction is investigated.
12:51PM X48.00009: Theory of superconductivity in an ultra-dilute fermionic liquid in the proximity of a quantum phase transition. Piotr Chudzinski (Presenter), School of Mathematics and Physics, Queens Univ Belfast — We study the problem of superconductivity in an extremely weakly doped narrow gap semiconductor, driven by electron-phonon coupling in a non-adiabatic regime. We derive an analytic theory analogue to Eliashberg equations that shall allow us to determine the critical temperature. In the first stage, based on our recent correlated electron-ion dynamics study, we obtain the effective non-adiabatic electron-phonon coupling function. We then add long-range Coulomb type interactions to derive propagators for the emergent collective state. Since the electron-phonon coupling is highly anisotropic, in the second step we test whether coupling to cooperons is able to induce a thermodynamic phase transition. Finally, we discuss transport properties of the emergent superconducting condensate, in particular (magneto-)thermoelectricity driven by vortex states. Our study is applicable in various classes of novel superconducting phases in materials with extremely small carrier concentrations such as doped SrTiO, but also a mysterious case of elementary bismuth.

*SFI-DfE NI Investigators Programme Partnership #15/IA/3160

1:03PM X48.00010: Suppression of quantum metallic state in disordered Ta thin films with the addition of artificial periodic pinning centers Eunseong Kim (Presenter), Junghyun Shin, Sun-gyu Park, Suhyeon Noh, Korea Adv Inst of Sci & Tech — We studied the low temperature transport properties of perforated superconducting Ta films with periodic triangular array of holes to investigate the role of pinning effect on superconductor-insulator transition. Magnetic field and temperature dependence of transport characteristics in 7 perforated Ta thin film samples with uniform thickness but different densities of holes are investigated and compared with a reference sample without holes. High density artificial periodic pinning centers increase activation energies for motion of vortices and induce cusp-like magnetic field dependence of resistance due to commensurate matching effect of interstitial vortices between holes as well as trapped vortices inside holes. As hole density increases, matching effects is observed up to higher field. Besides Resistance of field cooling decreases as Arrhenius form of thermal activated model up to higher magnetic field and, zero-temperature limit metallic state is more suppressed.
**1:15PM X48.00011: Thickness dependent study of superconducting behavior and contact dynamics in atomically thin Fe(\text{Te}_{0.7}\text{Se}_{0.3}) Flakes**  
ANDREW STEELY (Presenter), CHUNLEI YUE, YUN LING, ABIN JOSHY, Tulane Univ, ZHIQIANG MAO, Pennsylvania State University, JIANG WEI, Tulane Univ — We present evidence of thickness dependent superconducting behavior in strain-free Fe(\text{Te}_{0.7}\text{Se}_{0.3}) flakes. Due to non-uniform Te/Se spatial distribution, we find that R(T) behavior in flakes <10nm can be explained and confirmed using the BKT transition for inhomogeneity model, as well as finite state effects (FSE). For >10nm flakes we find a systematic suppression of the superconductivity and broadening of the superconducting phase transition. Additionally, we present a self-heating model at the metal-superconductor-metal (MSM) interface to explain unusual observed switching behavior in I-V characteristics for flakes thinner than 10nm. We propose a 2D network of superconducting paths connecting superconducting islands within Fe(\text{Te}_{0.7}\text{Se}_{0.3}) thin flakes to describe the thickness-dependent behavior of this natural percolating system.

**1:27PM X48.00012: Gaussian state superposition ansatz for quantum impurity problems: Numerical methods and applications**  
SAMUEL BOUTIN (Presenter), BELA BAUER, Station Q, Microsoft Quantum — Recent work of Bravyi and Gosset [1] demonstrated that superposition of Gaussian states can approximate efficiently the ground state of gapped quantum impurity problems. We introduce an efficient numerical method for finding the ground state approximation in this variational manifold. As a benchmark, we first apply our method, based on imaginary time evolution, to the Anderson impurity model. We then study a generalization of this approach to models of superconducting islands in the Coulomb blockade regime.

Two-dimensional superconductors have attracted growing interest because of their scientific novelty, structural tunability, and useful properties. Studies of their magnetic responses, however, are often hampered by difficulties to grow large-size samples of high quality and uniformity. We report here an imaging method that employed NV$^-$ centers in diamond as sensor capable of mapping out the microwave magnetic field distribution on an ultrathin superconducting film of micron size. Measurements on a 33nm-thick film and a 125nm-thick bulk-like film of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ revealed that the ac Meissner effect set in at 78K and 91K, respectively; the latter was the superconducting transition temperature ($T_c$) of both films. The unusual ac magnetic response of the thin film presumably was due to thermally excited vortex-antivortex diffusive motion in the film. Spatial resolution of our ac magnetometer was limited by optical diffraction. The technique could be extended with better detection sensitivity to extract local ac conductivity/susceptibility of ultrathin or monolayer superconducting samples as well as ac magnetic responses of other two-dimensional exotic thin films of limited lateral size.

11:15AM X49.00001: Phase Diagram of Spin Triplet Superconductor UTe$_2$ Under Pressure and Magnetic Field  

WEN-CHEN LIN (Presenter), DANIEL J CAMPBELL, University of Maryland, College Park, DAVID E GRAF, Florida State University, SHENG RAN, NICHOLAS BUTCH, National Institute of Standards and Technology, JOHNPIERRE PAGLIONE, University of Maryland, College Park — The heavy fermion superconductor UTe$_2$ has recently drawn much attention due to several exotic properties. It exhibits two reentrant superconducting states under extremely high magnetic fields that appear correlated with ferromagnetic interactions [1-2], and has been proposed as a candidate three-dimensional topological superconductor [3-4]. Here, we report details of the field-temperature-pressure phase diagram of UTe$_2$ under pressures up to 18.8kbar and high magnetic fields. Electrical resistivity and tunnel diode oscillator (TDO) measurements were performed under external magnetic field along the crystallographic b axis (hard axis), revealing a systematic progression of the superconducting and field-polarized phases that have relations to those observed at ambient pressure [2][5]. We will discuss our observations and their relevance on the interplay between ferromagnetism and superconductivity in this rich system.

11:27AM X49.00002: Anomalous heat capacity of spin triplet superconductor UTe$_2$  

IAN HAYES (Presenter), TRISTIN METZ, YUN SUK EO, SHENG RAN, University of Maryland, College Park, NICHOLAS BUTCH, National Institute of Standards and Technology, JOHNPIERRE PAGLIONE, University of Maryland, College Park — The recently discovered superconducting state in uranium ditelluride is a playground of exotic phenomena, including field-reentrant superconductivity up to sixty tesla and spin-triplet pairing.[1, 2] In addition this system shows a large residual density of states at zero temperature, suggesting that about half of the electrons fail to condense, and an apparent violation of entropy balance across the superconducting transition.[1, 3] This talk will present millikelvin specific heat data on UTe2 as a function of magnetic field applied along multiple crystallographic axes. The specific heat shows an upturn at the lowest temperatures. The form of the upturn in temperature and its evolution in magnetic field suggest that it has its origin in critical ferromagnetic fluctuations, supporting the idea that UTe2 is the paramagnetic end member of the series of uranium-based ferromagnetic superconductors. Furthermore, subtracting this upturn restores entropy balance to the superconducting transition. The talk will conclude with a discussion of the implications of these observations for the triplet pairing scenario.

**11:39AM X49.00003: NMR Study of the Spin-triplet Superconductor UTe$_2$**

(QING-PING DING (Presenter), Ames Laboratory and Dept. of Phys. and Astro., Iowa State University, SHENG RAN, NICHOLAS BUTCH, NIST Center for Neutron Research, National Institute of Standards and Technology, YUJI FURUKAWA, Ames Laboratory and Dept. of Phys. and Astro., Iowa State University — Recently, spin-triplet superconductivity has been discovered in nearly ferromagnetic (FM) heavy fermion UTe$_2$ [1]. Here, we report the $^{125}$Te nuclear magnetic resonance (NMR) studies of UTe$_2$ in both the normal and superconducting (SC) states. The magnetic fluctuations in the normal state, and the SC gap information in the SC state has been revealed. We will also discuss the relationship between FM spin fluctuations and superconductivity in UTe$_2$.

*The research was supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences, Division of Materials Sciences and Engineering. Ames Laboratory is operated for the U.S. DOE by Iowa State University under Contract No. DE-AC02-07CH11358.

**11:51AM X49.00004: The electronic fluid in cuprate superconductors and NMR**

(JUERGEN HAASE (Presenter), Univ Leipzig — Nuclear magnetic resonance (NMR) is a powerful technique to explore quantum fluids in solids. Recently it was found that a number of early conclusions derived with NMR about the cuprates were flawed, as is easily seen from an overview of all cuprate planar copper shifts [1] and relaxation data [2,3]. For example, there is no evidence for special electronic spin fluctuations [2,3], and, the uniform magnetic response above Tc shows hitherto unknown behaviour [1,2]. The latter implies a large spin shift below Tc for one direction of the external magnetic field, while the nuclear relaxation ceases completely for all cuprates [3]. This must have consequences for the pairing. To shed more light on this peculiar behaviour, we discuss data for other nuclei and their relation to the local charge symmetry, which sustains the existence of this unusual spin shift.

12:03PM X49.00005: Identify the Chiral Superconductivity in 4Hb-TaS2 through Magnetic-Spectral Responses  XUEJIAN GAO (Presenter), KAM TUEN LAW, Department of Physics, Hong Kong University of Science and Technology, PATRICK A LEE, Department of Physics, Massachusetts Institute of Technology — Chiral superconductivity, which breaks time-reversal symmetry spontaneously, is an alternative ingredient to cook up a topological superconductor holding the Majorana fermions that can be used to perform fault-tolerant quantum computation. A recent experiment [1] showed signatures of time-reversal symmetry breaking in superconducting 4Hb-TaS2 which abruptly appeared at the critical temperature Tc, implying possibility for the existence of chiral superconductivity. Through group theory analysis, we argue that only a chiral and a non-chiral superconducting states are allowed by the crystalline symmetry and strong Ising-type spin-orbital coupling in 4Hb-TaS2, both of which are mixed singlet-triplet states. It is further shown that the non-chiral superconducting state is more susceptible to an in-plane magnetic field and can be magnetically driven to a nodal superconducting phase, while the chiral one does not share this property. According to their different magnetic-spectral responses, an experimentally feasible way concerning the measurement of specific heat is proposed to identify the chiral superconductivity from the non-chiral one for this particular material.

12:15PM X49.00006: Mixed-parity superconductivity near Lifshitz transitions in strongly spin-orbit-coupled metals* MATTHEW TROTT, CHRISTOPHER HOOLEY (Presenter), School of Physics and Astronomy, SUPA, University of St Andrews, UK — We consider a strongly spin-orbit-coupled metal, one of whose Fermi surfaces is close to a Lifshitz (topological) transition. Via a renormalization group analysis of the square-lattice Hubbard model with strong Rashba spin-orbit coupling, we show that such a metal is generically unstable to the formation of mixed-parity superconductivity with a helical triplet component.

*This work has been funded by the Engineering and Physical Sciences Research Council (UK) under grant numbers EP/L015110/1 (Trott) and EP/R031924/1 (Hooley).
12:27PM X49.00007: Superconductivity mediated by ferroelectric fluctuations: anisotropic gap structure and possible application to SrTiO$_3$  MARIA NAVARRO GASTIASORO, University of Minnesota, THAIS VICTA TREVISAN (Presenter), Ames Lab, RAFAEL FERNANDES, University of Minnesota — SrTiO$_3$ is a semiconducting oxide that undergoes a phase transition to a superconducting state upon electron doping. Although such superconducting phase was first observed more than 50 years ago, its nature and origin remain an unsettled puzzle. Interestingly, recent experimental and theoretical works suggest an interplay between ferroelectricity and superconductivity in this material. Motivated by these studies, we study superconductivity mediated by odd-parity ferroelectric modes. We consider a Rashba-like coupling between the electrons and the ferroelectric fluctuations, which is possible due to the presence of spin-orbit coupling. We derive the effective pairing interaction and solve the resulting linearized gap equation away from quantum criticality. We find that the effective coupling, which is attractive in the singlet channel, is dominated by the soft transverse optical mode. Moreover, the superconducting gap is shown to develop an anisotropy that grows as the system approaches the ferroelectric phase. Finally, we discuss the competition with other even-parity superconducting channels and the possible application of our results to SrTiO$_3$.

12:39PM X49.00008: Enhancement of superconductivity mediated by antiferromagnetic squeezed magnons* EIRIK ERLANDSEN (Presenter), AKASHDEEP KAMRA, ARNE BRATAAS, ASLE SUDBO, Norwegian Univ Tech (NTNU) — We theoretically investigate magnon-mediated superconductivity in a heterostructure consisting of a normal metal and a two-sublattice antiferromagnetic insulator. The attractive electron-electron pairing interaction is caused by an interfacial exchange coupling with magnons residing in the antiferromagnet, resulting in p-wave, spin-triplet superconductivity in the normal metal. Our main finding is that one may significantly enhance the superconducting critical temperature by coupling the normal metal to only one of the two antiferromagnetic sublattices employing, for example, an uncompensated interface. Employing realistic material parameters, the critical temperature increases from vanishingly small values to significantly larger values than 1 K as the interfacial coupling becomes strongly sublattice-asymmetric. We provide a general physical picture of this enhancement mechanism based on the notion of squeezed bosonic eigenmodes.

**12:51PM X49.00009: Nonlinear optical effects in inversion-symmetry-breaking superconductors**

TIANRUI XU (Presenter), Physics, University of California, Berkeley, TAKAHIRO MORIMOTO, Applied Physics, The University of Tokyo, JOEL MOORE, Physics, University of California, Berkeley — We study nonlinear optical responses in superconducting systems with inversion ($I$) symmetry-breaking order parameters. We first show that any superconducting system with $I$ and time-reversal ($T$) symmetries requires an $I$-breaking order parameter to support optical transitions between particle-hole pair bands. We then use a 1D toy model of an $I$-breaking superconductor to numerically calculate linear and nonlinear conductivities, including shift current and second harmonic generations (SHG) responses. We find that the magnitude of the signal is significantly larger in shift current/SHG response than in the linear response due to the matrix element effect. We also present various scaling behaviors of the SHG signal, which may be relevant to the recent experimental observation of SHG in cuprates[1]. Finally, we confirm the generality of our observations regarding nonlinear responses of $I$-breaking superconductors, by analyzing other models including a 1D three-band model and 2D square lattice model.

1:03PM X49.00010: Energy-scale relationship between magnetic excitations and superconductivity in Hg-family of high-$T_c$ cuprates

LICHEN WANG (Presenter), Solid State Spectroscopy, Max Planck Institute for Solid State Research, GUANHONG HE, International Center for Quantum Materials, Peking University, ZICHERN YANG, Solid State Spectroscopy, Max Planck Institute for Solid State Research, MIRIAN GARCIA-FERNANDEZ, ABHISHEK NAG, KEJIN ZHOU, I21 Inelastic X-ray Scattering, Diamond Light Source, MATTEO MINOLA, Solid State Spectroscopy, Max Planck Institute for Solid State Research, MATTHIEU LE TACON, Institute for Solid State Physics, Karlsruhe Institute of Technology, BERNHARD KEIMER, Solid State Spectroscopy, Max Planck Institute for Solid State Research, YINGYING PENG, YUAN LI, International Center for Quantum Materials, Peking University — High-temperature superconductivity in the cuprates is realized upon doping antiferromagnetic parent compounds, in which spin excitations have a band width of a few hundred meV. At such high energies, paramagnons and two-magnon excitations are known to persist well into and beyond the superconducting doping range [1,2,3], but it remains unclear to what extent they contribute to Cooper pairing [4] or how the magnetic and superconducting energy scales are related to each other. We have used resonant inelastic X-ray scattering and Raman scattering to study the first two members of the Hg-family of cuprates, HgBa$_2$CuO$_{4+d}$ and HgBa$_2$CaCu$_2$O$_{6+d}$, which have nearly identical crystal structure in the charge-reservoir layers but different electronic environment in the quintessential Cu-O layers. We find that the latter compound, which has higher $T_c$ and larger superconducting gap, also has considerably higher magnetic excitation energies.

1:15PM X49.00011: Hidden Spin-Momentum Texture in High Tc Cuprate Superconductor

CHIU-YUN LIN (Presenter), KENNETH GOTLIEB, University of California, Berkeley, MAKSYM SERBYN, Institute of Science and Technology, Austria, WENTAO ZHANG, Physics and Astronomy, Shanghai Jiao Tong University, CHRISTOPHER SMALLWOOD, Physics and Astronomy, San Jose State University, CHRIS JOZWIAK, ZAHID HUSSAIN, Advanced Light Source, Lawrence Berkeley National Lab, ASHVIN VISHWANATH, Physics, Harvard University, ALESSANDRA LANZARA, University of California, Berkeley — Cuprate superconductor is one of the most well studied compounds. Even so, experiments discover new results after thirty years of intense study by the community. Spin-orbit coupling (SOC) in cuprate superconductors was not a focus of condensed matter research due to the negligible SOC value of the conducting orbitals comparing with the strong electronic correlations and its centrosymmetric crystal structure. However, using spin- and angle-resolved photoemission spectroscopy, we directly probed the spin-momentum entangled texture in Bi2Sr2CaCu2O8+x. The unexpectedly strong spin asymmetry in such globally inversion-symmetric crystal highlights the importance of the local environment that carriers see, meanwhile, poses the intriguing question of how the high-temperature superconducting state emerges in the presence of this nontrivial spin texture.
1:27PM X49.00012: NCCO: Examining antiferromagnetic hotspots and spin texture comparison with Bi-based cuprates*  KAYLA CURRIER (Presenter), Physics, University of California, Berkeley — Recent work on cuprate Bi2212 has revealed a nontrivial spin texture with a rashba-like spin orbit coupling. This texture has been attributed to local inversion symmetry breaking that causes a local electric field within the material. Theory suggests that this property is due to the specific structure of the layers in Bi2212. We examine the spin texture in single-layer electron-doped cuprate NCCO and show how it fits in with the proposed theory. In addition, equilibrium data taken on different dopings of NCCO are compared to recent work showing fermi surface reconstruction. Here we focus on the antiferromagnetic hotspots along the zone boundary. Overall we show part of the picture of how NCCO fits in with the current understanding of cuprates and some of their properties.

11:15AM X50.00001: Temperature dependence of the Mott gap in single-layer 1T-TaSe2 revealed by scanning tunneling spectroscopy  WEI RUAN (Presenter), YI CHEN, University of California, Berkeley, JINWOONG HWANG, Lawrence Berkeley National Laboratory, SHUJIE TANG, Stanford, RYAN LEE, HSIN-ZON TSAI, SALMAN ABDUL GAFFAR KAHN, FRANKLIN LIOU, ANDREW AIKAWA, University of California, Berkeley, ZHIXUN SHEN, Stanford, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, MICHAEL F CROMMIE, University of California, Berkeley — A key to unraveling the high-temperature superconductivity mechanism in cuprates is to understand the Metal-insulator transition in Mott insulators that can be induced by either doping charge or raising temperature. While the doping dependence of the Mott gap in cuprates has been studied extensively, it is difficult to explore the gap’s temperature dependence in these systems due to its large size (typically 1~2 eV) and the resulting high temperature scale required to melt the Mott-state. Here we use scanning tunneling microscopy/spectroscopy to investigate the temperature dependence of the electronic structure of the single-layer Mott insulator 1T-TaSe2 which has a much more modest Mott gap of ~ 0.1 eV. We observe that the gap closes rapidly at a temperature scale that is significantly smaller than the gap size. This is accompanied by changes in the exotic orbital texture of the upper Hubbard band that are consistent with reduced screening at elevated temperatures. This phenomenon is unique among strongly correlated systems and is compatible with recent theoretical predictions where spin fluctuations are responsible for the rapid gap closing.
Manipulation of electron-phonon energy transfer pathways in 2D transition metal dichalcogenides through ultrafast excitation

EMMA CATING-SUBRAMANIAN (Presenter), CHRISTIAN GENTRY, XUN SHI, YINGCHAO ZHANG, WENJING YOU, SINEAD RYAN, JILA, University of Colorado Boulder, BALDWIN AKIN VARNER, Norfolk State University, KAI ROSSNAGEL, Christian-Albrechts-Universitat zu Kiel, HENRY KAPTEYN, MARGARET MURNANE, JILA, University of Colorado Boulder — The complex phase landscape of quantum materials provides tremendous opportunity for design, manipulation, and coherent control of material properties using light. Understanding that complexity also poses a significant challenge, and multiple techniques are needed to map and exploit the rich phase space of strongly correlated materials. For example, using ultrafast electron calorimetry via time- and angle-resolved photoemission (ARPES), a bi-directional energy transfer between strongly-correlated electron and phonon modes in a material has been observed for the first time - in this case a charge density wave (CDW) material \( \Gamma - \text{TaSe}_2 \).

Here we use visible pump-probe spectroscopy to further explore and manipulate the couplings between the electron and phonon systems. By varying the pump fluence, we can alter the relative coupling strength of multiple phonon modes, demonstrating the use of light to control material properties and select available vibrational relaxation pathways in quantum materials.

Negative Parabolic Magneto-resistance in a strongly interacting 2D Hole system in GaAs/AlGaAs

ARVIND SHANKAR KUMAR (Presenter), CHIEH-WEN LIU, SHUHAO LIU, Case Western Reserve University, LOREN PFEIFFER, KENNETH WEST, Princeton University, XUAN GAO, Case Western Reserve University — Electron-electron interactions are believed to be an important factor in the origin of the 2D Metal-Insulator Transition observed in strongly correlated 2D electron/hole systems. In the weakly interacting (Fermi Liquid) regime, these interactions can be shown to cause a negative parabolic correction to the magneto-resistance of the 2D electron/hole system. In the strongly interacting regime (\( \omega_c \tau > 1 \)) for a strongly interacting 2D hole liquid (\( r_s = 20-30 \)) in a GaAs/AlGaAs quantum well at low temperatures (\( T = 0.09 - 1 \) K), in a hole density range (\( p = 0.98-1.98 \times 10^{10} / \text{cm}^2 \)) close to the critical density for the 2D Metal-Insulator transition, where the temperature dependence of resistivity is non-monotonic. We study the extracted hole-hole interaction correction to Drude conductivity in this regime and compare its temperature dependence to conventional Fermi Liquid theories. This study gives insight on the validity of a Fermi Liquid picture in the strongly interacting regime and explores whether this conventional picture of interacting electron systems can be used to explain the origin of the 2D metallic state.

11:51AM X50.00004: Theory of Strain Effects on Extremely Correlated Metals in Two-dimensions*  
MICHAEL ARCINIAGA (Presenter), University of California, Santa Cruz, PEIZHI MAI, Oak Ridge National Laboratory, B SRIRAM SHASTRY, University of California, Santa Cruz — We study the strain dependence of anisotropic resistivity [1] within the t-t'-J model, applicable to cuprate superconductors. This model is treated using the recently developed extremely correlated Fermi liquid theory (ECFL). We obtain the temperature, density and strain dependence of the anisotropic resistivity. We compute the strain response functions in different geometries for comparing with planned experiments [1]. We also study the strain dependence of the optical weight and the local density of states (LDOS) at low T. Our results provide quantitative predictions of these quantities for experimental tests on strongly correlated materials such as high-Tc materials.

12:03PM X50.00005: Construction and classification of point group symmetry protected topological phases in 2D interacting fermionic systems*  
JIANHAO ZHANG (Presenter), Institute for Advanced Study, Tsinghua University, QING-RUI WANG, Department of Physics, The Chinese University of Hong Kong, SHUO YANG, Department of Physics, Tsinghua University, YANG QI, Department of Physics, Fudan University, ZHENGCHENG GU, Department of Physics, The Chinese University of Hong Kong — The construction and classification of symmetry protected topological (SPT) phases in interacting bosonic and fermionic systems have been intensively studied in the past few years. Very recently, a complete classification and construction of space group SPT phases were also proposed for interacting bosonic systems. In this paper, we attempt to generalize this classification and construction scheme into interacting fermion systems systematically. In particular, we construct and classify point group SPT phases for 2D interacting fermion systems via lower-dimensional block-state decorations. We discover several intriguing fermionic SPT states that can only be realized in interacting fermion systems (i.e., no free-fermion and bosonic SPT realizations). Moreover, we also verify the recently conjectured crystalline equivalence principle for 2D interacting fermion systems. Finally, a potential experimental realization of these new classes of point group SPT phases in 2D correlated superconductors is also addressed.

12:15PM X50.00006: The Non-Gaussian Exact Diagonalization Method and Its Application to the 2D Hubbard-Holstein Model*  
YAO WANG (Presenter), ILYA ESTERLIS, Harvard University, TAO SHI, Institute of Theoretical Physics, Chinese Academy of Sciences, JUAN IGNACIO CIRAC, Max-Planck-Institut für Quantenoptik, EUGENE DEMLER, Harvard University — We propose a novel numerical method that embeds the variational non-Gaussian wavefunction approach with exact diagonalization, allowing for efficient treatment of correlated systems with both electron-electron and electron-phonon interactions. Using a generalized polaron transformation, we construct a variational wavefunction that minimizes the entanglement between electrons and phonons; exact diagonalization is then used to treat the electronic part of the wavefunction exactly, thus taking into account high-order correlation effects beyond the Gaussian level. Keeping the full electronic Hilbert space, the complexity is increased only by a polynomial factor relative to the exact diagonalization calculation for pure electrons. As an example, we use this method to study ground-state properties of the two-dimensional Hubbard-Holstein model, providing evidence for the existence of intervening phases between the spin and charge-ordered states.

*This work is supported by the MPHQ fellowship, Harvard-MIT CUA, and AFOSR-MURI grant (Award No. FA9550-14-1-0035 and Award No. FA9550-16-1-0323).

12:27PM X50.00007: Electro-magnetic duality in 2D topological orders with gapped boundaries  
HONGYU WANG (Presenter), YINGCHENG LI, Fudan University, YUTING HU, Department of Physics and Institute for Quantum Science and Engineering, South University of Science and Technology, YIDUN WAN, Fudan University — We generalize the Electro-magnetic (EM) duality and the mapping to the Levin-Wen (LW) model of the quantum double (QD) model to the case of topological orders with gapped boundaries. To achieve our goal, we Fourier transform the extended QD model defined on the lattice with boundaries. The input data of the model is finite group $G$ and the boundary condition is characterized by subgroup $K \subseteq G$. After the Fourier transform, we find while the bulk degrees of freedom become $\text{rep}_G$, the boundary condition is now characterized by Frobenius algebra $((\mathds{C}[G]/\mathds{C}[K])^*)$, the quotient of the group algebra of $G$ over that of $K$. We also show that our Fourier-transformed extended QD model can be mapped to an extended LW model on the same lattice via enlarging the Hilbert space of the extended LW model. Moreover, our Fourier transform of the extended QD model provides a visualizable explanation of the phenomenon of splitting and partial condensation of anyons.
**12:39PM X50.00008: Catastrophe theory classification of Fermi surface topological transitions in two dimensions**

ANIRUDH CHANDRASEKARAN (Presenter), Boston Univ, OLEKSANDR SHTYK, Quantlab Group, JOSEPH BETOURAS, Physics, Loughborough University, CLAUDIO CHAMON, Boston Univ — We classify all possible singularities in the electronic dispersion of two-dimensional systems that occur when the Fermi surface changes topology, using catastrophe theory. For systems with up to seven control parameters (i.e., pressure, strain, bias voltage, etc), the theory guarantees that the singularity belongs to one of seventeen standard types. We show that at each of these singularities the density of states diverges as a power law, with a universal exponent characteristic of the particular catastrophe, and we provide its universal ratio of amplitudes of the prefactors of energies above and below the singularity. We further show that crystal symmetry restricts which types of catastrophes can occur at the points of high symmetry in the Brillouin zone. For each of the seventeen wallpaper groups in two-dimensions, we can list which catastrophes are possible at each high symmetry point.

**12:51PM X50.00009: Symmetry protected long-lived excitations and tomographic dynamics in 2D electron fluids**

PATRICK LEDWITH (Presenter), HAOYU GUO, Harvard University, LEONID LEVITOV, Massachusetts Institute of Technology — We will discuss the peculiar collective behavior in two-dimensional Fermi gases arising from head-on carrier-carrier collisions. These collisions dominate at cold temperatures, $T \ll T_F$, due to the combined effects of Pauli blocking and momentum conservation. Odd-parity harmonics are protected from these collisions and hence have anomalously long lifetimes. They instead slowly relax via small angle scattering which leads to a strange "superdiffusive" behavior. These long-lived modes give rise to a "tomographic" transport regime dominated by fermionic jets with an unusual hierarchy of time scales and scale-dependent transport coefficients with nontrivial fractional scaling dimensions. We will also discuss proposals for experimental realizations and implications for ongoing studies of electron hydrodynamics.

1:03PM X50.00010: Hydrodynamic electron flow in 2D semiconductor heterostructures*
AYDIN KESER (Presenter), DAISY QINGWEN WANG, University of New South Wales & FLEET ARC, OLEH KLOCHAN, UNSW Canberra, ADFA, FLEET ARC, DEREK HO YEW HUNG, SHAFFIQUE ADAM, Physics, Yale NUS College, DOMITRIE CULCER, ALEX HAMILTON, OLEG SUSHKOV, University of New South Wales & FLEET ARC — We propose simple geometries to directly test hydrodynamic flow in 2D electron systems by longitudinal resistance measurements. We model the boundaries of the electron fluid as `slippery', i.e. supporting no longitudinal stress, hence, we show that the viscous component of resistance depends significantly on the geometric features while it vanishes along the straight featureless sections. Moreover, since the viscous resistance increases quadratically with the inverse scale of the system, we show that channels in which the viscous and Ohmic effects are comparable can be manufactured with current technology. Elementary, bent or nozzle/diffuser type channels show significant departure from their diffusive counterparts in the hydrodynamic regime.

1:15PM X50.00011: Atypical Behavior of Collective Modes in Two-Dimensional Fermi Liquids
MATTHEW GOCHAN (Presenter), JOSHUAH TIMOTHY HEATH, KEVIN SHAWN BEDELL, Boston College — Since its development by L.V. Landau sixty years ago, Fermi liquid theory continues to serve as a formidable model for interacting Fermi systems in addition to providing the standard which all other models are held to. Of the numerous accomplishments of Fermi liquid theory, the calculation of various transport properties is of particular interest. In this talk we apply the Landau kinetic equation to a two-dimensional Fermi liquid and discuss the consequences of the reduced dimensionality on the behavior of the collective modes. As a function of the usual dimensionless parameter $s = \omega/\nu_F$, we find expected behavior in addition to new results for the behavior of the zero sound mode $c_0$. Additionally, we investigate the effect of a Coulomb interaction on the system resulting in an expression for plasmon frequency $\omega_p$ in 2D with a crossover as a function of $q$ to the zero sound mode.

1:27PM X50.00012: A determinantal quantum Monte Carlo study of deconfined quantum criticality*
CHAO WANG (Presenter), YONI SCHATTNER, STEVEN KIVELSON, Stanford Univ — We study an interacting electron-dimer model on the square lattice using the determinantal quantum Monte Carlo technique. We present evidence for a deconfined quantum critical point between antiferromagnetic and columnar valence-bond solid phases and examine the properties of the critical point.

*This work was supported in part by the Department of Energy, Office of Basic Energy Sciences, under contract no. DE-AC02-76SF00515 at Stanford. YS was also supported by the Zuckerman STEM Leadership Program.
Among various ground states of rare earth monotelluride, bulk GdTe is metallic with antiferromagnetic order (AFM) at low temperature. We grow GdTe thin films by molecular beam epitaxy (MBE) and study their properties by scanning tunneling microscopy (STM) and magnetic property measurement. Density of states (DOS) obtained by STM exhibits insulating gap, which can be closed by magnetic field for certain film thicknesses, indicating a transition from insulator to metal. The gap size can be as large as 30 meV and closed by relatively weak magnetic field of 2.6 T for 6 layers of GdTe. We attribute the observed effects to the exchange interaction between d and f electrons.

Session X51 DCMP: Transport in Graphene Systems Mile High Ballroom 1D - Gregory Stephen, Laboratory for Physical Sciences

11:15AM X51.00001: Flat-Band Magnetism and Half-Metallicity in Twisted Bilayer Graphene* ALEJANDRO LOPEZ BEZANILLA (Presenter), Los Alamos National Laboratory — Evidence of flat-band magnetism and half-metallicity in compressed twisted bilayer graphene is provided with first-principles calculations. We show that dynamic band-structure engineering in twisted bilayer graphene is possible by controlling the chemical composition with extrinsic doping, the interlayer coupling strength with pressure, and the magnetic ordering with external electric field. By varying the rotational order and reducing the interlayer separation an unbalanced distribution of charge density results in the spontaneous apparition of localized magnetic moments without disrupting the structural integrity of the bilayer. Substitutional doping shifts the chemical potential of one spin distribution and leads to half-metallicity.

*This work was supported by the U.S. DOE Office of Basic Energy Sciences Program E3B5.
11:27AM X51.00002: Evidence for a three-layer-coherent quantum Hall state in graphene triple layers  
ANNA OKOUNKOVA (Presenter), YIHANG ZENG, CORY DEAN, JAMES C HONE, Columbia University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science — Heterostructures consisting of two graphene monolayers separated by a thin BN spacer provides a rich platform in which to study correlated states driven by strong interlayer interactions. In the quantum Hall effect regime, tuning this system to total filling fraction $\nu_{\text{tot}} = 1$ (i.e. half filling of the lowest Landau level in each layer) results in a spontaneously formed interlayer coherent state believed to be a Bose-Einstein condensate of indirect excitons or a pseudo spin ferromagnet. Here we report the first realization of a triple layer system where three monolayer graphene layers are strongly coupled via coulomb interaction while maintaining negligible interlayer tunneling. We demonstrate independent control of the density in each layer, giving access to the entire phase space of this system. Tuning the relative filling fraction between all three layers allows us to effectively shift the exciton condensate between different layer pairs and then probe this phase with the third layer. When the total filling factor of all three layers equals 1, we observe simultaneous quantization of Hall resistance in the drive and drag layer and vanishing longitudinal resistance, suggesting a generalized exciton condensate phase with macroscopic phase coherence across all three layers.

11:39AM X51.00003: Nonlocal transport in twisted double bilayer graphene*  
SUBHAJIT SINHA (Presenter), PRATAP ADAK, SURYA KANTHI R. S., L. D. VARMA SANGANI, Tata Institute of Fundamental Research (TIFR), KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, MANDAR M DESHMUKH, Tata Institute of Fundamental Research (TIFR) — In the spectrum of 2D materials, superlattices have emerged as a promising platform to modulate band structure. In graphene, it does the job of breaking the inversion symmetry between the K and K' points. In the case of bilayer graphene, spatial inversion symmetry can also be broken by applying a transverse electric field, which opens up a gap at CNP. Both these ways result in the generation of a valley current via the valley Hall effect. This shows up as non-local resistance, away from the path of charge current.
We integrate both these ways of valley current generation and implement it on dual gated twisted double bilayer graphene device, where the two copies of bilayer graphene have been rotated by 1.18°. We observe large non-local resistance few microns away from local probes. We further demonstrate its tunability with electric field and with charge density. One can thus explore this additional valley degree of freedom to transmit information coherently over distances of few microns in graphene. This may open up new avenues in the emerging field of valleytronics.

*We acknowledge funding from Department of Atomic Energy, India and Department of Science and Technology, India.
XI ZHANG (Presenter), KAN-TING TSAI, YUJIE LUO, KE WANG, University of Minnesota — Ballistic Dirac-Fermion transport across gate-defined PN junctions exhibits strong dependence on incident angle due to the linear dispersion relationship. Multiple experiments have been performed utilizing the angle-dependence of Klein tunneling, in which novel electron-optics concepts including electron collimation [1] and Veselago lensing [2][3] have been demonstrated. Here we demonstrate preliminary experimental observations of quantum interferences based on these concepts. Preliminary transport data across carefully-engineered PN junctions will be presented and quantitative analysis based on Klein-tunneling probability will also be discussed.

NARGESS ARABCHIGAVKANI (Presenter), RATCHANOK SOMPHONSANE, HARHIREA RAMAMOORTHY, GUANCHEN HE, JUBIN NATHAWAT, SHENCHU YIN, BILAL BARUT, State Univ of NY - Buffalo, JONAS FRANSSON, Physics and Astronomy, Uppsala University, JONATHAN P BIRD, State Univ of NY - Buffalo — The transport properties of bilayer graphene are known to be affected by weak localization at low temperatures. In this study, we use differential conductance mapping to explore the transport properties in bilayer graphene at low temperatures, under conditions for which they are influenced by the proximal of the graphene to a ferromagnet (Co). The low-temperature differential conductance is measured around the Dirac point, with the floating Co “gate” both included in, and absent from, the current path. In the latter case the differential conductance shows the characteristic dip that is known to provide a signature of weak localization. With the Co gate in the current path, however, the differential conductance shows a zero-bias anomaly, implying the suppression of the weak localization at certain energies that are insufficient to cause dephasing of the carriers. The presence and the magnitude of the zero-bias anomaly is depending on the carrier concentration in graphene, making it gate controllable.

12:15PM X51.00006: Mini-Dirac cones in AB-stacked graphene in perpendicular electric fields
RYUTA YAGI (Presenter), KOTA HORII, RYOYA EBISUOKA, SHINGO TAJIMA, Graduate School of Advanced Sciences of Matter, Hiroshima University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science — AB-stacked multilayer graphene with number of layers shows semi-metallic band structure arising from the overlap of bilayer-like bands. By conducting low temperature magnetotransport experiments using encapsulated graphene samples with a top and a bottom gate electrode, we observed that mini-Dirac cones are formed in a perpendicular electric field. In zero perpendicular electric fields, Landau level near the charge neutrality point showed structures which are characteristic of semi-metallic band structures. The structure showed significant variations in perpendicular electric fields. The variations of the Landau level structure were interpreted as a formation of levels arising from mini-Dirac cones from numerical calculations of dispersion relations and the Landau levels. The mini-Dirac cones originate from a trigonal warping in the band structure. The perpendicular electric field opens energy gaps between bilayer-like band, and the trigonal warping closes the gaps locally, thereby mini-Dirac cones form.

12:27PM X51.00007: Anomalous Quantum Hall States in Bilayer Graphene*
JUNG-JUNG SU (Presenter), Natl Chiao Tung Univ, CHUN NING LAU, Ohio State University, ALLAN MACDONALD, Physics, University of Texas at Austin — Bernal stacked bilayer graphene has a collection of competing broken symmetry states characterized by flavor-dependent spontaneous valley polarization.[1] The possible states include polarized and unpolarized orbital magnets and various quantum anomalous Hall states. By carefully evaluating the orbital magnetizations of the competing states, we find that the phase diagram is profoundly altered by a B field by favoring states of which its natural filling factor $\nu_N = \sigma_H/(e^2/h)$ is close to the actual filling factor $\nu$, increasingly so as the B field strengthens. We have explored how coupling of orbital magnetization to external B fields is manifested in the dependence of ground state properties on weak gate $V_g$ and magnetic fields $B$ that favor particular states. We construct the ground-state phase diagram of this system, vs. $V_g$ and $B$ at fixed $\nu$, and vs. $V_g$ and $\nu$ at fixed $B$, and obtain excellent agreement with two-point conductivity measurements. This work explains why the $\nu_N = \pm 4$ quantum Hall Effect in bilayer graphene is stable to anomalously weak B fields, and suggests that $\nu_N = \pm 2$ anomalous quantum Hall effects could occur in the absence of a B field in samples of sufficiently high quality.

12:39PM X51.00008: Electronic Thermal Conductance Suppression in Lightly Doped Bilayer Graphene Measured via Johnson Noise Thermometry*  ARTEM TALANOV (Presenter), JONAH WAISSMAN, MARINE ARINO, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, PHILIP KIM, Harvard University — Systems with strongly interacting and correlated electrons can exhibit exotic new physics, such as the hydrodynamics regime, where particles' behavior is best collectively described as a viscous fluid rather than as individual particles. Several such systems have recently been both predicted and shown experimentally to have thermal conductivity enhanced or reduced relative to the near-universal Lorentz value expected from Wiedemann-Franz Law. Bilayer graphene presents a strong candidacy for quantum criticality and hydrodynamics at charge neutrality, where the carrier-carrier Coulomb energy dominates the kinetic energy of quasiparticles. We explore such behavior by measuring the electronic thermal conductivity of bilayer graphene encapsulated in boron nitride and gated by dual graphite gates, with residual density below $3 \times 10^{10}$ cm$^{-2}$. We use our high-frequency Johnson noise thermometry technique to measure the electronic cooling of the electron system, extracting out the thermal conductivity. We observe a large reduction of the thermal conductivity below the Wiedemann Franz Law at electron doping slightly away from charge neutrality. We discuss these results in the context of hydrodynamics.

*NDSEG Fellowship

12:51PM X51.00009: Designing transport properties of graphene nanoribbon junctions*  KRISTIANS CERNEVICS (Presenter), OLEG V. YAZYEV, Ecole Polytechnique Federale de Lausanne — Graphene nanoribbons (GNRs) have recently emerged as promising candidates for next-generation electronic devices, including the realization of all-graphene nanocircuitry. Junctions connecting two or more GNRs are the elementary components of GNR circuits. We systematically address the electronic transport properties of 60°- and 120°-angled junctions connecting a pair of GNR leads of identical width and chirality utilizing tight-binding model calculations. An exhaustive exploration of GNR junctions carried out by screening over 50,000 configurations allows us to formulate general guidelines into engineering transport properties GNR circuits. For instance, we find that 120°-angled junctions with sublattice imbalance have a perfect transmission via a resonant state occurring at zero energy, and thus identified as ideal GNR interconnects.

1:03PM X51.00010: In-situ TEM observation of suspended graphene during Joule heating process

DONG HOON SHIN, EWHA Woman's Univ, JUN-HEE CHOI, Surface Technology Division, Korea Institute of Materials Science (KIMS), HEENA INANI, KIMMO MUSTONEN, Physics, University of Vienna, HYUNJEONG JEONG, EWHA Woman's Univ, JANI KOTAKOSKI, Physics, University of Vienna, SANG WOOK LEE (Presenter), EWHA Woman's Univ — Dynamic surface modification of suspended graphene at high temperature was observed using in-situ transmission electron microscope (TEM) measurement. The suspended graphene were prepared on top of the SiN membrane with hole substrate so that TEM observation was conducted under Joule heating processes. Current-voltage characteristics of suspended graphene devices inside of TEM chamber were measured to monitor and control the high temperature condition of graphene surface by estimating electrical power on the devices. During the in-situ TEM observation, it was found that residual materials, previously remained on the graphene surface, were removed at high temperature. Dynamic movement of residue on the graphene surface and shrinkage of atomic distance of graphene were also observed while the Joule heating process.

1:15PM X51.00011: Excitonic Condensate Phase in Hybrid double-layer structures

XIAOXUE LIU (Presenter), Department of Physics, Brown University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CORY DEAN, Department of Physics, Columbia University, JIA LI, Department of Physics, Brown University — In this talk I will present Coulomb transport measurement of exciton condensate phase in a hybrid double-layer structure, where twisted bilayer graphene (tBLG) and monolayer graphene (MLG) are separated by a thin insulating barrier. With a large twist angle, the lowest Landau level in twisted bilayer graphene features eight-fold degeneracy, where each broken symmetry state in the quantum Hall effect regime is described by Landau wavefunction with orbital index N=0 [1]. As such, excitonic pairing across the insulating barrier is expected to be robust over a large phase space, characterized by filling fractions \(n_{\text{MLG}}\) and \(n_{\text{tBLG}}\), along with perpendicular electric field \(D\). Using Coulomb drag measurement, we discovered multiple copies of fully developed exciton condensate phase in both the electron-electron and electron-hole quadrants of the phase space. Over a large filling fraction range, -5 < \(n_{\text{total}}\) < 5, the value of quantized Hall resistance plateaus varies with total filling fraction \(n_{\text{total}}\). Most interestingly, the strength of exciton pairing is shown to be tunable with layer polarization in tBLG. This tunability adds an extra dimension to the phase space, which allows us to investigate the behavior of exciton condensate in a three-component system with three layers of graphene.
1:27PM X51.00012: High-order fractal quantum oscillations in highly doped graphene/BN superlattices* WU SHI (Presenter), SALMAN KAHN, Lawrence Berkeley National Lab and UC Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, MICHAEL F CROMMIE, ALEX ZETTL, Lawrence Berkeley National Lab and UC Berkeley — High temperature quantum oscillations have been reported in graphene/BN superlattices beyond secondary Dirac points both for electron and hole doping [1,2]. These so-called Brown-Zak (BZ) oscillations originate from periodic emergence of delocalized Bloch states in high magnetic field. However, the BZ oscillations is much less visible for hole doping than for electron doping due to strong electron-hole asymmetry. Here, we employed a newly developed electron beam doping technique to induce high electron and hole carrier densities in graphene/BN superlattices while maintaining high mobilities. Enhanced BZ oscillations are observed beyond the third-generation neutrality points at high temperatures. High-order magnetic Bloch states are also seen even for hole doping, demonstrating the effectiveness of our doping technique. Theoretical simulation of the magnetotransport provides qualitative agreement of the carrier density dependence of BZ oscillations with our experimental results.

1:39PM X51.00013: Proximity-induced spin-orbit coupling in bilayer graphene/WSe₂ heterostructures probed by quantum Hall measurements DONGYING WANG (Presenter), SHI CHE, GUIXIN CAO, Department of Physics, The Ohio State University, RUI LYU, Department of Physics and Astronomy, University of California, Riverside, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, CHUN NING LAU, MARC W BOCKRATH, Department of Physics, The Ohio State University — The physical properties of 2D materials are highly sensitive to the interface in a van der Waals heterostructure [1], leading to intensive studies into the resulting proximity effects. In particular, significant effort has been made to increase the spin-orbit coupling (SOC) in graphene by coupling it to transition metal dichalcogenides [2]. However, it remains challenging to study high-quality quantum Hall signatures, which acts as a precise probe of SOC strength [3]. Here we report a direct observation of SOC in a bilayer graphene/WSe₂ heterostructure in quantum Hall measurements [4]. A distinct Landau level (LL) crossing pattern emerges when tuning the charge density and displacement field, originating from a layer-selective SOC proximity effect. By analyzing the LL structure, we simultaneously estimate both Ising (~2.2 meV) and Rashba SOC (~15 meV) energy scales, which are consistent with the theoretical predictions of interlayer twist angle dependence. Our study provides a high mobility system with potential to realize novel topological electronic states and manipulate spin in nanostructures.

1:51PM X51.00014: Atypical Quantized Hall Resistances in Millimeter-Scale Epitaxial Graphene $p$-$n$ Junctions  
ALBERT RIGOSI (Presenter), National Institute of Standards and Technology, DINESH PATEL, National Taiwan University, MARTINA MARZANO, INRIM, MATTIAS KRUSKOPF, HEATHER M. HILL, HANBYUL JIN, JIUNING HU, ANGELA HIGHT WALKER, National Institute of Standards and Technology, CHI-TE LIANG, National Taiwan University, MASSIMO ORTOLANO, Politecnico di Torino, LUCA CALREGARO, INRIM, DAVID B NEWELL, National Institute of Standards and Technology — Epitaxial graphene (EG) on silicon carbide (SiC), which grows on hexagonal SiC at high temperatures, can be nearly defect-free on the centimeter scale and exhibits properties that make it suitable for large-scale and high-current applications. We have demonstrated the millimeter-scale fabrication of monolayer epitaxial graphene $p$-$n$ junction devices using simple ultraviolet photolithography, thereby significantly reducing device processing time compared with electron beam lithography typically used for obtaining sharp junctions. This work presents the resulting experimental data obtained from these devices when introducing multiple current inputs in several different configurations. Furthermore, the LTspice circuit simulator is used to examine the various rearrangements of the electric potential in the device when injecting current at up to three independent sites. These measurements yield nonconventional, fractional multiples of the typical quantized Hall resistance at the $v=2$ plateau ($R_H = 12.9$ kΩ) that take the form: $a/b * R_H$. Here, $a$ and $b$ have been observed to take on values such 1, 2, 3, and 5 to form various coefficients of $R_H$. These results support the potential for drastically simplifying device processing time and may be used for many other two-dimensional materials.

2:03PM X51.00015: Spin waves in canted antiferromagnet of bilayer graphene  
HAILONG FU (Presenter), KE HUANG, Pennsylvania State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, JUN ZHU, Pennsylvania State University — Antiferromagnets are promising candidates for spintronics applications thanks to their high-frequency dynamics and insensitivity to external magnetic field perturbations. The $\nu=0$ quantum Hall state in bilayer graphene supports a canted antiferromagnetic (CAF) phase when a small electric field is applied perpendicular to the plane. This state is predicted to support dissipationless spin transport through a superfluidity mechanism [1]. Previous experiments showed that spin waves can be excited by a finite dc bias on one side of a quantum Hall region and detected on the other side using a non-local transport setup [2, 3]. Here we report on spin wave transport through the $\nu=0$ CAF state of bilayer graphene. In our devices, we observe spin wave excitations with non-zero dc bias thresholds similar to what’s reported [2]. We also observe, in certain measurement setups, strong non-local signals with a dc bias threshold close to zero, only when the $\nu=0$ state is in the CAF phase. We present the temperature, magnetic field, and electric field dependence of the zero-threshold signal and discuss potential origins.

11:15AM X52.00001: Spin Relaxation Times of Copper Phthalocyanine (CuPc) Qubits diluted in Diamagnetic Zinc Phthalocyanine (ZnPc) Host Matrices*  
CHANDLER MERRILL (Presenter), HENNA POPLI, HANS MALISSA, Physics and Astronomy, University of Utah, RYAN STOLLEY, JOEL MILLER, Chemistry, University of Utah, VALY VARDENY, CHRISTOPH M BOEHME, Physics and Astronomy, University of Utah — We report on electron paramagnetic resonance (EPR) measurements of powder CuPc prepared in a solid-state complex, ZnPc. The free electron spin of CuPc constitutes a two-state quantum system that may potentially be a candidate as a quantum bit (qubit) for quantum computing applications [1]. We test whether the CuPc electron spin increases its spin dephasing time, $T_2$, when the exchange interactions between adjacent CuPc qubits is reduced by diluting CuPc molecules in a zinc phthalocyanine (ZnPc) host matrix [2] at concentrations of 0%, 1%, 5%, and 10%, which modifies the average distance between CuPc molecules. ZnPc is a diamagnetic molecule that nominally does not exhibit an EPR signal and, also, the dominant Zn isotopes are I=0. We study the system using continuous wave and pulsed EPR, and we find similar results to previous studies on CuPc in liquid host matrices, $T_2$ on the order of 1 µs observed for both, CuPc as well as another yet unidentified paramagnetic center that is likely due to an admixture to the ZnPc matrix. We also study the temperature dependence of the EPR signals between 5 K and room temperature. [1] M.Warner et. al, Nature, 503, 504(2013). 11:27AM X52.00002: First Principles Studies of the Structural Evolution of a Dicyanobenzene Molecular Junction with Gold Electrodes  
MO LI (Presenter), JOSHUA YOUNG, New Jersey Inst of Tech, MANUEL SMEU, Physics, Binghamton University — Molecular electronics have attracted attention due to their potential in decreasing the size of transistors to the molecular scale. We present our first principles studies of the structural and electronic properties of a single-molecule dicyanobenzene junction with gold electrodes. Density functional theory (DFT) was used to simulate the formation process of the dicyanobenzene molecular junction by elongating a gold nanowire with a dicyanobenzene molecule placed above a thin gold wire. As the wire was stretched and broken, we found four significant stages of system rearrangement. The molecule first rotated (the first stage) and then gradually slipped into the junction and bonded to the gold atomic tips in three stages. For each stage, we performed calculations using the non-equilibrium Green's function combined with the DFT (NEGF-DFT) method to obtain the electronic transport pathway and the conductance of the molecular junction. We found that after the main transmission channel switches from via the gold bridge to via the molecule, the conductance increases while the junction is elongated, which is due to an interesting alignment between the frontier molecular levels and the Fermi energy of the electrodes.
11:39AM X52.00003: Scanning tunneling microscopy study of atomistic energy level engineering in donor-acceptor molecules  GIANG DUC NGUYEN (Presenter), GARY TOM, Stewart Blusson Quantum Matter Institute, University of British Columbia, CHRISTOPHER M TONGE, ZACHARY M HUDSON, Department of Chemistry, University of British Columbia, SARAH A BURKE, Stewart Blusson Quantum Matter Institute, University of British Columbia — Donor-acceptor materials show highly tunable electronic properties via exchange of the donor and acceptor units, making them appealing for light-harvesting and light-emitting applications. While ab-initio calculations can be used for guidance in molecular design of these complexes, there has been little microscopic characterization of the donor-acceptor electronic interaction at the molecular level. Here we present atomistic energy level engineering in N-heterotriangulence derivatives functionalized with different acceptor units. Individual isolated molecules deposited on Ag(111) substrate were studied with scanning tunneling microscopy (STM). The bond-resolved STM (BRSTM) technique was performed to confirm the molecular structure. We performed STM spectroscopy to obtain the molecular energy levels with the spatial distribution mapping of molecular orbitals respectively. Our STM results are corroborated by density function calculations and macroscopic optical absorption/emission measurements.

11:51AM X52.00004: Temperature and Pressure Dependent Properties of A3Ti2O7* SIZHAN LIU (Presenter), New Jersey Inst of Tech, ELI STAVITSKI, ZHENXIAN LIU, Brookhaven National Laboratory, SUYIN WANG, YU-SHENG CHEN, Argonne National Laboratory, BIN GAO, JAEOOK KIM, SANG-WOOK CHEONG, Rutgers University, SANJIT GHOSE, Brookhaven National Laboratory, TREVOR TYSON, New Jersey Inst of Tech — Theoretical models of the A3Ti2O7 system suggest that electric polarization is due to the combination of the coherent TiO6 octahedral rotation and tilting, both being nonpolar. For the doped A3Ti2O3 systems, different size atoms enable the possibility of site-selective substitution in A’ or A site to tune the TiO6 octahedral rotation and tilting. In this work, a structural study over a broad range of temperatures and pressures has been conducted by x-ray diffraction, Raman spectroscopy, x-ray absorption spectroscopy, x-ray pair distribution function measurements and DFT modeling. The long-range and local symmetries and local atomic and electronic structural changes will be discussed and compared with previous work.

*This work is supported by NSF Grant No. DMR-1809931.
12:03PM X52.00005: Characterizing Cellulose Crystallographic Texture in Plant Cell Walls Using Grazing Incidence X-ray Scattering* SINTU RONGPIPI (Presenter), DAN YE, Department of Chemical Engineering, Pennsylvania State University, WILLIAM JOHN BARNES, SARAH KIEMLE, Department of Biology, Pennsylvania State University, ARTHUR WOLL, Cornell University, Cornell High Energy Synchrotron Source, CHENHUI ZHU, Advanced Light Source, Lawrence Berkeley National Laboratory, CHARLES ANDERSON, DANIEL COSGROVE, Department of Biology, Pennsylvania State University, ESTHER WINTER GOMEZ, ENRIQUE D GOMEZ, Department of Chemical Engineering, Pennsylvania State University — Cellulose, the most abundant biopolymer on earth, is a versatile material with tuneable properties. It exists as semi-crystalline microfibrils in plant cell walls. This crystalline structure is important for plant growth and determines properties of cellulosic materials. However, several aspects of this crystalline structure remain elusive - one of them being orientation of cellulose crystallites. We studied the structure of cellulose in plant primary cell walls through grazing incidence wide angle X-ray scattering (GIWAXS). GIWAXS of cell wall reveal strong texturing of cellulose. The degree of texturing is determined through pole figures constructed from combination of GIWAXS and XRD rocking scans. We find that cellulose texturing depends on developmental age of tissue. GIWAXS of cell wall mutants reveals interactions between wall polysaccharides. We find that cellulose texture is disrupted in pectin and cellulose mutants but not in xyloglucan mutants. These findings provide insights on cellulose crystalline structure which can help design cellulose-like materials and efficient biomass conversion process.

12:15PM X52.00006: Redesign and Develop Effective Liposomal Formulation for Prodrug Delivery Through Synchrotron X-ray Studies of Molecular Interactions* TIEP PHAM (Presenter), PAOLA LEON-PLATA, PIN ZHANG, CHANG LIU, Chemical Engineering, University of Illinois at Chicago, WEI BU, BINHUA LIN, Institute of Molecular Engineering, University of Chicago, YING LIU, Chemical Engineering, University of Illinois at Chicago — Liposomal formulations may provide advantages for drug delivery to overcome high dose and toxicity issues of anticancer chemotherapy prodrugs such as capecitabine. However, because of the enormous combination and the unique molecular structure of the prodrug, it is difficult to prepare liposomal-capcitabine formulations with high drug loading and long-term stability based on empirical trials.

In this study, we synthesized a capecitabine analogue by conjugating a carbon chain of cetyl chloroformate with 5-fluorouracil (5FU) (5FU-PAL). We optimized the liposomal formulation of 5FU-PAL for prolonged blood circulation and sustained release based on the understanding of molecular packing and interactions of 5FU-PAL and phospholipids at the gas-water interface by employing synchrotron X-ray reflectivity (XR) and grazing incidence X-ray diffraction (GIXD) integrated with a Langmuir trough. It was found that 5FU-PAL interacts strongly with positively charged lipid in the head group region. The studied could precisely quantify the maximum drug loading in the liposomal formulations. It is also found that 5FU-PAL at the air-water interface folded into highly-ordered multiple layer structures.

Long-Term Performance Prediction of Mixed Matrix Membranes at Different Adsorbent Dose and Operating Conditions*  
RAKA MONDAL (Presenter), Chemical Engineering, Indian Institute of Petroleum and Energy, Vizag — Mixed matrix membranes (MMMs) with nanoparticles showing adsorption property of small sized solute can find wide application in large-scale water purification. The breakthrough behavior of the membrane dictates its life indicating need for regeneration or eventual replacement. A two-dimensional transient model was developed using equations of continuity, motion and convective-diffusive-adsorption based solute transport. The governing partial differential equations has been solved using finite element method by COMSOL v5.3® software package. The model was verified for adsorptive removal of chromium(VI) from synthetic solution using graphene oxide incorporated MMM hollow fibers. The model parameters were evaluated using experimental data of long-term filtration the solution with respect to throughput and rejection characteristics. The validated model was extended for simulation of large-scale filter interrelating feed concentration, adsorbent dose, trans-membrane pressure drop and cross flow rates. From the simulation, at a fixed operating condition, a performance curve was generated linking and breakthrough volume of the MMMs. It can be extended for design of any large-scale hollow fiber MMM based filtration system.

Time-dependent mechanical response of ice adhesion on metal substrates*  
MARINA MACHADO DE OLIVEIRA (Presenter), Chemical Engineering, University of Wyoming, JOSEPH R MURPHY, WILLIAM RICE, Physics, University of Wyoming, JOHN ACKERMAN, VLADIMIR ALVARADO, Chemical Engineering, University of Wyoming — Ice adhesion on aerospace-relevant materials is both complex and poorly understood. Measuring and understanding the underlying physics requires reliable testing techniques that can yield multifaceted datasets. The latter includes surface morphology (i.e., roughness and its spatial correlation structure), resolving substrate-induced strain, and direct mechanical testing of adhesion. Our initial creep test data using a stress-controlled rheometer showed an apparent adhesion dependence on both surface roughness and temperature: namely, that the adhesion strength is higher for rougher surfaces and seems to increase with temperature. To shed light on these initial findings, we performed time-dependent stress ramps from -20 to -7°C to determine the dynamical stress relaxation mechanism. Additionally, we investigated the spatial correlation surface roughness maps for aluminum specimens. Stress-ramp results confirmed a connection between surface roughness and apparent adhesion. Moreover, the creep-test behavior appears to represent an upper bound of the time-dependent adhesive behavior of ice. These results take us a step forward to understanding ice adhesion mechanisms.

*We acknowledge funding support from NASA Grant WY-80NSS17M0049
12:51PM X52.00009: Electrical Measurement of Water Assisted Ion Desorption and Solvation on Isolated Carbon Nanotubes  PATRICK EDWARDS (Presenter), BO WANG, Physics, University of Southern California, STEVE CRONIN, Electrical Engineering, University of Southern California, ADAM W. BUSHMAKER, Physical Sciences Laboratories, The Aerospace Corporation — With continued reduction in the feature size of device structures we are quickly approaching the one-dimensional limit of electrical conduction. In this regime it becomes increasingly important to study the effects of individual dopants and defects on device performance. Recent studies on the electrical properties of suspended carbon nanotube field-effect transistors (CNT-FETs) have revealed extreme sensitivity in device conductivity in the presence of individual gaseous ions adsorbed at the nanotube surface. We will present an investigation on the mean residence time of gaseous ions adsorbed on the surface CNT-FETs with and without native surface water layers that exist in atmospheric conditions. Devices dehydrated by various methods were all found to have substantially higher mean ion residence times. We propose that native water molecules in ambient conditions provide a reduction pathway for incoming gaseous ions, yielding Hydronium ions ($\text{H}_3\text{O}^+$). We characterize the interaction between these ions with the CNT-FET surface via large switching events in device conduction and compare to measurements taken on desiccated devices.

1:03PM X52.00010: Enhancing Superionic Conductivity in Cluster-Based Sodium-Rich Antiperovskites  HONG FANG (Presenter), PURUSOTTAM JENA, Virginia Commonwealth Univ — Sodium (Na) superionic conductors are the key to developing next-generation solid-state batteries with safety and low cost. However, most of the known Na-conductors exhibit limited ionic conductivities at room temperature (RT), hindering their practical applications. To meet the challenge, a series of Li- and Na-rich antiperovskite superionic conductors based on cluster ions (e.g. $\text{BH}_4^-$ and $\text{BCl}_4^-$) have been theoretically developed [e.g. Fang et al. PNAS 114, 11046, 2017; ACS App. Mat. Inter. 11, 963, 2018]. These materials exhibit superior properties as solid electrolytes with greatly enhanced ionic conductivities at RT. One cluster-based solid electrolyte of such, $\text{Na}_3\text{O(BH)}_4$, has been successfully synthesized for the first time most recently and its measured RT ionic conductivity is well above $10^{-3}$ S/cm which is four orders of magnitude higher than that of its halogen counterparts Na$_3$OX (X = Cl, Br, I) [Sun et al. J. Am. Chem. Soc. 141, 5640, 2019]. In this work, we aim to further enhance the ionic conductivity of the Na-superionic conductor by using chemical mixing according to the size effect. The study further shows the advantage of utilizing cluster ions as building blocks, introducing additional degrees of freedom into tuning the properties of superionic conductors.

1:15PM X52.00011: Absorption spectra and density of states of cubic Frenkel exciton system with Gaussian diagonal disorder*  ABDELKRIM BOUKAHIL (Presenter), Physics Department, University of Wisconsin - Whitewater, NOUREDINE ZETTILI, Department of Physical and Earth Sciences, Jacksonville State University — We used the coherent potential approximation to investigate the density of states and the optical absorption of Frenkel exciton systems in cubic lattices with nearest neighbor interactions and a Gaussian diagonal disorder. Our results for the simple cubic are in good agreement with previous investigations using finite-array calculations.

*A.B. acknowledges support from the University of Wisconsin-Whitewater.
Flexible bimodal photoemission electron source based on Au-coated fiber optic nanotips

SAM KERAMATI (Presenter), University of Nebraska - Lincoln, ALI PASSIAN, Oak Ridge National Laboratory and University of Tennessee, VINEET KHULLAR, Oak Ridge National Laboratory, JOSHUA BECK, CORNELIS UITERWAAL, HERMAN BATELAAN, University of Nebraska - Lincoln — Ultrashort laser-driven coherent electron sources based on nanotip needles have been studied motivated by their desired properties for ultrafast electron diffraction and microscopy, electron point projection microscopy, etc. While the conventional schemes require focusing the fs laser beam on or near the apex of a nanotip, which is prone to misalignment and unwanted scattering, we demonstrate and characterize a nanotip electron source based on tapered optical fibers coated with Au on one end. Our theoretical analysis followed by detailed experiments at a range of visible wavelengths confirm that the observed nonlinear electron emission is assisted by surface plasmon excitation in the metallized fiber taper. Fiber tips leverage over the conventional tips in two major ways: 1) They are alignment-free by end-fire coupling, 2) They emit not only using ultrashort pulsed lasers but also by low-power CW diode lasers in the long wavelength regime. The fiber tips are useful where back-illumination or raster scanning an electron source is needed as in electron nanolithography using a single fiber or a bundle for parallel processing.

Investigation of multicolored and white light emission from IR-excited nano-particles

LIDONG MA (Presenter), BALDASSARE DI BARTOLO, Boston College — The search for multicolored light produced by some IR laser-excited luminescent nano-powders has revealed, for laser power exceeding a threshold value, the emission of white light (WL) with black-body characteristics. We are directing our research to the study of the physical parameters that may influence the threshold power of the laser and the efficiency of the WL emission.

A typical compound that we are investigating consists of nano-powders of SrZrO3 doped with Yb. The parameters of relevance include Yb concentration, pressure, temperature, size of nano-crystals, exciting power and wavelength of the laser, dynamical parameters such as decay and build-up patterns.

The aim of this research is both theoretical and experimental: theoretical for I will try to uncover the mechanism of the WL production and experimental for the possible application as efficient light sources of systems similar to the ones that we will investigate (oxide nano-powders doped with lanthanide or transition metal ions).

The “new” light sources in the market (fluorescence lights sources, and LED lamps) beat the Edison bulbs in efficiency, but they do not produce the black-body emission of the Edison bulbs that is most pleasing to the eye.
On-and-off chip magnetic cooling for semiconductor nanostructures below 1 mK*  

DOMINIK ZUMBUHL, MOHAMMAD SAMANI (Presenter), University of Basel — Magnetic cooling has the potential to make the regime beyond dilution refrigerators and below 1 mK accessible to experiments, to investigate interesting novel physics such as exotic quantum phases, new (topological) quasi particles and unprecedented quantum coherence, e.g. in quantum transport. In Basel, the strategy is to cool each of the sample wires with its own, separate demagnetization refrigerator and to simultaneously provide on-chip cooling. This approach reduces external heat leaks (off-chip cooling) and provides local cooling (on-chip) where it’s most effective.

This strategy has proven highly successful in metallic Coulomb blockade thermometers, where temperatures below 1 mK were recently demonstrated. Efforts in semiconductors such as 2D gases and nanostructures are underway, integrating ideas such as large metallic reservoirs on low-resistance ohmic contacts and metallic back gates for on-chip cooling. Semiconductor noise of typical micro-eV scale (corresponding to 10s of mK) presents a serious obstacle for on-chip thermometry. We are exploring methods which are insensitive to charge-noise and employ these as integrated on-chip microkelvin thermometers.

A realistic dimension-independent approach for charged defect calculations in semiconductors  

HUI-XIONG DENG (Presenter), JUN-WEI LUO, Institute of Semiconductors, SUHUAI WEI, Beijing Computational Science Research Center — First-principles calculations of charged defects have become a cornerstone of research in semiconductors and insulators by providing insights into their fundamental physical properties. But current standard approach using the so-called “jellium model” has encountered computational difficulty for low-dimensional semiconducting materials. In this presentation, we propose a physical, straightforward, and dimension-independent universal model to calculate the formation energies of charged defects in both three-dimensional (3D) bulk and low-dimensional semiconductors. This realistic model reproduces the same accuracy as the traditional jellium model for most of the 3D semiconducting materials, and remarkably, for the low-dimensional structures, it is able to cure the divergence caused by the artificial long-range electrostatic energy introduced in the jellium model, and hence gives meaningful formation energies of defects in charged state and transition energy levels of the corresponding defects. Our realistic method, therefore, will have significant impact for the study of defect physics in all low-dimensional systems including quantum dots, nanowires, surfaces, interfaces, and 2D materials.

Session X53 DCMP: Superconducting, Electronic and Chemical Properties of 2D Materials Mile High Ballroom 1F - Amber McCreary, National Institute of Standards and Technology
11:15AM X53.00001: Andreev Reflection in Pseudospin-1 System*  XIAOLONG FENG
(Presenter), YING LIU, YEE SIN ANG, SHENGYUAN YANG, Singapore University of Technology and Design — An incoming electron can be reflected as a hole at a normal-metal (N)/superconductor (S) interface, known as Andreev reflection. And a perfect Andreev reflection is predicted at two-dimensional metal/s-wave superconductor interface. Compared with previous models in which the N sides are of two-dimensional electron gas and graphene, we find a perfect Andreev reflect with a larger incident angle allowed at pseudospin-1 metal/s-wave superconductor interface. Additionally, an all-angle perfect Andreev reflection occurs in the limits. To support our discoveries, we study the differential conductance which can be observed directly in experiments.

11:27AM X53.00002: Tunneling spectroscopy as a probe of fractionalized excitations in RuCl3/graphene stacks*  ALESSANDRO PRINCIPI (Presenter), Physics and Astronomy, University of Manchester, MATTEO CARREGA, NEST, Istituto Nanoscienze, Consiglio Nazionale delle Ricerche — Recent studies of alpha-RuCl3 have spurred a significant deal of interest. This material is predicted to well approximate a Kitaev quantum spin liquid, a topologically-ordered state that supports fractionalized spin excitations. Several experimental studies have focused on large bulk samples, while few of them have dealt with lateral transport in proximity to thin multilayers finding unexpected results. In this work, we model the electron tunnelling through thin alpha-RuCl3 samples encapsulated with graphene and study signatures of fractionalised excitations in spin-unpolarized tunnelling currents. Since such devices can be produced by several labs in the world, our aim is to validate tunnelling spectroscopy as a tool to address the intriguing physics at play in thin alpha-RuCl3 multilayers.

11:39AM X53.00003: On-Chip Strain Enhanced Superconductivity in 1T'-MoTe₂* TARA PENA (Presenter), WENHUI HOU, AHMAD AZIZIMANESH, Electrical and Computer Engineering, University of Rochester, CARLA WATSON, Physics and Astronomy, University of Rochester, ARFAN SEWAKET, STEPHEN M WU, Electrical and Computer Engineering, University of Rochester — Two-dimensional transition metal ditellurides have been found to have unique electronic/structural phase transitions with respect to strain. Bulk Weyl semimetal 1T'-MoTe₂ has been shown to exhibit enhanced superconductivity from the nominal value of 100 mK up to 7 K under applied hydrostatic pressure. In this work, we explore the use of on-chip thin film stress capping layers to achieve the same effect from in-plane strain on exfoliated 1T'-MoTe₂. These stress capping layers are analogous to the SiNₓ capping layers used in industrial strained silicon processes. We examine 1T'-MoTe₂ channels under various thin film stressors and observe superconducting onsets at temperatures as high as 4 K. Devices are sensitive to both geometry and stressor layer composition. Control devices eliminate the potential of this effect arising from defect formation or unintended doping. Challenges related to low-temperature thin film strain transfer, and thermal matching of the stressor layers will be explored. Upon further optimization and standardization, this technique can be used to explore the superconducting phase diagram of MoTe₂ with respect to strain, temperature, and thickness.

11:51AM X53.00004: Unconventional Superconductivity in Semiconductor Artificial Graphene* TOMMY LI (Presenter), Freie Univ Berlin, HARLEY SCAMMELL, Harvard University, JULIAN P INGHAM, Boston University — Unconventional superconductivity featuring large pairing energies has attracted immense interest, yet tractable microscopic theories have proven elusive. A major breakthrough has been the advent of twisted bilayer graphene (TBG), which serves as a simple model system to `look under the hood' of unconventional superconductivity. We propose a new model, within current experimental reach, to investigate the microscopics of strong-binding superconductivity. Our proposed device is semiconductor artificial graphene, a two dimensional electron gas overlaid with a periodic potential. We demonstrate that this system realises a new mechanism for pairing, whereby the topology of the Dirac points gives rise to an attraction in the \( p + ip \) channel. The pairing interaction, which originates from charge dynamics on the interlocking sublattices, dominates due to antiscreening, and -- in contrast to graphene -- can be strongly enhanced through device engineering. The unconventional superconducting gap provides a realisation of a Fulde-Ferrell-Larkin-Ovchinnikov state. The pairing strength is similar to TBG, and within the accuracy of our calculations we find \( T_c \) up to 20 K for InAs heterostructures.

12:03PM X53.00005: Structural, Topological, and Superconducting Properties of 2D Tellurium Allotropes from \textit{ab initio} Predictions*  
CHUNYAO NIU (Presenter), CHUNXIANG ZHAO, Zhengzhou University, Zhengzhou 450001, China, XIAOLIN CAI, Henan Polytechnic University, Jiaozuo 454000, China, YU JIA, Zhengzhou University, Zhengzhou 450001, China, ZHENYU ZHANG, University of Science and Technology of China, Hefei 230026, China — 2D Tellurium, will extended the realm of two-dimensional (2D) materials to group-VI elements beyond the discovery of graphene, phosphorene, and borophene, and it will provide new candidates for next-generation electronic and optoelectronic device applications. Through the particle-swarm optimization searches combined with \textit{ab initio} calculations, we further predict 31 novel stable 2D tellurium allotropes with various geometric structures which sorted by different thickness of atomic layers (termed as M-α, B-α, T-α, T+α, and so on). Their thermodynamic stabilities have been carefully verified by the phonon modes calculations. We show that four (the B-α, B-β, B-γ, and B-η phases) exhibit topological insulators, and three (B-β, B-ε and T-κ phases) are intrinsic superconductors with Tc ~8 K. Interestingly, B-β phase possesses both topological and superconducting properties, which is the 2D monolayer material that have such intrinsic properties and may provide an appealing platform for exploring topological superconductivity in 2D systems.

12:15PM X53.00006: Proximity induced spin-orbit splitting in graphene nanoribbons on transition metal dichalcogenides*  
ENRICO ROSSI (Presenter), SATRIO GANI, ERIC J WALTER, Physics, William & Mary — We study the effect of transition metal dichalcogenides (TMD) on the electronic structure of graphene nanoribbons (GNRs) from first-principles. We consider both semiconducting TMDs and metallic TMDs and different stacking configurations. We find that when the TMD is semiconducting the effects on the band structure of the GNRs are small. In particular the spin-splitting induced by proximity on the GNR's bands is only of the order of few meV irrespective of the stacking configuration. When the TMD is metallic, such as NbSe2, we find that the spin-splitting induced in the GNRs can be very large and strongly dependent on the stacking configuration. For optimal stacking configurations the proximity-induced spin-splitting is of the order of 20 meV for armchair graphene nanoribbons, and as high as 40 meV for zigzag graphene nanoribbons. This results are encouraging for the prospect of using GNR-TMD heterostructures to realize quasi one-dimensional topological superconducting states.

12:27PM X53.00007: Electron-electron interactions, valleys, and band nesting in gated MoS$_2$ quantum dots. LUDMILA SZULAKOWSKA (Presenter), University of Ottawa, MACIEJ BIENIEK, Wroclaw University of Science & Technology, PAWEL HAWRYLAK, University of Ottawa. We report on the effect of valley, spin and band nesting on the many-electron properties of gated MoS$_2$ quantum dots. We start with single electron atomistic calculation for a computational box with periodic boundary conditions containing up to $10^6$ atoms, using a tight binding model developed from ab-initio methods for MoS$_2$ [1,2]. The effect of the metallic gates is modelled as a parabolic lateral confining potential. We find a twofold degenerate energy spectrum of confined electrons originating from the two non-equivalent valleys K and -K as well as a sixfold degenerate ladder of states associated with six secondary conduction band minima Q [3]. These electronic states up to 5 K-derived shells are then populated with up to 6 electrons and electron-electron interactions are turned on. We demonstrate that the large intra-valley exchange interaction determines the many-electron ground state of these QDs. As a consequence, with varying QD size and confining potential, a valley-polarized and spin-polarised broken symmetry ground states emerge.

12:39PM X53.00008: Ultra-thin van der Waals crystals as semiconductor quantum wells* JOHANNA ZULTAK (Presenter), SAMUEL MAGORRIAN, VLADIMIR FAL’KO, ROMAN GORBATCHEV, Univ of Manchester. Control over the electronic spectrum at low energy is at the heart of the functioning of modern advanced electronics which highly relies on meticulous engineering of the size quantization of electrons in quantum wells. This avenue hasn’t yet been explored in 2D materials. Here we transfer this concept onto the van der Waals heterostructures which utilize few-layers films of InSe as quantum wells. Precise control over the energy of the subbands and their uniformity guarantees extremely high quality of the electronic transport in such systems. Using novel tunnelling and light emitting devices, we reveal the full subbands structure by studying resonance features in the tunnelling current, photoabsorption and light emission. [1]

Observation of tunable plasmons in large area type-II Weyl semimetal films*  CHONG WANG (Presenter), SHENYANG HUANG, QIAOXIA XING, GUOWEI ZHANG, FANJIE WANG, YANGYE SUN, YUANGANG XIE, YUCHEN LEI, ZHENGZONG SUN, HUGEN YAN, Fudan Univ — The observation of the highly tunable and confined plasmons in Graphene has stimulated the exploration of plasmons in other 2D materials. Here, for the first time, plasmonic resonance modes are observed in CVD-grown large area films of WTe$_2$, which is known as a type-II Weyl semimetal, by far-infrared absorption spectroscopy. Plasmon-phonon hybridization is revealed by mapping the plasmon dispersion on Si/SiO$_2$ substrates. The plasmon frequency is tunable by changing the temperature and film thickness. Moreover, the plasmon modes are still observable with film thickness down to 8 nm, indicating the potential for tuning by gate. Our results represent a first look at the plasmon in large area CVD-grown Weyl semimetal films and suggest a practical platform to experimentally study the topological plasmons.

The Origin of Hydrophilicity on 1T'-MoS$_2$  LAURA NICHOLS, XIAO SHEN (Presenter), Univ of Memphis — Single-layer MoS$_2$ has been shown to excel in many applications like as a catalyst, supercapacitor, transistor, and biosensor. It has been shown that there is a correlation between the catalytic activity and the metallic character of the surface. Consequently, the metallic phase of MoS$_2$ has been shown to surpass the performance of the semiconducting phase. However, the metallic phase is less energetically favorable than the semiconducting 2H phase, and it is unstable in air. Recently, it has been shown that a metallic phase of MoS$_2$ is stable in water. This metallic phase is also found to be hydrophilic which provides additional advantages in applications as a supercapacitor or biosensor. We attribute this metallic phase to 1T'-MoS$_2$ and investigate the origin of the hydrophilic behavior. Through first-principles calculations, we found that, with a sulfur vacancy on the surface, dissociative adsorption of a water molecule is favorable only on the 1T' surface. The water dissociation on the surface not only increases the hydrophilicity of the surface, but it also explains the enhanced stability of 1T'-MoS$_2$ in water by reducing the energy difference between the 1T' and 2H phases.
**1:15PM X53.00011: Metal-based nanomats as catalysts for self-oscillating Belousov-Zhabotinsky reactions**

**VISHESH SHARMA** (Presenter), **KABEER JASUJA**, **PRATYUSH DAYAL**, Indian Inst of Tech Gandhinagar — Chemical reactions exhibiting self-sustained oscillations have been used to replicate “life-like” characteristics in various synthetic systems. Belousov-Zhabotinsky (BZ) reactions are such reactions that exhibit a periodic color change of the solution, facilitated by oxidation and reduction of the metal-ion catalyst. Recently, we have shown that by using 0D-2D heterostructures as catalytic mats, specifically graphene-based nanosheets decorated with Ce or Ru nanoparticles, the frequency of oscillations for the BZ reactions are significantly enhanced. Here, however, we establish that bare metal nanosheets can also be used to catalyze BZ reactions. In particular, we show that when bare Ceria and Ru nanosheets are used as catalysts for BZ reactions, the oscillations change depending upon the presence of oxy-functional groups. Also, we designed hybrid 0D-2D metal catalysts, decorating Ce and Ru NPs on respective Ru and Ce nanosheets. Our experiments reveal that the frequency of oscillations is dependent on the conductivity of the bare metal nanosheets and the NP loading. Although our work focusses on BZ reactions, our findings open up new avenues to tune characteristics of dynamical systems through the use of catalytic nanomaterials.

**1:27PM X53.00012: Stable out-of-plane piezoelectric group-IV monochalcogenide monolayers with a buckled honeycomb structure**

**SHIVA POUDEL** (Presenter), **SALVADOR BARRAZA-LOPEZ**, Physics, Univ of Arkansas-Fayetteville — We used DFT to study 12 group-IV monochalcogenide monolayers MX (M=Si, Ge, Sn, Pb and X =S, Se, Te) with a 2-fold degenerate honeycomb structure. The exchange of M and X atoms yields a two-fold degenerate structure and the bucking of atoms in the unit cell provides a thickness Δz and an out-of-plane electric polarization. A 2D structural phase transformation is discussed from the perspective of elastic energy barriers J \[1,2,3,4\]; J is the smallest energy required to change the buckled unit cell (Δz>0) onto a planar unit cell (Δz=0). These materials will not undergo a 2D phase transformation. For comparison, silicene has a similar structure and a lower J and undergoes the 2D structural transformation \[5\]. This study increases the understanding of relationships among the structure, ferroelectric behavior, and structural phase transformations in 2D materials with structural degeneracies.

1:39PM X53.00013: A spectrum of exfoliable 1D van der Waals materials and their electronic properties*  
YANBING ZHU (Presenter), Stanford University, DANIEL A REHN, Los Alamos National Laboratory, EVAN ANTONIUK, GOWOON CHEON, RODRIGO MOURA FREITAS, ADITI KRISHNAPRIYAN, EVAN J. REED, Stanford University — Data-mining efforts suggest there are hundreds of bulk materials with the potential to be exfoliated into one-dimensional (1D) structures. We combine data-mining with DFT calculations to elucidate the properties of 1D wires. We identify several materials that have the potential to be more readily exfoliable than the commonly studied 1D-like materials tellurium and selenium and examine the bulk and single-wire electronic characteristics. While layered materials have received significant attention, their 1D van der Waals counterparts have received relatively small amounts, yet are likely to have many of the same qualities that make layered materials of interest for a number of applications.

11:15AM X56.00001: Role of Coulomb correlations in the charge density wave of CuTe
SOORAN KIM (Presenter), Kyungpook National University, BONGJAE KIM, Kunsan National University, KYOO KIM, Max Planck POSTECH/Korea Research Initiative — A quasi-one-dimensional layered material CuTe undergoes a charge density wave (CDW) transition in Te chains with a modulation vector of \( q_{\text{CDW}} = (0.4, 0.0, 0.5) \). Here, using first-principles calculations, we demonstrate that the correlation effect of Cu is critical to stabilizing the 5 × 1 × 2 modulation of Te chains. The phonon calculation with the strong Coulomb correlation exhibits the imaginary phonon frequency at \( q_{\text{ph0}} = (0.4, 0.0, 0.5) \), indicating the structural instability. The corresponding lattice distortion of the soft mode agrees well with the experimental modulation. These results demonstrate that the CDW transition in CuTe originates from the interplay of the Coulomb correlation and electron-phonon interaction. Furthermore, we investigated the stability of the CDW state in a CuTe monolayer, Similarly to its bulk structure, we find the phonon soft mode at \( q = (0.4, 0.0) \), indicating structural instability, which only appears with the correlation effect on Cu. Interestingly, by reducing the interlayer interactions, tuning of the CDW modulation may be possible, as demonstrated by the modulation pattern in quasi-one-dimensional Te chains being different from that in the bulk counterpart.

**11:27AM X56.00002: Optical Enhancement of Superconductivity via Targeted Destruction of Charge Density Waves**

HOSSEIN DEHGHANI (Presenter), ZACHARY RAINES, VICTOR GALITSKI, MOHAMMAD HAFEZI, UMD, Joint Quantum Institute — It has been experimentally established that the occurrence of charge density waves is a common feature of various under-doped cuprate superconducting compounds. The observed states, which are often found in the form of bond density waves (BDW), often occur in a temperature regime immediately above the superconducting transition temperature. Motivated by recent optical experiments on superconducting materials, here, we propose a new approach for the enhancement of superconductivity by the targeted destruction of the BDW order. Since BDW states are usually found in competition with superconductivity, suppression of the BDW order enhances the tendency of electrons to form Cooper pairs after reaching a steady-state. By investigating the optical coupling of gapless, collective fluctuations of the BDW modes, we argue that the resonant excitation of these modes can melt the underlying BDW order parameter.

**11:39AM X56.00003: Charge density waves in a quantum plasma**

ZHAOYU HAN (Presenter), Department of Physics, Stanford University, SHIWEI ZHANG, Center for Computational Quantum Physics, Flatiron Institute, XI DAI, Physics Department, Hong Kong University of Science and Technology — We analyze the instability of an unpolarized uniform quantum plasma consisting of two oppositely charged fermionic components with varying mass ratios against charge and spin density waves. Using density functional theory, we treat each component with the local spin density approximation and a rescaled exchange-correlation functional. Interactions between different components are treated with a mean-field approximation. In both two and three dimensions, we find leading unstable charge density wave modes in the second-order expansion of the energy functional, which would induce the transition to quantum liquid crystals. The transition point and the length of the wave vector are computed numerically. Discontinuous ranges of the wave vector are found for different mass ratios between the two components, indicating exotic quantum phase transitions. Phase diagrams are obtained, and a scaling relation is proposed to generalize the results to two-component fermionic plasmas with any mass scale. We discuss the implications of our results and directions for further improvement in treating quantum plasmas.
**11:51AM X56.00004: A Quantum Monte Carlo Study of the Effect of Strain on Charge Density Wave Order in the Holstein Model**

BENJAMIN COHEN-STEAD (Presenter), RICHARD THEODORE SCALETTAR, University of California, Davis, NATANAEL C. COSTA, International School for Advanced Studies, EHSAN KHATAMI, San Jose State University — We investigate charge ordering in the Holstein model in the presence of anisotropic hopping, $t_x t_y = (1-\delta)(1+\delta)$, as a model of the effect of strain on charge density wave (CDW) materials. Using Quantum Monte Carlo simulations, we show that the CDW transition temperature is relatively insensitive to moderate anisotropy $\delta \leq 0.3$, but begins to decrease more rapidly at $\delta \geq 0.4$. However, the density correlations change significantly for moderate $\delta$. Accompanying mean-field theory calculations show a similar qualitative structure, with the transition temperature relatively constant at small $\delta$ and a more rapid decrease for larger strains. We also obtain the density of states $N(\omega)$, which provides clear signal of the charge ordering transition at large strain, where finite size scaling of the charge structure factor is extremely difficult because of the small value of the order parameter.

**12:03PM X56.00005: Charge Density Waves on a Decorated Honeycomb Lattice**

CHUNHAN FENG (Presenter), University of California, Davis, HUAIMING GUO, Beihang University, RICHARD THEODORE SCALETTAR, University of California, Davis — Tight binding models like the Hubbard Hamiltonian are most often explored in the context of uniform intersite hopping $t$. The electron-electron interactions, if sufficiently large compared to this translationally invariant $t$, can give rise to ordered magnetic phases and Mott insulator transitions, especially at commensurate filling. The more complex situation of non-uniform $t$ has been studied within a number of situations, perhaps most prominently in multi-band geometries where there is a natural distinction of hopping between orbitals of different degree of overlap. In this paper we explore related questions arising from the interplay of multiple kinetic energy scales and electron-phonon interactions. Specifically, we use Determinant Quantum Monte Carlo to solve the Holstein Hamiltonian on a \`decorated honeycomb lattice', consisting of hexagons with internal hopping $t$ coupled together by $t'$. This modulation of the hopping introduces a gap in the Dirac spectrum and affects the nature of the topological phases. We determine the range of $t/t'$ values which support a charge density wave phase about the Dirac point of uniform hopping $t = t'$ as well as the critical transition temperature $T_c$.

12:15PM X56.00006: Charge-density-wave melting in the one-dimensional Holstein model*
JAN STOLPP (Presenter), Institut for Theoretical Physics, Universität Göttingen, JACEK HERBRYCH, Wroclaw University of Science and Technology, FLORIAN DORFNER, Arnold Sommerfeld Center for Theoretical Physics, Universität München, ELBIO DAGOTTO, Department of Physics and Astronomy, University of Tennessee and ORNL, FABIAN HEIDRICH-MEISNER, Institut for Theoretical Physics, Universität Göttingen — We study the real-time dynamics in the half-filled Holstein model starting from different initial states that are charge-density-wave (CDW) ordered. The regime where the relaxation dynamics is dominated by electron-phonon coupling is considered (complementary to the case studied in [1] where strong electron interactions were present) and we focus on the far-from-equilibrium regime. Here, a clear separation of time scales between electron relaxation and phonon equilibration is identified. In the transient dynamics we observe effects like a temporal self trapping of the electrons. The study of such regimes is enabled by extending the time-evolving block decimation algorithm with local basis optimization, previously applied to single-polaron dynamics [2], to a half-filled system.

12:27PM X56.00007: Tuning of physical properties through chemical intercalation in two dimensional Fe_xNbTe_2
SHENG LI (Presenter), HANLIN WU, University of Texas at Dallas, KEITH TADDEI, Oak Ridge National Laboratory, XIQI WANG, University of Houston, GARETH A OFENSTEIN, University of Texas at Dallas, CLARINA RELOJ DELA CRUZ, Oak Ridge National Laboratory, LI YANG, Washington University in St. Louis, BING LV, University of Texas at Dallas — The layered materials with weak van der Waals interlayer interaction have created a rich platform to exhibit exotic properties such as charge density wave (CDW), topological properties, 2D magnetism, and superconductivity. NbTe_2 is a layered materials with the same structure as 1T' WTe_2 phase. It has a CDW transition above 550K, and meanwhile exhibits superconducting transition below 0.74K. By intercalation of magnetic iron atoms, we are expecting to observe the interplay among superconductivity, CDW and magnetism in this NbTe_2 system. Indeed, through manipulation of the synthetic conditions, we observed drastic changes of crystal symmetry and physical properties in the same material Fe_xNbTe_2 with ground state from spin glass insulator to antiferromagnetic metal down to 2K, with more exotic magnetoresistivity and Hall behavior observed. The details of these results will be presented and the interplay of multiple orders in this system will be further elaborated.
12:39PM X56.00008: Unity-order refractive index tunability at room temperature in 1T-TaS$_2$, a strongly correlated material  WEIJIAN LI, MING YI, KEVIN F KELLY, GURURAJ NAIK (Presenter), Rice Univ — Strongly correlated materials could greatly respond to a stimulus due to their collective behavior. Thus, strongly correlated materials are well studied in the past for their tunable properties, especially electrical and thermal. However, their optical properties remain to be explored. In this work, we study the optical properties of 1T-TaS$_2$, a quasi-2D material supporting charge density waves (CDW). 1T-TaS$_2$ is the only material to exhibit a nearly commensurate CDW phase at room temperature and its electrical and thermal properties are shown to exhibit a large change with temperature, DC and AC biases, pressure, and light. Here, we study the optical properties of 1T-TaS$_2$ under DC and AC biases, different intensities of optical illumination, and at different temperatures. Under all these conditions, we observe a unity-order change in the refractive index of thin films of 1T-TaS$_2$. We hypothesize that the stacking of CDWs in this material changes with stimulus resulting in its optical constants to change. ARPES and STM measurements are underway to verify the hypothesis. Our discovery of the large tunability of optical constants of 1T-TaS$_2$ presents opportunities in studying light-matter interaction in strongly correlated materials and its application to nanophotonic devices.

12:51PM X56.00009: Probing Finite-Momentum Charge Collective Modes in Electron Doped SrTiO$_3$ * SAMANTHA RUBECK (Presenter), MELINDA S RAK, MATTEO MITRANO, ALI HUSAIN, JIN CHEN, University of Illinois at Urbana-Champaign, ALEXANDER EDELMAN, University of Chicago, PETER B LITTLEWOOD, Argonne National Lab, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — Electron doped strontium titanate, SrTiO$_3$, becomes a bulk superconductor at carrier densities as low as 5.5×10$^{17}$ cm$^{-3}$. The pairing mechanism in this dilute material, which is unconventional and widely debated, has recently been explained in terms of hybridization between the longitudinal optic phonons and the electronic plasmon collective modes. Using momentum-resolved inelastic electron scattering (M-EELS), we observed sub-200 meV acoustic and optic phonons, which have previously been implicated in the superconducting pairing, and a valence plasmon from the free carriers. For a carrier density of 2.137×10$^{20}$ cm$^{-3}$, the plasmon blueshifts with decreasing temperature, while its width and dispersion deviate from RPA predictions. In this talk, I will discuss evidence for hybridization of these modes for different carrier densities.

1:03PM X56.00010: Understanding the relationship between the structural and dielectric changes at the order-disorder transition in TEA(TCNQ)$_2$* ADAM BERLIE (Presenter), Rutherford Appleton Lab, IAN TERRY, MAREK SZABLEWSKI, Physics, Durham University, MARK TELLING, Rutherford Appleton Lab — Triethylammonium bis-7,7,8,8-tetracyanoquinodimethane (TEA(TCNQ)$_2$) shows an interesting dielectric behaviour, at approximately 220 K, where both the capacitance and the loss exhibit clear anomalies. This corresponds to the order-disorder transition where it is believed that the TEA cations freeze within the structure promoting both a structural change which manifests itself also as a change in dielectric properties. To understand this further, we have coupled quasi-elastic neutron scattering and other techniques to provide information on how these TEA cations are actually moving and what motions freeze out. We find that two things happen; firstly at 100 K we believe the methyl groups start rotating but at 220 K, the TEA cations rotate with a spherical radius of ~1.7 Angstroms.

*We would like to acknowledge the ISIS Neutron and Muon Source and the Institute Laue-Langevin for access to beam time.

1:15PM X56.00011: The Raman study of the structural transition in metallic LiOsO$_3$ single crystal under high pressure up to 40 GPa* JUNJIE GAO, SUYU FU, JUNG-FU LIN, Geological Sciences, University of Texas at Austin, KAZUNARI YAMAURA, Research Center for Functional Materials, National Institute for Materials Science, JIANSHI ZHOU (Presenter), Geological Sciences, University of Texas at Austin — LiOsO$_3$ is a novel metal that undergoes a second order phase transition from a centrosymmetric R-3c structure to a polar R3c structure at $T_s=140$ K [1]. In this work, we report the measurements of Raman scattering including polarized and unpolarized models on LiOsO$_3$ single crystal at different pressure up to 40 GPa with a diamond anvil cell. There are four phonon peaks in the phase at ambient condition; new peaks emerge for $P > 8.5$ GPa. The feature of the high-pressure phase resembles that of LiOsO$_3$ below $T_s$ at ambient condition [2]. The polar phase appears to be stabilized under high pressure, which is consistent with the observation of $dT_s/dP > 0$ from the resistivity measurement [3]. Results from the symmetry analysis and first-principles calculations will also be presented.

*This work was supported by NSF, DMR 1905598.
The interplay between electronic correlations and spin-orbit coupling often gives rise to novel quantum phases of matter. When spin-orbit coupling is strong and orbital degeneracies are present, the lattice also plays an important role in determining magnetic ground states. In the Lacunar spinel GaTa$_4$Se$_8$, electronic correlations localize a single unpaired electron on tetrahedral clusters of Ta ions, while spin-orbit coupling generates $J_{\text{eff}}=3/2$ magnetic degrees of freedom. At ambient pressures and $T=50$ K, GaTa$_4$Se$_8$ undergoes a magnetic transition to a valence bond solid state accompanied by a structural dimerization. Hydrostatic pressures can induce an insulator to metal transition, but the evolution of magnetic correlations and the crystal structure across this transition is not known. I will present a series of low temperature, high pressure x-ray diffraction measurements following the evolution of the structural dimerization in GaTa4Se8 across the pressure-induced insulator to metal transition. These measurements shed light on the coupling of spin-orbital pseudo spins with the crystal lattice.

NMR Investigation of Ferroquadrupolar Order in TmVO$_4$*  

TmVO$_4$ undergoes a tetragonal to orthorhombic structural phase transition below 2.2K due to a cooperative Jahn-Teller distortion. The Tm ions experience a crystal-field effect with a non-Kramer's ground state doublet, and undergo ferroquadrupolar order that breaks the C$_4$ symmetry of the lattice. This material is therefore is a model system to investigate Ising nematic ordering without competing phases. While previous $^{51}$V NMR has been hampered by significant line broadening due to demagnetization fields at low temperature, here we present improved results in a single crystal of ellipsoidal shape for which this broadening is absent. These are the first NMR measurements in which an ellipsoidal sample is used that has been carefully cut by a focused ion beam (FIB).

*Work at UC Davis was supported by the NSF under Grant DMR-1807889.
The interplay between competing ordered states and superconductivity has long been identified as key to understanding high-temperature superconductivity. In the case of the iron pnictide superconductors, superconductivity coexists with SDW order and electronic nematicity. BaNi$_2$As$_2$, a structural analogue of the high temperature pnictide superconductor BaFe$_2$As$_2$ has recently been reported to host CDW order and electronic nematicity in conjunction with superconductivity. Interestingly, as a function of Sr doping, CDW and nematicity in the system is suppressed. Upon suppression of this order to absolute zero, a dramatic, six-fold enhancement of the superconducting transition temperature is observed. This system could thus serve as a model system to study the enhancement of superconductivity in the vicinity of quantum critical fluctuations. Here we present detailed high-resolution ARPES measurements of the Sr$_x$Ba$_{1-x}$Ni$_2$As$_2$ series as a function of temperature, comparing the measured band dispersion and Fermi surfaces to density functional theory calculations of the electronic structure carried out in different phases. Utilizing both the experimental and theoretical data, we discuss various mechanisms for the CDW and electronic nematicity.

Effects of Electron Irradiation on Nematic-Like Phase Transition in BaNi$_2$P$_4$* ELIZABETH KRENKEL (Presenter), MAKARIY A TANATAR, ERIK I TIMMONS, JIAN WANG, LIN-LIN WANG, KIRILL KOVNIIR, RUSLAN PROZOROV, Ames Lab, MARCIN KONCZYKOWSKI, Ecole Polytechnique — We present the results of an experimental study of a tetragonal-to-orthorhombic phase transition with rather high transition temperature (T$_{TO} \sim 380$ K) in the clathrate material BaNi$_2$P$_4$. The transition is accompanied by formation of structural domain patterns which are revealed in polarized optics studies. The electrical resistivity shows metallic behavior both above and below T$_{TO}$. The transition temperature is notably affected by the low-temperature (20 K) irradiation with relativistic 2.5 MeV electrons. Additional insight into the nature of the transition is obtained from Hall effect measurements and band structure calculations. Similarity to the behavior found in the parent compounds of iron based superconductors will be discussed.

*This work was supported by the US DOE, Office of Science, BES Materials Science and Engineering Division under contract DE-AC02-07CH11358.
11:15AM X57.00001: First-principles studies of defect-induced electron-phonon interactions in 2D semiconductors* JUN-HO LEE (Presenter), Physics, UC Berkeley, LIANG TAN, Molecular Foundry, Lawrence Berkeley National Laboratory, JONAH HABER, Physics, UC Berkeley, KATHERINE COCHRANE, BRUNO SCHULER, ALEXANDER WEBER-BARGIONI, Molecular Foundry, Lawrence Berkeley National Laboratory, JEFFREY B NEATON, Physics, UC Berkeley — Point defects have played an important role in semiconductor physics to tune physical and chemical properties of the host material. A variety of point defects have been uncovered in monolayer transition-metal dichalcogenides (TMDs), showing unique fingerprints in structural, electronic, and vibronic properties. In this talk, I will summarize calculations of electron-phonon interactions in monolayer TMDs with point defects using density functional theory and density-functional perturbation theory. We find that local atomic-scale structure in the vicinity of point defects is distorted, leading to spatially-localized electronic states, which in turn possess strong electron-phonon coupling. We discuss our calculations in the context of ongoing scanning tunneling spectroscopy measurements.

11:27AM X57.00002: Defect hydrogenation in monolayer transition metal dichalcogenides LEHUA GU (Presenter), GUANQUN ZHANG, DI HUANG, SHUAI ZHANG, SHIWEI WU, Department of Physics, Fudan University — Structural defects in two-dimensional semiconducting transition metal dichalcogenides (TMDs) play an important role in modifying their physical properties. In this talk, we will present our optical spectroscopic study on the defect engineering of monolayer TMDs through hydrogenation. Photoluminescence spectra show the evolution of defect exciton upon hydrogenation, which behaves differently from that of free excitons. Time-resolved photoluminescence measurement further reveals the change of defect-induced exciton dynamics in monolayer TMDs after hydrogenation process. Based on the experimental observations, we propose a microscopic picture for the hydrogenation process in monolayer TMDs. Our work thus demonstrated the ability to tune the defect emission and gained the knowledge of structural defects in monolayer TMDs.
11:39AM X57.00003: Optical quantum emitters in monolayer MoS$_2$ fabricated with nm-precision by He ion microscopy*  ELMAR MITTERREITER, Walter-Schottky-Institut, TU Munich, BRUNO SCHULER, ALEXANDER WEBER-BARGIONI, Molecular Foundry, Lawrence Berkeley National Laboratory, ALEXANDER HOLLEITNER, CHRISTOPH KASTL (Presenter), Walter-Schottky-Institut, TU Munich — Atomistic defects in semiconductors can serve as single photon emitters for applications in quantum technologies. However, in conventional semiconductors, defects are often buried in the bulk hampering integration of defect centers into photonic circuits. Recently, it was demonstrated that color centers with narrow emission are generated in single layer MoS$_2$ by focused He-ion beam irradiation [1], opening a natural pathway for device integration. Here, we investigate atomistic defects in MoS$_2$ deliberately induced by focused He ion bombardment. We use scanning tunneling microscopy (STM) to resolve the atomistic defect states. By imaging line patterns with atomic resolution, we can quantify the lateral resolution of the defect patterning to be better than 7 nm.

11:51AM X57.00004: Crucial Role of many-body van der Waals interaction in understanding the stability of point defects in MoS$_2$ monolayer  ARUNIMA SINGH (Presenter), SASWATA BHATTACHARYA, Physics, Indian Institute of Technology Delhi — The present study investigates the stability of native point defects in MoS$_2$ monolayer by first-principles based approach under the framework of density functional theory (DFT). The property of band gap transition from indirect to direct on going from bulk to monolayer in MoS$_2$, establishes a huge potential in the optoelectronic industry. Defects being inevitable, their role in tuning the band gap for photovoltaics is an important approach. Initially, we have obtained the phase diagram that shows the most stable defect states with minimum Gibbs free energy of formation. We have considered charged and neutral states, of three vacancies and five antisites with the inclusion of many-body vdW interaction, which have posed a significant change in the stability pattern. The stable defect states as observed by HSE06 functional are, V$_S$ (-2,+2), V$_{Mo}$ (-2,+2), S$_{Mo}$ (-2) antisite and S$_{2Mo}$ (+2) antisite. They also have significant concentration at the finite temperature range of 50K-1000K, which is achieved by ab-initio atomistic thermodynamics along with the DFT input. Further, the S$_{Mo}$ (-2) and S$_{2Mo}$ (+2) antisites have tuned the band gap in the range 1.1 – 1.8 eV. These states have shown optical response in the visible region, hence increasing the absorption capability of MoS$_2$ monolayer.
12:03PM X57.00005: Electrical control of neutral and charged excitons in few-layer InSe*
ZHENGGUANG LU (Presenter), Natl High Magnetic Field Lab, DMITRY SHCHERBAKOV, Ohio State University, YUXUAN JIANG, SHAHRIAR MEMARAN, WENKAI ZHENG, Natl High Magnetic Field Lab, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, LUIS BALICAS, Natl High Magnetic Field Lab, CHUN NING LAU, Ohio State University, DMITRY SMIRNOV, Natl High Magnetic Field Lab — Indium selenide(InSe), a layered metal chalcogenide semiconductor with a layer dependent band structure, high electron mobility and strong light-matter interaction, has gained considerable interests as a promising material system for optoelectronics applications. Monolayer InSe is predicted to be an indirect band gap material. However, few-layer InSe maintains direct band gap optical properties and enables electrostatic gating. Here we report the observation of the electrical field controlled neutral and charged excitons in high-quality hBN encapsulated few-layer InSe devices. Near the charge neutrality point, the photoluminescence (PL) spectra display a strong and narrow peak with 4meV linewidth (at 20K) associated with the recombination of neutral excitons. By adjusting the Fermi energy, we can tune the PL emission so that the PL spectra are dominated either by positively charged or negatively charged trions. We found relatively large trion binding energies of about 8meV, which further indicates the potential of few-layer InSe for optoelectronics.

12:15PM X57.00006: Trions in doped MoS2 monolayer. YAROSLAV V. ZHUMAGULOV, ITMO University, ALEXEI V. VAGOV, Institute for Theoretical Physics III, University of Bayreuth, DMITRY GULEVICH, ITMO University, VASILI PEREBEINOS (Presenter), State Univ of NY - Buffalo — Transition metal dichalcogenide monolayers are semiconductors with a direct transition at the K-point of the Brillouin zone. The band structure of these materials has unique features that makes them ideal candidates for valleytronics. Tightly bound negative trions, a quasiparticle composed of two electrons and a hole, can be optically optically created with valley and spin polarized holes. They possess a large binding energy and large oscillator strength, such that they dominate optical spectra even at room temperature. Here, we solve Bethe-Salpeter equation for the three particle wavefunction at finite momentum. Our results enable us to explain existing data on temperature and doping dependence and predict new spectroscopic features in doped MoS2.
12:27PM X57.00007: Visualizing Electrically Driven Photon Emission from Individual Defects in WS\textsubscript{2} with Atomic Resolution [Invited]  
BRUNO SCHULER (Presenter), KATHERINE COCHRANE, JUN-HO LEE, Lawrence Berkeley National Laboratory, CHRISTOPH KASTL, Technical University Munich, ED BARNARD, ED WONG, Lawrence Berkeley National Laboratory, NICHOLAS J BORYS, Montana State University, ADAM SCHWARTZBERG, FRANK OGLETREE, JEFFREY B NEATON, Lawrence Berkeley National Laboratory, JAVIER GARCIA DE ABAJO, ICFO – The Institute of Photonic Sciences, ALEXANDER WEBER-BARGIONI, Lawrence Berkeley National Laboratory — Point defects in two-dimensional semiconductors are exciting atomic quantum systems. Recently, we established the correlation of atomic structure, electronic and optical properties of native point defects in monolayer WS\textsubscript{2} [1] and MoSe\textsubscript{2} [2] using atomically resolved scanning probe microscopy techniques. We identified isoelectronic chalcogen and transition metal substitutions as the dominant defects based on their unique electronic fingerprint [1,2]. Sulfur vacancies that are absent in as-grown samples could be selectively generated by high temperature annealing in vacuum and exhibit strong spin-orbit splitting [3].

Here we demonstrate electrically driven photon emission from individual, atomically defined defects in a 2D semiconductor [4]. We show atomically resolved luminescence maps from sulfur vacancy defects and native chromium substituents. The widely tunable optical emission generated by charge carrier injection into localized defect states in a 2D material is a powerful platform for electrically driven single-photon emission.

1:03PM X57.00008: Unexpected symmetries in twisted bilayer MoSe\textsubscript{θ}  
PRIYA MAHADEVAN (Presenter), POONAM KUMARI, S N Bose Natl Ctr Basic Sci — Spin-orbit interactions lead to a large spin-splitting of the valence band maximum at K in MoSe\textsubscript{2} monolayers. However, on stacking a second layer of MoSe\textsubscript{2} in the same manner (2H) as found in the bulk, one finds that there is no spin splitting. This has been attributed to the presence of inversion symmetry. As exploiting the spin splitting at the K valleys allows us to increase the functionality, an obvious route to making the bilayers useful for exploring the coupled spin and valley physics is through breaking inversion symmetry. We examined this by rotating the top layer of the bilayer by an angle θ with respect to the lower layer. The choice of angles was restricted to those for which one had reasonable sized supercells and were otherwise arbitrary. Surprisingly, we found several instances where the spin splitting vanished, though there was no breaking of inversion symmetry. An unusual mechanism behind this is identified. Additionally, we found that while the spin splitting existed for theta, it vanished for 60 - θ. This unusual behavior, we find, is a consequence of the symmetry of the hexagonal Brillouin zone.
Twist-Angle Dependence of Moiré Excitons in MoSe$_2$/MoS$_2$ Twisted Heterobilayers

BO-HAN LIN (Presenter), YUNG-CHUN CHAO, CHIEN-JU LEE, FU-HSIEN CHU, LE-CHIH CHO, LI-SYUAN LU, JUNG-JUNG SU, WEN-HAO CHANG, Electrophysics, National Chiao Tung University — Twisted heterobilayers (hBLs) of transition metal dichalcogenides can form a moiré superlattice of periodically varying atomic registry between the two layers. The excitonic properties in twisted hBLs can be altered drastically by the formation of moiré minibands that depends sensitively on the moiré periodicity controlled by the twist angle. To study the twist-angle dependence, conventional methods based on mechanical exfoliation and transfer of individual crystals are tedious to fabricate many hBLs with various twist angles within 5°. Here we report on the study of moiré excitons in MoSe$_2$/MoS$_2$ hBLs fabricated by stacking a large MoSe$_2$ flake on an ensemble of highly-oriented MoS$_2$ flakes grown by chemical vapor deposition. The small angle variations in the MoS$_2$ flakes form a large number of hBLs with various small twist angles, enabling the study of twist-angle dependence of moiré excitons. We observed systematic energy shifts and fine structures in intralayer excitons with the twist angle, signifying the formation of moiré minibands. The polarization selection rules of moiré excitons were also investigated by photoluminescence excitation spectroscopy. Understanding the twist-angle dependent properties of moiré excitons provides insights for future developments of “twistronics”.

Twist-angle dependent interlayer exciton diffusion in MoS$_2$-MoSe$_2$ heterobilayers

CHIEN-JU LEE (Presenter), BO-HAN LIN, FU-HSIEN CHU, LE-CHIH CHO, LI-SYUAN LU, WEN-HAO CHANG, Department of Electrophysics, Natl Chiao Tung Univ — Heterobilayers (HBLs) of transition metal dichalcogenides can form a moiré superlattice with a periodic potential landscape, which can modulate the electronic structure and confine excitons. HBLs can host interlayer excitons (IXs) with electrons and holes separated in different layers, forming a dipolar exciton gas with repulsive Coulomb interactions among the aligned vertical dipoles. The presence of moiré superlattice further imposes an additional length scale that can change the dynamics and transport properties of IXs in HBLs. Here we study the influence of moiré periodicity on the IX diffusion in MoS$_2$-MoSe$_2$ HBLs. We prepared a series of HBLs with small twist angles by stacking monolayer MoSe$_2$ onto MoS$_2$ with well-aligned orientations grown by chemical vapor deposition. Twist-angle dependent photoluminescence (PL) energy of interlayer exciton (IX) were observed, signifying the formation of moiré potential. We further investigated the IX diffusion by time-resolved PL and spatially resolved PL imaging. The interplay between moiré potentials and dipole-dipole interactions of IX leads to exciton-density and twist-angle dependent diffusion length. Our results provide insights in understanding of the localization and delocalization of interlayer excitons in the moiré superlattice.
1:39PM X57.00011: Exciton physics in organic-inorganic 2D perovskites

JEAN-CHRISTOPHE BLANCON (Presenter), HAO ZHANG, WENBIN LI, Rice Univ, MERCOURI KANATZIDIS, Northwestern University, ANDREAS V. STIER, Walter Schottky Institute, Technical University of Munich, JACKY EVEN, PHOTON, INSA Rennes, ADITYA MOHITE, Rice Univ — Organic-inorganic (hybrid) 2D perovskites (2DPKs) is an emerging class of layered materials that feature unique structural characteristics related to the soft and dynamic nature of their lattice structure and organic-inorganic interfaces. There is still little knowledge of the interplay between the physical and structural characteristics. Here, using optical spectroscopy and magneto-absorption, coupled with structural probes, we report the dependence of the formation, dynamics, and recombination of exciton states on the structural and compositional details of 2DPKs. Our work reveals the changes in the exciton properties due to the tuning of the 2DPKs thickness and the size of the organic molecules in the lattice [1]. Moreover, we demonstrate the existence of unique electronic states located at the edge surfaces of 2DPKs that are beneficial for optoelectronic applications [2,3]. Finally, we provide insight into the hetero-coupling between 2D perovskites and monolayer WS$_2$, which yield photoluminescence enhancement by more than one order of magnitude as compared to their constituent [4].

1:51PM X57.00012: Plasmon-Resonant Enhancement of Photocatalysis on Monolayer WSe$_2$

JIHAN CHEN, STEVE CRONIN (Presenter), Univ of Southern California — We present plasmonic enhancement of photocatalysis by depositing 5 nm Au nanoislands onto tungsten diselenide (WSe$_2$) monolayer films.\textsuperscript{1} Under 532 nm wavelength illumination, the bare WSe$_2$ film produces a relatively small photocurrent (20 nA). With the addition of Au nanoparticles, we observe enhancements of up to 7X (0.14 μA) in the measured photocurrent. Despite these relatively small photocurrents, it is remarkable that adequate charge separating fields are generated over just 7.3 Å of material. Here, the improvement in the photocatalytic performance is caused by the local electric field enhancement produced in the monolayer WSe$_2$ monolayer by the plasmonic Au nanoislands, as verified by electromagnetic simulations using the finite different time domain (FDTD) method. The near-field optical enhancement increases the electron–hole pair generation rate at the surface of WSe$_2$, thus, increasing the amount of photogenerated charge contributing to photoelectrochemical reactions.

2:03PM X57.00013: First principles studies of magnetic ion-intercalated transition metal dichalcogenide bilayers*

JONATHAN REICHANADTER (Presenter), ELIZABETH A PETERSON, Physics, UC Berkeley, JEFFREY B NEATON, Lawrence Berkeley National Laboratory — Monolayer transition metal dichalcogenides (TMDs) offer a promising framework for valleytronic applications given their degenerate, yet non-equivalent K,K' points from broken inversion symmetry which exhibit significant spin-orbit interaction induced spin-valley coupling. Recent experimental work1,2 in transferring monolayer TMDs onto ferromagnetic substrates has shown splitting of the K-K' band degeneracy associated with the breaking of time-reversal symmetry. Here we perform ab initio density functional theory calculations of the structural, electronic, and magnetic properties of magnetic ion intercalated MoS2 bilayers. Through investigation of intercalant element, intercalant density, and bilayer spacing and registry, we assess the promise of intercalated bilayer architectures for valley splitting and valleytronic applications.

Session X58 DCMP: Topological Phases in Floquet Systems Mile High Ballroom 3B

11:15AM X58.00001: Phonon-assisted Floquet engineering of second-order topological phases*

SWATI CHAUDHARY (Presenter), ARBEL HAIM, YANG PENG, GIL REFAEL, Caltech — The co-existence of spatial and non-spatial symmetries together with appropriate commutation/anticommutation relations between them can give rise to static higher-order topological phases, which host gapless boundary modes of co-dimension higher than one. Alternative to spatial symmetries, space-time symmetries in a Floquet system can lead to anomalous Floquet boundary modes of higher co-dimensions, presumably with alterations in the commutation/anticommutation relations with respect to non-spatial symmetries. In this work, we discuss how a coherently excited phonon mode can be used to promote a spatial symmetry with which the static system is always trivial, to a space-time symmetry which supports non-trivial Floquet higher-order topological phase. We present two examples— one in class AIII and another in class D where a coherently excited phonon mode promotes the reflection symmetry to a time-glide symmetry such that the commutation/anticommutation relations between spatial and non-spatial symmetries are modified. These altered relations allow the previously trivial system to host gapless modes of co-dimension two at reflection-symmetric boundaries.

**11:27AM X58.00002: Majorana states in a spin or qubit chain with a resonantly modulated coupling**  
MARK DYKMAN (Presenter), Michigan State Univ — We show that a spin or qubit chain with the qubit coupling modulated close to twice the qubit frequency maps on the Kitaev chain. This is an example of topologically nontrivial Floquet dynamics induced in a trivial system by a simple sinusoidal modulation. The nontrivial regime exists in the frequency range with a width determined by the strength of the qubit coupling. Preparation of the system in this regime involves going through a quantum phase transition where the excitation gap closes, in the limit of an infinite chain. The results are compared with a quantum phase transition induced by a resonant parametric modulation of a system of coupled nonlinear mesoscopic oscillators, which remains topologically trivial [1].

*The work was supported in part by the NSF, DMR-1708331 and DMR-1806473, and by the Google faculty research award.

**11:39AM X58.00003: A periodic classification of local unitary operators**  
FENNER HARPER, XU LIU, RAHUL ROY (Presenter), University of California, Los Angeles — We present a complete topological classification of single particle local unitary operators, which are usually represented by local unitary matrices. The classification is performed in the ten symmetry classes and leads to a “periodic table”. Local unitary operators arise naturally in systems with an evolution generated by a quantum possibly time-varying (Hermitian) Hamiltonian. They also describe unitary operations in more general contexts, such as in quantum walks or models for information flow. The classification is complete in the sense that two local unitary operators have the same topological invariants if and only if they can be continuously deformed into each other. It allows one to distinguish “locally generated” unitary operators in a given symmetry class (generated by local Hamiltonians) from those that are not locally generated and provides a complete table of local operators which are not locally generated.

*NSF Career DMR-1455368

**11:51AM X58.00004: Classification of Interacting Floquet Phases with U(1) Symmetry**  
CAROLYN ZHANG (Presenter), MICHAEL LEVIN, University of Chicago — Recently, it has become clear that periodically driven many-body systems can support new types of topological phases that have no counterpart in static systems. These anomalous Floquet topological phases have been studied for both interacting and non-interacting systems in different symmetry classes. In this talk, we consider interacting Floquet topological phases with U(1) charge conservation symmetry in two spatial dimensions. We propose a complete classification of Floquet phases of this kind, in the case where the Floquet eigenstates are short-range entangled, and we show that each phase can be labeled by a topological invariant which can be computed either at the edge of an open system or in the bulk. The latter formula provides a way to measure the invariant and also reveals a connection to the bulk magnetization density discussed in previous work.

*This work is supported by the National Science Foundation Graduate Research Fellowship Program under Grant DGE-1746045 and the Simons Foundation through the “Ultra-Quantum Matter” Simons Collaboration.
Emergent topological phases in synthetic dimensions with low-frequency laser pumping

PEIZHE TANG (Presenter), SHUNSUKE SATO, ANGEL RUBIO, Theory Department, Max Planck Institute for the Structure and Dynamics of Matter — In the Floquet-Bloch theory, when a physical system is driven by a strong external optical field, its dynamics can be conveniently represented in a higher dimensional Floquet lattice. Here, we consider the 2D Dirac systems under strong external optical driving. In the low-frequency limit, new topological states of matter emerge in the synthetic 2+1D, including Dirac nodal line, helix nodal lines, and Weyl fermions. In contrast to conventional Floquet topological states under the high-frequency limit, there is no anomalous Hall signal observed in this system although the time-reversal symmetry is broken and the Floquet energy gap opens at the crossing point. Furthermore, we use the quantum Liouville equation with phenomenological dissipation to simulate the evolution of 2D Dirac fermions under the strong optical field with low frequency, we confirm the existence of the Floquet states and find the simulated transport properties consistent with our prediction from Floquet theory in synthetic 2+1D.

*This work was supported by the European Research Council (ERC-2015-AdG694097). We acknowledge funding from the European Unions Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No 793609.

Floquet second-order topological insulator

RANJANI SESHADRI (Presenter), Physics, McGill University, ANIRBAN DUTTA, DIPTIMAN SEN, Centre for High Energy Physics, Indian Institute of Science — Higher-order topological insulators (HOTIs) are a recent entrant to the field of topology in condensed matter physics. Usually, two-dimensional topological insulators host robust one-dimensional edge modes. These are related to the bulk properties via topological invariants such as the Chern number. However, in HOTIs, there are zero-dimensional corner modes, which, in case of a square-shaped sample, say, are confined to the four vertices of the square. In this work, a variant of the well-known Bernevig-Hughes-Zhang (BHZ) model is used to construct a two-dimensional HOTI. When this system is driven periodically by varying one of the model parameters in time, i.e., using a Floquet drive, multiple corner states may appear depending on the driving frequency and other parameters. The system can be characterized by topological invariants such as the Chern number and a diagonal winding number. The behavior of these invariants can be understood in terms of the value of the Floquet operator at some special points in momentum space.
Out of equilibrium higher-order topological insulator: Floquet engineering and quench dynamics

TANAY NAG (Presenter), SISSA, VLADIMIR JURICIC, NORDITA, BITAN ROY, Lehigh University — Higher order topological (HOT) states, hosting topologically protected modes on lower-dimensional boundaries, such as hinges and corners, have recently extended the realm of the static topological phases. We here demonstrate the possibility of realizing a two-dimensional \textit{Floquet} second-order topological insulator, featuring corner localized zero quasienergy modes and characterized by quantized Floquet quadrupolar moment $Q_{xy}^{\text{Flq}} = 0.5$, by periodically kicking a quantum spin Hall insulator (QSHI) with a discrete four-fold ($C_4$) and time-reversal ($\mathcal{T}$) symmetry breaking mass perturbation. We also analyze the dynamics of a corner mode after a sudden quench, when the $C_4$ and $\mathcal{T}$ symmetry breaking perturbation is switched off, and find that the corresponding survival probability displays periodic appearances of complete, partial and no revival for long time, encoding the signature of corner modes in a QSHI. Our protocol is sufficiently general to explore the territory of dynamical HOT phases in insulators (electrical and thermal) and gapless systems.

Floquet topological flat bands in two-dimensional systems

MUHAMMAD TAHIR (Presenter), HUA CHEN, Colorado State University — Flat electronic bands in equilibrium condensed matter systems have been a common avenue to nontrivial correlation effects, with the twisted bilayer graphene being a most recent prominent example. It is expected that flat quasienergy bands can also enhance interaction effects in time-periodic Floquet systems and may lead to novel interaction driven metastable phases. Here, we propose a general approach to realizing Floquet flat bands with nontrivial topology in 2D or quasi-2D systems subject to circularly-polarized light. By using a simple model that can interpolate between Schrödinger and Dirac electrons, we demonstrate their different band flattening behaviors within Floquet theory. The flat band condition, determined by the ratio between the time-periodic electric field strength and its frequency, can be qualitatively obtained from perturbation theory. Moreover, flat bands argued in this work can be realized without the need of fine tuning in contrast to twisted bilayer graphene. Our proposal may pave the way to novel interaction-driven phases in nonequilibrium systems.

12:51PM X58.00009: Topological Correspondence between Hermitian and Non-Hermitian Systems: Anomalous Dynamics*  JONG YEON LEE (Presenter), Harvard University, JUNYEONG AHN, Physics, Seoul National University, HENGYUN ZHOU, ASHVIN VISHWANATH, Harvard University — The hallmark of symmetry-protected topological (SPT) phases is the existence of anomalous boundary states, which can only be realized with the corresponding bulk system. In this work, we show that for every Hermitian anomalous boundary mode of the ten Altland-Zirnbauer classes, a non-Hermitian counterpart can be constructed, whose long time dynamics provides a realization of the anomalous boundary state. We prove that the non-Hermitian counterpart is characterized by a point-gap topological invariant, and furthermore, that the invariant exactly matches that of the corresponding Hermitian anomalous boundary mode. We thus establish a correspondence between the topological classifications of \((d + 1)\)-dimensional gapped Hermitian systems and \(d\)-dimensional point-gapped non-Hermitian systems. We illustrate this general result with a number of examples in different dimensions. This work provides a new perspective on point-gap topological invariants in non-Hermitian systems.

1:03PM X58.00010: Bulk-edge correspondence and robustness of edge states in a non-unitary three-step quantum walk with PT symmetry  HIDEAKI OBUSE (Presenter), MAKIO KAWASAKI, KEN MOCHIZUKI, Department of Applied Physics, Hokkaido University, NORIO KAWAKAMI, Department of Physics, Kyoto University — Topological phases in non-Hermitian systems have attracted great attention in recent years. It has been shown that a photonic quantum walk with effects of loss is an ideal platform to study topological phases in non-Hermitian systems with parity-time reversal symmetry (PT symmetry)[1]. In the present work, we study topological phases and the associated multiple edge states in non-unitary three-step quantum walks with PT symmetry in one dimension[2]. We show that the non-unitary quantum walk has large topological numbers and numerically confirm that multiple edge states appear as expected from the bulk-edge correspondence. We also study stability of the edge states and find extra stabilization mechanism of the edge states unique to non-unitary systems.

1:15PM X58.00011: A bulk edge connection for Class AIII Floquet insulators*  XU LIU (Presenter), FENNER HARPER, RAHUL ROY, University of California, Los Angeles — We propose edge and bulks invariants for Floquet systems in Class AIII in arbitrary dimensions. These indices are physically motivated and locally computable even in systems with disorder. Finally, we derive a bulk-edge correspondence which relates the nontrivial bulk behavior with the edge modes present on a boundary at the end of the evolution.

*NSF Career DMR-1455368
Kagome lattice network model as a chiral Floquet topological insulator

MATTEO WILCZAK (Presenter), ITAMAR KIMCHI, VICTOR GURARIE, University of Colorado, Boulder, DMITRY K. EFIMKIN, The School of Physics and Astronomy, Monash University — The magnetic proximity effect can open a gap in the spectrum of Dirac electrons at the surface of a topological insulator; on the other hand, topological defects in the magnetization can host topologically protected localized (isolated skyrmion) and propagating (domain walls) states. Here we argue that the electronic structure of Dirac electrons coupled to the skyrmion lattice phase in an insulating magnet (for example, Cu$_2$OSeO$_3$) can be described by the Chalker-Coddington network model (CCN) with the Kagome geometry. We study this model relying on a recent insight that CCN should be thought of as a chiral Floquet topological insulator. While in static systems the number of edge modes is completely determined by calculation of the Chern number for each energy band, in Floquet systems there may be edge modes even when the Chern number for each band is zero. We describe a new topological invariant which is a modified version of the chiral Floquet invariant proposed by Rudner et al. and does not require the construction of an effective Hamiltonian, and which correctly counts the number of edge modes in each spectral gap. We apply this invariant to the Kagome lattice network model and show that it includes both Chern and chiral Floquet phases.

Analysis of Topological States in a Floquet-driven Non-Hermitian System*

ANDREW HARTER (Presenter), NAOMICHI HATANO, Institute of Industrial Science, University of Tokyo — Non-Hermitian Hamiltonians offer a good description of many open systems in which gain and loss are present; crucially, in contrast to their Hermitian counterparts, they may have a complex eigenspectrum. Interestingly, non-Hermitian Hamiltonians which possess PT symmetry [1] can be shown to admit an entirely real eigenspectrum within a certain range of their parameters. It has been shown [2] that certain PT-symmetric lattices can admit topologically non-trivial phases; however, this phase only coincides with the PT-symmetry broken phase, and the topological edge states correspond to imaginary eigenvalues. We examine Floquet driving of this system which, for high enough driving frequencies [3], has been shown to stabilize the edge states. By using a simple two-step, pulsed time dependence, we explore the entire range of driving frequencies to highlight new regions of stability, including those which are explicitly below the high-frequency regime.

X58.00014: Light-induced Topological Insulator with Superlattice Structure* 
HWANMUN KIM (Presenter), HOSSEIN DEHGHANI, University of Maryland, College Park, HIDEO AOKI, Department of Physics, The University of Tokyo, IVAR MARTIN, Material Science Division, Argonne National Laboratory, MOHAMMAD HAFEZI, University of Maryland, College Park — We study the superlattice structure created by light on 2D material. Specifically, we investigate the monolayer graphene irradiated by circularly-polarized (CP) beam where the beam amplitude has spatial periodicity. We numerically study the phase transition between the topological insulator and the normal insulator depending on the superlattice size. To examine the role of lattice shape in the topological property of the system, we investigate the topological phase transition happening in the sheared lattice. By superposing different kinds of beams, our scheme can create a more complicated lattice such as kagome lattice. This wide tunability of lattice can be used for further investigation of interesting dynamics of electrons.

*This research was supported by the Physics Frontier Center at the Joint Quantum Institute.

X58.00015: High-temperature Floquet fractional quantum Hall state in a Kagome lattice with photo-inverted hopping* HANG LIU (Presenter), GURJYOT SETHI, YINONG ZHOU, University of Utah, JIA-TAO SUN, SHENG MENG, Institute of Physics, Chinese Academy of Sciences, FENG LIU, University of Utah — High-temperature fractional quantum Hall (FQH) state is predicted to emerge from geometrically frustrated lattices with topological flat bands, but yet to be demonstrated in realistic systems due to very unusual lattice hopping requirements. Here we show that time-periodic circularly polarized laser (CPL) can effectively invert second-nearest-neighbor kinetic hopping in a Kagome lattice and simultaneously enhance spin-orbit coupling (SOC) in one spin channel, so as to produce an isolated flat Chern band exhibiting high-temperature Floquet FQH effect. CPL-driven monolayer HTT-Pt possesses an unprecedented high flatness ratio $\Delta/\nu \sim 40$, which paves the way to observing the high-temperature FQH state in realistic 2D systems. Meanwhile, the CPL decreases the SOC strength in the other spin channel to form a chiral Kagome band with a high Chern number. Our approach may be generally applicable to engineering exotic topological quantum states in other crystal lattices.

**11:15AM X59.00001: Novel Magnetic Weyl Semimetallic State in Layered Material: Fe$_2$Sn**

BISHNU KARKI (Presenter), BISHNU PRASAD BELBASE, MADHAV PRASAD GHIMIRE, Central Department of Physics, Kirtipur, 44613, Kathmandu, Nepal, Tribhuvan University — Weyl Semimetals (WSMs) are the crystalline substances that are believed to be the sources for massless but charged particle called Weyl fermions. They are found to possess exotic properties such as high mobilities, magneto transport phenomenon, large magneto resistance and quantum hall phenomenon. These properties are expected to be highly applicable for high speed electronics and spintronics, quantum computing, hall effect devices and even in the catalysis. Here we focus on studying the electronic, magnetic and transport properties of hexagonal Fe$_2$Sn. From our density functional theory calculations, the magnetic ground state is found to be ferromagnetic with a total magnetic moment of 4.56μ$_B$/formula unit. The electronic state shows metallic behavior with the band crossing close to the Fermi level. Fe$_2$Sn is predicted to be magnetic WSM based on the identification of 16 Weyl points within an 0.01 eV around the Fermi level with chirality.

**11:27AM X59.00002: Engineering Weyl phases and nonlinear Hall effects in T$_d$-MoTe$_2$**

SOBHIT SINGH (Presenter), JINWOONG KIM, KARIN M RABE, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, New Brunswick, NJ, USA — MoTe$_2$ has recently attracted much attention due to the observation of pressure-induced superconductivity, exotic topological phase transitions, and nonlinear quantum effects. However, there is debate on the intriguing structural phase transitions among various observed phases of MoTe$_2$, and their connection to the underlying topological electronic properties. In this work, by means of density-functional theory (DFT+U) calculations, we describe the structural phase transition between the polar T$_d$ and nonpolar 1T’ phases of MoTe$_2$ in reference to a hypothetical high-symmetry structure T$_0$ that exhibits higher-order topological features. We obtain a total of 12 Weyl points, which can be created/annihilated, dynamically manipulated, and switched by tuning a zone-center polar phonon mode in the T$_d$ phase. We also report on the existence of a tunable nonlinear Hall effect in T$_d$-MoTe$_2$, and predict an emergent nonlinear surface current under the application of an external electric field. The potential technological applications of the tunable Weyl phase and nonlinear Hall effect will be discussed.

11:39 AM X59.00003: Multiple types of van Hove singularities induced by band inversion*

JIAWEI RUAN (Presenter), Nanjing University, University of California at Berkeley, and Lawrence Berkeley National Laboratory, HUAIQIANG WANG, Physics, Nanjing University, STEVEN LOUIE, University of California at Berkeley, and Lawrence Berkeley National Laboratory, HAI-JUN ZHANG, Physics, Nanjing University — Saddle-point Van Hove singularities in the electron density of states can cause system instabilities that lead to exotic phases of matter. Here, we show that such singularities are very common near the Fermi level of topological semimetals and insulators. Using a k.p model analysis, we find that multiple types of saddle points with different divergence behaviors can be induced by band inversion. In particular, we uncover a new type of saddle-like dispersion (called “saddle line”) that significantly enhances the divergence in the density of states. We present examples of ab initio electron band structures of topological materials including monolayer 1T'-WS₂, monolayer decorated stanene, and Dirac semimetal Na₃Bi. Our results suggest a new universal property of topological materials that can lead to further opportunities.

11:51 AM X59.00004: Cd₃As₂: Dirac semimetal to Weyl semimetal*

SANTU BAIDYA (Presenter), DAVID VANDERBILT, Department of Physics and Astronomy, Piscataway, NJ 08854, Rutgers University — Dirac and Weyl semimetals have attracted much attention in the past few years. The Dirac compound Cd₃As₂ has seen renewed interest due to reports of proximity-induced surface superconductivity [1] and quantum Hall effect in thin films [2]. Using first-principles based theoretical methods, we show that by breaking time-reversal symmetry upon the application of an external Zeeman magnetic field, the four-fold degenerate Dirac node in Cd₃As₂ splits into four non-degenerate Weyl nodes, of which two are simple Weyl nodes of chirality ±1 and other have chiral charges of ±2. We calculate the evolution of the Fermi surfaces and their contributions to the anomalous Hall conductivity as a function of magnetic field and Fermi level position. Our work forms a basis for understanding how the resulting hole and electron pockets may play a role in generating complex states such as unconventional forms of superconductivity.

12:03PM X59.00005: Dirac and triple point semimetallic phases in Heusler alloys

CHIRANJIT MONDAL (Presenter), Discipline of Metallurgy Engineering and Materials Science, Indian Institute of Technology Indore, CHANCHAL BARMAN, Department of Physics, Indian Institute of Technology, Bombay, BISWARUP PATHAK, Discipline of Chemistry and Discipline of Metallurgy Engineering and Materials Science, Indian Institute of Technology Indore, AFTAB ALAM, Department of Physics, Indian Institute of Technology, Bombay — We predict full Heusler compounds XInPd$_2$ (X = Zr, Hf and Ti) to be potential candidates for type-II Dirac semimetals. The crystal symmetry of these compounds have appropriate chemical environment with a unique interplay of inversion, time reversal and mirror symmetry. These symmetries help to give six pairs of type-II Dirac nodes on the $C_4$ rotation axis, closely located at/near the Fermi level. Using first principle calculations, symmetry arguments and crystal field splitting analysis, we illustrate the occurrence of such Dirac nodes in these compounds. Bulk Fermi surfaces have been studied to understand the Lorentz symmetry breaking and Lifshitz transition (LT) of Fermi surfaces. Bulk nodes are projected on the (001) and (111) surfaces which form the surface Fermi arcs, that can further be detected by photo-emission and scanning tunneling spectroscopy. By analyzing the evolution of arcs with changing chemical potential, we prove the fragile nature and the absence of topological protection of the Dirac arcs. Our predicted compounds overcome the limitations of the previously reported PtTe$_2$ class of compounds. Further we show breaking of inversion symmetry leads to realize triply degenerate nodal points in Heusler family.

*We thank DST SERB and MHRD India for financial supports.

12:15PM X59.00006: First-Principles Study of Robust Magnetic Weyl Nodal Loops in 5d Cubic Double Perovskites

YOUNG-JOON SONG (Presenter), KWAN-WOO LEE, Division of Display and Semiconductor Physics, Korea University — Topological phenomena have been extensively studied due to their interesting properties in the condensed matter physics. In particular, topological nodal line phases have special features of dispersionless surface states, so-called drumhead surface states. These flat states lead to a large surface density of states, implying instabilities toward surface magnetism or superconductivity.

In this presentation, we will address a few Os-based cubic double perovskites possessing robust magnetic Weyl nodal lines (WNLs), protected by the mirror symmetry, even for considering spin-orbital coupling (SOC). Using first-principles and tight-binding approaches, we have investigated the nature of topological properties in the osmates. Our effective 3-band model of the isolated $t_{2g}$ orbitals indicates that the $dd\sigma$ and $dd\pi$ hoppings result in the nodal lines on the mirror planes. When including both correlation and SOC, these nodal lines are robust only in the broken time-reversal symmetry (TRS) case. Besides, remarkably, our calculated anomalous Hall conductivity shows a single sharp peak at the energy of WNLs due to a strong magnetic anisotropy, implying these WNLs to be experimentally observable.

12:27PM X59.00007: A Dirac semimetal with surface hourglass fermions: BaHgSn  TAN ZHANG (Presenter), ZHIJUN WANG, HONGMING WENG, ZHONG FANG, Institute of Physics, Chinese Academy of Sciences — We proposed that BaHgSn is a Dirac semimetal which hosts hourglass-like surface states protected by glide symmetry. Compared with the topological crystalline insulators (TCI) K'HgSb, BaHgSn has the similar crystal structure, but it has an additional band inversion induced by the stronger bonding and antibonding state splitting at Γ point, which leads to the bulk Dirac point on AΓ path. Due to this additional band inversion, BaHgSn has the $M_2^z$ mirror Chern number $C_{\pm i}^\pm = \pm 3$, while K'HgSb has $Z_2^\prime = (0;000)$ and $C_{\pm i}^\prime = \pm 2$. BaHgSn has the same hourglass-like states as K'HgSb along the $\tilde{X}\tilde{U}$ path on (010) surface, but it has bulk Dirac cone projection along $\tilde{Z}\tilde{\Gamma}$ path and zigzag surface states protected by $C_{\pm i} = \pm 3$ along $\tilde{\Gamma}\tilde{X}$ path. When 5% pression is applied along the y axis, the bulk Dirac point is gapped, and BaHgSn becomes a strong topological insulator (TI) with $Z_2 = (1;000)$. The change of surface states is that bulk Dirac cone projection opens a gap and nontrival zigzag surface states protected by nontrivial $Z_2$ appear along $\tilde{Z}\tilde{\Gamma}$ path. We also calculate the Wilson-loop spectral for (010) surface, the results are consistent with the surface states.

12:39PM X59.00008: Computational search for Dirac and Weyl nodes in f-electron antiperovskites*  ANNA PERTSOVA (Presenter), R.M. GEILHUFE, NORDITA, MARTIN BREMHOLM, Aarhus University, ALEXANDER V BALATSKY, NORDITA — We present the results of a computational search for three-dimensional (3D) Dirac materials in the scarcely studied group of lanthanide antiperovskites [1]. There is no photoemission data available for these materials. We calculate electronic structures using density functional theory which accounts for spin-orbit coupling and strong correlations. We identify massive bulk Dirac states close to the Fermi level in $A_3B$, where $A=$Sm, Eu, Gd, Yb and $B=$Sn, Pb. The 3D Dirac nodes along the $\Gamma$-$M$ direction originate from the band inversion of the cation and anion bands at the $\Gamma$ point. This band inversion is also an indication of a topological crystalline insulator phase [2]. Most of the predicted materials display a finite magnetic moment due to unpaired electrons in the 4f shell. Specifically, in magnetic Eu$_3$BO the degeneracy of the Dirac nodes is lifted, leading to appearance of Weyl nodes. This offers intriguing possibilities of combining magnetism and Dirac/Weyl physics in pristine materials without doping or proximity effects.

12:51PM X59.00009: Strain induced Kramers-Weyl Fermions  JINXIN HU (Presenter), YINGMING XIE, CHENGPING ZHANG, XI DAI, KAM TUEN LAW, Physics, Hong Kong University of Science and Technology — Kramers-Weyl fermions are recently found to be widely supported in chiral crystals and exhibit many novel properties. However, in achiral crystals due to the presence of mirror or roto-inversion symmetries, Kramers Weyl fermions are often obscured to emerge due to the presence of nodal lines. In this work, we show Kramers-Weyl fermions are easily generated by removing the degeneracy of these nodal lines through strain effects. Remarkably, based on realistic DFT calculations, in the strained Rashba semiconductor BiTeI, we find a single Kramers-Weyl fermion near Fermi energy. Moreover, a strain induced quantized circular photogalvanic effect (CPGE) is further established. Our work paved a way to study the topology, optoelectronics by the tuning the chirality of crystals.

1:03PM X59.00010: Insights from magnetic Weyl semimetals: the Berry phase and beyond* [Invited]  BINGHAI YAN (Presenter), Weizmann Institute of Science — It is known that Bloch electrons pick up an anomalous velocity because of the Berry curvature in the magnetic material. Recent discovery of magnetic Weyl semimetals (WSMs) provides a novel, ideal platform to examine the Berry curvature-induced transport phenomena, such as the anomalous Hall effect (AHE) and the thermal version of AHE. We focus on the Wideman-Franz law that governs the fundamental correlation between the charge and heat transport. We reveal a novel mechanism [1] to violate the Wideman-Franz law at the finite temperature by the Berry curvature distribution rather than the inelastic scattering effect, which is distinct from the ordinary (longitudinal) transport. Beyond the linear-response phenomena like AHE, WSMs can generate giant nonlinear optical response (such as the DC photocurrent), which is commonly attributed to the Berry curvature too. As a WSM turns magnetic, however, we find a new class of photocurrent [2,3] by re-examining the nonlinear response theory. It is contributed by the diabatic effect, instead of the Berry phase. Because this is a leading-order phenomena, the induced photocurrent is expected to be much larger compared to the non-magnetic case.

1:39PM X59.00011: Pseudo Dirac Nodal Sphere and its Topological Phase Transitions in a Semimetallic Carbon Network  SHI-ZHANG CHEN (Presenter), Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University, Beijing 100084, China, YUAN-PING CHEN, Faculty of Science, Jiangsu University, Zhenjiang, 212013, Jiangsu, China, WENHUI DUAN, Department of Physics and State Key Laboratory of Low-Dimensional Quantum Physics, Tsinghua University, Beijing 100084, China — Because the global symmetry requirement is hard to achieved, topological nodal sphere is generally a pseudo phase, in which multiple nodal rings form the spherical backbone while the other points on the sphere are approximately degenerate. The physical understanding of nodal sphere, however, remains unclear. Here, we present a tight-binding (TB) model in a tetragonal crystal to simulate the evolution from a nodal sphere to a nodal surface. To provide clear picture, by performing first-principle calculations, a tetragonal carbon network, in which carbon nanotubes (CNTs) interconnected by graphene nanoribbons, is used to identify the pseudo nodal sphere phase. By applying strains, many topological phase transitions and novel semimetallic phases are achieved. The tensile strains lead to a transition from a nodal sphere to a nodal point, and eventually a trivial insulator; while a compressive strain leads to a transition to a nodal tube (uniaxial strains) or a nodal crossbar (biaxial strain), eventually to nodal surfaces, which is in good agreement with our TB modeling. Our results suggest that nodal sphere and nodal surface share the same origin, and their morphologies depend on the inter-CNTs hopping.

1:51PM X59.00012: Topological metals induced by Zeeman effect  SONG SUN (Presenter), ZHIDA SONG, HONGMING WENG, Chinese Academy of Sciences, Institute of Physics, XI DAI, Physics, Hong Kong University of Science and Technology — In the present work, we propose a new way to classify centrosymmetric metals by studying the Zeeman effect caused by an external magnetic field described by the momentum dependent g-factor tensor on the Fermi surfaces. Nontrivial U(1) Berry's phase and curvature can be generated once the otherwise degenerate Fermi surfaces are splitted by the Zeeman effect, which will be determined by both the intrinsic band structure and the structure of g-factor tensor on the manifold of the Fermi surfaces. Such Zeeman effect generated Berry's phase and curvature can lead to three important experimental effects, modification of spin-zero effect, Zeeman effect induced Fermi surface Chern number and the in-plane anomalous Hall effect. By first principle calculations, we study all these effects on two typical material, ZrTe$_5$ and TaAs$_2$ and the results are in good agreement with the existing experiments.

Session X60 DMP: Weyl semimetal, Theory II  Mile High Ballroom 4A - Tag(s): Focus

11:15AM X60.00001: Topological semimetals: from classification to material realization  [Invited] JENNIFER CANO (Presenter), Department of Physics and Astronomy, Stony Brook University — The field of topological semimetals continues to reveal new insights. I will discuss recent developments in the field, starting with the classification of nodal fermions in both magnetic and non-magnetic space groups. I will then introduce new aspects of the bulk-edge correspondence, which elucidate the topological nature of certain non-chiral fermions. Finally, I will discuss routes to material realizations.
11:51AM X60.00002: Topological Vortices in Superconducting Time-Reversal Symmetric Weyl Semimetals  RAUF GIWA (Presenter), PAVAN HOSUR, Univ of Houston — Recent years have shown that superconducting vortices in topological insulators and strongly spin-orbit coupled semiconductors are natural platforms for obtaining Majorana zero modes. We ask the question, "under what conditions do superconducting vortices in Weyl semimetals trap protected Majorana zero modes on the surface?" We show that sufficient conditions for a time-reversal symmetric type I Weyl semimetal (TWSM) to host Majorana modes as above when ordinary BCS superconductivity is induced in them, are (i) the TWSM forms by perturbing a Dirac or a nodal line semimetal, so that kz=0,pi planes contain pairs of opposite chirality Weyl nodes with a small k-space separation (where z is the vortex axis), and (ii) the number of quadruplets of Weyl nodes in these planes is odd. We analytically calculate the topological invariant in this limit using Kitaev's Pfaffian criterion and support it with numerics on a cubic lattice model. Using our criteria, we predict TaAs and its isovalent counterparts to form topological trivial vortices, devoid of Majorana modes. Also, we propose Na(3-x)KxBi with broken inversion symmetry, where doping occurs via interstitial substitution, to be an ideal platform for realizing a non-trivial superconducting vortex with Majorana zero modes at its ends.

12:03PM X60.00003: Finite-Size Effects in the Dynamic Conductivity and Faraday Effect of Quantum Anomalous Hall Insulators  JUNJIE ZENG (Presenter), TAO HOU, ZHENHUA QIAO, Department of Physics, University of Science and Technology of China, WANG KONG TSE, Department of Physics and Astronomy, The University of Alabama — We theoretically study the finite-size effects in the dynamical response of a quantum anomalous Hall insulator in the disk geometry. Semi-analytic and numerical results are obtained for the wavefunctions and energies of the disk within a continuum Dirac Hamiltonian description subject to a topological infinite mass boundary condition. Using the Kubo formula, we obtain the frequency-dependent longitudinal and Hall conductivities and find that optical transitions between edge states contribute dominantly to the real part of the dynamic Hall conductivity for frequency values both within and beyond the bulk bandgap. We also find that the topological infinite mass boundary condition changes the low-frequency Hall conductivity to e^2/h in a finite-size system from the well-known value e^2/2h in an extended system. The magneto-optical Faraday rotation is then studied as a function of frequency for the setup of a quantum anomalous Hall insulator mounted on a dielectric substrate, showing both finite-size effects of the disk and Fabry-Perot resonances due to the substrate. Our work demonstrates the important role played by the boundary condition in the topological properties of finite-size systems through its effects on the electronic wavefunctions.
12:15PM X60.00004: Interplay of non-Abelian band topology with crystalline symmetry
TOMAS BZDUSEK (Presenter), Paul Scherrer Institute, QUANSHENG WU, EPFL Lausanne, ALEXEY SOLUYANOV, University of Zürich, ADRIEN BOUHON, NORDITA, ROBERT-JAN SLAGER, Harvard — We discuss the recently discovered non-Abelian topological invariant that characterizes band nodes inside the momentum space of certain non-interacting metals. This non-Abelian topology prominently arises in systems with PT symmetry (space-time inversion) or with C\textsubscript{2}\textsubscript{T} symmetry (composition of π-rotation with time-reversal). Given the prevalence of these symmetries in most space groups, one expects important implications of the non-Abelian invariant for real materials.

In this talk, we first introduce the quaternion formulation of this topological invariant as obtained by Ref. [1]. We subsequently reformulate the topology using frame rotations and Euler class [2] as developed recently by Ref. [3]. We finally present new results concerning the interplay of the non-Abelian band topology with point-group symmetry. We find that this interplay implies non-trivial conversions between Weyl points, nodal lines, and nodal chains as the system parameters (such as strain or tight-binding coefficients) are tuned.

*Work supported by Moore Foundation's EPIQS initiative and by SNSF Ambizione grant.

12:27PM X60.00005: Strain engineered higher order topological phases for spin-3/2 Luttinger fermions
ANDRAS SZABO (Presenter), RODERICH MOESSNER, Max Planck Inst, BITAN ROY, Lehigh University — Recently, the notion of topological phases of matter has been extended to higher order incarnations, supporting gapless modes on even lower dimensional boundaries, such as corners and hinges. We here identify a collection of cubic spin-3/2 fermions with bi-quadratic touching of Kramers degenerate valence and conduction bands as a platform to strain-engineer higher-order topological (HOT) phases: external uniaxial strain gives birth to a HOT Dirac semimetal or an insulator, depending on its sign, featuring topological \textit{hinge} modes in the strain direction. The insulator in fact exhibits \textit{mixed} topology, and in addition supports edge modes on orthogonal planes. These outcomes are germane when the external strain is applied along one of the C\textsubscript{4v} or coordinate axes, as well as C\textsubscript{3v} or body-diagonal, directions. Our findings place HgTe, gray-Sn, 227 pyrochlore iridates and half-Heusler compounds at the frontier of strain engineered electronic HOT phases.
12:39PM X60.00006: Wiedemann-Franz law and Mott relation for transport coefficients in the non-linear regime*  
CHUANCHANG ZENG (Presenter), Department of Physics and Astronomy, Clemson University, SNEHASISH NANDY, Department of Physics, University of Virginia, ARGHYA TARAPHDER, Department of Physics, Indian Institute of Technology Kharagpur, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University — In contrast to their counterparts in the linear regime, the non-linear anomalous Hall, Nernst, and thermal Hall effects can survive in time-reversal symmetric system in the presence of inversion symmetry breaking. Within the framework of semiclassical Boltzmann theory, we calculate the analytical expressions for the non-linear anomalous transport coefficients, namely, the non-linear anomalous Hall, Nernst, and thermal Hall coefficients. With these expressions, we predict the fundamental relations between the non-linear anomalous electric and thermo-electric transport coefficients, which are the analog of the Wiedemann-Franz law and the Mott relation in the non-linear regime. We also make several experimental predictions for non-linear anomalous Nernst Hall effect in bilayer WTe2 and for non-linear anomalous thermal Hall effect for monolayer transition metal dichalcogenide which can be verified in experiments.

12:51PM X60.00007: Phonon induced topological phase transition in ZrTe5*  
NIRAJ ARYAL (Presenter), XILIAN JIN, WEIGUO YIN, Brookhaven National Laboratory — Layered crystalline material ZrTe5 is a unique material to study topological phase transitions; it is very close to the phase boundary between a weak and strong topological insulator (TI) and one can switch from one phase to another by small perturbations like strain. Recently, photoinduced topological transition from the TI regime to the Dirac semimetallic phase has been reported in this material. Motivated by the aforementioned work, using first-principles calculations and effective model Hamiltonian, we study the transition from the TI regime to the Dirac and Weyl semimetallic phases induced by various phonon modes. The experimental implications of our results are also discussed.

*U.S. Department of Energy
1:03PM X60.00008: Diagnosing and observing topological degeneracies in AI class systems
TIANTIAN ZHANG (Presenter), Department of physics, Tokyo Inst of Tech - Tokyo, HU MIAO, Brookhaven national lab, LING LU, Chinese academy of sciences, SHUICHI MURAKAMI, Department of physics, Tokyo Inst of Tech - Tokyo, ZHONG FANG, Chinese academy of sciences, MARK DEAN, Brookhaven national lab, HONGMING WENG, CHEN FANG, Chinese academy of sciences — Topological states have been widely studied in Fermionic systems for many years, wherever, they are sporadically explored in Bosonic systems, even both Fermions and Bosons are fundamental particles in condensed matter physics. Actually, Bosons can offer a better platform to get spinless band structures where nodal lines can be realized with only parity-time reversal (PT) symmetry, such as phonons. By combining first-principles calculations and meV-resolution inelastic x-ray scattering, we demonstrate the first realization of PT symmetry protected helical nodal lines of phonons in a real material. The combination of theoretical analysis and experimental measurements demonstrate the PT-protected helical nodal lines for the first time in phononic materials. This nodal line is robust because of the spinless nature of phonons, which will open a new route to explore exotic topological states in crystalline materials.

1:15PM X60.00009: Effects of Van der Waals interaction on the phonon and electron band structures of ZrTe$_5$
XILIAN JIN (Presenter), College of Physics, State Key Laboratory of Superhard Materials, Jilin University, NIRAJ ARYAL, WEIGUO YIN, Condensed Matter Physics and Materials Science Division, Brookhaven National Laboratory — Since the theoretical prediction of the existence of the topological insulating phase, ZrTe$_5$ has attracted a lot of interests in its topological nature, which may lead to the low-energy transport edge channels and the quantum spin Hall (QSH) effect in its two-dimensional form. Possible strain or photon induced topological transition from the topological insulator (TI) to the Dirac semimetal in ZrTe$_5$ has been recently suggested by experiments. Due to the layered structure of ZrTe$_5$, the van der Waals (vdW) interaction becomes an essential factor to study atomic vibrational behavior in the topological transition. In this theoretical work, phonon vibration modes and the corresponding electron band structures are explored systematically without and with vdw force correction to reveal the microscopic mechanism of the phase transition in ZrTe$_5$. 
1:27PM X60.00010: Bulk and surface polaritons in Weyl semimetals* ALEXEY BELYANIN, QIANFAN CHEN (Presenter), RYAN KUTAYIAH, Texas A&M University, MARIA ERUKHIMOVA, IVAN OLADYSHKIN, MIKHAIL TOKMAN, Institute of Applied Physics, Russian Academy of Sciences — We report theoretical studies of the optical properties and polariton modes of Type I Weyl semimetals with two Weyl nodes. We present rigorous quantum-mechanical derivation of bulk and surface conductivity tensors including both intraband and interband optical transitions and taking into account all possible combinations of bulk-to-bulk, bulk-to-surface, and surface-to-surface transitions. We show how the information about the electronic structure of Weyl semimetals, such as position and separation of Weyl nodes, Fermi energy, surface states etc. can be unambiguously extracted from their optical response, namely from the reflection, transmission, and polarization change of incident radiation. We predict the optical Hall effect and anomalous dispersion for surface polaritons excited by a nanotip. We show that Weyl semimetals represent a new class of gyrotropic materials with unique electrodynamics due to the combination of strongly anisotropic and gyrotropic bulk conductivity, surface conductivity, and surface dipole layer.

*This work has been supported in part by the Air Force Office for Scientific Research through Grant No. FA9550-17-1-0341.

1:39PM X60.00011: Hourglass Weyl loops in two dimensions: Theory and material realization in monolayer GaTel family WEIKANG WU (Presenter), YALONG JIAO, SI LI, XIAN-LEI SHENG, ZHIMING YU, SHENGYUAN YANG, Singapore University of Technology and Design — Nodal loops in two-dimensional (2D) systems are typically vulnerable against spin-orbit coupling (SOC). Here, we explore 2D systems with a type of doubly degenerate nodal loops that are robust under SOC and feature an hourglass type dispersion. We present symmetry conditions for realizing such hourglass Weyl loops, which involve nonsymmorphic lattice symmetries. Depending on the symmetry, the loops may exhibit different patterns in the Brillouin zone. Based on first-principles calculations, we identify the monolayer GaTel-family materials as a realistic material platform to realize such loops. These materials host a single hourglass Weyl loop circling around a high-symmetry point. Interestingly, there is also a spin-orbit Dirac point enabled by an additional screw axis. We show that the hourglass Weyl loop and the Dirac point are robust under a variety of applied strains. By breaking the screw axis, the Dirac point can be transformed into a second Weyl loop. Furthermore, by breaking the glide mirror, the hourglass Weyl loop and the spin-orbit Dirac point can both be transformed into a pair of spin-orbit Weyl points. Our work offers guidance and realistic material candidates for exploring fascinating physics of several novel 2D emergent fermions.
X60.00012: Fermionic analogue of Hawking radiation in bilayer black phosphorous*  
HANG LIU, JIATAO SUN (Presenter), Chinese Academy of Sciences, HUAQING HUANG, FENG LIU, Utah University, SHENG MENG, Chinese Academy of Sciences — **Topological matters upon the periodic driving of laser can lead to nonequilibrium topological states, which is not accessible in equilibrium topological materials.** Here we propose that the periodically driven two-dimensional black phosphorous (BP) thin film with a spatial gradient of Floquet-Dirac states can mimic the “gravity” felt by fermionic quasiparticles as that for a Schwarzschild black hole (SBH). Quantum tunneling of electrons from a type-II Dirac cone (inside BH) to a type-I Dirac cone (outside) emits a SBH-like Hawking radiation spectrum. The obtained $T_H$ of a fermionic analog of BH in BP is approximately 3 K, which is several orders of magnitude higher than previous works. Our work sheds some light on increasing the $T_H$ from the perspective of nonequilibrium topological states under periodic driving of laser. The obtained SBH accessible in nonequilibrium BP provides some clues to access the more Fermionic analogues of astronomy phenomena in solids.

*We thank financial support from the National Key Research and Development Program of China (Grants No. 2016YFA0300902 and No. 2016YFA0202300), National Basic Research Program of China (Grant No. 2015CB921001), NSF of China (Grants No. 11774396 and No. 11474328).

11:15AM X62.00001: Domain wall spin-texture in quantum Hall magnets*  
NEMIN WEI (Presenter), CHUNLI HUANG, ALLAN MACDONALD, University of Texas at Austin — Recent experiments [Stepanov Petr, et al. *Nature Physics* 14.9,907; Wei et.al *Science* 362.229-233; Haoxin,arXiv:1904.11485] reported long range transport of spinful collective modes in single-layer graphene based quantum Hall magnets(QHMs), including transport across junctions between states with different Landau level filling factors. These experiments motivate a detailed study of the various junctions that can be formed between N=0 QHMs since the microscopic electronic and spin-texture structure near the junction influences the collective mode transmission rate. Using a self-consistent Hartree-Fock calculation, we show that the spin-textures around the junction of $\nu=0$ and $\nu=\pm 1$ QHMs are wide, reaching ~140nm at $B=8T$. For the junction of $\nu=-1$ and $\nu=1$ QHMs, however, the domain wall is narrower and the spin-texture depends on the sublattice potential. I will explain the microscopic physics that controls these junction properties.

11:27AM X62.00002: Spin transport in quantum Hall magnets*  
CHUNLI HUANG (Presenter), NEMIN WEI, ALLAN MACDONALD, University of Texas at Austin — Recent nonlocal electrical measurements [Stepanov Petr, et al. Nature Physics 14.9, 907; Wei et.al Science 362, 229-233; Haoxin et.al, arXiv:1904.11485] have revealed remarkable spin transport properties in devices that host various graphene quantum Hall magnet (QHM) states. I will discuss our efforts to understand several different aspects of these experiments: 1) using an electric circuit model, we provide an explanation for the finite range of bias voltages over which nonlocal voltages are observed across insulating magnetic states and 2) using a microscopic spin-wave theory we estimate the transmission probabilities of magnon-like collective modes across junctions between QHMs that have different Landau level filling factors.

*Work supported by DOE grant DE- FG02-02ER45958.

11:39AM X62.00003: Enhanced thermal Hall effect in nearly ferroelectric insulators*  
JING-YUAN CHEN (Presenter), STEVEN KIVELSON, XIAO-QI SUN, Stanford Univ — In the context of recent experimental observations of an unexpectedly large thermal Hall conductivity in insulating La$_{2-x}$Sr$_x$CuO$_4$ and SrTiO$_3$, we theoretically explore conditions under which acoustic phonons can give rise to such a large thermal Hall effect. Both the intrinsic and extrinsic contributions to the thermal Hall conductivity are large in proportion to the dielectric constant and the flexoelectric coupling. While the intrinsic contribution is still orders of magnitude smaller than the observed effect, an extrinsic contribution proportional to the phonon mean free path appears likely to account for the observations, at least in SrTiO$_3$. We predict a larger intrinsic contribution to thermal Hall effect in certain insulating perovskites.

11:51AM X62.00004: Probing quantum spin liquids in equilibrium using the inverse spin Hall effect  JOSHUA AFTERGOOD (Presenter), Physics, The Graduate Center - CUNY, SO TAKEI, Queens College CUNY — We propose an experimental method utilizing a spin orbit coupled metal to quantum magnet bilayer that will probe quantum magnets lacking long range magnetic order, e.g., quantum spin liquids, via a dc resistance measurement across the metal. The bilayer is held in thermal and chemical equilibrium, and spin fluctuations arising across the single interface are converted into voltage fluctuations in the metal as a result of the inverse spin Hall effect. In thermal equilibrium, changes to the voltage noise in the metal are measurable as changes to the resistance via the fluctuation dissipation theorem. We examine the theoretical workings of the proposed bilayer system, and offer predictions for the temperature scaling of the enhancement to the dc resistance measured across the metal for three quantum spin liquid models. We consider the Heisenberg spin-$\frac{1}{2}$ kagomé lattice model and extract the spinon gap. We find characteristic $T^3$ scaling of the dc resistance enhancement for the Kitaev model in the gapless phase. Finally, for fermionic spinons coupled to a $U(1)$ gauge field we find subdominant $T^{4/3}$ scaling of the dc resistance enhancement. We therefore show that our proposed bilayer can test the relevance of a quantum spin liquid model to a given candidate material.

12:03PM X62.00005: Improved quantum transport calculations for interacting nanostructures* EMMA MINARELLI (Presenter), ANDREW MITCHELL, Univ Coll Dublin — Nanoelectronics devices such as semiconductor quantum dots and single molecule transistors exhibit a rich range of physical behavior due to the interplay between orbital complexity, strong electronic correlations and device geometry. Understanding and simulating the quantum transport through such nanostructures is essential for rational design and technological applications. In this talk I present theoretical reformulations of the Kubo and Meir-Wingreen formulae for mesoscopic quantum transport calculations in linear response, and demonstrate the improvement over standard methods with several example applications using the numerical renormalization group.

*Emma Minarelli acknowledges funding from the Irish Research Council Enterprise Partnership Scheme, through Grant No. EPSPG/2017/343.
Resistive switching duality: insulator-to-metal vs. metal-to-insulator switching*  

PAVEL SALEV (Presenter), University of California, San Diego, RANI BERKOUN, Laboratoire de Physique des Solides, CNRS, DAYNE SASAKI, University of California, Davis, JAVIER DEL VALLE, YOAV KALCHEIM, University of California, San Diego, YAYOI TAKAMURA, University of California, Davis, MARCELO ROZENBERG, Laboratoire de Physique des Solides, CNRS, IVAN SCHULLER, University of California, San Diego — Electrical triggering of metal-insulator transitions offers an opportunity to build energy-efficient and scalable electronics. While insulator-to-metal (I-M) switching in materials such as VO$_2$ is thoroughly studied, much less is known about an opposite metal-to-insulator (M-I) switching. We present a detailed study of M-I switching in (La,Sr)MnO$_3$ (LSMO). Negative differential resistance (NDR) region in the I-V characteristic is necessary for the resistive switching. By comparing LSMO to VO$_2$, we observe an interesting duality: the N-type NDR in LSMO is a “mirror reflection” of the S-type NDR in VO$_2$. Using Kerr effect imaging, we found that an insulating blocking domain perpendicular to the current flow forms in the LSMO during the NDR. This behavior is reciprocal to VO$_2$ in which a conducting filament parallel to the current flow emerges during the NDR. M-I and I-M resistive switchings complement each other providing a broad range of nonlinear electrical properties, which could allow designing of complex electronic devices.

*This work was supported as part of the Quantum Materials for Energy Efficient Neuromorphic Computing (Q-MEEN-C) Energy Frontier Research Center (EFRC), funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award # DE-SC0019273.

Quantum aspects of “hydrodynamic” transport from weak electron-impurity scattering*  

AARON HUI (Presenter), SAMUEL LEDERER, Cornell University, VADIM OGANESYAN, The Graduate Center, City University of New York, EUN-AH KIM, Cornell University — Recent experimental observations of apparently hydrodynamic electronic transport have generated much excitement. However, theoretical understanding of the observed non-local transport (whirlpool) effects and parabolic current profiles has remained at the level of a phenomenological analogy with classical fluids. A more microscopic account of genuinely hydrodynamic electronic transport is difficult because such behavior requires strong interactions to diffuse momentum. Here, we show that the non-local conductivity effects can indeed occur for fermion systems in the presence of disorder. By explicit calculation of the conductivity at finite wavevector $\sigma(q)$ for selected weakly disordered free fermion systems, we propose experimental strategies for demonstrating distinctive quantum effects in non-local transport at odds with the expectations of classical kinetic theory. Our results imply that the observation of whirlpools or other "hydrodynamic" effects does not guarantee the dominance of electron-electron scattering over electron-impurity scattering.

12:39PM X62.00008: Integrable systems of heterogeneous qubits* NIKOLAI SINITSYN (Presenter), Los Alamos Natl Lab, VLADIMIR Y CHERNYAK, Mathermatics, Wayne State University, CHEN SUN, Physics, Brown University — We explore an unusual type of quantum spin matter that can be realized by qubits having different physical origin, such as in bound states near defects in Dirac materials. Interactions of different qubits in this matter are described by essentially different coupling operators that do not commute with each other. We show that at least the simplest such models satisfy integrability conditions that we use to describe pseudospin dynamics in a linearly time-dependent magnetic field. Generalizing to arbitrary numbers of qubits, we construct a spin Hamiltonian, which we call the gamma-magnet. For arbitrarily strong interactions, nonadiabatic dynamics, and any initial eigenstate, we find that quantum interference suppresses spin-flips, so that the system remains close to the initial state. This effect may not have a counterpart in classical physics and can be a signature of a new type of spin ordering, which is different from both disordered spin glasses and ordered phases of spin lattices.

12:51PM X62.00009: Looking into thermalization and localization through the lens of quantum coherence* SAYANDIP DHARA (Presenter), Univ of Central Florida, ALIOSCIA HAMMA, Physics, University of Massachusetts Boston, EDUARDO R MUCCIOLO, Univ of Central Florida — Quantum coherence quantifies the amount of superposition a quantum state can have in a basis. Since there is a difference in the structure of eigenstates of the ergodic and many-body localized systems, we expect them also to differ in terms of their coherences. Here, we numerically calculate different measures of quantum coherence in the excited eigenstates of an interacting disordered Hamiltonian as a function of the disorder. We show that these can be used as an order parameter to detect the well-studied ergodic to the many-body localized phase transition. We also perform quantum quench studies to distinguish the behavior of coherence in thermalized and localized phases. We present a protocol to calculate measurement-based localized coherence to investigate the thermal and many-body localized phases. The protocol allows looking at the correlation in a non-destructive way since tracing out a subsystem always destroys coherence and correlation.

1:03PM X62.00010: Measurement-induced criticality in random quantum circuits  
CHAO-MING JIAN (Presenter), Station Q, Microsoft, Santa Barbara, YIZHUANG YOU, University of California, San Diego, ROMAIN VASSEUR, University of Massachusetts, Amherst, ANDREAS W LUDWIG, University of California, Santa Barbara — We investigate the critical behavior of the entanglement transition induced by projective measurements in (Haar) random unitary quantum circuits. Using a replica approach, we map the calculation of the entanglement entropies in such circuits onto a two-dimensional statistical mechanics model. In this language, the area- to volume-law entanglement transition can be interpreted as an ordering transition in the statistical mechanics model. We derive the general scaling properties of the entanglement entropies and mutual information near the transition using conformal invariance. We analyze in detail the limit of infinite on-site Hilbert space dimension in which the statistical mechanics model maps onto percolation. In particular, we compute the exact value of the universal coefficient of the logarithm of subsystem size in the nth Rényi entropies for n≥1 in this limit using relatively recent results for conformal field theory describing the critical theory of 2D percolation, and we discuss how to access the generic transition at finite on-site Hilbert space dimension from this limit, which is in a universality class different from 2D percolation.

1:15PM X62.00011: Temperature dependence of quantum information scrambling in gapped local systems*  
SUBHAYAN SAHU (Presenter), BRIAN SWINGLE, University of Maryland, College Park — We study temperature dependence of quantum information scrambling, specifically, in systems with a gap. Firstly, we perform large scale tensor network based numerics in gapped chaotic one dimensional spin chains to obtain scrambling data at different temperatures. We find that our numerics work very well even at low temperatures, and we are able to determine the temperature dependence of butterfly velocity to be √(T/m), where m is the mass, for T<m. From our numerics, we also observe a broadening of the operator wavefront at finite temperatures, which had been observed in the context of infinite T previously. Secondly, we perform a perturbative calculation to study scrambling in the paramagnetic phase of a 2+1 D non-linear sigma model to analytically understand the temperature dependence of the butterfly velocity. Using the ladder diagram techniques, we verify the √(T/m) behavior of the butterfly velocity at low temperatures, T<<m. Thirdly, we discuss these results in the context of a recently proposed state dependent bound on scrambling, and show that our results are in accordance with the bound, and in fact provides a clear physical picture of scrambling at low temperatures.

1:27PM X62.00012: Magnetic Hamiltonian Engineering by Light-Matter Interaction*  
ZEXUN LIN (Presenter), MARTIN RODRIGUERZ-VEGA, GREGORY A FIETE, University of Texas at Austin — In this work, we explore the flexibility and magnitude of Hamiltonian engineering by considering photon-electron coupling and photon-phonon coupling. We compare the pros and cons of both routes in simple toy models, and extend our results to more realistic models.

*This work was supported by the NSF Materials Research Science and Engineering Center Grant No. DMR-1720595 and NSF Grant No. DMR-1949701.
Hydrogenated Rare-Earth Nickelate Nanojunctions with Synaptic Behavior Studied by X-ray Nanodiffraction

IVAN ZALUZHNYY (Presenter), PETER OLIVER SPRAU, University of California, San Diego, QI WANG, HAI-TIAN ZHANG, Purdue University, NELSON HUA, BOYAN STOYCHEV, University of California, San Diego, SHRIRAM RAMANATHAN, Purdue University, ALEX FRANO, OLEG SHPYRKO, University of California, San Diego — Rare-earth nickelates have been the target of intense fundamental and application-focused studies due to their rich phase diagram and possible utilization of these materials as novel sensors, memory devices and hardware elements for artificial intelligence. For example, hydrogenation of SmNiO$_3$ (SNO) drastically changes its electronical properties giving rise to a new insulating phase. Moreover, application of voltage pulses allows one to repeatedly switch the hydrogenated SNO films between the lower and higher resistance states. This allows one to create a device with synaptic behavior, which is a crucial hardware element for neuromorphic computing. With nanofocused x-ray diffraction and spectroscopy we performed in-situ spatially-resolved studies of the microscopic mechanism behind the potentiation and depression of an SNO-based device. We revealed changes in both electronic structure and crystal lattice between pristine and hydrogenated SNO films, as well as before and after electrical switch of the device.

Unveiling electron correlation in semiconducting Heusler FeVSb by angle-resolved photoemission and dynamical mean field theory

ESTIAQUE HAIDAR
SHOUROV (Presenter), PATRICK STROHBEEN, SEBASTIAN MANZO, DONGXUE DU, Materials Science and Engineering, University of Wisconsin Madison, FANNY RODOLAKIS, JESSICA L MCCHESENY, Advanced Photon Source, Argonne National Laboratory, ZACH KREBS, WYATT A BEHN, Physics, University of Wisconsin Madison, FELIPE CASTRO DE LIMA, Instituto de Física, Federal University of Uberlândia, Brazil, ABHISHEK SHARAN, Physics and Astronomy, University of Delaware, VICTOR BRAR, Physics, University of Wisconsin Madison, ANDERSON JANOTTI, Materials Science and Engineering, University of Delaware, TURAN BIROL, Chemical Engineering and Materials Science, University of Minnesota Twin Cities, FELIPE CASTRO DE LIMA, Instituto de Física, Federal University of Uberlândia, Brazil, ABHISHEK SHARAN, Physics and Astronomy, University of Delaware, VICTOR BRAR, Physics, University of Wisconsin Madison — Electron-electron correlations are responsible for many of the exotic properties of transition metal oxides and chalcogenides; however, the role of correlations in transition metal Heusler compounds is often overlooked. Here, combining angle-resolved photoemission spectroscopy (ARPES) and dynamical mean field theory (DMFT), we directly probe the single particle spectral function of the Heusler FeVSb. ARPES measurements on epitaxial FeVSb films reveal a mass renormalization of $m^* / m_{\text{bare}} = 1.4$, where $m_{\text{bare}}$ is the mass from DFT-LDA calculations that do not include a Hubbard $U$. This mass renormalization lies in dramatic contrast to other Heuslers LnPt(Sb,Bi) (Ln = lanthanide) [1-3] and CoTiSb [4], for which bare DFT calculations are in quantitative agreement with ARPES. By treating the many-body interactions more accurately at the level of DMFT, we quantitatively reproduce the measured electronic structure and comment on the differences between FeVSb and other Heuslers. Our work calls for a re-thinking of the role of correlations in FeVSb and in Heuslers more generally.

Session X65 DCMP: 1D Materials: Nanowires, Nanotubes, and Nanoribbons Mile High Ballroom 4F - Paula Fekete, US Military Academy
Designing nano-biocomposite materials using CVD grown CNTs and ZnO nanostructures for hybrid interfaces and hydrogel environments with future biomedical applications

Nicholas Schaper (Presenter), Brannan Hutchinson, Silviya Zustiak, Irma Kuljanishvili, Saint Louis University — One dimensional (1D) nanostructures, carbon nanotubes (CNTs) and other nanowires, have been proven useful for many biomedical applications. Their high aspect ratio allows for functionalization with specific biological molecules or other nanoscale moieties through covalent bonding, physisorption or chemisorption. Controlled production of CNTs and zinc oxide nanowires (ZnO NWs) has been shown to provide avenues for tailoring interfaces at the nanoscale. These materials are excellent candidates for biomedical use due to unique physical/electrical properties and biocompatibility. When incorporated into nonconductive environments, CNTs/ZnO NW will efficiently transmit electrical signals to biological cells and improve the mechanical strength of composite materials. Here we investigate CVD-grown CNTs, ZnO NWs and CNTs/ZnO hybrid structures interfaced with hydrogels. We have demonstrated that sw-CNT/hydrogel interfaces guide healthy neuronal cell behaviors like cell attachment and neurite growth. Designing new hybrid nanomaterials such as CNTs/ZnO/Hydrogel composites with controlled morphology and functionalized interfaces provide a useful platform for investigating critical biomedical problems simultaneously targeting neural cell regeneration, cancer treatments, and drug delivery.

Unfolding the temperature induced dual bandgap in TiO$_2$ nanotubes with improved photocatalytic application

Sangita Bhowmick (Presenter), Physics, Shiv Nadar University, Chetan Prakash Saini, Saif Khan, Physics, Inter University Accelerator Centre, Mukul Gupta, Physics, UGC-DAE Consortium for Scientific Research, Khandwa Road, Rahul Singhal, Physics, Malaviya National Institute of Technology Jaipur, Raja Sen, Alok Kanjilal, Physics, Shiv Nadar University — Since the discovery of photocatalytic water splitting, TiO$_2$ has gained enormous interest in improving efficiency by generating stable electron-hole (e-h) pairs upon proper light illumination [1]. In particular, anodic TiO$_2$ nanotubes have attracted wide interest not only for their high surface-to-volume ratio with scalable structures [2]. However, the overall efficiency is limited by the recombination of the photo-generated (e-h) pairs in the bulk and electrode/electrolyte interfaces. To overcome this tuning the crystallinity and the bandgap of them are required. Among various approaches, thermal annealing dependent control over the anatase/rutile phase ratio of TiO$_2$ and their inter-granular charge transfer process exhibit a relatively high photocatalytic performance. Here, we report the efficacy of dual-phase mediated bandgap modulation and the subsequent improvement of photocatalytic activity of TiO2 nanotubes as a function of temperature by various complementary techniques like UV-Vis, XRD, XPS, XAS, Raman, etc. and supported by DFT calculations.

11:39AM X65.00003: Modulation Doping of Template-Defined InGaAs Nanowires*
KRISTOPHER CERVENY (Presenter), University of Basel, MARTIN FRIEDL, Ecole Polytechnique Federale de Lausanne, MOHAMMAD SAMANI, University of Basel, DIDEM DEDE, Ecole Polytechnique Federale de Lausanne, CHUNYI HUANG, LINCOLN J LAUHON, Northwestern University, ANNA FONTCUBERTA I MORRAL, Ecole Polytechnique Federale de Lausanne, DOMINIK ZUMBUHL, University of Basel — Templated semiconductor nanowires with strong Rashba spin-orbit interaction are a great platform to create and study novel quantum states of matter, such as helical states and spin helices, Majorana- and para-fermions. Here, we report recent results on templated InGaAs nanowire Y-junctions grown on GaAs nanomembranes[1] with modulation doping. Modulation doping has been successfully used in many high-performance systems to create structures with enhanced mobility and higher carrier concentrations. We investigate modulation doping in GaAs nanomembranes grown via molecular beam epitaxy in a selective area growth approach. In a novel process, the dopants migrate up through the GaAs membrane during growth. This remote doping process has enabled major improvements in notable system parameters such as mean free path, coherence length, and spin-orbit length. With a top gate, we can tune between weak localization and antilocalization. The improvements suggest ballistic transport may be within reach. Further, experiments with superconducting contacts for proximitizing and Majorana zero modes can be envisioned.

11:51AM X65.00004: Reflection of light from gold coated InP NW arrays*
CHIAWEI TU (Presenter), Department of Physics, Univ of Cincinnati, QIAN GAO, HOE TAN, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Research School of Physics and Engineering, Australian National University, MASOUD KAVEH, Department of Physics and Astronomy, James Madison University, HEIDRUN SCHMITZER, Department of Physics, Xavier University, MARTIN FRAENZL, Department of Physics, University of Leipzig, HANS-PETER WAGNER, Department of Physics, Univ of Cincinnati — To optimize light coupling into a plasmonic nanowire (NW) array as a function of incident angle and excitation wavelength, we investigated the reflection of light from two different bare and gold coated InP NW arrays. The NWs in the arrays have a diameter of 180 nm, heights of 2 and 1 micrometers and pitches of 666 and 500 nm. A nominally 10 nm thick gold film was deposited around the NWs to investigate the influence of plasmonic effects. The arrays were irradiated with s- and p- polarized light. The spectral reflectance was measured with an incandescent light source ranging from 500 to 1000 nm and the angle resolved reflectance was investigated with a cw laser at 880 nm. The p-polarized angle resolved reflectance of gold deposited NW arrays significantly differs from the reflectance of uncoated InP NW arrays. The differences are attributed to surface plasmon polariton effects. The measured spectrally and angle resolved reflectance was compared with finite-difference-time-domain (FDTD) simulations. The simulations show very good agreement when an air-gold effective medium according to the granularity of the deposited gold films was used.

*The support of the Australian Research Council and URC is kindly acknowledged.
We study theoretically the Dresselhaus SOI of electrons in zinc-blende NWs of various growth directions. We present qualitative and quantitative results for low-symmetry NW cross-sections modeled after sectors of rings or circles. Our analysis enables predictions for a variety of NW cross-sections, such as those of recently fabricated GaAs-InAs nanomembrane-NW structures (Friedl et al., Nano Lett. 18, 2666, 2018). While a specific configuration exists where the Dresselhaus SOI is suppressed, many configurations allow for a strong Dresselhaus coupling on the order of meV. By introducing dimensionless and material-independent functions, it is straightforward to recalculate the spin-orbit length and energy. The inclusion of a similarly strong, gate-induced Rashba term, enables electrical control of the overall SOI. Our results (arXiv:1910.00562) can serve as a guideline for NW-based setups with applications that rely on SOI.

12:15PM X65.00006: Investigating the magneto-optics in quantum wires for designing the optical amplifiers  MANVIR KUSHWAHA (Presenter), Physics, Rice Univ — Quantum wires occupy a unique status among the semiconducting nanostructures with reduced dimensionality -- no other system seems to have engaged researchers with as many appealing features to pursue. This paper aims at a core issue related with the magnetoplasmon excitations in the quantum wires characterized by the confining harmonic potential and subjected to a longitudinal electric field and a perpendicular magnetic field in the symmetric gauge. Crucial to this inquiry is an intersubband collective excitation that evolves into a magnetoroton -- above a threshold value of magnetic field -- which observes a negative group velocity between the maxon and the roton. The evidence of negative group velocity implies anomalous dispersion in a gain medium with the population inversion that forms the basis for the lasing action of lasers\(^1\)-\(^6\). Thus, the technological pathway that unfolds is the route to devices exploiting the magnetoroton features for designing the novel optical amplifiers at nanoscale and hence paving the way to a new generation of lasers. 1. M. S. Kushwaha, Phys. Rev. B \textbf{76}, 245315 (2007); 2. Phys. Rev. B \textbf{78}, 153306 (2008); 3. J. Appl. Phys. \textbf{109}, 106102 (2011); 4. Mod. Phys. Lett. B \textbf{28} 1430013 (2014); 5. Europhys. Lett. \textbf{123}, 34001 (2018); 6. Mod. Phys. Lett. B \textbf{33} 1950062 (2019).

12:27PM X65.00007: Mid-infrared photoconductivity of tellurium nanowire devices*  PENGKE LI (Presenter), IAN APPELBAUM, University of Maryland, College Park — Elemental tellurium is a narrow bandgap (0.34 eV) semiconductor, whose trigonal lattice is composed of weakly-bound, three-fold helical atomic chains. This unusual lattice allows the formation of nanowires with highly anisotropic electronic and optical properties. Here, we present photocurrent spectroscopy of single tellurium nanowire devices in the mid-infrared range close to the band gap, demonstrating interesting anisotropic features closely related to the linear polarization of the incident light and the resonant modes of the nanowires. It is found that the photosensitivity is strongly dependent on the temperature and the back-gate bias.

*We acknowledge support from the Office of Naval Research under Contract No. N000141712994.
12:39PM X65.00008: Quantum confinement and edge effects in zigzag green phosphorene nanoribbons*  
CHI MA (Presenter), TIANXING MA, Beijing Normal Univ, XIHONG PENG, Arizona State University — *Ab initio* calculations were carried out to study size and edge effects on the electronic properties of zigzag green phosphorene nanoribbons (ZGPNRs) with edge chemical functionalization including H, OH, F, Cl, O, and S for the ribbon width up to 3.7 nm. The electronic properties of the ZGPNRs are strongly dependent on the ribbon width and edge chemical species. The ribbons are either semiconducting or metallic depending on the edge functionalization species. The ZGPNRs demonstrate semiconducting behavior with the edge passivation of H, OH, F, or Cl (Group I), while show metallic feather with pristine or O, S edges (Group II). The conduction band minimum (CBM) and valence band maximum (VBM) of the ZGPNRs with the Group I edges are mainly contributed by the inner P atoms and the edge P and functionalization atoms have little contribution. However, for the Group II edges, the electronic bands crossing the Fermi level are dominantly located at the edge atoms. It was also found that the band gap and work function of the ZGPNRs are tunable by varying ribbon width and edge functionalization species.

*The authors acknowledge Beijing Normal University for the financial support and Arizona State University for the computational resources.

12:51PM X65.00009: Lifetime analysis of quasistationary states of an electron in open quantum wires*  
RUEI-FU JAO (Presenter), School of Information Technology, Guangdong Industry Polytechnic, HUA-YI HSU, Department of Mechanical Engineering, National Taipei University of Technology, MING-CHIEH LIN, Department of Electrical and Biomedical Engineering, Hanyang Univ — The quasistationary states of an electron in a cylindrically N-layered open quantum wire are investigated. A complex eigen-solver is developed to determine both the resonant states $E_R$ and the corresponding lifetimes $\tau$ of the system. Here, we solve the eigenvalue equations for the quasibound states of an electron in open quantum wires using the adaptive finite element method (FEM). We have carefully examined the convergence of this approach for the desired accuracy and efficiency. All the quasistationary states of the system can be determined via this eigen-solver. For illustration, the numerical calculations are carried out for the GaAs/Al$_x$Ga$_{1-x}$As/GaAs multi-layered open quantum wire. Both the energy levels and the lifetimes of the quasistationary states are found as functions of the geometric parameters of the system. The lifetime of an electron in such a system is very sensitive to the geometric characteristics. Figure 1 shows our preliminary results are in good agreement with a previous work done by M. Tkach et al. which analyzed the cases of the quasiparticle lifetimes using the $S$-matrix theory.

Session X66 DCMP: Superconducting Electronics and Cryogenic Memory  
Four Seasons 1 - Nathan Satchell, Univ of Leeds - Tag(s): Invited
Superconducting circuits are under development as a solution to the demand for ultralow power computers. Logic technologies based in superconducting materials, such as Reciprocal Quantum Logic (RQL) require the development of a superconducting memory in order to build complex computers. Josephson Magnetic Random Access Memory (JMRAM) is a non-volatile memory utilizing the 0-π phase characteristics of pseudo-spin valve magnetic barrier Josephson junctions as a phase element within more traditional superconductor-insulator-superconductor (SIS) SQUIDs, which are used to read the phase state. Here, we present a demonstration of JMRAM from a single unit cell to 2x2 and 8x8 arrays. All arrays are built based on Ni/Cu/NiFe pseudo-spin valve junctions with 50-100 Oe switching field and high critical current of 0.5 mA. All array elements were functional with 100% switching between 0 and 1 state using external magnetic fields. This foundational demonstration serves as the basis for a more complete assessment of the progress of this technology toward practical implementation.

Superconducting vortex-based memory cells

TARAS GOLOD, LISE MORLET-DECARIN, OLENA KAPRAN, ALESSANDRO PAGLIERO, ADRIAN IOVAN, VLADIMIR KRASNOV (Presenter), Department of Physics, Stockholm Univ — Non-volatile quantized states are ideal for the realization of classical Boolean logics. Abrikosov vortex represents the most compact magnetic object in superconductors with the size determined by the London penetration depth \( \sim 100 \text{ nm} \). Therefore, it can be utilized for creation of high-density digital cryoelectronics. In this talk we will describe operation of memory cells, in which a single vortex is used as an information bit [1]. The vortex is pinned at a nano-scale trap and is read-out by a nearby Josephson junction [2,3]. Unlike SQUID-based memory cells, such cells have non-degenerate 0 and 1 states, which greatly simplify the device architecture. Furthermore, SQUID-based devices have a problem with increasing write current upon decreasing the SQUID loop size, preventing a straightforward miniaturization. To the contrary, write current for a vortex is determined by the depinning current density and, therefore, scales with the size. All together this allows simple miniaturization down to sub-micron sizes. We demonstrate that vortex memory cells have a high-endurance operation, are characterized by an infinite magnetoresistance, do not require external magnetic field, have a short access time, and a low write energy. Non-volatility and perfect reproducibility are inherent for such devices due to the quantized nature of the vortex. We argue that vortex-based memory can be used in superconducting digital supercomputers.

Superconducting nanowire-based memories

KARL BERGGREN (Presenter), Massachusetts Institute of Technology MIT — A persistent current in a superconductor provides a nearly perfect physical token for data storage. It is nonvolatile (so long as the loop remains cold), and can be read out precisely, thus enabling digital (and perhaps even multi-level) electronic memory. However, the quantisation of flux in units of \( \Phi_0 \), means that relatively large inductors (on the order of 10s of \( \mu \text{m} \)'s long) are typically required for such systems, somewhat limiting their potential. The solution until recently was to use Josephson junctions as a compact source of inductance, but even this approach resulted in memory-cell dimensions at the many-\( \mu \text{m}^2 \) level. Recently, however, high-quality thin superconducting films with long penetration depths (and thus high kinetic inductance) have become available. These materials enable much smaller persistent-current loops without requiring the use of a Josephson junction. Novel nanowire-based electronic devices, also not using Josephson junctions, have also emerged that can be used to read out the nanowire state. With this, working single-cell memories with negligible bit-error rates have been realized. I will describe these developments. I will also present a new family of novel superconducting electronic elements that can be used with these memories to enhance their capabilities and function.
Controlling supercurrents and their spatial distribution in ferromagnets

[Invited] JAN AARTS (Presenter), KAVEH LAHABI, REMKO FERMIN, Leiden University, MIKHAEL SILAEV, University of Jyväskylä — Spin-triplet Cooper pairs induced in ferromagnets form the centerpiece of the emerging field of superconducting spintronics. Control over the magnetization of the stacked ferromagnetic layers that generate the triplets allows, for instance, making controllable pi-junctions. In such stacks, crucial for triplet generation is the presence of different uniform magnetization directions. The mechanism at work is that the spin-dependent scattering of a singlet in one layer generates an $m_S = 0$ component of the triplet state, which, in the next ferromagnet with a different magnetization direction, manifest itself as an $m_S = 1$, or ‘equal-spin’ triplet. There are other configurations, however, which give rise to controllable triplet currents. Using more intricate magnetic texture even permits control over the spatial distribution of supercurrent. Here we discuss two types of experiments, both based on a disk-shaped ferromagnetic layer as supercurrent carrier. The in-plane magnetization forms a vortex, with in the center a core where the magnetic flux is forced out. In the first experiment, two superconductor / ferromagnet contacts on top of the disk allow us to generate a triplet supercurrent in the disk, and by using superconducting quantum interferometry, we show the existence of two channels. Moreover, we show how the supercurrent can be controlled by moving the vortex with an in-plane magnetic field. Micromagnetic simulations are used to make the connection between the behavior of the supercurrent and the magnetic texture of the disk. In the second experiment, we show that a triplet current can even be generated by placing the superconducting contacts directly on top of the disk, without the presence of the second ferromagnet. Again, the supercurrent is sensitive to the position of the magnetic vortex core. The rotating magnetization, combined with the edges of the structure, yields the correct kind of inhomogeneity. This is not entirely trivial as will be discussed.

Electromagnetic long ranged proximity effect in superconductor-ferromagnet structures

[Invited] ALEXANDRE BUZDIN (Presenter), LOMA UMR-CNRS 5798, University of Bordeaux, France — The spread of the Cooper pairs into the ferromagnet in proximity-coupled superconductor – ferromagnet (SF) structures is shown to cause a strong inverse electrodynamic phenomenon, namely, the long-range transfer of the magnetic field from the ferromagnet to the superconductor. Contrary to the previously investigated inverse proximity effect resulting from the spin polarization of superconducting surface layer, we found a very generic orbital mechanism of the magnetic moment transfer from a ferromagnet to a superconductor, which is unavoidable in S/F hybrids. It is related with the fact that the common superconducting wave function in S and F (near the interface) does not permit to exclude the vector-potential of the magnetization by gauge transformation. From the experimental point of view, this phenomenon reminds the Aharonov-Bohm effect since the current inside the attached superconductor is induced by the ferromagnetic layer, which cannot create the magnetic field in the outside in the absence of such superconducting environment. At the same time, the true physical key point is that the wave function penetrating the ferromagnet is responsible for this effect. Let us stress that the characteristic length of the proposed inverse electrodynamic effect is of the order of the London penetration depth.
11:15AM X67.00001: Higher order topology in superconducting and interacting electronic systems* [Invited] TITUS NEUPERT (Presenter), Univ of Zurich — Topological states with hinge and corner modes, so-called higher order topological insulators, have been predicted to exist in various crystalline materials such as elementary bismuth and WTe2. I will start with a review of the theoretical foundations of higher-order topology, introducing topological invariants to identify such phases as well as an explanation for their generalized topological bulk-boundary correspondence. Second, I will discuss venues for realizing higher order topology in superconductors, magnetic, and strongly interacting systems. To define (crystalline) topology in superconductors, I will discuss the question how theoretically a trivial reference state has to be defined (an atomic limit), and how a topological classification can be built up on this. For magnetic systems, the possibility of topological Kondo insulators hosting a phase with hinge states upon undergoing a magnetic instability is outlined. Finally, the generalization of the bulk-boundary correspondence of higher-order topology will be elevated to the interacting case, including the possibility of surface topological order.

11:51AM X67.00002: Probing the topological properties of Bismuth, a second order topological insulator [Invited] SOPHIE GUERON (Presenter), ANIL MURANI, BASTIEN DASSONNEVILLE, ALEXANDRE BERNARD, ALIK KASUMOV, RICHARD DEBLOCK, MEYDI FERRIER, HÉLÈNE BOUCHIAT, Laboratoire de Physique des Solides Orsay, U. Paris Sud, U. Paris Saclay, CNRS, France — Higher Order Topological Insulators are a new family of materials whose conduction paths are located not at the crystal boundaries but at the boundary of the boundaries: Thus, three dimensional Second Order Topological Insulators should conduct via one dimensional paths at the crystal hinges. In the talk I will demonstrate how mesoscopic physics experiments (along with some theory!) led to the discovery that Bismuth was the first example of a solid state Second Order Topological Insulators [1]. I will show how we detected such hinge states in monocristalline nanowires connected to superconducting contacts, and further used the supercurrent-versus-phase relation [2,3] to demonstrate their ballistic nature. I will also present our recent measurement of the nanowire's linear response to an ac phase difference excitation. I will argue that the response's sharp dissipation peak when the superconducting phase difference is π is a telltale sign of topological protection at the hinges [4,5].

12:27PM X67.00003: Sankar Das Sarma Invited Talk [Invited] —
Partial Lattice Defects in Higher-Order Topological Insulators

RAQUEL QUEIROZ (Presenter), Weizmann Institute of Science, ION COSMA FULGA, Institute for Theoretical Solid State Physics, IFW Dresden, NURIT AVRAHAM, HAIM BEIDENKOPF, Weizmann Institute of Science, JENNIFER CANO, Center for Computational Quantum Physics, Flatiron Institute — Nonzero weak topological indices are thought to be a necessary condition to bind a single helical mode to lattice dislocations. In this work we show that higher-order topological insulators (HOTIs) can, in fact, host a single helical mode along screw or edge dislocations (including step edges) in the absence of weak topological indices. When this occurs, the helical mode is necessarily bound to a dislocation characterized by a fractional Burgers vector, macroscopically detected by the existence of a stacking fault. The robustness of a helical mode on a partial defect is demonstrated by an adiabatic transformation that restores translation symmetry in the stacking fault. We present two examples of HOTIs, one intrinsic and one extrinsic, that show helical modes at partial dislocations. Since partial defects and stacking faults are commonplace in bulk crystals, the existence of such helical modes can measurably affect the expected conductivity in these materials.

Resolving the topological classification of bismuth using topological defects*

HAIM BEIDENKOPF (Presenter), ABHAY NAYAK, JONATHAN REINER, RAQUEL QUEIROZ, HUIXIA FU, Weizmann Institute of Science, CHANDRA SHEKHAR, Max Planck Institute for Chemical Physics of Solids, BINGHAI YAN, Weizmann Institute of Science, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, NURIT AVRAHAM, Weizmann Institute of Science — The growing diversity of topological classes leads to ambiguity between classes that share similar boundary phenomenology. This is the status of bulk bismuth. Recent studies have classified it as either a strong or a higher-order topological insulator, both of which host helical modes on their boundaries. We resolve the topological classification of bismuth by spectroscopically mapping the response of its boundary modes to a screw-dislocation. We find that the one-dimensional mode, on step-edges, extends over a wide energy range and does not open a gap near the screw-dislocations. This signifies that this mode binds to the screw-dislocation, as expected for a material with nonzero weak indices. We argue that the small energy gap, at the time reversal invariant momentum \( L \), positions bismuth within the critical region of a topological phase transition between a higher-order topological insulator and a strong topological insulator with nonzero weak indices.

11:15AM X68.00001: Machine learning quantum states in the NISQ era [Invited]  
ROGER MELKO (Presenter), University of Waterloo — We discuss the development of machine learning techniques for the purpose of reconstructing quantum states from projective measurement data. Technology adapted from a branch of unsupervised learning, called generative models, are well-suited for learning representations of quantum states from real experimental data. We discuss quantum state reconstruction with several classes of generative model, and compare in particular the performance of tractable and approximate density models. We demonstrate their practical use for state reconstruction, moving systematically through increasingly complex classes of pure and mixed quantum states. As an example of a use case for a real experimental noisy intermediate-scale quantum (NISQ) device, we review recent efforts in reconstructing a cold atom wavefunction. Finally, we discuss the outlook for scalable experimental state reconstruction using machine learning, in the NISQ era and beyond.

11:51AM X68.00002: About that useful little corner of Hilbert space and its neural network representations [Invited]  
GIUSEPPE CARLEO (Presenter), Center for Computational Quantum Physics, Flatiron Institute — The vast majority of quantum states of interest for practical applications have distinctive features and intrinsic structure. These typically occupy only a very limited corner of the vast manifold of allowed quantum states, making them often amenable for compact classical representations.

In this talk I will overview a recently introduced classical representation of many-qubit states based on artificial neural networks.

First I will present results concerning their expressive power, reviewing representation theorems and arguing that these representations are not limited by the amount of entanglement they can encode. In this context, I will also show a new explicit and polynomially efficient mapping from contractible tensor-network states.

Then, I will show several applications of these variational representations, with a focus on quantum computing applications. Most notably, I will focus on a variational technique useful to simulate large structured quantum circuits, as well as applications of classical neural-network states to benchmark and improve NISQ quantum hardware.
12:27PM X68.00003: Machine Learning and Quantum [Invited] PENGFEI ZHANG (Presenter), Caltech — In this talk, I will first talk about “machine learning of quantum problems”. Since quantum problems are governed by well-defined physical rules, they are good platforms to investigate explainable machine learning. Here I will give one example of learning potential-to-density mapping by the recurrent neural network, from which we can extract the Schrodinger equation. Secondly, I will talk about “machine learning for quantum experiments”. Especially, I will describe how to use the idea of active learning to optimize quantum control, which requires minimal number of experimental data. Finally, I will talk about “machine learning on quantum compute”. I will bring together the concept information scrambling and quantum machine learning. I will show that the tripartite information developed for quantifying information scrambling can be used to diagnose the training dynamics of a quantum neural network.

1:03PM X68.00004: Machine Learning with Tensor Networks [Invited] EDWIN STOUDENMIRE (Presenter), CCQ, Flatiron Institute — Tensor networks are a technique developed to compress otherwise exponentially large, many-body wavefunctions into a form such that they can be optimized and their properties computed with only polynomial effort. Key examples including the matrix product state (MPS) and projected entangled pair state (PEPS) tensor networks, which give state-of-the-art results for challenging systems of strongly correlated electrons. But in recent years, it has been appreciated that tensor networks are a broader technique for compressing very large linear functions, which can appear in many different problem domains. One very promising domain is machine learning of real-world data, where certain powerful models closely resemble wavefunction tensors and where tensor networks can be directly applied, just as in physics.

I will give a progress update on work over the last few years bringing tensor network methods to bear on machine learning. In addition to empirical benchmark results on challenging data sets, there has been recent progress in obtaining theoretical results for machine learning too. I will discuss how a theory of generative modeling of data can be developed in the context of matrix product state models. Other interesting developments include a theoretical understanding of the expressive power of various families of models, and a direct connection between tensor networks and proposals for quantum machine learning.
